A NUMBER of leading questions were fired at hygienists and physiologists in the course of a paper which was read before the Institute of Sanitary Engineers on April 2nd. The purpose of the author, Mr. Arthur Barker, was to consider some neglected aspects of the twin problem of heating and ventilation. Although the paper seemed to be little more than a prolonged note of interrogation, it was something gained to have the engineer sitting at the feet of the physiologist and expressing himself able and ready to distribute air and heat to any specification if only he can have some physiological data. Two sets of factors are concerned in the problem—namely, the physical and the physiological; the latter question has a wider reach than the obvious adjustments of the body mechanism; it is concerned also with the subjective sensations. No engineer can wholly disregard the part played by the imagination in heating and ventilating rooms, and while the introduction into sanitary science of this indeterminate element of psychology adds to that science a greater interest and subtlety, it also makes it immeasurably more difficult to reduce it to the figures which the engineer demands. At the root of the whole heating and ventilating problem, however, is the question of the abstraction of heat from the human body, and the author expressed some surprise that this question had not received more analytical consideration. Looking on the human body as a radiator, he estimated that an individual weighing 10 st. had a store of heat within him at any moment equal to 4,000 British thermal units, a British thermal unit being the amount of heat necessary to raise 1 lb. of water 1° F. By radiation and contact of air alone, without taking account of loss by breath and evaporation, it was estimated that such a person might lose 300 British thermal units an hour. But the amount of heat actually lost from the body varied with the body's surface temperature and dampness, with the actual temperature and humidity of the immediately surrounding air, and also with what might be called the general radiant temperature. Physiologists were therefore asked whether it was merely the physical loss of heat which determined the degree of warmth or cold actually felt by a person, and, if so, what were the physical features in the condition of a room which determined the sensation. The thermometer alone could not interpret truly the heating of a room; it could only indicate its own temperature. The human being was more or less in the condition of a wet-bulb instrument maintained at 93°, and parting with heat to air and solid bodies at a lower temperature than its own; while the thermometer was

a dry-bulb instrument at 60° emitting heat by radiation to bodies on the whole at a lower temperature, and receiving heat from air on the whole at a higher temperature. What, Mr. Barker asked, were the conditions which determined how much heat was abstracted from the body? Could it be accepted as a fact that the main function of ventilation was to control this loss of heat? He complained that engineers were working in the dark with regard to the hygienic composition of air, and its temperature, humidity, and movement. The causes of the ill effects of respired air were commonly given as excessive temperature, humidity, smell, or stagnation. Yet foul air might be cold, dry, and odourless, and there might be complaints of draughts and of bad air simultaneously. In a final question he took the case of slowly moving air which was neither excessively moist nor excessively hot, and which had no considerable smell and no abnormal amount of dust. Was any definite assurance forthcoming that such air was perfectly good to breathe, without any introduction of fresh air, no matter how many people had already breathed it? And if not, why not? After all, perhaps the matter is simpler than these questions suggest, and the modern doctrine that the sensation of comfort—or, rather, the absence of any sensation of discomfort—is a very fair standard of efficiency in both heating and ventilation may prove to be correct.

THE LEARNED PROVOST OF STONEHAVEN.

WHEN Emeritus-Professor J. G. McKendrick retired from the active duties of the Chair of Physiology at Glasgow he went to live at Stonehaven, Kincardineshire, where he had built himself a house. He entered the town council and was speedily elected to be chief magistrate, and held that office until the other day. When he recently announced that, owing to the state of his health, he would not seek re-election, the burgesses determined to give expression to their esteem for his eminent attainments as a man of science and his great services to the burgh of Stonehaven by presenting to him a chain of office carrying the burghal coat of arms on the pendant. The chain, the cost of which was defrayed by private subscription, was presented on April 21st, and accepted in a suitable speech by Provost McKendrick.

A MEMORIAL to Dr. Laleaca, the Parsee physician who lost his life in the brave attempt to save Sir Curzon Wylie from the assassin in the Jehanghir Hall of the Imperial Institute on July 1st, 1909, was inaugurated on April 16th. The memorial, which is the work of Mr. F. W. Doyle Jones, consists of a bust, in white Pentelic marble with pale green Cippolino plinth, standing upon a pedestal of dark green Tinos marble, and bearing a bronze panel with a suitable inscription; it has been placed in the vestibule of the Jehanghir Hall. Sir M. M. Bhowmaggree made the presentation on behalf of the Bombay Committee of subscribers, and gave some particulars of the movement to do honour to the memory of Dr. Laleaca in Bombay, in London, and in Shanghai, where he had practised for many years. The memorial was unveiled by Lord George Hamilton and accepted by Professor Wyndham Dunstan, Director of the Imperial Institute. A replica of the bust is being erected in Bombay.

AT a meeting of the Child Study Society, on April 10th, it was argued by Mr. Holman that not only should a medical man be regarded as an essential member of a school staff, but there should also be a psychologist on the staff unless the medical member were versed in psychology. One of the best things the Board of Education could do would be to set up a psychology side to its work. Why, he asked, should not those forming the National Union of Teachers start a psychological institute of their own as had their fellows at Leipzig?

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Tuberculosis (Advisory Committee).—In reply to Mr. O'Grady, who inquired whether it was the intention of the Treasury to establish the Advisory Council recommended by the Departmental Committee on Tuberculosis, and, if so, would provision be made for the inclusion of representatives of approved societies on such council, Mr. Robertson stated that the answer to the first part of the question was in the affirmative. With regard to the second part he referred to the answer given by the Prime Minister on April 3rd. The function of the Advisory Council was to advise with regard to the application of moneys devoted to research; these moneys were derived entirely from a special State contribution and not from the funds of approved societies as stated in the question.

Bovine Tuberculosis.—In reply to Sir Fortescue Flannery, Mr. Runciman said that he did not propose to extend to pigs the Tuberculosis Order relating to compensation for cattle slaughtered on account of tuberculosis.

Compensation for Tuberculous Cattle.—In reply to Mr. C. Bathurst, who inquired as to whether in the event of the local authority obtaining from the sale of a carcass of an animal slaughtered under the Tuberculosis Order a greater amount than the sum paid to the owner for compensation, would the excess be paid to the owner of the animal, Mr. Runciman said that, after allowing for reasonable expenses, that would be so, and instructions had been issued to that effect.

Infant Mortality.—Mr. King asked the President of the Board of Education whether he was aware that the figures of the recent census entirely disproved the contention that the declining birth-rate was not compensated by reduced infant mortality; and whether, in view of this fact, he would withdraw the present Estimates and propose others based on correct figures.—Mr. Pease said: I have seen no figures of the recent census which tend to show that I have underestimated the number of children in respect of whose attendance at public elementary schools grants will fall due in the financial year 1913-14; but, on the contrary, since those Estimates were framed I have received further returns, showing that the slight diminution in the number of children which was noticed last year has still continued. With regard to the relation between the decline in the birth-rate and in the death-rate as bearing upon the matter, I may point out that the schools feel the whole brunt of the fall in the birth-rate, but only experience a share in the counterbalancing gain arising from the fall in the death-rate.

School Children (Medical Treatment).—In reply to Mr. Wright, Mr. Pease stated that 229 local education authorities had shared in the grant of £50,374 16s. 7d. distributed last year, and that the amounts received by the different authorities varied from £2 8s. 3d. paid to Chelmsford to £13,683 13s. 10d. paid to London.

Sleeping Sickness.—In reply to Mr. Cathcart Wason and Dr. Chapple, Mr. Harcourt stated that in August last the illness of an official of the Native Department, who had been stationed in the Sebungwe district and who had since died, was diagnosed as trypanosomiasis. A small commission of inquiry was at once formed by the Administration of Southern Rhodesia, and eleven more cases were discovered among the natives, the source of infection being traced to the same or a neighbouring district. Further investigations were being made. The Administrator had informed the High Commissioner that he proposed to remove all natives from these areas to areas free from fly, and the High Commissioner had replied that he was prepared to approve an Order of removal.

Poor Law Officers' Appointments.—In reply to Mr. W. Thorne, who inquired whether the President of the Local Government Board would provide in his new Poor Law

Order that no medical or other Poor Law officer should hold office at the same time in any capacity connected with the administration of justice or the registration of deaths, Mr. Burns said that the matter was under the consideration of the Departmental Committee.

Forcible Feeding.—In reply to Mr. Keir Hardie and Mr. W. Thorne respecting the death of an inmate of the Stafford Asylum stated to have died as the result of forcible feeding, Mr. McKenna said that the patient died of disease of the heart after forcible feeding; that the patient's death was inevitable if he had been left without food, and that the medical authorities of the institution (which was a hospital and not an asylum) were therefore compelled to take the risk of feeding him artificially. This course was clearly necessary, and the jury so found.

Boric Acid in Cream.—Mr. Charles Bathurst enquired whether the attention of the Local Government Board had been drawn to the action of the Westminster City Council in threatening proceedings against retail dealers in respect of the sale of preserved cream containing less than 26 grains of boric acid to the pint, on the ground of injury to health, and whether, seeing that Dr. Hamill, the Medical Inspector of the Board, recommended in a recent report to the Board that a quantity up to 28 grains might be permitted in the summer months without injury to health, the Board would issue a circular advising local authorities that no proceedings ought to be taken, provided sales are made in compliance with the recently published regulations, and where the quantity of preservative does not exceed Dr. Hamill's recommendation. Mr. Burns replied that the statement with respect to the Westminster City Council was correct, but that he did not consider it necessary at present to issue such a circular as had been suggested.

Sheep Disease.—In reply to Mr. C. Bathurst, who enquired as to whether Mr. F. W. Twort, of the Brown Institution, had successfully cultivated the bacillus of scrapie in sheep, Mr. Runciman replied that he had ascertained that the statement made was incorrect, and that it had probably arisen from some confusion between scrapie and Johne's disease, which was really quite distinct.

Hop Substitutes.—In reply to Mr. Rowlands, who inquired whether it was the intention of the Board of Agriculture to introduce legislation to prohibit the employment of hop substitutes, as recommended by the Select Committee on the Hop Industry, 1908, Mr. Runciman said that the matter was engaging the attention of the Board, but he was not able as yet to make any definite statement.

Rural Housing.—In reply to Lord Henry Cavendish-Bentinck, who inquired whether the attention of the Local Government Board had been drawn to a statement in the report of Dr. Webb to the Kingsbridge (Devon) Rural District Council to the effect that one-eighth of the cottages in the district were unfit for human habitation and that there was nowhere for the people to go if these were condemned, Mr. Burns replied that the latest report in his possession did not indicate the existence of any such unsatisfactory conditions, but that the matter was being looked into. In reply to Lord Henry Cavendish-Bentinck, who called attention to the report of the Medical Officer of Health for the Sedgfield Rural District Council in respect to houses at Trindon Grange and Trindon Colliery, where he stated that after inspection he had only found six out of sixty-three houses fit for human habitation, and what action it was proposed to take in the matter, Mr. Burns replied that the council had applied in January last for permission to build twenty-five houses and for sanction to a loan for the purpose, but that it had not yet furnished the necessary particulars before the application could be further dealt with. In reply to Lord Henry Cavendish-Bentinck, who called attention to the special report of the Housing Committee appointed by the Ramsbury (Wilts) Rural District Council, where it was stated that out of fifty-two cottages in the village of Axford ten had one bedroom only, whilst only seven had three bedrooms, that five cottages were overcrowded, three unfit for habitation, seven are dilapidated, and twenty-six needed general repairs, and

while the Ramsbury Rural District Council admit the need for more cottages, they had decided to defer action in the matter, Mr. Burns stated that he had been in communication with the council for some time, and that the chairman had been interviewed by the Local Government Board, and that the matter was still receiving its attention. In reply to Lord Henry Cavendish-Bentinck, who directed attention to the report of the Medical Officer of Health for Cornwall, in which it was stated that the consumption prevalent was largely connected with the bad housing, and in which it was stated that there was a dearth of houses in eight out of the sixteen rural districts of the county—namely, Boscawen, Camelford, Liskeard, St. Colomb, St. Austell, Truro, East Kerrie, and West Penwith—whilst in the Bodmin district many houses should be condemned altogether, Mr. Burns stated that he was in communication with the authorities concerned, and hoped that the difficulties might be overcome.

Asylum Officers (Employment, Pensions, and Superannuation) Bill.

This bill has been introduced by Lord Wolmer, supported by representatives of all the parties. It is identical with the bill as amended by the Select Committee last year and represents a compromise to which the different parties have been able to give their consent.

It lays down the principle that excessive hours for attendants in asylums are injurious to the service and contrary to the public interest, and, whilst allowing for ordinary elasticity in administration and for emergencies, institutes a seventy-four hour week for asylum attendants.

The qualification for the superannuation of female established officers or servants of the first class is applied to those who have twenty-five years' service whatever their age, and a qualification of the former bill which applied to those who are not less than 55 years of age is omitted, the length of service being extended from twenty to twenty-five years regardless of age. Special provisions are made to enable the visiting committee to grant allowances to persons incapacitated by illness not due to their own fault and attributable to the nature of their duties, and in a similar way a visiting committee may grant gratuities to dependants. It may also grant gratuities to female officers or servants who retire after ten years' service, on the basis of a return of the contributions under the principal Act, together with a sum not exceeding one-fiftieth of the salary and wages or wages for each completed year of service.

The Visiting Committee is not allowed to delegate their power of dismissal to an individual officer.

Service in parochial asylums in Scotland is to be counted as service in respect of this Act, and provision is made for the sums which are provided under the principal Act to be distributed on the death of a pensioner dying intestate to be distributed in the case of those who are illegitimate by the Visiting Committee according to the directions of the Treasury.

Any established officer or servant may, within three months after the time of the passing of this Act, adopt the provisions of the principal Act as amended by this Act.

Finally, the powers of the Secretary of State under the principal Act are transferred by this Act to the Commissioners in Lunacy.

Mental Deficiency Bill.—In reply to Colonel Burn, Mr. Lloyd George stated that the Government intended to proceed with this bill, and to give time for its different stages, and hoped to pass it this session.

Bee Disease.—The effect of this bill, which has been introduced by Mr. Runciman, would be to give power to the Board of Agriculture and Fisheries to make orders prohibiting the introduction into England and Wales of any pest or disease affecting bees, and for this purpose to regulate or prohibit the introduction by post or otherwise of bees or any article or appliance used in bee-keeping whereby a pest or disease might be spread, and to make various orders for the administration by local authorities of the necessary preventive and remedial measures.

Scotland.

POST-GRADUATE TEACHING IN EDINBURGH.

THE development of post-graduate teaching in Edinburgh has shown steady progress of recent years, so that now the courses which are held every autumn form an integral and important part of the work of the medical school. The terms for undergraduates leave a long vacation of three months during July, August, and September, and this quarter of the year serves as a post-graduate session. During this period the whole teaching staff, with the clinical and laboratory resources of the school, are available for the post-graduates. The preliminary preparation for the present post-graduate movement began in the summer of 1905, and in 1906 a joint committee, appointed by the University and the school of medicine of the Royal Colleges, arranged for a course of three weeks, which was carried through in the month of September, and was attended by over seventy graduates. In 1907 the course was extended to occupy the whole of September, and was divided into two parts, so that graduates could attend for a fortnight or a month as suited their needs and convenience. A course of operative surgery was added in 1908; this has proved to be most popular, the twenty-five places to which it is limited having been taken up each year long before the beginning of the teaching. In 1909 a course upon methods of diagnosis employed in internal medicine was inaugurated for the month of August, and this, as well as the September courses, underwent further development in 1910. A course for specialists in diseases of the ear, nose, and throat was added in 1911; and in 1912 the time over which the courses had extended was augmented by holding a course upon diseases and defects of children during July. The history of the post-graduate movement in Edinburgh has thus been one of cautious but steady progress, and now every summer about 100 graduates (last year they numbered 99) come from all parts of the world to take part in the different courses.

This year (1913) the various courses will be held as before, with the addition of some classes and the deletion or rearrangement of some others. In the second half of July the diseases of children will be considered mainly in the Royal Hospital for Sick Children. In August diagnostic methods in medicine will occupy the greater part of each day, and there will also, as in the past, be teaching in the diagnosis and treatment of morbid pregnancies in the prematernity ward of the Royal Maternity Hospital. The courses in July and August are limited to twenty-five members. September will be fully taken up by the general course on medicine, by various special classes on subjects of recent interest, by the course on the ear, nose, and throat, and by the course on operative surgery. In addition to these, the Executive Committee has decided that there shall be a class upon advanced surgery, dealing with a special region of the body, and for 1913 the region to be dealt with is the genito-urinary tract.

Last year sixty-nine teachers took part in the courses, and this year the number will not be less, for Edinburgh is fortunate in being able to draw upon a large number of extramural lecturers, as well as upon the staff of the university.

PRESENTATION TO DR. A. M. EASTERBROOK.

Dr. Alexander Maitland Easterbrook, Gorebridge, is the Secretary of the Lothians Division of the British Medical Association, and has also acted as Chairman of the Colliery and Public Works Surgeons Committee for Scotland. His brethren in the Division recognize that Dr. Easterbrook has put in an enormous amount of real work on behalf of the profession in the Lothians both in connexion with the Insurance Act campaign and in the organization of the profession generally. It was therefore thought fitting to acknowledge his great endeavours, and a committee representative of all the three Lothians was formed for the purpose of entertaining Dr. Easterbrook to dinner, and of presenting him with a tangible token of the appreciation of his colleagues.

At the dinner, which took place on March 29th, Dr.

John Keay of Bangour presided, and Dr. A. D. R. Thomson of Musselburgh acted as croupier. After the loyal toasts had been given by the Chair and acknowledged by Lieutenant-Colonel Kirk, V.D., R.A.M.C. (T.F.), and Major Cameron of Loanhead, R.A.M.C. (T.F.), Dr. Martine proposed the toast of "Our Guest" in a short and happy manner. Before closing he presented Dr. Easterbrook with a silver cigarette case with suitable inscription and a purse of sovereigns, and Dr. A. D. R. Thomson presented a gold bangle for Mrs. Easterbrook as a token of esteem and of the unselfish interest shown by her in her husband's labours. Dr. Easterbrook, in reply, expressed the pleasure it gave him to accept these tokens for himself and his wife. The toast of "The Committee" was proposed by Dr. Mitchell of Dalkeith in a racy speech, and Dr. Fowler replied. Dr. Ronaldson proposed "The Chairman," and Dr. Keay replied. The menu card, headed "List of Benefits," contained many humorous topical allusions.

ADVISOR FOR INDIAN STUDENTS IN EDINBURGH.

Some time ago reference was made to the opening of the rooms of the Edinburgh Indian Association at 11, George Square, and now there is another event to be recorded which again shows the new state of affairs that has arisen in connexion with the coming of Indian students in large numbers to the universities of this country. It has been considered desirable to appoint an advisor for such of these students as are under the guardianship of the Indian Office; and Dr. James Miller, Lecturer in Pathology at the New School of Medicine, has been selected to carry out the duties involved. The appointment is the outcome of the visit paid to Edinburgh some time ago by Mr. C. E. Mallet, Secretary for Indian Students, London.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

WOMEN'S NATIONAL HEALTH ASSOCIATION.

THE Countess of Aberdeen, in presenting the report to the sixth annual meeting of the Women's National Health Association, held in Dublin last week, said that there were approximately 19,000 members and 151 branches. During the year the association had been incorporated, and had received gratifying recognition, being entrusted with a Government grant for carrying out the work of providing sanatorium accommodation for patients recommended under the Insurance Act. From the reports of the various branches it appeared that in between eighty and ninety schools throughout the country school meals were being given. Towards the cost of the establishment of dental school clinics a Government grant covering half the expense of equipment and maintenance had been obtained. The following resolution was adopted and referred to a subcommittee to consider the steps to be taken to give effect to it:

That the existing law dealing with the disinfection, and, in proper cases, the destruction, of infected dwellings requires amendment in the direction of making its operation more rapid and certain, and that the Women's National Health Association desire to impress on the Irish Government the necessity of amendment and extension of the present law dealing with this matter.

The following resolution was passed unanimously:

That this Council of the Women's National Health Association, representing all parts of Ireland, gathered at our half-yearly meeting in Dublin, record our conviction that there is urgent need for the better housing of the working classes in the cities and towns of our country. The present conditions are a menace to the health of the people and a reproach to our civilization. They are the means of spreading consumption and other diseases, of reducing the vigour and vitality of our people, and of raising the death-rate to undue proportions. We are informed that a suitable sanitary house cannot now be built to let at an economic rent which an urban labourer can afford to pay, and that, therefore, private enterprise cannot solve the problem. As the public health is a matter of imperial as well as of local importance, we respectfully request the Government to provide such assistance for urban authorities as will enable them to build comfortable sanitary houses for the working classes, to be let at a rent within their means. We further record our conviction that every batch of such houses built should be provided with a playground of ample dimensions for the children.

On April 17th the Skáinte Restaurant, which has been established under the auspices of the association, was opened by the Countess of Aberdeen; it is situated at the Ormonde Market, and is intended to supply the poor—especially mothers and children—with good wholesome food. A sixpenny lunch was provided, the menu consisting of mutton broth, cold beef, ham, corned beef, potatoes, rice pudding, cheese, butter, and bread; this, it was stated, was a fair sample of what could be obtained on any day of the week in the place.

TYPHOID FEVER.

At the last meeting of the Limerick Corporation Public Health Committee a report was read from the urban superintendent of health, saying that since March 28th 17 cases of typhoid fever had occurred. The superintendent and a medical inspector of the Local Government Board had visited the Parks and Water Gates districts, and found them to be in an insanitary state. These two districts were responsible for 12 of the cases of typhoid.

Owing to an outbreak of typhoid fever in the town, the Newry Urban Council asked Professor W. J. Wilson, Queen's University, Belfast, to make an inspection of the water supply of the town and the Camlough Lake, the source of the supply. Professor Wilson reported that he had failed to discover the typhoid bacillus in the water; but from his inspection of the water and the gathering ground he considered that the supply was contaminated with sewage. He recommended the removal of the sources of pollution in the catchment area and the provision of a properly installed system of sand filters. The Council has appointed an engineer to report on the matter.

DIPHTHERIA IN BLACKROCK.

Dr. Browne, Local Government Board inspector, informed the Blackrock Urban Council last week that the number of cases of diphtheria was 33 in the Blackrock Urban District and 7 in the adjoining districts. The disease was of a severe type, and had terminated fatally in 6 or 7 of those affected. It was ascertained on March 26th that all the families affected had a common milk supply. Inquiry elicited the fact that three of the dairyman's family suffered from diphtheria; one of these, a child aged 10 years, was ill about March 17th, but was not medically attended until March 26th, when other members of the family became ill and were seen by a doctor, who pronounced them suffering from diphtheria. The child mentioned visited the dairy daily during her illness. Certain defects at the dairy and at the dairyman's house were being remedied, the cattle had been put on pasture, and the sheds would not be occupied for the next six months. The dairy cattle were all examined by a veterinary surgeon, who pronounced them healthy. "The supervision," he stated, "over the milk supply is not adequate. The visits paid by the dairy inspector were not frequent enough. Each dairy premises should be visited twice or three times in each week, and particularly when the cattle are being milked. It is important that the health of the dairy cattle should be inquired into, and for this purpose a veterinary inspector should be appointed and report result of examinations to the Council." It was unanimously decided to adopt the recommendations contained in the report.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LONDON.

METROPOLITAN ASYLUMS BOARD.

Treatment of Resident Staff under the Insurance Act.

THE Metropolitan Asylums Board in January last (BRITISH MEDICAL JOURNAL, February 1st, p. 253) decided to arrange for a collective agreement with its employees for the provision of medical treatment, drugs, etc., under the Insurance Act, whereby the Board would receive the remuneration available for those services and the Board's medical officers would continue to treat the staff as heretofore. The Finance Committee on April 19th, however, reported to the Board that since January the circum-

stances had undergone a considerable change, and, after prolonged correspondence with the London Insurance Committee and the Commissioners, the Finance Committee was advised that the most effective arrangement would be for a representative medical officer of the Board—namely, the medical officer for general purposes—to enter into a formal agreement with the London Insurance Committee for the attendance and treatment of the insured staff resident in the London institutions only on a capitation basis, it being understood that the medical officer for general purposes would give such treatment by deputy through the medical superintendents and assistant medical officers, and would pay to the treasurer of the Board the fees for medical benefit when received from the Insurance Committee. The personal duties of the medical officer for general purposes would be merely nominal; the medical officers would continue to give medical attendance to the staff by the terms of their appointments; the additional work entailed upon them would be the keeping of certain records of sickness and the signing of such certificates as might be necessary. A proportion of the fees received from the Insurance Committee should be allocated to the assistant medical officers who would carry out these extra duties. The Committee proposed that similar arrangements be made for institutions outside the London area, at the same time remarking that modifications might be necessary in the case of institutions with a non-resident medical officer, who might or might not be already on the local panel.

The Board approved recommendations embodying these proposals.

Appointment of Research Pathologist.

The Hospitals Committee reported that, in regard to the proposed appointment of a research bacteriologist, it had considered the conditions which the Local Government Board attached to its approval—namely, that the officer should be designated "pathologist"; that the appointment should be annual in the first instance, and that at first the officer should not be required to devote his whole time to the Board's service (BRITISH MEDICAL JOURNAL, February 15th, p. 364). The Committee agreed with the Board as to making the appointment annual in the first instance; it thought, however, that the title of the officer should be "research pathologist," and it was strongly of opinion that a whole-time officer should be appointed. The Committee quoted in support the opinion of the Board's consultative bacteriological adviser, Professor G. Sims Woodhead, who wrote that the pathologist must be able to devote the whole of his time, thought, and energy to the solution of problems which had hitherto baffled many men giving their whole attention, though perhaps under less favourable conditions than those under which the proposed officer would work. It was decided to place these views before the Local Government Board.

The Special Hospitals for Children.

In view of representations that an unsuitable class of case was being admitted to Queen Mary's and the Park Hospitals for children, the Board, acting on a report by Dr. H. E. Cuff, medical officer for general purposes, decided to offer boards of guardians special inducements to send, in place of chronic cases, those coming under the following heads:

- (a) Non-pulmonary tuberculosis in its various forms.
- (b) Lateral curvature and other deformities, including patients requiring Swedish exercises.
- (c) Paralysis.
- (d) Diseases of bones and joints not due to tubercle.
- (e) Those requiring any operation.

A Shortage of Nurses.

The announcement was made that owing to the difficulty of obtaining nurses there was a likelihood of the Board refusing to take any cases of measles and whooping-cough other than those from districts already included in the permissive Order recently issued by the Local Government Board.

PROFESSOR PAVLOV has been appointed director of the Institute of Experimental Medicine at St. Petersburg, a post which in the first instance was offered to Professor Metchnikoff.

Correspondence.

MALINGERING AND MEDICAL REFEREES.

SIR,—An interesting feature of the JOURNAL for April 19th is the inclusion within its pages of no fewer than three admirable articles dealing with the subject of malingering and its prevention. This question is of peculiar interest at the present time, for there is evidence that under the operation of the National Health Act the incidence of sickness, or rather the claims in respect of sickness, will prove to be considerably above the original estimates. It is well known that since the introduction of the Workmen's Compensation Acts the premiums of accident insurance companies have gradually increased to the extent of about 100 per cent., and it is only too probable that under the Insurance Act there will be a corresponding rise in the expenditure in respect of sickness claims.

In his convincing paper, Sir John Collie has made out a clear case for the employment of medical referees, and it is evident that the adoption of some plan such as that outlined by him will prove necessary at no distant date. The medical attendant is at an obvious disadvantage when suspecting the honesty of his patient, and he can hardly be expected to act upon his suspicions except in the clearest cases. It is not merely an advantage, but an absolute necessity, that he shall have access to some independent examiner, with whom to share the responsibility of dealing with this class of cases.

Financially, the employment of medical referees would, one may imagine, prove a good investment, for the expenditure involved would doubtless be a minor matter compared with the resulting saving of the funds.

It is to be hoped the articles to which I have referred, and the suggestions they contain, will receive the attention due to them.—I am, etc.,

London, S.W., April 21st.

EDWIN SMITH.

SIR,—I wish to enter a protest against the line of reasoning and policy expressed in your article on malingering in the JOURNAL for April 19th, in that portion of it dealing with certificates, commencing with the words "The fears frequently expressed" and finishing with "The profession has enough problems of its own without unduly burdening itself with difficulties which are not of its making, and which, after all, are the primary concern of the insured person."

The views there laid down are to my mind entirely erroneous, and their expression in an official way, with all the weight which such official expression carries, most unfortunate.

Curiously, in the same issue we have an article, very important and necessary at the present time, on "The Organization of the Profession," and it is there laid down that the policy of the Association is "the promotion of the medical and allied sciences, and the maintenance of the honour and interests of the medical profession." The whole of this article is an urgent appeal to the profession to stand firm together in the defence of these principles.

To return to our grievance. We are asked not to burden ourselves with difficulties not of our own making. This seems foolish. A man does not knowingly erect difficulties for himself and then proceed to demolish them, but all men have, whether they wish it or not, to contend with difficulties not of their own making. The medical profession in their daily round are doing very little else.

The National Insurance Act is not of our own making, but we most assuredly have to burden ourselves with the administration of the medical portion of it. It is not the policy of a young and what should be a virile organization to say, when faced with difficulties, "Never mind; let it go; we are not responsible for the difficulties." We are responsible for the "honour and interests" of our profession, and we must accept whatever may be the accompanying burdens of our responsibility.

The termination of the paragraph, "and which, after all, are the primary concern of the insured person," seems to suggest that this question of certification is in reality of very little concern to us. Medical men in some respects, perhaps, do not rise to the level of a similar class

of cultured persons. Our lives are wide in human sympathies, but, obsessed by minutiae, we suffer from the defects of our own strength and are apt to be short-sighted and narrow, and in broad issues are continually stumbling over trivial details.

There has always been one quality, however, which has lifted the profession above the level of mediocrity—that is, our constant unswerving faithfulness to the needs and interests of our patients, and professional secrecy is an integral and very necessary part of the faithfulness.

There is a comparison between giving evidence in court and signing wholesale the conditions our patients are suffering from, which seems to reveal an extraordinary want of grasp of the principles of the question. It is held, and perhaps rightly, that where justice is in the balance it should take precedence over privilege.

But where can justice, either on behalf of our patients or the funds of the Act, require us to insert the nature of illness on our certificates? It can only demand it on the extraordinary assumption which the article in question seems almost to court—that the medical profession are not fit or able to determine when our patients are well enough to return to work, and that justice requires that we should hand over this prerogative to the approved societies, who, as the fit and proper bodies to determine this, would no doubt have tables of duration of incapacity from influenza, pneumonia, bronchitis, etc.

Even the conception of the Act, lacking in merit as it is, rises to greater heights than this. The idea of the Act is that persons shall receive early and continuous treatment until they are reasonably fit to follow their employment. And who can in justice ask to determine this? Without arrogance or conceit, but as a statement of bald fact, only the medical profession can decide, and it is only just to the insured, for whose benefit the funds are established, that we should decide. It is clear, therefore, that in withholding conditions on our certificates we are doing injustice to no one.

It is also stated in the article "that the insured makes application for the certificate, and that he must be assumed to be acquainted with conditions which the society to which he belongs has laid down." It is evident that the insured for their own sakes have had to go to some approved society, and not become deposit contributors, it is equally evident that in this wholesale herding they have not had time to consider, nor have they been asked or consulted as to their wishes with regard to rules. The implied assumption that the insured are willing and wishful to make a public display of their pathological conditions is absolutely and entirely disproved by practice. We have in this area very many cases where the approved societies have carried out their threat not to pay for four, five, and six weeks, and our patients have entirely agreed with our attitude. The only reason they have for asking the insertion of a condition is this threat of non-payment.

I have also resolutions from many organized trades in the district strongly supporting our action.

Ought not friendly and approved societies' rules to reflect the wishes of the majority of its members, and not only those of its management? The State guarantees for a certain payment certain benefits to the insured. It is a simple contract, and as binding on the insurer as on the insured. How can outside bodies, such as the approved societies who are neither the insurer nor the insured, but agents from one to the other, interpolate conditions which, if allowed, take away from the insured these benefits, he still having fulfilled his contract?

We have been asked in this area why we do not fill up the certificates? May I ask, on behalf of my colleagues and myself, why should we?

It was stated by the late Medical Secretary, amongst others, that the fight—shall I say, for the "honour and interest of our profession"—would be keenest when the Act was in force. It is so, I think, because before we were only skirmishing, now we are in active conflict. Shall we not still justify ourselves by not shirking the burden of our responsibilities, and shall we not still ask the British Medical Association and its mouthpiece, the BRITISH MEDICAL JOURNAL, to act up to its tenets and belief?—I am, etc.,

G. H. SNAW,

Honorary Secretary, Leigh Division, and Local Medical Committee, Lancashire County Area 21.

April 21st.

TRADE UNIONISM AND MEDICINE.

SIR,—In your last issue you very kindly printed a letter from myself in which two specific questions were asked. The first was whether the British Medical Association could become a trade union, and the second whether it could maintain a member of Parliament.

I did not expect a definite reply, because that could only have been in the negative. I, however, looked for and found a reply in the leading article on the organization of the profession. I do not know exactly what authority attaches to the editorial "we," but if I assume too much you will no doubt correct me.

As regards the first question, I note that it (the British Medical Association) is "fettered by many legal restrictions," and also, "we distrust these short cuts." The latter remark should be read in conjunction, I take it, with your references to "earnest but misguided persons" and "recent attempts, some of which have actually materialized, to form new organizations." From this I deduce that the British Medical Association cannot form a trade union, and that the editorial "we" does not even desire to do so.

I have suggested that without a trade union, supplementary to the British Medical Association, the profession is devoid of certain powers which it ought to possess. Let us take a concrete example. In a certain district a medical aid association is set up, and a medical man accepts service under this association on terms which the rest of the profession indignantly repudiate. The staff of the local hospital, or the local Division of the British Medical Association, say that they are not going to be used to break down the resistance of their fellow practitioners, and in consequence publish a resolution that they will not meet the medical officer of this association, nor, except in case of grave urgency, treat any of his patients at the hospital.

Now take the possibilities one step further. The people who have formed the medical aid association say that they will not be beaten by the doctors, and encourage their own doctor to bring an action against the hospital staff, or the local Division of the British Medical Association, accusing them of conspiracy to prevent him from disposing of his labour on whatever terms seem good to him and claiming damages. Is there any doubt that an action would lie, and is there any power in the British Medical Association to resist such an action, or to pay the damages?

But a trade union cannot be attacked on these grounds; it is just one of the most important immunities of that particular form of organization. I suggest that where any members of the British Medical Association felt it necessary to take such action they could protect themselves by belonging to a trade union, and that the latter body would be a very desirable supplement to the powers of the British Medical Association.

My second question dealt with the maintenance of a member of Parliament. I had to look rather further for my answer, but I think I found it in the SUPPLEMENT in the form of a recommendation of the Metropolitan Branch which will be discussed at Brighton. I quote the whole reference because I presume we may consider the suggestions of that Branch in this matter as more or less inspired. Am I not right in supposing that the plans for reorganization of the British Medical Association which recent events have necessitated are herein enshrined? It reads as follows:

"To appoint a Parliamentary Committee, with power to co-opt additional members, to maintain and increase the influence of the Association in the Houses of Parliament, to keep in touch with all legislation, existing or proposed, that affects the medical profession, and to perform all such duties as at present are entrusted to the Parliamentary Subcommittee of the Medico-Political Committee."

Now, frankly, I can only regard this as one of those compromises which are unfortunate for the profession, but inherent in the British Medical Association, owing to the legal restrictions which you deplore.

I suppose that 99 per cent. of any new legislation is decided on in unofficial conferences between the members of the two sides or in Committees of the House sitting "upstairs" or on the floor of the House—please excuse technicalities. In none of these can the new British Medical Association Committee take any part. The most

it can do is to negotiate with members of Parliament who may be in a position to take part in any of the various phases of law-making. These will probably not be medical men, judging from the number of lay members of Parliament who have been in correspondence or connexion with the British Medical Association during this year. As a consequence they cannot be ready to answer the sudden clever question or statement of possible difficulties which the opposite side can launch at any moment. They must run outside and consult the Parliamentary Committee, if they happen to be there, and meanwhile the point goes against them by default. This is compromise. Either we need a member in the House or we do not. Either we need acknowledged representation at every stage of every discussion or we do not. But a Parliamentary Committee as at present suggested is nothing but a makeshift.

Look, however, to the possibilities of a trade union as a supplement to the British Medical Association. It can have a member of Parliament and it can ensure representation of the profession in the House at every stage. It can hand on to that member anything that the British Medical Association may wish to say which has not already been said by the union.

The British Medical Association is a fine organization, and the profession owes much to it. Your leading article says in effect: "Let it grow and include all the profession, and then we shall be all-powerful to protect our professional interests." The position of the British Medical Association reminds me of that of Winchester Cathedral. Could any edifice have seemed more secure? But one day some one noticed that the edifice was cracking, and it was found that half of it was founded on water. It was slowly breaking its back. So may it be with the British Medical Association if it will not realize that its foundation is deficient. It is useless that it should grow; let it first look to the foundations on which it is based, and, if they are not wide enough, avail itself of the necessary reinforcement. I am not one of those who advocate knocking it all down and building on a new foundation, but I do think that, since the strengthening for its foundations is at hand, it would be folly to decline to make use of it.

Possibly I misunderstood the sense of "We distrust these short cuts" in your leading article, but, if that is not the case, I think some better reason should be given for this distrust than is yet forthcoming.

I must apologize for using so much space; may my "earnestness" be held responsible.—I am, etc.,

London, W., April 19th.

GORDON R. WARD.

SIR,—I write in support of Mr. Gordon R. Ward's argument in the correspondence column of our JOURNAL for April 19th, 1913. I consider his contention a just one, and as a member of the British Medical Association I wish to emphasize his claim for recognition.

No one will deny that our Association has done yeoman service in the past, and we are now profiting by its action; but surely we must admit that our machinery is somewhat old-fashioned and not quite up to date. True, we are making heroic attempts to improve the defects, but quite on the old methods, which in these days are somewhat antediluvian.

Now, Sir, I venture to hazard the opinion that in the issue of our JOURNAL of above date we have arrived at quite a unique position. In the leading article the claims of our Association are advocated, and considerable care and thought are evinced in setting forth the plea for continuing under the old régime. How exasperating to the ordinary general practitioner that has proved, I, amongst others who have had to go through it, can freely bear testimony. On the other hand, the claims of the National Medical Guild are tabulated in plain and unmistakable language.

The former recommends us to walk round the two sides of the triangle, as has been our wont in times gone by; the latter to pursue a course along the base. It must still be fresh in the memory of most of us—for we have all been to schools of various sorts during our chequered careers—that the square on the base of an isosceles triangle is less than the square on the two sides. Who will allege the methods of the National Medical Guild are not unquestionable on the square? Let us take the shortest cut.

Therefore, I say, it is the duty of our Association, the parent of this guild, to bless its child, the fruit of its travail through the fight with the Government over the National Insurance Act. One would have thought to see more enterprise evinced, and that we should be found only too ready to claim parentage, to have given this offshoot a house-warming and wished it God-speed.

I sincerely hope that this view of the situation will receive the careful and considered attention of our members at the Annual Representative Meeting at Brighton on July 18th, that they will accord the National Medical Guild their cordial support, and recommend every general practitioner to join.—I am, etc.,

London, N.E., April 22nd.

A. W. MILLER.

RHEUMATOID ARTHRITIS.

SIR,—Dr. Luff asks for my evidence that the proximate cause of rheumatoid arthritis is "a mild chronic acidosis, which extracts the lime salts from the fibrous tissue, muscles, nerves, cartilages, and bones." This query, which I should have thought quite unnecessary, may seem natural to a man who does not deal in proximate causes, but has half a score of causes for a simple phenomenon. Those who want proof of this latter statement will find it in his diffuse and inconclusive article on fibrositis in the BRITISH MEDICAL JOURNAL of April 12th, 1913. If Dr. Luff doubts the extraction of some of the lime salts from, say, the ends of the bones involved in the affected joints in cases of rheumatoid arthritis, he had better inspect some skiagrams of this disease; there are plenty about. There is no suspicion that these salts are carried away by an all-devouring phagocyte. The lime salts in the bones are well fixed, and it is here no question of calcium metabolism; even the thyroid secretion, with all its power in this direction, does not and cannot extract these salts, otherwise it would be a bad look-out for those suffering from exophthalmic goitre. The only substances that I know that will and do dissolve out these salts from the bones, cartilages, etc., are acids, or rather acid salts; as the blood is the vehicle, and all the acids in the blood—even carbonic acid and Dr. Luff's *bête noire*, uric acid—are in more or less close or loose combination (according to the manner in which you care to view the union) with some base or other. In using the term "acidosis," I wish to guard myself against such criticism as the late Professor Anderson bestowed on a young Glasgow chemist who found sulphuric acid and suboxide of copper in Scotch whisky. Anderson said you might as well expect to find a red-hot poker in a barrel of gunpowder.

With the rather free administration of phosphoric or citric acid, especially when the lime salts are cut out of the diet, it is a very easy matter to produce pains in the joints, neuralgia, muscular weakness, increase of the deep reflexes, and excessive excretion of lime. I have tried the experiment on myself, so I know all about it, but I have not done myself any harm; in fact, I think I have benefited, as I have succeeded in establishing a calcium equilibrium. Moreover, it rather sharpens your wits, and after a long course I can strongly recommend the treatment to Dr. Luff.

By a combination of decalcifying agents with respiratory exercises you can extract the lime salts from rigid costal cartilages. When the treatment gives rise to any albuminuria, I think you have carried the decalcifying process too far, and it should then be stopped. With the addition of some milk to the diet, and perhaps the administration of calcium iodide, the albuminuria quickly disappears.

Dr. Luff continues: "He further states that the extraction of the lime salts from the fibrous tissue causes it to swell, while the loss of the lime salts from the muscles causes them to waste—two apparently contradictory statements." Well, really! What next? Wherein does the contradiction lie? I merely stated a fact, and after all you can only explain a fact by stating other facts more or less well understood. I cannot therefore forecast whether Dr. Luff will comprehend my explanation or not, but I hope others will not require it. The presence of soluble calcium salts prevents the free imbibition of fluids by fibrous tissue or laminaria tents. The absence of lime

cannot cause them to swell, but the removal of the inhibition allows them to do so, always provided there is fluid present to imbibe, and in these cases there is plenty of blood serum about. This imbibition increases the watery constituents of the fibrous tissue and causes it to swell, but it does not primarily cause any hypertrophy. It admits, however, of increased vascularity and subsequent proliferation of the fibrous tissue elements. There is no obligation on muscular tissue to take on the same rôle in its relations to the calcium salts. The presence of calcium is absolutely essential for muscular contraction, and fortunately in these cases it is never absent, otherwise the muscle would cease to functionate, and the patient to exist. Its diminution increases the irritability of the muscle, but lessens the efficiency of its contraction; the nutrition fails, and the muscle wastes. There may be, and often is, effusion into the fibrous sheath of the muscle. The varying amount of lime in the cardiac muscle, and the quantity of free calcium ions in the circulation have much to do with the irritability, tone, and contractility of the heart. I have recorded a case where the amount of lime in a gram of the left ventricle was double that in a gram of the right ventricle.

He takes strong exception to my statement about the uselessness of potassium iodide, and guaiacol, and winds up: "I have employed guaiacol carbonate and potassium iodide in some thousands of cases, and I am convinced that this combination is capable in the great majority of cases of arresting the disease, and so of preventing the frightful suffering connected with movements of the affected joints, a condition which is so common in cases of unrelieved rheumatoid arthritis." (The italics are mine.) Marvellous! Some thousands of cases treated with guaiacol carbonate and potassium iodide, and I presume many more thousands treated with other drugs before he arrived at this panacea. I am really sorry for these patients, as they must have swallowed hundreds of thousands of doses of this nauseous and, in my opinion, useless mixture. In order to have arrived at his very definite conclusion he must have had these patients under observation for a long time. Some thousands of cases of rheumatoid arthritis and not one cure, but the great majority arrested, not by a policeman, but by guaiacol carbonate and potassium iodide. *Mirabile dictu*. That the disease may have been arrested by the removal of the cause while the patient was swallowing these drugs I am quite ready to admit, but that the mixture ever arrested the disease since Adam was a little boy I do not believe. What evidence have we that these drugs ever arrested the disease, except the *ipse dixit* of Dr. Luff? The patients must swallow something, but surely he does not expect me to swallow his statement *holus-bolus*.

I do not see how the problem is going to be solved by Dr. Luff's mixture. In the name of all that is holy, just, and true, how is potassium iodide going to arrest rheumatoid arthritis? It may stimulate the thyroid gland and thus increase calcium metabolism, which from my point of view is injurious. It may spoil the patient's appetite, which is also deleterious. Guaiacol carbonate as an antipyretic is not required in this disease, and as an antiseptic it is a very indifferent substance loudly vaunted by manufacturing chemists. If it were shown that rheumatoid arthritis is microbic in origin, any little germ which guaiacol carbonate would kill might be safely neglected. It has also been largely used in phthisis, but it has sickened the patients rather than the tubercle bacilli. These *post hoc, propter hoc* arguments of Dr. Luff won't wash. One advantage of his mixture is that it is cheaper than his treatment of fibrositis by a change of residence and a damp-proof house. It would almost seem as if the versatile Judge Parry had been consulting Dr. Luff, as I find in his article in to-day's *Sunday Chronicle* that he refers to the custom of Hamlet's father to sleep of an afternoon on the damp grass in his orchard, and says that in the natural order of things this must have ended in rheumatoid arthritis. He kindly refers to what he is pleased to call my "iconoclastic attitude towards former workers and writers on this subject," and in appreciation of his kindness I hope he will afford me another opportunity of pulverizing a few more of his treasured idols. I must also thank him for this opportunity of expanding my address.—I am, etc.,

JAMES BARR.

Liverpool, April 20th.

SIR,—I waited a week for another issue of the JOURNAL, thinking that part of Dr. Luff's and Sir James Barr's addresses must have been left out, especially the parts dealing with treatment, but in this week's issue (April 19th) I see no notice to this effect. The lectures, as printed in the issue of April 12th, contain nothing beyond what we find in all the textbooks on medicine that have been issued for the last thirty years. The newer and more efficacious treatment is conspicuous only by its absence. Are we to believe that neither of the above authors has ever seen the wonderful improvement that follows in some cases of rheumatoid arthritis after the usual seaweed bath, given at a temperature of something over 104° F. (this bath consists of boiled seaweed with a strong alkali), when followed by the injunction of a suitable ointment into the spine and stiff joints? Strange as it may seem we are also forced to believe that neither of the writers is familiar with the results that usually follow applications of the thermopuncturing current to the spine, and the affected parts.

So far as I can learn, about one-third of the practitioners in Britain are at present treating this disease with serums, with results much superior to what were obtained by the ancient treatment recommended by Dr. Luff and Sir James Barr. There is still a great diversity in the profession as to the efficacy of the various serums, as also in the method of preparing them; as a rule, practitioners do not rely solely on the serums, but use them as valuable aid to other treatment. I see no mention of a single serum, the method of preparing it, or the results of its use in either lecture. Are we to believe that neither of the writers has any experience of the antirheumatic serums now in common use? "Arsenic, potassium iodide, guaiacol, etc.," may be worse than useless if they are given without any selection of cases. The same may be said of all the other treatment advised in both lectures. I have only glanced cursorily through them, but I have failed to notice any indications as to what treatment should be adopted in individual cases. Each author seems to have treated all his cases of fibrositis somewhat after the manner of the sixpenny doctor, who is supposed to have his pharmacopoeia in about half a dozen barrels, and every case that appears gets a bottle from one of the taps. In Sir James Barr's case the barrel contains mostly lime. In Dr. Luff's case a mixture of potassium iodide, arsenic, aspirin, guaiacol, nux vomica, and a little syrup of the glycerophosphate. I see no mention in either lecture of the best counter-irritant to be applied to the spine and painful parts; how to determine which ointment should be used in each case; when one has learnt this he gets results of a most encouraging character, far superior to any that I have obtained by ionization—a method that I have occasionally used during the last twenty years, but have failed to notice more marked improvement than I have seen to follow the same doses of galvanism when the electrodes have been soaked in warm water.—I am, etc.,

Llandudno, April 19th.

JAMES CRAIG.

THE WATER CURE FOR HYDROPHOBIA.

SIR,—It will be interesting to supplement the record of the use of water in the old time before us in the treatment of hydrophobia, given in the JOURNAL of April 5th, p. 721, by an article upon the subject from the pen of the renowned Dr. Haygarth, of Chester (of whom a full account was given lately in your *Nova et Vetera*), which is to be found in the form of a communication from Dr. Haygarth respecting hydrophobia, made to Dr. Withering. This paper was published in 1822 in the first of the two volumes of *The Miscellaneous Tracts of the late William Withering, M.D., F.R.S.*, from the pen of Dr. Withering's son. It will be remembered that Dr. Withering was a distinguished physician in Birmingham, where his memory is especially cherished as of a patron saint in therapeutics, where he was a physician to the great General Hospital, and where he wrote *The Botanical Arrangement of British Plants*, in four volumes, and much else, and where he wrote and published in 1785 his immortal book, *An Account of the Foxglove and some of its Medical Uses: with Practical Remarks on Dropsy and other Diseases*. Dr. Haygarth was an intimate correspondent of Withering, and this paper of his upon the treatment of some of the effects of

the bite of a mad dog is of the greatest therapeutic interest. Perhaps it has been lost sight of by being included in a posthumous volume of medical tracts and memoir.

Dr. Haygarth wrote to his friend: "Near Wrexham, in North Wales, three men died of canine madness in October and November, 1788. These melancholy cases spread a general alarm. But it ought to give great comfort and satisfaction to any one who may be bit to know that there is a safe, easy, and effectual method of preventing infection, which can seldom give pain or require skill, and is in the power of every person to employ. It is universally allowed by physicians that the spittle of a mad animal, infused into a wound, is the *only* cause, hitherto known, that can communicate canine madness to the human body. This poison does no immediate mischief, but is slowly absorbed into the blood, and sufficient opportunity is given to remove it before any danger can arise. Whenever any one is bit, the plain and obvious means of preventing future injury is, first, to wipe off the spittle with a dry cloth, and then to wash the wound with cold water—not slightly and superficially, but abundantly—and with the most persevering attention; in bad cases, for several hours. After a plentiful affusion of cold water, warm water may be employed with safety and advantage; a continued stream of it, poured from the spout of a tea-pot or teakettle, held up at a considerable distance, is peculiarly well adapted to the purpose. After the bite has been carefully washed, colour it with spittle tinged by ink, etc. When some hours have elapsed wash out the stain. A visible proof may thus be obtained how soon and perfectly water can cleanse the wound from spittle. As a proof that slight washing of the wound is not sufficient to cleanse it effectually from the poison, we may mention that in some cases, after inoculation for the small-pox, the poisonous matter has been attempted to be washed out of the wound by persons who wished to prevent its effects, yet the inoculated small-pox appeared at its proper period.

"These unsuccessful attempts were performed secretly, hastily, and timidly by a female hand; but, in a case where the inoculated incisions were probably washed with greater care, infection was prevented. They teach us the importance of patient perseverance in washing away the poison, but they need not abate our confidence that such perseverance will certainly be successful. The ablution should be accomplished with great diligence and without delay, and may be performed by the patient or any assistant. However, as the apprehension of this dreadful disorder always excites the greatest anxiety, a surgeon's advice and assistance ought to be obtained as soon as possible in all cases where the skin is injured. He will execute these directions most dexterously and completely. In a bad wound the poison may be conveyed deep into the flesh by long teeth or by lacerations. In such circumstances he will open and wash every suspicious place, and whenever any uncertainty can remain that may occasion future solicitude, he should cup and syringe the wound. By this method of purification it cannot be doubted that every particle of poison, and consequently that every cause of danger, may be effectually removed. If the bite have been neglected till inflammation has commenced, it should be washed, syringed, and cupped (after the inflamed surface has been shaved off) with double diligence."—I am, etc.,

JAMES SAWYER, M.D., F.R.C.P.

Birmingham, April 7th.

BOVINE AND HUMAN TUBERCULOSIS.

SIR,—Dr. J. Preston Maxwell has written stating that in the part of China in which he resides—as in districts more to the north—tuberculosis, including tuberculosis of the joints and bones, is common. The importance of this observation rests upon the fact that only where China borders on Thibet is cow's milk used as a food. Elsewhere the drinking of milk is regarded by the Chinese with a similar abhorrence to that with which we regard their habit of eating dogs and cats.

It must be obvious, therefore, that tuberculous disease of the joints and bones may be prevalent where there is no risk of infection from the cow. It is necessary to reconcile this fact with results of laboratory experiments such

as those recorded by Dr. John Fraser (BRITISH MEDICAL JOURNAL of April 12th). Dr. Fraser does not deny that joints and bones may be attacked by the human bacillus, but contends that under the age of 3 years the disease in those parts of the body is generally of bovine origin. His conclusion rests upon the belief that the tests given as to differences between the bovine and human bacilli are absolutely reliable. The greatest confidence is placed upon the difference of virulence of the bovine and human bacillus towards the rabbit. The bovine bacillus is said to kill the rabbit comparatively quickly, while the human bacillus has little effect. Apparently tubercle bacilli obtained from children under the age of 3 years much more often than not killed rabbits quickly, and on this result mainly it is concluded that the tubercle bacillus found in young children is generally bovine.

Such a conclusion ignores what may be described as the peculiarities of the human body as a culture medium. It assumes that the human body may be considered to act in a uniform way towards bovine and human bacilli at all ages, and that the only differences to be noted are those observed as the result of experiments outside the body. That is to say, although we know the human body in early life to be, in the majority of instances, a much better culture medium for the bacillus than in later life, for laboratory purposes a bacillus derived from the human body when outside the body is assumed to act in the same way whether derived from a body favourable or comparatively unfavourable to its growth. Such an assumption seems open to question. Can we assert that the tubercle bacillus during growth in the body at an early age does not acquire certain qualities in consequence of the character of the medium in which it has grown? We want to know whether tubercle bacilli obtained from babies, such as those in China, who cannot have been infected with bovine bacilli, will not kill rabbits as readily as bacilli obtained from babies in Edinburgh.

However that may be, if bovine and human bacilli possess such marked differences in virulence that one will kill a rabbit and another will not, then in a sensitive medium, such as is provided by the tissues of a baby, we ought to expect some marked differences in the behaviour of the two types of bacilli.—I am, etc.,

Sidcup, April 12th.

THEODORE FISHER.

SYPHILIS AND CANCER OF THE TONGUE.

SIR,—In your issue of the 12th inst. there is an interesting communication from Dr. Arnold Renshaw, in which he refers to a lecture of mine recently published in the BRITISH MEDICAL JOURNAL.

My point is that, as a result of investigation of cases of tongue cancer which have come under my observation, 80 per cent. have given a previous history of syphilis, and in the majority of these cases there have been marked syphilitic lesions of the tongue present.

One would therefore conclude that in the greater number of these cases a positive Wassermann reaction would be found, and such in fact has been our experience at the Cancer Hospital. I have referred the matter in Dr. Renshaw's letter to Dr. Archibald Leitch, the pathologist to the Cancer Hospital, and he writes:

In the last seven cases of tongue lesions which were operated on and which were clinically and histologically malignant, five gave a positive reaction. The method employed was that of Browning and MacKenzie, which is the most critical of all the methods used.

Every serum was tested separately with two different complements, not less than eighteen and not more than twenty-four hours old. The advantage of this duplicating of the complements was evidenced by the fact that one particular complement used on two serums tested on the same day was supersensitive, whilst the other complement was not.

I may add that I regard a positive Wassermann reaction as indicative of syphilis; but it does not exclude cancer.—I am, etc.,

London, April 22nd.

CHARLES RYALL.

SIR,—With regard to the interesting relationship between syphilis and cancer of the tongue on which you have recently thrown a good deal of light, it may be of interest to recall that Mr. Clement Lucas used to teach us that the three great causes were the three S's—syphilis, smoking, and salivation. In his opinion the stomatitis of

greater or less degree resulting from the prolonged use of mercury—needful though it was—was a factor which could not be neglected when summing up the various forces at work.—I am, etc.,

Southsea, April 18th.

M. ASTON KEY.

TUBERCULOSIS OFFICERS, SCHOOL MEDICAL OFFICERS, AND THE MEDICAL OFFICERS OF HEALTH (SUPERANNUATION) BILL.

SIR,—From all parts of England and from the North of Scotland replies to my letter in your issue of April 12th have reached me. Every one of them strongly urges the necessity of including in the bill school medical inspectors and tuberculosis officers. Widespread discontent with the remuneration at present offered, especially to school medical inspectors, is almost invariably shown in these replies. Those who have written have also brought the bill to the notice of their member of Parliament.

To the following gentlemen I have sent the appended letter: Sir Philip Magnus (presenter of the bill), Sir Henry Craik, Mr. Lough, Mr. Charles Bathurst, Sir Henry Norman, Mr. Godfrey Locker-Lampson, and Mr. Glyn-Jones, supporters of the bill.

A copy has also been sent to the Secretary of the Society of Medical Officers of Health, and to the Secretary of the British Medical Association, and to Dr. Addison.

Dear Sir,—I have the honour to request your attention to, and consideration of, the following amendment, which I hope you will see has a strong claim for insertion in the bill during the Committee stage:

Amendment.—That the words "medical officers of health" in the title and throughout the bill include "school medical inspectors and tuberculosis officers."

Reasons.—1. Medical inspectors and tuberculosis officers have salaries ranging on the average from a fourth to a half of that paid to medical officers of health.

2. Being whole-time officers, they are precluded from augmenting their salaries by engaging in other work.

3. About three out of every four medical inspectors and tuberculosis officers will not receive promotion from their present position, because their numbers are so much greater than those of medical officers of health.

4. They form the junior branches of the Public Health Service.

5. All the arguments adduced in the bill in favour of public health officers apply in the case of medical inspectors and tuberculosis officers.

—I am, etc.,

ALEXANDER GRAHAM,
School Medical Inspector, West Ham, E.

London, E., April 21st.

THE NEGLECT OF VACCINATION.

SIR,—I have to thank Dr. Killick Millard for the lucid statement of his case in his letter of April 7th. I admit that efficient infantile vaccination is by itself insufficient to check the spread of imported small-pox and to make small-pox hospitals unnecessary. In the absence of re-vaccination, and with the prospect of vaccination becoming optional and of emergency vaccination (limited by lymph supply and time and lay persuadability) being carried out, we must hope that the community may have less small-pox than can be reasonably foreboded.—I am, etc.,

Drent Knoll, April 14th.

J. W. PAPILLON, M.R.C.S.

THE "MILWARD FUND."

SIR,—A fund under the above title has been started in Cardiff to assist the widow and three young children of the late Dr. Courtenay Milward, who are left practically without means.

Reference to the manner of Dr. Milward's death is made in your obituary columns, and the members of the profession in Cardiff and district feel that it is their duty to do all that they can for those he has left behind. The fund is open to all, medical and lay, and donations will be gratefully received by the undersigned.—We are, etc.,

WILLIAM SHEEN,
2, St. Andrew's Crescent, Cardiff,
Honorary Treasurer.A. L. THORNLEY,
18, Windsor Place, Cardiff,
Honorary Secretary.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

SURGEON-GENERAL SIR JAMES PORTER, K.C.B., has been awarded the Good Service Pension of £100 per annum vacant by the death of Inspector-General of Hospitals and Fleets John Fisher.

Flying Pay.

By an Order in Council, published in the *London Gazette* of April 18th, the following arrangements have been sanctioned: (1) Medical officers who obtain the certificates of the Royal Aero Club at their own expense to be eligible for gratuity of £75, provided the permission of the Admiralty to undergo such training has first been obtained. (2) Medical officers trained at the Central Flying School, or at a naval flying school, to be paid half the authorized rate of flying pay while under instruction. (3) After attaining such standard of proficiency as may be laid down, medical officers to be paid the authorized rate of flying pay (a) for any days on which they may be required to fly en duty, (b) for days on which it may be necessary for them to carry out practice flights not exceeding two days per month.

THE INDIAN MEDICAL SERVICE.

THE *Gazette of India* of February 15th, 1913, notifies that Colonel G. W. P. Denny, Inspector-General of Hospitals in the Central Provinces, is granted leave for eight months, and that Lieutenant-Colonel H. E. Banatvala acts in his place. This announcement is of interest as being the promotion of an Indian member of the I.M.S. to officiate in the administrative grade and as Principal Medical Officer of an Indian province. No Indian has yet attained permanently to such a post, but one, Lieutenant-Colonel E. P. Frenchman, C.I.E., acted in the same office, in Burma, in 1909.

It was a strict rule of the East India Company that only men of pure European extraction should be appointed to the I.M.S. The India Act of 1853, Acts xvi and xvii Viet., cap. 95, introduced competitive examination, open to all natural-born subjects of Her Majesty, for admission to the service. The first examination was held in January, 1855, when the list was headed by S. C. G. Chuckerbutty, a Bengali Christian, who had been one of the Indian students sent to study in England, under the guardianship of Dr. H. H. Goodeve, ten years before. Chuckerbutty took the diploma of M.R.C.S. in 1848, the degree of M.D. Lond. in 1849. From 1850 to 1854 he served in the Unconvenanted Medical Service. Of the five students sent home with Goodeve, Chuckerbutty was the only one who was young enough, in 1855, to enter for the examination for the I.M.S.

Since 1855 over 100 men with pure Indian names have gained admission to the I.M.S., of whom nearly forty-nine have joined on the General List instituted in 1896. Some twenty others, with Portuguese or Armenian surnames, have also entered; as well as a considerable number of Anglo-Indians of mixed blood, who, of course, cannot be identified by their surnames.

It is not perhaps surprising that no Indian has yet risen permanently to the administrative rank. More than half of the Indians admitted are still too junior for any question of their promotion to have arisen. Of the seniors, comparatively few, only some ten in all, have put in the full thirty years' service necessary for promotion or full pension. Many have taken the first opportunity of retiring as soon as they had earned the first pension. Several have held appointments of importance with credit and success. Chuckerbutty became professor of *materia medica* in the Calcutta Medical College, and second physician of the Calcutta Hospital, in 1864, and held the post till his death, when on leave, in London, on September 29th, 1874. Another Indian, R. C. Chandra, was his successor in these offices, and held them for nearly twenty years, till his retirement on October 16th, 1891. Lieutenant-Colonel Frenchman for several years held the Inspector Generalship of Prisons in Burma. Another Indian officer held that post in the province of Eastern Bengal and Assam, and now holds it in the new province of Bihar and Orissa. Ten have risen to the rank of brigade surgeon, or its modern equivalent, lieutenant-colonel, on the selected list.

Lieutenant-Colonel Hormusjee Eduljee Banatvala is a Parsi by birth. He was born on October 20th, 1859, so has a year and a half yet to run before attaining the age for compulsory retirement. He was educated at the Grant Medical College, Bombay, where he took the L.M. and S. in 1881, and at St. Bartholomew's Hospital, taking the M.R.C.S., L.R.C.P. Lond., and L.S.A. in 1882. He entered the Bombay Medical Service as surgeon on April 1st, 1884, passing third, and a few months later was transferred to

Bengal, became surgeon-major on April 1st, 1896, lieutenant-colonel on April 1st, 1904, and was placed on the selected list on January 1st, 1910. For the first nine years he remained in military employ, serving in Burma from 1886 to 1889, when he took part in the operations of the First Brigade and in the pursuit of Hla Oo; he received the medal with two clasps. He also served in the Lushai expedition of 1892. For the last twenty years he has been in civil employ in the Central Provinces, where he now becomes Acting Inspector General of Hospitals.

GLASGOW UNITS, ROYAL ARMY MEDICAL CORPS.

THE annual gathering and presentation of prizes in connexion with the Glasgow units of the Royal Army Medical Corps (Territorial) took place in the new head quarters at Yorkhill Parade. Lieutenant-Colonel A. D. Moffat, M.D., Commanding the 2nd Lowland Field Ambulance, presided, and there were also present Colonel D. J. Mackintosh, M.B., M.V.O., Assistant Director of Medical Services, Lowland Division; Lieutenant-Colonel H. Wright Thomson, Lowland Mounted Brigade Field Ambulance; Lieutenant-Colonel George H. Edington, M.D., 1st Lowland Field Ambulance; Lieutenant-Colonel A. G. Hay, M.D., 3rd Scottish Hospital; Colonel Alexander Napier, M.D., 4th Scottish Hospital, and others. The chairman said that the aggregate authorized strength of the units was 32 officers and 730 other ranks, and that there were serving on February 28th 29 officers and 743 other ranks. Since then the shortage of officers had been made good, and he congratulated those present on being members of a highly prosperous and admirably equipped corps. So far as the crisis in the Territorial Force was concerned they had no knowledge of it in the Glasgow units of the Royal Army Medical Corps. Colonel Mackintosh presented the prizes gained during the past season, and congratulated Colonel Moffat on the excellent report. He was glad to learn that a large number of men proposed to re-engage for a further period, which showed their patriotism and their loyalty to the Territorial Force.

Universities and Colleges.

UNIVERSITY OF LONDON.

Graham Scholarship in Pathology.

THE late Dr. Charles Graham, Professor, and later Emeritus Professor of Chemical Technology in University College, by his will bequeathed the residue of his estate to the University of London, to found at the School of Advanced Medical Studies of University College a Charles Graham Medical Research Fund. The Senate was empowered to establish a Graham scholarship in pathology of not more than £200 a year to enable a young man to continue his pathological researches, while at the same time he gives his services to the school as a teacher under the Director of Research appointed under the Graham bequest. The Senate now invites applications for the Graham scholarship in pathology, which is of the value of £200 per annum for two years. Applicants stating the research upon which the applicant proposes to work, and marked "Graham Scholarship," must be sent to the Principal, University of London, South Kensington, S. W., by May 31st, accompanied by the names of not more than three references, one at least of which should be the name of a professor, lecturer, or teacher of the university or college in which the candidate has conducted his studies in pathology.

CONJOINT BOARD IN ENGLAND.

THE following candidates have been approved at the examination indicated:

FIRST COLLEGE (Part IV, Practical Pharmacy).—O. H. B. Avarne, A. J. Bado, O. Baler, P. W. Barnden, C. A. Bernard, J. W. Bouwer, H. H. Castle, A. J. Chillingworth, G. D. Compston, D. T. Corke, H. L. Cronk, F. W. Crook, J. D. L. Currie, G. Dayal, S. B. Depree, E. Donaldson, K. M. K. Duff, P. Green, H. S. Groves, H. Gwynne-Jones, W. T. Gwynne-Jones, A. R. Hacker, T. W. Hancock, T. C. Higgins, G. G. B. Holroyde, T. R. Kenworthy, G. H. S. Letchworth, A. R. Muir, W. E. Neale, F. A. M. Nelson, D. W. Pailthorpe, A. B. Preston, F. N. Reynolds, A. N. Rushworth, T. W. Sheldon, A. H. Tynmour, G. O'N. Waddington, L. M. Waldron, A. S. Westmorland, G. W. Wheldon, L. H. Woods.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—W. Brown, N. S. Bruce, R. P. Crawford, H. G. Fitz-Maurice, J. A. Murray.
SECOND COLLEGE.—J. Crawford, A. Evans, D. A. Imrie, R. MacGregor, J. Y. McLean, J. M. A. McVey, G. L. Pillans, I. H. Shaw, W. Templeton, F. W. Thompson, R. L. Wright.
THIRD COLLEGE.—J. W. Cowie, J. R. C. Gordon, W. L. Paterson.
FINAL.—S. Cochrane, A. M. Robertson, W. N. P. Williams, Madeline MacWilliam, W. E. Cruickshank, M. J. Ahorn, R. Craig, M. R. Mahlangeni, J. F. Bourke, J. R. Gwynne, G. L. Clark, S. Swaminathan, R. S. Miller, U. R. Hattiangadi.

Obituary.

RAYMOND BROADLEY ETHERINGTON-SMITH,
M.A., M.B.CANTAB., F.R.C.S.ENG.,

WARDEN OF THE COLLEGE OF ST. BARTHOLOMEW'S HOSPITAL.

THE toll paid to death by the medical profession during the past few months has been exceptionally heavy, but no loss is likely to be more generally deplored than that arising from the death, on April 19th, of Mr. Raymond Broadley Etherington-Smith in his 36th year.

St. Bartholomew's Hospital, medical students, and rowing men of the present and of the future are equal sufferers. The hospital has lost a member of its staff who did credit, and was certain to do constantly increasing credit, to its repute; the students have lost a teacher whom they could not fail to admire, both as a man and as a source of information; and Surgery has lost an exponent who, apart from his professional capacities, was possessed of such personal charm that he was bound to win its friends. Etherington-Smith, in short, was not a man whom any profession, or, indeed, any nation, could afford to see snatched away from it in the very prime of his life without the deepest regret, and a kind of wonder as to what great purpose of Providence was served thereby.

He was born in 1877, and was the second son of Mr. J. R. Etherington-Smith, Recorder of Derby and a Bencher of the Inner Temple; his mother was a daughter of Sir Thomas Pears, K.C.B. Educated, like his father, at Repton, Etherington-Smith entered Trinity College, Cambridge, in 1895, and graduated in Arts and Medicine in 1903. He received the later part of his professional education at St. Bartholomew's Hospital, which he entered as a university student, and was admitted a Fellow of the Royal College of Surgeons in England on the same day that he received his membership in June, 1907.

At the hospital he made his way very rapidly, and held the posts successively of surgical registrar, demonstrator of surgical morbid anatomy, assistant surgeon, and warden of the college. He was also assistant surgeon at the West London Hospital. In all these positions he exerted himself to the full limit of his strength, and the end of a long winter found him unable to resist an attack of pneumococcal peritonitis, which seized him suddenly on the evening of April 16th, and ended in his death on April 19th, in spite of the most devoted surgical and nursing attention. Just before his illness he had had occasion to operate on a case of gangrene of the lung, and there is reason to believe that his death adds another to the long list of those directly due to the performance by medical men of obviously dangerous duties.

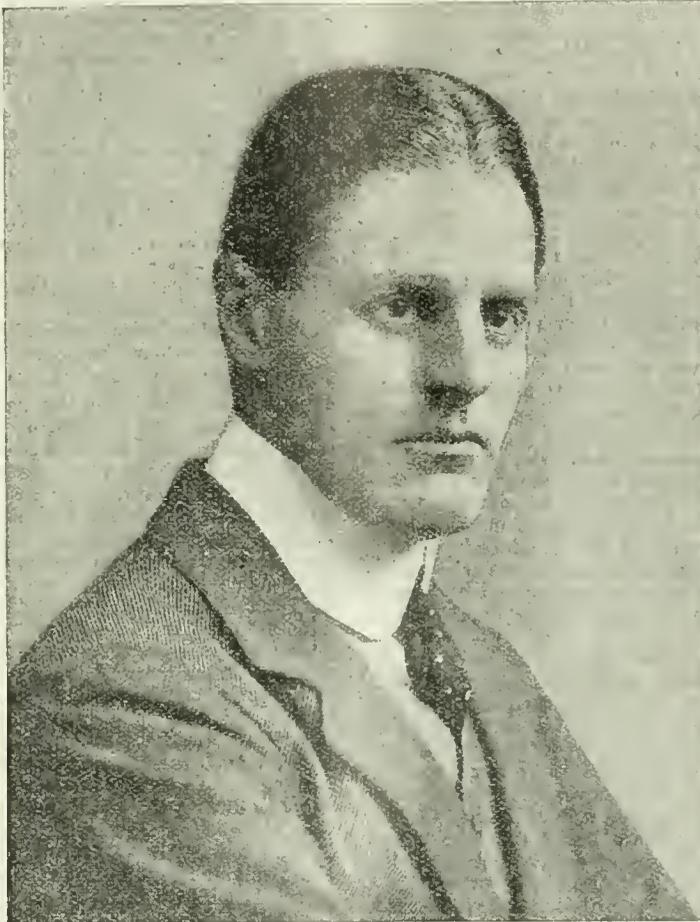

Etherington-Smith was already a man of mark when he entered the medical profession some ten years ago. Quite early in his career at Cambridge he attained a

reputation on the river, and subsequently he became one of the best-known English oarsmen and most successful coaches of his day. That day, too, lasted unusually long, for it began in 1895 and ended only in 1908; meantime he had stroked many London Rowing Club, Leander, and Cambridge crews to victory, and in addition had carried off the Diamond prize for sculling on more than one occasion. His crowning performance was the captaincy of the English crew which, despite unfavourable presages, won the Olympic regatta of 1908.

Rowing, however, did not exhaust his energies. He entered fully into every side of the life of his hospital, and though the amenities of professional life obliged him of late years to use a motor car, he was also an ardent motor cyclist. Driving in his car, commonly with a friend, he was a familiar sight in the streets of London on his way to the chief athletic events of the year.

As a surgeon Etherington-Smith was, of course, only at the beginning of his career, but he had already made considerable progress in several special departments of his science, and had also attained some degree of surgical repute among the general public. This may have been partly due to his connexion with athletic circles, but his own personal qualities and professional skill were of such a kind that, had he lived, he was bound sooner or later to have come to the front as one of the surgeons of the day.

No man unpossessed of physique and character could have attained and kept for so long a period the position of Etherington-Smith as an oarsman, and both were obvious almost at first sight. Not only was he a tall, decidedly handsome man, but there was a quality in his face which was a true index of his character. Full of grit and intelligence, absolutely loyal to his friends, he was a clean living man who could not fail to attract all those who came into contact with him. Even-tempered, courteous in manner

R. B. ETHERINGTON-SMITH.

[Elliott and Fry, Ltd.

and quiet in address, he held decided opinions based upon assured knowledge, and expressed them clearly and pleasantly. In professional subjects his opinion was always sound, for it was based upon a broad platform of accumulated facts.

His influence on his contemporaries and juniors was always of the very best kind. His contemporaries were his devoted friends, and their familiar talk of "Ethel Smith" was invariably and wholly to his credit, whether it was in connexion with school subjects or the towing path; and junior men revered him with the affection and awe commonly felt by athletic aspirants for one who has outshone all others in his own department. He was therefore ideally fitted for what may be regarded as the more important of the three posts which he was filling at the time of his death—that of Warden of the college of St. Bartholomew's Hospital. It brought him into intimate contact with medical students fresh from home and school, and he maintained for the post the prestige which the office acquired many years ago under the sway of Sir James Paget.

Though Etherington-Smith's death is deplorable, he did not live in vain, for he impressed the genius of his character not only on his own friends but on men of several younger generations, who will live with higher ideals owing to their association with him. Etherington-Smith was unmarried.

The first part of the funeral service on April 23rd was held in the Priory Church of St. Bartholomew the Great, which was filled to overflowing. The coffin was carried from the hospital to the church by those members of the hospital staff who had been most closely associated with him as colleagues and house-surgeons. It was draped with the Cambridge University Boat Club and the Leander Club flags. The service was conducted by the Rev. H. S. Close, the Hospitaller. The committal service was carried out in the Putney Vale cemetery amongst a wealth of flowers and the first verdure of spring, the coffin being lowered into the grave by six Cambridge Blues who had shared with him many a hard-won race.

THOMAS HAYES, M.D., J.P.,
RATHKEALE, CO. LIMERICK.

DR. THOMAS HAYES, of Rathkeale, co. Limerick, passed away at his residence in that town on April 3rd in the 81st year of his age. At the time of his death he still held several appointments, and, despite his advanced age, was by no means a titular occupant thereof. Only some four months before his death he performed a successful operation on a case of strangulated femoral hernia in a woman 80 years of age. Even the illness which, after lasting three months, terminated his life, left his mental faculties unimpaired, and throughout its course he used to discuss with his medical attendants (two of his own sons) the different phases of the diabetes, complicated by gangrene, from which he was suffering.

An admirable example of a medical man of the old school, Dr. Thomas Hayes had been at work in the province of Munster for over fifty years, his practice extending over a very wide area of Munster. He performed its various duties, which included much surgery and consultation work, in such fashion as to gain the full confidence of his patients and the affection of a large proportion of the inhabitants of the province. Indeed, there were many who regarded him as a true Irish prototype of the Scottish country surgeon rendered so famous by the novelist Ian Maclaren under the name of Weelum Maclure.

He was born in Fairy Street House, Athlea, in August, 1832, being one of a family of eight children orphaned when all were still quite young. It thus came about that he received his early general education at the local national school—a fact of much interest, in view of the high degree of culture and knowledge of classical and other languages which he constantly evidenced in adult life. On reaching the age of 20 he joined the medical side of Trinity College and had a successful career there, being appointed a prosector and winning prizes in sundry class subjects; among them was botany, in which he snatched the prize from a student who afterwards became a distinguished professor of the same subject in Trinity College. Subsequently he spent several years between Edinburgh and London, completing his student life by becoming M.D. Edin. and M.R.C.S. Eng. in 1856.

His first intention was to join the Indian Medical Service, but eventually he determined on general practice in Ireland. After working some years in the Shanagolden district of Munster, he became medical officer to the Rathkeale workhouse and dispensary, and settled in Rathkeale, where he continued to reside during the rest of his life, meantime taking up a good many other appointments. As a young man at Edinburgh he had studied the use of chloroform as an anaesthetic under Simpson himself, and he was one of the first to use it extensively in practice. He was an able surgeon, and when occasion arose he was never afraid to operate, even in the discouraging conditions often encountered in country practice. Some of his characteristics and the impression he made on those well acquainted with him are well brought out in the following letters. Mr. W. O. Stevenson, of Steevens's Hospital, Dublin, after describing how he was to be seen driving for long distances in his outside car, in

every kind of weather, and at all times of the day and night, continues:

Thirty years ago he was one of the best known general practitioners in the South of Ireland, and until recently enjoyed a very extensive practice and was the respected and esteemed family physician to many county families. He was a man of many parts and always derived a great deal of pleasure from the study of nature, and possessed a surprising knowledge of the geology and botany of his county. . . . He was a good diagnostician, and frequently obtained brilliant results by a fearless administration of a drug which would surprise the younger generation. Dr. Hayes was a strong man and an erudite physician and surgeon also of the old school. His stout rule and conviction that a doctor should have no politics made his services acceptable to all parties alike. At home he was a most hospitable and courtly gentleman. . . . His death after a very strenuous and useful life severs a link with the past in a way which only those who knew him can appreciate.

Other points in his character are equally well brought out in the following letter from Dr. D. Mahony of Glasnevin, who after some preliminary observations, writes:

A large section of the province of Munster mourn their wise counsellor, their "beloved physician." His was in truth a noble personality, a living example of what a physician ought to be. Invariably comely and serene, genial, kindly, and painstaking, we have lost in him what we can ill spare, the embodiment of the best type of traditional Irish medical man. None to whom he ministered in the course of his extended career can ever forget his lovable character, his all-embracing sympathy, his loyalty to his friends, his human-kindness. Of wide general culture and literary tastes, he had in addition the talisman of the successful doctor—that elusive "healing touch"—the power to inspire confidence and to cheer the depressed. We have left but his memory and the example of his life—a long life consecrated to acts of duty and kindness, and to the welfare of his fellow men. But—

To live in hearts we leave behind
Is not to die.

In the venerable Gaelic tongue which he loved so well—
Go mbeannuide Dia ar a anam.

A high-minded man himself and an uncompromising opponent of anything in the nature of sham, Dr. Hayes exercised his keen powers of observation to advantage throughout his life, and thus had much that was interesting to relate of those who were great medical authorities in his student days. For Sir Dominic Corrigan, under whom at the Whitworth Hospital, Dublin, he first learnt the treatment of fevers, he had a particular admiration. Dr. Hayes wrote as he spoke, both forcibly and fluently, and was never at a loss for an apt quotation from classic authors. Some of the subjects on which he contributed papers to the medical press were the surgery of severe gunshot injuries, excision of the tonsils, the treatment of chronic inflammation of the knee-joint by Corrigan's cautery, and the importance to be attached to a uterine bruit as a sign of life after apparent cessation of the movements of the fetal heart. He was also a student of Hebrew and Welsh, and conversant with several modern languages. In Gaelic he was a ready speaker, and was engaged during the latter months of his life in translating the *Odes of Horace* into this language.

Dr. Thomas Hayes, who was at one time President of the Munster Branch of the British Medical Association, married in 1861 a daughter of Mr. Henry Bouchier, of Fort William, and is survived by three sons and one daughter. The latter kept house for him during the later years of his life, and of the former two are medical men—Dr. J. T. Bouchier-Hayes, J.P., of Rathkeale, and Dr. H. Bouchier-Hayes of Charleville.

WILLIAM COURTENAY MILWARD, B.A. OXON.,
M.R.C.S., L.R.C.P.,
CARDIFF.

WE much regret to record the death of Dr. William Courtenay Milward of Cardiff at the early age of 41. His death occurred with startling suddenness from angina pectoris on April 9th; that he was ill was known practically to none. Having regard to the nature of his illness, it is no exaggeration to say that overwork and much mental strain in connexion with the Insurance Act materially contributed to his death. His loyalty and devotion to the needs of the local profession were unceasing, and amidst much contention and difference of opinion he had the confidence of every one. He took a sane, level-headed view of all problems, and thoroughly understood the difficulties and anxieties of the recent troublous times.

As senior secretary of the Cardiff Division and Representative of the Division at the Representative Meetings the calls upon him were unceasing, and he was always ready and willing to give advice and assistance.

Mr. Milward was educated at the University of Oxford and Guy's Hospital. He had practised in Cardiff since 1902, where he held the appointments of Poor Law medical officer and medical officer to the Clerks' Association, and was physician to the French Consulate. He was a man of wide reading and considerable culture.

His professional work, though hard, was relatively unremunerative. His work for the profession and his refusal to go "on the panel" until formally released from the "pledge" must have acted detrimentally to his practice.

Dr. Milward attended, on March 19th, a meeting of the Subcommittee of the State Sickness Insurance Committee appointed to consider the amendments to the Insurance Act which are desirable. At its meeting on April 15th that Subcommittee adopted a resolution of regret and sympathy with the relatives of the late Dr. Milward in their bereavement, and this resolution was endorsed by the State Sickness Insurance Committee at its meeting on April 17th.

The local profession feels that it is an obligation on it to do something for his widow and three young children, who are left almost totally unprovided for. A fund has therefore been opened, to be called "The Milward Fund," to which reference is made in our correspondence columns. The fund is open to all, and we hope that it will be liberally supported to mark the appreciation of one who gave his life for the profession.

THE LATE SIR HENRY SWANZY.—At a meeting of the members of the Council of the Royal Victoria Eye and Ear Hospital, Dublin, on April 15th, the following resolution was adopted:

The President and Council of the Royal Victoria Eye and Ear Hospital desire to place on record their deep sense of the irreparable loss which has been sustained by them personally and by the hospital in the decease of their Honorary Secretary, the late Sir Henry Rosborough Swanzy. The hospital owes its origin almost entirely to his initiative and public spirit, and the present existing excellence of its structure and organization is largely to be ascribed to the unremitting personal attention which he devoted to every detail. It was through his loyal and single-hearted effort that the many difficulties surrounding the effectual amalgamation of the two older hospitals—St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary—were surmounted through the machinery of the Act of Parliament obtained in 1895. Since that date he never spared himself in seeking to arouse in others his own enthusiasm on its behalf and in promoting its development and improvement in everything that modern science could suggest. This hospital was the great aim of his life, and it stands to-day as a lasting and worthy monument to his memory. The President and Council desire to convey to his family their heartfelt and sincerest sympathy with them in the sorrow of their great bereavement.

Dr. WILLIAM ROBINSON EVANS of Dublin died suddenly on April 7th. He attended a meeting in the Merrion Hall that evening, and was one of the speakers; resuming his seat after his remarks, which had occupied about twenty minutes, he almost immediately became weak, and died a few minutes later from heart failure, in spite of all the efforts of another doctor who was present at the meeting. Dr. Evans was educated at Trinity College, Dublin, where he graduated M.B. in 1870 and M.D. in 1879. He studied for some time in Vienna. For many years he had been a well-known and respected practitioner in Dublin. He was consulting physician to the Orthopaedic Hospital. His sister, who has been ill for some time past, was greatly distressed by her brother's death, and died about twelve hours later.

SURGEON-LIEUTENANT-COLONEL ALEXANDER BREBNER, late Army Medical Service, who died on March 30th at the age of 72, took the degrees of M.B., C.M.Aberd. in 1862 and that of M.D. in 1873. He entered the service in April, 1863, became surgeon in March, 1873, and surgeon-major in April, 1876, retiring in May, 1888, with the honorary rank of surgeon-lieutenant-colonel. He served in the Bhutan expedition in 1865, taking part in the capture of Dewangiri, and received the medal with clasp.

DR. AGNES McLAREN, who died at Antibes on April 18th, was one of the pioneers of the medical education of women. It was at the house of her father, the late Mr. Duncan McLaren, M.P. for one of the divisions of the City of Edinburgh, that the agitation for the medical education of women, the chief actors in which were Dr. Sophia Jex-Blake and Miss Peachey, was begun. Their object was to open the medical schools, university, and extramural, as well as the clinical wards of the Royal Infirmary of Edinburgh, to women. To a large extent their efforts were in the long run successful. Dr. Agnes McLaren graduated at the University of Montpellier, and afterwards settled at Cannes, where she had a large practice. Some years ago she retired to Cap d'Antibes, and gave herself up to a vigorous campaign against the white slave traffic, and to other social reforms with reference to women. She was a woman of strong individuality and character, and was known to a large circle of philanthropic workers of many nations, of many kindreds, and of many creeds—she had herself become a Roman Catholic. She has died at an advanced age, though somewhat unexpectedly, and will be greatly missed by many. She was the sister of Lord Aberconway; of the late Lord McLaren, one of the judges in the Supreme Court in Scotland; of Mr. Walter McLaren, M.P., and of Mr. Duncan McLaren, of St. Oswald's, Edinburgh.

Medico-Legal.

LIND-AF-HAGEBY VERSUS ASTOR AND OTHERS.

THIS case, which had occupied practically the whole time of Mr. Justice Bucknill and a special jury since April 1st, came to a conclusion on Wednesday, April 23rd. The claim was for damages for libel, the action being brought by Miss Emelie Augusta Louise Lind-af-Hageby against Mr. William Walford Astor, the proprietor of the *Pall Mall Gazette*, Mr. David Cameron Forrester, the printer, and Mr. James Louis Garvin, the editor, and Dr. Caleb Williams Saleeby, the writer of the articles complained of. The defendants denied that the words referred to the plaintiff, and in the alternative said that they were true in substance and in fact. They also pleaded bona fide comment on a matter of public interest.

The plaintiff appeared in person.

Mr. Duke, K.C., Mr. McCardie, and Mr. S. J. Field appeared for Dr. Saleeby; and Mr. Shearman, K.C., and Mr. Hugh Fraser for the *Pall Mall Gazette*.

Dr. Saleeby had written about the exhibition of the Animals Defence and Antivivisection League in Piccadilly, and in the *Pall Mall Gazette* of May 7th had referred to "the systematic campaign of falsehood without which the antivivisectionist societies could not exist," and cited this window as an illustration of "the unscrupulous mendacity of their hirelings." He pointed out that there was no indication given that the animal upon the board was chloroformed, and asked, "What point would there be in the exhibition if that fact were known?"

The plaintiff was the honorary general secretary of the Animals Defence and Antivivisection League and editor of the *Antivivisection Review*, and had taken a prominent part in the antivivisection campaign.

The defendants, in support of their defence that the words in question were true, had set forth a large number of extracts from various publications issued by or with the authority of the plaintiff. The documents most frequently quoted from were *The Shambles of Science* and the *Antivivisection Review*. Each member of the jury was supplied with a copy of these particulars.

A large number of witnesses were called on either side; those called for the plaintiff included Dr. Robert H. Perks, Mr. Stephen Smith, Lieutenant-Colonel Lawrie, I.M.S.(ret.), Dr. Valentine Knaggs, Dr. W. J. Cameron, and Dr. Richard Cowen; and for the defence, Professor E. H. Starling, Sir Victor Horsley, Dr. C. J. Martin, Director of the Lister Institute of Preventive Medicine; Dr. J. W. H. Eyre, Director of the Bacteriological Department of Guy's Hospital; Dr. Alice Corthorn; and Dr. William Bulloch, Bacteriologist of the London Hospital.

Mr. Justice Bucknill, in the course of his summing up, said that after a long inquiry he had the most difficult duty of any one in court—namely, to remind the jury of the real facts and issues at stake. It was a question of fact which the jury had to deal with, not a religious question or question of sentiment. Had Dr. Saleeby defamed the character of the plaintiff so as to give her a legal right to sue for damages for defamation? Looking at the passages which were said to be libellous, they were said to amount to this—that the plaintiff had untruthfully and dishonestly with her associates carried on a campaign against the practice of vivisection. She had undoubtedly been a very hard worker in a very laudable cause. In her honour he said that he could not help admiring the vigour with which she had fought the battle of the antivivisection. She was entitled to be an antivivisection. She was a lady of marvellous power, able to stand

in court day after day showing no sign of fatigue, not losing her temper, and able to cross-examine as well as any counsel at the Bar. All that was to her credit. But it was her duty to be truthful and fight her opponents fairly. He could not help thinking that she must now regret the attack upon the Royal Commission which was embodied in the letters signed "Nemesis," admittedly written by her. In one of those letters she had said of Lord Cromer: "You are not the first man of prominent position who has warmly championed cruelty." It was true she might express her opinion as strongly as she liked; but she was not entitled to further the cause by making statements which were dishonest and untruthful. There was no evidence to show that she had done anything to ascertain the truth with reference to her statement that 6,500,000 people had died from plague in India as a result of serum inoculation; she had made a statement of which she had no knowledge. [At this point the plaintiff interjected the remark: I relied on Dr. Helen Bouchier, who had been in India.] Reviewing the evidence given by the plaintiff, his lordship remarked that she had said in terms that she had adhered to the open letter written to Lord Cromer. If that was so, Lord Cromer might well bring an action against her. He (the learned judge) disliked the practice of writing "open letters," and in saying that he was not speaking of Miss Lind alone. Many men did not want to go to law to set up a character which they knew they had never lost, but some people were so sensitive that, if accused of being untruthful, they would take sixteen days before a judge and jury to prove the contrary. He felt much puzzled by the antivivisectionist argument that one may cut up a mouse to save the mouse's life, but one must not do so to save a human life. The jury had to ask themselves whether Dr. Saleeby's letters might have been considered by a reasonable person to apply to the plaintiff, and whether the language was defamatory. Had no evidence been called on the part of the defendants, the only questions would be, was there malice and the amount of the damages. As to damages, the plaintiff had not said much as to how much she wanted. She had said that she felt very deeply that her character had been impugned, but she also said she had come, not for the purpose of obtaining money, but to vindicate her character. If they found in her favour, they would give her damages which would not be so small as that people might point the finger at her and say that she had been awarded the smallest coin of the realm. They must mark in a sensible way the wrong which had been done her. His lordship then reviewed the evidence for the defence at considerable length. He pointed out that Dr. Saleeby, in an earlier part of the article attacked, had said that he, too, disapproved of cruelty. As to the suggestion of the plaintiff that an air of levity sometimes pervaded the lecture theatre, the evidence showed that students would joke and laugh, but whether they were laughing about football or not, they were not laughing at animals in pain. Did they think that the defendants had made out their case? Had they satisfied them (the jury), in the first place, on the plea of justification? It was not necessary that every single fact alleged in the plea of justification should be proved. The question was, Had the truth of the allegations been substantially proved? If they thought that the list of particulars of justification had been substantially proved to their satisfaction; that what Dr. Saleeby wrote he was justified in writing, and wrote on facts which had been proved to be true; that, in point of fact, the plaintiff had been proved to be guilty of mendacity; that the campaign had been carried on untruthfully; that she and her associates had during this long time been attempting to destroy the vivisectionist stronghold, and take to themselves the people as antivivisectionists—if they were satisfied on all these points, and that the plaintiff had knowingly taken an active part, they would be entitled to say that the plaintiff's case had not been proved. But that was not all. There was the plea of fair comment. Let the jury imagine they were all antivivisectionists, and ask themselves the simple question, "If we were to carry on a campaign against vivisection, would we have carried it on as this campaign has been carried on?" Would they have carried on a truthful campaign if it had been conducted on these lines? He would add one word as to Miss Lind in conclusion. She had spoken very strongly and very deeply when appealing to them at the close of her reply. Verdicts, however, must be given on evidence, not on sentiment. If they thought Dr. Saleeby was justified in writing the letters, their verdict must be for him. However sorry they might feel for her, they must do their duty.

After an absence from court of about twenty minutes, the jury returned a verdict for both defendants.

Judgement was entered accordingly, in both cases with costs.

THE late Sir Thomas Frederick Chavasse, F.R.C.S., left estate of the gross value of £17,407, of which £16,010 is net personality.

A NEW system of lighting operating theatres has recently been brought out by Messrs. Leitz, of Wetzlar and London, and appears to merit examination by surgeons. Its central feature is the distribution of the light of an arc lamp by a series of reflectors, so placed that one or other of them must continue to supply adequate illumination whatever the position or attitude adopted by the operator. An installation of a corresponding kind is stated to have been in use at the new obstetric school at Strasburg for about a year and to have proved successful.

Public Health

AND

POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL RELIEF AT BURNLEY.

IN our issue of April 12th, p. 797, it was pointed out that the Local Government Board had refused to sanction the proposals of the Burnley Guardians with regard to the arrangements for medical relief in the union, pending their consideration by the new board about to be elected. That board has just held its first meeting, and the matter was again considered. It is to be regretted that after what seems to have been a very cursory examination of the subject under dispute, and in spite of urgent representations from some of the newly-elected guardians, the board by a large majority instructed the Clerk to forward the same scheme again to the Local Government Board for its approval, without any alteration. The Burnley Guardians had before them a strong protest from the Corporation of Colne, and a request from the local profession to receive a deputation to discuss the matter in order, if possible, to come to an amicable arrangement. Several of the guardians were strongly in favour of receiving this deputation, and Mr. Procter (a guardian) considered that there was much information the old members had never had before them. But a large majority of the board was opposed to all compromise, and desired to ignore the objections both of the local authorities in their area and the Burnley profession. No attempt was made to answer the numerous objections that have been put before the Local Government Board, and no further reason was given in favour of their proposals than a plea based on Art. 159 of the Consolidated Order of July, 1847, that a medical district should contain a population of not more than 15,000. As this regulation is practically a dead letter in most parts of England and Wales, it can hardly appeal very strongly to the Local Government Board, and is certainly no answer to the weighty objections that have been urged on the other side. The matter is now entirely in the hands of the Local Government Board, which can hardly approve of the high-handed action of the Burnley Guardians. It is earnestly to be hoped that before deciding the matter it will itself institute some inquiry on the spot.

Medical News.

VACCINATION has been made compulsory in Bosnia and Herzegovina.

THE eleventh International Congress of Pharmacy will be held at The Hague in September (17th to 21st).

DR. D. J. CALLOWAY has been reappointed an unofficial member of the Legislative Council of the Straits Settlements.

THE annual meeting of the London and Counties Medical Protection Society will take place next Wednesday, April 30th, at 4 p.m., at the society's home, 32, Craven Street, W.C.

AN Anglo-German exhibition is to be held this year from May to October at the Crystal Palace. Of its seven sections, one will be devoted to questions of education, and another to those of food supplies.

FOURTEEN French colonization companies have contributed funds for the institution of a complementary course of colonial studies (pathological protohistology) in Paris, with a laboratory in connexion therewith.

THE Council of the Royal Sanitary Institute, believing that the Medical Officers of Health Superannuation Bill would tend to the better administration of the public health service, has resolved to petition Parliament in favour of it.

THE Gresham Professor of Physic, Dr. F. M. Sandwith, will on Tuesday, Wednesday, Thursday, and Friday of the week beginning May 13th give four lectures on the cradle of pharmacy, on opium, on arsenic, and on mercury respectively. The lectures will be given at 6 p.m. on each day at the City of London School.

A SOCIETY of Jewish doctors and scientists in Palestine has been founded for the purpose of improving the sanitary conditions of the country. It is intended to establish a bacteriological laboratory, central clinics for the education of those who have charge of infants, and departments for the study of malaria and the suppression of trachoma. The president is Dr. Sandler, Droysenstr. 6, Charlottenburg.

DR. LE FLEMING, Chairman of the Bournemouth Division; Dr. Eleanor Bond, Secretary; Dr. Johnson Smyth, Representative; and Dr. Willans, Secretary of the Bournemouth Practitioners Union, were entertained at a banquet and musical evening at the Mont Dore Hotel, Bournemouth, on the evening of April 16th. As a further mark of the

appreciation of their labours during the Insurance Act crisis, each was presented with a silver salver suitably engraved.

THE Swiss Esperanto Medical Association has invited the Universal Esperanto Medical Association to hold its annual congress in Berne during the ninth International Esperanto Congress, which commences on August 24th next in the buildings of the University of Berne. There will be one or two meetings of the Universal Esperanto Medical Association during the seventeenth International Medical Congress in London.

A NATIONAL league against cancer has been founded in Belgium with the title "The Mauve Cross." The head quarters are at Brussels, and it is intended that there shall be local committees in the provinces. It is in contemplation to create an institute of cancer with a laboratory and annexes, and to subsidize the four Belgian universities with the object of founding in them centres for the study of cancer. The initiative of the movement is due to Professor Jacobs, the well-known gynaecologist.

A SPECIAL meeting of the Section of Medicine of the Royal Society of Medicine is to be held next Tuesday evening for the purpose of witnessing a demonstration by Dr. Monod of Vichy of the possibilities of the cinematograph in the teaching of biology. The films to be shown by him include a new method of demonstrating the heart's action by animated cardiograms, one relating to the development, fecundation, and segmentation of cells, and others bearing on the circulation of the blood and the digestion of albumen, fibrin, and starch. The section extends an invitation to be present to all members and Fellows of the society.

ON December 18th, 1912, the medical profession of the State of New York organized and duly incorporated under the State law an association entitled the American Society of Medical Economics for the study, investigation, and control of the economics of the profession. Membership is open to all duly licensed practitioners, and the society aims at the unification of the entire medical profession in economic matters. It is hoped that it will thus become possible to develop a degree of concerted medical activity for the protection of the public against ignorant, improper, and corrupt legislation, medical frauds, the substitution of drugs in the dispensing of doctors' prescriptions, the sale of impure drugs and foods, and quackery in general. The society has provided for the immediate establishment, through the development of branch societies in every State in the Union, of a national body for the management and control of medical economics.

ON May 1st, under an Order in Council signed last October, carbolic or liquid preparations sold as carbolic or as carbolic acid, or as carbolic substitutes, or as carbolic disinfectants, and which contain not more than 3 per cent. of phenols, become substances to which Section 5 of the Poisons and Pharmacy Act, 1908, applies; that is to say, in whatever form they are put up for sale they must be labelled not only with the name of the substance and the name and address of the vendor, but also with the word "Poison." Failure to observe this rule may be punished by a fine not exceeding £5. The Local Government Board points out that when liquid disinfectants are either distributed gratuitously or used by their own officers, local authorities ought to observe the same precautions as those which are enforceable by law when such substances are dispensed or sold.

THE Local Government Board has issued a general order accompanied by a circular letter to boards of guardians outside London expressing the desire that the arrangements now in force in London for securing a more uniform and satisfactory treatment of the problem of the tramp should be extended to the rest of the country. In London the Metropolitan Asylums Board co-ordinates the work of dealing with casuals, and in more than twenty counties of England arrangements are in force or in contemplation based on the "way-ticket" system. The Local Government Board desires that in every county a committee, representative of the various boards of guardians and of the police, shall be established to co-operate with the guardians in securing: (a) Uniformity of administration in regard to casuals; (b) discrimination in favour of those genuinely in search of work; and (c) the provision of a mid-day meal for vagrants.

THE annual meeting of the General Association of the Medical Practitioners of France was held on April 6th under the presidency of Professor Gaucher. The budget showed a deficit of £280; last year the deficit was £240. After consideration of the financial situation, there was a discussion on the nomination of physicians and surgeons to provincial hospitals. A report presented by Dr. Maunoury, of Chartres, recommended that in large towns

they should be elected by public competition, and that in towns of less than 5,000 inhabitants the hospital appointments should be distributed in turn among the local practitioners. The meeting approved the recommendations. What the profession is anxious to do is to withdraw the physicians and surgeons of the hospitals of small towns from the arbitrary authority of the Mayor, the Prefect, and administrative commissions.

THE Société d'Hygiène de l'Enfance offers a prize for the best essay on the following subject: The place which notions of puericulture and the hygiene of infancy should occupy in modern education. Essays sent in competition must be unpublished and may be written in French, German, English, Italian, or Spanish. They must be authenticated by a device or motto reproduced on a sealed envelope containing the name and address of the author. Manuscripts should be sent before December 31st, 1913, to the President of the Société d'Hygiène de l'Enfance, 10, rue St. Antoine, Paris (4e). No essay will be returned; all, without exception, will remain the property of the society, and must not be published by their authors. The society reserves to itself the right to extract from the best essays matter for a pamphlet of propaganda and instruction. The prizes consist of gold, silver-gilt, silver and bronze medals and honourable mentions. The prizes will be awarded at the public annual meeting of the society in 1914.

SUPPORTERS of the National Hospital for the Paralyzed and Epileptic met at the Hôtel Métropole on April 16th, when the festival dinner took place, under the presidency of Lord Stratheona, who, in proposing the toast of "Success to the Hospital," spoke of the value of the institution as a field for medical training. Sir Frederick Macmillan, Chairman of the Governors, in response, mentioned the improvements that had been made in the last eleven years in the equipment of the hospital. The Dean of Canterbury submitted the toast of "The Medical and Surgical Staffs." He said that the medical and surgical staffs of hospitals had been the means of changing the significance of the word "hospital." Whereas a hospital was formerly a place of refuge for the destitute, it had now become a place, not of resignation, but of hope. It was largely due to the efforts of the medical staff of the National Hospital that the advances of the last fifty years in the study of nervous diseases had been made. Sir Victor Horsley, who responded, said that no medical staff ever received better support from the board of management than did the one attached to the National Hospital. The toast of "The Chairman" was proposed by H.S.H. Prince Alexander of Teck. It was announced that a collection made during the evening on behalf of the hospital funds amounted to £2,316. Lord Stratheona subscribed £1,000.

SOME interesting types of primitive humanity are to be seen at the Victoria Palace, Victoria Street, S.W., where Mr. Alfred Butt is presenting a series of animated pictures reproduced from photographs taken by Mr. Martin E. Johnson, who accompanied Mr. Jack London, the famous American novelist, on his four-years' voyage among the islands of the South Pacific. The little band, which consisted of Mr. London, his wife, and their four companions, visited New Zealand, Sumatra, Java, Borneo, New Guinea, the Hawaii, Fijis, Solomons, Marquesas, and the New Hebrides, and made their way into regions hitherto unknown even to the missionary or the trader. The results of this adventurous cruise, as recorded in Mr. Johnson's beautiful photographs, will be of great interest to every student of ethnology. The inhabitants of the South Sea Islands comprise many widely varying racial types, from the comparatively civilized mongolian of the Zulu Archipelago to the debased negroid type usually found amongst the cannibals of the Solomons and New Hebrides: the flat noses, thick lips, and woolly hair of a group of Solomon Islanders photographed by Mr. Johnson (one of whom showed unmistakable signs of elephantiasis in the right forearm) present a striking contrast to the light brown skins and more regular features of the natives of Samoa or Hawaii. The language, dress, habits, religious beliefs, and manner of warfare of these primitive races differ as much as their personal appearance; and save where they have been modified by contact with the white man, their customs have remained unchanged. Mr. London and his party availed themselves to the full of their opportunities for studying native life at close quarters, and thanks to their courage and perseverance in the face of dangers and difficulties of every kind, it is possible to obtain an insight into the conditions in which the South Sea Islander lives and dies. Mr. Johnson's collection of photographs is now on view for the first time in England, and forms an interesting memorial of the expedition.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

V. asks to be referred to some recent summary on the vaccine treatment of chronic bronchitis, together with any statistics of successful cases, the class of case most likely to be benefited, and the best time of year to adopt such treatment.

A. H. asks for suggestions for the treatment of angio-neurotic oedema in a man aged 49, of abstemious habits. The attacks are accompanied by transient urticaria, and the patient has had one illness believed to be due to gout. He has been carefully dieted, oral sepsis attended to, and such drugs as bismuth and calcium lactate administered without relief. A short course of vaccine treatment led to no marked result.

INTERMITTENT GLYCOSURIA.

DR. THOMAS writes: I am much obliged to Dr. Cammidge for his valuable information—not given in the ordinary text books—on the above subject. But the question on which I desired enlightenment was whether the faulty glyco-genic metabolism, as evidenced by the glycosuria, and, in this case, accompanied by bacilluria, was chemical or bacterial in origin; or, to put it another way, what caused the particular hormones to go on strike and stay in their native home in the pancreas, or wherever they may dwell or are born?

RHEUMATOID ARTHRITIS.

CHRONIC RHEUMATISM writes: Doubtless many readers have enjoyed Sir James Barr's paper on the above in the **JOURNAL** of April 12th. As it introduces the question of a logical basis for certain alleged clinical facts may I be allowed to ask Sir James one or two points? Is not the statement that the pain of rheumatoid arthritis is only nocturnal rather too "universal" to be made by a single observer, this apart from its supposed cause which for Sir James Barr is the superposition of an acid tide in the tissues at night? Are rhubarb and oatmeal condemned on theoretical grounds or as the result of large personal observation—the views of the latter on the former are well known and based on the "acid" theory. If the "alkaline treatment," quite an old one, is a "cure" (the word "cure" is used in the last paragraph of the paper), how has it given place to guaiacol, vaccines, etc., and how far do the dwellers on limestone and chalk formations suffer or undergo automatic cure as compared with those enjoying a soft (acid) water supply?

INSTITUTIONS FOR MENTAL DEFICIENTS.

A MEMBER of the Association, who expects to be consulted with regard to the erection of institutions for mental deficient, asks to be referred to (1) textbooks on the subject—he is acquainted with the Report of the Royal Commission and the National Conference for Prevention of Destitution, 1911—and (2) to any institutions in England, if not abroad, where the practical working of the subject such as the bill now before Parliament contemplates could be studied.

* * (1) In addition to the two reports mentioned, there is a scheme outlined in Sherlock's book, *The Feeble-minded* (London: Macmillan and Co., Limited, 1911, price 8s. 6d.), Chapter VII. The secretary of the National Association for Promoting the Welfare of the Feeble-minded, Denison House, Vauxhall Bridge Road, London, S.W., has pamphlets and descriptive particulars of American institutions, and would, we have no doubt, be happy to show them. (2) The National Association has a farm colony at Hildenborough, Kent; in addition to these are in England the Starcross Institution (farm and industrial) near Exeter, the Darenth (farm and industrial) Colony of the Metropolitan Asylums Board at Dartford, Kent; the colony of the Lancashire and Cheshire Society for the feeble-minded at Sandlebrieg, and the colony established by the Birmingham Board of Guardians. For American colonies, see the report of Royal Commission. Our correspondent might also refer to the report on the family care of the insane poor, published in the **BRITISH MEDICAL JOURNAL** of 1905, vol. ii, but most of the facts contained in this report were, we believe, given to the Royal Commission by Dr. Cunyngnam Brown.

ANSWERS.

HIPERNIA.—No doubt a considerable number of infants are vaccinated when under 4 weeks old. There is no special reason why this should not be done in the case of healthy infants, except that parents are disposed to attach the blame

to vaccination where skin affections appear subsequently. By waiting until 4 to 6 months old the liability of the infant to skin troubles will have been ascertained. During the prevalence of small-pox in any locality there should be no hesitation about vaccinating infants under 4 weeks old.

INCOME TAX.

A. D. M.—A practitioner in general practice, holding also the office of medical officer of health, is allowed, upon notifying his intention to do so, to include his emoluments in his general return under Schedule D. The form of return under Schedule E should be sent to the assessor or surveyor with an endorsement to the effect that it is proposed to follow this course.

HYPERTROPHIED PROSTATE.

DR. H. D. MCCULLOCH (London) writes in reply to "X. X." to recommend either of the two following methods: (1) By x-ray irradiation in the lithotomy position, without divestment of garments, through the perineum. A medium hard tube with a Belot's shield and localizer and thick leather filter; twelve bi-weekly applications of ten minutes' duration each. Histologically the prostate is an adenoid gland, closely related to lymphatic glands, which are peculiarly amenable to such applications. (2) By a six weeks' course of drinking radium emanation water daily. The emanation is eliminated by the lungs and kidneys; the abnormal fibrous tissues would be resolved. These methods are contraindicated in acute inflammatory processes. Attention may also be drawn to the abstract which appears on page 59 of the *Epitome of Current Medical Literature*, **BRITISH MEDICAL JOURNAL**, April 12th, 1913.

* * For information with regard to the emanation, reference might be made to the report of the Radium Institute published in the **BRITISH MEDICAL JOURNAL** of January 25th, 1913, page 149.

THE HALF-PAY LIST.

HALF PAY.—It is not correct to say that half pay is unknown in the Royal Army Medical Corps, though it is true that the conditions under which an officer is placed on the half-pay list differ essentially from those applying to half pay in the Royal Navy. In the Royal Army Medical Corps the term "half pay" is only used in two connexions: (1) A full colonel on completion of four years in that rank may be placed on the half-pay list, but is eligible for restoration to the active list and promotion to higher rank subject to the usual rules as to retirement on account of age. (2) Any officer who is pronounced physically unfit for duty, and who is still pronounced unfit for duty at the end of the regulation period of possible sick leave, may then be placed upon half pay; but he is eligible to return to the full-pay list at any time within five years if found fit for duty. If not found fit for duty within five years he must retire on any retired pay or gratuity for which his service may render him eligible.

LETTERS, NOTES, ETC.

FOOT SUPPORTS.

A FOURTH edition has been issued of *Scientific Correction for Ailments of the Feet*, a pamphlet issued by the Scholl Manufacturing Company. It contains a general description of the anatomical conditions which have been deemed by surgeons to be benefited by appliances worn in the boots, and then gives descriptions of some two dozen or more of the devices manufactured by itself. These include arch supports intended for various degrees of flat-footedness, one intended to be worn by those whose foot fatigue arises mainly from their being engaged in occupations necessitating their standing for prolonged periods, and several means of relieving cases of bunion and obviating conditions which result therein. Such of the appliances of the firm as we have examined have seemed well devised, and were generally made of a silvery material which oxidized only to a very limited extent on exposure out of doors for several days. The firm does much of its work apparently through agents, a special feature of its arrangements being the supply to each of them of a simple piece of machinery designed to adapt the exact curve of any support to its intended wearer's foot when this has been relieved of all weight. Copies of the pamphlet can be obtained from the firm at 1-4, Giltspur Street, E.C.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

An Address

ON

THE PRESENT EVIDENCE FOR AND AGAINST THE USE OF TUBERCULIN AS A SPECIFIC CURE.

DELIVERED AT A COMBINED MEETING OF THE CITY DIVISION
OF THE BRITISH MEDICAL ASSOCIATION AND
THE FINSBURY MEDICAL SOCIETY.

BY

H. BATTY SHAW, M.D., F.R.C.P.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; LECTURER ON
THERAPEUTICS, UNIVERSITY COLLEGE HOSPITAL MEDICAL
SCHOOL; AND PHYSICIAN TO THE HOSPITAL FOR
CONSUMPTION AND DISEASES OF THE
CHEST, BROMPTON.

It is a fact that no such unanimity exists in the profession as to the specifically curative effects of tuberculin in any of its forms in cases of tuberculosis as exists with regard to the use of diphtheritic antitoxin against infection with the Klebs-Loeffer bacillus. It is also a fact that tuberculin is nevertheless being widely used as a true specific, and observers are to be found—some who are certainly convinced of its efficacy; some who, though they are uncertain, are driven to use it by the force of opinion of those who are certain. There are others who are equally sure that the evidence of its specific value is insufficient, and even that it is a harmful drug, and they will not prescribe it.

With such a chaotic state of affairs it is reasonable to consider the whole subject critically, to take the evidence for and against its use, and to endeavour to arrive at some satisfactory conclusion.

KOCH'S FUNDAMENTAL EXPERIMENT.

It cannot be out of place, with such a programme, to go back to Koch's own experiments and to examine calmly his statements and see whether, after all the years that have elapsed since 1890-91, any support for his contentions has been advanced.

Koch's first public utterance on the use of what was known as tuberculin three months later was made at the first general session of the Tenth International Medical Congress, held in Berlin on August 4th, 1890, and can be found in the reports of the congress in various periodicals—for example, in the *Deutsche medizinische Wochenschrift*¹—and in the *BRITISH MEDICAL JOURNAL* of August 16th, 1890, p. 383. His address was largely a general survey of the accomplishments and the hopes of bacteriological study. After referring to the efforts he had made to discover something which, whilst checking the growth in the body of tubercle bacilli, effected no harm on the body, he said, with a very pointed observation, that his investigations, though carried out for nearly a year, were not complete, and

that guinea pigs, which, as is well known, are extraordinarily susceptible to tuberculosis, if exposed to the influence of this substance cease to react to the inoculation with tuberculous virus, and that in guinea-pigs suffering from general tuberculosis, even to a high degree, the morbid process can be brought completely to a standstill without the body being in any way injuriously affected.

In the same German periodical² during the month of November, 1890, he published an article on "*Weitere Mitteilungen über ein Heilmittel gegen Tuberkulose*," giving the results of the application of this substance to the cure of human tuberculosis. In 1891 Koch gave further experimental details:

If a healthy guinea-pig is injected with a pure culture of tubercle bacilli, the inoculation puncture as a rule closes and in the beginning appears to heal; in the course of ten to fourteen days a small nodule occurs which soon breaks through the skin, forming an ulcer which lasts until the animal dies. Quite a different result occurs if a guinea-pig which is already tuberculous is inoculated, especially if the inoculations take place four to six weeks after the first one. In such an animal the seat of inoculation at

first closes as in the above animal, but no small nodule forms; on the next or following day a peculiar change takes place at the site of the inoculation. This becomes indurated and darker in colour, and these changes spread over the neighbouring parts until the total area measures about 0.5 to 1.0 cm. across. During the next days necrosis of the skin takes place, and there remains a superficial ulcer which ordinarily heals quickly and permanently without the neighbouring lymphatic glands being infected. The injected tubercle bacilli act quite differently upon the skin of a healthy as compared with that of a tuberculous guinea-pig. This striking change does not belong exclusively to living tubercle bacilli, but occurs just the same with dead tubercle bacilli, whether they have been killed by prolonged low temperatures or by heat or by certain chemicals.³

If you will peruse the works of modern writers (Löwenstein, Cornet,⁴ Romer, Bandelier, and Koepke⁵) who concern themselves with the use of tuberculin, you will find the above paragraph. They all fall back upon it as the original statement published by Koch in support of the use of tuberculin. Löwenstein, who is responsible for the article on the therapeutic application of tuberculin in man, in Kraus and Levaditi's *Handbuch der Technik und Methodik der Immunitätsforschung* (Erste Band, S. 821, 1903), goes on further to say that by means of these fundamental observations of Koch it was established that the animal body after a single injection developed definite resistance against reinfection—a statement which every reader will acknowledge is quite in accordance with the experimental data given by Koch. Löwenstein proceeds to say that the idea of using these agencies which rendered the second injection innocuous as a means of influencing the deposits brought about by the first injection led Koch to the specific treatment of tuberculosis. Koch thought if antecedent tuberculosis profoundly modified subsequent inoculation, it was possible that inoculation also profoundly affected the antecedent tuberculosis. He experimented, and stated the experiments confirmed his speculations.

At this point it is necessary to pause and realize how the modern worker views the fundamental experiment above detailed. What must be noted was that Koch in the first part of his experiments practically performed a von Pirquet test upon his tuberculous guinea-pig. The superficial ulceration which healed and which resulted from the second inoculation was an expression of the phenomenon now known as a von Pirquet test, and is explained, as will later be seen, by the laws which govern anaphylaxis or hypersensitiveness. Now follow Koch's further observations.⁶ He found that if the second inoculation of a tuberculous guinea-pig with tubercle bacilli was a large one, the animal died. This again is easily understood, thanks to the development of our knowledge of anaphylaxis, as being an example of anaphylactic death. The crucial point now remains, and that is that Koch⁶ observed that if small frequently repeated doses of tubercle bacilli were injected into a tuberculous guinea-pig, not only was the general condition of the animal improved, but the ulcerating wound, situated where the tubercle bacilli were originally injected and which caused the animal to become tuberculous, also showed favourable retrogressive changes, and the disease was brought to a standstill in the animal.⁶ It was, in fact, cured.

Now, this definite statement of the actual bringing the disease to a standstill, or of the favourable influence upon tuberculous lesions in guinea-pigs, coming from such an authority, ought only to be questioned with the greatest care. There is no need to recall the stir made by subsequent papers, in which marvellous cures in men were announced, because of the many disastrous consequences to life which also were so obvious. It is said now that too great doses were given and the wrong cases were treated. These statements have been repeated all over the world, and it must be admitted the swing of the pendulum has brought tuberculin into use again.

But what has happened with regard to the original experiments? Has any one been able to repeat Koch's experiments, and show that an infected guinea-pig can be cured by the use of tuberculin, whether old tuberculin (T.A.) or the second tuberculin (T.R.), or the third tuberculin (B.E.), or albumen-free tuberculin, or bovine tuberculin, or tuberculin derived from avian or other sources? Has it ever been successfully essayed to cure cattle of

tuberculosis by such means rather than slay them because they have been proved to be tuberculous by the tuberculin test? Is it not a certainty that if bovine tuberculosis could be cured by the use of tuberculin, its use for such purposes would be world-wide? On the contrary, we hear of numbers of cattle being slain in order to stamp out the malady. We even hear of cattle being "doctored" so that they will not give the tuberculin test, and so be saved from destruction. If it were proven that tuberculous cattle could be cured by vaccination by means of tuberculin, we may be quite sure (1) that it would be widespread in veterinary practice, (2) that the whole medical profession would have adopted it with very little hesitation, and they would have been justified. But where are the reports on cattle which should make us at ease on this point? Frankly, they do not exist. There are many reports dealing with the preventive treatment of calves by means of tuberculin, but even that important question cannot be satisfactorily answered because of fallacies which in part beset Koch's own original investigation. Supposing a calf does not give the tuberculin test, and therefore is considered to be free from tuberculosis, and a prophylactic course of tuberculin is given to it, and it neither yields a tuberculin test eventually nor becomes tuberculous, how can any one argue from such data that the apparent freedom from tuberculosis is a reality, when it is known—

- (1) That an animal may cure tuberculosis spontaneously (and yet give a tuberculin test);
- (2) That it may be tuberculous and yet not give a tuberculin test, and
- (3) That the undetected tuberculosis that it may already be burdened with may be (see Koch's experiment) the reason why it cannot be reinfected?

These facts have plagued veterinary surgeons to such an extent that there is not unanimity amongst them as to the value of the evidence for using even prophylactic vaccination in calves, and it also explains why there is no attempt to vaccinate tuberculous cattle in order to cure them. Can it be wondered at that the medical profession is not unanimous in its advocacy of the present fashion for curing human tuberculosis with any form of tuberculin administered in any particular method? Contemporary textbooks and guides to the use of tuberculin do not face these difficulties of comparative therapeutics, and one well known one is a standing example of the troubles caused by Koch's unconfirmed experiments—on one page it makes out that when the tuberculous guinea-pig was injected with subsequent doses of tubercle bacilli the ulcerating wound formed where the *first* injection was made, which caused the guinea-pig to become tuberculous, healed as a result of the second injection, and yet on a later page the author says it was the small superficial necrosis of the *second* site of inoculation which healed.

To sum up the evidence in favour of the allegation that tuberculin can cure a tuberculous animal, whether calf or guinea-pig, there is *no evidence but Koch's*. Bandler and Roepke⁷ admit that they must confess that the healing of infected guinea-pigs and rabbits by means of tuberculin preparations has been accomplished by only a few authorities who have been engaged in such extremely tedious studies, and shield themselves from criticism in this direction by saying that rabbits and guinea-pigs are such unsuitable animals to work upon. And yet these two authors, like all others who advocate the use of tuberculin, set out in full the details of Koch's experiments which led to the introduction of tuberculin and say that the basis of its use is these self-same experiments on guinea-pigs. What has been said to be a proof is entirely nullified by the fact, admitted by bacteriologists, that both varieties of animals may be spontaneously tuberculous and may spontaneously cure themselves of the tuberculosis, and yet this cannot be established until after the death and complete dissection of the animal. If this is the case with guinea-pigs and cattle, the lives and deaths of which can be so fully observed and encompassed, it is just as certain with regard to human beings, who, like the animals, may be tuberculous and yet yield no test, chemical or otherwise, that they are.

To many physicians the result of animal experiments is quite enough, or shall we say the difficulty of establishing

or not the fact of tuberculous disease in animals is great enough to make them set their faces against the practice of using tuberculin to cure human tuberculosis? And yet hard things have been said about withholding tuberculin from tuberculous mankind. The pendulum has swung back in favour of using tuberculin again; but it is even more impossible to-day than it was in the years immediately succeeding 1890-91 to quote evidence in support of Koch's experimental results.

The Modern Dosage in the Use of Tuberculin.

Ignoring the unsatisfactory nature of Koch's alleged cures of tuberculosis in animals which have never been confirmed and which will not stand criticism, though such of his experiments which show merely the truth of the principles of anaphylaxis have been fully confirmed, workers abroad have developed the practice of giving the tuberculin in infinitesimal doses compared with the original ones. But in face of the objections already raised in the last section, it really does not matter whether the dosage is large or small so long as the experimental proof of cure by means of tuberculin has never been established. Neither large nor small doses of tuberculin are used to cure the tuberculosis of cattle.

The Experience of Urinary Surgeons of the Value of Tuberculin.

It is pointed out that, despite the abandonment of the use of tuberculin in other affections, certain urinary surgeons have remained loyal to the use of tuberculin in this disease. Marvellous cures of the disease are recorded even during the years immediately succeeding 1890-91.

Later on it will be pointed out that the element of "control," without which no specific cure can be established, forms no part of the demonstration of the extreme usefulness of tuberculin in these cases. It is usually found that some of the number to whom tuberculin is given are "better after receiving it."

The Post-mortem Demonstration of Cured Pulmonary Tuberculosis.

Much capital has been made out of such well-known phenomena. There is no hesitation whatever in admitting that tuberculosis may be completely cured, but to argue that because tuberculin does produce a reaction in a large number of tuberculous animals and in man it must be a means of effecting this cure is illogical. No one questions that the Widal test is a proof of typhoid fever, and yet no one has established that typhoid vaccine is a cure for typhoid fever already contracted. Observations seem to show that it is a prophylactic against typhoid fever for one or two years, and so tuberculin may be a prophylactic against tuberculosis for a period of three months in cattle, but no one has the right to say that a process which is an effective agent in preventing a disease must *ipso facto* be effective when the disease has already begun.

The Encouraging Effect upon the Patient and Doctor of doing something for the Patient instead of leaving him to specifically Cure or Not Cure Himself.

It almost seems out of place to consider such a matter in the discussion of so serious a subject as the adoption of tuberculin to cure tuberculosis. No reference would be made to it were it not that we are in direct contact with patients. Patients ask for tuberculin to be administered, and how can we refuse them when the public press lends its advocacy, when tuberculin is even used in obedience to the permission of the Insurance Act? What every man must feel is that if his convictions are that such and such a remedy cannot cure specifically he must say so and withhold it.

The Antitoxin Treatment of Diphtheria.

So impressive was the great reduction of the mortality after the introduction of diphtheria antitoxin that the hope arose that all infections would yield the same happy issues. It is a fact that there are many who to this day think that tuberculin is an antitoxic serum, and should therefore be successful. The final section of this address will serve to show that such a view is utterly wrong. The use of the serum of a horse which carries in it material which is capable of neutralizing the poisonous effects of diphtheria bacilli, and that

this can be shown to occur in a test tube as well as in the human body, is one thing, but to cure an infection with the tubercle bacillus by means of tuberculin derived by breaking up tubercle bacilli and making an emulsion of them is quite another.

The Variety of the Cures of Tuberculosis.

There are those workers who still maintain that sanatorium methods are the only ones which effect a cure of tuberculosis; there are others, again, who repudiate all such claims, and who advocate treatment with tuberculin alone; and now there is a group of workers who maintain that the combination of tuberculin and sanatorium treatment is necessary. These facts alone point to a difference of opinion which begets the suspicion that perhaps the tests applied to prove the efficacy or not are at fault. A most important paper has recently been published by Messrs. Palin Elderton and Perry.⁸ They show that tuberculin treatment does not contribute any increased length of life to the patient when carried out in conjunction with sanatorium treatment, as judged by the large amount of material for investigation provided by Dr. Lawrason Brown in America and Drs. Prest and Guy in Scotland. The same suspicions are aroused when distinguished Continental workers put forward the idea that the disease is after all to be cured by an antituberculous serum, and when it is said a "cure" is to be found in quite a different direction—namely, by the production of artificial pneumothorax. Of Friedmann's cure we have still to await further details. We have heard of "pneumosan" and "dioradin." With such a varied list of cures, blessed by one school and condemned by another, is it remarkable that the layman should also offer his "remedies" for a cure? Further, is it remarkable that members of our profession are also convinced that the specific cure has yet to be found? Professor Metchnikoff in his recent address⁹ delivered in London has nothing to tell us of a remedy which specifically cures tuberculosis.

The Method Adopted to Test the Value of Tuberculin.

No one can look into the problem of the cure of tuberculosis without becoming aware that the secret which underlies the existence and development of so many vaunted "cures" is to be discovered in our ways of estimating their value. When the layman copies these ways we are angry, and condemn him, and feel justified in doing so (1) because he does not announce his cure through channels which we consider proper, and (2) because we argue that he does not know the nature or course of the disease. We have seen with regard to tuberculin that there is no confirmation that an animal can be cured of tuberculosis by means of it; therefore in advocating it, we put ourselves in a faulty position similar to that of the layman with his "causal" cure. There remains, then, but one way in which we differ from him—we know the nature and course of tuberculosis, and he does not. It seems to me that we have not made enough of our knowledge of the course of tuberculosis if left unaided. Of 1,532 cases of pulmonary tuberculosis (tubercle bacilli being present in the sputum), it was found that one-seventh lived five years and more from the date of the manifestation of tuberculosis, one-thirtieth lived over fifteen years, and in five cases there was documentary proof that they had lived sixteen, eighteen, twenty-four, twenty-five, and forty years. Not one of these cases had been treated in a sanatorium nor had they received tuberculin.¹⁰

The fact is that as a profession we are wrong in our methods of estimating "cures" in the only sense a layman wants to hear of them—real "cures," complete eradication of the cause. We have too long judged of "specific" cures without allowing for the *post hoc, propter hoc* fallacy. We cannot afford to do so any longer, because our statements are being revised by skilled mathematicians; our "impressions" of proof of cure have been put into the scales and they are found wanting. Professor Karl Pearson tells us¹¹ that, taking our own death certificates as supplied to the Registrar-General, it is clear that a fall in the death-rate from tuberculosis of the lungs had begun in 1835 and continued till 1891. Since then it has ceased to fall, despite the help that has come, so it is said, from the use of sana-

toriums and of tuberculin. It has been said that tuberculosis dispensaries have led to a great fall in tuberculosis in a certain town, but the same critic is able to show that the fall was paralleled in two other towns in which the dispensary system had not been introduced. We physicians, therefore, have failed to establish by our own death certificates or by our methods of inquiry any improvement due to sanatoriums, tuberculin, or dispensaries. The improvement was due to a natural process of which we have been unmindful.

It is not without interest that I should have figured as one of the collectors of evidence in favour of the use of tuberculin.¹² In 1905 tuberculin was not used in this country for the cure of pulmonary tuberculosis. I circularized every institution which had to do with this disease and found this out. Following out non-critical methods, I published results such as the following: Of 656 early cases treated with tuberculin, 91 per cent. reached a certain standard of improvement, whereas, of 611 not treated with tuberculin, only 62 per cent. reached the same standard. But when the individual accounts of certain workers whose reputation is world-wide were looked at, the large difference of 29 per cent. disappears. Dr. Turban treated 86 cases with tuberculin, and of these 52.6 per cent. achieved permanent good results; of 241 not treated with tuberculin, only 39.4 per cent. achieved the same result—a difference of 13.2 per cent. Dr. Trudeau was able to find that the use of tuberculin was followed by an increase of cures of 8 per cent.

Now it may be argued that these last figures are quite good enough, and until they are found to be wrong it would be useless to deny the use of tuberculin simply because experiments on animals had failed to establish the same happy results. At the time I wrote that article I thought so too, but subsequent experience has shown that cases reported to be cured too often broke down again later, that "permanent good results" gave place to permanent and final bad ones, and that physicians are not sufficiently skilled in making mathematical deductions. It is obviously difficult to find proof of the efficacy of tuberculin treatment by methods which do not take into consideration the whole of the life, or which cannot be controlled as can those in animals, by slaughter and the examination for active disease. An interested critic of our methods of testing the value of tuberculin propounded to me a method which, if carried out in a large number of cases, would satisfy him. I was to find a group of cases of pulmonary tuberculosis which were recognized by tuberculin advocates as suitable for treatment with a reacting dose of tuberculin; half were to be treated with tuberculin and half without, other conditions being equal. The choice of each half was to be left to chance; I was not to pick out those "specially" favourable ones as suitable for tuberculin. This method of testing the value of tuberculin is opposed entirely in principle to that advocated by modern workers. Bandelier and Roepke¹³ lay it down as an axiom that the cases must be selected ones—individualization is the secret of success—extremely early cases are the only likely ones to give satisfactory results (*sic*); they do not give sufficient prominence to the fact of spontaneous cures in such cases. As a test of the improvement of the lung condition, I chose the method of registration of the advance or retrogression of rales after three months' treatment. Dr. Rigg, the house-physician who bore the burden of the test, has recently published the results.¹⁴ Of the 10 tuberculin treated patients, 1 improved, 4 became worse, and 5 remained *in statu quo*. Of 9 non-tuberculin treated patients, 4 improved, 3 were worse, and 2 remained *in statu quo*. It cannot be said that this is a clear argument against the tuberculin effects on the lung, because it might equally well be maintained that it was an argument against using a remedy which so raised the temperature as to keep the tuberculin treated patients in bed, whilst the others were up and about; but still this method of giving tuberculin is advocated at the present time and is being extensively used. We are now trying a series of cases in which this difficulty will be met.

The Evidence of Individual Cases, or of Series of Cases, Neither Controlled.

No greater fallacy needs exposing than that which underlies the statements of individuals who have been "cured" after this, that, or another treatment. One has

only to ask, as veterinary surgeons have now to ask themselves, How can one be sure when a human being or animal appears to overcome a tuberculous lung affection that such victory has necessarily followed, not from Nature's efforts, but because of the remedy used before the improvement comes? It is certain that if any proprietary article or quack remedy, etc., were applied to cases of pulmonary tuberculosis, some of the individuals would get better after its use. The same may be said of tuberculin. Such evidence is set at naught because patients recover spontaneously just as cattle do. But there have been many series of cases reported in which it is said there is evidence that tuberculin is a specific cure. The criteria have differed in different reports. Banielier has published results of tuberculin treatment; he found that 100 per cent. of the cases in Turban's first stage lost their tubercle bacilli; 87 per cent. of the cases in Turban's second stage and 44.2 per cent. of the cases in Turban's third stage also lost their tubercle bacilli. The total cases treated numbered 202. We have a right to ask, What would such cases have done without tuberculin? And it is right to object that disappearance of tubercle bacilli from the sputum is too often but a temporary phenomenon.

What Does Tuberculin Do?

Like all vaccine treatment, tuberculin is certainly capable of effecting a change in the aspects of the disease. But it has never been experimentally proved that such changes are curative; the alleged curative changes can be explained on anaphylactic grounds. To explain this requires technical consideration.

We know that when diphtheria bacilli invade the body, they poison the body by means of diphtheria toxin; the patient may resist the effects of this toxin by manufacturing his own antitoxin; nowadays we do not wait to see if he does, we administer antitoxin developed experimentally in the horse. The toxins of tetanus and botulism or sausage poisoning can be met by a similar mechanism. The chemical response of the cells of the body to and against the toxin are figuratively expressed as receptors of the "first" order of Ehrlich. Their interaction is diagrammatically figured in most textbooks of bacteriology. These receptors are certainly of therapeutic value.

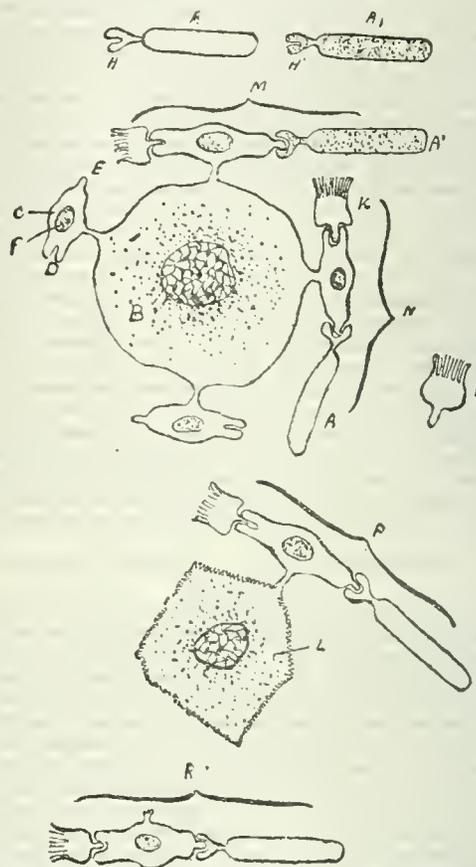

When the typhoid organism assails the body, a different group of chemical actions is developed on the part of the body cells; the serum of the body now possesses not antitoxic but agglutinative properties; no one has demonstrated that this development of what are known as receptors of the second order has any therapeutic significance, though the diagnostic value is of the greatest importance (Widal test for typhoid fever).

It is seen, then, that receptor development following upon bacterial invasion is not necessarily of benign curative purpose. We may expect more complicated receptors than those of the first and second order to be developed, of different properties, and again not necessarily of therapeutic value.

This brings us to the consideration of another group of receptors—the third order—which has particular interest in connexion with this address. It enables us to understand better the meaning of anaphylaxis, of a von Pirquet test, and of a tuberculin test; it also enables us to understand such complicated tests as the "complement fixation" test for tuberculosis, and if recent experiments are confirmed it will enable us to understand how the effects of tuberculin administered as a curative agent can be explained on other grounds than therapeutic ones; finally, it will help us to understand why two cases—one under the care of A. Fraenkel and one under Wolff-Eisner—developed a tuberculous ulcer on the tongue and tuberculosis of the lungs respectively, whilst undergoing a course of tuberculin treatment for lesions located elsewhere in the body.¹⁵

Let us suppose that a tubercle bacillus (A) enters into the body of an animal. It may, and probably does, in countless instances suffer annihilation by agencies which have been transmitted from the animal's parents. No infection occurs, and the animal is none the worse. But supposing there is more than one bacillus, or that the one gaining access is more virulent, or suppose that the animal has inherited from the parent no insusceptibility, something like the following takes place: A cell of the

body (B) in the neighbourhood of the deposit of tubercle bacilli is busy with one of its physiological duties of absorbing nourishment; it includes the tubercle bacilli in this category, and the effect upon the cell is to increase its appetite for more (a popular expression for Weigert's law that an excessive stimulus provokes an increased supply of receptors or chemical affinities). Let us represent this increased appetite by a cell with several receptors attached to it of the pattern c. This is known as an "amboceptor," because it can attach at D a special agent known as complement (K), which is present in all living healthy animals, more in some than in others; at its opposite extremity, E, it can also attach to itself a tubercle bacillus (A) or tuberculin (A'), which also

DIAGRAMMATIC REPRESENTATION OF CELLS, RECEPTORS, ETC.

A, Tubercle bacillus, with its chemical affinity for cells of the body represented by a receptor, H. A', Tuberculin, with its chemical affinity for cells of the body represented by a receptor, H'. B, A cell of the body showing four fixed or sessile affinities or amboceptors, c, capable of uniting with a tubercle bacillus or tuberculin at E and with complement, K, at D. M, Tuberculin-anaphylatoxin, composed of three elements—complement, amboceptor, and tuberculin. N, Tuberculo-anaphylatoxin, composed of three elements—complement, amboceptor, and tubercle bacillus. F, A ferment present in each amboceptor. The combinations M or N when completed lead to the dissolution of the tuberculin or the tubercle bacillus and the cell B. The liberation of digestion products is accompanied, according to the quantity liberated, by the phenomena of anaphylaxis in slight or extreme degree, anaphylactic death, anaphylactic shock, or "tuberculin reaction," with rise or fall of temperature, etc. P, Tuberculo-anaphylatoxin operating on a "prickle" cell, L, of the skin. The change in the cell, L, contributes to the production of what is known as a "von Pirquet" reaction; if it took place in a conjunctival cell, to a "Calmette" reaction. R Represents "free" tuberculo-anaphylatoxin. Were it possible to demonstrate the existence of "free" tuberculo-amboceptors, then the serum treatment of tuberculosis would be reasonable. Were it possible to demonstrate "free" tuberculin amboceptors, the tuberculin treatment of tuberculosis would be reasonable; but in both cases the undesirable effects of anaphylaxis would have to be met.

have chemical affinities represented figuratively as receptors (H and H'). We must also suppose that resident in the amboceptor is a special ferment (F) which is capable of acting upon protein and breaking it up into much simpler bodies—for example, peptones or albumoses, or amino-acids, and into some substance capable of influencing temperature. We will suppose (at first) that these amboceptors are anchored to the cell B. When to this "sessile" or "fixed" amboceptor complement is attached at D and

antigen (in the shape of tuberculin or tubercle bacilli) at E, it is as if a match had been put to a firework. The ferment resident in the amboceptor can now operate on the cell B and the antigen E, and lead to the above proteolysis of both. If this is complete a liquid residue is all that remains, if incomplete the cell B is swollen and its nucleus obscured; cell death is more or less complete. Presumably when a focus of tuberculosis develops all the cells in the neighbourhood undergo change, and we recognize a "tubercle" by the naked eye—grey, white, or caseating according to the stage of action. But it is possible that cells far removed from the seat of tuberculosis may also have their special receptors developed—for example, in the skin L, subcutaneous tissues, etc. We must suppose, too, that these receptors may be inherited, or they may develop after birth as the result of an infection. They may exist, therefore, although there is no certain tuberculosis present in any part of the body. In other words, these receptors are a sort of hall mark of infection which may be inherited or acquired.

Now let us introduce into such a tuberculous animal a dose of tuberculin as Koch did in his original experiments. This reaches E in numerous cells; complement is fixed and a "reaction" is set going, so thoroughly described by Koch years ago. One thing we now know is that such reaction is a test of the presence of suitable receptors, *not necessarily of active tuberculosis*. The reaction is slight or brisk, and may be fatal, according to the available receptors and the dose of tuberculin. This helps us to understand the catastrophes following on Koch's introduction of tuberculin. The temperature may rise or fall or remain unaltered according to the amount of poisonous material let loose when the reaction takes place. The combination of complement, amboceptors and antigen, for example, tubercle bacilli or tuberculin, is known as "anaphylatoxin," the reaction this brings about as "anaphylaxis." If tuberculin is given repeatedly, it will use up all the tuberculo-amboceptors, until reaction is no longer given. The individual can, as is well known, become completely insensitive to tuberculin; this insensitiveness cannot experimentally be transmitted from one animal to another.¹⁶ We begin to see why it is that the giving of tuberculin is not necessarily followed by cure because there is no reaction, and we see why Fraenkel and Wolff-Eisner's cases, though undergoing treatment with tuberculin, were yet developing fresh tuberculous lesions elsewhere. Koch was able to show the difficulty of reinfecting his tuberculous guinea-pigs when he reinjected them with tubercle bacilli in small amounts; it is easy now to see why; the tubercle bacilli were at once fixed by tuberculo-amboceptors and digested, producing symptoms or not according to the amount of available receptors and tubercle bacilli; these experiments, first announced by Koch, have now been shown by Römer¹⁷ to be true. Whether temperature alterations occur is dependent upon the amount of poison liberated (Thiele and Embleton).¹⁸

Now, the theory thus given says nothing about an attack upon the tubercle bacilli which are responsible for the formation of the amboceptors in the first case. Such organisms may be locked up in some fibrous focus, they may be quite unaffected, they may be busy provoking the formation of fresh amboceptors. Indeed, so far as animal experiments go, no one has ever succeeded since Koch did, *pace* the "few cases" referred to by Bandler and Roepke¹⁹ (no reference given), in showing that the injection of tuberculin does affect the life of these organisms, to the extent of bringing the tuberculous process to a standstill. This part of his original statement has never been confirmed, whereas the rest has been repeated by Römer. Römer gives no statement to the effect that in repeating Koch's experiments he also was able to cause the original tuberculous process to come to an end. Römer's writings show only too well the impossibility, which he fully recognizes, of ruling out spontaneous cures and infection. It is so common to hear that vaccines, including tuberculin, increase the individual resistance, that the increase of the resistance is shown in the diagram, and that the diagram is a perfect support of the contention that just as the amboceptors attach themselves to artificially introduced tuberculin or tubercle bacilli, so they will attach them-

selves to tubercle bacilli naturally occurring and causing the development of amboceptors. The reply must be that the absence of proof of this last happy issue in animals negatives such a view, and it is also understandable that tubercle bacilli ring-fenced in inaccessible fibrotic or caseous foci are not approachable by such a mechanism. There is nothing of a curative nature to be discovered from anaphylaxis; it is a reaction, not necessarily defensive, of the body to any foreign protein introduced from without, whether bacterial or other.

The recent work of Drs. F. H. Thiele and D. Embleton²⁰ on some observations on the production of temperature variations should be read by those who are interested in the problems associated with tuberculin treatment. They show that very probably the poisonous effects produced in the body by bacterial invasion are not the results of poisons developed in and by the living bacteria, but are due to the operations of the invaded organism which, by means of its amboceptors, produces poisons by the digestion of the invading bacteria. Indeed it looks as if the body may tolerate infection well enough, but what it cannot always tolerate is the poisoning which is set agoing when the body cells react against these bacteria. Tuberculin when administered actually helps this poisoning; in 1890 and 1891 such catastrophes were frequently seen because large doses of tuberculin were used; when, since 1905 and 1906, some form of tuberculin has been administered in small doses the poisoning has been whittled down to small injuries as tuberculin reactions and tuberculin cures. This may sound a revolutionary doctrine, but it is one which follows upon the advent of the discovery of anaphylaxis.

The Bearing of the Success of Antityphoid Inoculation.

So far my task has been an easy one; practically all the points in favour of the use of tuberculin to cure disease already existent have been met with counter-explanations, and I sincerely hope my arguments have been fair and have convinced you that the tuberculin cure of human tuberculosis so far is unproven.

But I admit to you I am in a great difficulty when I contemplate the fact announced by Sir William Leishman in this country and by workers abroad in favour of antityphoid inoculation. It has been shown that the prophylactic inoculation with a typhoid vaccine confers on the individual for about two years a lessened risk of contracting typhoid fever; or if contracted, of reducing the case mortality until at the present time, amongst those so inoculated, the number of soldiers in the British army who contract typhoid fever is less than the number who died from it a few years ago. The advocates of the tuberculin treatment of *established* tuberculosis, or for the vaccine treatment of any *established* infection, feel that if typhoid fever can be reduced in case incidence and in case mortality by vaccination before the disease is developed, it should be able to be controlled by vaccination after the disease is developed. I can say at once that figures have yet to be published to establish this speculation. It is not difficult to see that if antityphoid amboceptors are developed in a healthy individual before he contracts typhoid fever, when the infection does occur it finds the cells of the body *ready* to digest the bacilli as they arrive. Every cell to which the typhoid organisms gets access is provided with receptors whose life is about two years, which are ready to behave in the manner above described.

If tubercle bacilli, on the other hand, gain access to the body, if they surround themselves with an almost impenetrable ring of fibrous tissue, caseous or calcified material, then any subsequent development at a remote part, say, of the skin or subdermic tissues of "sessile" tuberculin- or tuberculo-amboceptors by means of injections of tuberculin or tubercle bacilli, may be quite unable to reach the tubercle bacilli. Once again, and finally, until animal experiments can be made showing that this difficulty can be overcome, or until a critically controlled application of tuberculin to a large number of tuberculous human beings can be shown to cure the tuberculous lesion, I submit that the case for tuberculin cure is unproven.

There still remains one more point which must be discussed, and it is this: It may be fairly asked whether it is

not possible that some of the alleged cases of cure of tuberculosis by means of tuberculin are, after all, real and explainable on the ground that all the tuberculin-amboceptors figured in the above diagram do not exist in the form of "fixed" receptors—that some are "free," circulating in the blood stream, and are capable in certain "suitable" "early" cases of tuberculosis of gaining access to the tubercle bacilli present in the focus of tuberculous disease before the latter is rendered inaccessible by fibrosis or other processes of caseation, etc. Such a possibility must be admitted, because by the "complement" fixation method it is possible to demonstrate in certain tuberculous subjects the presence of antibodies in the serum. The answer is that, though infection with living tubercle bacilli may be productive of the formation of tuberculo-amboceptors, which will react to living tubercle bacilli introduced at a second injection or to tuberculin, and which may be free in the blood stream and may give a positive complement fixation test, no one has ever succeeded in proving that if a healthy animal is injected with tuberculin, tuberculin-amboceptors are produced, which will react to living tubercle bacilli, causing their death and solution, or that the serum of such an animal gives a complement fixation test, using living tubercle bacilli as antigen. Moreover, it is well known that no one has ever succeeded in demonstrating in a non-tuberculous man a positive von Pirquet reaction, simply dependent upon repeated previous injections with tuberculin.

Though experimentation has shown that previous tuberculosis, by means of tuberculo-amboceptors, certainly "fixed" in character and may be "free," may prevent subsequent infection with tuberculosis, it has not shown that tuberculin-amboceptors, "fixed" or "free," can prevent subsequent tuberculous infection. Römer²¹ has supplied some evidence which supports this latter contention, for he has found that cattle immunized by living tubercle bacilli and normal animals both show about the same sensitiveness to tuberculin, while the immunized animals show a high degree of hypersensitiveness to tubercle bacilli as a sign of their immunity, and the control normal animals do not.

THE *Liverpool Daily Post and Mercury* has succeeded in collecting £2,000 in ten days for the purpose of supplying radium for the treatment of cancer at the Liverpool Royal Infirmary.

AN international congress on the protection of infancy is to be held in Brussels in July. The work of the congress will be divided among two sections: (1) Children morally abandoned, with special reference to the competence of the courts in respect of children, and the organization of supervision, having regard to liberty. (2) Infancy and puericulture, including the establishment of uniformity of the bases of statistics of infant mortality; consideration of the means of popularizing the principles of hygiene and puericulture; measures of protection for the child outside the home, whether of the father, the mother, or the legal guardian. The sections will discuss together the question of the creation of an international bureau for the protection of infancy.

PLEA FOR UNIFORM METHOD OF TREATMENT WITH TUBERCULIN.

By H. HYSLOP THOMSON, M.D., D.P.H.,

TUBERCULOSIS OFFICER FOR THE COUNTY OF HERTS: LATE MEDICAL SUPERINTENDENT OF THE LIVERPOOL SANATORIUM.

NOTWITHSTANDING much excellent work which has been accomplished during recent years in connexion with the specific treatment of tuberculosis, there still exist much confusion of thought and diversity of practice with regard to the best method of administering tuberculin. There is little or no uniformity of practice in the variety of tuberculin used, in the method and frequency of administration, or in the cases selected for treatment. To the writer it seems that what is urgently required at the present moment is the placing of the treatment of pulmonary tuberculosis with tuberculin on a rational uniform basis which will provide a guide to the general practitioner, who rightly complains against the multiplicity of tuberculins recommended and the difference of opinion regarding treatment which exists among experts. It is not possible, nor in view of the value of comparative studies is it desirable, that a uniform method of treatment with tuberculin should be applied to the whole country. It is certainly desirable, however, that some uniform procedure with regard to the methods and variety of tuberculin used should be applied in each county or district in which the machinery for dealing with tuberculosis is now being established. The aim of tuberculin treatment is to evoke a focal immunizing response *pari passu* with the production of a well-marked degree of tolerance both to the endotoxin and the exotoxin of the tubercle bacillus. The production of a rapid and well-marked tolerance to the exotoxin alone by the inoculation of filtrates of various strengths does not protect the patient sufficiently against the body of the bacillus, and may indeed mask the presence of a slowly progressive lesion. The researches of Koch, Wright, and other observers have demonstrated that it is the body of the bacillus with the contained endotoxins to which we must look for the production of any efficient and permanent immunizing response. Moreover, clinical experience bears this out. Recently I examined a patient who had received over 90 inoculations of exotoxic tuberculins of increasing strengths. There was an entire absence of constitutional symptoms, but crepitations were audible over four lobes, there was a large interarytenoid ulceration, and the urine contained tubercle bacilli. This patient followed his occupation up to a few weeks before death. Clearly in his case the production of tolerance proved a curse in disguise.

It has generally been accepted that the method of treatment with tuberculin is the same at the dispensary as in the sanatorium, but this is not the case. In the sanatorium patients are under constant medical supervision, and the amount of muscular and respiratory activity is regulated according to the requirements of each individual case. In the sanatorium treatment by auto-inoculation takes the place of the preliminary course of treatment with exotoxic tuberculin at the dispensary. I have previously¹ pointed out the excellent results obtained in a sanatorium by a course of tuberculin containing both endotoxin and exotoxin administered when patients have ceased to react to the maximum amount of walking exercise and manual labour; in other words, when a certain degree of tolerance to exotoxin has been secured. At the dispensary, on the other hand, the muscular and respiratory movements of the patients are not under intelligent control. The patient is liable to show sensitiveness to auto-inoculation with the exotoxin of the bacillus, hence a degree of tolerance sufficient to steady the temperature must first of all be produced by a course of treatment with exotoxic tuberculin. The method of administration and frequency of dosage are a source of no little diversity of opinion. In my experience the most efficient and permanently beneficial focal result is obtained by inoculating the patient once a week and by gradually increasing the dose without the production of any marked general or focal reaction, 99° F. being regarded as the danger zone. It is true that if the doses are rapidly increased and reactions are ignored a high degree of toxic tolerance may be obtained, but this is secured at the

expense of tissue immunity, so that the last stage of the patient becomes worse than the first.

The following is the method of treatment with tuberculin which I have adopted.

At the Dispensary.

(a) A course of treatment with T.O.A. (exotoxic) until a certain degree of tolerance is produced.

The following doses are given every eighth day:

0.00001 c.cm., 0.00002 c.cm., 0.00003 c.cm., 0.00004 c.cm., 0.00005 c.cm., 0.000075 c.cm., 0.0001 c.cm., 0.0002 c.cm., 0.0003 c.cm., 0.0004 c.cm., 0.0005 c.cm., 0.00075 c.cm., 0.001 c.cm., 0.001 c.cm., 0.001 c.cm.

(b) When the dose of 0.001 c.cm. has been reached a course of treatment with tuberculin T.R. or new tuberculin W., both of which contain endotoxin and exotoxin of the human bacillus, is commenced. The cost of tuberculin T.R. is 8s. 6d. per c.cm., and the cost of new tuberculin W. 6s. per c.cm. The filtrates of the tubercle bacillus are much cheaper, and it is unfortunate that our views regarding the value of tuberculin preparations are no doubt influenced by their price. I employ new tuberculin W. in the following doses:

Immediately following 0.001 c.cm. T.O.A., 0.00005 c.cm., 0.000075 c.cm., 0.0001 c.cm., 0.0002 c.cm., 0.0003 c.cm., 0.0004 c.cm., 0.0005 c.cm., 0.00075 c.cm., 0.001 c.cm., 0.002 c.cm., 0.003 c.cm., 0.004 c.cm., 0.005 c.cm., 0.0075 c.cm., 0.01 c.cm., 0.02 c.cm., 0.03 c.cm., 0.04 c.cm., 0.05 c.cm., 0.075 c.cm., 0.1 c.cm. This is the maximum dose, and it is repeated at gradually increasing intervals.

The above course of treatment applies to well-marked types of the disease with evidence of slight phases of recurring or persistent auto-inoculation. I have not found it necessary or desirable to go above the maximum dose of 0.1 c.cm. of pure tuberculin.

In the Sanatorium.

In the sanatorium a course of treatment with exotoxic tuberculin is replaced in the majority of cases by treatment with induced auto-inoculation. The patient with an active tuberculous focus is thus led from a period of rest through the various stages of induced auto-inoculation to a full course of treatment with tuberculin containing both the endotoxin and exotoxin of the human bacillus. Part of this course will be commenced at the sanatorium, but it will usually be completed at the dispensary.

Elsewhere¹ I have described the excellent results obtained by a course of treatment with tuberculin T.R. following treatment with auto-inoculation, and I recommend in the sanatorium a course of new tuberculin W. in the following doses:

0.00001 c.cm., 0.00002 c.cm., 0.00003 c.cm., 0.00004 c.cm., 0.00005 c.cm., 0.000075 c.cm., 0.0001 c.cm., 0.0002 c.cm., 0.0003 c.cm., 0.0004 c.cm., 0.0005 c.cm., 0.00075 c.cm., 0.001 c.cm., 0.002 c.cm., 0.003 c.cm., 0.004 c.cm., 0.005 c.cm., 0.0075 c.cm., 0.01 c.cm., 0.02 c.cm., 0.03 c.cm., 0.04 c.cm., 0.05 c.cm., 0.075 c.cm., 0.1 c.cm. The maximum dose to be repeated at gradually increasing intervals.

It is desirable that, in the various districts which embrace sanatorium and dispensary in the scheme for dealing with tuberculosis, there should be some uniformity with regard to the method of administering tuberculin in the sanatorium and dispensary, so that when the patient passes from the sanatorium to the after-care of the dispensary there should be no marked cleavage in the methods of treatment.

Conclusions.

1. It is desirable that the various districts in which the machinery for the treatment of tuberculosis is being established a uniform system of treatment with tuberculin should be adopted.

2. It is especially desirable that the system of tuberculin treatment carried out in the sanatorium should correspond with the method adopted at the dispensary.

3. A short course of treatment with T.O.A., followed by a course of treatment with new tuberculin W., should form the basis of treatment at the dispensary.

4. A course of treatment by auto-inoculation followed by a course of treatment with new tuberculin W. or tuberculin T.R. should form the basis of treatment in the sanatorium.

PROGNOSIS IN PULMONARY TUBERCULOSIS: THE RESULTS OBTAINED BY ARNETH'S METHOD.

By J. B. H. HOLROYD, M.R.C.S.ENG., L.R.C.P.LOND.,
LATE ASSISTANT MEDICAL OFFICER, SHEFFIELD UNION
HOSPITAL.

THE prognosis in pulmonary tuberculosis is of vital importance both to the patient individually and to the health of a community. But to make a correct prognosis is in many cases very difficult, and in some almost impossible if physical diagnostic signs are the only guides available.

Arneth's method of blood counting offers, however, some solution of the difficulties encountered in this connexion. When he devised this method he took the neutrophilic leucocyte, which may have I, II, III, IV, or V nuclei, as the cell, and on this he made his count. He then assumed that the cells with I or II nuclei were less resistant than the cells with III, IV, or V nuclei, and that when those less resistant cells were present in large numbers the severity of the case varied directly as the number of these cells.

I adopted this method at the Sheffield Union Hospital, and applied it to 30 cases extending over a period of three months. The observations made on these cases suggested that Arneth was right, and that the prognosis varied inversely as the increase in neutrophiles having I or II nuclei.

The technique employed is as follows:

The specimen of blood is obtained in the usual way by pricking the finger and spreading the drop of blood thus obtained on a clean slide by means of another slide held at an angle of 45 degrees. The slides should be kept in a mixture of equal parts of ether and alcohol, and when required for use are wiped dry with a soft duster. The film of blood thus prepared is allowed to dry in the air, after which staining is proceeded with.

The stain used varies with different observers, and in this particular series of cases Jenner's stain was employed throughout. The slide is flooded with stain, which is kept on for five minutes and then washed off with water, dried and mounted in xylol balsam, care being taken to have an adequate quantity of stain to obviate the danger of the slide becoming dry. The slide is now examined microscopically, and $\frac{1}{2}$ in. oil immersion lens is used. If a larger lens is substituted it is very difficult to be sure of the number of nuclei in the cells. A movable stage should also be used in order to alter the position of the slide as easily as possible so as to avoid the accident of counting the same field twice; 100 neutrophilic leucocytes are then counted and classified according to the number of their nuclei.

The count is then compared with the normal one observed by Arneth, which has been used as the standard in all the results of this series of cases. The normal is as follows:

| I. | II. | III. | IV. | V. |
|-------------|--------------|--------------|--------------|-------------|
| 5 per cent. | 35 per cent. | 41 per cent. | 17 per cent. | 2 per cent. |

It is noticed that in an unfavourable case there is an increase in the number of cells with I or II nuclei, and usually both I and II are increased; in other words there is a drift to the left. This drift has been present in all cases in this series.

The following examples are given:

1. A. P., aged 33. Physical signs definite and the patient ill. Tubercle bacilli numerous. The count showed on June 14th, 1911:

| I. | II. | III. | IV. | V. |
|--------------|--------------|--------------|-------------|-------------|
| 44 per cent. | 31 per cent. | 20 per cent. | 5 per cent. | 0 per cent. |

Death occurred on August 10th, 1911.

2. P. R., aged 55. Patient ill. Cavitation present; tubercle bacilli also present. Count on June 19th, 1911, showed:

| I. | II. | III. | IV. | V. |
|--------------|--------------|--------------|-------------|-------------|
| 45 per cent. | 40 per cent. | 12 per cent. | 2 per cent. | 1 per cent. |

Death on June 22nd, 1911.

3. G. E., aged 39. Patient ill, signs definite, and tubercle bacilli present. Count on June 26th showed:

| I. | II. | III. | IV. | V. |
|--------------|--------------|--------------|-------------|-------------|
| 20 per cent. | 44 per cent. | 29 per cent. | 7 per cent. | 0 per cent. |

Death on July 1st, 1911.

4. A. H., aged 45. Signs definite; tubercle bacilli present.

| I. | II. | III. | IV. | V. |
|--------------|--------------|-------------|-------------|-------------|
| 51 per cent. | 39 per cent. | 8 per cent. | 2 per cent. | 0 per cent. |

Death took place in four days after the count had been taken.

5. J. G., aged 28. Patient ill; signs definite.

| I. | II. | III. | IV. | V. |
|-------------|--------------|--------------|-------------|-------------|
| 6 per cent. | 34 per cent. | 16 per cent. | 4 per cent. | 0 per cent. |

Death in ten days after the count.

6. B. J. G., aged 15. Signs definite and ischio-rectal abscess present, tuberculous in origin. Count taken June 14th:

| I. | II. | III. | IV. | V. |
|--------------|--------------|--------------|-------------|-------------|
| 33 per cent. | 35 per cent. | 25 per cent. | 5 per cent. | 2 per cent. |

On September 8th patient appeared well. No temperature; abscess healed. Count gave:

| I. | II. | III. | IV. | V. |
|--------------|--------------|--------------|-------------|-------------|
| 12 per cent. | 40 per cent. | 42 per cent. | 4 per cent. | 2 per cent. |

As the condition improved the drift to the left was not quite so marked.

The conclusions arrived at after the above observations were that in cases with an unfavourable aspect the cells with I or II or I and II nuclei were present in greater numbers than normally, and that as the improvement of the general condition takes place the drift to the left of the picture is not so marked; or in other words, the cells with I and II nuclei are not so numerous, and approach nearer the normal.

THE EPIGLOTTIC SUTURE: ITS VALUE IN INDIRECT LARYNGOSCOPY.*

By CYRIL HORSFORD, M.D., F.R.C.S.,

LONDON.

THE object of this brief communication is to draw the attention of the members of this Congress to the fact that the field of vision obtained by indirect laryngoscopy may be greatly improved by the passage of a suture through the epiglottis, and that this suture may now be rapidly and safely passed. The suture is recommended as a substitute, more efficient in all respects than the many forms of epiglottis lifters introduced to facilitate intralaryngeal inspection.

I am fully conscious of the enormous boon the direct method has become to laryngeal surgery, and many enthusiasts have entirely given up the indirect method for it. The time is therefore opportune for bringing forward a plea for the revival of the indirect method, supplemented by the suture.

The method is not new, but is a resuscitation of an old idea. I admit that in my first publication on this subject¹ I described it as original, as I could not at that time find any evidence to the contrary. Sir Felix Semon, however, drew my attention to previous work in this field when I demonstrated it at the meeting of the Laryngological Section of the Royal Society of Medicine of London in December, 1907.²

I propose to make no reference to the many varieties of instrumental epiglottic retractors which require the continuous use of the hand to hold the instrument in position. Whether that hand be one of the operator's or that of his assistant is immaterial, for such a method is obviously unsuitable or inconvenient in intralaryngeal operations.

Türk³ published in 1866 a description of two instruments which he devised for the purpose of utilizing a thread as an epiglottis lifter. With the first a small hook with a thread attached, was inserted into the epiglottis, but the thread did not penetrate the epiglottis. With the second, however, a needle and thread were passed through the epiglottis and the thread was held by an assistant. This instrument was complicated and its use extremely difficult, largely owing to the fact that local anaesthesia by cocaine was not in use at that time. He further feared that the thread would tear through the epiglottis—a complication which can only be caused by

great local unrest. It is no wonder, therefore, that the method fell into disuse. The great value of the principle was, however, recognized, and the instrument was modified and simplified by Schrötter and Tobold.⁴

Jurasz and Jelenffy⁵ recommended the suturing of the glosso-epiglottic ligament instead of the epiglottis, and by this they lifted the epiglottis. Sir Felix Semon and Sir Victor Horsley,⁶ in a series of experiments on dogs, passed a thread through the epiglottis in order to see better the interior of the larynx.

Dr. Gleitsman⁷ of New York has devised an instrument which, from the illustration, appears to be very similar in principle to my latest pattern, and he has found it of great value in rendering possible both a correct diagnosis and an intralaryngeal operation.

The idea of using an epiglottic suture first occurred to me in July, 1906, when I adopted it in order to facilitate an operation of exceptional difficulty—namely, the excision of a very tough fibrous web which united the anterior halves of the vocal cords and extended some way down into the cavity of the larynx. The epiglottis was not overhanging, but I wished to get it out of the way because I was using a sharp-pointed Heryng's knife, followed by sharp punch forceps, and it was necessary to get the best possible view. I used a pair of Spencer Wells forceps, curved at the point, with which I held a small curved and threaded needle. With the aid of the laryngeal mirror the needle was pushed through the epiglottis from before backwards, the point being then caught by the forceps and drawn through. There was not much difficulty in passing the suture and not the slightest discomfort to the patient, who had already been thoroughly cocaineized in preparation for the operation.

Fig. 1.

In the following year I used a needle-holder made to my design by Messrs. Mayer and Meltzer (see Fig. 1), its principle and use being as above described. This instrument was shown, and the method described and demonstrated on a patient, at the meeting of the Laryngological Section of the Royal Society of Medicine already referred to.² Soon after I still further simplified the method by

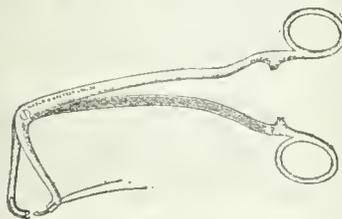

Fig. 2.

the suture forceps shown in Fig. 2, which was made for me by Messrs. Mayer and Meltzer. It is a modification of Kurz's forceps used for the passage of deep sutures in pelvic surgery. This instrument and its use were demonstrated at another meeting in April, 1908.⁸ The mechanism of the catch greatly simplified the passage of the suture. Though I have used it with complete success in a large number of cases, I have again modified and simplified it, and my latest pattern, which I call the epiglottic suture forceps No. 2, is the instrument which I now

Fig. 3.

recommend (see Fig. 3); it may be obtained from Messrs. Mayer and Meltzer or H. Pfau, Berlin.

The successful use of either pattern depends, as in other intralaryngeal operations, upon the efficient preparation of the patient for local anaesthesia. Cocaine should be applied to both surfaces of the epiglottis and to the centre of the root of the tongue. It is as well also to apply a little adrenalin to the epiglottis to prevent the possibility of haemorrhage obscuring the field of operation. The needle is first threaded with a long piece of silk and placed in the proximal blade, and the whole carefully sterilized. With the aid of the laryngeal mirror, the

* Read at the Third Rhino-Laryngological Congress in Berlin, September, 1911.

forceps are introduced into the throat until the upper border of the epiglottis is seen to pass between the point of the needle and the distal blade, the blades are then firmly closed and then opened and the instrument withdrawn; it will be found that the suture has passed through the epiglottis. The ends are then brought over the centre of the tongue and gripped by a large pair of Spencer Wells or any similar forceps, and allowed to hang some distance below the jaw. The tongue is held for examination in the usual way, and it will now be seen that the epiglottis is held up against the root of the tongue by the weight of the forceps only and the intralaryngeal view greatly improved. On the occasions in which I have used this method the patients have neither strained nor coughed, and were not conscious of the presence of the suture so long as the effect of the cocaine lasted, though in some cases there were feelings of nausea, which, however, soon passed off. The use of the instrument entails no risk to the patient. The needle is held sufficiently firmly in the proximal blade to prevent it falling out before it is passed, and should it do so, it falls into the glosso-epiglottic fossa only, and is easily withdrawn by the thread, which is held in the hand. When the blades are closed it is firmly caught in the distal blade, and cannot be released until the instrument is withdrawn and the needle turned on its long axis to be liberated; there is, therefore, no risk of its falling into the cavity of the larynx. The epiglottis does not suffer by the passage of the needle, and I have never observed any inflammatory or other complication following it. The suture occupies no space in the mouth, and, unlike other epiglottis lifters, does not require the assistance of a third hand. It further helps to steady the larynx and increases the laryngeal illumination. Though the shaft of some laryngeal forceps may be used to pull the epiglottis forward during their use, it is a decided advantage to be independent of that action, so that the operator may be free to place the forceps in any position he desires, so as to prevent the shaft from hiding the point and obscuring the light.

I consider that the preliminary use of the epiglottic suture for facilitating intralaryngeal operations should not be limited to cases of obscured field of operation caused by a markedly overhanging epiglottis, but should be used in all cases where the epiglottis in any way hinders a delicate intralaryngeal manipulation, whether it be cutting or cauterizing, especially where a perfect vocal result is desired. This method may also be used simply for diagnosis, when other methods of lifting the epiglottis have failed. It may in a few cases be used without the aid of a laryngeal mirror, when it is found, on depressing the tongue, that the upper border of the epiglottis can be seen.

It is scarcely necessary to illustrate my remarks by relating cases in which I have adopted this method, the majority of them having been for innocent growths within the larynx, and these include ten vocalists, who are now singing successfully before the public. I would like, however, to refer to one case, for it is the best illustration I have had of the value of the method.

The patient, a tenor vocalist, had been unable to use his voice effectively for four years because of a small fibroma situated on the upper surface of the right vocal cord, overhanging its edge and near the anterior commissure. The larynx was situated rather low in the neck, so that the vocal cords were not easily reached by the ordinary sized laryngeal forceps. This probably explains the fact that during three years numerous attempts by two expert laryngologists failed to remove the growth. These attempts included the use of many varieties of instruments, the direct method once under cocaine and once under chloroform. I succeeded at the first visit with a pair of Whistler's forceps, and my success was entirely due to the use of the epiglottic suture.

The best proof of the accuracy of this method of manipulation was the fact that two months after the patient sent me a press cutting of his successful appearance at a concert.

Since I brought the subject before the Laryngological Section of the Royal Society of Medicine of London I have had many encouraging reports from those of my colleagues who have used the method, and I should like to quote the experience of Sir St. Clair Thomson, who writes to me as follows:

I have used your epiglottic suture forceps (No. 1) on several occasions and always with complete satisfaction. I have found it most useful in cases of overhanging epiglottis where the

growth was situated near the anterior commissure, a site where the use of the direct method is not so satisfactory as might be expected.

I know of several patients who have welcomed it as an agreeable alternative to the uncomfortable attitude created by the requirements of the direct method.

CHEILOLOGY: A FUNCTION-RESTORING OPERATION IN CRIPPLING TRAUMATIC ARTHRITIS OF THE HIP-JOINT.

[WITH SPECIAL PLATE.]

BY

W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,

SURGEON WITH CARE OF OUT-PATIENTS TO THE MIDDLESEX HOSPITAL; AND

C. PRESTON BALL, M.D., M.R.C.P.I., D.P.H.I.,

VISITING PHYSICIAN, ROYAL HOSPITAL FOR INCURABLES, DUBLIN.

This brief paper is to be regarded as a preliminary communication on an operative method which may prove to be of wide application in the treatment of chronic hypertrophic arthritis, especially if it be uniaxial and of traumatic origin. It is a record of the two first cases in which the method has been applied. Both were of traumatic origin, and in both the hip was the joint affected. In both, while flexion remained relatively free, the movements of abduction and rotation were lost, so that riding was impossible and walking was slow and difficult. In the first case continuous severe sciatic pain, dating from the accident, made the patient's life a misery to him.

Stereoscopic radiograms showed clearly that the principal obstacle to the movements of the joint in both cases was an osteoarthritic lip or cornice around the head of the femur. It occurred to one of us (C. P. B.) that it might be possible to chisel away this lip sufficiently to relieve pain if not to restore a useful range of movement to the joint. An operation for this purpose was devised and successfully carried out, with functional results in both cases which up to the present have surpassed our expectations. The operation consists in opening the hip-joint and removing the cornice on the head of the femur, so far as it is accessible, by suitable bone-cutting instruments devised to work in a cramped space. On account of its technical difficulty the operation is somewhat prolonged, but in both instances shock has been absent and convalescence uneventful.

It will probably be found that this operation is applicable in other joints than the hip. It may, for instance, be of service in the knee-joint, using the same transarticular incision which has been employed by one of us for difficult fractures of the lower end of the femur.¹ A procedure so definite, and possibly of such wide application, appears to need a distinctive name. We suggest the name *cheilotomy* ($\chi\epsilon\iota\omicron\varsigma$, lip) as convenient.

So far as we have been able to ascertain, the operation of cheilotomy—at any rate, in the hip-joint—had not been performed prior to our first case in January, 1913.

CASE I.

Mr. J., aged 56, four years ago had a fall in the hunting field. His horse came down on the left side without dismounting him, so that his left hip was crushed between the ground and the horse's side. He managed to ride home, did not consult a doctor, and only lay up for three or four days. But from this time forward he began to suffer from severe left sciatic pain, which has gradually reduced him to a crippled condition. For the last two years he has been unable to ride.

He first consulted Dr. Preston Ball in July, 1911. He was then suffering from general rheumatism especially affecting the joints, but more especially the left hip-joint.

At times he was seized with most acute pain, not only in the left hip but in the lumbar region, and also in the shoulders and arms. Varied medical treatment had proved of no avail up to this time, and Dr. Ball gave him a course of inoculations with streptococcus vaccines at intervals of seven days, beginning with small doses of one million, and gradually increasing the injection up to fifty million, the last six being of a mixed vaccine containing along with the strains of streptococci the *Micrococcus rheumaticus* of Poynton and Paine. At the same time the patient was given suitable tonics, and ionic medication was adopted for the left hip. His condition greatly improved in a comparatively short time, his general health was better, and he could walk and play golf without pain, and in November, 1911, he appeared almost cured, the only trouble then being a little stiffness in the left hip.

For several months he continued to be free from pain, and was well in every way, but in September, 1912, the pain returned in the left hip and rapidly became worse, and it was only with great difficulty he could walk at all. Golf had to be abandoned. He consulted Dr. Ball again, and ionic medication was continued, but the hip-joint continued to give him great trouble, and a skiagram of the joint showed distinct osteo-arthritis, with considerable "lipping" around the acetabulum. An abnormal bony outgrowth, shaped like a canine tooth, could be seen projecting from the lower margin of the articular surface of the head of the femur, immediately in front of the sciatic nerve. The patient now consulted Mr. Handley with a view to the removal of the bony lipping of the femur. A stereoscopic radiogram showed that the tooth-like projection was directed downwards and forwards, not downwards and backwards as had been assumed, so that it could not press on the sciatic nerve. But it also showed other outgrowths (see Fig. 1) surrounding the margin of the head, some of which might be pressing on the nerve, and it seemed right to attempt the systematic removal of the lip so far as it could be reached. An element in this decision was the patient's helpless condition, for he had given up walking altogether, except for the shortest distances, and with a painful effort. Moreover, a resort to sedatives had become inevitable, and even morphine had been necessary on many occasions.

Prior to operation he was seen by Dr. W. H. Willcox, who allows us to quote the following extract from his notes made at this time:

The patient was seen by me on January 9th, 1913. He had had during the past few years spa treatment at Droitwich and Buxton and all the usual forms of medicinal treatment. On examination it was found that the only joint affected was the left hip. There was deficient movement of flexion and extension, but there was some range of free movement in this direction. The lateral movement was very deficient, and any attempt at circumduction gave considerable pain. As there was no evidence of any acute inflammatory condition of the hip-joint, and as no other joints were affected, and as the x-ray examination showed bony changes which no medicinal treatment could possibly affect, I advised operative treatment.

It may be added that all the muscles of the left lower limb were flabby and atonic from disuse. There was no definite tenderness along the course of the sciatic nerve, and pain was felt in the front of the thigh as well as at the back. Actual sciatic neuritis could therefore be excluded.

Operation.

On January 13th, 1913, the operation was carried out, and abduction and external rotation at the close of the operation were found to be restored to a large extent. By the tenth day the wound was soundly healed. During the first two or three nights morphine was necessary, more on account of restlessness and the tedium of a fixed position than for actual severe pain. By the fourth day the patient was entirely free from the pain which had made his life a misery for years. Slight rotation of the joint caused no uneasiness. Passive abduction was begun gently on the fourth day, it was free without the use of any force whatever. By the twentieth day the patient was allowed to get up and sit in a chair. A day or two later he was permitted to stand, and to walk about wearing a temporary apparatus supplied by Mr. G. Ernst to limit the movements of the hip and prevent undue strain on the sutured capsule. He left the home on the twenty-fifth day absolutely free from pain, and with a large range of abduction and external and internal rotation in the joint.

To illustrate the patient's relief after the operation it is permissible to quote from a letter to one of us just before he left the nursing home: "I feel a different man, and am only too thankful I came and saw you."

Before returning to Ireland he was seen by Dr. A. P. Luff, who in reply to a recent letter respecting the case writes:

I saw him with you on February 6th, and the notes that I have with regard to his examination are that there was extremely good mobility of the joint as regards internal and external rotation and abduction. I think the result of your operation is an extremely satisfactory one.

He has been seen by Dr. Ball on two occasions since his return home. His general condition has greatly improved, and he can walk quite well. Both external and internal rotation appear to be normal. He is greatly pleased with the results of the operation, and the improvement is well maintained up to the date of writing (April 9th, 1913).

CASE II.

Major A., aged 62, was sent to Mr. Handley by Dr. Preston Ball on March 26th, 1913, for traumatic arthritis of the left hip with increasing fixation of the joint and difficulty in walking. The patient is a healthy man, looking much less than his age, and has lived an active outdoor life, first in the cavalry and since his retirement in sports and country pursuits. For some years the condition of the hip has prevented him from riding, though until recently he has been using a bicycle. Walking has become a slow and laborious process, though it is not painful. The patient felt his increasing disabilities keenly since they cut him off from his principal active interests, and he was quite willing to undergo an operation if there was any prospect of improvement.

Twenty-two years ago, as the result of a fall in a steeple-chase, he damaged his left hip. After treatment of several weeks by his local doctor in Carlou, who "fired" the joint, he came over to Dr. Wharton Hood. The treatment was so successful that fourteen days later he was able to begin riding. For many years after this the joint does not appear to have troubled him very much, but in 1904, after a critical attack of double pneumonia, the hip began to stiffen.

In 1910 the situation was becoming serious, and he underwent a course of manipulations and fomentations. Last summer he went to Aix and had baths and exercises. He noticed that passive movements of the joint did not produce any improvement, and left it rather painful. He consulted Dr. Preston Ball in October, 1912. Dr. Ball noted that the history was similar to that of Case I, and that the pain and loss of power were confined to the hip-joint, his general health being quite good. It was agreed from the first that he should consult Mr. Handley with a view to operation: but in the interval between October and March he had ionic medication and electrical massage, which possibly gave him slight relief, though there was no marked change or improvement. An ordinary skiagram showed distinct overgrowth of bone around the hip-joint.

He was first seen by Mr. Handley on March 27th, 1913. The great trochanter on the left side was about $\frac{3}{4}$ in. higher than on the right side, the left thigh was 1 in. less in circumference than the right, and the left calf $\frac{1}{2}$ in. less than the right. The movements of the spine were good though perhaps slightly limited. There was no grating in any of the joints, except in the right shoulder-joint, where slight crepitus was present, probably the result of an accident which fractured the right clavicle. Flexion of the right hip was free, but flexion of the left hip was very limited. Rotation of the left hip was practically absent, while that of the right hip was free. Abduction of the left hip was entirely absent, while on the right side it was nearly normal.

The patient stated that his doctor at Aix considered bony ankylosis to be present in the left hip. While this statement is difficult to explain in view of the amount of flexion, it emphasizes the fixity of the joint as regards rotation and abduction. In contrast to Case I, the patient had suffered hardly any pain, and it was entirely on account of disability that he desired relief.

A stereoscopic radiogram, taken by Mr. Coldwell (Fig. 2), showed exuberant lipping surrounding the whole of the head of the femur. Judging by this alone, the case seemed extremely favourable for cheilotomy. There were, however, other changes in the joint, namely, some bony deposit round the acetabulum, apparently in the capsule, and a disappearance of the cartilage interval over the convexity of the head of the femur, showing that in this situation cartilage had disappeared. These changes, however, were not sufficiently marked to contraindicate operation. A stereoscopic radiogram of the right hip showed some similar changes, but in a very early stage. Dr. W. H. Willcox confirmed Dr. Ball's opinion that the patient was medically sound, and allows us to quote as follows from his notes:

The patient was seen by me on March 28th, 1913. I found him a thin, spare, muscular man who was perfectly sound and fit except for lameness arising from the left hip. He walked very

lame, and experienced pain in walking. All the joints were practically normal except the left hip. The left hip showed great impairment of movement. There was only slight flexion, about 10 degrees, and very little lateral movement was possible. The *x*-ray examination showed very marked lipping, and bony changes round the left hip-joint. The patient had had all forms of medicinal treatment and had visited various spas without any benefit. As it was obvious that medicinal treatment could not improve or affect the marked bony changes round the left hip-joint, and since there was no inflammation round the joint, and no other joint was affected, I advised surgical treatment.

Operation.

On March 30th the operation of cheilotomy on the left hip was performed through a posterior incision in the capsule, securing free rotation and a considerable amount of abduction. The operation proved to be more difficult than in Case I, mainly on account of the bony deposit in the capsule at the margin of the acetabulum. The bony lip round the margin of the head of the femur was removed for a considerable portion of its circumference, and the capsule was sewn up.

On the evening of the day of operation the patient was quite free from pain, and he is making an uneventful convalescence. There seems every prospect that the result in this case will be just as satisfactory as in Case I, for abduction and rotation already, only ten days after the operation, are free and painless, though there is more tendency to muscular spasm than in Case I.

Dr. W. H. O'Meara of Carlow writes on April 26th: I saw Major A. yesterday, and must congratulate you on the great success of your operative treatment. He can walk about with comfort, and can rotate, extend, and abduct the leg freely.

It is probable that the restoration of movement produced by cheilotomy, while depending mainly upon the removal of actual bony obstacles to rotation and abduction, is also due to another cause. The head of the femur is unduly large and the capsule is consequently stretched, and does not possess that reserve of "slack" which is necessary to allow a good range of movement. The restoration of this "slack" by the operation is an important factor which must not be lost sight of.

May we, in conclusion, utter a word of warning against the indiscriminate application of the operation in unselected cases. For cases where the constitutional or toxic element of osteo-arthritis predominates, the method is obviously unsuited, and other methods of treatment, including the vaccine treatment, of which one of us has made a special study,² should always be tried. Nor should the operation be undertaken save under the best conditions, with ample assistance, with all possible aseptic precautions, and with the essential preliminary of a good stereoscopic radiograph of the joint.

The best and most suitable cases are probably those in which medical and vaccine treatment has improved the patient in relation to his or her general health and where the smaller joints (probably those most recently affected) have improved, but the one joint shows distinct osteitic changes as described.

A CASE OF ENTEROLITHS.

[WITH SPECIAL PLATE.]

BY

J. ANDERSON, M.B., CH.B. ABERD.,

HONORARY ASSISTANT SURGEON, DUNDEE ROYAL INFIRMARY.

AN *x*-ray photograph of enteroliths *in situ* must be comparatively rare. In fact, I can find no evidence of any such having been recorded. The main factors responsible for this appear to me to be: (a) Intestinal concretions are distinctly uncommon.¹ (b) In many cases the symptoms are so insidious in their onset and of so long duration that medical aid is summoned only when there is evidence of intestinal obstruction, and the diagnosis is made when the abdomen has been opened. (c) Only recently has *x*-ray examination become a routine method in abdominal diagnosis.

The case is that of J. O., a ploughman, aged 39, seen by me with Dr. Gowans of Broughty Ferry on July 23rd, 1912. Except for seven years, when he was working in

an oilcake factory, he has followed this employment since the age of 13. His habits have been regular and he has had no other illness. The history was that for the past eighteen years he had been subject to attacks of colic in the right iliac region, varying in duration from a few minutes to half an hour, and recurring generally three or four times a month. They commenced with distension of the lower abdomen, associated with gradually increasing discomfort till the pain suddenly began to diminish and the indisposition culminated in complete relief followed by the passage of a large quantity of flatus. He had also had flatulence not associated with pain. The bowels had been fairly regular, but he had had occasional attacks of diarrhoea followed by constipation. There had been no vomiting and no urinary symptoms. During the last month these attacks had increased in frequency and severity, and had been accompanied by marked anorexia and slight loss of weight.

On examination, the teeth were good and his tongue clean. An irregular tumour of stony hardness and about the size of the fist was felt in the right iliac fossa. It was fairly mobile, and gave the impression of being intimately connected with the caecum. I was unable to feel it by the rectum. He was advised to go to hospital for *x*-ray examination and probably exploratory operation but delayed till his general health began to suffer and his discomfort increased.

He was admitted to Dundee Royal Infirmary on August 20th, 1912. His condition on admission was very much as above noted but with a general aggravation of all symptoms and somewhat severe intestinal stasis: the tumour was less movable.

The *x*-ray photograph reproduced was taken by Dr. Pirie, and gave the foundation for definite diagnosis.

On August 22nd, under chloroform, I opened the abdomen through the right rectus (Battle's incision). The lower portion of the ileum was found to be very much increased in calibre, and its walls markedly hypertrophied. The tumour consisted of two portions, the larger fixed at the ileo-caecal valve, the other free in the lumen of the ileum some 5 in. from its lower end.

The smaller concretion was removed with ease through an incision in the longitudinal axis of the gut. The portion of bowel containing the second calculus could not be brought up to the abdominal wound, so it was deemed expedient to pack off the general peritoneal cavity and attempt removal through the same intestinal opening. This enterolith was roughly hourglass shaped, and impacted at the valve, and the caecal portion had to be broken down and the mass delivered with a large stone forceps. The bowel was closed with Lembert sutures.

Convalescence was uneventful, and the patient was discharged well on September 20th. He is now nearly 2 st. heavier than before the operation.

The specimens² look like pieces of compressed felt.

(a) The smaller, which was wedge shaped, with two large facets, measured 16 x 14 cm. in circumference.

(b) The larger showed no facet, and measured 19½ x 24 cm. (the last measurement is approximate, owing to damage in removal). The capsule and nucleus, which were well marked in the skiagram, were found chemically to consist mainly of calcium phosphate, while the intervening material appeared to be mostly faecal and vegetable matter bound together by fine hair-like substance. Since removal they have lost quite half their weight.

The case is interesting mainly from the following points of view:

- The large size of the concretions.
- The fact that these, though situated at what is normally the narrowest portion of the gut, did not give rise to more marked obstructive symptoms.
- The duration of the symptoms without disturbance sufficiently grave to necessitate medical attention at an earlier date.
- The extreme value of *x*-ray examination in arriving at a correct diagnosis.

Two points of interest noted in the history were that porridge had been one of his most frequent articles of diet.

² The specimens were shown at a meeting of the Forfarshire Medical Association, November, 1912.

and that he very frequently bit hairs from his moustache and swallowed them.

The patient was again referred to me in March, 1913, with a breaking-down tumour situated about the middle of Scarpa's triangle on his right leg. I excised it and found it to be a spindle-celled sarcoma growing from the superficial fascia.

His general condition is excellent.

REMOVAL OF INTRATHECAL TUMOUR FROM LUMBAR REGION OF SPINAL CORD.

BY

J. MICHELL CLARKE, and
M.D., F.R.C.P.,

C. A. MORTON,
F.R.C.S.,

PHYSICIAN, BRISTOL GENERAL
HOSPITAL.

SURGEON, BRISTOL GENERAL
HOSPITAL.

This case illustrates the symptoms produced when a tumour compresses both the upper roots of the cauda equina and the spinal cord itself, and affords another instance that these intrathecal growths are so often single and non-malignant.

HISTORY.

The patient was under the care of Dr. Harvey Bird, of Bridgwater, who recognized the nature of the case, and sent her to the Bristol General Hospital. She was married, aged 52, had had six children, and had enjoyed good health until the present illness; there was no suspicion of syphilis.

ORDER OF SYMPTOMS.

Towards the end of 1909 she began to suffer from "rheumatic pains" in the right thigh, which henceforth recurred at gradually decreasing intervals. In 1912 the pains became worse, they were sharp and shooting in character, from the hip down into the leg and foot, and the right leg became weak. In April, 1912, the pains greatly increased; she also felt "pins and needles" in the toes, and increasing numbness and loss of power in the whole limb. By May the right leg was paralyzed, and from this and increased pain she could no longer get about. At the end of May shooting pains were also felt in the left leg, though not so severe as in the right, and were accompanied by numbness and gradually increasing loss of power in it. She also suffered from pains in the back, and a feeling of tightness around the lower abdomen.

At the end of July, 1912, there was paraplegia; she was unable to walk or stand. For a fortnight during August she had retention of urine, but recovered control of her bladder under use of the catheter; from this time, however, she was liable to occasional incontinence. Bowels constipated. Severe pains continued until admission to Bristol General Hospital on September 7th.

CONDITION ON ADMISSION.

She was well nourished, but had a drawn, haggard expression. She was completely paraplegic and moved or turned herself in bed with the greatest difficulty. Passive movements of the lower limbs caused great pain, especially at the joints. She complained so constantly of great pain, when moved or touched, that it was both difficult to examine her or to do anything for her; possibly she was unmoved by the pain she had suffered, which had necessitated morphine injections. She slept badly. The thoracic and abdominal organs were normal. The urine was normal. The cranial nerves, upper extremities, and trunk muscles were entirely unaffected.

Motor Symptoms.

The right lower extremity could not be moved at all in any part of it; she could draw up the left thigh a little way and bend the left knee slightly, but these were the only movements possible in this limb.

The paralysis was of the flaccid type; there was double foot-drop and the toes were flexed.

The anterior thigh muscles were not wasted, except from disuse. There was marked wasting of all muscles below the knees in both legs, predominating in the tibialis anticus, peronei and extensors of feet, more marked on the right than on the left side, though the circumference of each calf measured the same. The glutei and hamstring muscles were also wasted.

Electrical Reactions.

Diminished reaction to both electrical currents was present in both quadriceps extensor muscles, especially the right, and in the glutei and hamstring muscles. Reaction of degeneration was present in tibialis anticus, peronei, extensors of toes, calf muscles, and plantar accessorius. The peroneal nerves reacted very feebly to the faradic current; to the constant the formula for the right nerve was $KCC=0$, $ACC=20$ milliampères, and for the left $KCC=10$ milliampères, $ACC=8$ milliampères.

Sensory Symptoms.

The sensory affection is shown on the chart (Fig. 1). Apparently the border of loss of sensation to cotton-wool

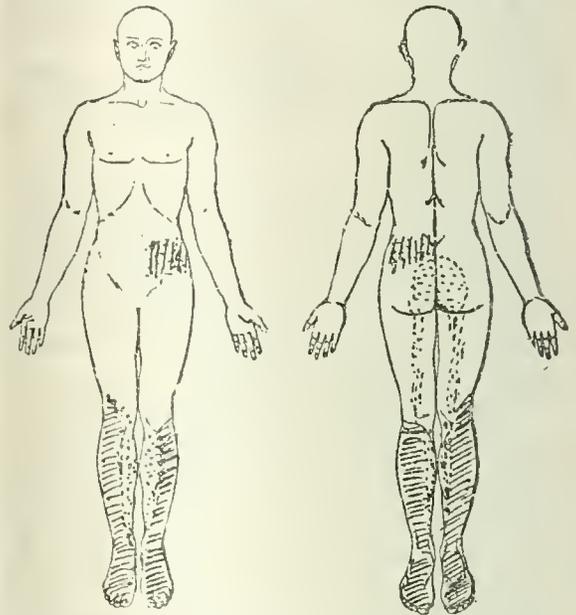

Fig. 1. Loss of sensation to touch, pain, and temperature; dotted area, defective sensation to touch, pain, and temperature; ill-defined band of hyperaesthesia.

and pin-prick was coterminal. The loss to heat and cold was absolute over the affected areas, whilst there was diminution of sensation to pressure over the same distribution. Both feet felt very cold to the touch. There was also some loss of the sense of position of the limbs; she had constantly a feeling that her legs were floating in the air and not lying on the bed. There was an indefinite zone of hyperaesthesia on the left side in the lower lumbar or upper sacral and lower abdominal regions.

The chart gives the result of a number of observations on the sensory changes, and can be regarded as approximately correct; she was a difficult patient on whom to make any investigations of this kind.

Reflexes.

Abdominal present and normal. Plantar absent or (?) feebly flexor on strong stimulation.

Knee-jerks and ankle-jerks present. Right knee-jerk active. Marked ankle clonus on right side, not on left; no knee clonus. The bladder was not distended; there was occasional slight incontinence of urine, which seemed partly due to inadvertence, as she was not always aware of it; she could not hold her water for more than an hour at a time. There was no anaesthesia of bladder or rectum. The anal sphincter contracted normally.

There were no trophic lesions of the limbs, and no actual bedsores; but on admission the skin over the sacral and lower lumbar regions of the back was in a very unhealthy state and on the verge of breaking down.

X-ray examination and lumbar puncture showed the spinal column and cerebro-spinal fluid to be normal.

DIAGNOSIS.

From the above signs the diagnosis of an extramedullary tumour at the level of the fourth and fifth lumbar and first sacral roots, chiefly on the right side, was made and operation advised.

The operation had to be considerably delayed until the skin of the back could be got into a more healthy condition, which was a matter of some difficulty.

OPERATION.

On October 15th, 1912, Mr. C. A. Morton removed the aminae of the eleventh and twelfth dorsal and the first and second lumbar vertebrae. When the dura mater was thus exposed it was seen to be pushed backwards, and on splitting it up the cord was found also pushed backwards, so that it lay closely pressed against the dura mater sheath, and the latter had to be divided with great care, so as not to cut into the underlying cord. When the lumbar enlargement of the cord was exposed, it was seen to be not only pushed backwards, but also much flattened and spread out, on a plum-coloured, smooth tumour lying anterior to it and chiefly to the right side. There was a free escape of cerebro-spinal fluid as soon as the dura mater was exposed. The growth lay opposite the body of the twelfth dorsal vertebra; it was about an inch in length, and seemed to fill the anterior part of the spinal canal. By means of the flat end of a small probe some very delicate connexions of fine membrane between the front of the cord and the tumour were broken down, and the cord was then lifted off the tumour, and gently drawn to one side. Some very loose connexions of the tumour with the dura mater sheath in front were then easily torn through with the probe, and the tumour readily enucleated. It was not necessary to divide any nerve roots in order to remove the tumour, as in this part of the cord they all pass obliquely downwards, and those underlying the tumour were turned aside with the cord. The tumour was very soft, of a pink colour, and about the size of the part distal to the last joint in an average-sized middle finger. After its removal the cord fell back into the canal. The dura mater was closed with a continuous suture of fine silk. This prevented any leakage of cerebro-spinal fluid, which was evidently distending the sewn-up sheath at the completion of the suturing. There was practically no bleeding within the spinal canal. The mass of muscle and aponeurosis reflected from the laminae, before these were removed, was brought together over the gap in the spine. No drain was employed. She did not suffer from shock.

The muscles united firmly across the gap in the spine, and the skin wound was soundly healed a fortnight after the operation. There were no signs of any inflammatory changes in the spinal membranes during the healing of the wound.

Nature of Growth.

Microscopical examination of the growth showed it to be a soft fibroma. No other tumour could be found, and its large size accounted for the wide extent of the symptoms, and its situation, chiefly anterior to the cord, for their roughly symmetrical character.

AFTER-HISTORY.

She made a good and uneventful recovery from the operation.

On October 23rd, she had recovered power over the bladder, could move the left leg and toes, and flex the right knee. She could feel a light touch over both thighs and legs, but imperfectly over the calf of the leg, and not at all over the feet, and a pin-prick over the right leg, but not over the left. The right ankle clonus was still present, and a flexor plantar reflex was present on each side. At the end of another week there was further gain of power, especially in the left leg. She looked well, and had greatly improved in appearance, although she still complained of much pain. She had no more morphine after this time. She insisted on going home—a journey of 35 miles—early in November. Her friends found it, however, impossible to nurse her at home, so she returned to the hospital on November 18th.

Two months after operation the condition of sensation was: Pain (pin-prick) felt over whole posterior surface of both buttocks, thighs, and legs, but defective, often felt as touch only, over front of thighs, legs, and dorsum of right foot; normal over dorsum of left foot. Sensation to light touch (cotton-wool) defective over areas shown in Fig. 2; localization was defective over right leg and foot; pressure was felt everywhere, but distinctly unpleasant on right leg and thigh. This defect of sensation in the areas of the third lumbar and increased loss in those of the fourth lumbar roots on the right side had appeared since the operation, and probably represented a slight but unavoidable bruising of these roots in holding them aside in order to deliver the tumour from under the cord. To the same cause is to be attributed a decrease of the right knee-jerk, and almost complete loss of response of the right quadriceps extensor to both faradic and constant currents after the operation.

By this time she had regained power over her bladder, and could hold her water for several hours; the unhealthy condition of the skin had entirely disappeared, and the feet and legs no longer felt cold.

Without going into details, the further history of the case was one of steady but slow recovery of sensation and

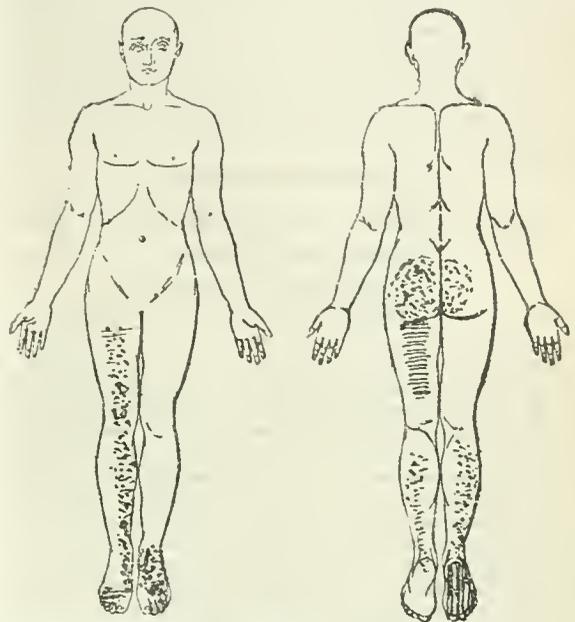

Fig. 2.—November 28th. Tactile sensation (cotton-wool): Dotted area, defective; \equiv absent; \times hyperaesthesia to cotton-wool.

of muscular power. Recovery was much more rapid in the left than in the right leg, owing to the more extensive damage done by the pressure of the tumour to the spinal cord and roots on this side.

She made up her mind to go home again early in January, 1913, and left the hospital on January 14th, three months after operation. Her condition then was that she could sit up in bed and in a chair quite well, and had recovered power in the left leg; lying in bed, she could raise it in the air and move it freely in all directions; she was not able to stand alone, but with help she could almost support her weight on the left leg. The wasted muscles had filled up very much, and reacted normally to faradic and constant currents.

Right leg: Recovery in this limb had not proceeded so far; there was still foot-drop; she could move the toes and flex and extend the foot; there was feeble flexion of the knee and hip, but this was all. The muscles of this limb were still much wasted and many of them tender; they only reacted feebly to a very strong faradic current; they reacted to a constant current of 8 to 10 milliamperes. ACC = KCC, with the exception of the quadriceps extensor, which hardly reacted at all. The knee-jerk was present; ankle clonus still continued to be marked. The reflexes in the left leg were normal.

Sensation to touch and pain had returned over the sacral region and over the whole of the left lower extremity, but over the right, although improved, was still somewhat defective; and over the back of the right

thigh and leg a touch was disagreeable (protopathic sensation); sensation to heat and cold normal except over the front of the right thigh.

Dr. Bird reports that on March 25th—five months after operation—sensation over both legs is normal, the left leg has recovered, and she can support her full weight upon it; there is still right foot-drop, but she can move the right foot and toes, and can extend the right knee, so that steady recovery is proceeding in this limb also. She can sit up, and has not had any morphine.

The history of the case with the severe root pains increased by moving the limbs, the muscular wasting, the reaction of degeneration in the muscles, the distribution of tingling, and loss of sensation—the latter so far as could be made out of posterior root type—in certain root areas together with slight affection of the bladder, pointed to a lesion chiefly on the right side and affecting certain roots of the cauda equina high up. There was one symptom, however, which definitely indicated that the spinal cord was also involved from pressure, and not only aided in the diagnosis of the side of the tumour, although this was clear enough from the predominance of sensory and motor troubles in the right leg, but also of the main position of the tumour as above the origin of the first sacral root and below that of the third lumbar, and that was the persistent and very marked ankle clonus on the right side in presence of an active right knee-jerk. The slower recovery in the right leg is due to the more severe damage to the roots on this side, which must take a considerable time to recover, though it is to be anticipated that she will regain the use of this leg in from eight to twelve months from operation.

CLASSIFICATION OF TUMOURS OF THE PITUITARY BODY.

By GERHARDT v. BONIN.

(From the Laboratory, Royal College of Surgeons, England.)

WHEN I was engaged in work upon a recent case of acromegaly¹ I was constantly met by a practical difficulty due to the absence of a generally accepted or standard nomenclature of pituitary tumours. It has therefore occurred to me that a useful purpose might be served by suggesting a new scheme of classification that would be easy of application and might recommend itself for general adoption, because it is based on the principle of histogenesis, and thus takes into consideration the physiology of the tumours; for epithelial tumours, even when malignant, lead to hyperpituitarism, whereas tumours developed from the stroma will destroy the glandular tissue and thus lead to hypopituitarism.

The following scheme differs in some important respects from that published by Roussy and Clunet,² and it is hoped that for the reason above explained it will afford a still better basis of classification.

I. Heterotopic Tumours.

1. Tumours of the cranio-pharyngeal duct.
2. Teratomata.

II. Homotopic Tumours.

1. Epithelial tumours:

- | | | |
|--------------------------|--|--|
| (a) From anterior lobe | (Chromophile Chromophobe Combined) | Cubic cell adenoma. Round cell adenoma. |
| (b) From pars intermedia | | Carcinoma. |

2. Tumours developed from connective tissue:

- | | |
|--|----------------------|
| (a) From anterior lobe and pars intermedia | Fibroma. Sarcoma. |
| (b) From posterior lobe | ... Glioma. |

3. Mixed tumours

| | | |
|-----|-----|----------------|
| ... | ... | Fibro-adenoma. |
|-----|-----|----------------|

1. The group of heterotopic tumours comprises those which develop from a tissue normally not present in the pituitary.

1. Tumours of the cranio-pharyngeal duct were first recognized as such by Erdheim³ eight years ago. They arise from *Anlagen* of the epithelium of the duct which are frequently met with in normal pituitaries and which have been developed from the ectoderm of the buccal cavity. They consist of squamous epithelium, often

containing *Schichtungskugeln*. They occur in the infundibulum or in the pars anterior of the hypophysis and are either benign or malignant. Erdheim collected a number of cases from the published literature which were described under different names, some of them as adenomas, but which really belonged to the category of tumours of the cranio-pharyngeal duct.

2. Teratomata in the pituitary are rare, but great importance has been attached to them by some authors, especially by Marburg.⁴

II. Homotopic tumours arise from a tissue normally present in the gland.

1 (a) According to Courtellemont⁵ the following features are characteristic of the epithelial tumours of the anterior lobe:

1. A tendency towards the development of a single cellular type.
2. Rarefaction or entire disappearance of interlobular connective tissue.
3. Diminished disposition of the cells to arrange themselves in acini.

The first characteristic holds good for most pituitary tumours, although it is to be remembered that some cases have been described in which both kinds of cells were present in the new growth.

Three types of glandular tumours can be distinguished: Chromophile, chromophobe, and combined; each type may deviate more or less from the normal structure of the gland—that is, it may be more or less degenerated. Adenomas with cubical cells approximate most closely to the original glandular structure, so closely, indeed, that some authors designate them as struma of the hypophysis. The cells are still arranged in acini, which, however, are larger and more irregularly disposed, and contain less connective tissue than is the case in the normal gland.

If these tumours begin to degenerate the glandular structure is almost completely lost, and the cells are grouped round the blood vessels, which are mostly sinusoidal capillaries. The specific cells are slightly smaller than the cells of the adenoma. At the same time they assume a round shape. Hence these tumours are described in the scheme as round cell adenomas. Clinically these tumours, should be regarded as benignant. Malignant tumours seem to have the same histological appearance; they can only be distinguished by their behaviour in forming metastases. The germs from which such metastatic tumours arise are carried not only by the blood stream, but also by the cerebro-spinal fluid. Malignant tumours of the pituitary are, however, extremely rare. If the histological examination of an extirpated tumour reveals a tumour possessing the features just described, it will in the vast majority of cases be a round cell adenoma, which permits a good prognosis.⁶

(b) Tumours of the pars intermedia appear to be rare. These tumours described as glandular tumours of the posterior lobe seem really to have developed from the pars intermedia, the cells of which normally show a tendency to proliferate into the pars nervosa.

2. The tumours developed from connective tissues in the pituitary exhibit the same feature as those formed in other parts of the body.

3. The term "fibro-adenoma" is proposed for the mixed tumours first described by Zak,⁷ in which the stroma, instead of being rarefied, has undergone considerable increase. These tumours are said to be a sign of diminished glandular function; they have never been found to be associated with acromegaly, but only with degeneratio adiposo-genitalis.

Wissensch., Wien., Bd. 113, Abt. 3, 1904. ⁴ Marburg, *Wien. Klin. Woch.*, 1907, p. 2514. ⁵ Courtellemont, *Revue neurologique*, 1911, v. Eisselsberg, *Arch. f. Klin. Chir.*, Bd. 100, 1908, p. 1. ⁶ Zak, *Wien. Klin. Rund.*, 1904.

⁷ These "round cell adenomas" are often very similar to sarcomas, so that the differential diagnosis can be extremely difficult. Sarcomas, however, are very rare; most sarcomas of the literature are really adenomas. Von Eisselsberg⁶ has recently published his cases of pituitary tumours; in his paper will be found some instructive illustrations of the histological appearance of these tumours.

THE estate of the late Dr. Henry William Cross of Whitely has been declared at a net value of £17,993. Dr. Cross, who became M.D. Durh. in 1886, was formerly in practice at Newcastle.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

WESTMINSTER HOSPITAL.

A CASE OF CAESAREAN SECTION UNDER SPINAL ANAESTHESIA.
(Reported by KAYE F. RASHELL DAVISON, Resident
Obstetric Officer.)

The patient in the following case—a primipara, aged 26—was admitted to the medical wards on December 27th, 1912.

She had had two attacks of rheumatic fever—the first at 10 years of age, the second five years later—and had developed valvular lesions of the heart—namely, double mitral and double aortic. The heart was much enlarged, and she was slightly cyanosed and dyspnoeic, but there was no oedema of the legs or elsewhere.

In view of the condition of her heart and the fact that she was eight and a half months pregnant (last menses May 16th, 1912), and a primipara, Dr. Purves Stewart, in whose ward she was, advised her to avoid the strain of labour by undergoing the operation of Caesarean section after the administration of a spinal anaesthetic. To this she consented, and the operation was performed on February 8th, 1913, by Dr. Drummond Robinson. He was assisted by Dr. Stanley Dodd, while the spinal anaesthetic was administered by Dr. Purves Stewart himself. Three-quarters of an hour before he introduced the anaesthetic the contents of one capsule of embonoposcopolamine were injected subcutaneously. The spinal injection consisted of a solution containing 10 cg. of stovaine and 0.0075 mg. of strychnine hydrochloride. It was introduced between the twelfth dorsal and first lumbar vertebrae. For the next ten minutes the patient remained lying in the supine position, and was then found to have total anaesthesia and analgesia below a horizontal line drawn 2 in. beneath the nipples; the operation was then commenced.

Operation.

A median vertical incision, only 5 in. in length, was made below the umbilicus through the linea alba, and the peritoneum opened. The whole of the anterior wall of the uterus was then visible, after retracting the upper angle of the incision, and this was made especially easy by the completely relaxed condition of the abdominal wall. A median vertical incision about 5 in. in length was made through the anterior uterine wall, and the placenta was then found to be attached to this wall; it was therefore separated digitally and the child delivered by its legs. After delivering the placenta and membranes, the cervix was dilated from above by passing the hand into the uterine cavity. At this point 20 minims of liquor ergotini were injected hypodermically. The uterus, after the application of hot towels, retracted well, and was then closed by a double row of silk sutures. The patient was then sterilized by the excision of the interstitial portion of each Fallopian tube. At this stage the pulse became irregular and weak, and a hypodermic injection of 5 minims of liq. strych. hydrochlor. was administered with the desired effect. The abdominal wound was then closed in its several layers. Throughout the operation there was only slight haemorrhage.

The child, a male weighing 6½ lb., was fully formed and well developed. There was no respiratory embarrassment.

Remarks.

The patient behaved admirably throughout. For a few seconds only after the injection of stovaine she complained of subjective sensations of "pins and needles" in her feet and legs, which were attributed by Dr. Stewart to transient stimulation of the nerve roots. After this she felt absolutely nothing during the operation, and conversed freely with the persons present. She felt thirsty, and was given small quantities of water to drink.

The operation lasted thirty minutes, and two hours after the time at which the spinal injection had been given the patient was able to move her legs; sensation and complete motor power then rapidly returned. She has since made a complete recovery; the wound is perfectly healed, her heart is beating regularly at almost a normal rate, she is on a full diet, and she is able to nurse her baby.

Note by Dr. Drummond Robinson.

In this case I was struck by (1) the extreme relaxation of the abdominal wall, which allowed the uterus to be dealt with through a small incision; (2) the excellent general condition at the end of the operation.

ROYAL SOCIETY OF MEDICINE.

RESUMED DEBATE ON ALIMENTARY TOXAEMIA.

April 21st and 28th, 1913.

Sir FRANCIS CHAMPNEYS, President, in the Chair.

Nature of Adhesions: Short Circuiting.

Mr. P. LOCKHART MUMFERY remarked that even a small delay in the passage of intestinal contents caused symptoms of toxæmia, and in long-standing cases the liver became so damaged that it allowed poisons to pass through into the blood. Mr. Lane, he thought, attributed too much to the action of gravity. The lesions found were seldom inflammatory, but mostly owed their origin to chronic constipation and overloading of the bowel in early life. He did not think Mr. Lane's theory was correct with regard to the formation of adhesions. They were often not adhesions, but folds of normal peritoneum. They were not mere thickenings in the normal peritoneum but double folds of its membrane. Apart from this, Mr. Lane seemed to disprove his own case by admitting that these bands were found in young children, in whom the forces to which he attributed their origin had not begun to act. The symptoms due to the presence of poisonous material in the alimentary canal could be remedied in three ways: (1) By preventing the formation of poisonous material in the tract; (2) by preventing its absorption; (3) by removing that portion of the tract in which the toxin was formed. The first of these could often be carried out by alterations of diet. The second result could only be secured by preventing the material remaining in the tract long enough to form a toxin. But the occurrence of stasis was not necessary for the production of toxæmia. Conversely, there were many instances of severe stasis in which no toxæmia occurred; this was best seen in congenital dilatation of the colon, where the patient's bowels acted only a few times a year. Yet he had not seen one such case which suffered from toxæmia. Sometimes stasis could be remedied by washing out through an appendicostomy opening, or by short-circuiting the large bowel. Some of the most important conditions were those associated with joint lesions. Some cases of crippling arthritis were due to poisons formed in the large bowel, and in such cases lipping of cartilages and a tendency to the destruction of the joint might be observed. By early operation in these cases it seemed that the joint condition could be prevented. The operation chosen should depend on the cause of the stasis in the particular case, and every effort should be made to arrive at a correct diagnosis. He had found the sigmoidoscope of the utmost value in diagnosis, and much information was also obtained by giving a bismuth meal and taking an *x*-ray picture. Examination of the stools was often misleading, and was seldom of much value. Short-circuiting should be reserved for cases in which appendicostomy failed to give relief. His objection to a short-circuiting operation was that it left the large bowel blind at one end. He had never seen a case in which he considered colectomy justifiable, except where the patient was so ill as to negative that operation. His experience of short-circuiting had been disappointing, as in several cases it had failed to produce complete cure. He had noticed acetonaemia more often in cases of the nature now under discussion than in those where alimentary toxæmia was not present. He had had three such cases during the last year, and one of them was fatal. It was advisable to administer dextrose in all such cases before operation. The after-treatment he regarded as of great importance. Care was required during convalescence, especially as the patients were usually neurasthenic and had lost confidence in themselves. Attention should be devoted to them for three months, or even longer if their normal health was not re-established. Sometimes great benefit followed cutting off nitrogenous food for a time.

Anatomical Consequences of the Erect Posture.

Professo ARTHUR KEITH dealt first with the formation of peritoneal adhesions, a matter which, he said, was

receiving a great deal of attention from anatomists; it brought under consideration one of the most striking of all the developmental changes seen during the growth of the fetus. Man came of a stock in which the mesentery and bowel were originally arranged in a primitive and simple manner, for in the second month of development the human intestine and its mesentery had the lineal arrangement seen in the lowest mammals. During the third, fourth, and fifth months of fetal life a profuse adhesive process set in—a regulated embryological peritonitis—which led to the cohesion of mesenteries and viscera to the posterior wall of the abdomen, an adaptation, as was supposed, to the upright posture, for it was only in upright forms that these adhesive changes took place. After the fifth month the process of adhesion proceeded more slowly, and was completed about the time a child learnt to walk. The extent of the process was extremely variable, as might readily be seen by consulting recent papers by Dr. Douglas Reid, the monograph by Drs. Henry M. W. Gray and W. Anderson, or the fine treatise on the appendix by Kelly and Hurdon. In about one newly-born child out of every ten the process of adhesion bound the mesentery of the lower part of the ileum to the pelvic fossa, giving the condition associated with ileal kinking. The extent to which adhesions were produced between the caecum and ascending colon varied, but a condition which gave rise to a "Jacksonian membrane" was not rare; wide adhesions at the region of the hepatic and splenic flexures were always present. All these adhesions were parts of a normal embryological and useful process, but all peritoneal adhesions in the ileo-caecal region were not embryological and normal. Occasionally there was in adult bodies a degree of adhesion never seen in the child at birth, and anatomists recognized that some of the adhesions were the result of pathological processes. The majority of the adhesions, often regarded as pathological, were in reality mere expressions of a normal and healthy fetal process. Anatomists had recognized that ptosis, or dropping of the viscera, was frequently to be observed before they became aware that Glénard had scheduled visceroptosis as a distinct pathological entity, and long before the clinicians were convinced of the frequency and the importance of the condition. The discovery of Roentgen placed a new means of inquiry in the hands of anatomists. A study of the living diaphragm convinced anatomists that the essential feature of the abdominal viscera was not their fixity but their mobility; they were so attached that they could move freely with the respiratory tide. It became apparent that mesenteries and visceral ligaments only came into action when the limits of normal movement were reached; the musculature of the abdominal wall was the essential mechanism for supporting the viscera. The pathology of visceroptosis was therefore to be sought in a better understanding of the nerve relationships between the viscera and their supporting walls. The researches of Sherrington, Hill, Mackenzie, Elliott, and many others showed how closely the tone and contraction of the abdominal parietes were related to the posture of the body and to the condition of the viscera. The problem of how the tone and contraction of the musculature of the body wall and of the alimentary canal are co-ordinated had not yet been solved, but the evidence led to the suspicion that they were regulated by a common nerve mechanism and that this mechanism could be acted on and deranged by pathological products generated in the intestine, so that visceroptosis was one of the manifestations of alimentary toxæmia. The essential question in the discussion was, What is the functional value of the human great intestine? At the beginning of the present century a sharp divergence of opinion set in. In the years 1902 and 1903 three men—an anatomist (Barelay Smith), a bacteriologist (Metchnikoff), and a surgeon (Arbuthnot Lane)—came independently and by a different train of reasoning to the same conclusion, which was that, so far as man is concerned, the great intestine is not only a useless but a pernicious structure. It was a very significant fact that in Paris, London, and Berlin, the position of the great intestine should have forced itself on the attention of thoughtful medical men at the same date. To anatomists, who knew that the great intestine was an intrinsic part of every air-breathing vertebrate, that it reached a high

degree of development and specialization in every mammal that included a vegetable element in its diet, that in all the animals immediately allied to man—his contemporaries and his very ancient predecessors—the great intestine was shaped, arranged, and developed as in him, the conclusion that the human great bowel was a useless structure seemed a flat contradiction of every law applicable to the animal body. What suggested itself was, not that the organization of the great intestine had failed, but that the modern dietary set it a task for which it was not adapted. Examination of the evidence on which the useless and pernicious nature of the great bowel was based was twofold. The great bowel could be excised and health maintained, which proved that it was not an essential structure. If diseased, excision might lead to improved health, which proved that to have no colon was better than having a diseased colon. What must be proved, however, before the colon could be regarded as a useless structure was that a man without a colon was in a better state than the man with a healthy colon. Knowledge of the function of the great bowel in the economy of the animal body was vague. Remembering the history of the progress of medicine, it would be rash to presume that, because the use of the colon was not known, it had no function, and was a useless structure. Every year saw some structural part formerly placed with the useless or vestigial structures removed from that list. Only a few years ago, Pavlov and Starling demonstrated the elaborate mechanism which controls the exit of the contents from the stomach to the duodenum. By their investigations Professor Keith had been led to look for a similar mechanism at the junction of the ileum and colon. Elliott had demonstrated that such a mechanism existed at the time he was carrying out research on the movements of the great intestine. Professor Keith felt certain that Dr. Hertz was right in attributing the effects (which Mr. Arbuthnot Lane ascribed to a kinking at the terminal part of the ileum) to a derangement of the ileo-caecal sphincteric mechanism. Every step forwards in knowledge cut the ground from under those who took a purely mechanical view of the action of the great intestine. He felt justified by the evidence he had accumulated lately in supposing that the mechanism for regulating the passage of food from the ileum to the caecum of man was more elaborate than had been supposed. Besides the muscular fibres situated directly at the ileo-caecal orifice and evidently designed to secure that orifice against reflux from the caecum, there was another for regulating, as Dr. Hertz suggested, the passage of the contents of the ileum to the caecum. The musculature of the terminal part of the ileum for an extent of nearly 4 in. (roughly 10 cm.) above the ileo-caecal junction was endowed with a special tonic function, and served as a sphincter for the terminal part of the ileum. Every diseased colon removed by operation should be systematically and minutely investigated. Professor J. W. Smith, of Manchester, had recently had results affording him an opportunity of examining a very complete specimen removed by operation. There was mucous colitis throughout the whole of that part of the great intestine which was excised, with abundance of intestinal sand scattered along the lumen. A typical ileal kink was present 4 in. above the ileo-caecal orifice. The musculature of that part of the ileum was strongly contracted. The terminal 4 in. of ileum was bound down to the pelvic fossa by a peritoneal adhesion exactly similar to that seen in a proportion of normal newly-born children. There was nothing in the nature of the iliac adhesion to suggest that it differed in origin and nature from the natural bond seen so often in children.

Chronic Intestinal Stasis.

Mr. GEORGE ROWELL said that no one who had seen Dr. C. Mayo's photographs of the ileal kink would doubt the existence of the characteristic band; he had seen it demonstrated to the onlookers at operations scores of times in the most unmistakable manner and had seen also the fastened up appendix, crossing and obstructing the end of the ileum, similarly demonstrated on numerous occasions. Whether the new structures causing these two forms of abnormality were of inflammatory origin or not did not affect reference

to the results produced. In both cases there was a fixed point, and it was obvious that the sagging of the bowel in the vertical position of the trunk must in each case cause some obstruction. Long lengths of intestine were frequently drawn up out of the pelvis in these operations, of which the only fixed attachment was this point, and cases exhibiting these structures displayed in a definite manner the symptoms described by Mr. Lane as those of chronic intestinal stasis. He had seen the bands developed in connexion with the duodenum and the sigmoid demonstrated many times in the clearest possible manner, and had constantly seen the duodenum dilated, sometimes very dilated, in these cases. In operations undertaken for duodenal ulcer he had several times seen ileal obstruction found. The adhesions described at the splenic and hepatic flexures and those supporting the stomach were also quite familiar to onlookers at Mr. Lane's operations. Most of the operations for the relief of chronic intestinal stasis at which he had been present during the last few years had previously been examined by the x rays and reported upon by Dr. Jordan. Nearly always the report had predicted accurately the condition found. The precision with which, when assisted by the x rays, the exact causation and degree of stasis could be diagnosed before operation was indeed most striking. The x rays sometimes showed less than was found at operation; a kink was occasionally missed, but he had never seen a dilated duodenum diagnosed by the use of the x rays that could not be demonstrated at the operation. In patients in whom pain had persisted after the appendix had been removed he had seen the ileal band divided and immediate relief result, although it was realized that the relief might not be permanent without a short-circuiting. It was no doubt difficult to understand how, as was claimed, the general effects of chronic intestinal stasis could include the impairment of every tissue. For example, if it were true that a connexion existed with thyroid enlargement, it followed that the relief of stasis ought to diminish the size of the thyroid. In addition to the case related in Mr. Lane's introduction, Mr. Rowell had on two occasions seen an enlarged thyroid diminish very rapidly after short-circuiting. Dr. Hale White had adduced a case of exophthalmic goitre which disappeared during an attack of typhoid. The rest in bed, the milk diet, and the diarrhoea during the illness obviously must have kept the patient without stasis for some weeks, so that instead of affording an argument against the theory that exophthalmic goitre was associated with chronic intestinal stasis, the case would seem to be in perfect accord with that belief. The cure of duodenal ulcer by rest in bed had a similar significance. Symptoms of long-standing chronic intestinal stasis were often demonstrated in cases of cancer of the breast, and repeatedly in cases of cancer of the bowel. In disease of the gall bladder and of the pancreas the ileal kink was clearly shown. In pyorrhoea, a condition held by Mr. Lane to be a result of chronic intestinal stasis though probably he would not deny the possibility of direct infection, as for example from pet dogs, complete cure might follow the use of vaccines or scrupulous local treatment, but in many cases the cure was much aided by paraffin internally.

Bacteriology.

Dr. LANGDON BROWN said that toxæmia only resulted when either (1) abnormal intestinal flora became established which produced specific toxic substances, or (2) the normal flora acquired an abnormal habitat. He had a young man now under care in whom the rhinitis with offensive exudate from which he suffered was due to *B. coli*. The reason for the comparative failure of the phenol compounds as intestinal antiseptics was that by combining with the sulphates they deprived the body of the power of rendering harmless those putrefactive substances the formation of which they could not altogether prevent. Sulphates in the treatment of intestinal diseases had not only an aperient but also an antitoxic action. Mr. Mackenzie Wallis had recently pointed out how unstable a substance indican was, making it necessary to examine for it as soon as the urine was passed. The association of paroxysmal hæmatoporphyrinuria with an intestinal toxæmia was practically certain. The simple chemical poisons of the body did not stimulate the production of antibodies; they were neutralized by

substances normally present. When pyorrhoea, which played an important part in the production of atonic dilatation of the stomach, was cured the rapidity with which the stomach might regain its tone was remarkable.

Mr. PETER DANIEL thought that in seeking for the cause of a toxæmic state intrauterine conditions were too frequently overlooked. And a toxic upbringing of the fetus was likewise very important. He did not agree that visceroploosis was the result of civilization, or that the erect posture was the cause of intestinal stasis. Intestinal toxæmia was due not to stasis but to the presence of harmful microbes. He dwelt on the importance of pyorrhoea and gingivitis.

Mr. K. W. GOADBY, in a careful consideration of the subject from the bacteriological point of view, reported that in a series of 150 consecutive and unselected cases of suppuration of the alveolar process of the jaws, 24 per cent. had no general symptoms, notwithstanding the constant swallowing of pus for at least two years; 42 per cent. had gastrointestinal affection, 56 per cent. had rheumatic and joint symptoms. In none of the 150 cases was gastritis an acute symptom. The main symptoms pointed to affection of the large bowel. The essential pathological change in pyorrhoea alveolaris was rarefying osteitis of the alveolar process, as well as of the body of the bone; hence the drastic removal of teeth advocated by dentists did not always get at the root of the matter. The treatment should be both local and general.

Results of Operation.

Mr. EDRED CORNER said that a certain amount of alimentary toxæmia was physiological and natural. Certain patients who had had colectomy or short-circuiting done, with or without appendicostomy, had been greatly improved, and he did not think the improvement could have been attained in any other way. Patients who had found life a burden for ten years had, after that operation, become rejuvenated to a remarkable degree. But as some cases so treated did not show that improvement, the point was to choose the right sort of case. The procedure was to make the alimentary tract only one of a number of excretory systems; the skin, kidneys, and lungs were others, and where the operation failed it was probably because one of the other systems was at fault. The terms "alimentary stasis" and "alimentary toxæmia" should not be used more or less synonymously. Some people with intestinal stasis yet enjoyed good health.

Mr. C. H. FAGGE was a strong supporter of the views of Mr. Arbuthnot Lane, because he had had the opportunity of observing his work. In nearly every case of his own he had received definite and reliable evidence from the skiagrams taken and interpreted by Dr. Jordan. He noted with satisfaction the shifting of view of a large number in the profession from harsh antagonism and denial of the occurrence of these bands to criticism of method of their production, and to objection to Mr. Lane's view that any symptoms could occur therefrom. He dealt in detail with the operative aspect, expressing the view that caeco-pleiation was not sound.

Mr. CARSON said there were two conditions the cure of which almost depended upon the correction of intestinal toxæmia—these were parenchymatous goitre, to which Major McCarrison had drawn attention, and chronic or sub-acute mastitis. Delay in the passage of intestinal contents caused increased bacterial activity and absorption of toxins. First, constipation occurred, the amount of contents maintained in the erect posture for sixteen hours a day produced a great strain on the caecum and ascending colon, causing sometimes prolapse of the caecum. Nature's effort to overcome this led to the formation of bands, passing from the parietal peritoneum on the outer side of the ascending colon, downwards and inwards, to be attached to the colon on its anterior surface. A similar band was often seen at the beginning of the sigmoid flexure. These bands he regarded as protective in the first instance, and not inflammatory. The kind of operation done must depend on the condition found on opening the abdomen. Whatever operation was chosen, medical treatment should be continued for at least six months.

Mr. E. C. HUGHES dealt with the question of the origin of the bands, and expressed his agreement with Mr. Lane's views. The band in connexion with the small intestine

was responsible for the ileal kink. The upright attitude was followed by important changes in the position of the appendix, and in adults it was his experience to meet with an appendix abnormally situated more often than not. He had seen cases of Still's disease and of rheumatoid arthritis in which the relief from operation had been marvellous.

Oral Sepsis and Pernicious Anaemia.

Dr. WILLIAM HUNTER, after observing that alimentary processes began in the mouth, were continued in the stomach and intestine, extended to the portal blood, and might be said to end in the liver, said that of toxæmic blood conditions commonly met with the most mysterious and severe was associated with oral sepsis; he had been led to look from disturbances of the stomach and intestines back to infective lesions in the mucosa, which were an invariable accompaniment. He showed, by means of the epidiascope, specimens of disease in various viscera, as well as a most instructive set of crowns and plates of teeth used in conservative dentistry which proved to be prolific culture-beds for bacteria. The portal blood was always toxic, even in health; the causes might be classified as: (1) non-infective; (2) infective. The first embraced the various products of digestion formed by the ferments of the salivary, gastric, pancreatic, and intestinal digestion. The second were those caused by the *coli* group of organisms. Nature's provision against harm produced by the latter was, first, the daily removal of the mass of excrement, and secondly, the provision of protective mucus lining the whole gastro-intestinal tract, and of protective muscular movements which kept the gastro-intestinal contents in more or less continuous movement. Dr. Hunter discussed the uses of the other flora of the intestine, especially the lactic acid group, which were the most beneficial and least harmful. The streptococcal group played an important part in disease, especially in diarrhoea, congestion, inflammation, and ulceration. Pernicious anaemia was due to the haemolytic infective organism. Oral sepsis was a double-handled weapon of offence in relation to the blood, and the effect of removal of the offending mouth trouble on the general health was like magic.

Selection of Cases for Operation.

Sir BERRAND DAWSON said that although the terms "alimentary toxæmia" and "intestinal stasis" were open to criticism, they conveyed a definite clinical picture—the sallow, dirty complexion, the inelastic skin, the dusky lips and nails, the dirty tongue, evil-smelling breath, constant abdominal discomfort of one kind and another, the doughy inelastic abdomen, cold extremities, the physical and mental depression. That such a condition could be produced by colon block and stasis was clear, and that, when thus produced, it was curable by putting the colon out of action by short-circuiting was demonstrable. He thought, however, that Mr. Lane gave too great prominence to motor defects. Mechanical delay was not a necessary condition of alimentary toxæmia. It might equally be caused by chronic infection of the gums, stomach, or appendix. Some of the most marked cases of alimentary toxæmia he had seen had been associated with diarrhoea and an empty colon. Bad cases of stasis were benefited by operation, not only because short-circuiting removed the obstruction, but because the colon was diseased and had become an active influence for evil. The key to the condition might often be found in its early chapters. The sequence in time might be in one case infection-stasis, and in another stasis-infection. If an infection, it might begin in the gums, tonsil, or stomach, and finally manifest itself in the appendix or colon; or the order of the infection might be reversed. Acute infection of the stomach had been long recognized; but it was equally true that chronic infection, usually by a streptococcus, was a definite and fairly common cause of gastric disturbance. Sometimes such chronic infection existed alone; at other times in association with, say, disease of the appendix or colon. A study of appendix operations brought out well the infective and motor aspects of gastro-intestinal toxæmia. In one group of cases the appendix was not the seat of inflammation, but the caecum was distended

and toneless, perhaps tied down in the pelvis, and the ileum might be kinked. The prime cause of the trouble in such cases was mechanical; the small intestine could not empty, and toxæmia ensued. The efficient treatment was to cure the stasis; removal of the appendix alone was futile. In such a case the first event was motor failure of the colon; the later stages were infective or toxic, and might extend to the stomach or mouth. In another group a chronically inflamed appendix, containing muco-pus, was found, and as the result of its removal the patient was cured of colitis or gastritis, the tongue cleaned, the breath ceased to smell, and he became well. Here the prime cause was infective. If the appendix focus were not removed, the colitis might progress, and what had begun as an infection in the colon might pass on to motor failure, and everything which Mr. Lane described as intestinal stasis ensue. Colitis comprised conditions which were widely different. In one case the passing of mucus, and it might be of blood, went with obstruction of the colon, and, if the conditions were severe, the only cure would be to graft the ileum into the sigmoid. In another case colitis might be associated with an infection of the appendix, or was the final expression of an infective attack taking its origin in the throat, stomach, or upper intestine. It was not uncommon for a patient who passed mucus in the stools to have acute attacks, which commenced it might be with sore throat or gastric discomfort, and then passed in a few hours to pain in the colon and the passage of much mucus. All cases should be systematically investigated, both from the infective and the motor standpoint. It would not be sound reasoning to put down vague symptoms to intestinal stasis merely because there was objective evidence of colonic block. With some people a loaded colon was not incompatible with health. After the existence of toxæmia had been established, careful investigation was needed to show whether the prime cause was infective or obstructive. If obstructive, careful examination of the anus and rectum should be made. In many cases the obstruction of the colon was due to fibrotic sphincter ani; in other cases the simple operation of appendicostomy sufficed. In a large proportion of cases, however, systematic medical treatment, carried out with persistency, was followed by success. Such treatment comprised suitable diet, hydrotherapy, massage, exercises, petroleum oil, carefully regulated lavage, and other measures. The success of such treatment depended on careful regulation of every detail carried out in an institution, and no class of disease emphasized more the need of sanatorium treatment. The reason why the treatment of gastro-intestinal disease was sometimes more successful on the Continent than in England was that the treatment was more methodical and carried out in institutions which in this country were lacking. Finally, there remained cases in which the colon was hopelessly diseased, powerless to perform its functions, and in some way an active influence for evil; in these suitable cases, and by suitable hands, ileo-sigmoidostomy gave truly wonderful results, and was a great advance in treatment.

Chemical Problems.

Dr. MELLANBY confined his attention to the purely chemical aspect of the subject, laying special emphasis on the amines and the proteolytic ferments. A great impetus to the study from the physiological point of view of the process of intestinal absorption had been given by Starling, Bayliss, and Cow.

Electricity.

Dr. ETTIE SAYER spoke of the value of high-frequency currents in promoting excretion and reducing blood pressure. It was important to remember the heating effect of such currents on their passage through the body. She had encountered a number of cases of constipation and toxæmia which yielded to the high-frequency current when other measures had failed. Galvanic currents caused no muscular contraction except when switched on and off; their tension was too low to have any appreciable heating effect, but their ionizing action was a most useful stimulant of excretion. Where systemic toxæmia preponderated over the local symptoms, a combination of high frequency current and massage was excellent. For local patches of fibromyositis, ionization with lithium iodide gave great relief, and the electrical treatment acted

as a nerve sedative. Much care, however, was needed where there was any failure of ventricular compensation.

Dental Conditions.

Dr. SIM WALLACE laid great stress on the lodgement and proliferation of micro-organisms, and defective elimination or control of the toxins generated. Among the physiological processes which kept the mouth in a hygienic state, and prevented the ever-present bacteria from stagnating and so causing toxic effects, the action of tongue and teeth was most important; the former not only moved the bolus of food about, but subsequently cleaned the teeth and gums. No food residue should be permitted in the mouth after a meal. The coating of mucus over the teeth prevented harm to them from acid foods. Superseptic states, together with recession of the gum and extensive absorption of the alveolar process, could occur without the occurrence of pyorrhoea alveolaris. Tender teeth and gums should at once be put right, because function in their neighbourhood was inhibited, and inefficient action resulted. There was great harm in the retention of functionless superseptic teeth. He concluded by insisting on a very careful and systematic mouth ritual.

Cardiac Complications.

Dr. BEZLY THORNE recalled a paper he had read seventeen years ago on self-poisoning and heart disease. Therein he pointed out that many of the affections of the circulatory mechanism were associated with some catarrhal condition of the alimentary canal, especially the gastro-duodenal portion; and that coincidentally it was common to find evidences of rheumatoid arthritis. He, however, fully recognized the gravity of sepsis originating in the mouth, nares, and accessory cavities. Normal formed faecal matter could be retained several days with no result beyond discomfort. Fluid stools were due to interference with the bio-chemistry of digestion. Drab or yellowish stools, especially if fluid, were always toxic. Without a sufficient supply of the biliary and pancreatic juices the door was opened to morbid bacterial activity. The person with frequent watery stools was undergoing rectal feeding on his excremental poisons. This was accompanied by a rise of blood pressure, and conducted to a degenerative change in the myocardium, and especially of the tunica media of the arteries. It favoured also the production of fibrositis. He concluded by quoting illustrative cases in his own experience.

Other Complications.

Dr. ADAMSON said that the eruptions caused by various drugs, and by special foods such as shellfish, tinned meats, and certain poisons, were generally regarded as phenomena of anaphylaxis, or a hypersensitiveness to foreign proteids. That explained why a person who had once had such a poisoning remained hypersensitive to the food which caused it. Abdominal symptoms associated with erythema multiforme were probably due to the occurrence of the same lesions in the mucous membrane of the intestinal canal.

Dr. R. MURRAY LESLIE considered that in some cases the symptoms of alimentary toxæmia were aggravated by defective functional action of the liver, as shown by a patient of his own in whom indican and skatol, as well as urobilin, were found in the urine. More than one speaker had said that there was no necessary relation between the amount of stasis and the degree of toxæmia; there were marked idiosyncratic differences. Shortly before death, when the vital forces were at a very low ebb, the *B. coli*, streptococci, and other bacteria passed readily through the intestinal mucous membrane and so into the circulation, while their toxins, not being neutralized, accumulated in the circulating blood. The thyroid and other ductless glands played an important part in the vital resistance, and he believed the internal secretions of the genital glands also had an effect in counteracting the effects of alimentary toxæmia.

Mr. LEWIN PAYNE believed pyorrhoea alveolaris to be a curable disease, and that the number of cases cured without resorting to extraction was increasing. In advanced cases extraction was necessary, but carbohydrate dyspepsia was aggravated by removal of the

teeth. A combination of local treatment with the use of vaccines he had found of great benefit.

Dr. ACKERLEY approached the problem from the point of view of the spa physician, and pointed out that absolute control over only one part of the alimentary tract—namely, the mouth—could be obtained. He deplored the lack of teaching on the importance of complete insalivation of the food, especially to children; and he related how, by means of taking milk in various ways, he had demonstrated to his own satisfaction the importance of proper admixture of saliva with the food, which was best brought about by a sucking action. He also alluded to the harm done by merely swallowing pappy foods and the modern methods of preparation of foods which called for a minimum of masticatory effort.

Mr. S. F. ST. J. STEADMAN did not agree with Mr. Lane that pyorrhoea alveolaris was secondary to intestinal stasis. The work of Mr. J. F. Colyer and Mr. J. G. Turner showed that the chief factors causing disease of the tract were the lodgement and subsequent decomposition of the sticky carbohydrate food. He was in close agreement with Mr. Goadby's contentions, but he could not satisfy himself, as the result of a good deal of observation, that vaccines had any permanent benefit on the disease.

The discussion will be continued on Monday, May 5th.

SECTION OF MEDICINE.

At a meeting on April 22nd, Dr. FREDERICK TAYLOR, President, in the chair, Dr. H. LYON SMITH, in a paper on *Gout and chronic rheumatism*, pointed out that the infection was chronic and its nature must vary enormously; it was uncommon to find two cases presenting identical infections with identical symptoms. Probably the time was not far distant when the old clinical terms would be replaced by names which expressed more accurately the nature of the malady. He had not attempted to produce gout or chronic rheumatism by means of the organisms found in these cases. Fibrositis he regarded as inflammatory infiltration of the connective tissues. Bacteriological investigation showed that a closer relationship existed between gout and chronic rheumatism than clinicians usually thought. There were a number of lesions which served as foci of infection, such as pyorrhoea, chronic pharyngitis, post-nasal catarrh, bronchitis, gastro-intestinal catarrhs, urethritis, cystitis, pyelitis, vaginitis, and even some forms of dermatitis. Considerable divergence of opinion existed as to what constituted pyorrhoea alveolaris, some holding that it was not present unless pus could be extruded from between the teeth and the gums; but that was the advanced stage of the condition. Most of the cases of chronic rheumatism he had seen had a gum affection, and the infection of the joints was usually a mixed one. Frequent bacteriological examination of pathological exudates would often afford valuable clues to diagnosis and treatment. Dr. LUFF declared his belief that all cases of so-called rheumatoid arthritis were of infective origin, though not due to any one organism. So-called chronic rheumatism he regarded as fibrositis—that is, a hyperplasia of the white fibrous tissues in various parts of the body. There was no evidence that the causal microbes were in the joints, the affection of which was toxic, such toxin probably originating in the intestinal tract. Dr. McWALTER (Dublin) commented on the lack of success in the treatment of the conditions under consideration, though the profession had been studying the problem for hundreds of years. The uric acid hypothesis seemed to mark an advance, but Dr. Luff had declared that to be a harmless by-product of metabolism. Dr. T. R. LISTER, in a paper on *Treatment of ambulant cases of pulmonary phthisis* by T.R. and bacillary emulsion in the out-patient room, said there were disadvantages in the treatment of patients in these circumstances, partly due to the difficulties of the patients and partly to the intermittent observation. The practice had been to take the mouth temperature on first waking in the morning and one hour after tea. In the wards, with the patients under continuous observation, dosage could be spaced with more regard to positive and negative phases. There was even greater need for selection of cases for tuberculin treatment in the out-patient department than

for sanatorium treatment. Nutrition was, of course, an essential point. Many unfavourable results, he felt sure, were due to failure of nutrition. General physique had also to be taken into account, and the manner in which the organism withstood the infection. There must be a great number of cases of the disease which simply got well. A theory had been advanced that nine-tenths of the population recovered from infection by tubercle owing to the general infection and possible immunization consequent thereon. Each case must be decided by itself in regard to suitability for the treatment and prognosis. The adverse factors were poor physique, extreme poverty, bad family history, rapid pulse, and severe anaemia. Cases which had a primrose tint of the soft palate, with general anaemia of the buccal mucous membrane, generally did not do well. He usually began with 0.00001 to 0.00002 mg. of T.R.; this was experimental. Patients were instructed to carefully register their temperature during the first two or three days, and to report on their feelings. He usually injected on Friday afternoons, so that any reaction would be manifest on the Sunday and they would be able to rest. If there had been no evidence of undue susceptibility the dose was increased to 0.00004 to 0.00005 mg., subsequently mounting to 0.0001 mg. He protested strongly against the present indiscriminate use of tuberculin, especially as it was a toxin, not an antitoxin. He was not able to say when treatment should be discontinued. He had taken no out-patients up beyond 2 mg. of bacillary emulsion. The patient should come up at intervals of one or two months to repeat the dose. He described the technique he followed, and concluded by saying that his present attitude towards tuberculin in cases of ambulant phthisis was one of investigation rather than of conviction. Dr. McWALTER spoke of the results following the use of tuberculin in phthisis in a pessimistic tone; indeed, he regarded the treatment of tuberculosis as one of the most hopeless things in medicine. There was a danger of being misled by some of the tuberculin statistics which were put forward. He thought much of the supposed reduction in the death-rate of phthisis was due to the disease sharing in the benefits ensuing on the improved conditions of living. Dr. FENTON thought it difficult to assess the effect of a remedy when cases were selected, and he had treated with tuberculin all his cases in which tubercle bacilli were found in the sputum. The net result was to leave him in grave doubt as to what was the real value of tuberculin in the condition. In the case of out-patients much depended on the patients' home circumstances, and the kind and quantity of food they could get. Dr. BATTY SHAW recommended a study of the published records of the efforts to stamp out tuberculosis in cattle by means of tuberculin. He also emphasized the varying but definite tendency to get well, which made it a difficult matter to prognose about any patient. Dr. LISTER, in reply, pointed out that his attitude on the matter was one of inquiry rather than dogmatism. He felt, however, that some of his ambulant cases had done well under tuberculin.

SECTION OF BALNEOLOGY AND CLIMATOLOGY.

At a meeting on April 17th, Dr. MOULLOT, of Harrogate, in the chair, Dr. EDGECOMBE (Harrogate), in a paper on *The significance, treatment, and prognosis of high blood pressure*, expressed the view that there was a condition of functional or "neurotic" high blood pressure not due to arterio-sclerosis, and distinguishable from hyperpiesis. In the majority of such cases direct treatment was unnecessary, and might be harmful. The condition did not readily lead to arterio-sclerosis. The treatment of early cases of hyperpiesis was imperative, and usually satisfactory. Spa treatment gave the best results. Dr. A. MANTLE (Harrogate), in a paper entitled *The undesirability in confirmed cases of high blood pressure of actively applying therapeutic means to reduce it*, said that one of the unfortunate results of ability to determine a patient's blood pressure in millimetres of mercury was that the sight of the column near the top of the tube often led to immediate active treatment to reduce it at any cost. Consequently cases had been sent to him with a history of high blood pressure in which treatment had effected some reduction, but at the expense of the heart losing the compensatory hypertrophy necessary for the control of the circulation. The fact was

that owing to the gradual increase of blood pressure each individual readjusted his cardiac vascular physiology to compensate this, and the physiological limit was not now 140 or 150 mm. Hg, but possibly 220 or 250 mm., and to reduce the pressure below this new physiological limit was not only not indicated, but bad therapy; he met with cases in which he had to give cardiac tonics to raise the pressure rather than adopt vaso-dilator treatment to reduce it. Some cases of high blood pressure due to disturbances of the alimentary canal in free livers—so-called "hyperpiesis"—might be cured if caught early before any fibrosis of the vessels took place. It was advisable to put the patient on a régime limiting the intake and assisting the natural outlets of waste products; it was only after some months of observation that one could say that a pressure was permanently supernormal. Dr. BUCKLEY (Buxton) reported a case in a woman of 38, whose systolic pressure had persisted between 240 and 270 mm. for the three years during which she had been under observation. Her most troublesome symptoms were neurotic, chiefly obsessions. Treatment had proved unavailing, even rest in bed for a prolonged period, but thyroid gland seemed to be of some benefit. Cardiac hypertrophy gradually developed, also albuminuria. He referred also to a case with a similar range of pressure in a woman of 55 with no symptoms definitely referable to this condition, but who had rapidly developed all the appearance of an old woman. Dr. BEZLY THORNE endorsed the views expressed by both Dr. Edgecombe and Dr. Mantle. In the course of 15 observations he had never known digitalis to raise blood pressure. On the other hand, he had found the solution of adrenalin, orally administered, to lower maximal readings, apparently by bringing the muscular tissue of the arteries into action and stimulating conductivity. He strongly advised making diastolic, in conjunction with maximal, records of pressure. Dr. ACKERLEY (Llandrindod Wells) could not regard high blood pressure as the cause of the symptoms associated with it. As regards food, he did not think red meat or any other form of nitrogenous food was necessarily dangerous. Few meals, moderate or small in quantity, avoidance of common salt, and free flushings with water apart from meals, were the essential dietetic rules. Starchy foods, imperfectly insalivated, were dangerous, as they fermented in the bowel. Dr. C. O. HAWTHORNE held that to present sphygmometric readings in terms of blood pressure was hardly justifiable, and agreed that a mere high reading was not a claim for active treatment. He doubted if any drugs had a sustained effect on high readings, and thought the action of nitrites short-lived. Dr. HUMPHRIS agreed with the prevailing sentiment, but protested against the suggestion that the treatment of a high blood pressure by high frequency was disappointing. If it were so it was either the choice of case or technique in fault. Too often the current used (d'Arsonval) was limited in amount to 250 to 300 milliampères, whereas it should be 1,000 milliampères and upwards. With this current the reading should be 10 per cent. lower at the end than at the beginning of the treatment.

MEDICO-LEGAL SOCIETY.

The Futility of the Coroner's Inquest.

At a meeting on April 22nd, Dr. W. A. BREND, Barrister-at-Law, read a long paper on the futility of the coroner's inquest. He pointed out that the coroner, whose office dated from the twelfth century, was originally a revenue officer of the Crown, and his object in inquiring into a death was to ascertain whether there was property to seize for the Crown, which was the case if the deceased was an outlaw or felon. He had also to assess the value of the deadand, that is, the animal or inanimate object which had led to a death, and which was forfeited to the Crown. But these functions had disappeared, and nothing had been definitely substituted for them. Hence there was great lack of uniformity in the practice and procedure of coroners. Some only inquired into deaths under suspicious circumstances, others investigated deaths where the pathological cause was unknown, though free from suspicion. Some coroners considered they were bound to hold inquests upon all deaths under anaesthetics, others only if there were allegations of negligence. Some went fully into accident cases with the object of settling claims

for compensation, others considered this no part of their duty. One coroner would scarcely hold an inquest without calling medical evidence, another only required such testimony occasionally. The statistics showed remarkable variations between different localities, and pointed generally to the fact that a much larger proportion of inquests are held in towns than in country districts. This was not due to a greater incidence of violence, and meant either that unnecessary inquests were held in towns, or inquests were not held in the country when they should be held. Either explanation indicated an unsatisfactory state of affairs. From the legal point of view a coroner's verdict carried little weight. In criminal cases the courts were almost always guided by the magistrate's decision. If a person was committed for trial on a coroner's warrant, but the charge was dismissed by the magistrate, it was the practice not to offer evidence on the coroner's warrant. Two preliminary investigations before trial, in addition to the grand jury's inquiry, were superfluous. In such cases either the coroner or the magistrate alone should conduct the inquiry. In accident cases the verdict had no legal meaning. Insurance companies were not bound to accept it and often did not. If a claim for compensation was disputed, the whole of the evidence had to be heard over again in the county court or higher courts, and a different decision might be reached. Juries sometimes strained the evidence in order to find a verdict of accident, with the object of assisting a defendant to obtain compensation. This encouraged persons to undertake useless litigation. In cases of alleged suicide verdicts of natural death or accident were sometimes found in the face of clear evidence to the contrary. The publication of details of suicide had a strong suggestive effect upon weak-minded persons. The publication of letters left by suicides, which often contained unfounded charges against innocent persons, was demoralizing, inflicted great distress upon relatives, and served no good purpose. Coroners' juries were not competent to investigate deaths under anaesthetics, and the frequent accounts in the newspapers of inquests upon deaths from this cause raised public alarm and increased the risk of giving an anaesthetic. As regards sources of information open to coroners other than the police, registrars were not competent to revise medical certificates of death, and frequently failed to inform coroners of cases which should be investigated. The coroner's officer was unknown to the law. He might be quite inefficient and was sometimes amenable to bribery. Owing to the pain and publicity attaching to inquests, strong pressure was brought to bear upon practitioners to avoid them if possible, and in consequence they did not always report cases in which the cause of death was unknown if free from suspicion. According to the Registrar-General's returns, there were in 1910 in England and Wales 199 deaths from accident and negligence upon which no inquests were held, and 690 deaths which were neither certified nor reported to coroners. Coroners did not always fully appreciate medical evidence, and serious results sometimes followed. The procedure in some districts was very lax and irregular, and inquests were sometimes scandalously hurried. A coroner's inquest did not settle legal questions, and the scientific results were small. In the matter of reform two alternatives presented themselves. It could be decided that the inquiry was fundamentally for legal purposes, in which case legal weight and meaning should be given to the verdict. The coroner, then, should be a lawyer of high standing; legal procedure would be observed, he would be bound by the laws of evidence, and his court would rank as one of first instance. He alone would investigate charges of murder or manslaughter and would commit for trial. In cases of accident he would possess the powers of a county court judge, and his verdict would be legally binding until upset by a court of appeal. The other alternative was to regard the inquiry as held essentially for medical and scientific purposes. The coroner under this proposal would be a highly qualified medical man, and his primary function would be to determine the pathological cause of death, leaving all legal questions to be settled by other tribunals. In the case of accidents he would settle once for all whether the condition was due to disease or injury, but would not enter into questions of responsibility or compensation. On the other hand, he would investigate deaths from natural and unknown causes more fully than

at present, but with simplified and semiprivate procedure. The jury would be abolished and only representatives of the deceased, of persons concerned, and of the police would have a right to be present. Medical men would then hesitate less to report cases. Of the two alternatives the latter was preferable, since the legal aspect was already largely covered by other tribunals. The absence of any satisfactory method of investigating deaths from the scientific point of view militated against the progress of medicine. The system should be combined with reform in the method of certifying deaths. At present medical men hesitated to put down causes of death reflecting upon the character of the deceased. All medical certificates should be sent straight to the medical coroner instead of to the registrar, who would revise them and adopt the simplified procedure in cases where they were not satisfactory. A private inquiry did not lead to "hushing up" in Scotland, and the present system in England was, in fact, already open to this objection. Agitation for reform must come from the medical profession, for they alone knew the dangers and deficiencies of the present system. The discussion was adjourned until May 20th.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

At a meeting on April 11th, Professor E. W. HOFF, President, in the chair, Dr. P. BOOBYER, opening a discussion on the *Administration of sanatorium benefit*, said that the heart of any scheme was the dispensary, which was at once a head office, a clearing house, a diagnosis and treatment centre, and an information and instruction bureau for the entire movement. While centralization in the administrative department necessarily made alike for economy and efficiency, it must not be forgotten that even with the best means of communication it was undesirable in a large proportion of cases to call upon the patients to travel long distances. The dispensary administration should be closely linked up with the health and housing departments, and this union should be centred in the person of the medical officer of health. No scheme should be considered complete without a hospital for advanced cases, a farm colony, and an open-air school for tuberculous children. The incorporation of Mothers' and Babies' Welcomes in any schemes was important. They should be used as branch dispensaries, more especially for the examination, sorting, and treatment of children suffering, or suspected of suffering, from tuberculosis, and who lived in the neighbourhood of these institutions. Dr. EUSTACE HILL dealt with the question from the county area point of view, and maintained that the county councils, and not the insurance committees or the local sanitary authorities, were the proper bodies to carry out sanatorium benefit schemes. Although there should be co-operation between the Insurance Committee and the County Tuberculosis Committee, the latter should be an independent committee and not a subcommittee of the Housing Committee of the county council. Co-operation between district and county councils was essential to success, and he recommended the use of existing isolation hospitals for tuberculous cases, suggesting that additional pavilions should be put up by the district councils and rented by the county councils at an annual sum which would repay the outlay in thirty years. The administration, he advised, should be in the hands of the district council, the county authority paying a fixed sum per patient for maintenance, nursing, etc. Dr. KAYE was also in favour of using isolation hospitals for tuberculous patients, and stated that in the West Riding workmen's houses for discharged patients were to be erected in connexion with a scheme for the treatment of acute and advanced cases. He objected to the use of the terms "chief" and "assistant" in connexion with tuberculosis officers, and suggested that they should be styled "tuberculosis officer" and "district tuberculosis officer" respectively. Dr. S. G. LAWRENCE feared there might be differences of opinion between the county and district authorities as to the sites of the head and branch dispensaries and as to the tuberculosis nurses. As regards the latter, he considered they should be on the staff of the medical officer of health of the district. Mr. F. E. FREMANTLE advocated the use of the existing nurses as tuberculosis nurses as it was difficult to divorce preventive from curative action. Dr. CORFIELD, on the other hand, advised the employment of a special nurse for preventive work who

would act as a health visitor. Dr. W. G. WILLOUGHBY said that there was sometimes a sentimental objection to school nurses dealing with tuberculous cases on the score of possible infection. Dr. SANDILANDS considered that the dispensary nurses should be on the staff of the medical officer of health. Dr. CALDWELL SMITH thought it was not the duty of a dispensary nurse to attend people at their homes and make beds, empty slops, etc. The people themselves should do this. Dr. BYGOTT was afraid that tuberculosis work might get into the hands of voluntary charitable societies, whose standard was not usually very high. Dr. GERARD TAYLOR urged the importance of co-operation with the general practitioners who were just now suspicious of innovations, and feared the time might come when their work would be taken from them by public officials. Dr. HERBERT JONES, Dr. F. ROBINSON, and Dr. HOWARD-JONES also took part in the discussion, a portion of which took place at an adjourned meeting of the society on April 25th, when Dr. W. G. Willoughby presided.

ULSTER MEDICAL SOCIETY.

At a meeting on April 17th, Dr. R. W. LESLIE, President, in the chair, Professor SYMINGTON demonstrated a method of making anatomical preparations by filling the hollow cavities with gelatine. Transverse sections of the human body an inch thick could be made in this manner, and could then be handled without displacement of structures, which so frequently happened when sections were made by other methods. Exact poker-work models could be made of these sections in wood, and transfixed in column by a long iron rod. Mr. CRYMBLE gave a demonstration on the living body of the palpation of the ileo-colon, the caecum, the transverse colon, and the lower end of the ileum where it enters into the caecum; and subsequently showed lantern slides of some abnormalities of the large intestine, and their relation to intestinal stasis. The other exhibits included demonstrations by Dr. MALCOLM of the paracolic folds and fossae, and some sections showing pericardial effusion; of the form and capacity of the renal pelvis, by Dr. KERR; of the motor area in a case of brachio-facial monoplegia in an infant, by Dr. DICKEY; and of a method of improved technique of staining tubercle bacilli, which was especially useful when there were a large number of specimens, by Dr. W. J. WILSON.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on April 17th, Mr. F. T. PAUL in the chair, Mr. JEANS, after showing some specimens of *Desmoid tumours*, said the term was applied to tumours consisting of fibrous tissue growing from muscle and fascia, especially in the lower part of the abdominal wall. It was supposed that they might originate from inflammation, haemorrhage, or from friction. They sometimes appeared in cicatrices. Mr. Lockwood had described them and had recommended that they should be treated as suspect of malignancy. The specimen shown was about the size of a pigeon's egg, and had occurred in a fat, healthy woman of 22 in the region of McBurney's point, and had been noticed for three years, and was slowly growing and becoming painful. Mr. PAUL said the tumour was of a class of spindle-celled tissue which might become malignant, but when removed in time would not recur. Dr. J. MURRAY BLYTH, in a note on the *Tuberculin reaction*, said he had used Koch's old tuberculin in 60 cases, all children, half of whom had no symptom of tuberculosis, and half with evident tuberculous disease. His general conclusions were that tuberculin reaction was of no practical value for diagnostic purposes. He mentioned that in 9 cases of chorea tested 8 gave a positive reaction to human or bovine tuberculin, or to both, and after the chorea was cured they gave negative reactions. Professor BEATTIE said that a positive reaction in cases where there was no evident disease might arise from tuberculous disease being present in the tonsils. He had found this in cases where there was no other tuberculosis. The cases of chorea might give a reaction, as sore throat was a common accompaniment of chorea, and it might be tuberculous, and so explain the high percentage of reactions in chorea cases. Dr. PERCY MARSH had found, after extensive use of von Pirquet's method, that it was of little value, but in children under 1 year a positive reaction had invariably meant a fatal result in that case.

Keibel.

HUMAN EMBRYOLOGY.

ALTHOUGH the science is but of yesterday, the two handsome volumes of the *Manual of Human Embryology*,¹ by KEIBEL and MALL—one consisting of over 500 pages and the other twice as large—illustrate in a striking fashion the enormous output of work in this subject since the late Professor Wilhelm His began, by means of serial sections, the systematic examination of human embryos. He it was who made the great change in technique, and who constructed the apparatus for section cutting which, primitive as it now seems, led the way to our modern microtome, and he also thought out a method of graphic reconstruction which has been greatly improved, especially by Born,² and which is now absolutely indispensable in embryological investigation. It was with this equipment that His began the study of human embryology, and a whole army of investigators—many of whom received their first inspiration to the study of the subject in his laboratories—have continued the work.

The idea of working out a complete account of the development of the human body was always before the mind of His, but as time went on the hope of accomplishing the task single-handed failed him, and he suggested to Professor Keibel of Freiburg that he should collaborate with him in writing a textbook on the subject. Unfortunately, through the death of His in 1904, the plan was never carried out, but Professor Keibel, on whom His's mantle has fallen, has been able by means of his *Normentafel zur Entwicklungsgeschichte der Wirbeltiere*, to carry the plan further, and to prepare the way for its fulfilment. Obtaining the assistance of one of His's most distinguished pupils in America, Frankliu P. Mall, of the Johns Hopkins Medical School, he has been able to bring to completion such a handbook of human embryology as His and he had planned. To do this they have enlisted the services of a number of colleagues, the necessary similarity of treatment being secured by a common purpose and by editorial supervision. No one can examine the pages of these two volumes without being struck by the fact that each contributor writes with a complete mastery of his subject. In vol. i Keibel has written on the germ cells, fertilization, segmentation, and young embryos; Grosser has contributed the article on the egg membranes, the placenta, and menstruation; Mall has written on the pathology of the human ovum and the determination of the age of human embryos and fetuses; Pinkus has contributed the chapter on the development of the skin; Barden that on the skeleton; and Lewis that on the muscles. The first volume is completed by an article by Mall on the development of the diaphragm and the body cavity.

In vol. ii Streeter has a long article on the development of the nervous system; Zuckerkandl a short one on the suprarenals and chromaffin organs; Grosser, Lewis, and McMurrich have collaborated to write the chapter on the development of the digestive tract and its derivatives; whilst Minot, Evans, Tandler, and Sabiu together have contributed the article on the development of the blood, the vascular system, and the spleen. One of the most comprehensive chapters—that dealing with the urino-genital system—has been written by Felix, and the work is rounded off by Keibel, who has summarized in a brief closing chapter the interdependence of the various developmental processes.

Within the limits of this review it is not possible to give any detailed criticism of the work, and we cannot do more than speak in general terms of the high character of the whole series of articles contributed. It has been a gigantic task, and embryologists the world over are under a great debt of gratitude to the distinguished editors and authors for providing such a record of present knowledge of the embryology of the human body, a record which must remain the standard work to which all investigators in this field will turn for reference. It is a work also which indicates in a critical way the lines along which future work must develop. The usefulness of the book is greatly

¹ *Manual of Human Embryology*. By various Authors. Edited by F. Keibel and F. P. Mall. London and Philadelphia: J. B. Lippincott. Two vols. (Imp. 8vo, vol. i, pp. 555, illus. 425; vol. ii, pp. 1040, illus. 658. 30s. net each.)

enhanced by the free use of illustrations—it contains over one thousand—and also a very full bibliography; in short, it is a mine of authoritative information, to which the physician and surgeon will doubtless turn, as well as the teacher and student of anatomy, whenever helpful knowledge is required in connexion with the development of any part of the human body.

THE TREATMENT OF INFANTILE PARALYSIS.

THE English translation of the book on this subject by Dr. OSCAR VULPIUS of Heidelberg,² has been made by Dr. ALAN TODD, and we may say at once that he has succeeded in rendering the German into clear and idiomatic English. Beginning with the history of infantile paralysis Dr. Vulpinus gives an interesting summary of the recorded epidemics of the disease in Europe and America. He inclines to the disquieting opinion that its prevalence has increased, although it must be admitted that the increase may be apparent only, owing to the increased attention given to disease in general and to nervous diseases in particular. The surgical treatment of infantile paralysis may be roughly classified as correction of position by means of operations on the skin, bones, joints, and tendons, or correction of function by operations on tendons and nerves, designed to restore lost powers of voluntary movement. These latter proceedings are of quite recent date, for although Nicoladoni's first operation was done in 1880, it is only since 1892 that much attention has been given to the subject by surgeons, and notably by Professor Vulpinus himself. His statement, therefore, in this book of his experience and of his opinions is bound to have great weight and interest, and we do not think that the student of the subject can find anywhere a more complete account, or one which will give him more full practical advice, always remembering that the author is somewhat of an enthusiast in tenoplasty, and that some authorities, notably Professor Kirrmisson of Paris, would very heavily discount his account of the benefit to be expected from it. The work includes a great deal of valuable information upon the incidence of the different forms of paralytic deformities, discussions of the best treatment for each, and a very good section on orthopaedic instruments. The illustrations are many and excellent.

RADIOLOGY.

A BRIEF account of the methods employed in the *x*-ray examination of the stomach and intestines is given by HOLZKNECHT.³ It is illustrated by diagrams showing the appearances that may be considered normal, and comparing them with the signs found in such disorders as hypermotility, duodenal obstruction, chronic constipation, ulceration or new growth in the colon, enteroproposis, and so on. He recommends the use of barium sulphate, *chemice purissimum ad usum internum*, as the best salt for the purpose. Of this, 80 grams (2½ oz.) may be given by the mouth in milk-gruel; when the large intestine is to be examined, 300 grams (10½ oz.) of it may be administered to an adult in a starch enema, 500 to 1,000 c.cm. being slowly injected in children, 1,500 to 1,700 c.cm. in adults. The *x*-ray examination should be made immediately after the enema has been given, and, in general, both six and twenty-four hours after the barium sulphate meal has been taken. Holzknrecht notes that the enema commonly fills the whole colon and caecum, often the appendix too, not rarely part of the ileum. The pamphlet may be warmly recommended to the attention of skiagraphers and clinicians.

Dr. H. E. SCHMIDT, of Berlin, who is well known as a dermatologist and radiologist, has written a small practical manual on radium-therapy, but it would not be claiming too much for it to describe it also as a book of reference.⁴

² *The Treatment of Infantile Paralysis*. By Oscar Vulpinus, M.D. Translated by Alan H. Todd, M.B., B.S., B.Sc. Lond. With introduction by J. Jackson Clarke, M.B. Lond., F.R.C.S. London: Baillière, Tindall and Cox, 1912. (Med. 8vo, pp. 328; 243 figs. 10s. 6d. net.)

³ *Die Röntgenuntersuchung des Darmes*. Von Priv.-Doz. Dr. G. Holzknrecht. (8vo, pp. 12, with 12 figures.) Reprint from *Jahreskurse für ärztliche Fortbildung*, Munich, August, 1912. J. F. Lehmann.

⁴ *Kompendium der Röntgen-Therapie*. By Dr. H. E. Schmidt. Third and enlarged edition. Berlin: August Hirschwald, 1913. (Demy 8vo, pp. 233; Abb. 80. 5s.)

The German style is easy, terse, and to the point, and the subject is treated so simply that the English reader will have no difficulty in understanding even the technical section, which occupies the first sixty-eight pages of an admirably illustrated book. The advantages and disadvantages of the many varieties of appliances now on the market are shortly reviewed in this section, and the study of it will amply repay any intending purchaser of an *x*-ray outfit. The second part is a compendium of *x*-ray therapy, and includes a very clear description, under subheadings, of the development of the art, *x*-ray dermatitis and carcinoma, sensitization and desensitization to *x* rays, deep-level technique, prophylaxis for the operator, and the detail for the individual treatment of all the skin disease indications, with simple diagrams to illustrate his exact meaning. The survey concludes with a reference to the applications of radio-therapy in general medicine, and the treatment of such diseases as leukaemia, malaria, Graves's disease, arthritis deformans, etc. Neuralgia, uterine myomata, tuberculosis, hypertrophy of the prostate, inoperable carcinomata, and certain diseases of the larynx and air passages are discussed. Every worker should possess a copy of this book.

NOTES ON BOOKS.

AN issue of the Twentieth Century Science Series which has not hitherto been noticed is by Dr. SIDNEY HILLIER of Stowmarket, Suffolk, whose volume is entitled *Medical and Surgical Science*,⁵ the scope of the work being further indicated by the subtitle, "Conception and Progress." Considering the modest size of the volume, the account supplied by it of the evolution of the science and art of medicine from the earliest ages up to the present time must be deemed remarkably complete. For the most part it is schools of thought and those who have founded or represented them that are considered; but in the later pages the author deals in some degree with modern treatment, and indulges himself in a cautious forecast of future developments. Obviously keen as is his interest in the subject, he nowhere allows it to run away with him, the result being that all periods receive a well-balanced meet of attention, and that the volume may be read with interest either by laymen or by members of the medical profession. In addition to a good index and some reproductions of old pictures of early surgical procedures there is a comparatively brief bibliography.

MEDICAL AND SURGICAL APPLIANCES.

An Antiseptic Toothbrush.

IN 1910 Dr. D. W. Carnalt-Jones and Mr. Herbert Smale read a joint paper before the British Medical Association on "Some Points in the Bacteriology of Toothbrushes," in which they advocated the sterilization of those articles, because it appeared to them that even in an infected cavity such as the mouth it was preferable that an instrument which is so used that it may scarify the gums should not convey any additional organisms directly into the wound. This paper appears to have attracted some attention in America, and Dr. Carnalt-Jones and Mr. Smale inform us that an American dentist, Dr. Ernest C. Dye, of Greenville (S.C.) has devised a toothbrush which is efficiently sterilized by formalin vapour. It consists of a cylinder closed at one end by a hemispherical cap which contains wool soaked in formalin and kept in place by wire gauze. The other end carries the brush, which is screwed on for use and after use is reversed and screwed inside the cylinder, where it is exposed to the formalin vapour and rendered sterile. A more practical modification is, they consider, the use of a long cylinder in which an ordinary toothbrush can be kept while out of use. If the toothbrush is damp when put into the cylinder all ordinary mouth organisms are killed.

⁵ *Medical and Surgical Science: Its Conception and Progress*. By S. Hillier, M.D. Twentieth Century Science Series. Halifax: Milner Company, 1911. (Crown 8vo, pp. 133; plates 6. 1s. net.)

AT the meeting of managers at the Royal Infirmary, Edinburgh, on April 28th, it was intimated that of the 2,862 patients admitted to the wards for treatment between January 15th and April 14th, 1,197 were insured persons; of the 7,966 out-patients treated during these three months 2,535 were insured persons.

DEPUTATION TO THE PRIME MINISTER IN SUPPORT OF THE STATE REGISTRATION OF NURSES.

ON April 28th the Prime Minister received in his private room at the House of Commons a deputation from the Central Committee for the State Registration of Nurses, which was introduced by Dr. CHAPPLE, M.P. The various bodies represented by the deputation were the British Medical Association, the Matrons' Council of Great Britain and Ireland, the Royal British Nurses' Association, the Fever Nurses' Association, the Association for Promoting the Registration of Nurses in Scotland, the Scottish Nurses' Association, the Irish Nurses' Association, and the Society for the State Registration of Trained Nurses. With Mr. Asquith was Mr. Burns, President of the Local Government Board.

Dr. CHAPPLE, in introducing the deputation, said that practically the whole of the institutions connected with nursing and attendance on the sick were represented. Two vested interests were affected by the State registration of nurses; one was that of the unqualified nurses and the other consisted of one or two hospitals which, it was not too much to say, exploited nurses for the financial advantage of the institutions. The training of nurses was as essential as training and skill in the medical profession, and unqualified nurses were just as great a danger to the community and the patients whom they attended as an unqualified medical man would be. The deputation did not ask that there should be any exclusive right to nurse, but simply that there should be a distinction between those who were qualified and those who were not. It was difficult to get young girls to go through a difficult and tedious curriculum unless at the end of their training they were given a status. The public interest should be the first and greatest consideration, and as a medical man he knew no greater danger in the sick room than an unqualified nurse. With the increase of scientific surgery and greater accuracy in medication it was just as essential to have a trained nurse as a doctor who was trained. The various associations represented by the deputation felt that if the Prime Minister could give facilities for a bill aiming at State registration this country would come into line with others which had already passed this reform and had found it very successful both in the interests of the public and the nurses.

Sir VICTOR HORSLEY, who, with Dr. Cox (Medical Secretary), represented the British Medical Association, remarked that four years ago Mr. Asquith very courteously received in that room a deputation consisting almost of the same persons as were now before him. He claimed that the British Medical Association was the only organization which represented the whole medical profession, and that claim was the more justified because there was no record of any resolution having been passed in opposition to the objects of the deputation by any gathering of medical men, any more than of the nursing profession. The situation therefore was unaltered. On the last occasion the Prime Minister told them that the various interests concerned were not unanimous in making their demands, because he held in his hand expressions of opinion in opposition by various medical and nursing authorities. Sir Victor Horsley remarked that he was not aware of any nursing body having passed a resolution hostile to the objects of the deputation. The Prime Minister had indicated on the last occasion that in view of the letters he had received, he could not accede to the request. Nevertheless, the deputation felt its request to be a democratic one because it embodied resolutions passed at various meetings of the societies concerned. It was a democratic request, made constitutionally, whereas the opinions quoted by the Prime Minister were bureaucratic ones, and were put forward unconstitutionally. Those opinions could not be held to represent the views of the medical profession; moreover, they should not be anonymous. Those who asked for this reform asked for it publicly, and the opposition should be public also. On this occasion they found themselves on a stronger footing because since 1909 the Government had re-established the registration of teachers, having recognized that in that profession registration was essential. It was an extremely complicated matter to

carry out the registration of teachers; the registration of nurses, on the other hand, was just as simple as the other was complicated. The portals to the nursing profession could be controlled quite easily. Members of the medical profession knew the advantages they gained by registration, and wanted the same advantages for the nursing profession, because the public would benefit. Medical work had now become imperial; they were trying to get reciprocity in this respect with the Dominions. This also applied to nursing, but the Dominions had nursing registration, and their nurses complained because when they came to this country they found they had not the same professional status. That was a just complaint, and one it was hoped Mr. Asquith would see his way to remedy, and that he would, on behalf of the Government, accept the view that State registration of nurses was necessary.

Miss COX-DAVIES, speaking on behalf of matrons and nurses, said it was now twenty years since the Matrons' Council adopted as one of its chief objects a uniform system of education and the State registration of nurses. Urgent as the need was then, it was more so now when demands were made for trained nurses to fill most responsible positions, both as preventive agents and in assisting the medical profession. It was of paramount importance to the community not only that the supply should be adequate but that the members of the nursing profession should be educated for their responsible duties. At present fully-trained nurses found themselves in competition with semi-trained and unreliable persons who were often found unsuitable even for supervised work in hospitals. Miss Cox-Davies alluded to the shortage of nurses experienced by the Metropolitan Asylums Board and reported in the last issue of the *BRITISH MEDICAL JOURNAL*. She remarked that this experience was general throughout the country.

Lady H. MUNRO FERGUSON, who addressed herself to the general aspects of the question, urged that this was a matter which not only affected doctors and nurses, but the public also. It was practically impossible for a member of the public to be sure of getting a nurse suited to his or her requirement, because there was no standard and nothing to ensure that a particular institution or hospital gave the necessary training. It was no safeguard for the public to pay high fees at a nursing home, for, in the absence of any standard, it was open to any organization to state that its nurses were fully trained. It was not proposed to prevent untrained women from practising; only that the public should have a means of assuring themselves of the services of a fully trained nurse if they required one. The passing of the Insurance Act and the campaign against tuberculosis had made this reform more urgently needed, owing to the fact that in the future nurses would be employed more largely than ever before.

Dr. D. J. MACKINTOSH (Glasgow) spoke on behalf of Scottish nurses. He said he agreed with what other speakers had said, and would merely add that there was no opposition at all in Scotland to the proposals urged by the deputation. They were supported by the whole nursing profession.

Mr. ASQUITH: Is that so?

Dr. MACKINTOSH: So I believe.

Dr. MCGREGOR ROBERTSON (Glasgow) said that the nurses in Scotland had organized themselves as they had not been before, because they all recognized the need for a standard of training and examination, and for State recognition of that standard. He was sent by a very large body of Scottish nurses of many grades and forms of qualification. Amongst that large body there had never been a doubt that the bill now before Parliament was in the highest interests of the nursing profession as well as in those of the public. The bill was practically unanimously supported by the nursing profession in Scotland.

Miss HUXLEY, on behalf of the Irish Nurses' Association, said that fewer well-educated women than formerly offered themselves for entry into the nursing profession, although the advances of medicine and surgery demanded more intelligent and accurate work from the nurses. The absence of a standard was the reason for this regrettable change.

Mr. ASQUITH asked what he or the Government were requested to do.

Dr. CHAPPLE: We want to get your sympathy with the bill now before Parliament.

Mr. ASQUITH: You want us to give facilities for the bill?

Dr. CHAPPLE: We might be satisfied with something short of that.

Mr. ASQUITH: Nothing short of that will be of any use to you. Have you had a second reading?

Dr. CHAPPLE: We have not.

Mr. ASQUITH: Then there is not much chance for it to get through.

Dr. CHAPPLE remarked that it was the unanimous opinion of all those concerned in this question that never before had there been so much sympathy with the objects of the bill exhibited in so many different quarters. They were hopeful that if the Government gave facilities the bill would have an easier passage through the House than on the former occasion.

Mr. ASQUITH, in reply, said he was glad to receive the deputation, although he did not profess to have any special knowledge of the subject; nor, indeed, was he the Minister, or one of the Ministers, responsible for this particular branch of administration. Nevertheless, the subject raised issues which affected the welfare of the community at large, and was one to which he could not be indifferent. It was a question of growing importance that our nursing system should be recruited from the best possible sources, and should be carried on by persons who were more and more qualified for what were now generally regarded as very difficult and arduous duties. All of them in their time had been interested, either as subjects or as spectators, in the operations of a nurse, and he did not suppose there was any profession, unless it was the medical profession itself, in which was needed a more careful and well-adjusted combination of the head, heart, and hand. He understood it to be the view of the deputation that by the machinery which in this bill it was proposed to set up two, at any rate, of these qualities would be better secured; he did not suppose that the third could be affected by legislative means. Mr. Asquith said he had been very much impressed by the arguments brought forward, and he recognized, as no one could fail to do, the representative and authoritative character of the deputation, which, as Sir Victor Horsley very properly said, could claim to speak as the mouthpiece of a number of organizations that had publicly expressed representative opinions on the subject. On the other hand, they would forgive him for saying that Dr. Chapple took too sanguine a view when he thought that the opposition to the proposals now advanced had diminished either in amount or in authority. He gave them on the last occasion a wearisome catalogue of those who were opposed to any change in this matter. The list had been brought up to date, and it was now a more formidable and menacing array than it was before. It consisted, he was informed on the best authority, of ninety-one chairmen of hospitals. Sir Victor Horsley called them bureaucrats, but, after all, they were chairmen of hospitals, and obtained their position by free election on the part of subscribers.

Sir VICTOR HORSLEY: May I explain? I referred to men who are in office. I meant they were not speaking on behalf of the board of management; they are speaking as individuals. We do not recognize them.

Mr. ASQUITH: I am in office, and exactly the same thing might be said of me. He added that there were also amongst the opponents 66 London matrons and 178 provincial ones. They were not bureaucrats.

Sir VICTOR HORSLEY: They are not speaking in the names of their nurses.

Mr. ASQUITH: Presumably they are persons of experience. There are also 1,332 nurses and 340 doctors. I do not say they are right for a moment. I do not say my sympathies, so far as they are worth anything, are not with you, but it is impossible to say, in view of these facts, that there is anything like unanimity in the medical or even in the nursing professions on this matter (because the matrons must be included amongst the most experienced and authoritative section of the nursing profession), or that the measure would not encounter, as I am certain it would, a very vigorous opposition in the House of Commons, and perhaps elsewhere. We are face to face now, as we were four years ago—I wish it were otherwise—with a position in which it cannot be said that

substantial unanimity prevails; and while I do not for a moment attempt to controvert or even to criticize your views, or even to say that I do not in a great measure agree, yet, looking at this matter from a purely parliamentary point of view, I cannot say, if the Government gave this measure facilities as compared with measures of its own, that it would have the sympathy of the House and an easy course, and not excite a great deal of opposition. I am obliged to have regard to the exigencies of the parliamentary situation, and I should not be dealing honestly with you if I do not say that until—as very likely you may—by conviction, argument, persuasion, and every legitimate process you have, I won't say completely annihilated, but substantially mitigated that somewhat formidable opposition, which I am sure would make itself articulate and operative in the House of Commons just as it does outside—until this is the case I cannot honestly say I think any Government would give facilities, or, in other words, practically adopt as a Government measure a bill which is of a definitely controversial character. I have spoken quite plainly because it is best to tell the honest truth, but you must not think I am expressing any kind of hostility or want of sympathy. I think it is most desirable that the medical and nursing professions should arrive at a concordat; I do not mean unanimity—you will never get that in this imperfect world—but something approaching unanimity. Whether it is possible by modifying any details of your scheme I am not in a position to say, but it might be desirable to take into counsel or negotiation the more authoritative and representative of your present opponents and see whether it is not possible for you jointly to elaborate proposals which will command the substantial assent of the great body of the medical and nursing professions. If you do that, you will find no more ardent sympathizers than the Government, or any one more desirous of co-operating with you. I am afraid, cold as the comfort may seem, that is all I can say to you at present.

Sir VICTOR HORSLEY: May I ask for the names of the 340 medical men? We have never heard of them; if we had their names we could start on the campaign at once.

Mr. JOHN BURNS: You shall have them.

Mr. ASQUITH: I have the matrons too. He added, in reply to an inquiry whether any opposition under that head came from Scotland, that there was not very much.

Dr. CHAPPLE, in acknowledging Mr. Asquith's advice, remarked that it would be impossible to get complete unanimity on this question. Unanimity could not be secured amongst individuals, especially when those who opposed had vested interests in untrained nurses. For instance, it would be impossible to get the Chairman of the Committee of the London Hospital to support the view of the deputation. The London Hospital only gave a two years' training, which the deputation maintained was absolutely inadequate. Before that time had expired nurses who cost the hospital £28 a year were sent out, and their work brought in a revenue to the institution at the rate of £100 a year.

Mr. ASQUITH: Do you mean to say we do not get good nurses from the London Hospital?

Dr. CHAPPLE: The nurses do not get adequate training.

Mr. ASQUITH: I shall communicate what you said to the Chairman of the London Hospital.

Dr. CHAPPLE: I shall be very glad if you will do so.

Sir VICTOR HORSLEY (to Mr. Asquith): We have absolute unanimity among 40,000 people—doctors and nurses—and we are opposed by a handful of people, who do not even give us their names.

Mr. ASQUITH: Here they are. (At the same time the Prime Minister handed to Sir Victor Horsley certain names which he had before him.)

A vote of thanks to Mr. Asquith concluded the proceedings.

THE fourth Italian Congress of Occupational Diseases will take place at Rome in June (8th to 11th), under the presidency of Professor Guido Baccelli. The following are the subjects proposed for discussion: Ankylostomiasis, diseases of the blood of professional origin, infant mortality in relation to the occupations and social conditions of the parents, forms of dermatitis of professional origin, professional pathology of railway employees.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

THE ADVERTISEMENT OF MEDICATED WINES IN THE MEDICAL PRESS.

At the commencement of the sitting on April 24th, the Chairman (Sir Henry Norman) said the Committee had received a letter from Dr. Cox with reference to certain answers given before the Committee on March 27th by Mr. W. Rudderham on behalf of the proprietors of Wincarnis (BRITISH MEDICAL JOURNAL, April 5th, p. 725). Dr. Cox recalled that the witness was questioned by Mr. Lawson as to the conditions under which the advertisements of Wincarnis were withdrawn from the medical press, and the impression conveyed by the evidence was that no objection was raised to the acceptance of the advertisements by those responsible for the conduct of the BRITISH MEDICAL JOURNAL, but that the advertisement was withdrawn by the proprietors for "ordinary commercial reasons." Dr. Cox said that this statement was misleading and not in accordance with facts as far as the JOURNAL was concerned. When the contract for the advertisement expired the manager was instructed by the Council to decline to accept in the meantime any advertisement for Wincarnis, or for any other medicated wine of the same kind. On September 22nd an order was tendered for thirteen insertions of an advertisement of Wincarnis, and this was not accepted. Dr. Cox added that he had the authority of the manager of the *Lancet* to say that the *Lancet* definitely refused the advertisement of Wincarnis some time before the BRITISH MEDICAL JOURNAL.

Mr. Harry Lawson: Of course it will be open for rebutting evidence to be given?

The Chairman: Obviously the Committee will receive any statement which Mr. Rudderham desires to make.

THE ANALYSES IN "SECRET REMEDIES."

Mr. E. F. Harrison, the consulting analyst engaged by the British Medical Association in connexion with the analyses in *Secret Remedies* was then recalled, the Chairman remarking that he appeared both by his own desire and that of the Committee. Mr. Harrison said that what he wished to say fell under three divisions: First, some of the evidence in regard to the contents of the *British Pharmacopœia*, and the qualifications of an analyst competent to deal with medicines, was, in his opinion, misleading; secondly, he wished to deal with some of the evidence which appeared to be intended to convey that the articles mentioned in *Secret Remedies* and *More Secret Remedies* had not any considerable sale; thirdly, he would discuss the analyses that had been challenged.

With regard to the *Pharmacopœia*, the impression apparently left upon the minds of the Committee by the evidence of Mr. Umney was that only 44 out of 235 vegetable preparations in the *British Pharmacopœia* could be discovered.

Mr. Glyn-Jones: Mr. Umney used the phrase, "by chemical analysis."

Mr. Harrison proceeded to criticize the way Mr. Umney and Mr. Parry used the terms "discover" and "determine" in an analytical connexion. He said that the number 44 was nowhere near the truth unless, when Mr. Umney spoke of their being "determined," he meant "quantitatively determined." The number of drugs which could be identified when in the form of their preparations had nothing to do with the number of those which could be quantitatively determined.

Mr. Lawson at this stage raised a point of order. He suggested it was unusual to have detailed replies to other witnesses by witnesses who had been already in the box, because it led to an interminable series of rebuttals. He thought that whilst it would be quite in order for the witness to refer to matters in a general way, it would be a great mistake for the Committee to allow any witness to enter into detail question by question. Obviously it would be necessary to recall the witnesses challenged.

Sir Philip Magnus (who was in the chair at the time) thought there was a great deal in what Mr. Lawson said. At the same time Mr. Harrison was a very important witness, and many of his statements had been controverted by Mr. Umney. In the interests of the Committee,

it was very desirable that Mr. Harrison should have an opportunity of rebutting statements which he considered to be incorrect. To do this it would be necessary to go into them in some detail. After Mr. Harrison's statement, if Mr. Umney thought it important that he should be called again, the Committee would have to give him an opportunity of reappearing. That should entirely close the arguments for and against.

Mr. Lawson suggested that Mr. Harrison's evidence should be confined to a few of the main points which required reply.

Mr. Newton remarked that Mr. Harrison appeared to be dealing at the moment with the misuse, or varying use, of a certain term by previous witnesses.

Mr. Glyn-Jones said there was no denying the importance in the present investigation of the two books for which Mr. Harrison was in the main responsible. He felt it would be necessary to put definitely to Mr. Harrison the various allegations of error.

Mr. Harrison proceeded to deal with the number of vegetable preparations in the *British Pharmacopœia*. Mr. Umney spoke of 235. There were only 160 separate and distinct vegetable drugs in the *Pharmacopœia*: it was, perhaps, an arguable question what should be counted a preparation of a drug, and, according to his counting, there were 301 galenical preparations of vegetable drugs. Whatever the principle upon which Mr. Umney made his selection of these, it was clear that different preparations of one drug were counted as different articles. He had roughly arranged the different vegetable drugs in the *Pharmacopœia* in five classes as follows: (a) Those containing definite constituents capable of being determined by chemical means, 36; (b) those containing constituents readily recognizable by physical means—taste, smell, colour, etc.—with or without chemical tests as well, 48; (c) drugs of little or no therapeutic activity, used chiefly as excipients, or suspending, flavouring, or sweetening agents, 13; (d) drugs which could be detected, but might not be completely identified, 28 (in this class examination might only show that the substance being tested was one of three or four, without enabling the analyst to say exactly which); (e) drugs which would probably not be detected when in the form of their preparations, 26. The other respect in which Mr. Umney's evidence on this matter seemed to be misleading was his repeated implication that an analyst was limited to chemical tests, and was debarred from other methods, such as the use of taste and smell, which were available to Mr. Umney. Mr. Harrison then began to quote Mr. Umney's statement that a consulting analytical chemist could not get the knowledge arising from handling, tasting, and smelling drugs, which came to one engaged in the drug trade.

Mr. Lawson thought it would be most objectionable to have matters of personal controversy brought to the notice of the Committee.

Sir Philip Magnus: I think you desire to point out that the analyst responsible for these analyses had that additional knowledge and capacity of detecting drugs?

Mr. Harrison agreed, and said that it was not a question of personal rivalry between himself and other witnesses. His point was that he spent many years gaining pharmaceutical experience in the wholesale manufacturing houses, and exactly the kind of experience that Mr. Umney mentioned. He had some other remarks as to actual qualifications; he thought that some of the evidence on this point was rather misleading, but he would leave it alone if the Committee desired.

As to the extent of the sale of the articles in the two volumes, Mr. Waring and Mr. Barclay both stated that they were ignorant of a large proportion of the remedies mentioned, but as to this Mr. Harrison pointed out that the books included sixty German nostrums. These appeared to be of sufficient interest to be included, but it had never been suggested that they had any appreciable sale in this country, and they occupied very little of the two books, though numerically they were considerable. Another large proportion of the remedies mentioned was distributed through the post, and therefore would not be known to the two witnesses he had named. The witness mentioned a case in which he wrote to Barclay's for a medicine for analysis, and received a letter from the firm stating that the maker would not supply through them, but only direct. Also a number of the articles in the two books probably

had chiefly a local sale: such medicines were commonly quite numerous, but it was thought best to include a certain number of them as representatives.

Passing on to the allegations of inaccuracy in the analyses in *Secret Remedies*, Mr. Harrison said he did not feel called upon to defend his reputation in this matter. When he was before the Committee on the first occasion he insisted on the limitations of what analysis could do. The fact that Mr. Umney had found ingredients which he (the witness) had not found would not be held to be final proof that they existed in the preparations he analysed. That was not a mere academic point; there was very strong evidence in some cases of alteration of formulæ, intentional or otherwise. Mr. Harrison recalled that some of the witnesses had admitted that variations in the formulæ had occurred; he had compared two bottles of Seigel's Syrup, and found there was undoubtedly far more capsicum in one bottle than the other. Other instances were referred to in *Secret Remedies*. The maker might put forward statements in good faith which nevertheless must be received with scepticism; for example, Mr. Lawson said in his evidence: "The statement in *Secret Remedies* that the weight of a Daisy powder is 6 grains would show that the analyst must have examined a very old packet. The dose had been 5 grains for at least nine years." The packet in question was bought from Barclay's in April, 1906, and it was hardly likely that they had kept it in stock for over two years.

DETAILED REPLY TO ALLEGED INACCURACIES IN ANALYSIS.

Mr. Harrison proceeded to deal in detail with each of the cases in which inaccuracy of analysis was alleged in *Secret Remedies* and *More Secret Remedies*. In regard to Seigel's Syrup, Mr. Harrison quoted Mr. Umney's statement that it was not possible to separate the special vegetable ingredients, except by very long processes, and that he had determined the total solid extractive matter and then deducted from that the amount due to saccharine bodies. He took this to mean that Mr. Umney had determined the total solid matter, and also the total saccharine matter or sugars, and, having deducted the latter from the former, he regarded the difference as the "special vegetable extracts," added in making up the medicine. Treacle, however, contained a proportion of non-saccharine extractive, which varied very much. The formula of Seigel's Syrup given in *Secret Remedies* gave 60 parts of treacle in 100 parts by measure, and he believed it had not been alleged that this proportion was incorrect. The evidence given on behalf of the proprietors was that 181 lb. of extracts went into 250 gallons of the syrup, which was 7.9 parts in 100 parts by measure, so that if Mr. Umney regarded the quantity of the total solids minus the sugars as evidence of the amount of extracts added, and was satisfied at finding the proportion stated by the proprietors to be added, more than this quantity would be accounted for by the non-saccharine solids of the treacle, and there was therefore no analytical evidence as to the amount of extracts present.

Mr. Glyn-Jones: Is this important in view of the fact that eleven vegetable extracts are stated to be in the preparation, and Mr. Umney and Mr. Parry both definitely say they have found some? Is not the important thing whether you are prepared to say that those ingredients which they say they found are or are not present? Are you prepared to say that?

The Witness: Certainly not; but what I want to come to is that there is no evidence to show that this case is not covered by what I said before—that a maker might put in a small quantity of a large number of extracts, and an analyst cannot find them. In this case the non-saccharine matter of the treacle is so large that it would more than account for the extractive. If Mr. Umney relied on that he could not say anything about the quantity of the extracts, and there is no analytical evidence on the point.

The Chairman: You admit they may have been there?—Certainly.

As to Clarke's Blood Mixture, Mr. Harrison suggested that the criticism raised in this case was quite frivolous. It was stated that the ammonia was not there as aromatic spirit of ammonia, but since the ammonia and the alcohol were admittedly there it seemed quite immaterial whether

they were added together in the form of sal volatile or not. The amount of sal volatile stated would contain about one-thirtieth of a grain of oil of nutmeg and one-twentieth of a grain of oil of lemon, and it would hardly be seriously suggested that these quantities in a bottle of sixteen doses were of any consequence at all.

With regard to Woodward's Gripe Water, he had a small quantity left of the supply of this which he had tested, and after reading the evidence given he tasted it again and was prepared to admit that it contained a trace of the pungent aromatic substance which had been named privately to the Committee. The amount was so minute that the Government analyst reported it as a trace of capsicum resin. Nevertheless there was a well-known test for distinguishing them, showing presumably that the quantity obtained was too minute for this test to be applied. Mr. Umney called this trace of the unnamed substance "the most important ingredient," and much was said about its value by Mr. Woodward. Mr. South and Mr. Hake had asserted, in regard to another infants' medicine, that the presence or absence of a trace of the far more potent drug, opium, was immaterial. This well illustrated what he had said in his former evidence—that so long as a proprietor could keep a medicinal ingredient secret, he could and did make very large claims for its medicinal value.

As to Mr. Parry's evidence in regard to Beecham's pills, that he found one ingredient after its name had been disclosed to him by the makers and another without such disclosure, Mr. Harrison remarked that it did not appear that the presence of the latter was confirmed by the makers; and as for the test suggested by Mr. Parry, the appearance, smell, and taste, and behaviour on putting into water—all these characters might be affected by differences in the excipient or non-medicinal ingredients of the pills.

In reply to Mr. Glyn-Jones, the witness said he was not prepared to say that the ingredients mentioned by the other witnesses were not there, but he insisted that if there they were only present in small quantity; further, the tests described by Mr. Parry really amounted to nothing.

As to Doan's dinner pills, the witness pointed out that in *Secret Remedies* the pills were only stated to contain "a resin that appeared to be jalap resin," and "an extract that resembled extract of henbane." No more definite statement was made. The absence of conclusive tests for the last-mentioned ingredient was expressly mentioned, and the formula given was only stated to give a similar pill. There was, therefore, nothing surprising in Mr. Parry's statement, made with a full knowledge of the formula.

As to Ozerine, Mr. Harrison said that he did not make this analysis. The six articles dealt with in Chapter XIII of vol. i were analysed before he took up the work by a gentleman who was now dead. He was a very competent chemist and pharmacist, and it was unlikely that he made any mistake in analysing a simple mixture, chiefly of inorganic salts, like this one. Mr. Parry had told the Committee that two other ingredients were there; Mr. Harrison did not think they could have been present in the batch examined by the deceased analyst.

As to Pond's Arthritics, Mr. Harrison quoted Mr. Parry's statement that an important constituent was omitted from the analysis in *More Secret Remedies*, which he found to be present to the extent of nearly 10 per cent., and this he had identified chemically. That would amount to a very serious allegation indeed, but, in reply, Mr. Harrison said he had been informed by a gentleman (who was prepared to substantiate the statement before the Committee) that the principal ingredient was formerly potassium acetate, but that a batch was made and sent out without any potassium acetate. The gentleman making this statement was at that time a director of the company manufacturing the medicine. In the light of Mr. Parry's statement, he had carefully gone through his analytical results again, and could affirm without any doubt that the mixture he analysed did not contain any appreciable quantity of this substance or anything else but the ingredients given on page 13 of *More Secret Remedies*. This case illustrated the fact that Mr. Parry, in assuring the Committee that formulæ were not altered, was speaking of matters not wholly within his cognizance.

Similarly, with regard to Johnson's Soothing Syrup, Mr. Harrison pointed out that whereas Mr. Parry found only a trace of sodium chloride, he found 5.7 parts in 100 parts by measure. He did not think Mr. Parry or any one else would suggest that he was incapable of determining sodium chloride correctly, or that "a trace" could possibly be mistaken for 5.7 per cent. The inevitable conclusion, therefore, was that Mr. Parry and he were examining liquids of very different composition. Nevertheless, he must protest against Mr. Parry's suggestion that, having found certain things, he "jumped" to a conclusion. Mr. Parry added that this was what he himself would probably have done. Without disputing that statement, Mr. Harrison said he did not jump to a conclusion, and the assumption was quite gratuitous.

Mr. Glyn-Jones referred to a description in the BRITISH MEDICAL JOURNAL of this preparation, stating that it was a preparation for rubbing on children's gums which contained hydrochloric acid. The witness said the JOURNAL was not to blame for making that statement; it was guided by the analysis in *Secret Remedies*. He agreed as to the possibility of the preparation containing lemon juice, saffron, and tolu, but he found it hard to account, on that basis, for the amount of acid he found.

Mr. Cawley: Is it your opinion now that your original analysis was right?

The Witness: Yes, I think on the balance of probability it is. At any rate, very nearly right.

Mr. Harrison dealt in passing with this comment on himself in Mr. Parry's evidence: "I have verified that he jumped to the conclusion, because there was an alkaloid present in Marza wine and it was labelled 'coca wine,' that it must have been cocaine." Mr. Harrison said he jumped to no such conclusion; the words of his report were: "The alkaloid was bitter, and caused numbing when applied to the tongue . . . its solution showed the fluorescence characteristic of quinine or quinidine." That was a plain record of observed facts, and cocaine was not even mentioned. Mr. Parry was therefore going beyond what was justifiable in speaking in that way.

With regard to Cicfa, as to which Mr. Parry stated the ingredient which Mr. Harrison called diastase to be a much more expensive article, Mr. Harrison said he knew of no means of distinguishing in such a mixture between the diastatic ferments, diastase, ptyalin, and taka-diastase, and he knew of no difference in their physiological action except the quantitative one. As the activity was determined quantitatively and recorded, it appeared quite immaterial that the name "diastase" was used. If a price had been given for the ingredients based on the assumption that the cheaper substance was present when actually the tablets contained the dearer, there might have been some cause for complaint, but in this case as in others when the results did not allow of fairly exact pricing, no price was mentioned.

As to Powell's Balsam, the fact that Mr. Parry found no alkaloid had no bearing on the fact that he found a trace in another sample of the medicine some years previously. It was not denied that the composition of this medicine had been altered at least once. As to Mr. Hake's statement that an ingredient not mentioned in the analysis of Steedman's powders contained a minute proportion of an alkaloid, the analysis in *Secret Remedies* stated that a minute amount of an alkaloid was present, so that the only omission appeared to be that the drug from which it was derived was not named. He thought it likely that the drug in question was powdered *ipccacuanha*; without a prior knowledge it would not be readily detected in the presence of the large proportions of maize starch and calomel. As the powders in one packet were found by him to vary in weight from 1.9 to 4.5 grains, pointing to extreme carelessness in putting up, it was not unreasonable to suppose that there might have been some carelessness in mixing, and that the powders examined by him might have contained even less of this ingredient than the quantity intended to be present.

In reply to Dr. Lynch, who pointed out that in some of the cases in which preparations analysed in *Secret Remedies* were submitted to the Government analyst the results arrived at varied considerably as compared with Mr. Harrison's, the witness said it did not follow that either

of the analyses was incorrect; it was clear evidence of variation of composition. When the analyses in *Secret Remedies* were made, he had not in view such a searching inquiry as this; had he foreseen it, he would not have exercised more care, but he would probably have operated on larger quantities of materials. The analyses were made in the first instance for the information of medical men, to give them as accurate an account of the composition of proprietary medicines as could be done with a reasonable expenditure of time. If the work had been done for the purposes of the Committee it would have been justifiable to have taken longer, and to have used far more of the medicines.

Sir Philip Magnus: Then your results would have been a little more accurate?

The Witness: They would have been a little more full—more accurate in that sense.

In reply to Mr. Cawley, the witness said that, in regard to Woodward's gripe water, he was quite satisfied, whatever the missing substance was, its amount was very minute.

Mr. Lawson: Do you find, in the case of preparations made up by chemists according to the *Pharmacopœia*, variation to a greater or less degree?

The Witness: The *Pharmacopœia* allows variation, and then after analysis standardization.

Mr. Glyn-Jones suggested to the witness that it would have been more in keeping with what was fair if the British Medical Association had submitted the material in the second volume of *Secret Remedies* to the Committee instead of publishing it.

The Chairman (Sir Henry Norman) said the witness must consider if he felt justified in answering for the British Medical Association.

The witness said that personally he saw nothing unfair in it, especially as all the matter was before the public in the JOURNAL, but was only rendered more accessible by the volume.

Mr. Glyn-Jones: Would it not have been fairer to have withheld it from publication until the proprietors had had an opportunity of answering before the Committee?

The Witness: That point I was never called upon to consider, but in my own opinion it was perfectly fair to publish it at the time it was published.

The Chairman: It may have been for the convenience of the Committee.

Mr. Harrison: That was certainly so. I pressed on the compilation of the second volume for the sake of putting it before the Committee.

Sir Henry Norman: Do I understand that you still maintain, in spite of all criticism, the substantial accuracy of the analyses in these two volumes?

The Witness: Yes; the perfect accuracy of a very large number and the substantial accuracy of, at any rate, the large majority of the remainder.

In reply to further questions by the Chairman, the witness reiterated his earlier statements of the limitations of analysis, and agreed with the Chairman's suggestion that it was possible for any one to add to a mixture of drugs a small quantity of vegetable substances and claim that analysis was impossible. There was nothing in the limitations of scientific analysis, if the Government decided to set up an analytical bureau, to prevent such a bureau from deciding upon the nature of medicines submitted to it. It would find some of the limitations he had referred to already, but as regards essential ingredients the limitations would be small.

THE PHARMACEUTICAL SOCIETY.

Mr. C. B. Allen, President of the Pharmaceutical Society, described the work and methods of the Pharmaceutical Society in connexion with the Poisons and Pharmacy Act. He remarked that, although the organization was a purely voluntary one, it had performed an immense volume of work, as much in the interests of public safety as for the benefit of its members. It might be supposed that the Pharmaceutical Society would be in possession of important rights and privileges in return for its earnest work, but this was not the case, and apart from certain provisions in the Insurance Act, there had been practically no State recognition of a vocation for which men undertook a laborious training.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, 1913.

SECTION OF MEDICINE.

The President is Sir William Osler, Bart., and the honorary secretaries Dr. John Cowan (Glasgow), Dr. Lovell Gulland (Edinburgh), Dr. A. R. Parsons (Dublin), and in London, Dr. A. E. Garrod, Dr. W. Pasteur (acting secretary), Dr. H. D. Rolleston, and Dr. W. Hale White.

The meetings of the Section will be held at the Royal Society of Medicine, 1, Wimpole Street, and its work will comprise (1) discussions, (2) selected papers, (3) a clinical museum, and (4) demonstrations of clinical apparatus, methods, etc. The following discussions have been arranged:

August 7th: The Clinical Aspects of Haemolysis. Reporters: Professor G. Banti (Florence) and Professor P. Vidal (Paris).

August 8th: Correlations of the Organs of Internal Secretions and their Disturbances. (Jointly with Section II, Physiology.) Reporters: Professor E. Gley (Paris), Professor Dr. Baron Alex. von Koranyi (Budapest), and Professor Dr. Frederick Kraus (Berlin). Drs. Bernard, Carnot, and Claude (Paris), Biell and Falta (Vienna), Hedou (Montpellier), Meltzer (New York), and Ferrannini (Camerino) have intimated their intention of taking part in the discussion.

August 9th: The Pathology of Heart Failure. Reporters: Professor H. Vaquez (Paris), Professor Dr. H. F. von Weuckebach (Strassburg).

August 11th: Diabetes. Reporters: Professor George Dock (St. Louis, U.S.A.) and Professor Dr. Karl von Noorden (Vienna).

August 12th: Differentiation of the Diseases included under Chronic Arthritis. Reporters: Professor L. F. Barker (Baltimore, U.S.A.) and Professor Dr. Freidr. von Müller (Munich).

The afternoon sittings will be devoted to the reading and discussion of independent papers. Among many already promised the following may be mentioned:

Treatment of leukaemia with benzol (A. von Koranyi). Treatment of pulmonary tuberculosis by artificial pneumothorax (Ch. Saugman). Insuffisances pluriglandulaires (H. Claude, Paris). Der augenblickliche Stand der Diagnosis der Pancreas-Erkrankungen (F. Wohlgenuth, Berlin). Chronic bacterial endocarditis, with a series of preparations illustrating the condition from the Pathological Museum, Mount Sinai Hospital, New York (E. Libman). The recognition of the status lymphaticus in adults (Haven Emerson, New York). Diagnosis and treatment of duodenal ulcer (Max Einhorn, New York). A modified form (?) of sporadic typhus, Brill's disease (Brill, New York).

Demonstrations of clinical cases of special interest will be held in connexion with the morning and afternoon meetings of the Section, and a strong committee has been formed to bring together the best available material for this purpose. Facilities will also be given to any member of the Section who wishes to demonstrate any new clinical apparatus or clinical method. All applications should be addressed to the Acting Secretary, Dr. W. Pasteur, 4, Chandos Street, Cavendish Square, W.

The dinner of the Medical Section will be held at the Connaught Rooms on Friday, August 8th. For information about the dinner, members of Congress are requested to apply to the Secretary of the Dinner Committee, Mr. George Bethell, 11, Chandos Street, Cavendish Square, W.

SECTION OF SURGERY.

The Surgical Section will meet under the presidency of Sir W. Watson Cheyne, Bart., F.R.S.; connected with it are the subsections of Orthopaedics, presided over by Mr. Robert Jones of Liverpool, and Anaesthetics, with Dr. Dudley Buxton in the chair.

The meetings of the principal section will take place in the large lecture theatre on the ground floor of the Imperial College of Science and Technology.

The list of set subjects for discussion are: (1) The operative treatment of malignant disease of the large intestine, excluding the rectum, introduced by Professor Bastianelli of Rome and by Professor Körte of Berlin. (2) A discussion, conjointly with the Section of Neuro-pathology, on the treatment of tumours of the brain and the indications for operation. Professor Bruns of Hanover; Professor Harvey Cushing of Harvard University; Professor von Eiselsberg of Vienna; and Dr. Howard Tooth will speak. (3) A discussion on the diagnosis and treatment of early renal and vesical tuberculosis will be held jointly with the Section of Urology. It will be introduced by Professor Leguen of Paris; by Professor Rochet of Lyons; and by Dr. Wildbolz of Berné. (4) The surgery

of the arterial system will be reported upon by Professor Matas of New Orleans and Professor Oppel of St. Petersburg. (5) Intrathoracic surgery will be considered on the last day of the Congress by Professor Sauerbruch of Zürich and Professor Tuffier.

Papers will also be read by individual members. Many have already been received, but it is noteworthy that they all come from abroad, and no English surgeons have yet offered any contribution. There seems, too, to be some ill-defined idea that the Section is a gathering of London surgeons who are inviting their colleagues from other countries. This is in no sense true. It is the surgeons of the United Kingdom who are endeavouring to make an international congress as truly representative of British surgery as is possible. The vice-presidents, the council, and the secretaries of the Section have been chosen, therefore, with a due regard to representation of surgery in England and the provinces, in Scotland, Ireland, and His Majesty's oversea dominions.

The Social Side of the Section.

The sectional work of the social side of the Congress is also in an advanced state of preparation, thanks largely to the energy of an influential Ladies' Committee under the direction of Lady Watson Cheyne. It is proposed, amongst other things, that a party of one hundred surgeons and their wives shall be shown round the University of Cambridge on Saturday, August 9th, where they will be received by Mr. Howard Marsh, the Master of Downing College, who is also Professor of Surgery in the University. By the kind permission of the Master and Warden of the Company there will be a personally-conducted party of seventy surgeons and their wives or daughters to Barbers' Hall, which owing to its position in the City is rarely visited. The hall is interesting from its historical associations, as well as its architecture and art treasures. It has remained on the same spot for at least nine hundred years, and thus represents the cradle of English surgery. No sectional dinner will be held, but this omission will be more than supplied by the offers of private hospitality which have already been received. The Hon. W. F. D. and the Lady Esther Smith have invited members of the Section to a garden party at Henley, and the Ladies' Committee will hold an afternoon reception in the Botanical Gardens.

THE SIGHT TESTS OF THE BOARD OF TRADE.

The following statement has been sent to us for publication:

We, the undersigned, are of opinion that the sight tests of the Board of Trade are not satisfactory for the following reasons:

1. The types used in the form vision test should be printed on a smooth flat surface, preferably white porcelain, and not on a roll of canvas which has to be held down by the examiner.
2. The wool test for colour blindness is not an efficient test.
3. Any lantern used for testing for colour-blindness should have means for regulating the luminosity of the lights shown.

A DEPARTMENT for the treatment of hydrophobia has just been added to the International Hygienic Research Institution in Jerusalem. Hitherto patients have had to be sent to Cairo.

THE ETHICS OF ANTIVIVISECTION.

ANTIVIVISECTIONISTS profess to act up to a higher standard of ethics than the ordinary moral law accepted by the rest of mankind. When they cannot deny that knowledge useful for the relief of man and the cure and prevention of disease has been obtained by experiments on animals, they reply that this is no justification of that method of research. "The whole question of man's rights and duties towards the helpless animals given into his dominion by the Ruler of the Universe is," Mr. Stephen Coleridge told the Royal Commission on Vivisection, "a moral question, and has nothing to do with science." By parity of reasoning it might be held that the killing of animals for food and raiment, the infliction of acute suffering on them for personal adornment, and their mutilation for various purposes that have nothing to do with their own good, are moral questions that have nothing to do with any real or supposed benefit to man. In regard to these things, however, the ordinary antivivisectionist is usually content to accept the benefits without allowing inconvenient ethical scruples to interfere with his convenience.

It is far better, Mr. Coleridge said on the same occasion, to do without physiology than to be without pity. This, if it stood alone, would be a truism; but in the mouth of the antivivisectionist it means that a sentimental pity for animals should override all active pity for suffering human beings. It is not strange, therefore, that many antivivisectionists are not only hostile to the advance of knowledge by experimental research, but are by no means remarkable for good nature and consideration for the comfort and feelings of their fellow creatures. Miss Frances Power Cobbe made the strange boast that she loved animals by nature, and her own kind only by grace. We need only glance at their literature to see how they strive to wound not only the "wicked" vivisector, but those of their own side, if they happen to differ from them on some point of detail, or seem to threaten to displace them in the eyes of the public.

A fierce light is thrown on the manner in which some of the antivivisectionists apply the ethical principles on which they profess to take their stand by the following incident.

In a letter circulated in the press and reprinted in the *Zoophilist* of September, 1912, Mr. Stephen Coleridge gave an account of a visit he had himself paid to the Physiological Institute at University College. He said that he had frequently been taunted with refusing invitations to visit laboratories and see for himself how happy are the animals therein vivisected. He had never accepted such invitations, because, he said, he regarded them as similar to the invitation of a motorist to a policeman to drive in his car and observe that he never exceeded the speed limit. He did not imagine that animals would be in visible agony when he arrived by invitation. A surprise visit, however, he regarded as similar to a police trap on a straight piece of road, and that was the test he proposed to institute at University College Laboratory. The circumstances which led Mr. Coleridge to depart from his fixed policy of declining to see things for himself are set forth as follows:

On the 18th of October, 1911, I received a letter from a reputable source complaining of the dreadful sounds of the howling of dogs in suffering that were constantly to be heard in the neighbourhood of the laboratory attached to University College in Gower Street. Having first sent others to ascertain whether these complaints were well founded, and having received confirmation of them, I determined to visit the neighbourhood myself. Accompanied by Mr. Arthur Veasy, I went to some premises behind the college, and from the windows myself heard the dreadful cries of the dogs. The pitiful howlings seemed to me to indicate that the wretched animals were enduring miseries more poignant than the mere discomfort of confinement. With the desire and intention of ascertaining personally whether or not I was mistaken, and in order to give those responsible for the laboratory the opportunity of showing me that I was wrong in attributing these mournful cries to physical pain, I went over to the college with Mr. Veasy, and, with the assistance of two courteous students, was guided to the foot of the stairs, at the top of which was the door into the laboratory.

Mr. Coleridge goes on to say:

That there might be no subsequent dispute as to why I came and what I asked, I sent up my card with the following note, a copy of which I kept:

"February 21st, 1912. Mr. Stephen Coleridge requests permission to go over the laboratory of University College, registered under the Act 39, 40 Vic., cap. 77, for experiments on living animals."

Mr. Veasy and he awaited a reply at the landing next the door, a view of which they commanded. The rest is better told in his own words.

In a very few moments there emerged a person whom I deemed to be one of the twenty-one licensed vivisectors who are attached to this laboratory, followed by four or five of his pupils. This person, a small man in a brown holland pinafore, appeared to be labouring under an access of violent excitement. I think he feared that I had come with the intention of making an entry by force, and was desperately determined to prevent it, assisted by his students, who were more stalwart and more composed than himself. He proceeded to display the manners and the temper of a vivisector. "How dare you come here, sir?" he vociferated several times, while I regarded him with amused patience. "You don't wish to show me over the laboratory?" I replied. "Certainly not!" he spluttered; "get out of this; get out!" "Would you like to know why I came?" I asked. "No," he cried; "I won't listen to you. Get out!" "By all means," I said; "I will get out, but I should like to know your name." "Starling is my name," he replied. "Ah!" said I, "I remember having the pleasure of seeing you in the witness-box in Mr. Bayliss's action."

The pleasure of a sight which recalled this incident was probably not altogether unmixed, and the "amused patience" of Mr. Coleridge during the interview on the stairs did not leave him sufficiently cool to prevent his confusing the "small man in a brown holland pinafore" with Dr. Starling, who spoke to him and who was dressed in blue serge. There the interview ended. Mr. Coleridge concludes as follows:

I make the obvious and necessary and conclusive deduction from Professor Starling's conduct throughout this transaction that he feared to admit me to the laboratory because he knew what I should find there, and because if admitted instantly I should have come away from the spectacle armed with ocular demonstration that the dreadful cries which I had heard emanated from dogs whose dolorous clamour was caused by the wounds in their bodies inflicted on them under certificate B.

Mr. Coleridge professes to be shocked at a split infinitive—perhaps because the operation is performed without an anaesthetic. We suppose, therefore, the mixture of metaphors here must be set down to excitement. One would like to have seen him leave the laboratory "armed with ocular demonstration" of dreadful cries. The sentence reminds one of Bottom's question whether Theseus would like to see the epilogue or hear the Bergamask dance. Ocular demonstration of cries, however, is the kind of proof that seems to satisfy antivivisectors. But how was it, if dreadful sounds of dogs in suffering were constantly to be heard, that Mr. Coleridge did not see them when he was actually on the threshold of the chamber of "torture"? It may be added that even if Mr. Coleridge had seen anaesthetized dogs with wounds in their bodies inflicted on them under certificate B, and had had "ocular demonstration" of cries, this would not have proved that the animals were suffering. If he would go into an operating theatre in any hospital he could scarcely fail to hear dolorous clamour from patients under the knife, who yet will tell him when they recover from the anaesthetic that they had felt nothing whatever. The "obvious and necessary and conclusive deduction" to be drawn from Professor Starling's conduct throughout the transaction, taking Mr. Coleridge's account as strictly accurate, is simply that a busy man objected to being disturbed by one who has reviled him for years and who, it was natural for him to assume, did not come with the intention of seeing impartially, but with the wish to find some semblance of justification for his unfounded charges. Can it be supposed that a man with a mind so biased as Mr. Coleridge could have gone to the laboratory with any other intention than to find fault? We say nothing of Mr. Coleridge's language further than to suggest that he might ponder in his heart the following words of a French writer: *Il est si facile d'être insolent! C'est un art qui demande peu d'étude, qu'on possède de naissance, et où les plus sots excellent, une musique qu'ils chantent d'inspiration, à livre ouvert.*

That Mr. Coleridge's description of what took place is grossly exaggerated is shown by a letter from Professor Bayliss, dated August 27th, 1912, which appeared in the *Yorkshire Post*. He says he happened to be passing

during the interview spoken of by Mr. Coleridge and heard the reason given to him why he was not shown over the laboratory. It was this: "You have done all in your power to hinder us in our work here, and you are requested to leave at once." In a further letter published in the same paper of September 2nd, Professor Bayliss says the time at which Mr. Coleridge appeared was by no means inopportune, as all the workers in the laboratory were at tea, and no experiments were being made. He goes on to say that: (1) Visitors capable of understanding what they saw would be admitted at any time without giving notice. (2) Any unprejudiced person would be welcomed. But, he asks, what would be gained by admitting people who had already made up their minds with respect to what they would see, and would see exactly what they wished to see? (3) He adds: "The falsity of Mr. Coleridge's description of University College laboratory was shown in the court of the Lord Chief Justice, and in consequence of this he had to pay damages of £2,000."

Though this may be the first time Mr. Coleridge has sought to have "ocular demonstration" of the cries of suffering animals, it is not the first time that he has endeavoured to harrow the feelings of the public by descriptions supplied by other people of the howlings of dogs supposed to be in the hands of vivisectors. In his evidence before the Royal Commission he stated that he had received a letter from some undergraduates of Keble College, Oxford, in which they said that, living directly opposite the laboratory, they heard screams of vivisected animals. Mr. Coleridge did "the obvious thing a gentleman ought to do." He wrote at once to the professor, told him the information he had received, and asked for his explanation. The answer was that the head of the laboratory gave the lie to the six gentlemen at once. Mr. Coleridge's comment is that "all he could say was that in a court of justice the six witnesses would go against the one." The Commission was not impressed by the testimony of Mr. Coleridge's six witnesses, however, and it was elicited from him that after he had received a further letter from his informant saying that the professor was a liar, he had left the matter there. "That," he said, "was a flat contradiction. It was no use carrying the matter further." We think it would have been of great use, for it would have given him another and better opportunity of doing the obvious thing a gentleman ought to do. That is to say, instead of leaving on record a story—as it stands unaltered in the reprint of his evidence published by his society in 1907—based on nothing but the imagination of some undergraduates, ignorant of science and knowing nothing of laboratories, he would have frankly withdrawn the charge and expressed his regret at having been made the medium of a false accusation. If he does not know the facts which he might have discovered by carrying the matter further, we have much pleasure in bringing them to his knowledge. The undergraduates apologized, and withdrew the statements made in their communication to Mr. Coleridge; what they heard was

not howls of dogs under the vivisector's knife, but the yelps of a litter of young puppies at play, which were kept not for experiment, but because a laboratory guard dog had borne them. Mr. Coleridge cannot divest himself of the responsibility of having by his speeches and publications contributed to bring about a state of mind which could lead a set of young men at once to assume, merely because the sounds happened to proceed from the backyard of a laboratory for physiological research, that the noise produced by a batch of puppies during their youthful gambols was in reality due to the piteous howls of dogs writhing under the vivisector's knife.

It may not be amiss to recall that on a previous occasion Mr. Coleridge made a violent attack on University College. At the annual meeting of the National Antivivisection Society held on May 1st, 1903, he fiddled the ears of the groundlings at St. James's Hall with the following detectable piece of rhetoric:

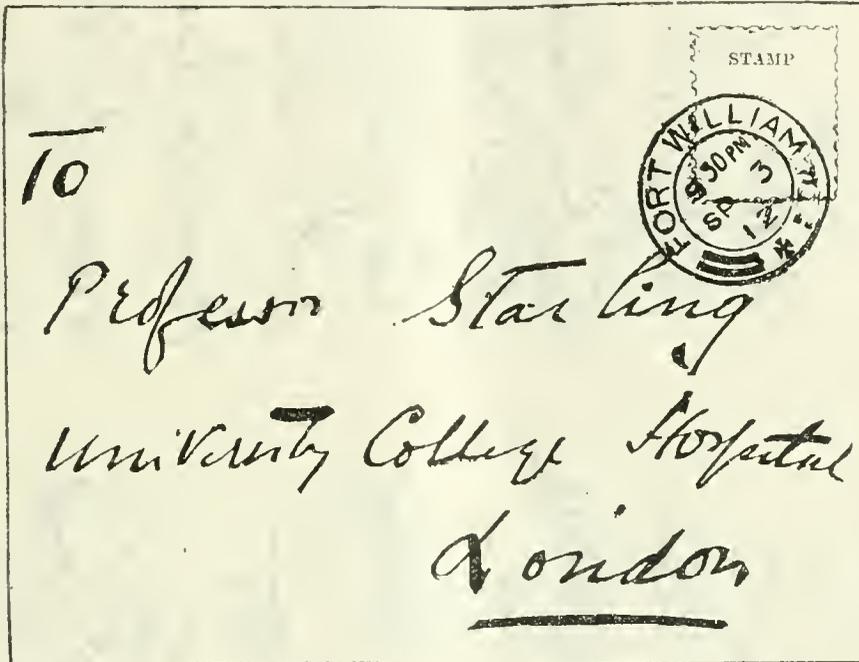

Within the walls of University College there was a laboratory licensed for vivisection, and into its dark portals there passed a never ending procession of helpless dumb creatures. Dogs, lost or stolen from their homes, where they had known nothing but love and affection, followed one another down that Via Dolorosa into a scene of nameless horror, where man degraded his race and his manhood, and brought on that University a smirch that time itself would never erase. Within the precincts of the college and close to this Pit of Tophet was a school dedicated to one of the purest and loftiest of human studies—that of the fine arts. Between this place of peace and the place of torment, the dividing wall was slight, and into the serene and silent school of the beautiful rose distinctly from the vivisectors' den the shrieks and piteous cries of the dogs in their agony. Surely in this world Heaven and Hell were never brought so near together! But the love of beauty never yet failed to keep the soul alive, and

through the Slade School students had the inarticulate sobs and moans of these wretched creatures reached the ears of those less piteous than their tormentors. Thus through him had the piteous cries reached the thousands in this hall, and he trusted they would reach a million ears through the press. There might be some few persons so hard to convince that even the shrieks heard in the Slade School might not be sufficient, and they might say that until he could produce the testimony of an eye-witness they would not believe. He had come prepared even for them.

Then Mr. Coleridge quoted the testimony of his eye-witnesses, which we will not repeat, as it had the effect of landing him in the law courts, where he was mulcted in heavy damages. But we wish to call special attention to another part of the same speech. After professing that he "desired to observe the amenities of gentlemanlike debate," he went on to say that

so certain was he of the deep and abiding humanity of the British race that he felt sure that did they know what he knew went on in these dens of infamy, they would not wait for supine legislation; they would not wait for the second readings or third readings of bills in Parliament; but they would go in their irresistible thousands; they would set free the victims from their cages; they would smash to atoms the horrible instruments of torture; and they would leave every laboratory in the kingdom a heap of ruins.

It must charitably be supposed that Mr. Coleridge was on this occasion, to use Disraeli's phrase, "intoxicated by

You will receive
the same torturing
agonies you give to
dogs.

It shows pretty well
what you do to
the poor creatures
as you are so afraid
of anyone seeing
the laboratory. I
look upon you as

the exuberance of his own verbosity." None the less, he must be held responsible for an incitement to violence and destruction of property which, addressed to the kind of audience he had gathered to hear him, might very easily have led to the perpetration of unlawful acts.

That his appeals to fanaticism might possibly lead to even more serious results is shown by a letter received by Professor Starling since the publication of Mr. Coleridge's account of his visit to the Institute of Physiology at University College. Professor Starling receives communications of the kind very frequently. The following, therefore, may be taken as a sample of the kind of feeling the vituperations of Mr. Coleridge may be capable of exciting:

[Copy.]

Argyllshire,
N.B.
September 3rd.

Sir,

Having heard that you refused admittance to The Hon. Stephen Coleridge, I write to say I consider you an absolute blackguard.

The cries from the tortured dogs are being continually complained of, and I intend to make this known to many People of Position and influence on my return to England.

I sincerely trust and confidently think and believe that your deathbed will be one of the most agonizing ever known, and that in the next world you will receive the same torturing agonies you give to dogs.

It shows pretty well what you do to the poor creatures as you are so afraid of anyone seeing the laboratory. I look upon you as an incarnate fiend and hope you may meet with your death sooner than you think.

In my opinion it is not wrong to kill a man who tortures animals as fiendishly as you do.

R.F.C. M.P. [? M.D.]

The last sentence may be taken as representing the ethics of antivivisectionism in their extreme form. The letter, which from the handwriting would seem to have been written by a woman, is signed with initials and with a description doubly underlined, which may be M.P. or M.D. Possibly the ambiguity was not unintentional. We cannot find the name of any member of Parliament with the initials "R. F. C." The letter is reproduced in facsimile by photography, and it is perhaps possible that the writer may be identified. It is, indeed, intolerable that men who are seeking to enlarge the bounds of human knowledge and to discover means of relieving human suffering should be subjected to this form of persecution. Foolish as it is, it represents a state of mind which might very well become dangerous. Possibly some of our readers may remember that some years ago an attempt was made to organize the destruction of vivisectionists by prayer. The document was published in the JOURNAL of January 23rd, 1909. The text need not be given again, but one significant passage may be quoted. The writer, M. Cowan, stated that she had thought of prayer as a means of "removing" vivisectionists. She thought first of experimenting on Dr. Starling, but, strange as such a scruple may seem, it seemed to her unfair to give such a stab in the dark without first letting it be known what was intended.

It was therefore finally decided to make earnest prayer, giving much thought to the subject, that the Almighty, if the prayer were in accord with His will, would promptly remove the man most likely to cause future suffering to innocent subjects by his experiments. About a fortnight later one of our most distinguished medical scientists dropped, and the newspapers were lamenting the loss to science of this vivisectionist and the discoveries he was just about to make.

We do not know who this victim of homicidal prayer may have been, but it obviously was not Professor Starling. The idea was not original, for it is recorded in the life of Dr. Anna Kingsford that she used to boast of the vivisectionists whom she had done to death by the power of her will. The poor lady had to confess that she had found Pasteur too tough a subject, and we have not heard of any special mortality among vivisectionists as a result of M. Cowan's prayer. This kind of folly can only excite a smile, but the letter here reproduced in facsimile is in a different category, for its last sentence must mean, if it means anything, that the assassination of a vivisectionist would, according to the code of ethics held by this particular follower of Mr. Coleridge, be a justifiable act. Such an expression of opinion by a person who conceals her name and address has no importance except as evidence of the state of mind which may be produced by the inflammatory appeals

of antivivisection agitators. It may safely be assumed that the people who read and are moved by these appeals do not make any investigation into the truth of the allegations upon which such appeals rest, and it is therefore all the more incumbent on those who make such allegations to make sure that their facts are correct, and that the deductions are "obvious and conclusive and necessary," and not wholly erroneous and superfluous.

Mr. Coleridge dissociated himself from M. Cowan's prayer league; will he also publicly express his disapproval of R. F. C.'s code of ethics? It may seem absurd to take serious notice of such threats as the letter contains, but we cannot forget that a Belgian newspaper once published a direct incitement to murder Pasteur. The terms of the letter would appear to show the effect which Mr. Coleridge's rhetorical appeals may have on an excitable mind, and that we are afflicted at the present time with many persons who are prepared to translate hasty words into rash deeds there is abundant evidence. We invite Mr. Coleridge to consider whether he would not be well advised in future first of all to ascertain the facts, and then to state them without exaggeration. Should he and other antivivisectionists then find that they do not supply material for prolonging their agitation, that will be the fault of the facts.

It may be asked, Was Mr. Coleridge, then, mistaken in thinking that he heard the howls of dogs? Not necessarily. But he was certainly mistaken in believing that they proceeded from animals undergoing "torture." We have ourselves heard the most appalling shrieks emanating—if we may borrow a word from Mr. Coleridge's elegant vocabulary—from a terrier frenzied with the lust of blood owing to the neighbourhood of some mice he could not reach. Most workers in laboratories within the precincts of which dogs are allowed to ramble have had similar experiences. We recommend Mr. Coleridge not to rush into print again with descriptions of "dolorous clamour" caused by wounds inflicted under certificate B till he has had "ocular demonstration" that the dreadful cries do not emanate from untouched dogs protesting that they are debarred from following the instinct of "Nature red in tooth and claw."

ONE HUNDRED YEARS AGO.

TYPHUS FEVER.

IN May, 1813, typhus fever was much in men's minds. As has so often happened, it came not alone, but was accompanied by famine and war; these three grim forms stood menacingly over Central Europe in the spring months of the year. In 1812 there had been the rush of a great wave of armed men from west to east across the Continent. More than half a million soldiers, constituting *la grande armée* of Napoleon, poured over the territory held by the Confederation of the Rhine, and, gathering numbers, flowed on with slackening speed into Russia, to break against the walls of Moscow and to stream back again over Poland and Prussia from east to west in feeble, shattered wavelets. It was General Typhus, allied with Generals Famine and Frost, who had come to Russia's aid, had scattered these invading thousands, and had sent them back as bands of disease-stricken stragglers, dying by hundreds on the way, across Germany, and carrying the pestilence wherever they went. In May, 1813, a second great eastward flow was in progress; it was now France with some Westphalian, Bavarian, and Saxon contingents, which was opposed to Russia in alliance with Prussia and later with Austria too, and this wave broke into spray in the terrible three days' battle of Leipzig—without exaggeration termed the "Battle of the Nations"—in which there was a total loss of not less than 120,000 men (October 16th to 19th, 1813). To quote from the *Cambridge Modern History* (vol. ix, p. 541), Napoleon "brought back to France only about 70,000 men, of whom 30,000 soon afterwards fell victims to typhus, and many others wasted away; within little more than a year two French armies, amounting together to nearly a million of men, had perished." Exactly how much of this mortality and disablement was due to typhus fever cannot, of course, be determined, but there can be no doubt at all that both in the campaign of 1812 and in that of 1813 this malady was terribly fatal.

To the medical men of the beginning of the nineteenth

century typhus fever was no unknown or little known disease; under the names of nervous fever, spotted fever, exanthematic typhus, putrid fever, and febris pestilens, it was always in the thoughts of the doctors, and the vernacular terms *jail, hospital, ship, and camp fever* tell only too plainly something of the places in which it wrought its devastating effects. We hear nothing nowadays of "black assizes," but our ancestors were not so blissfully ignorant. Many of us at the present time have never met with a patient suffering from typhus fever; the writer of this article has only seen one case of it, and that was thirty years ago this May when he was a medical student in his final term of study. Its name appears but seldom in our medical journals. But to the medical practitioners of the time the typhus epidemics of 1812-13 were as fresh reminders of the unmanageable nature of this dire scourge, and a new flow of books and articles on the subject came from the medical press of Germany, France, and Great Britain during the years which immediately followed the Moscow campaign and the battles round Leipzig. For instance, Professor Parrot of Dorpat dipped his pen in ink and wrote his paper, *Ueber das im jetzigen Kriege entstandene typhöse Fieber und ein sehr einfaches Heilmittel desselben*; and this contribution to the etiology and treatment of *Nervenfieber* (as he preferred to call it) appeared in Hufeland and Himly's *Journal der practischen Heilkunde* for May, 1813. It is, indeed, the principal article in the May monthly instalment of that widely read periodical, occupying 72 out of the 128 pages of which it consists.

Dorpat, it is true, lay to the north of the line of advance of the *grande armée* through Russia upon Moscow, but it was well within the zone of the typhus fever epidemic which accompanied and spread out on all sides from the path of retreat of the broken and dispirited masses of men struggling through snow and storm to regain the banks of the Niemen. Professor Parrot had abundant opportunity of observing cases of typhus and of testing his remedy, which was acetic acid or vinegar. He speaks very highly of its efficacy, and in a later number of Hufeland's *Journal* (July, 1813) he is able to supplement his earlier report with further evidence furnished by an independent writer. As for the rest of his article, the part which deals with etiology and with what he calls his "fundamental hypothesis," it has fallen quite dumb to us of the twentieth century; its terminology is almost obsolete, and the ideas which underlie it have passed away. The illustrative cases, which meant so much to Parrot for the support which they gave to his fundamental hypothesis, are interesting to us for other reasons. The paper was no doubt eagerly scanned by the readers of Hufeland's *Journal* who had typhus cases to treat, and there were many of them we may be sure; but to us it stands simply as an indication of the severity of the epidemic of 1812-13, and as a grim reminder of the medical aspects of Napoleon's march upon Moscow.

Now, a hundred years later, Dr. Achilles Rose¹ of New York, has taken pains to collect into one volume the contents of many scattered and almost inaccessible pamphlets and books bearing upon the medical details of the campaign of 1812. He has worked the historical into the medical in a way that makes the work very interesting and almost absorbing reading; and from beginning to end we feel that it was disease more than all the other opponents of the march which Napoleon had to fear. Dr. Rose utilizes books and dissertations published soon after the war, as well as those journals and diaries which have only recently become available, in order to tell his story with effect and graphic accuracy. Among the former he relies largely upon Dr. Krantz's *Bemerkungen über den Gang der Krankheiten welche in der Königl. preuss. Armee vom Ausbruche des Krieges im Jahr 1812 bis zu Ende Waffenstillstandes (im Aug) 1813 geherrscht haben*, published in 1817, and upon Dr. Ch. Jo. de Scherer's dissertation (Tübingen, 1820) *Historia morborum, qui in expeditione contra Russiam anno MDCCCXII facta legiones Württembergicas invaserunt*, etc. Among the latter he draws upon the works of Bleibtren (1908), Johann von Boreke (1888), Heinrich von Brandt (1870), Carpon (1902), Chnquet (1912), Wilhelm Ebstein (1902),

Paul Holzhausen (1912), Karl Schehl (1912), and von Yelin (1911). It is now possible from these various sources to reconstruct, with some degree of accuracy and also with an appalling sense of horror, the medical history of the events of 1812 and of the sequel to them in 1813.

Napoleon's great army, containing, let it not be forgotten, many thousands of Westphalians and Württembergers and of other nationalities which were not French, was in reality annihilated before it reached Russia. These are Rose's striking words, and he is able to furnish facts which show his statement to be not unfounded: forced marches over the sandy plains of Poland and Lithuania, the drinking of stagnant water, dysentery, immoderate use of spirits, insufficient food, and the absence of medical supplies and of proper hospitals, all tended to sap the soldier's strength and make him unfit for the campaign in Russia itself. Further—and this has a bearing upon recent work on the causation of typhus fever²—the army "found Prussia, and especially Poland, ugly, dirty, miserable, all the houses were full of dirt and vermin, domestic animals of all kinds were the intimate *syntrophoi* of the peasants in their living rooms." In Russia medical conditions became rapidly worse; each battle added to the misery of the troops, and served to demonstrate the inefficiency and inadequacy of the hospital arrangements. Already at Wiasma there were numerous cases of typhus; but when the long retreat from Moscow began then that dread scourge fell upon the wretched, starved, half-frozen soldiery and swept them off in thousands. Dr. Rose gives details from contemporary narratives, almost too horrible to be read calmly, of the frightful ravages of typhus fever. The track of the army became infected, so that whoso passed along it afterwards caught the contagion. Thus, "the first East Prussian regiment of infantry, when it came to the Vistula, had not a single case of typhus in it, while after a march of fourteen miles on the highway which the French had passed before them there were fifteen to twenty men sick in every company, every tenth or even every seventh man." Along with the typhus came epidemic ophthalmia. "All the hospitals between the Vistula and Berlin . . . were thoroughly infected and thus transformed into regular pest-houses, exhaling perdition to every one who entered, the physicians and attendants included." A typhus patient's best chance was to be treated on the march, a fact which excited surprise then but need not do so now. Hospital treatment consisted in the exclusion of fresh air and the hourly administration of medicines!

It is only within recent years that some light has been thrown on the transmission of the infection of typhus fever, but the causal organism remains unknown. In fact we have in this fever the curious phenomenon of a malady which has almost entirely disappeared in many parts of the world without its cause having been discovered. But there seems to be now no doubt that the natural agent of transmission of typhus fever is the common body louse; and, further, there is evidence to show that the second generation of progeny of infected lice are able to confer a certain degree of immunity (*vide* annotation in this *JOURNAL* for August 24th, 1912, p. 452).

Now, if body lice be indeed the carriers, there is abundant evidence in Dr. Rose's book and in other articles that the conditions both in 1812 and 1813 were most favourable for their activities. Take this passage from Rose's work (pp. 102-103):

And the vermin! Carpon, a surgeon-major of the grand army, in describing the days of Wilna . . . speaks on this subject. It is revolting. Strange to say, it is hardly ever mentioned in the medical history of wars, although every one who has been in the field is quite familiar with it. At last I have found—in Holzhausen's book—a description of the most revolting lice plague (phthiriasis) from which, according to his valet, Constant, even the emperor was not exempted. As a matter of course under the circumstances—impossibility of bodily cleanliness—this vermin developed in a way which baffles description. Suckow, a Württembergian first lieutenant, speaks of it as causing intolerable distress, disturbing the sleep at the camp fire. Johann von Boreke became alarmed when he discovered that his whole body was eaten up by these insects. A French colonel relates that in scratching himself he tore a piece of flesh from the neck, but that the pain caused by this wound produced a sensation of relief.

Again, when the Prussian troops reached their own

¹ *Napoleon's Campaign in Russia, Anno 1812: Medico-Historical.* By Dr. A. Rose. Published by the Author. New York, 1913. (Pp. 212.)

² *BRITISH MEDICAL JOURNAL*, 1912, ii, p. 451.

land in 1813 one of their first occupations was to remove from their faces the mask of dirt which had accumulated there; and their fellow countrymen of all ranks made a good wash the first part of their hospitality. Here is another short extract from Dr. Rose's book:

Sergeant Schoebel, together with a comrade, was quartered in the house of an honest tailor, who, seeing how the soldiers were covered with lice, made them undress and, while the wife boiled the undergarments, the tailor ironed the outer clothing with a hot iron.

It seems strange that a hundred years have had to pass before the carrier of the contagion of typhus fever has been identified as the body louse; but, assuredly, the annals of the wars of 1812-13 furnish abundant evidence that there then existed no lack of opportunities for this etiological factor coming into action.

ROYAL MEDICAL BENEVOLENT FUND.

At the April meeting twenty-one cases were considered, and grants amounting to £200 voted to eighteen of the applicants. Appended is an abstract of the cases relieved:

1. Widow, aged 57, of L.R.C.P. Edin. Only income about 10s. a week from lodgers; children unable to help. Relieved three times, £34. Voted £10.
2. Widow, aged 51, of M.B., C.M. Glasg. Since husband's death, ten years ago, has been supported by a son, but asks for a little help to relieve him. Voted £5.
3. Daughter, aged 45, of late M.R.C.S. Was a district nurse for many years, but had to give up her post owing to feeble health, and now tries to support herself by letting rooms. Relieved twice, £20. Voted £10.
4. Widow, aged 39, of L.R.C.P., L.R.C.S. Edin. Lost her husband about twelve months ago, after several years' illness, and is now suffering from a grave internal complaint. No income; three children, the eldest only 16. Voted £24.
5. Widow, aged 48, of L.R.C.P., L.R.C.S. Edin. Health too feeble to admit of occupation, and is allowed £1 a month by the Working Ladies' Guild. Is a candidate for a pension from the British Home and Hospital for Incurables. One child dependent and the others unable to help. Relieved seventeen times, £195. Voted £12.
6. Widow, aged 43, of M.B., C.M. Aberd. Supplements an income of a few shillings a week by taking boarders, but having four young children finds great difficulty in meeting her unavoidable expenses. Relieved twice, £20. Voted £10.
7. Daughter, aged 66, of late M.R.C.S. Is mentally feeble, and for many years has been practically dependent on this Fund and a small pension given by another society. Relieved fourteen times, £144. Voted £12.
8. Daughter, aged 42, of late L.R.C.P., L.R.C.S. Edin. Endeavours to support herself by nursing but finds great difficulty in obtaining engagements and has recently been incapacitated by illness. Relieved eight times, £61. Voted £5.
9. Widow, aged 50, of M.B. Aberd. After husband's death supported herself by nursing but broke down in health and has now for the last few years been quite incapacitated. No income and dependent on a small weekly allowance from a sister and a little help from a married son. Relieved five times, £49. Voted £12.
10. Widow, aged 46, of M.R.C.S. Quite unprovided for at husband's death a few years ago from a new growth, and has been obliged to give up a situation as mother's help on account of uncertain health. Is practically dependent on a stepson whose earnings are small. Relieved four times, £48. Voted £12.
11. Widow, aged 64, of M.R.C.S. Income less than 5s. a week and is deprived for the present of the help given by two of her children. Relieved three times, £36. Voted £12.
12. Daughter, aged 51, of late M.R.C.S. Used to be a governess but has become nearly blind, and is quite unable to maintain herself. Relieved twice, £24. Voted £12.
13. M.D. Aberd., aged 60. Has suffered for several years from a spinal complaint and is now practically bedridden. Receives help from other charitable societies, but having three children dependent is obliged to seek further assistance. Relieved three times, £33. Voted £10.
14. Widow, aged 68, of L.R.C.P., L.R.C.S. Edin. Only income a small pension from a charitable society and is quite incapacitated by rheumatoid arthritis. No children. Relieved three times, £29. Voted £10.
15. Daughter, aged 60, of late M.D. Is quite helpless owing to an advanced nervous disease and is practically dependent on this fund and slight help given by friends. Relieved four times, £44. Voted £18.
16. Daughter, aged 67, of late M.R.C.S. No income, and only able to occasionally earn a few shillings a week. Relieved once, £12. Voted £12.
17. Wife, aged 43, of L.R.C.P., L.R.C.S. Edin. Since the mental breakdown of her husband five years ago has endeavoured to support herself by taking boarders; two sons, aged 20 and 17, the elder barely self supporting, and the younger an apprentice not yet earning anything. Relieved three times, £48. Voted £2, and case to be reconsidered next month.

18. Daughter, aged 70, of late M.R.C.S. At father's death many years ago was fairly provided for, but lost some of her capital through the failure of a bank and the rest in the endeavour to establish a boarding house; now dependent on this fund and a sister who can ill afford to help. Relieved three times, £36. Voted £12.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole Street, London, W.

LITERARY NOTES.

STAFF-SURGEON-GENERAL MORI, of the Japanese army, has translated Goethe's *Faust* into Japanese.

Messrs. Baillière, Tindall, and Cox will publish a new edition of Castellani and Chalmers's *Tropical Medicine*, which embodies the most recent researches. The book has been revised throughout, and special attention has been bestowed on many of the chapters—notably those on protozoa, fungi, skin affections, pellagra, enteric fever, and trypanosomiasis. About 250 new illustrations have been introduced, while some 500 pages have been added to the text.

The May issue of the *Arena* opens with two articles answering from differing standpoints the question: "Are views on women's suffrage inculcated at girls' schools and colleges?" The writers are Mrs. Elizabeth Sloan Chesser, M.B., and Mrs. Frederick Harrison. The former sums up her view in the concluding sentences of her article:

If suffrage is spreading in the schools, let us welcome the fact as a sign that the modern girl is developing an interest in the affairs of the nation and the empire which will in no way diminish her zest for tennis or for her *joie de vivre*.

There are not a few golf players, however, who might say that it tends seriously to diminish their opportunities of playing their favourite game. On the other hand, Mrs. Harrison holds that it cannot be the purpose of education to turn its pupil into a party politician, and that the teachers are seldom well prepared to treat of the Feminist movement. She adds that the cultivation of a sense of humour would greatly improve the situation. "It is not for school girls to make revolutions!" Professor Strong contributes an amusing account of the early days of the University of Liverpool, and of the struggles of that institution to obtain a permanent footing. Another university dealt with is that of El-Azahr, the great Mohammedan university in Cairo. The author makes an interesting comparison between that institution and Oxford; both universities began as semi-religious foundations, and have carried their atmosphere of the Middle Ages with them down to the present time. We take this opportunity of again expressing our appreciation of the excellence of our contemporary. The skill with which the literary fare is varied to suit the intellectual palates of different readers reflects the highest credit on the editor, Mr. Horace W. Wyatt.

In the *Married Life of Queen Victoria*, published recently by Eveleigh Nash, the author, Clare Jerrold, states that at the birth of the Princess Royal (the late Empress Frederick), Locock, who officiated on that auspicious occasion, received a fee of a thousand pounds; probably the other physicians present—Blagden and Sir James Clark—were paid on the same scale. A comic poet of the period celebrated the services of those learned men in the following verse:

Doctors Locock, Blagden, Clark,
They made the great discovery,
And having brought the goods to town,
Were paid upon delivery.

It was also announced—not, it need hardly be said, officially—that Prince Albert intended to present Locock with a piece of plate bearing the inscription, "To the great deliverer of his country."

In *Paris Medical* of March 15th Dr. Julien Rosheim gives an account of a French medical journal of the seventeenth century. It was entitled *Le Temple d'Esculape*, and was intended to chronicle new discoveries in medicine. The first number was published in Paris in January, 1680, the editor being Nicolas de Bligny, a well-known surgeon of the time. He

explains the name and the object of his periodical in the following announcement :

Nothing has more served to render medicine dogmatic than the tablets formerly placed in the pagan temples where Esculapius was adored as the god of medicine because these tablets contained not only the names of those who had been cured by extraordinary remedies, but also an exact description of the remedies and of the use that had been made of them. For the same reason it is hoped that the new discoveries made in that science being recorded and published according to the design of the author will make the good fortune of individuals available for others and furnish for the future more certain principles and more infallible rules for the art of preserving life.

He describes the nature of the contents of the periodical more in detail as follows :

The reader will always find in these numbers the discoveries made at the opening and dissection of bodies, the extraordinary features that may be observed in common diseases, the signs and features of those which are newly identified, the histories and illustrations of monsters and other prodigies of nature, descriptions of remedies and newly-invented instruments which facilitate the cure of diseases, new chemical experiments, remarkable things seen in the art of healing, the reasonings of scientific men on all these various subjects, new systems of physics and generally everything relating to the knowledge of natural bodies.

Blégné must have been a man of considerable boldness since his very first article was on the causes and effects of ecstasy as to which he says that, although theologians looked upon the condition as an effect of grace, it may also sometimes have natural causes. The case was an ordinary one of apparent death. Some of the articles boom remedies of which the nature is not disclosed, together with the names of physicians who used them successfully. It would almost seem, therefore, that the gentle art of palming off on the innocent reader paid advertisements as original contributions to science was not unknown in the reign of the Sun King. Reviews of books are also among the contents of the *Temple d'Esculape*, and the editor did not spare the rod. For instance, he says of a certain compendium of medicine :

Those who love good books well enough to be provided with them will easily be able to dispense with this one because it contains hardly anything which cannot be found elsewhere.

—a criticism which could be applied to much literature of the present day. There are also prescriptions which show that John of Gaddesden's distinction between medicine for the rich and medicine for the poor still existed. Thus we have a sudorific for the rich and one for the poor, a cordial for the rich and one for the poor, and so on. The periodical seems to have been well received, for from a monthly it was transformed into a fortnightly from its second number. By the end of 1680 it had changed its title to *Nouveaux journalières concernant les sciences et les arts qui font partie de la médecine*, and became a weekly. As to its subsequent fate we are left in the dark.

In the February number of the *Chemical World* Sir William A. Tilden states that three letters in the handwriting of Sir Humphry Davy have recently come into his possession. Two of these are addressed to Professor W. T. Brande, who in 1813 succeeded Davy as Professor of Chemistry in the Royal Institution. These letters were written during Davy's travels on the Continent in 1818. The first, dated June 26th, is from Vienna, and conveys Davy's congratulations to Brande on his approaching marriage. The second letter supplies a few facts of biographical importance which help to fill a lacuna in John Davy's life of his famous brother. In the journey to which the letter relates Davy, who was accompanied by Lady Davy, passed through Flanders, ascended the Rhine, crossed Germany to Ratisbon, and passing down the Danube reached Vienna about June 13th. After visiting Venice they made their way over the Apennines to Rome, and afterwards to Naples, where they began experiments on the unrolling of the Herculaneum papyri. The letter is dated Idría, April 23rd, 1818. Davy writes :

Since I wrote to you at Vienna we have made a very long journey. I have visited the most interesting parts of Hungary, Styria, Saltzburg, and Carinthia, and have seen some mountain

scenery quite as worthy of admiration as any I ever saw in the Swiss Alps. I have lived amongst the mountaineers purer and more uncorrupted than even the Swiss. We have had delightful weather and have had full enjoyments of a summer fine—but not sultry, in districts where without fine weather there could have been but little pleasure.

I will not write to you a geological letter or describe to you the great calcareous mountain chain that runs from Kermond in Hungary to Berchtesgaden in Bavaria and to the centre of Carniola with its belts of Breccia, and its intersections of Shist and its central column of Granite—I will not tire you with a page that might claim a place in the transactions of the plumb pudding stone Society; but I will give you a line on the *quicksilver mines* which I came here to see. The formation is in Bituminous Shist which sometimes emits inflammable air and which alternates with limestone like the Derbyshire. I have this day been down 1,120 feet and returned without being salivated. I pity the poor workmen, who all lose their teeth in a very short time. The veins of cinnabar are very beautiful and one I saw nearly a foot in thickness. My Wife went down with me and visited the whole mine which is rather a feat to be talked of for a lady.—I found a good deal of inflammable air Carb. Hyd. in the great salt mine at Halstadt. The salt is like the quicksilver here in Bituminous Shist.—I taught them the use of the lamp, which notwithstanding the science of their imperial proprietor they were still unacquainted with. A good many men had been burnt a few months ago. The inflammable air is found in largest quantities where the *blue salt* is. I have been again searching in vain for the cause of this extraordinary colour.

I am now in the *Proteus Country*, and I hope to send Sir Everard some alive. I go to the caverns where they are found the day after to-morrow.

Sir William Tilden points out that the "*Proteus country*" here mentioned is in Carniola and Carinthia, where the subterranean waters occurring in some of the caves of that district are inhabited by the curious amphibian, the *Proteus anguinus*, which seems to have interested Davy very much. One of the divisions of his *Consolations in Travel* is headed, "The Proteus or Immortality." The "Sir Everard" mentioned in the letter is Sir Everard Home.

In the JOURNAL of December 21st and 28th, 1912, reference was made to the powers formerly possessed by bishops of granting licences for the practice of medicine. We regret that by an oversight we omitted to quote an interesting document sent us a considerable time ago by Dr. James Griffin of Banbury. It is a diploma from the Archbishop of Canterbury granted to an ancestor of his to practise at Deddington some six miles from Banbury. It may be mentioned that members of the family have been in practice in the county of Oxford since 1600. The diploma was granted by the Archbishop to William Griffin of Deddington on August 3rd, 1734. Our readers may be interested to see the text of the document :

WILLIAM by Divine providence Archbishop of Canterbury Primate of all England and Metropolitan to our beloved in Christ WILLIAM GRIFFIN of Deddington in the County of Oxon and of our province of Canterbury Health and Grace WHEREAS we have been credibly informed that you have for some time past been conversant in the practice of Physick and Surgery and by God's assistance have cured many who have been desperately sick and wounded and have received a laudable Testimonial from several practitioners of your experience fidelity diligence and industry in performing the cures which you have undertaken in these arts of Physick and Surgery We do for the causes aforesaid and others justly moving us in this behalf as far as in us lyes and we can by the Statutes of this Realm and not otherwise nor in any other manner admit and approve of you and do by these presents give and grant to you our Licence (as long as you shall behave yourself well and laudably) to practice the said Arts of Physick and Surgery in and through our whole Province of Canterbury the places in the Act of Parliament mentioned being excepted you having first taken the Oath of fidelity and allegiance to his Majesty King George and of renouncing all Foreign Jurisdiction power authority and superiority according to an Act of Parliament of this Kingdom made and provided in this behalf IN WITNESS whereof We have caused the Seal which we use in this behalf to be hereunto put this Third . . . day of August—in the year of our Lord one thousand Seven hundred thirty four and in the Nineteenth year of our Translation.

(signed) JOHN HAYNES Register.

Attached to the diploma is a seal bearing the archiepiscopal arms and the inscription, "The seal of the Vicar General to His Grace of Canterbury." The document is stamped to the amount of fifteen shillings.

British Medical Journal.

SATURDAY, MAY 3RD, 1913.

THE ANTIVIVISECTOR AT LARGE.

For some years one of the antivivisection societies has maintained in Piccadilly, nearly opposite Burlington House, where so many scientific societies have their homes, a shop for the purpose of advancing the propaganda in which it is engaged by an appeal to the eye of the passer-by.

In the window were displayed models, pictures, and literature—one of the models purporting to represent a dog gagged and bound to a board for vivisection without anything to suggest the use of an anaesthetic; one of the drawings showed a large saw, such as might be used for cutting up logs; and the literature included examples of the class usually circulated by the opponents of the experimental method in physiology and pathology. The exhibition in the shop window was provocative and misleading, more especially owing to the absence of any suggestion of the use of anaesthetics. It provoked Dr. Saleeby, a graduate in medicine of the University of Edinburgh and a journalist of long experience, to write a denunciation, and the editor of the *Pall Mall Gazette* had the courage to publish it. The denunciation was strongly worded. The plaintiff in her opening statement said (according to the report in the *Times*) that Dr. Saleeby had not said that she had made a mistake, or that she might have been carried away by her enthusiasm for the cause, but had emphasized the charge that she had carried on a systematic, carefully-thought-out campaign of falsehood or deliberate suppression of the truth, and that she had shown the greatest audacity in the attempt to keep the antivivisectionist society alive. The verdict of a special jury rendered in the Court of King's Bench has established that the denunciation was not stronger than the circumstances could be held to justify.

That it required no little courage to publish the article is sufficiently shown by the fact that the case occupied nearly all the working hours of the court for over a fortnight, and any one who has any experience of the law can form some idea of the financial risk run in respect of costs alone, to say nothing of damages. Antivivisectionists, though critics by profession, have before now shown themselves very sensitive to criticism, and this *JOURNAL* some years ago had to defend an action for libel brought by the editor of another review which devoted much space to this propaganda. That case fortunately terminated in a few hours, and the verdict was for the defendants; but the case which the *Pall Mall Gazette* has recently had to defend dragged on day after day, and, though it terminated by the finding of a similar verdict, the expenditure must have mounted up to a very considerable total.

The judge paid the plaintiff a high compliment on the forensic ability with which she had conducted her own case. The questions he left to the jury were, first, whether the plea of justification advanced by Dr. Saleeby and the *Pall Mall Gazette* was substantially proved: and, secondly, if that plea failed, were they satisfied that the comment was fair and bona fide, and would the jury, had they been antivivisectionists themselves, have carried on the campaign as it had been carried on by the plaintiff? The jury after a short absence returned a verdict for the defendants, in which the judge said he entirely concurred.

The long-drawn-out proceedings in this case have been very fully reported in the daily press, and it may therefore be hoped that they will have the effect of enlightening the public mind as to the real character of the methods pursued by certain leaders of this agitation. The general line the plaintiff took was that experiments on animals were useless, and her contention was supported by such statements as that Harvey had embodied and put in order the discoveries of others who had not experimented by way of vivisection; that the germ associated with a disease was not its cause, but a symptom: that the use of diphtheria antitoxin was followed by an increase in the number of cases of paralysis; and that plague inoculation had increased plague, and was responsible for six and a half million deaths in India. This last statement must have been a blunder of the plaintiff or her informant, but that it should have been for one moment believed is an instance of the almost incredible readiness with which an assertion to the disadvantage of the experimental method is prone to be accepted by those engaged in this agitation. The plaintiff, moreover, maintained to the end that though the six and a half million persons had not been inoculated, yet plague had been spread through this inoculation, so that instead of lasting seven months, which she said was the normal period of an outbreak of plague, it had lasted twelve years.

Mr. Stephen Coleridge, who seems always anxious to convince the public that he is the *preux chevalier* of the agitation against the application to physiology and pathology of the experimental method which has been so fruitful in advancing other sciences, hastened, as soon as the trial was over, to disclaim for his society that it had ever been associated in any way with any of the issues involved, and to announce that its policy in Parliament and elsewhere would not be "altered or modified in any manner whatever in consequence of this action." Nevertheless, it might be well that he should seriously reflect on the possible results of some of the methods by which his policy is pursued. He has allowed himself on at least one occasion to invite the British race, or those among it who accept him as a guide, not to wait for legislation, but to go in their irresistible thousands and leave every laboratory in the kingdom a heap of ruins. As is shown by the letter published elsewhere (p. 952), another utterance of his so worked upon the mind of one of his admirers as to induce an anonymous letter to be addressed to a physiologist of eminence in this country expressing the confident hope that his death-bed would be agonizing, and that he would be tortured in the next world, and the opinion that it would not be wrong to hasten his exit from this. Mr. Coleridge no doubt would be careful before wrecking the laboratory to afford the professor and his assistants an opportunity to make good their escape; there is just a risk, however, that others might not be so humanely considerate.

QUACKERY IN LONDON IN THE EIGHTEENTH CENTURY.

LADY MARY WORTLEY MONTAGU seems to have regarded her fellow countrymen as peculiarly susceptible to the lures of the quack. Writing in 1748, she says: "I find tar water has succeeded to Ward's drop: it is possible by this time that some other quackery has taken the place of that; the English are easier than any other nation infatuated by the prospect of universal medicines: nor is there any country in the world where the doctors raise such immense fortunes. I attribute it to the fund of credulity which is in all mankind." She adds the shrewd remark: "We have no longer faith in miracles and reliques, and therefore, with the same fury run after receipts and physicians; the same money which three hundred years ago was given for the health of the soul, is now given for the health of the body, and by the same sort of people, women and half-witted men: in the country where they have shrines and images quacks are despised, and monks and confessors find their account in managing the fear and hope which rule the actions of the multitude." It is quite probable that even at the present day the nostrum vendor does not find so good a market for his wares in countries where faith in miracles is prevalent as in those where secret remedies are regarded as more potent than relics. The superstitions are to a large extent incompatible. That the Englishman of Lady Mary's day was more the slave of quackery than other men is probable enough, for the intelligent citizen of the United States did not then exist. There is ample evidence that charlatanism of every kind was rife in this country, especially in London.

In the eighteenth century there was no accepted code of medical ethics, and we read of physicians whose names live in medical history doing things which the General Medical Council would now treat as infamous conduct in a professional respect. If these things were done in the green tree, it may easily be guessed what was done in the dry. Indeed, except the possession of a diploma—and even that was not absolutely necessary—there was little to distinguish the regular doctor from the quack. Smollett, who was a member of the medical profession, though his irritable temper did not make for success, has much to say of the arts by which physicians sought to make themselves known in his day. He also gives, in *Ferdinand Count Fathom*, a vivid picture of the contemporary quack. When that ingenious blackguard found all his attempts to pose as a man of fashion fail, he "wisely came to the resolution of descending one step in the degrees of life, and of taking upon him the title of physician, under which he did not despair of insinuating himself into the pockets of his patient and into the secrets of private families so as to acquire a comfortable share of practice, or captivate the heart of some heiress or rich widow whose fortune would at once render him independent and happy." After acquiring a smattering of medical lore from books he determined to make Tunbridge Wells his first scene of action. On arriving there he went to the shop of an apothecary and wrote a prescription, which he desired to be made up forthwith. While the physic was being compounded he discoursed on the virtues of the Tunbridge water and on medicine in general, impressing the apothecary so much that he spoke of the new oracle of medicine to every family in the town. In the meantime Fathom did his best to push himself. He was not at first well received by the ladies, but at

last he found his chance. A young lady crossed in love was seized with a nervous attack when her ordinary physician happened to be out of the way. Fathom was called in and by good luck succeeded in curing the patient. When the season at the Wells came to an end he repaired to London, where he bought an old chariot which he had repainted, and hired a footman whom he clothed in laced livery. Fathom found that the field was wholly occupied by a few practitioners who, having reached the height of reputation, were no longer obliged to cultivate the arts by which they rose, while the rest of the business was parcelled out into small enclosures occupied by different groups, each composed of a waiting woman, nurse, apothecary, surgeon and physician, and sometimes a midwife, who all played into each other's hands. Fathom took lodgings over an apothecary's shop, and advertised that every day at a certain time and place he would give advice to the poor for nothing, hoping that some lucky cure might bring him fame and patients. In the meantime his chariot rolled during the whole forenoon through all the most frequented streets, and at the usual hour he never failed to put in an appearance at the medical coffee house, where he mingled freely with the company there. "The other means used to force a trade, such as ordering himself to be called from church, alarming the neighbourhood with knocking at his door at night, receiving sudden messages in places of resort, and inserting his cures by way of news in the daily papers, had been so overdone that they had lost their effect on the public." Fathom therefore decided to wait till he should have acquired interest enough to erect a hospital by the voluntary subscriptions of his friends—a method which had paved the way to success for many doctors. But even in the middle of the eighteenth century it "was so overdone that almost every street was furnished with one of these so-called charities." A "lucky miscarriage," brought about by means of a remedy so violent in its action that it nearly killed the patient, made him talked about, and he neglected no method of advertisement to keep himself before the footlights. His practice increased so rapidly that he seemed to be on the high road to fortune, when the seduction of a patient, followed by the death of a nobleman whom he had ordered to be bled, brought about his ruin, and he was finally laid by the heels in prison. There we may leave him.

The various devices for gaining practice mentioned by Smollett were used by doctors and quacks alike in the eighteenth century. John Huxham, a highly respectable physician of Plymouth, who was one of the first to describe diphtheria, did not disdain to ride hurriedly out of one of the gates of the town and return by another that he might be thought to be busy. All the arts practised by Tom Sawyer, late Nock'emorf, were in use long before the day of that enterprising practitioner. Dickens in his youth was a great reader of Smollett, and he may have taken hints from *Ferdinand Count Fathom*. With regard to the founding of hospitals by doctors, who hope in this way to raise themselves into notice "on the carcasses of the poor," as Smollett crudely puts it, many people probably think this a modern invention. It is well known that in times not remote special hospitals have sometimes had their origin in the desire for professional advancement. Yet we see that in the eighteenth century this device was already regarded as "overdone."

The methods of professional pushfulness and quackery are much the same in all ages, and, we venture to add, in all countries. Although the

profession is better disciplined now than it was in the eighteenth century, quackery flourishes with even ranker luxuriance than it did in Smollett's time. As we have often pointed out, the only cure is by scientific education to create an intellectual atmosphere in which superstition and credulity cannot live. We have little hope, however, that this state of general enlightenment will ever be reached. In the immortal words of Robert Macaire: *Tout passe, mais les badauds ne passeront jamais.*

THE POSITION IN SOUTH WALES.

WE venture to invite the attention of all members of the Association to the paragraphs in the annual report of the Council, published in the SUPPLEMENT for this week, dealing with the position in South Wales, and the use that is there now being made of Section 15 (3) of the Insurance Act, which gives to insured persons the right to apply to the Local Insurance Committee to be allowed to make their own arrangements for medical attendance and treatment.

In South Wales an attempt is being made to use this subsection in a way never intended and contrary to the spirit of the Act, and contrary more especially to the tenor of the provisions designed to ensure free choice of doctor. There has been in existence in South Wales for many years a system under which the workman made a weekly or fortnightly contribution to cover the cost of medical treatment of himself and his dependants. When the Insurance Act came into force the medical profession put forward certain proposals to meet the situation. The general effect of these proposals was that insured persons whose personal needs were provided for under the panel system instituted by the Insurance Act would make a monthly payment, usually 1s., to provide for medical attendance on their dependants, and that those who had no dependants would make a monthly payment of half the amount so that the burden on all those engaged in the industry might be equalized. The friendly societies and various trade unions did not accept this just, and indeed generous, proposal, but set to work to form combinations to impose much more onerous terms upon the medical profession. With the assistance of the Local Insurance Committees and the connivance of the Welsh Insurance Commissioners, they are endeavouring to formulate schemes, the general drift of which is to obtain the whole-time service of men willing to work for a stated salary under conditions unhesitatingly condemned by the profession.

The Council, in its report, points out that combinations of workmen and their dependants formed for the purpose of employing medical practitioners, either whole or part time, having failed in many instances to secure recognition under the Harmsworth amendment (Subsection 4 of Section 15), on the ground that they were not in operation at the time of the Act coming into force as the subsection requires, are now receiving encouragement from the Welsh Commissioners to ask the Insurance Committees to give them permission to make their own arrangements collectively under Subsection 3 of Section 15. The approval of some of the Insurance Committees has already been given to a number of such schemes. If the action of the Insurance Committees receives the approval of the Welsh Insurance Commissioners the effect will be to exploit the local medical profession, and to place them more

completely under lay control than is possible under the panel system, or indeed was achieved under the old system of medical aid associations now universally condemned by public opinion in Great Britain. Should the Welsh Insurance Commissioners give their consent it will be regarded as a distinct breach of faith with the medical profession on the part of the Commissioners and of the Government. Such a step would raise to exasperation the feelings of medical men in South Wales.

The medical men in Swansea are unanimous in their decision not to accept such service, and the honorary medical and surgical staff of the Swansea Hospital have given their support by resolving that they will in no circumstances meet in consultation, or have any professional dealing, either at the hospital or privately, with any medical man holding office under a society or association having for its object the employment of medical men under conditions not approved by the medical profession, and will decline, except in cases of gravest emergency, to treat in hospital any member of such a society. In taking this action the honorary medical and surgical staff is fully aware that it may come into conflict with the managing committee of the hospital on which representatives of the friendly societies serve. The whole position is explained in the able letter by Dr. Reid, chairman of the Medical Board of the hospital, which is published in the SUPPLEMENT, and nothing we can say will add to the force of his statement, which is tantamount to an appeal to the whole profession to support their brethren in South Wales.

The position already brought about emphasizes a point to which we have already frequently referred; this is, that there is urgent need for the Joint Committee of Insurance Commissioners to exercise the controlling and co-ordinating powers they possess in order to prevent the increasing dissatisfaction aroused in many parts of the country by the dictatorial or pettifogging proceedings of Insurance Committees, backed up, as in this case they have been, by the Insurance Commissioners responsible.

ANNUAL MEETING IN ABERDEEN, 1914.

THE Aberdeen Branch has decided to invite the British Medical Association to hold its annual meeting for 1914 in Aberdeen. This announcement will, we feel sure, be received with great pleasure by members of the Association. Many of them will, we do not doubt, be glad to take advantage of the opportunity to visit a city which has taken so large a part in the intellectual development of Scotland, and has recently extended the facilities its University affords for academic instruction and research. To those who have never visited the "silver city by the sea," it will be a pleasure to see its stately buildings, and especially the magnificent pile recently added to Marischal College, which forms the medical side of the University.

ORGANIZATION OF THE PROFESSION IN SCOTLAND.

It becomes increasingly evident that the new problems created by the National Insurance Act will call for greater attention on the part of the profession in all parts of the country to questions of organization; and in regard to Scotland an important decision was arrived at by the Council at its meeting on April 23rd. For some years the special needs of Scotland have been dealt with by the Scottish Committee, which consists of the Secretary of each Scottish Branch of the British Medical Association and of all the members of the Council who represent the

Scottish Branches. After the Insurance Bill was introduced, and it was found that a Special Commission was to be set up for Scotland, the Scottish profession thought it necessary to set up an emergency organization called the Scottish National Insurance Council, composed of representatives of the Scottish universities and medical corporations, representatives from each insurance area, and the members of the Scottish Committee. The time has now arrived in the opinion of the Council of the Association when medical organization in Scotland should be put upon a more permanent and efficient footing. The Scottish National Insurance Council having served its purpose, the Scottish Committee has retired from it, and it is, we believe, probable that the first-named emergency organization will now be dissolved. At any rate, the Council of the Association has decided that the Scottish Committee shall be given a special grant for the purpose of employing a part-time officer for its clerical work, and to assist it in holding conferences, at least once a year, with representatives of the Scottish Local Medical Committees. Full power has been placed in the hands of the Scottish Committee to make arrangements for the holding of these conferences, and the Council is now considering the desirability of transferring to the Scottish Committee the entire duty of organizing the Branches and Divisions of the Association and the Local Medical Committees in that country. At present this duty is shared with other committees of the Association. It is believed that the new arrangement will enable the profession in Scotland to deal with its own peculiar problems under the Insurance Act in a more direct and efficient manner, that it will decentralize some of the work of the Association with advantage to all concerned, and will in addition give an impetus to the work of organizing the profession in Scotland by placing full responsibility for it to a much greater extent than before on a body thoroughly representative of all parts of Scotland, while not too large for regular meetings and effective committee work. At the same time the arrangement, being under the aegis of the British Medical Association, will preserve that co-ordination of the interests of the profession in the various parts of the United Kingdom which is so essential.

DIPHTHERIA ANTITOXIN.

It is now more than eighteen years since Behring introduced his antitoxin for the treatment and prevention of diphtheria, and the efficacy of the treatment has been fully recognized. The statistics of the Metropolitan Asylums Board and of the various hospitals in this country and abroad have proved conclusively that if the injections are carried out early the disease can be cured with something like certainty. Dr. Eckert deals with a number of points which still require to be cleared up in connexion with this treatment, and which should be of importance to the practitioner as well as the laboratory worker.¹ He starts by calling attention to the endeavour of the manufacturers and institutes to produce a preparation of high valency at a reasonable price. It is possible to prepare a serum which contains 1,000 antitoxin units per c.c.m. The addition of 0.5 per cent. of carbolic acid is of practical value, but he points out that 18 c.c.m. of serum should be regarded as a maximum dose in view of the carbolic acid content. This would be equivalent to 9,000 units if the usual concentration is employed. The serum is standardized by Ehrlich's method, and Eckert considers that the French method of requiring an estimation of the curative power of the serum is unnecessary, and less reliable than the determination of the amount of serum required to neutralize a given quantity of toxin. With regard to the way in which the antitoxin acts he suggests three possibilities: there may be a reversible absorption of

antitoxin by the toxin, or a chemical combination may take place with a complicated molecule, or the antitoxin having become absorbed with the toxin may permit the complement to act on the latter and effect a fermentative dissociation. It has been proved that absorption does take place, and it is possible to regain the toxin from the mixture by treatment with acids. The second assumption would explain a large number of difficulties, and has much in its favour. The third is certainly not excluded, but has not been proved. As to the practical question of the best mode of application, Eckert recalls the observation of Berghaus, who has shown that antitoxin, when injected intravenously, acts 500 times more strongly than when given subcutaneously, and that the quantity absorbed after intramuscular injection within four to eight hours is eight times greater than after subcutaneous injection. The serum has been given by intralumbar injection, but this method has not obtained any popularity. The importance of giving the serum as early as possible is supported by the experimental evidence. The curative value of antitoxin is demonstrated by the official German statistics. In spite of an increase in morbidity in 1907-1908, the mortality has fallen from 15.8 per 10,000 of the population to 2.3 and even 2 per 10,000. The statistics of the various hospitals show in the majority of cases that when antitoxin is used on the first day of illness the mortality is *nil*, when used on the second it varies between 4 and 8 per cent., and is correspondingly higher when first used on the third, fourth, or subsequent days. Heubner maintains that after antitoxin the membrane never spreads locally; that a large number of cases of diphtherial croup can be cured with antitoxin alone; that a considerable improvement has been shown in cases of measles and laryngeal diphtheria, and that the relapses which were greatly feared in the pre-antitoxin days are now rarely seen. After considering the question of dosage and stating that large doses, measured as antitoxin units, should be given, especially in severe cases, he discusses post-diphtherial paralysis. It is in accordance with experimental and clinical observations that the earlier the antitoxin is given the less frequent and the less severe will be the paralytic sequela. An important point in the treatment of diphtheria is that dealing with anaphylactic symptoms. We dealt with this subject not long ago.² Dr. Eckert recommends in cases of reinjection the trial of a small quantity of serum subcutaneously, which will not only indicate the necessity of caution, but will at the same time induce a certain degree of anti-anaphylaxis. In conclusion, attention may be called to an excellent account of the experience of the Rudolf Virchow Hospital in Berlin during the year 1910-1911 in the treatment of diphtheria, by Dr. K. Blühdorn.³ The details given in this article generally confirm the statements made by Dr. Eckert.

THE LISTER MEMORIAL.

As has already been announced, the Committee of the Lister Memorial Fund proposes that the memorial should be of a threefold character: (1) A simple marble medallion bearing a sculptured portrait of Lord Lister to be placed in Westminster Abbey among the monuments of the nation's illustrious dead; (2) a larger and more conspicuous monument to be erected in some public place in London, the city wherein he lived and worked; (3) if funds sufficient shall be obtained, the founding of an International Memorial Fund from which either grants in aid of researches bearing on surgery or rewards in recognition of important contributions to surgical science shall be made, irrespective of nationality. The sum already subscribed or promised is perhaps sufficient for the completion of the

¹ *Deut. med. Woch.*, October 24th, 1912.

² *BRITISH MEDICAL JOURNAL*, October 19th, 1912, p. 1071.

³ *Muench. med. Woch.*, No. 23, 1912.

first two parts of the proposed memorial, which are of local character, but for the third, or international part of the memorial, an international appeal is now being made, and a letter has been addressed by the Secretary, Sir John Rose Bradford, to the principal universities and medical societies on the Continent of Europe and in the United States. A similar letter is being sent to the corresponding institutions in the British Dominions and Colonies. Among the subscriptions received for the international fund are the following: Academy of Sciences, Paris, 500 francs; University of Paris, 500 francs; Medical Faculty of the University of Montpellier, 250 francs; and the Karolinska Medico-Kirurgiska Institutet, Stockholm, £5; His Excellency Privy Councillor Vladimir Kowalevsky, President of the Technological Society of Russia, has made a donation of £5 "in memory of one of the greatest benefactors of the human race." The Universities of Michigan, Yale, Harvard, and Leland-Stanford (California) have already undertaken to promote the memorial, and the College of Physicians of Philadelphia has made a special appeal to its Fellows. In addition, as already noted, Dr. Keen, of Philadelphia, is making a somewhat wider appeal. The University of Toronto has appointed a special committee to promote the fund. We published recently a list of contributions of various medical societies in this country, and to it should now be added a subscription of 10 guineas from the Medical Society of London. The honorary treasurers of the fund are Lord Rothschild and Sir W. Watson Cheyne. The offices of the fund are at the house of the Royal Society, Burlington House, Piccadilly, London, W., and subscriptions, made payable to the fund, may be sent to the treasurers there.

THE TUBERCULOSIS DISPENSARY AT WORK.

THE economic value of the tuberculosis dispensary, apart from considerations of tuberculin treatment, is now fairly well established, and, even if full allowance be made for the enthusiasm always attendant on any new system, there can be no doubt that a recognizable amount of immediate success has followed the cautious use of tuberculin injections. Personal opinions have mainly to be relied upon at present, since no fair conclusions can be drawn from statistics which necessarily range over a limited period of experience. Time alone will show whether the ultimate results have justified the vast expenditure that is being made to bring the unfit into the working line. Activity in this direction is manifest in many large industrial centres, and a good beginning appears to have been made in Bradford, where the energy of the chief tuberculosis officer is being exerted on sound lines, as shown in his report upon the work done in the Tuberculosis Dispensary and Brierley Hall Hospital during the second half of the year 1912. Although started as an entirely new venture, the number of persons attending for diagnosis or treatment bore testimony to the need for such an institution. Of 508 patients examined, no fewer than 403 were found to be suffering from the disease, and in many instances it was possible to examine their "contacts" also, with the result that in 27 per cent. of such cases the presence of incipient mischief was detected. The importance of this means of discovery and early disease can hardly be exaggerated, and stands second only to the need for segregation of the advanced infecting case. Efforts to eradicate consumption must necessarily be one-sided, so long as the spitting patient is allowed to mix with the healthy or with those who may be especially sensitive to the effects of the bacillus. But failing segregation there remains the ever-spreading influence of education, and herein the work of the dispensary is far-reaching. By its means the knowledge of the simple rules of general and special hygiene is carried into the very homes of the people. Reports of 50 cases of tuberculosis in various

forms and stages which have been treated during the six months by tuberculin injections show a preponderance of present success, and have so far favourably impressed the tuberculosis officer as to warrant him in advising his committee to undertake a wide extension of the system.

THE PENAL SYSTEM.

THERE is an amusing misprint in the official reports of the proceedings of the House of Commons ("Hansard"), where, in an answer by the Chairman of the Joint Committee of Insurance Commissioners, the panel is printed the "penal" system. As the misprint occurs in a reply by Mr. Masterman dealing with an instance of the policy sanctioned by the Insurance Commissioners of penalizing the doctors in a district who have not thought fit to join the panel by introducing an outside doctor with special privileges for several years, the printer's devil seems for once to have been inspired from a higher source. Mr. Masterman admitted that the Commissioners had authorized the Leicestershire Insurance Committee, under the proviso to Section 15 (2) of the Insurance Act, to make a special arrangement whereby a medical practitioner had undertaken to attend and treat all the insured persons within certain parishes in the county on condition that he was given the exclusive right of practising among the insured persons in that area for a period of three years from January 15th last, and also that he would have the right of being included on a panel where a panel system existed. Mr. Cautley, in his question, had asked Mr. Masterman if he were aware that the cards of about 200 insured persons in the parishes concerned had been signed by their former medical attendant and desired to be attended by him, but, although he was ready and willing to attend them, the Insurance Committee had ordered them to go for medical treatment to the medical practitioner brought into the area from outside, stating that, if they went to their former medical attendant, they must do so at their own expense. Mr. Masterman did not reply to this part of the question, and appeared to be unaware of the facts, for he stated that the arrangement was made as a special arrangement under the proviso to Section 15 (2), because the alternative was that over 200 persons would have had no medical attendance at all. The result, as he further admitted, was that the insured persons in the district had no choice of doctor, but he appeared to believe that it was the best arrangement the Insurance Committee could make. Apparently, therefore, the Insurance Committee, with the sanction of the Insurance Commissioners for England, have forced upon the parishes in question a system approved neither by the medical profession nor by the insured persons.

LARGE FEES.

MILLIONAIRES are not always particularly liberal in rewarding the ministrations of their doctors. The business instinct which enables them to acquire vast wealth makes them always suspicious that their money may make them the prey of designing persons. This reproach cannot be brought against the executors of the late Mr. Pierpont Morgan, who, it is said, have paid very large fees in money to each of the three physicians in attendance and to the nurses. Other rich men have adopted unusual ways of feeing their doctors. It is related of Dupuytren that he was consulted several times by the head of the Paris house of Rothschild in his day. No fee was tendered at any of the visits, but a considerable time afterwards the surgeon was presented with a handsome sum, the proceeds of a Bourse transaction in which the financier had interested him without his knowledge. A Mr. Steer took the same way of expressing his indebtedness to Sir Astley Cooper, who had attended him as a friend. He sent the famous surgeon a draft, stating that it was the profit "on £2,000 of the ensuing loan, which I had an

opportunity, out of a very small sum Sir F. Baring has given me, of appropriating for your chance." A Mincing Lane merchant for years paid Cooper £600 a year for attendance. One of his largest fees was that given him by a West Indian merchant, Mr. Hyatt, who, after being operated on for stone, took off his nightcap and threw it at Cooper, saying: "There, young man, put that into your pocket." The cap contained a cheque for a thousand guineas. Sovereigns have sometimes considered that the honour of attending their august persons was a sufficient reward for their doctors, but there are many instances of princely generosity. Abu Nasr, who was believed to have saved the Caliph Nasr from the necessity of being cut for stone, is said to have received a fee equivalent in money value to £12,000, besides rich presents. Gabriel Baclitshua was paid by the Caliph, whose physician in ordinary he was, at the rate of £1,000 a month, and received a present of £1,250, besides robes of honour, every New Year's Day. On one occasion he is said to have received £25,000 as a single fee. Dimsdale, who went to Russia in 1768 to inoculate the Empress Catherine and her son, received a fee of £12,000, with a pension of £500 a year and the title of Baron, which is still borne by a descendant. In 1792 Dr. Willis (who had charge of George III in his periods of derangement) was called to Lisbon to undertake the treatment of the Queen of Portugal, who was suffering from mental disease, on the following terms: £1,000 a month as salary, the expenses of his journey, a table for himself and suite; and £20,000 if he succeeded in curing his illustrious patient. Willis was received at Lisbon with honours such as are usually reserved for royalty. Sir Morell Mackenzie received £13,000 for three months' attendance on the Emperor Frederick. But the largest fees paid by a monarch in modern times were those distributed among his medical attendants by Louis XIV after the famous operation for fistula. Like the public benefactor of whom it is recorded that

He, out of his great bounty,

Built this bridge at the expense of the county,

the Roi Soleil was liberal at the expense of his people. It is estimated that the *grande opération*, as it is known in French history, cost the nation some £40,000. Félix de Tassy, the operator, received 300,000 livres in addition to a landed estate. The surgeon was a favourite with the King, who two years before had given him 100,000 livres, and who four years later gave him a patent of nobility. The physicians present at the operation were also richly rewarded. D'Aquin received 100,000, Fagon 80,000, and Bessières 40,000 livres. Each of the four apothecaries received 12,000 livres. The apothecaries doubtless did something for their money, but the physicians were merely onlookers, and it must have been gall and wormwood to these haughty pedants to be compelled to leave the treatment of their royal master in the hands of one whom they despised as a mere handcraftsman.

DEATH IN THE STREETS.

DR. F. J. WALDO, Coroner for the City of London and the Borough of Southwark, in his annual report for 1912 draws special attention to a matter of great public interest—traffic fatalities. The conclusions formed by one possessing such unique opportunities of studying this question in all its details cannot fail to be interesting and instructive at a time when we are watching the transition from horse-drawn to motor vehicles. Dr. Waldo has come to the general conclusion that, bearing in mind the increase in the daily population of the City, there is no real increase in the number of traffic fatalities, and it will come as a surprise to many to learn that in the four years, 1908 to 1912, there were within his jurisdiction as many as 116 deaths due to the horse-drawn against 146 due to motor vehicles. Fatalities from motor traffic do not, in Dr.

Waldo's opinion, depend on increased speed or to the particular method of propulsion, but certain factors, unavoidable at the present time, such as crowded traffic, narrow streets, loss of control, skidding, carelessness on the part of drivers, carelessness also on the part of pedestrians, who, it is said, frequently alight from a moving vehicle or cross the street without due regard to the traffic. In this last respect the death-roll is particularly heavy among children, for the records show that in the combined areas of the City and Southwark over one-fourth of the traffic fatalities occurred to children under ten years of age, while in Southwark alone, where the number of children is far larger, the proportion reached one-third. The County Council and the omnibus companies are trying to combat this evil by means of handbills, notices, and other means, but Dr. Waldo thinks that much could be done in the schools to teach children the danger of crossing streets without looking out for the traffic, and to impress upon them the fact that legal punishment as well as injury may result to them from riding upon or hanging to the backs of vehicles. To educate the children with regard to the dangers they incur would seem to be the only useful plan, for it would be unreasonable, even if it were possible, to deny them the use of the streets in poor districts. Dr. Waldo, although agreeing with the principle of the speed limit, doubts its value in crowded centres, for the driver is apt to think that he may travel in any circumstances at a speed not exceeding the limit; again, there is no means at present of accurately estimating the speed of a vehicle in a crowded thoroughfare, though Dr. Waldo looks forward to the day when the engineer will provide a speedometer that is thoroughly trustworthy and will sound a continuous alarm when the speed limit is reached, and so assist the police to detect offenders. He suggests that the police should be entrusted with wider powers; that more refuges should be established in long streets and between tram lines as well as at crossings, and that subways and even light bridges should be employed in especially dangerous localities. At present there appears to be no really satisfactory fender or life-guard that can be applied to motor vehicles generally, but were one forthcoming the fatalities might be very considerably reduced. Attention is rightly called in the report to the fact that the metropolis (with the exception of the City) is far behind the great cities of other countries in not possessing a rapid ambulance service, though there seems some prospect that the co-operation of the London County Council and the Metropolitan Asylums Board, with the ever ready assistance of the police, will in the future result in providing the greatest city in the world with what is now regarded as an elementary necessity in most civilized countries.

THE GREAT WATER SPOUTER.

THE note on the "Human Aquarium," published on April 26th, p. 904, recalls Floran Marchand, who is immortalized in several works on eccentric men, and in particular in *The Book of Wonderful Characters: Memoirs and Anecdotes of Remarkable and Eccentric Personages in all Ages and Countries*, published by Mr. Camden Hotten in 1869. Hotten drew his information mainly from an older collection of biographies by Wilson and Caulfield. According to *Wonderful Characters*, a Frenchman named Floran Marchand professed to be able to "turn water into wine and at his vomit render not only the tincture but the strength and smell of several wines and several waters." It was said that he learnt the rudiments of his art from Bloise, an Italian. Cardinal Mazarin suspected sorcery and threatened Bloise with pains and penalties, upon which the unhappy man made a confession to the Cardinal, who, it appears, was then satisfied that there was no magic about the performance. Marchand was induced by two Englishmen to come to England in 1650,

where he seems to have astonished the public for some time, to his great profit. At length his two friends seem to have betrayed him by publishing a somewhat circumstantial account of Floran Marchand's "mystery." He never broke his fast on the days when he appeared on the stage until after the performance, when he made "a very good supper and ate as much as two or three other men who have not their stomachs so thoroughly purged." Just before coming on the stage he swallowed half a pint of a strong decoction of "Brazil," or logwood, took a big pill of heifer gall and flour, and then drank several pints of tepid water lest the mucus ejected with the water should make the latter turbid and offensive to the spectators. Bowing to his audience, Marchand first brought forward a pail of lukewarm water and six-teen wineglasses in a basket. The glasses were all washed in white vinegar, and when he took up the first glass on the stage he rinsed it out two or three times lest the vinegar might "discolour the complexion of what is represented to be wine." Then he drank four-and-twenty glasses of lukewarm water and vomited first what "seemed to be a full, deep claret." The gall pill and the free imbibition of lukewarm water facilitated the vomiting process, which Marchand could at the same time control. He clearly was a man of much nerve, for timid orators and public performers have been known to retch when their stomachs were empty. The "claret" being ejected into the first glass, Marchand then drank as many glasses of water as his stomach would hold. But of necessity, the staining of the injected water by the "Brazil" already swallowed, grew less and less, so that he appeared to vomit light wines into the glasses which he placed on the table in succession, all rinsed, as at first. After several glasses were filled, he placed on the table another, without rinsing it. Then ejecting water into it, the faint trace of logwood mixing with the white vinegar would give the colour of English beer, and no doubt make a froth, although the chroniclers do not say so. Marchand continued these rather nasty tricks, throwing out a white wine, that is, pure water which seemed to be wine. By pure sleight of hand he also ejected rose water and angelica water, really taken out of two glasses concealed behind the pails of lukewarm water which he swallowed freely throughout his performance. In conclusion, Marchand managed to slip into his mouth a tin instrument with "three several (separate) pipes." Then he put his arms akimbo and shot out three jets of clear water to a distance of four or five yards, which he did "with so much port and such a flowing grace, as if it were his masterpiece." The book from which these particulars are quoted has a portrait of Floran Marchand in the act of shooting three jets of water into three wineglasses. He holds a fourth glass, empty, in his right hand, and behind him on the floor are a small pail and a fifth glass. We are not informed of the ultimate fate of this conjurer. The first necessity for a performance of this kind is a capacity for holding great quantities of fluid in the stomach and ejecting them at will; the illusions in Marchand's case were due to tricks above explained.

HOBBIES.

EVERY medical man should have a hobby; most medical men have one or more which they delight in trotting out on occasions. Mr. Shandy—who said so many true things—affirmed that he could "draw my Uncle Toby's character from his hobby-horse." We will not go so far as to attempt to draw Dr. Boon's character from his hobby-horse—which is evidently photography—but will advise those who have the opportunity, to visit the rooms of the Royal Photographic Society, in Russell Square, and try to work out the problem for themselves. Dr. Boon, who practises his profession at Alassio, shows forty-two specimens of his hobbyhorse work. They are very

beautiful and strangely unlike the pictures of the professional photographer. He seems to be equally clever with interiors and exteriors. As an example of the former, what could be more delicate and satisfying than "Breakfast" (No. 19), and of the latter than "The Sting" (No. 25), or "The Landscape" (No. 15)? Dr. Boon seems to love sunlight, and most of his figures are fully basking in it. But he does not use it for the purpose of throwing the other side of his picture into shade—as is so often done. He makes his children, his fields, and his flowers actually absorb all the glorious rays which fall upon them. No doubt he is fortunate in that he rides his hobby-horse in a place where the sun is no stranger. Indeed, he has made it his warm friend and his inseparable companion. The two seem perfectly and fully to understand each other, and to play delightfully into each other's hands. The number of the house in Russell Square is 35, and the only passport needed is a visiting card. Further than this, from the porter in the hall to the secretary in his office, every visitor seems welcome. Once more we advise our readers who are likely to be interested in these sun pictures to try to spend a half-hour with them.

SNAKES AND WILD ANIMALS IN INDIA.

A BLUE BOOK has been issued giving statistics of the number of persons killed by wild animals and snakes in British India from 1880 to 1910. The figures show that the tiger is the animal most destructive to human life; during the last five years of the period it was responsible for 38 per cent. of the total number of deaths caused by wild animals, leopards accounting for 16, wolves for 12, and bears for 4 per cent. Of the total number of persons (2,382) killed by wild animals in the year 1910, the tiger accounted for 882, the leopard for 366, and wolves and bears for 428. Elephants and hyenas, the two other animals distinguished in the returns, were between them responsible for 77 deaths in 1910. Of the 629 deaths attributed to "other animals," 244 are assigned to alligators and crocodiles, 51 to wild pigs, 16 to buffaloes, 24 to wild dogs, and 220 to unspecified animals. In 1910 there were 22,478 deaths from snake-bite, compared with 21,364 in the previous year, but Bombay was one of the provinces which did not contribute towards the increase, and is in other respects one of the more fortunate parts of India. In Bengal, for example, 1,130 persons were killed in 1910 by wild animals and 7,767 by snakes; but Bombay is, with the exception of the Punjab, at the bottom of the list with 22 deaths by wild animals and 1,247 by snakes. The statistics regarding the number of cattle killed by wild animals are not very perfect, but it is estimated that in the five years ending 1910 the number of animals killed was about 100,000, leopards accounting for 48 per cent. and tigers for 32 per cent.

Dr. MONOD of Vichy, at the conclusion of a cinematograph demonstration given before the Section of Medicine of the Royal Society of Medicine on April 29th, announced that M. Widal had arranged to afford facilities, in the new clinical laboratories under his control at the Hôpital Cochin, for British medical men who desire to undertake research work under his supervision, while at the same time making themselves acquainted with the medical resources of Paris and the ideals and methods of the French school. In this M. Widal will have the co-operation of some of his colleagues who are arranging to afford similar opportunities in their clinics and laboratories.

THE new school buildings of Guy's Hospital Medical School will be opened by the Right Hon. A. J. Balfour, M.P., on Tuesday, June 3rd. The opening ceremony will be preceded by a luncheon at 1.30 p.m.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Work of the Session.—In view of the great amount of time which has been taken by the consideration of the bills relating to the temporary discharge of prisoners and to the provisional collection of taxes, it is very doubtful whether all the measures which it was desired to pass this session will get through Parliament by an early date in August. There are still eighteen days to be devoted to Supply and the final stages of the Finance Act of the year, which is now to be divided into two bills. In addition, the Plural Voting Bill is to be passed, and the closure resolutions allotting the time for the passage of the Home Rule and Welsh Disestablishment Bills, together with those bills themselves. It is quite certain, from the feeling of the House, that any proposal to prolong the session beyond the date contemplated would meet with very strong opposition, and it is difficult to see how any other bills which are likely to meet with opposition can get through during the time remaining for the parliamentary session. The Mental Deficiency Bill is likely again to meet with considerable opposition from at least a small section of the House, and, without having any official knowledge, it is difficult to be sanguine as to the prospects of this measure and of the different Milk Bills promoted by the Local Government Board. The reply of the Prime Minister to the deputation, the proceedings of which are reported elsewhere, declining to promise Government support for the Nurses Registration Bill, makes it practically certain that the bill will not secure a second reading, and, in view of what the Prime Minister said, it would seem that a great deal more spade-work is required on the part of the supporters of this proposal and a much greater unanimity amongst the authorities interested before a measure of this character can find its way on to the Statute Book.

Railway Accidents and Coroners' Inquests.—A bill has been brought forward by Mr. Hudson, supported by members of the Liberal and Labour parties, to amend the law relating to coroners' inquests in the case of fatal accidents on railways. Its purpose is to secure that when an inquest is to be held on the death of any person occasioned by an accident on the railway, the coroner shall send telegraphic notice to the Board of Trade of the time and place of the holding of the inquest, and shall have power to adjourn the inquest if an inspector or some person on behalf of the Board of Trade does not attend at the time appointed to watch the proceedings. The adjournment, however, need not interfere with the taking of evidence as to identification, or with the issue of an order for interment. The bill also provides that the coroner may require things to be left as at the time of the accident until the holding of the inquiry, unless compliance with such an order would increase or continue a danger or impede the working of the railway, and it also provides that any relative of a person whose death has been caused by the accident, or any person appointed by the committee of the trade society or friendly society of which the deceased was a member, shall be at liberty to attend and examine witnesses either in person or by counsel, subject to the order of the coroner.

Sight Tests.—In reply to a question by Mr. Peto, addressed to the President of the Board of Trade, Mr. J. M. Robertson said that from April 1st, when the new colour vision tests were instituted, until April 22nd, 138 candidates for certificates of competency were examined at London and Liverpool; 125 of these passed the local tests, 5 failed, and 8 were referred for special examination at South Kensington. One who failed had not yet appealed, and one who was referred had not yet been specially examined. The remaining 11 had been specially examined, with the result that 7 passed and 4 failed. The lights shown in the lantern test represented ships' side lights at a distance of one mile. He saw no occasion to take any steps in the matter. In further reply, Mr. Robertson said that he was not able to admit any claim

for compensation in the cases of those who failed to pass the tests.

Meals for School Children.—A short bill to amend the Education (Provision of Meals) Act (1906) has been introduced by Mr. Jowett, supported by members of all parties, whereby a local education authority would be authorized within the limits of the principal Act to provide meals for children ordinarily in attendance at any public elementary school in their area on any day of the week, including Sundays, whether the school is open or not—that is to say, during school holidays, if required.

Dental Inspection in Ireland.—In reply to Mr. Cathcart Wason, Mr. Birrell said that there were about 200 registered dentists in Ireland. A sum of £5,000 had been included in the Estimates for public education, Ireland, for the purposes of dental inspection in schools. The general principle on which the money was disbursed was a grant of £1 for each £1 of local contribution towards the total cost of dental inspection under each approved scheme.

Irish Creameries and Dairy Produce Bill.—In reply to Mr. Newman, who inquired as to whether it was not an understanding that this bill should be introduced into the House in the form in which it had been approved by the Advisory Committee on Dairying on October 3rd, 1912, Mr. T. W. Russell said that during the progress of the bill last session the House of Lords struck out a provision in Clause 1 which had been inserted at the request of the Board of Trade and the Board of Agriculture, and without which they declined to allow the bill to proceed. The only alteration of the slightest substance made in the bill as now introduced was the insertion of a subsection to Clause 1 which made the previous proviso clearer. In further reply to Mr. Muldoon, who inquired as to whether it was not a fact that the Irish Agricultural Society was hostile to the bill, Mr. Russell said that the Irish Agricultural Society was hostile to the views of the Board of Trade and the Board of Agriculture in this country, and to the proposal embodied in the proviso, which, however, he considered a necessary part of the bill. He could not admit that in trade circles the term "creamery" as applied to butter was universally understood to mean butter manufactured in an Irish creamery. The term might be used with perfect propriety in connexion with butter manufactured in an English, Scottish, or other creamery. Subsection (3) of Clause 1 of the bill would not, as suggested, have the effect of inferior butter being sold in England to the detriment of Irish creamery butter.

Artificial Colouring of Milk.—Mr. Charles Bathurst asked whether, in view of the fact that all, or very nearly all, the milk sold in London was artificially coloured by annatto to look like the milk of Jersey cows, and that thereby a false standard of quality was set up and London consumers deceived thereby, he would issue an Order prohibiting the dyeing of milk, and thus enable householders to judge of the quality of the milk by its appearance. Mr. Herbert Lewis replied that under the existing law the Local Government Board was not empowered to take action with regard to the process of colouring milk referred to in the question. This was one of the matters in respect of which it was proposed to take power to make Regulations under the Milk and Dairies Bill.

Scottish Prison Commission.—In reply to Major Hope, Mr. McKinnon Wood said that it was a fact that Dr. Devon's name was on the list of vice-presidents of the St. Rollox Liberal Association, but that he had been informed by the secretary that Dr. Devon had withdrawn from the association six years ago, and had not since subscribed to its funds or attended its meetings. He added that he was the best writer on criminology in Scotland; that his application had been supported by testimonials from magistrates, sheriffs, procurators fiscal, and others, many of them Unionists, who supported him on the ground of his eminent fitness for the post, and that his promotion had been welcomed by the *Glasgow Herald* as a "very popular" appointment.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

SHEFFIELD.

INSURANCE ACT AND HOSPITALS.

THE Sheffield medical charities, on the initiation of the panel system, issued a joint statement regarding their attitude towards insured patients. The only alteration of procedure is that an insured patient who after medical examination is found to be suffering from a condition which can be adequately treated by his panel doctor is referred to that doctor. As might be expected, this has not resulted in any material diminution of in-patient work. The casualty out-patient departments have been affected to the extent of several hundred cases a week. There has been very little friction, and one case only has been reported and discussed before the Insurance Committee; in this a medical man refused to take the responsibility of dressing a case of injury to the hand by a piece of steel. It was felt that there had been some misunderstanding, and that a private communication to the doctor would meet the case.

SCHOOL MEDICAL SERVICE.

Some indications of the rapid growth of this public service are visible in the scheme for new premises for the School Medical Service. These will be situated in Sims Street. The capital outlay on land and buildings is estimated at £12,300. About one-fourth of the building will be used for the purposes of a public tuberculosis dispensary, three-fourths being available for the School Medical Officers' Department. A report presented by the School Management Subcommittee expressed the hope that the Local Government Board would contribute £1,000 towards the capital outlay, while the Board of Education would defray approximately 50 per cent. of the annual outlay on the School Medical Officers' Department. But at the meeting of the Education Committee on April 29th, Mr. Harland stated that the Local Government Board could not defray any capital expenditure, but would contribute a sum towards the annual charge for services of debt, so that in the long run it was considered only about one-half the total cost would be put upon the rates.

There are also two new proposals with regard to open-air schools. At present there is an open-air school for 100 children at Whiteley Woods, about four miles from the centre of the city. The children are taken to the school in motor buses, but at the end of the day walk about one mile downhill to the nearest tram terminus. This makes the school rather expensive, and has hitherto limited its utility, as many tuberculous children could not undertake this walk, so that the school has been attended mainly by cases of "anaemia and malnutrition." The school has also been closed during the winter months. It is now proposed to convert it into a sanatorium school by acquiring some adjacent land and providing dormitory accommodation for forty children at an approximate cost of £1,300 for land and building. The cost for food is now £375 for 100 children (2s. 6d. a week a child provides all meals for the five days on which the children attend), whilst under the new scheme, whereby the school would be open throughout the year, for forty children it would come to 3s. 6d. a week or £364 per annum.

It is also proposed to open a new open-air school at Northfield Road, Crookes. This school is close to one of the tram routes, and it is hoped that the cases of anaemia and malnutrition which have hitherto been treated at Whiteley Woods will be treated here at a much smaller annual expenditure.

A grant of £1,502 4s. 6d. has been received in aid of expenditure incurred in the medical treatment of school children, and £183 15s. towards the cost of the present open-air school.

ACCOMMODATION FOR CRIPPLES.

The King Edward VII memorial in Sheffield has taken the form of an Institute for Crippled Children. The committee of the institute has approached the Education Committee and asked its co-operation in framing a scheme

"by which the management and maintenance of the crippled children's institution shall be undertaken by the Education Committee, subject to a proviso that the trustees of the institution shall have the option of the first call on a number of beds, subject to terms in respect thereof being from time to time arranged." The Chief Medical Officer of the Board of Education has stated that such a scheme would receive sympathetic consideration. A preliminary estimate of the annual expenditure, on a basis of provision for 120 children, is £4,839, of which about £2,000 would be required from the rates. It was stated that from £70 to £90 a bed, or a total of £9,600, would be given towards the cost of the building, the remainder of the total, £30,000, being provided by public subscription.

NEWCASTLE-UPON-TYNE.

OFFICERS OF THE NEWCASTLE DIVISION OF THE BRITISH MEDICAL ASSOCIATION.

AN event of more than local interest took place in Newcastle on April 25th, when a dinner was given in honour of the officers of the Newcastle Division of the British Medical Association. The gathering included some eighty medical men practising in the locality. The officers in whose honour they were assembled were: The Chairman of the Division (Dr. Andrew Smith), the Chairman of the Local Medical Committee (Dr. James Don), the Representatives at Representative Meetings (Dr. J. W. Smith and Dr. R. A. Bolam), and last, but not least, Mr. R. J. Willan (Surgical Registrar at the Royal Victoria Infirmary), who is Honorary Secretary of the Division. The chair was taken by Dr. J. D. Farquharson, who followed up his speech in honour of the guests of the evening by making presentations to each of them on behalf of the local profession. The principal gift was that made to Dr. Willan; it consisted of a silver tray and rose-bowl, inscribed:

Presented to R. J. Willan, F.R.C.S., in grateful appreciation of invaluable services rendered in strenuous times, 1911-13.

In making the presentations Dr. Farquharson remarked that, though it could not be claimed that the battle was entirely over, the Division could at least feel that the honour and dignity of the profession had been maintained under the wise leadership of those whom it had put into responsible positions. Despite many disparagements and discouragements, something to balance the account had been obtained. To Mr. Willan primarily they owed much of what had been accomplished. The Division deeply regretted that it was about to lose Mr. Willan as secretary, and did not intend to allow him to escape into the backwoods of obscurity. To their other guests he would say that the gifts made to them were accompanied by their hearty and grateful thanks for the work they had performed.

Each of the guests in turn made acknowledgement, Mr. Willan observing that he still hoped to serve the Division as secretary of its scientific meetings. A large section of the profession still resented the Insurance Act, but in Newcastle it was working somewhat better than had been anticipated. The Act required substantial amendments, and one subject which should be considered by the Commissioners was that of compensation. There were plenty of precedents for such compensation in connexion with former legislation, and plenty of need for it in the present instance. Certain practitioners, whose cases he proceeded to detail, had had their private practices totally destroyed by the operation of the Act. The future of the medical profession depended very largely on the British Medical Association. There were a few malcontents who had threatened to resign their membership, but remarkably few had actually resigned. The action of the latter seemed to him nothing short of contemptible, bearing in mind what the Association had done for them. The British Medical Association must receive the whole-hearted support of the profession.

This latter note was also struck by Dr. James Don, who said there would be need for unanimity even more in the future than in the past. The proceedings concluded after the health of the Chairman had been drunk, on the proposal of Sir Thomas Oliver, and duly acknowledged by Dr. Farquharson.

BIRMINGHAM.

THE CHILDREN'S HOSPITAL, BIRMINGHAM.

On April 23rd Her Royal Highness Princess Louise, Duchess of Argyll, accompanied by the Duke of Argyll, laid the foundation stone of the new buildings of the Children's Hospital, and unveiled the statue of King Edward VII. The statue and the new hospital, which is to be called the King Edward VII Memorial Children's Hospital, have been provided by public subscriptions "in loyal commemoration of the beneficent life and reign of a beloved monarch." These words will form part of the inscription to be carved on the back of the statue.

Her Royal Highness was received at the entrance of the site of the new hospital by the Lord Mayor, and there were also present the High Sheriff of Warwickshire, Sir Francis E. Waller, Bart., the Bishop of Birmingham, Major-General Keir, C.B., and the following representatives of the hospital: The President, Mr. Edward Cheshire; the Chairman of the Committee, Mr. Walter E. Pearson; the Chairman of the Medical Board, Mr. L. P. Ganjee, F.R.C.S.; and the Matron, Miss Tison Clarke.

The old Children's Hospital, which is now situated in Broad Street, was established in 1861 by the late Dr. Haslop in a private house. When the Lying-in Hospital vacated its buildings in 1870, they were converted into the in-patients' department of the Children's Hospital, the out-patients being retained on the old site, and a building, in the Gothic style, erected to accommodate them. The in-patient department was enlarged by the addition of detached wards in 1878, so that it contained sixty-two beds. In 1912 the number of patients treated at the hospital was 13,826, and of these 845 were in-patients, and 12,981 out-patients and casualties.

For many years there has been great difficulty in carrying on the work of the hospital in a full and efficient manner, owing to the age and inconvenient arrangements of the buildings. The hospital had become quite unfit for the increased demands made upon it, while the accommodation for the nurses was so deficient that they had to be quartered in four different buildings inconveniently scattered. In 1908 the committee issued a special appeal for the rebuilding of the hospital, and a new site was bought. Not enough money was subscribed to justify the committee in starting building operations, but in 1910 the rebuilding was made possible by the action of the proprietors of the *Birmingham Daily Mail*, who opened a King Edward Memorial Fund. The sum subscribed by their efforts was £32,808, and of this £2,700 has been devoted to the erection of the statue. The total cost of building and furnishing the new hospital is estimated at £52,000; including the contribution from the Memorial Fund, the hospital committee has in hand about £49,000, so that a further sum of £13,000 is required if the new building is to be opened free from debt.

The Memorial Hospital is being erected on an extensive site in Ladywood Road, and will be well situated, as it can easily be reached by omnibus, tram, or train. The administrative offices front on Ladywood Road, and here are arranged the quarters of the resident medical staff and the board room. At the extreme end on the right wing there will be a small out-patient department, for it is not proposed for the present to remove the out-patient department from the existing building. On the other wing there will be a large recreation room for the nursing staff. The wards, six in number, on three floors, in the rear of the administrative block, will be approached by a main corridor. Each ward has folding windows along the greater part of the southerly frontage, so that nearly the whole of one side of a ward can be opened. Each main ward will contain fourteen beds, and, attached to a smaller ward of five beds in which a warmer temperature can be maintained, a small room for the reception of children and where surgical dressings can be removed and medical examinations made, and the usual sanitary annexes. The hospital will provide accommodation for about 150 beds. The operating theatres are on the top floor in the centre, and are reached by a lift. The floors are to be made of fire-resisting reinforced concrete, and there will be an emergency staircase from each ward. There will also be an isolation ward for infectious patients, a laundry, and a pathological department.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE LATE DR. CECIL SHAW.

The following resolution was adopted at the meeting of the Senate of Queen's University, Belfast, on April 16th, on the motion of Dr. J. Walton Browne, seconded by Sir Peter O'Connell:

That the Senate have heard with very great regret the announcement of the death on April 10th of Dr. Cecil Shaw, lecturer in the university on ophthalmology and otology. They desire to place on record their sense of the eminent services which Dr. Shaw rendered to the advancement of the special branches of medical science to which he devoted himself, and to their teaching both here and in the hospitals in which the students of our medical school receive their clinical training. They request the Vice-Chancellor to convey this resolution to Dr. Shaw's widow, with the assurance of the Senate's sincere and deep sympathy with her in her bereavement.

At the meeting of the Ulster Medical Society, under the chairmanship of its president, Dr. Richard Whytock Leslie, on April 17th, the following resolution was placed on the minutes on the motion of Professor J. A. Lindsay, seconded by Professor Symington:

The fellows and members of the Ulster Medical Society desire to put on record their deep sorrow at the death of Dr. Cecil Shaw and their sense of the serious loss which the society and the medical profession have thereby sustained, and they desire to convey their sincere condolence to Mrs. Shaw and other relatives.

THE AMALGAMATION OF IRISH WORKHOUSES.

Mr. J. G. McSweeney, Local Government Board Inspector, who attended a recent meeting of the Clogheen Guardians to urge the necessity of a sewerage scheme for the workhouse, which has recently been furnished with a new water supply, was questioned on the matter of Poor Law reform; he said that he did not think those present would see amalgamation. It would cost 6 millions to carry out. Matters, he said, would mould themselves in time, and the necessities of the times would make such a place as the Clogheen Workhouse more and more of a district hospital with larger medical staffs.

At the last meeting of the Glenamaddy (co. Galway) Board of Guardians a report was read from the Local Government Board Inspector, containing complaints as to the condition of the workhouse. There were, it was alleged, no beds for the infirm men and women, and they were allowed to sleep on the floors. The Clerk, however, said that the infirm inmates had been sleeping on stretchers, and that they slept so near the floor that if they fell out they would not be hurt. An order to procure the necessary number of beds was nevertheless made.

SALARIES OF DISPENSARY MEDICAL OFFICERS.

For the thirteenth time in ten years the Carrick-on-Suir Board of Guardians have marked "Read" applications for increased salaries from the dispensary medical officers in the service of the board. Two of the doctors have each £80 a year, two £100, and one £115.

THE MENTAL DEFICIENCY BILL.

The Committee of Management of the Down District Asylum has passed a resolution expressing regret that Ireland is again excluded from the proposed benefits of the Mental Deficiency Bill. It points out that in the absence of other specialized institutions persons of the mentally defective class are received into the district lunatic asylums in Ireland, and that in consequence the yearly expense has been unduly increased, while at the same time there has been a yearly decrease in the grant-in-aid. It is suggested that a grant-in-aid should be provided for in the bill, and that, pending legislation, the said grant should be supplemental to the 4s. grant-in-aid, and paid to the different asylum authorities in the country.

MEDICAL PROGRESS IN BELFAST.

The *Belfast Evening Telegraph* of April 23rd contains a number of "tercentenary messages" in which the development of Belfast in various directions is traced by writers having special knowledge of the subject. One of the most interesting of these is a history of medical progress, by Sir John Byers. A very notable feature in

that history, since he began practice, is the growth of laboratories. Since 1894 new chemical, physiological, and pathological laboratories have been opened at Queen's College, Belfast (now the Queen's University of Belfast), a movement which has led to the establishment of a school of research workers, whose original contributions in many departments of medicine have brought the greatest credit upon the Belfast School of Medicine. When the buildings now in course of erection at Queen's University are completed there will also be new anatomical, physical, natural history, pharmacological, and public health laboratories. Sir John Byers thinks that one of the most important new developments will be the King Edward VII Memorial Block, which is shortly to be erected in connexion with the Royal Victoria Hospital. There, he says, it will be possible to employ for the benefit of patients as well as for the education of students the very latest practical applications to disease of chemistry, electricity, x rays, Finson light, radium, haematology, and vaccine therapy. Another notable feature in the medical progress of Belfast is the growth of hospitals. At the outset of Sir John Byers's professional career, with the exception of the old Belfast Royal Hospital and the Throne Convalescent Hospital attached to it, the District Lunatic Asylum, and the Infirmary and Fever Hospital at the workhouse, the only other hospitals were the Hospital for Cutaneous Diseases, the two Eye Hospitals, the Samaritan Hospital, and two Children's Hospitals. With the growth of the city and the development of specialization, the Hospital for Nervous Diseases (1896), the Mater Infirmerum Hospital (opened in 1883), and the Forster Green Hospital for Consumption have come into existence. In 1897 two cancer wards were added to the Samaritan Hospital for Women; in 1905 the Belfast Maternity Hospital, founded in 1794, was removed to its present site in Townsend Street; in 1903 the new Royal Victoria Hospital was opened by King Edward VII; and last year the new Ulster Hospital for Children and Women was opened in Ballymacarrett. During the same period the Belfast Board of Guardians has erected within the grounds of the workhouse, where they have accommodation for about 1,700 patients, a new maternity (1892), a new nursing home (1901), and the large "Dufferin" Hospital for Children (1907), while at "The Abbey" they have established and equipped one of the finest consumption sanatoriums in any country; it is about to be taken over by the City Corporation in connexion with their new scheme for dealing with the problem of tuberculosis. The public health department of the corporation in 1903 established a self-contained small-pox hospital with 60 beds, and in 1906 opened the municipal fever hospital at Purdysburn (containing 168 beds); this is shortly to be enlarged to provide accommodation for 100 more patients. In 1902 the Belfast Asylum was separated from the county of Antrim, and its further development to its present fine condition at Purdysburn has taken place under the auspices of the City Corporation. There have also sprung up all over the city private hospitals or nursing homes for patients who are able to pay for treatment. Another direction in which there has been an enormous advance is State medicine. Since Sir John Byers entered the medical profession the most important public health reforms in Belfast have been—

The regular and systematic removal of house refuse; house to house inspection;

The notification of infectious diseases and tuberculosis; the provision of the municipal fever hospitals at Purdysburn; house disinfection and disinfection of clothes; the notification of births, with early visitation by female inspectors in such cases;

The demolition of insanitary dwellings;

The provision of bacteriological examination of specimens;

The supervision of food supplies;

The improvement in the drainage of the city; the more complete inspection of dairies; and the provision of public baths.

As for the water supply, when the Belfast City and District Water Commissioners have, in accordance with their Act passed last year, constructed the great reservoirs in the valley of the Annalong river and in the valley of the Kilkeel river, there will be, he thinks, no city in the United Kingdom possessing a more perfect water supply than Belfast.

BRITISH DAIRY FARMERS' CONFERENCE.

The British dairy farmers are to hold a conference in Dublin from May 17th to 27th. An inaugural dinner will be held in Dublin on May 17th, at which it is expected that the Lord Lieutenant, the Countess of Aberdeen, and the Right Hon. T. W. Russell will be present. On May 19th the party will visit Straffon House to inspect the herd of pedigree shorthorns, one of the largest in the United Kingdom, and in its formation special attention has been given to milk production. The conference will be opened in the Royal College of Science in the evening. Among the subjects to be discussed are the elimination of the unprofitable cow, and the improvement of Irish dairy cattle. Various dairies and creameries will be visited throughout the country, and Mr. John Wills's herd of Kerries will be inspected. The conference will visit such places as Thurles, Limerick, Adare, Killarney, and Cork.

Scotland.

(FROM OUR SPECIAL CORRESPONDENTS.)

EDINBURGH AND THE INCLUSIVE FEE IN MEDICINE.

At its meeting, on April 21st, the Edinburgh University Court had under consideration a letter, dated March 31st, from the Lords Commissioners of His Majesty's Treasury, stating, with regard to the inclusive fee in medicine, that they were content that the University Court should await some further experience of the working of the inclusive fee before finally deciding whether it could be instituted or not in medicine and applied science. The next sentence in the letter was as follows:

My Lords are giving directions for the payment of the additional grant of £12,500 for the current financial year, but they must stipulate that, as a condition of receiving payment of the full amount of grant for which provision is made in votes of Parliament 1912-13, the Court will appoint a committee to inquire fully as to the difficulties in the way of instituting an inclusive fee in applied science and medicine, and as to the possibility of surmounting them, and they will be glad to learn that the Court agree to this course being adopted, and to receive the report in due course.

The University Court resolved to comply with the condition attached to the receiving of the grant—the appointment of a committee being a step which, in the circumstances, the Court of its own motive would have taken. The lecturers of the extra-mural school also discussed the question of the inclusive fee in medicine and applied science at a meeting on April 22nd; but no conclusion was then reached.

EDINBURGH MEDICAL MISSIONARY SOCIETY'S TRAINING HOME IN AGRA.

The Edinburgh Medical Missionary Society's Training Institution for Medical Missionaries in Agra has suffered a severe blow in the sudden death of Dr. William Huntly, the superintendent of the institution. Dr. Huntly was taken ill with pneumonia, and died on April 11th. The institution exists for the purpose of aiding in the training of Christian lads of the Agra Medical School who wish to become medical mission assistants, and twelve of these young Indians were under Dr. Huntly's care.

BACTERIOLOGICAL WORK IN PRIVATE PRACTICE.

As showing what can be done in connexion with bacteriological work in private practice, Dr. Lachlan Grant, Ballachulish, Argyllshire, forwards two reprints giving the results of one year's work in his private laboratory. In this laboratory he prepares his vaccines and 63 cases received vaccine treatment. Besides the preparation of vaccines Dr. Grant made numerous examinations of sputum, blood, throat cases, etc. Dr. Grant pleads for the establishment of laboratories for bacteriological work throughout the Highlands, under the control of the Local Government Board or county council. As the outcome of the Dewar report it is more than likely that facilities will be given for such work being carried out under Government control. Much credit is due to Dr. Grant for the work he has been doing in his private laboratory.

TUBERCULOSIS ADMINISTRATION IN EDINBURGH.

It will be remembered that in a former number (p. 850) the meeting of the expenses of the proposed tuberculosis administration for Edinburgh and other matters connected therewith were referred by the town council to the Treasurer's Committee for report. That Committee met on April 25th, when it was agreed to send the whole question to a subcommittee.

EDINBURGH PARISH COUNCIL APPOINTMENTS.

The little group of appointments which were referred to some weeks ago (p. 631) in connexion with Edinburgh Parish Council were made on April 28th. Dr. T. Y. Finlay was appointed medical officer, Craighelkharth Poorhouse; Dr. W. L. Martin was appointed consulting physician, Craighelkharth Poorhouse; and Mr. Lewis Beesly, consulting surgeon for Craighelkharth and Craighelkharth Poorhouses.

Special Correspondence.

PARIS.

Cystic Angioma of the Abdomen.—Hereditary Tuberculosis.—Tuberculosis or Hereditary Syphilis?—Pregnancy Complicated by Ovarian Tumour.—Ethmoidal Headache.

THE Congress on Pediatrics and Obstetrics was held in Lille from March 25th to 28th, under the presidency of Professor Pozzi. M. Gorse of Lille reported a case of cystic angioma of the abdomen in a child aged 4 years on whom the diagnosis of right inguinal hernia was first made. The operation revealed the fact that the condition was really one of large retroperitoneal cystic angioma. Pathological examination showed that the condition was due to a lymphomatous cyst.

M. Delearde added one more to the few recorded cases of hereditary tuberculosis. The mother was known to be tuberculous, and the child when born was taken away from her, but it fell ill and died. *Post mortem* no organs were obviously affected, but the bacillus was found abundantly in the pulp of the spleen, and guinea-pigs inoculated with the organs rapidly died of tuberculosis.

The subject of pseudo-tuberculous manifestations in hereditary syphilitic children was discussed by MM. Tridon, Le Fort, and Vidal. M. Le Fort remarked on the fact that cervical adenitis, cutaneous ulcerations, and disease of the bones and joints were frequently diagnosed tuberculous, when in reality the condition was due to hereditary syphilis, a diagnosis frequently confirmed by the Wassermann reaction. M. Vidal agreed with this, and said that in Algiers such cases, especially in the native population, showed marked improvement under treatment with mercury and iodide.

MM. Vauvert and Puech, in discussing the treatment of tumours of the ovary complicating pregnancy, expressed the opinion that during the first six months of pregnancy operation should always be performed, whereas during the last three months operation should only be performed when absolutely necessary. The tumours most difficult to deal with were pelvic cysts, which might cause abortion, prolapse of the cord, inertia, or even rupture of the uterus.

Dr. Guisez read an interesting paper at the Academy of Medicine on migraine of ethmoidal origin. In each one of 70 cases studied the complaint made was of severe repeated attacks of headache. In several trigeminal neuralgia was the first diagnosis made, and the treatment in some cases was medical; in some the nerve was operated on. In all these cases the pain was generalized at first over the head, and finally became most severe in the frontal region. That it was due to a vaso-congestion of the upper part of the nasal fossae and in the orbital plexus of the veins was shown by the congested appearance of the upper fossae, by the seat of pain, and by the marked improvement following applications of cocaine and adrenalin. He recommended as the only satisfactory treatment the removal of the front of the middle turbinate.

VIENNA.

Appointment of Professor Kraus to Buenos Aires.—Compulsory Vaccination in New Austria.—Instruction in Medical Ethics.

PROFESSOR RUDOLF KRAUS, whose name has become well known lately owing to the circumstance that he was called upon by the Bulgarian Government to deal with the outbreak of cholera during the Balkan war, has now accepted a proposal of the Argentine Republic that he should place his knowledge at its disposal. A large and very up-to-date institute for combating the prevalence of infectious diseases has been erected in Buenos Aires, and of this establishment it has been arranged that Professor Kraus shall be the director. His financial and social position in the Argentine will be very satisfactory, and his opportunities for scientific work will be of the most extensive kind. Among other duties he will have to organize, so to say, the prophylactic and therapeutic crusade against infectious disease of all kinds among cattle (the chief source of Argentina's wealth) as well as among the human population. Naturally the prospective loss of such an eminent teacher and investigator is greatly felt in Viennese scientific circles, and his very popular lectures on immunity will be much missed by students. He has arranged to leave in the summer.

An interesting law has recently been promulgated in the two provinces of Bosnia and Herzegovina called "New Austria." These provinces contain about 2 million inhabitants spread over an area of some 20,000 square miles, and hitherto have had few sanitary regulations except those of a kind easily enforced. Owing to the war there has been a large influx of immigrants, numerous Turkish families having sought refuge and a new home in these Austrian provinces. Hence the danger of small-pox and other infectious diseases being spread has been undoubtedly increased. For this reason vaccination is to be compulsory, and the law comes into force at once. Every healthy child must be vaccinated before it reaches its third year of age. It will be exempt if meanwhile it is attacked by true small-pox, or if it is deemed too weak to undergo the process safely. But this exemption is only temporary, for on reaching its eighth year every child must be revaccinated. If the first attempt at revaccination is ineffective the procedure must be repeated a year later. If this, too, is without effect another attempt must be made two years later. Each vaccinated child must be reported to the board of health, and in each case in which vaccination has been postponed or remains without effect, a report, with details, must also be sent to the board. Any practitioner besides the public vaccinator is entitled to vaccinate. No child which is not marked by small-pox may be admitted to school without a certificate of effective vaccination. It is intended to make vaccination compulsory also for grown-up persons within a short time.

The Association of Vienna practitioners has instituted a series of lectures for students of medicine and for practitioners, dealing with problems of medical ethics and economics. Some specific subjects with which they will deal are the following: The relations between the general public and the practitioner; the problems of State and contract practice; and the relations between general practitioners themselves and consultants. The vexed problems of income and other taxes, the legal rights of medical men and the forensic duties of medical men, and those duties in regard to notifications of births and deaths and infectious diseases, are also among the topics. The experiment (for such it was at the outset) has now become an important part of the unofficial equipment for preparing the young doctor for the struggles of practice—and the battle of clubs!

THE fourth International Congress on School Hygiene will be held at Buffalo, New York, in August next (25th to 30th), under the patronage of the President of the United States. The congress will be attended by delegates from all the leading nations, and from every university and college of note in the States and from many educational, medical, and hygienic organizations. All communications relative to the congress should be addressed to Dr. Thomas A. Storey, College of the City of New York, N.Y.

Correspondence.

THE MILWARD FUND.

SIR,—It was my privilege to know Dr. Courtenay Milward, and I was shocked to read in the *JOURNAL* of his untimely death on April 9th. His charm of manner always greatly impressed me, but what struck me above all things was the strenuous, whole-hearted, and self-sacrificing efforts which he was making to help the profession in our fight against the injustices of the Insurance Act.

He was one of few plucky ones who refused to break their pledge and join the panel until released by the Association, even though this refusal was detrimental to his own interests, and I appeal most earnestly to the profession to see that his wife and children do not suffer for his devotion to our cause.

For very shame let us not neglect our clear duty and privilege to mark our appreciation of a gallant English gentleman.—I am, etc.,

JOHN F. WALKER,

Representative, S. Essex.

Southend-on-Sea, April 26th.

RHEUMATOID ARTHRITIS.

SIR,—With reference to Sir James Barr's letter in your last issue, I cannot regard translucency of the ends of the bones, as exhibited in some skiagraphs of the affected joints in cases of rheumatoid arthritis, as proof of the extraction of lime salts from the fibrous tissue, muscles, nerves, cartilages, and bones. This is his only answer to my question as to the evidence on which he based his opinion that the proximate cause of the disease is "a mild chronic acidosis, which extracts the lime salts from the fibrous tissue, muscles, nerves, cartilages, and bones."

Sir James Barr recommends me to sharpen my wits by the administration to myself of phosphoric or citric acid, but, if the tone of his letter is an illustration of the direct effect of this treatment on his own person, I would rather abstain from following out his advice to similarly experiment on myself.

Sir James Barr liberally showers his gibes upon me, but I can assure him that I remain unaffected by them, and I am quite incapable of either adopting his peculiar polemical style or of replying in similar terms to his remarkable animadversions.—I am, etc.,

London, W., April 26th.

ARTHUR P. LUFF.

SIR,—The illuminating address by Sir James Barr, published in the *BRITISH MEDICAL JOURNAL* of April 12th, 1913, will be received with enthusiasm by very many physicians who have been puzzled and perplexed with the pathology of rheumatoid arthritis and more than disappointed at the futility of the most vaunted method of treatment—that of potassium iodide and guaiacal carbonate.

According to Dr. Luff, in a letter in the issue of April 19th, Sir James Barr has been "very iconoclastic in his attitude towards former workers and writers on the subject." But is this statement quite correct? Bath has been the Mecca, so to speak, for very many years for those afflicted with rheumatoid arthritis. Now, upon examination, what do we find? The mineral waters of Bath contain 111.5 grains of calcium per gallon in unknown association, but given in the analysis made by the *Lancet* laboratory as sulphate and carbonate. Personally I have always favoured the drinking of the mineral waters, rather than the bathing, in rheumatoid arthritis, and, if the patient will take as much, prescribe 20 oz. twice daily. At the time they are drinking this water I give them treatment daily for twenty minutes with the static wave current with a voltage up to 100,000. This acts generally upon the tissue metabolism of the body and at the same time raises the tone of the system as a whole. During the past six years I have been following this method with complete satisfaction to all interested. The beneficial results which have accrued have surpassed anything I at first expected, but the time required for the reparative process is from two to three years, giving a month's treatment as above described twice yearly.—I am, etc.,

Bath, April 25th.

GEORGE E. BOWKER, M.D.

SIR,—So far as I am concerned a few lines will suffice for my reply to the cursory glance and cursory remarks of Dr. James Craig of Llandudno in your issue of April 26th. In my opinion rheumatoid arthritis, as a prolonged disease, is a standing disgrace to the medical profession. The disease should be early recognized, the cause removed, and the patient cured. I do not take the recommendations of Dr. Craig too seriously, but if they be, as he says, new, then I feel inclined to say in this case what is new is not true.

I have heard about the use of vaccines in this disease, but let us hope that the serums only exist in the brain of Dr. Craig.—I am, etc.,

Liverpool, April 26th.

JAMES BARR.

DILATATION OF THE CERVIX IN ECLAMPSIA.

SIR,—Dr. Gibbons, in his lecture on puerperal eclampsia, refers to dilatation of the os uteri by means of Bossi's dilator, and expresses the opinion that it requires great care to avoid lacerating the cervix in its use. Bossi's dilator is an apparatus I have no liking for; it seems a most unmechanical idea to expand a circle by means of the angles of a square. The risk of tearing the cervix increases the more widely the blades are separated, as no support is afforded to the portions of the cervix between the blades.

A method which I devised about five years ago, and have not seen described elsewhere, seems to me to be superior to dilatation with this instrument. I first employed it in a case of puerperal eclampsia at the seventh month of pregnancy, in which I decided to empty the uterus by rapid dilatation of the cervix. I had no dilators with me except Hegar's, and these I used as follows: Dilatation was proceeded with as usual up to No. 26; this was then withdrawn, and three smaller sizes were inserted together. Another small one was then pushed in, in the middle of the three. When they were felt to be less tightly gripped another was added, and others again as dilatation proceeded, until there was a large bunch in the os, which eventually was sufficiently dilated for me to be able to deliver with forceps.

It is an easy matter with this method to determine how rapidly the os is responding to the pressure of the dilators, as the action is the same as with the dilators used singly. The pressure is evenly distributed round the os, and the risk of laceration is thereby reduced to a minimum.

The single-ended Hegar's dilators are the most suitable for this method; I have no doubt that Hawkins Ambler's form would be equally convenient, but these I have not tried.—I am, etc.,

Huddersfield, April 26th.

CLEMENT ROGERSON, M.D. LOND.

THE FORM AND POSITION OF THE STOMACH.

SIR.—After reading Mr. Gray's letter in your issue of April 19th and finding my writing extensively quoted, I can only say, "Is it possible that such an interpretation can be given?"

That this "middle sphincter" is, if it exists, of no practical importance is obvious to any one who does bismuth examinations to any extent—with the exception of cases of hour-glass contractions due to ulceration or to spasm, the interior of the stomach, when once canalized by the food, is invariably one undivided cavity. When peristalsis is powerful the waves will often divide the food almost completely, and we can watch this division travel slowly towards the pylorus; but this is no sphincteric action, it is simply peristalsis.

Mr. Gray has not grasped the fact that the empty stomach is a potential space whose walls are in a state of tonic contraction. When hypertonus is present it is only natural that the downward passage of the food, under the action of gravity and with the aid of peristalsis, will be more or less obstructed, and a small mouthful will often remain just below the air shadow for quite a long time. If I recollect aright I demonstrated this to Mr. Gray and then gave a little more food, and we saw the gastric cavity canalized, and, as is perfectly natural according to the laws of physics, the onward progress of the food was again arrested at the lowest point before turning to the right along the pyloric canal, simply because gravity ceased to act, and it was not until a wave of peristalsis

came to its assistance that the food passed round the corner.

On p. 854 Mr. Gray quotes me at length, and what I have just written is merely an attempt to make even more clear what I believe must be obvious to any one. The first paragraph simply refers to the way in which the food is held up in the upper part—that is, just below the cardiac orifice; the second paragraph definitely states that “it frequently happens that at the lowest part of the organ” there is a considerable pause in the progress of the food; while in the third paragraph I am writing of “spasmodic contractions of the middle of the body” of the stomach. Mr. Gray apparently claims all these sites as his “middle sphincter,” and I am absolutely at a loss to know where he believes this middle sphincter to be.

At the oft quoted demonstration I endeavoured to show the “normal anatomy of the stomach,” although, as I said at the time, I did not happen to have what I considered to be a perfectly normal stomach to show; but surely Mr. Gray knows that a slight increase or decrease in tonic action is of the commonest occurrence, and some of the cases I happened to show him were perfectly normal, except in that they exhibited what I considered to be slightly increased physiological tonic action. Both Professor Elliot Smith and I understood that Mr. Gray had mistaken the pause at the lowest point for the action of a sphincteric band of fibres. Certainly Mr. Gray gave us no indication then that he was going to claim a “middle sphincter” just below the cardiac orifice, in the middle of the body of the stomach as well as at the lowest point—in fact, anywhere from the cardiac orifice to the pylorus. It is a most elusive thing, this “middle sphincter”! The pause I have just described at the upper part and at the lowest part disappears and leaves no indentation as soon as the stomach is canalized by the food and the organ at once becomes one continuous cavity. I certainly thought Mr. Gray had shown us where he placed his middle sphincter—that is, at the lowest part of the stomach—and it was obvious that the simple mechanical explanation of the action of gravity was quite sufficient to account for the delay that occurred in the cases we observed together.

As to the spasmodic contractions that occur in the middle of the body of the stomach and elsewhere, although they occur in what is apparently a perfectly normal stomach, they are by no means normal. They do not always occur at the same point, and they are not seen on the operating table. Although they occur in the normal stomach, they are of very great pathological significance, and are probably reflex. On April 18th I read a paper before the Electro-therapeutic Section of the Royal Society of Medicine, in which I gave a considerable amount of evidence for believing that they are secondary to various toxic agencies, such as bad teeth, constipation, appendix inflammation, etc., but they are not dependent on any specially developed muscular bands, at any rate no trace of them has been found at operation, and when once the cause has been removed these contractions disappear.

It is simply waste of time, ink, and paper to continue correspondence on this subject, for apparently it lends itself to distortion by those who are not familiar with normal appearances. If Mr. Gray could spare an hour or so either here or with Dr. Hertz in London, I am quite certain that, if he could only locate this elusive middle sphincter for us, it would save him the trouble of bringing up the subject again, and of carrying on another lengthy correspondence.—I am, etc.,

Manchester, April 23rd.

A. E. BARCLAY.

OWING to the operation of the National Insurance Act, last year threatened to be a period of stress for the Metropolitan Hospital Saturday Fund. In the event, however, the diminution in the total receipts was inconsiderable. The income of the general fund, it is true, diminished by some 5 per cent., but the amounts received in part payment of benefits were higher, so the total for the year reached £45,118, as against £45,468 in 1911. The management expenses were 7.6 per cent. of the gross receipts. The number of benefits provided was 65,267, a considerable increase. But these satisfactory figures cannot be taken as a gauge of the ultimate effect of the Insurance Act on the prosperity of the fund, since the deductions from wages under the Insurance Act and the fall in receipts only commenced in the second half of the year.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

Degrees.

The following degrees have been conferred:

M.D.—P. Hamill, C. W. Hutt, L. Nicholls, W. E. Wood.
M.C.—G. H. A. C. Berkeley.
M.B.—H. G. Earle, H. M. D. Nicoll.
B.C.—H. M. D. Nicoll.

Examination.

The following candidates have been approved at the examination indicated:

SECOND M.B. Part II (*Pharmacology and General Pathology*).—
C. G. Ainsworth, M. L. Atkinson, J. Aydon, J. V. Bates, P. R. Boswell, C. C. Brewis, W. H. W. Cheyne, V. M. Coates, A. O. Curtis, C. S. Dodson, B. C. Ewens, B. J. L. Fayle, C. Gardiner-Hill, W. T. Hare, R. Hargreaves, C. B. Hawthorne, L. G. Jacob, A. H. Little, C. F. Mayne, G. C. Metcalfe, H. S. Miles, B. Mountain, E. C. W. Starling, P. Wallace, E. Watson Williams, W. L. Willett, A. G. P. Willis.

UNIVERSITY OF MANCHESTER.

Ashby Memorial Scholarship.

The committee of the Ashby Memorial Scholarship has decided, instead of selecting a subject for research this year, that candidates on applying for the scholarship shall propose their own subjects. The scholarship was founded for the promotion of the study of the diseases of children, and the research proposed must be in this subject. The award of the scholarship will be made early in July. Applications may be sent to the Registrar on or before June 30th. The announcement of an award previously made was due to an oversight as regards the regulations as to dates.

Examinations.

Owing to the early date of Whitsuntide the examinations for entrance scholarships and exhibitions will begin on May 19th next, and be continued on succeeding days.

UNIVERSITY OF SHEFFIELD.

The Council has appointed Mr. F. G. Mordaunt, L.D.S., to the post of Lecturer in Dental Surgery and Pathology, in succession to the late Mr. Frank Harrison.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on April 24th, Sir Thomas Barlow, Bart., K.C.V.O., President, being in the chair.

Admission of Members.

The following gentlemen, having passed the required examination, were admitted as Members of the College:

James Leatham Birley, M.B.Oxford, L.R.C.P.; Joseph le Fleming Coy Burrow, M.B.Edin.; Gordon Ley, F.R.C.S., L.R.C.P.; Gustave Jean Philippe Monod, M.D.Paris; Charles Sheard, M.B. Toronto, L.R.C.P.; Stanley Wyard, M.D.Lond.

Licences to Practise.

Licences to practise physic were granted to 88 gentlemen who had passed the necessary examinations.

Election of Fellows.

The following Members, nominated by the Council, were elected to the Fellowship:

John Oglethorpe Wakelin Barratt, M.D.Lond. (Liverpool); Edward Stainer, M.D.Oxford (London); Henry Russell Andrews, M.D. Lond. (London); Francis Hugo Thiele, M.D.Lond. (London); William Philip Sutcliffe Branson, M.D.Camb. (London); Walter Henry Maxwell Telling, M.D.Lond. (Leeds); Ernest Edward Glynn, M.D.Camb. (Liverpool); Thomas Grainger Stewart, M.D.Edin. (London); John Brian Christophersen, M.D.Camb. (Khartoum, Egypt); Alexander George Gibson, M.D.Oxon. (Oxford); Frederick Samuel Languead, M.D.Lond. (London); Henry Roy Dean, M.D.Oxon. (Sheffield); Thomas Lewis, M.D. Lond. (London); Maurice Alan Cassidy, M.D.Camb. (London); Charles Wilberforce Daniels, M.B.Camb. (London); James Mackenzie, M.D.Edin. (London).

Under By-law LXXI (b), which authorizes the Council to nominate registered medical practitioners who, not being members of the College, have in its opinion distinguished themselves in any branch of the science or practice of medicine:

Charles James Martin, M.B.Lond., F.R.S., Lister Institute, Chelsea, S.W.

Communications.

The following communications were received: (1) From the Secretary of the Royal College of Surgeons of England, reporting proceedings of the Council of the College on April 10th, 1913. (2) From Miss Ellen L. Wilks, asking leave to have a carbon print made of the portrait of the late Sir Samuel Wilks, Bart., which he left to the College. (3) From Mr. D'Arcy Power, asking leave, on behalf of the Section of History of Medicine of the Royal Society of Medicine, to photograph certain portraits of Harvey. Leave was granted in both instances.

Alteration in Regulations.

An alteration was made in the regulation appended to By-law CXVII whereby candidates for the membership should

be allowed three instead of four hours for each of the written parts of the examination.

Representative on the Senate of the University of London.

Dr. S. J. Sharkey was re-elected the representative of the College upon the Senate of the University of London.

Reports.

A report was received from Dr. A. E. Garrod concerning the Fourth International Congress of Physio-Therapeutics recently held in Berlin.

A report was received and adopted from the Committee of Management, dated March 4th, 1913, recommending that Blundell's School, Tiverton; Elizabeth College, Guernsey, and Boys' Grammar School, Watford, should be added to the list of institutions recognized by the Examining Board in England for instruction in Chemistry and Physics.

After some further formal business the President dissolved the Comitia.

SOCIETY OF THE APOTHECARIES OF LONDON.

THE following candidates have been approved at the examinations indicated:

SURGERY.—†J. T. E. Evans, *†G. Fildes, *†H. C. C. Hackney, *†R. Jones, *†A. J. V. Matthews, R. A. Robinson, *†H. P. Shackleton, †R. L. M. Wallis, *†S. Zarchi.
MEDICINE.—†J. T. E. Evans, *†G. Fildes, *†H. C. C. Hackney, *†G. R. Lynch, *†H. P. Shackleton, *†R. L. M. Wallis.
FORENSIC MEDICINE.—G. Fildes, D. Havard, H. P. Shackleton, R. L. M. Wallis.
MIDWIFERY.—H. P. Shackleton, R. L. M. Wallis, A. H. Willson.

* Section I. † Section II.

The Diploma of the Society has been granted to Messrs. J. T. E. Evans, H. C. C. Hackney, R. Jones, G. R. Lynch, A. J. V. Matthews, R. A. Robinson, H. P. Shackleton, R. L. M. Wallis, and S. Zarchi.

Medico-Legal.

GUARDIANS AND PROFESSIONAL FEES.

AT the Granard (Longford) Quarter Sessions Dr. F. C. Yorke was granted a decree for £2 2s. and £1 1s. expenses against the Granard Board of Guardians. Dr. Yorke was appointed to take the place of the workhouse doctor when he was called away on a Crown summons. The guardians submitted that, as Dr. Yorke was only employed for one day, a guinea was a reasonable fee. The Judge said he considered £2 2s. a reasonable fee.

A nurse sued the Ballymahon Board of Guardians to recover 12s. A car was sent to meet her by the guardians at a train, but she was detained by the hospital authorities in Dublin in removing a patient, and did not get home until a later train. She was obliged to hire a car at Mullingar, and the 12s. that she paid for it the guardians disputed, as the nurse had specific instructions as to the train by which she should return. The Judge gave a decree for the amount, remarking that "it was a miserable case and a mean defence."

CONSUMPTIVE LODGER.

AN interesting case was tried recently at the Monaghan Quarter Sessions. A boarding house keeper sued the executor of the will of a deceased man to recover £25 damages for injuries committed by the deceased when residing as a lodger in her house in June, 1912, for that he infected the house and furniture with a contagious disease. From the evidence it appeared that when the deceased and a friend came to the house to look for lodgings the plaintiff asked if he was suffering from consumption, and his friend assured her that it was congestion of the lungs, and on that assurance she took him in. A few mornings later he had a severe hæmorrhage and soiled the bed clothes, carpet, and wall paper with blood. The doctor would not allow him to leave for six weeks, and some other lodgers left the house, and the plaintiff could not get the house filled for the rest of the season.

The Judge quoted a number of decided cases, showing that a person who, knowing that he is suffering from an infectious disease, succeeds in gaining admission as a lodger to the house of another person, either by falsely representing that he is not suffering from an infectious disease or by warranting that he is not suffering from some particular infectious disease, renders himself liable in damages, the amount depending upon the actual loss which reasonably followed upon the false representation or breach of warranty. These cases were all concerned with diseases such as small-pox, scarlatina, or measles, that is, diseases included in the various Notification of Infectious Diseases Acts. Under regulations of the English Local Government Board, pulmonary tuberculosis was declared to be an infectious and notifiable disease, and it was likewise notifiable under certain local Acts. The Judge pointed out that it would be very inconvenient from a public point of view if it was established in the courts that the principles applicable to small-pox and the like were to apply without restriction and qualification to consumption. The plaintiff in this case had got an assurance that the lodger was not suffering from consumption, and on that assurance let the rooms to him, and she was therefore entitled to a decree for the amount of her loss through the disinfection of the room and the destruction of some of the articles and for the loss on lettings. A decree was therefore given for £16 4s. 2d.

Obituary.

WILLIAM HUNTLY, M.A., B.Sc., M.D. GLASG.,

AGRA.

WILLIAM HUNTLY was born on December 1st, 1859, and was educated at Hutcheson's Grammar School and the High School of Glasgow. He then passed to the university of that city, and graduated M.A. there in 1880; he had one session at the United Presbyterian Divinity Hall (1880-1), and then turned to medicine and science, graduating B.Sc. and M.B., C.M. at Glasgow in 1885. His desire was to be a medical missionary, and he was farsighted enough to recognize that such a calling would best be answered by gaining the most thorough knowledge possible of medicine and science; so he went through the arts, science, and medical curriculums, and put the copestone on the edifice of his training in 1889 when he graduated M.D. in Glasgow. He had already volunteered for service in India, and had been accepted by the United Presbyterian Church of Scotland for its medical mission work in Rajputana. To take up this work he sailed on October 30th, 1886. He had periods of service at Beawar, Nasirabad, Jodhpore, and Kotah in succession, and finally spent a year at Bundi, in the very centre of the famine-stricken districts of India. In this way fifteen years were spent. Then Dr. Huntly's health broke down, and in 1901 he had to return to Scotland to recruit. One who knew Dr. Huntly well has explained his great success by a reference to five characteristics which he possessed in particular—namely, his medical skill, his versatility, his accessibility, his evangelical earnestness, and his unselfishness. Added to these was his extraordinary sympathy with the natives of India; in their society he was most at home, and was perhaps seen at his best.

But Dr. Huntly's career in India was not yet finished. His health was so much restored that when Dr. Colin Valentine of Agra died, the thoughts of the directors of the Edinburgh Medical Missionary Society turned at once to Dr. Huntly as the most likely man to take his place as head of their Medical Missionary Training Institution in North India. So to Agra, in 1902, Dr. Huntly went, and there he laboured till his death from pneumonia on April 11th. As superintendent of the Agra Institution he was brought into close contact with the native Christian youths training to become hospital assistants, and upon them for some ten or eleven years he lavished all the sympathy of his nature, and gave them freely of the professional knowledge with which he was so well furnished. During recent years the number of students passing through the institute was somewhat diminished, a circumstance which occasioned Dr. Huntly a great deal of anxiety. It was to the action of the Government of India in requiring the standard of examination to be raised, and the consequent difficulty of finding among the comparatively limited numbers of the Christian natives of India sufficient young men who attained to that standard. It was a matter which would of course right itself in time with the raising of the school training, but it hampered Dr. Huntly's work to some extent in the past few years. It had this advantage, perhaps, that it made it possible for him to lend a helping hand to many other worthy causes in North India, and in giving such help he spared not himself.

Dr. Huntly leaves a widow and four children, two sons and two daughters. One of his daughters is married to a medical missionary in South India, Dr. Bulloch of Neyoor.

HUGH BEGBIE WILMOT, M.R.C.S. ENG., L.R.C.P. LOND.,
EDMONTON.

DR. H. B. WILMOT, who died on April 23rd, was educated at St. Mark's School, Windsor, and King's College Hospital. Soon after obtaining his diplomas in 1894 he joined Dr. J. H. Swanton at Edmonton, and on the latter's retirement to take up gynaecological work Dr. Wilmot succeeded to the practice, which has been carried on from the same house for more than a century. This house was the doctor's house when Edmonton was a country village of a few hundred inhabitants, and John Keats, the poet, was apprenticed to Dr. Harding, such

being the method of entering the medical profession in those days.

During his eighteen years of practice Dr. Wilmot witnessed the very rapid growth and development of Edmonton into a London suburb of over 67,000 inhabitants. His health, never robust, had been failing since a severe illness two years ago, but he remained at work, devoted to his patients, until a fortnight before his death.

The parish church of All Saints was the scene of his funeral service three days later, when the old building in whose churchyard the bodies of Charles and Mary Lamb repose, was full of Dr. Wilmot's patients, old and young, rich and poor, who thereby testified to their high esteem of his professional skill and sterling character. His professional brethren attended in large numbers, and a handsome floral memorial from the Edmonton Medical Society expressed their great regret at the early close of a useful life, and their deep sympathy with Mrs. Wilmot and her little daughter.

S. C. L.

WE regret to record the death of Dr. WILLIAM MICHAEL WILLIAMS at his residence, Penmachno, on April 20th, at the age of 56. He was born at Pwllheli in South Carnarvonshire, and received his medical education at the University of Glasgow, where he graduated M.B. and C.M. with commendation in 1881. He had held the appointment of medical officer of the Penmachno and Pentrevoclas District of the Llanrwst Union for twenty eight years, and at the time of his death was the senior medical officer of the union. He was surgeon to the Penmachno Slate Quarries and certifying factory surgeon for the district. Dr. Williams also took an active part in public life; for several years he was a member of the Carnarvonshire County Council, and only retired in March last owing to ill health. For the last nineteen years he had been chairman of the parish council, and although he desired to retire from that position this year the parishioners would not allow him and unanimously re-elected him. He was a regular attendant at the meetings of the North Wales Branch, and in 1908 filled the presidential chair with great credit. For the theme of his address he took the treatment of pneumonia, and it will be long remembered by those who listened to him, embodying as it did the fruits of his keen observation and sound judgement. Although resident in a somewhat remote part of the country amongst the Welsh hills, he never allowed his mind to rust, but kept himself thoroughly abreast of the times, as evidenced by his contributions to and the part he took in the debates of the Branch. Dr. Williams had a very extensive practice, and was a most conscientious practitioner. He had an exceedingly kind nature, and by his death the district sustains a great loss, especially the poor, to whom he was always considerate. He had been in failing health for several years, but he fought bravely to the end. On April 23rd he was buried at Denio Cemetery, Pwllheli, his native town. He leaves a widow and two daughters to mourn his loss.

Dr. SYDNEY WILLIAM CHEETHAM, of Forest Gate, E., met his death on April 27th, at the age of 49, in tragic circumstances. He had ridden his tricycle to visit a patient, and narrowly escaped disaster from a passing motor bus. Pushing on, he attended to his patient, and then immediately succumbed to an attack of heart failure, while still in the patient's house. Dr. Cheetham was educated at University College, Liverpool, and subsequently held the posts of Assistant Demonstrator of Anatomy and of Physiology there. After obtaining the diplomas of M.R.C.S. and L.R.C.P. in 1889, he was appointed Acting Senior House-Surgeon at Bootle Hospital. He had been established in Forest Gate for many years, and his professional skill, genial manner, and commanding presence had secured him the affectionate regard of his patients. To the care of an extensive practice Dr. Cheetham had recently added the responsible position of being one of the too few medical members of the West Ham Insurance Committee, a post which he accepted at the request of the West Ham Town Council. He was a frequent attendant at medical meetings, and his medical neighbours looked forward to the time when his cautious criticisms and his shrewd Mancunian common sense

would be heard yet more often at their councils and committees. Dr. Cheetham leaves a widow and two children, to whom all sympathy is extended in their sudden and tragic loss; yet the man is to be envied who, when the inevitable occurs, is found at the post of duty.

Dr. FRITZ GUSTAV VON BRAMANN, Professor of Surgery in the University of Halle, died on April 26th, aged 58. He was born at Willhelmsberg, in East Prussia, on September 25th, 1854, and studied medicine at Königsberg. In 1884 he was appointed assistant in von Bergmann's clinic at Berlin, and qualified as Privatdocent in 1888. In 1890 he was called to the chair of surgery at Halle, and was appointed director of the surgical clinic of that university. The name of Professor von Bramann was probably best known to the world at large from the fact that he performed tracheotomy on the late Emperor Frederick at San Remo. In this way he became involved in the violent controversies which raged round the death-bed and over the grave of that monarch. The memory of these painful events need not be revived. Professor von Bramann continued to enjoy the confidence and esteem of the present Kaiser, who is said to have sent him a telegram of hearty appreciation on the twenty-fifth anniversary of the operation, which was performed in February, 1888. The deceased professor was the author of writings on dermoids of the nose, the treatment of wounds with iodoform compresses, arterio-venous aneurysm, and other surgical subjects.

MUCH regret has been caused by the death of Dr. JAMES ROWAN, of Ballyward, co. Down, who was for many years the medical officer of the Ballyward Dispensary District. He was the son of Dr. Nathaniel Words Rowan, of Ballyward, and was born in 1838. After receiving his diplomas in 1860, he spent the first eight years of his professional life in Cambridge, and in 1868 he succeeded his father as medical officer in Ballyward. On retiring from active duty in 1910 he was presented with a purse of sovereigns and an address.

THE number of British medical practitioners in the French Riviera, which has for some years been a diminishing quantity, has been further reduced by the death of Dr. CHARLES EDWARD CORMACK of Hyères and Vichy. He was a son of the John Rose Cormack who was for some years entrusted with the fortunes both of the British Medical Association and its JOURNAL, fulfilling as he did simultaneously the office of secretary of the one and editor of the other. At the beginning of this period John Rose Cormack had not long come south from Edinburgh, and it was at Putney, where his father was then living, that Charles Edward Cormack, his second son, was born in 1851. In the early Sixties the family moved to France, where John Rose Cormack, after performing great services during the siege of Paris, became physician to the Embassy, and was subsequently knighted. It was in France, therefore, that Charles Edward Cormack received the greater part of his education. It was in France, too, that he passed practically all his professional life. For over thirty years he was a well-known personage at Vichy, where he practised during the summer, and for a somewhat shorter period he had been equally well known in the south of France. In regard to Vichy he published in 1887 an interesting handbook, which included a detailed description of its waters and notes on diseases in which its use is indicated, together with a large amount of miscellaneous information concerning the locality and its surroundings. At Hyères he began to practise a few years later, room for his services there being created partly by its growth in favour as a winter resort, partly by the failing health of the late Dr. G. Griffith. It was at his residence, the Villa Marie Thérèse, in the latter town that he died in February. Dr. Cormack, who maintained his membership of the British Medical Association up to the time of his death, was married, and is survived by his wife.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are: Dr. James A. Egan, for many

years Secretary of the Illinois State Board of Health and an earnest worker in the cause of higher medical education and of effective State regulation of medical practice; Dr. J. G. Egger, of Landshut, well known by his work in the province of geology and palaeontology, aged 89; Dr. Gagnon, Emeritus Professor of Surgical Pathology in the Medical School of Clermont-Ferrand; Dr. Amie Henri, Professor of Medical Physics in the Medical School of Rheims; Dr. George McClellan, surgeon to the Howard Hospital, the General Hospital, and St. Joseph's Hospital, Philadelphia, author of a work entitled *Regional Anatomy*, which went through six editions and was translated into French, aged 63; and Dr. E. Angus Stewart, Assistant Professor of Pathology in the College of Physicians and Surgeons, New York, and formerly Assistant Professor of Pathological Anatomy in the Johns Hopkins Medical School, author of contributions to the study of blood pressure and conditions of the heart, and of researches on the adrenal bodies, aged 30.

Medical News.

THE Board of Trade has issued an Order rendering obligatory on all persons who employ labour in the ready-made and wholesale bespoke tailoring trade in Great Britain, and make garments for male persons, the minimum time-rates of wages fixed by the Board last August.

AT a meeting of the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on May 20th, at 7.30 p.m., the Chairman of the Metropolitan Water Board, Mr. E. B. Barnard, will give an address on London's water supply, and on the following day a visit will be made to the King George's Reservoir at Chingford.

THE Henry Phipps Psychiatric Clinic of Johns Hopkins Hospital, Baltimore, for the treatment of mental disorders was formally opened on April 16th. An address on specialism in general hospitals was delivered by Sir William Osler.

THE proposal to establish in Glasgow, as a memorial to King Edward VII, an institute of preventive medicine primarily intended for research and the dissemination of knowledge in relation to tuberculosis has been abandoned on the ground that the work proposed to be done will now be undertaken through the operations of the scheme recommended by the Astor Committee (BRITISH MEDICAL JOURNAL, March 15th, p. 567).

THE first of three lectures on recent physiological inquiries to be given by Professor Stirling of Manchester at the Royal Institution, Albemarle Street, W., was delivered on April 29th, and dealt with motion and locomotion. The second will be given on May 6th, and will deal with equilibration and the sixth sense, and the third on May 13th, when the subject will be ductless glands. The lectures are illustrated by the cinematograph and epidiascope, and by experiments.

A WELL illustrated booklet, recently issued by the Highland Railway Company, and obtainable upon application, bears the title, *Strathpeffer Spa Medical Guide*, and has for authors four medical men resident in the locality. Each of these is responsible for one section of the book. Dr. H. W. Kaye deals briefly with the position and use of health resorts; Dr. E. H. Duncan gives a detailed account of the waters of Strathpeffer and the various ways in which they are used; Dr. W. Bruce discusses medical treatment at the same spa; and Dr. J. Pender Smith, supplementary treatment by electricity.

A SERIES of academic courses for foreigners will be held in Hamburg from July 24th to August 6th. The subjects range from pedagogy to natural science and clinical medicine, and sixty-five professors from various German universities and institutes will take part. There will also be a practical course in the German language commencing on June 16th to July 26th, and during this period there will be a clinical course at the Lppendorf Hospital, and a series of lectures by L. Brauer on diseases of the heart and lungs. Further particulars can be obtained from Geschäftsstelle der Akademischen Ferienkurse, Hamburg 20, Martinistrasse 52.

TO the physical and moral advantages resulting from the Seaside Camps for London Working Boys allusion has been made in these columns on several occasions. Their objects and the means adopted for their attainment are well described in the twenty-fourth annual report issued by the committee responsible for the upkeep of these camps, whose occupants are mainly youths belonging to the London Diocesan Church Lads' Brigade.

Last year's work seems to have ended with a rather heavy balance on the wrong side, so subscriptions of any amount will no doubt greatly be welcomed by the secretary, Mr. F. Abel Bloxam, 22, Northumberland Avenue, W.C.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on April 18th, 1913, when Dr. F. J. Allan was in the chair. The claim account for the quarter ending March 31st was presented, and it was shown that, owing to the epidemic of influenza, the society had had to pay out heavy sums but the numbers were already decreasing. The new business had been well up to the average, and the appeal made by the chairman at the annual meeting to members to use their best efforts in making the advantages of the society known was stimulating enquiries. The main feature of the society is the weekly payment during sickness, for, as members often point out, when laid aside by illness their expenses run on just the same, and in fact are increased owing to locomotion and other expenses. The society may justly claim to have experienced a unique record, in that during twenty-nine years it has paid over £200,000 in sickness and accident pay, and no claim has ever had to go to arbitration. Prospectuses and all information to be obtained from Mr. Bertram Sutton, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, W.C.

THE sixth annual Nursing and Midwifery Conference and Exhibition was held at the Royal Horticultural Hall, Westminster, from April 22nd to April 25th, and was attended by large numbers of nurses and midwives. A variety of interesting novelties were on view at the different stalls, including such useful articles as an invalid chair specially designed for wheeling up and down stairs without jolting the patient or fatiguing his attendants, a "running table" that can easily be moved by a person lying in bed, and a baby's feeding bottle in which the usual indiarubber attachments are replaced by a glass valve adjusted in such a fashion that it can neither leak, drop out, nor become clogged with milk. One of the most attractive stalls was that of *The Nursing Mirror*, whose doll-dressing competition had resulted in an amusing collection of dolls dressed in the uniforms of sisters and nurses at most of the principal hospitals in the kingdom; whilst the Women's Imperial Health Association was responsible for a stand containing model sets of cheap clothing for children. Another centre of interest was the stall belonging to the Royal National Pension Fund for Nurses, in connexion with which a Nurses' Insurance Society has recently been formed, where full particulars concerning the insurance of nurses under the National Insurance Act could be obtained. An interesting series of lectures on the different branches of nursing and midwifery was given daily during the course of the exhibition at the London County Council Technical Institute adjoining the hall.

PROFESSOR JOHN EDGAR, Professor of Education at the University of St. Andrews, has recently said that eugenics is a science, a matter of the head, whilst patriotism is enthusiasm, a matter of the heart, which in the hour of one's country's danger bursts into a mighty fire and becomes one of the greatest forces of the world. The spread of eugenics, in creating a new social atmosphere, would develop a new and benign spirit of patriotism. The eugenicist wanted not merely healthy, moral, and stronger animals, but better citizens, with all the variety that citizenship implied; and only through good nature and good nurture could the highest results be obtained. If it were true that the wealth of a country was efficient men, that its health lay in healthy men, and its glory in intelligent men, then there was a danger in Britain of an enemy steadily marching to threaten us with ruin. Whilst the number of marriages had increased the number of births had decreased; it was not the decrease alone which gave cause for anxiety, but the fact that the number of births tended to decrease disproportionately amongst the educated and most successful sections of the population. In an investigation made in his own neighbourhood amongst such classes, Professor Edgar said that he had found the average number of children per family to be a small fraction over one; yet consumptive families in England had an average of five children. During the last half of the nineteenth century the responsibility of maintaining the birth-rate had been shifted from the middle classes to the weak and the poor; and it was among the mass who were struggling for bare existence that fertility was maintained. The new spirit needed was, after all, the old patriotism of Spartan men and women translated to modern conditions. We no longer thought of eliminating the weak, but we

called science to our aid in eliminating the weakness. Eugenics was pointing the way of escape from a national peril.

The present-day worker in London probably knows a good deal less about the Mother City than his predecessor. The latter commonly lived within the actual confines of the metropolis, not infrequently walked to his work, and had not adopted the week-end habit; while the London worker of to-day is swished into town in a tube or on an enclosed tramway car in the morning, and swished out again in the evening, and in the interval usually confines his peregrinations to a very limited area. Rare indeed is the man who spends his spare time, his Sunday and Saturday afternoons, in wandering about London, in exploration on foot of its back streets and nooks and corners. Though he alone, perhaps, can thoroughly appreciate the vigilance of the Metropolitan Public Gardens Association, yet no habitual visitor in London can remain unaware of the growth of its open spaces and of the speed at which these tend to be converted into gardens, and all alike have reason to be thankful for these green oases in a land of bricks. Hence it should be remembered that their origin is by no means spontaneous. Each represents a victory in a probably prolonged fight on behalf of the interests of the general public against those of some corporation or individual. Even for a person who pays attention to the matter it is not always easy to discover to whom gratitude in any particular instance is due; commonly it is given to the London County Council or some equivalent body. Almost invariably, however, it is the Metropolitan Public Gardens Association which should also be remembered. There are few pies of this order in which it does not have a finger, but so soon as it has played its part by agitating, or otherwise helping to secure the retention of an open space, and its decoration by trees or enclosure as a garden, it retires from the scene in favour of the body which undertakes the responsibility for future maintenance. Hence we commend to the perusal of Londoners the annual report of this body, which shows what the association has effected during the previous twelve months, in what directions it has failed, and what projects it still has in hand. Such perusal is by no means unlikely to result in at least an impetus towards becoming a subscriber to the association's funds. Its head quarters are at 83, Lancaster Gate, the residence of the Earl of Meath, who for many years past has been both its chairman and its honorary treasurer.

A REPORT of the annual meeting of the After-care Association, formed in 1879 with the object of facilitating the readmission into ordinary social life of poor persons discharged recovered from asylums for the insane appeared in our issue of March 8th, p. 513. The report for 1912, now issued, sets forth the class of cases dealt with, and states that 391 applications for aid were received, though it fails to tell us how many of these were actually assisted. Subscriptions, donations (including offertories), legacies, and dividends on investments reached a total of £1,998 12s. 3d. during 1912; legacies amounted to £550 11s. 7d., and it is remarked that "although the income has increased, it is almost entirely owing to the receipt of legacies, and the result of the Model Market and Cafe Chantant kindly held by the Guild of Help in October," so that additional subscriptions are still wanted. Investments amount to £4,382 1s. 9d., and the actual expenditure during 1912 was £1,006 12s. 9d., including £48 14s. from a special advertising fund established in 1911 by the generosity of Mr. H. D. Greene, K.C. Salaries amounted to £264 8s., equivalent to about 26 per cent. of the total expenditure, which seems a moderate proportion considering the essentially personal character of the aid given. Of the value of the work carried on by the association and its officers there can be no doubt, and the personal services rendered call for much tactful discrimination. Some striking instances of cases assisted during 1912 are appended to the report, showing how suitable situations have been found in numerous cases; how clothes, artificial teeth, tools, and instruments have been supplied to those needing them to obtain employment, and how board, change of air and medical comforts have been provided in appropriate cases. The multifarious operations of the society meet the varied needs of a most pitiable class, helping those who by reason of their recent affliction have been cut off from the usual sources of employment, and giving them a fresh chance to make their way in the work-a-day world. By such means relapse is often prevented, and the work of the association is in many cases an essential supplement to that of the mental hospital. The offices of the Association are at Church House, Dean's Yard, Westminster, and further information will be furnished by the Secretary, Mr. H. Thornbill Roxby.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

ALPHA wishes to hear of any experience in erecting a surgery and waiting-room of semi-permanent or so-called temporary materials, and the cost.

C. J. S. D. asks for advice in the treatment of a lad, aged 19, who has suffered from nocturnal incontinence following an attack of measles at the age of 3. He has been treated for some months by the usual drugs, including belladonna and chloral, without improvement.

SUSSEX asks how to remove stains produced by scarlet-red and amido-azo toluol.

* * * The stains can be dissolved from linen or similar fabric with chloroform, but we are not aware of any means of removing them from the skin; apparently, from inquiries, no such means is known.

A CASE FOR DIAGNOSIS.

DR. FRANK ELVEY (Fouriesburg, South Africa) invites suggestions as to the diagnosis and treatment of a case which may be summarized as follows. The patient was born with a birth-mark extending from the right foot to the knee, and then up the front of the thigh to the right lower half of the abdomen, the right labium being much thickened. The right leg was distinctly larger than the left, and behind the knee was a circumscribed tumour covered by normal skin. Within a few days this tumour materially increased in size, the skin becoming adherent, while an ill-defined lumpy thickening appeared at the back of the upper third of the thigh; the leg was also swollen. At age 2 months a painful abscess-like swelling appeared on the inner side of the thigh, and from this about an ounce of thickened dark blood was removed. At age 5 months (that is, at the date of the report) the child was fat, well grown and healthy in itself, but its right leg had a circumference four times that of the left; the foot was almost shapeless and the skin over its dorsum shiny and flamed. The right thigh was also swollen, though not as much as the leg. The abdomen was large but symmetrical, and traversed by prominent veins about the epigastrium; its subcutaneous tissue beyond the limit of the birth-mark and up to the chest was irregularly thickened. The parents stated that about a month previously the child had an attack of pain, after which the swelling of the limb subsided, but subsequently returned. As conditions difficult to reconcile with one another, Dr. Elvey points to the absence of enlarged glands, the healthiness of the child as distinct from the local condition, the evacuation of blood and the lack of precise correspondence between the naevoid area and the subcutaneous infiltration. Would a trial of Coley's fluid, he asks, be warranted?

ANSWERS.

CORONERS' INQUESTS.

M.—A coroner is empowered by statute to order an analysis to be made of the stomach and its contents at any period between the issue of his warrant and the termination of the inquest, and the jury has no power to object. On the other hand, by Section 21 of the Coroners Act of 1887 the jury is empowered to call upon the coroner to order a *post mortem* examination or an analysis to be made if it is of opinion that the cause of death has not been satisfactorily determined from the evidence given at the inquest. Thus a jury, while unable to object to an analysis, can insist upon one being made. It would, we conceive, be the duty of a medical practitioner finding poison in the organs of a deceased person to communicate the fact to the coroner in any circumstances.

LETTERS, NOTES, ETC.

PRACTICE IN NEW ZEALAND.

M.B., C.M., F.R.C.S. EDIN., sends a word of warning with regard to the risk of British practitioners going to New Zealand to practise. He states that the population of New Zealand is only a little over 1,000,000, and of these 100,000 belong to friendly societies, who pay the lodge doctor on an average 15s. to 18s. for attendance on a man, wife, and family, and he adds that abuse is rife. He considers that, as there are 130 medical students studying in Dunedin and many New Zealanders are studying in Great Britain, the local output is sufficient or more than sufficient to meet the demands. He states that in some cases bush townships offer a guarantee of £200 or £300 a year, but that many who have accepted such conditions find that the net result is not satisfactory.

SHALL WE DRINK?

DR. JOHN HADDON (Hawick) writes: Reflecting on the lesson my dog has taught me as to drinking water, even when fasting, some facts are recalled to mind which seem worthy of note. An old gentleman of my acquaintance told me that a horse properly fed would hardly taste water, and at grass they never drink. An old lady of my acquaintance, who lived to 89, used to say she never ate more than she could "druck"—that is, than she could make moist enough with saliva to swallow—and I never saw water on her table. I have always known that dogs fed on animal food drink much, but not at all when animal food is withheld, and I had noticed that it was when horses had had too much food, or had been perspiring much, that they drank most water. The whole question of food and drink is deserving of further study in regard to disease, and it would be well if our research scholars would pay attention to the subject.

ARSENIC IN MALARIAL CACHEXIA.

MR. J. G. BERNÉ, L.R.C.P. and S. Irel., late Captain R.A.M.C., has forwarded us, with the permission of the Medical Superintendent of the Elder Dempster B.W.A.S.N. Company, some notes of a case of chronic malarial fever under his charge on board ship for upwards of two months. The infection dated back ten years, and the patient, who had habitually dosed himself freely with quinine and was very cachectic, had very marked anaemia and an enlarged spleen. His condition was at one time serious, but by the time he left the ship all grave symptoms had disappeared, and he was quite "fit." The chief treatment was the regular administration of liquor arsenicalis, quinine being given only when the temperature ran high. In the writer's opinion quinine is somewhat abused, laymen talking about taking it as if it were a food. He considers that in debility caused by malarial fever a combination of iron and arsenic is the sheet anchor, and that quinine should only be given when the fever persists beyond two days. He thinks the best hepatic stimulant in these cases is calomel.

TARAXIUM IN PARTIAL INTESTINAL OBSTRUCTION.

DR. JOHN BAIN (South Shields) writes: Last autumn two letters appeared in the JOURNAL regarding the beneficial effect of taraxicum when administered in cases of gradually increasing obstruction of the bowels, the obstruction being most probably of a malignant nature. The following case completely bears out all that was claimed for the treatment: Three months ago I was called to see Mrs. C., aged 53, who at that time was suffering from vomiting, flatulent dyspepsia, and increasing difficulty in getting the bowels to move. She was very much wasted, and had the sallow, yellowish tint of skin often associated with advanced malignant disease. The abdomen was distended and tympanitic, and on placing the hand on it peristalsis was very distinctly felt. Palpation did not, however, reveal any hard mass, and rectal examination failed to indicate any departure from the normal in the lower bowel. As the patient absolutely refused to entertain the idea of going into hospital, I was compelled to do my best for her at home. My efforts to relieve the vomiting and flatulence with sedatives and antiseptics were of no avail, and the only thing that gave her any relief was morphine in full doses. This, of course, increased the constipation, which was only very partially relieved by copious enemata. It was at this time that I remembered having read in the JOURNAL of taraxicum being used in similar cases, and decided to put the patient upon the drug. For the first week there was little improvement, except that the vomiting and dyspepsia were not so persistent. After this, however, matters began to go on much more smoothly. Slowly, but surely, all urgent symptoms began to disappear, and in three weeks from the commencement of treatment the patient stated that she felt like a new woman. The stomach symptoms were entirely gone, being replaced by a good, healthy appetite, which enabled her to do justice to every meal, while the bowels moved freely and naturally every morning. The only symptom that still troubled her was pain in the lower abdomen after defaecation, but this also is clearing up. To me, the most striking alteration in the patient was the look of returning health on her face; the sallow, cachectic tinge of the skin was gone, and the expression was no longer that of a person in continual pain. How long the woman will continue to enjoy her present state of health cannot, of course, be said, but there cannot be the slightest doubt that the administration of taraxicum was the first thing that relieved her symptoms and paved the way to an apparent return of good general health.

EMETINE IN PLACE OF IPECACUANHA.

BIBLIOPHILE writes: In view of the recent revival of iodine and certain other drugs, after many years of neglect, the following may be of interest, as showing that the proposed substitution of emetine for ipecacuanha may be included amongst these revivals. Volume xi of the *Annals of Philosophy* (Baldwin, Cradock, and Joy, 47, Paternoster Row, 1818) contains abstracts from a paper entitled "Chemical and Physiological Researches on Ipecacuanha," by Magendie and Pelletier, read before the Royal Academy of Sciences in February, 1817. The following constitutes one of the authors' conclusions: "Emetine may be substituted for ipecacuanha in all cases where we employ this medicine, and with the more advantage, as this substance in a determined dose has always constant

properties, which is not the case with the different species of ipecacuanha that are met with in commerce, and it has also the further advantage of having very little taste and scarcely any odour."

IS TUBERCULIN A FAILURE?

M.D. writes: I think that we must come to the conclusion that any remedy which has not been found to be frequently successful in the hands of the general practitioner, even when the latter has made a special study of the treatment of tuberculosis of the lungs by tuberculin, in the best clinics in Europe, is, at any rate, a comparative failure. Even if we grant that there are a few experts who have had good results in afebrile and selected cases of phthisis, it is quite open to argue that those cases were cured in spite of the tuberculin treatment, and that they would have been better without it. I have before me the details of the treatment by tuberculin of a young and healthy physician in whom the diagnosis was made in the very early stage of the disease, and who had the treatment at the best known sanatoriums—yet the result was fatal. The production of an artificial pneumothorax has given no better results. May I suggest the following experiment on animals having well-marked tuberculous foci in the lungs, namely, the production of pneumonia by the injection into the lungs at the site of the tuberculous lesion of a culture of the *Diplococcus pneumoniae*, made from a strain which has partially lost its virulence. A large number of experiments of a similar kind may lead to some definite result in producing an inflammatory condition in the lungs which will destroy the *B. tuberculosis*, and yet from which the patient will have a fair chance of recovery.

FRAUDULENT ADVERTISING.

THE *Perfumery and Essential Oil Record* for April contains an article under this title by "Observer" who certainly does not mince his words.

"The 'fraudulent advertiser' is as much a social pest as the 'three card trickster' or the blood-sucking money-lender, and by fraudulent advertiser is meant not merely the seller of worthless goods, but also the person who deliberately claims properties for his merchandise which they do not possess, or professes that he alone of all men engaged in his particular line produces goods worthy of the consideration of consumers. Fraudulent advertising is harmful and despicable in whatever light it is viewed. On moral grounds, on business grounds, on economic grounds it should be suppressed and killed with as little compunction as an obnoxious insect. . . ."

"Imagine the thousands of pounds which are annually extracted from the pockets of the public by means of fraudulent advertisements, and alas! too frequently the money is literally filched from the pockets of those who can ill afford it. It is all very well to argue that the public goes into the game with 'eyes open,' as it may seem that they do, but in reality they are hoodwinked from the first. . . ."

"The 'fraudulent advertising penny snatcher,' if he knows his game, has a whole bagful of rubbish to shoot out on the public, and just as fast as the sales of one of his trumpery fallals dries up he produces another, and, strange to relate, only too frequently catches the same 'flats' again and again. Well, as to the 'flats,' if they cannot protect themselves they ought to be protected. . . ."

Observer then goes on to express the opinion that advertising of this character is damaging to advertising generally:

"All will remember the famous saying of Abraham Lincoln, and, as all the people cannot be fooled all the time, some portion of the public, and perhaps no inconsiderable portion, may come to the conclusion—a false one admittedly—that all advertising is fraudulent. . . . It therefore behoves all honest men concerned with advertising, and all newspaper owners who place principle before pocket, to kill the fraudulent advertiser before the fraudulent advertiser kills advertising. . . . What is wanted, therefore, is the excision of the fraudulent and insincere; and this in the interest of advertiser, newspaper, public, agent, and every man and woman dependent for their livelihood on the advertising business."

The same issue of this periodical contains an interesting article from the pen of the editor, Mr. J. C. Umney, on *Grasse Revisited*, which with its illustrations gives a good idea of the magnitude of the trade in essential oil and perfumes obtained from plants and flowers.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|---------------------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | 0 | 4 |
| A whole column | ... | 2 | 13 |
| A page | ... | 8 | 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

A Lecture ON INTUSSUSCEPTION.

DELIVERED AT THE WEST LONDON HOSPITAL
POST-GRADUATE COLLEGE.

By H. S. SOUTTAR, F.R.C.S., M.Ch.,

ASSISTANT SURGEON, WEST LONDON HOSPITAL; SURGICAL REGISTRAR,
LONDON HOSPITAL.

Definition.

An intussusception consists, in the words of John Hunter, in the passing of one portion of the intestine into another. Except in certain rare instances, and in the multiple intussusceptions of the death agony, with which we have no concern, this passage is always of the upper into a lower portion. It may occur in any portion of the bowel, and we thus distinguish enteric, enterocolic, and colic varieties; but in the absence of some definite cause—some abnormality, congenital or pathological—the great majority of these occur in the neighbourhood of the ileo-caecal junction. We shall later on discuss the causes of this remarkable circumstance.

Anatomy.

A simple intussusception consists essentially of three tubes embracing one another—the outer layer or sheath, the middle or returning layer, the inner or entering layer. The sheath is, as we shall see, actively engaged in swallowing the other two layers, which are entirely passive. The sheath is therefore called the intussusciens, the other two layers being together the intussusceptum. The end of the intussusceptum is called the apex, the upper end of the intussusciens is the neck. This is, of course, the simplest form of intussusception. Double and treble varieties are not infrequent.

Let us now examine in greater detail the three tubes or layers we have just defined. The peritoneal coats face respectively outwards in the sheath, inwards in the returning layer, outwards in the entering layer. The sheath and the returning layer have, therefore, their mucous surfaces in contact, and whilst this stimulates the sheath to contract, it renders adhesions between these layers most unlikely. The returning and entering layers, on the other hand, have their peritoneal surfaces in contact, and early adhesion between these layers may be expected. In fact, such adhesion in the neighbourhood of the apex, or oldest part of the intussusception, is almost invariable in acute cases of any standing, and may offer a serious obstacle to reduction. These two layers are therefore rightly grouped together as the "intussusceptum."

Causation.

Intussusceptions are produced by a perversion of the normal mechanism of intestinal propulsion. We shall therefore briefly describe the normal mechanism and then discuss the abnormal factors which may lead to this condition.

In the normal propulsion of food the latter acts as a foreign body, exciting by its contact with the mucous membrane a reflex contraction above and a reflex relaxation below. The circular fibres above contract strongly, driving the bolus onwards; the longitudinal fibres over the bolus at the same time draw up the intestine over it as a sleeve, taking their purchase from the fixed constricted ring above. Now, an invaginated portion of intestine will act as a foreign body, and will tend to be driven onwards by this normal intestinal mechanism. The primary occurrence of the invagination depends upon certain abnormal conditions.

Of these abnormal factors, by far the most important is prolapse of the mucous membrane at the ileo-caecal valve. It is not sufficiently recognized that in this region we have a thickening of the circular muscular coat of the last few inches of the ileum forming a detrusor, and terminating in a tonic ileo-colic sphincter, both exactly comparable to the corresponding structures in the rectum. It is therefore not surprising that prolapse of the mucous membrane at this point is common, and exactly as in rectal prolapses this "foreign body," embraced by the

sphincter, will induce increased spasm, with congestion and swelling of the prolapse. But here the conditions diverge. A rectal prolapse projects into the air, and is largely increased by straining, being driven out by the resulting increase in intra-abdominal pressure. An ileo-caecal prolapse, on the other hand, projects into the large bowel, which grasps the swollen mass and endeavours to drive it onwards, whilst abdominal pressure, acting equally in all directions, has no power to either accelerate or retard its advance.

A second group of cases depend for their causation on growths, innocent or malignant, in the bowel wall, and on swollen Peyer's patches. The ordinary polypus is the commonest cause in this group, and giving rise, as it does, to symptoms resembling those of the intussusception it may induce, is apt to confuse diagnosis. As long as the surface of the polyp is covered by mucous membrane it is apparently without effect, but should it become ulcerated, contractions of the bowel are induced by its contact with the intestinal mucosa, and an intussusception may readily follow.

Finally, we have the inverted diverticula—Meckel or the appendix. The former is not uncommon; the latter exceedingly rare. The diverticulum becomes inverted, and projects into the bowel, an ulcer, thickening, or growth at its apex being frequently the primary cause of its inversion.

Varieties.

It is possible to divide up intussusceptions in an infinite number of ways, and the nomenclature which has been introduced for this purpose is astonishing. For the most part it is purely artificial and absolutely useless, for it is rarely possible, except at a *post-mortem* examination, to determine the exact class to which a case belongs. For practical purposes, as Fitzwilliams and Corner have pointed out, they may all be reduced to four types as follows:

1. *Enteric*, where small intestine is alone involved.
2. *Ileo-colic*, of ileum and colon.
3. *Ileo-caecal*, also of ileum and colon, but primarily headed by ileo-caecal valve.
4. *Colic*, of large intestine only.

Any of these may, of course, form the nucleus of a multiple intussusception, double, treble, and even more complex. But the form of the nucleus is alone of practical interest. The first and last groups are obvious, but the bulk of the cases occupy the second and third groups, and, to clearly understand the distinction between these, we must study the method by which an intussusception grows.

Method of Growth.

Growth takes place at the neck entirely. There is no exception to this rule. The apex soon becomes oedematous, stiff, and swollen, and once this has happened it is impossible for the apex to change. The driving force is supplied exclusively by the sheath. As in normal peristalsis, the circular fibres of the sheath contract strongly above, driving on the stiff intussusception and forming a fixed point from which the longitudinal fibres can act. These act in one of two ways. If the sheath is loose they pull it over the intussusception like a sleeve. If it is tight they drive the intussusception onwards into it. This is the only way in which an intussusception can grow, and, as Fitzwilliams points out, the old idea is untenable that the ileum as a whole can prolapse through the ileo-caecal valve with a changing apex, as the rectum can prolapse through the anus. The latter occurrence is dependent largely on intra-abdominal pressure, and bears no relation to the case in point. The only driving force is derived from the sheath.

How, then, do we account for the common ileo-colic form? It may occur in one of two ways. It may start as a true enteric intussusception, the initial cause being perhaps a small polyp or a swollen Peyer's patch. The point of origin remains, as always, the apex, but once the apex has passed the ileo-caecal valve and drawn through the end of the ileum, the result is anatomically identical with what would be found if a prolapse had occurred. Another method seems to be more probable, though so far as I know it has not been previously described. The mucosa of the termination of the ileum is by no means firmly attached to the muscular coat. It prolapses readily, as above described, and this prolapse will still further

loosen its hold in the neighbourhood of the valve. When, then, it becomes taut and can prolapse no further, it will drag upon the muscular coat and tend to intussuscept it, not at the valve, but at a point from one to two inches above. This exactly corresponds with what is actually found, for commonly the last part of an intussusception to be reduced (and therefore the first to be inverted) is at a point from one to two inches above the ileo-caecal valve. This is thus the natural result of the prolapse of mucous membrane through the ileo-caecal valve which we know to be so common.

The distinction between the ileo-colic and ileo-caecal forms has more than a mere academic interest, for in reducing an ileo-colic intussusception great difficulty occurs in the last stage in reducing the apparent ileal prolapse. In the rarer ileo-caecal form the valve is the apex, and there is no such apparent prolapse to deal with.

Pathological Changes.

We must next study the changes which occur in an intussusception as the immediate result of its development. The mesentery is dragged in between the entering and returning layers, and is subject to traction and to compression at the neck. At first it would seem that the drag on the mesentery must very soon bring the progress of an intussusception to a standstill. But it must be remembered that the mesentery is chiefly attached about the centre of the horseshoe formed by the great intestine, a fact which greatly modifies the elongation required; and also that in infants the peritoneal attachments of caecum and ascending colon are very incomplete, and that great mobility of these parts is the rule.

The effect of this drag on the intussusception is striking. It is forced into a curved form with the concavity towards the centre of the abdomen where the mesenteric root lies. The drag being entirely on one side, the orifice at the apex is dragged out into an elongated slit, whilst the apex itself is turned over and firmly pressed against the sheath. This change in the form of the orifice is probably responsible for the old idea that the apex was usually the ileo-caecal valve, especially as it was stated that the lips of the valve could be felt per rectum.

But of far more importance is the effect of tension and compression on the vessels of the mesentery. First the veins and lymphatics are obstructed, finally the arteries. As this occurs changes in the intussusception rapidly follow:

(a) There is marked oedema with extravasation of blood, especially at the apex. The glands of the mucosa take on an abnormal activity, and blood and slime appear in stools. The apex, and to a less extent the whole intussusception, become stiff and swollen, increasing the morbid activity of the sheath, and rendering reduction more and more difficult.

(b) The adjacent peritoneal surfaces of the entering and returning layers throw out lymph, which soon glues these surfaces together, this effect being also most marked in the oldest part—namely, at the apex—making reduction still more difficult.

(c) As soon as the arterial supply is cut off gangrene sets in. And now we are faced by a grave situation, for not only is the bowel obstructed, but it is occupied by a septic mass which must be removed if the patient is to survive.

(d) Its removal occasionally, but very rarely, occurs spontaneously, and the mass consisting of entering and returning layers is passed by rectum.

All these changes are more marked in the intussusceptum the middle layer especially suffering, whilst the sheath may be almost normal. Meanwhile the patient suffers not only from obstruction, but also from absorption of septic material from the damaged if not gangrenous tissues.

These characteristic changes are only seen, however, in the acute form of the disease. In the chronic form the peritoneal attachments have time to stretch, and consequently the pull of the mesentery is of much less importance. The contractions of the bowel are less violent, and may have little or no effect on the circulation. There is thus only slight swelling at the apex of the intussusceptum, and adhesions may be absent or be limited to this region. Severe oedema and gangrene only occur if the condition becomes acute.

Clinical.

In studying a large number of cases of intussusception we find that they fall naturally into two well-marked groups—the acute and chronic forms. These present, in almost every feature, a very remarkable contrast, and will require entirely separate discussion.

Acute intussusception occurs almost entirely in infants, and three-quarters of the cases are under 1 year. It presents an absolutely characteristic group of symptoms remarkably free from variation. As a rule no obvious cause for the condition exists.

Chronic intussusception, on the other hand, is rare in infants and occurs in children and adults. The symptoms are most irregular, and in at least 50 per cent. of the cases the diagnosis is anything but the correct one, varying from tuberculous peritonitis to new growths in the lung. In a large proportion of the cases a definite cause is discovered, such as a polypus or carcinoma. The clinical course of the two forms is in similar contrast, and the treatment involves very different considerations.

Acute intussusception occurs, as we have said, for the most part in young children: 100 cases, under 12, were distributed as follows:

| | | | | | |
|-----------------|-----|-----|-----|-----|----|
| Under 1 year | ... | ... | ... | ... | 72 |
| 1 to 6 years... | ... | ... | ... | ... | 22 |
| 6 to 12 years | ... | ... | ... | ... | 6 |

(Fitzwilliams.)

Above 12 it is rare, and, when it does occur, usually is the result of some definite cause.

But when we come to examine the cases under 1 year an even more striking result appears. Of the above 72 cases, 46 (64 per cent.) occurred during the four months from the fourth to the seventh inclusive. During the first three months the condition is exceedingly rare. Taking again cases under 12 years, two other facts of great interest appear. First, the boys outnumber the girls in the proportion of three to one. Secondly, there is a definite seasonal variation in the incidence, with sharp rises in April and December, and a great fall in numbers between.

From these statistical observations Fitzwilliams makes the deduction that improper feeding is an important factor in causation. At the fourth or fifth month the child is weaned, and after that we know only too well the sort of diet on which it is expected to subsist. And as Easter and Christmas are seasons of adult rejoicing it is considered only fair for the infant to participate.

As three-quarters of these cases occur in infants under 1 year, and as these are of a constant and characteristic type, we shall now describe in some detail the symptoms and signs of this group.

ACUTE INTUSSUSCEPTION OF INFANTS.

The child is usually well nourished and in perfect health. It rarely occurs in the subject of colitis or summer diarrhoea. The sudden onset of this severe condition in a fat and healthy baby is most characteristic. As a rule it starts with a severe and sudden abdominal pain, coming on in acute attacks with intervals often of complete relief. The child may vomit, but never to any great extent. Tenesmus is a marked feature, the child straining incessantly, but only passing a little blood and slime. At first a motion or two may be passed, but after this there is absolute obstruction, and no trace of bile will be found on the napkin. This sign, which was first pointed out by Barnard, is almost infallible, and should in every case be part of a routine examination. The blood and mucus are exuded from the intussusception in sufficient quantity to soon clear the lower bowel of its contents, in view of the violent peristalsis which is occurring.

On examining the child in a typical case the abdomen will be fairly lax unless the child is actively straining. In the course of the colon a tumour may be felt. It has very definite characteristics:

1. It is in the region of the transverse or descending colon.
2. It gradually shifts its position, advancing along the colon and increasing in extent.
3. It is sausage-shaped and of horseshoe form, the concavity being towards the centre of the abdomen.
4. Manipulation causes it to contract and become hard. This hardening is accompanied by an attack of pain and an increase in the tenesmus. The characteristic feature

is that, although the tumour may not be very tender, and manipulation may cause no instant pain, the pain rapidly follows and continues long after manipulation has ceased.

5. The apex may be felt by rectum.

The presence of this tumour is the essential sign of intussusception, and it is probable that if proper methods are adopted it may be discovered in all cases. A few words as to the examination of an infant's abdomen may therefore not be out of place.

First try without an anaesthetic. Sometimes the tumour may be felt at once, for between attacks of pain the abdomen may be quite lax. Usually, however, the child begins to cry, and the examination is given up as hopeless. This is an entire mistake. The abdomen of a crying infant can be readily palpated if the surgeon has patience and skill. Every now and then the child must inspire, and for an instant the abdominal wall is absolutely lax. This is the surgeon's opportunity, and yet it requires a nice touch to obtain satisfactory results. The slightest roughness is met by instant rigidity. The hand must be felt to form part of the abdominal wall, and to move with it, and at the instant of relaxation, when the diaphragm also moves downwards, the hand should perceive objects moving into contact with it from inside rather than attempt to reach these objects by a sudden plunge. With these precautions, the abdomen of a crying infant can be deeply palpated with certainty.

In any case of doubt an anaesthetic should be given. This enables one to carry out a most important manoeuvre, first suggested by Sir Frederic Eve—I mean a bimanual examination. A finger in an infant's rectum can, in conjunction with a hand outside, explore practically the whole abdomen. If after such an exploration no tumour is found, the case is probably not one of intussusception.

Contrasting with the tumour, a vacant space may be felt in the right iliac fossa—the famous *Signe de Dance*. It is the contrast between an empty and a full area that is of importance rather than the actual void itself. I would repeat that the abdomen as a whole is not rigid. Rigidity, apart from straining, and distension are signs that the case has gone too far for operation to be of any avail.

Let me recapitulate the cardinal signs of the acute intussusception of infants:

Pain, in sudden severe attacks.

Tenesmus and constant straining.

Blood and mucus in stools, and *no bile*.

Tumour, varying in consistency, increasing in size, advancing in position with each attack of pain.

Treatment.

The only treatment of intussusception is immediate laparotomy. Inflation by rectum is both useless and dangerous. Useless, because it rarely even appears to succeed, and because any reduction effected is almost always incomplete and rapidly renews. Dangerous, because it increases shock, wastes valuable time, and may do considerable damage. It was only justifiable in the days when the mortality of laparotomy was cent. per cent.

Precautions are taken for the avoidance of shock, the child being wrapped in wool and placed on a hot-water pillow in a hot theatre. The abdomen is opened through the right rectus, slightly below the middle. Two fingers are introduced and the bulk of the intussusception rapidly reduced, with sometimes an assistant's finger in the rectum. The last few inches may resist reduction. This portion of the gut will now be opposite the wound, and can be readily brought completely outside the abdomen, where it is carefully protected with hot pads. The reduction of these last few inches is always the crux of the operation. The mass is grasped in the left hand and gently, but firmly, squeezed. It will gradually unroll at the neck. Very slight traction on the entering layer is permissible, and may be necessary in the last stage, especially in the ilco-colic form. But the pressure of the left hand is the essential part. This not only tends directly to unroll the neck, but squeezes lymph out of the swollen apex, and enables it to pass the more easily. The peritoneum will probably crack at one or more places, but this must be disregarded. Complete reduction is essential. Very often the arrival of the appendix indicates the end. Any cracks in the peritoneal coat are closed with fine silk. The abdomen is closed by through-and-through sutures of

silkworm gut. The layers are too delicate for separate suture, and speed is essential. The after-treatment is simply directed against shock. Saline injections, either by rectum or subcutaneous, are started at once, and, if possible, kept up continuously. I would lay stress on the importance of the child receiving the fluid at a proper temperature (100°). Too often it cools in unprotected tubing, and is practically delivered as cold water. Adrenalin or pituitary extract are useful as accessories. Strychnine can only do harm, and should be entirely avoided.

But we may find that, in spite of every effort, the last few inches are irreducible, adhesions binding together the peritoneal coats or the apex being too large to pass the neck. This is a serious complication, for the continuity of the bowel must at all costs be restored. A faecal fistula is very unsatisfactory in an infant, and excluding, as it here does, the whole of the large intestine, is almost invariably fatal. Resection is attractive, but unjustifiable unless gangrene is present, for there is no recorded case of an infant under 1 year surviving this operation. Without any doubt, the best treatment is to bring the small and large intestines into apposition as close to the irreducible portion as is safe, and perform a lateral anastomosis. This relieves the obstruction and prevents a recurrence of intussusception. The irreducible part may gradually reduce itself, or may remain as a permanent condition, or the intussusceptum may slough away and be passed by rectum.

If the intussusceptum is gangrenous we have no choice but resection. In such a case Jessett's operation is probably the most hopeful, and certainly the easiest, to perform. A longitudinal opening is made in the sheath in a healthy region. Through this the intussusceptum is protruded till healthy tissue is reached. It is transfixed by two sutures at right angles and amputated. The sutures are divided so as to provide four sutures equally spaced round the stump and piercing all the coats. They are now tied and the stump returned into the sheath, which is closed by two layers of sutures. Two or three Lambert sutures may be inserted at the neck after as complete reduction as possible. In some cases direct resection with closure of the ends and lateral anastomosis may be more convenient. In an infant success is practically hopeless, though the attempt should be made, but after 5 years old several cases have recovered.

INTUSSUSCEPTION IN CHILDREN AND ADULTS.

In studying cases of intussusception occurring after the first year of life we are at once struck by three features in which they contrast forcibly with cases in infants. In 70 per cent. of the cases a definite cause can be discovered; they tend to be chronic; the symptoms are irregular.

Causation.

In an extensive series of cases (Eliot and Corscaden) the following were found to be direct causes:

1. Tumours were found in 40 per cent. Of these 24 per cent. were innocent and included mucous polyps, fibromata, lipomata, submucous haemorrhages; 16 per cent. were malignant—carcinomata and sarcomata.

2. Ulcers were found in 14 per cent., and were due to typhoid, dysentery, and tuberculosis.

3. Meckel's diverticulum (inverted) was the cause in 12 per cent.—a very remarkable number considering the comparative rarity of this abnormality.

4. Trauma, such as a blow or a violent strain, was a definite cause in a few cases.

We have already discussed the manner in which these causes act.

Chronicity.

More or less acute attacks occur, with intervals during which the patient is free from any acute symptom and only complains of general poor health. The attacks become more frequent and severe as time goes on, but they may go on over a period of from a month to a year.

Symptoms and Signs.

Pain is always a prominent feature. At first the attacks of pain are sudden and severe, and may cease as suddenly as they began. As, however, adhesions form and tend to check the progress of the intussusception, the pain takes

on a different character, and its onset and cessation are both more gradual.

Vomiting occurs in two forms, which should be carefully differentiated. With the pain we have the bilious vomit due to dragging on the mesentery. Apart from pain, and in the later stages, we have the dark vomit of infestinal obstruction, with all the grave characteristics of that condition.

Wasting and anaemia are always marked, and frequently lead to a false diagnosis, such as tuberculous peritonitis or carcinoma.

Either constipation or diarrhoea may be present. The former is more usual in enteric intussusceptions; the latter occurs in colic cases, and is accompanied by the passage of blood and mucus.

A tumour is to be felt in the abdomen in most, if not all, of the cases. It presents the characteristics we have already described. In form it resembles a concave sausage. With each attack of pain it becomes firm, increases in size, and advances in position, following always the path of the colon. In 30 per cent. of all cases its apex can be felt by rectum. It is tender and manipulation brings on an attack of pain.

The abdomen is not distended till obstruction has become a marked feature. Emptiness on the right side and fullness on the left are frequently noticed and are very characteristic.

Such are the symptoms of a typical case, but they may occur in such masked form that diagnosis is practically impossible. Of 55 cases collected by Rafinesque, 27 were incorrectly diagnosed, and other writers give an even larger percentage of error. A patient with wasting, obscure attacks of pain, and an indefinite tumour presents a fairer picture of the average case, and suggests a wide field for diagnosis.

The treatment of these cases only differs from that of the acute infantile form in a few details. Laparotomy is as essential in the one as in the other, but here we are dealing with an older patient, and extensive operations can be successfully carried out. And we have the further incentive to resection that we can thus remove the cause, which so often is of a definite nature in these cases. Once the condition is suspected operation should not be delayed, for many cases terminate with startling abruptness in a few hours, and, in any event, operation during an acute exacerbation is a very grave proceeding. Spontaneous recovery is rare, for although cases where the intussusceptum has passed by rectum are not very common, the great majority of these have died.

I have only dealt with the leading features of a very wide subject. Those who wish to study it in greater detail will do well to refer to the papers I mention below. In these full references to the literature will be found.

THE first State dental clinic for school children was opened in Vienna on March 13th.

ON January 15th, 1913, the total number of students in the medical faculties of France was 8,247. Of these 7,400, among whom were 803 foreigners, were men, and 847, of whom 358 were French and 489 foreign, were women. The schools as distinguished from faculties of medicine had 1,497 students, of whom 1,287, including 29 foreigners, were men, and 210 women, of whom 9 were foreign. The numbers for the several faculties were as follows: Paris, 4,211, as against 4,170 in 1912; Lyons, 1,055; Bordeaux, 751; Montpellier, 699; Toulouse, 346; Nancy, 306; Lille, 285; Algiers, 156. Among the medical schools Nantes stood first with 255 students; next came Marseilles with 245, and Rennes with 148. The others had numbers ranging from 52 (Limoges) to 220 (Grenoble). Of the foreign students the most numerous were the Russians, of whom there were 831. Of these 585 belonged to the Paris Faculty, and 133 to Montpellier. Next came the Turks, of whom there were 85; of these 68 belonged to Paris and 11 to Montpellier. There were 67 Bulgarians, of whom 20 were at Lyons, 28 at Montpellier, and 12 at Nancy. There were 59 Roumanians, of whom there were 54 in Paris and 5 at Montpellier. Among other nationalities represented were England (13), Greece (24), South American Republic (22), all studying in Paris.

REMARKS ON TRANSVERSE COLOSTOMY AS THE OPERATION OF ELECTION.

BY

LAWRIE MCGAVIN, F.R.C.S.ENG.,

SURGEON TO THE SEAMEN'S HOSPITAL, AND TO THE HOSPITAL FOR
WOMEN; LECTURER ON CLINICAL SURGERY IN THE LONDON
SCHOOL OF CLINICAL MEDICINE (POST-GRADUATE).

IN 1906, at a meeting of the old Clinical Society,¹ I ventured to draw attention to the question of the transverse operation of colostomy as opposed to the iliac method, and stated my belief that, of the two methods, the former was for many reasons the best. My views were at that meeting subjected to some criticism at the hands of certain leaders of the profession who had no better arguments to adduce than that the old iliac operation had always answered very well, that the control of faeces could not in the nature of things be so complete in the transverse operation, and that the length of colon excluded, being so much longer than that left by an iliac colostomy, could not but be a source of trouble.

I received these criticisms, coming as they did from such eminent authorities, in a somewhat chastened spirit, until on making inquiries I found that these gentlemen themselves had had very little more experience of transverse colostomy than I had myself, and two of them acknowledged that the question of anything better than the iliac method had never suggested itself to them. I therefore concluded that I had at least some ground for speaking on the subject.

Since that time I have continued to practise the operation of transverse colostomy as a routine method, and, judging from my own results, I have now very little doubt that the claims I put forward in 1906 were well founded; so much so that were I ever in the unfortunate position of having to undergo the operation of colostomy myself, I would stipulate most strongly for its performance by the transverse method, provided that the conditions permitted of its being done.

I am fully aware of the fact that the cases I have operated upon are not so numerous as to command the attention of surgeons who will never condescend to consider anything less than four-figure statistics, nor of those members of the profession who, being attached to the staffs of hospitals dealing solely with rectal conditions, are perhaps apt to look upon the work of others in their special domain as that of the unauthorized. It is not to such that I propose to address myself, but to those who, like myself, being attached to the staff of a general hospital, while dealing with a smaller number of such cases, have, from the varied nature of their work, developed a wider and perhaps more broad-minded outlook on surgery generally. I do not propose for a moment to attempt to defend the operation of colostomy, or make it out to be anything better than an unfortunate, and usually solitary, alternative to a very dreadful and necessarily fatal condition; it should never under any circumstances be performed if any better way out of the difficulty can be found; but that it merits the expressions of loathing and horror that are so frequently heaped upon it by those who have not stopped to consider its purposes, its results, and its surgical technique, I would most strenuously deny. Nothing is further from the truth than to say, as I have often heard said: "Better be dead than have a colostomy done."

It was with much interest and serious reflection that I read Mr. Paul's most excellent opening address in surgery at the meeting of the British Medical Association at Liverpool,² and while I realized that any statement coming from so well-known and famous a master of his craft as Mr. Paul must be accorded an attentive hearing, I must confess to no small measure of astonishment that not only does he advocate the lumbar route (which has long been considered obsolete) as a better method than the iliac, but that he refuses any place to transverse colostomy, and openly advises that it should never be performed. With all respect to Mr. Paul I would submit reasons why iliac and lumbar colostomy are not and cannot be in any way comparable to transverse colostomy, which, after practical experience, I have come to regard as the method *par excellence* from every point of view.

If we are to arrive at the ideal we must first of all have

a clear conception of what we consider the ideal—that is to say, what are the requirements which should be fulfilled by a really good colostomy? They may be stated as follows:

1. Good sphincter control.
2. Firm support for belt and plug.
3. Freedom from prolapse.
4. Accessibility.
5. Good spur formation.
6. Removal to a distance from the site of growth.

If these points are considered separately, I think it can be shown that the iliac operation—and what applies to the iliac will also apply, in some points more and in some less, to the lumbar—is singularly deficient in all of these desiderata, whereas the transverse operation has many advantages and few objections.

1. Good Sphincter Control.

Control of faeces in the absence of a *natural* sphincter depends on four conditions:

1. Elimination of the influence of gravity.
2. The formation of the most effective artificial substitute that can be devised for the natural sphincter.
3. The assistance of this artificial sphincter by a really efficient plug and belt.
4. The careful regulation of the diet and bowels in all colostomy cases.

In none of the first three of these points does the iliac operation satisfy our requirements. The best result obtainable is always marred by the imperfection of the control, and from time to time, sometimes unfortunately constantly, the patient is harassed by the extravasation of faeces when he is up and about, his life being rendered a misery to him by the constant necessity for repeated cleansing, and the unavoidable odour about his person. The reasons are not far to seek. The vertical position of the descending colon allows of a column of faecal matter accumulating above the colostomy opening, every fresh addition as it passes the splenic flexure increasing the weight of the column and the pressure on the artificial sphincter; thus the slightest exertion on the part of the patient tends to force this column past the sphincter, the influence of gravity being thus a very important factor.

2. Firm Support for Belt and Plug.

If this pressure is to be resisted, it must be met by a very efficient sphincter and a very efficient belt and plug. But what do we find? A sphincter made of the worst material and in the worst possible situation, and in a situation ill-suited to the requirements which the belt is expected to fulfil.

Now in iliac colostomy the sphincter may be placed in one of three positions, according to the length of meso-sigmoid.

- (a) In the substance of the oblique muscles.
- (b) In the linea semilunaris.
- (c) In the substance of the rectus muscle.

The first of these positions is that of the old method; it brings the opening too close under the vertical column of the descending colon; it is deficient in aponeurotic backing; and it is too close to the anterior superior spine of the ilium, with the result that when extravasation repeatedly occurs in elderly and thin people the skin over this prominence becomes macerated, and being rubbed by the belt, breaks down, and a painful ulcer, not unlike a bedsore in its intractability to treatment, is formed. Moreover, the action of these muscles is not particularly powerful at this point.

The second position is hopeless; the abdominal wall here is thin, aponeurotic not muscular, and the position has nothing to recommend it.

The third position is the best, but it is a long way from any fixed support; there is no aponeurotic backing, since the posterior sheath of the rectus muscle ends at the semilunar fold of Douglas; and this is the thinnest and weakest part of the rectus muscle. How do these positions suit the application of the belt? The belt to be efficient must have sufficient purchase to bring pressure on the opening. In all of these positions the alae of the pelvis are too widely separated to permit of this purchase, the abdominal wall, especially mobile at this point, simply giving to the pressure applied, and in this position a tight belt is not easily borne. Moreover, the slope of the loins and the prominence of the hips constantly tend to make the belt

"ride" upwards, and this necessitates the use of perineal straps if the belt is not to be quite useless; and this is especially so in women.

The fitting of a plug to a colostomy opening in any of these positions is also unsatisfactory, for to be efficient it must fit tightly without overstretching the opening or causing pain; and, although patients do not usually complain of the latter, the tendency of the opening to stretch is undeniable, since the muscle layer through which the bowel comes is lacking in aponeurotic support behind, and has only a comparatively feeble layer in front. The result is that frequently the plug has to be changed for a larger one in order to control the discharge of faeces, and ultimately the margins of the opening may become so flaccid that prolapse is favoured.

3. Freedom from Prolapse.

The comparative frequency with which this is seen in iliac colostomy is a strong point against the operation. It is true it does not occur in every case, but it occurs in certain cases, no matter how carefully the operation may have been conducted. One of the causes of the trouble has already been given; the other is again the effect of gravity; the conversion of the upper portion of the sigmoid into a receptacle subjecting it to dilatation, and the pressure of the vertical column of faeces in the descending colon bringing about a slipping down of the mucous membrane, if not actually of the bowel itself. I have more than once seen as much as 6 to 7 in. of bowel and everted mucous membrane protruding from the colostomy opening. Such prolapse is greatly aggravated by any excessive activity of the bowel, as from purgatives and irregularities of diet, of which it may, indeed, be to some extent the result.

4. Accessibility.

Although an iliac is more accessible to the patient than a lumbar colostomy opening (indeed, the latter could hardly be less conveniently placed), it is nevertheless in an awkward position, especially in stout patients with protuberant abdomens, since it tends to become overlung by abdominal fat. Again, when an action is intended, it does not permit of the placing of a receptacle over the opening while the patient is in the sedentary posture, unless the body is maintained upright, which position greatly lessens the purchase of the abdominal muscles for defaecation, and brings an undue strain on the inguinal regions.

For the comfort of the patient a colostomy opening should permit of accessibility both for cleansing and defaecation.

5. Good Spur Formation.

Some surgeons have denied the desirability of a double opening to a colostomy with a spur between, and maintain that the distal opening is bad because it catches any faecal matter which may pass the spur.

Personally I do not agree with this, and would always recommend a double opening and a good spur being made. If the operation is properly done and the plug fits snugly, nothing will pass the spur; and in cases of advanced rectal cancer it is a very great comfort to the patient to have the excluded loop of bowel washed out and cleansed of stinking debris and blood clot; and at times the pain may be much lessened by the introduction of various analgesic drugs. With a single opening, this could not be done. The idea that the excluded tract harbours a great quantity of secretion is entirely erroneous; it rarely harbours anything but a small quantity of the debris mentioned; but, if it did, surely the worst that could be done would be to shut it in by occluding the opening and compelling the bowel to absorb it, or pass it over the raw surface of the ulcer—the surest method of increasing the patient's anaemia and pain.

6. Removal to a Distance from Site of the Growth.

I have seen certain cases in which the proximity of a growth high in the rectum rendered the iliac operation difficult so far as carrying the bowel over towards the rectus muscle is concerned, the outer of the three positions having to be chosen. As the difficulty was caused by thickening and shortening of the meso-sigmoid, it is obvious that the iliac operation was unsuitable in these cases; in one of them the growth subsequently invaded the colostomy opening.

Thus it will be seen that iliac colostomy has little to recommend it, and a close comparison between the points above mentioned and those same points when applied to transverse colostomy will, I think, show the latter operation in a much more favourable light. The anatomical position of the transverse colon at once disposes of the effect of gravity in promoting extravasation; indeed, it does more, for since of the fixed points—the splenic and hepatic flexures—the former occupies a higher position, the colon passing between them, lying in the position of a hammock, it is clear that the passage of the faecal mass towards the stoma will, if this be placed to the left of the middle line, be accomplished *against* the force of gravity, consequently neither extravasation nor prolapse are likely to occur. I have never seen either of them in my own cases when once the belt and plug had been fitted; and with regard to prolapse Allingham has said, "Prolapse might happen, but we have not yet seen it, and it would scarcely be so likely to occur as in other places, for the transverse colon is in a way fixed at its hepatic and splenic flexures, and would thus tend greatly to prevent prolapse of the gut through the transverse opening."³

The portion of the bowel between the stoma and the hepatic flexure, from its position, acts as a receptacle, which, like the rectum, can be conveniently voided from time to time, and it is very remarkable to see the excellent control patients ultimately acquire over this act, the bowels being opened night and morning with great regularity, the patient gradually becoming aware of the need to void the contents of the colon. Such perfect control I have never seen in any case of iliac colostomy.

The sphincter provided for the stoma is as nearly perfect as anything can be. The opening should be made two inches to the left of the linea alba, and the same distance below the costal margin. There are excellent reasons for the efficiency of the sphincter when made at this point. The rectus muscle here is thicker and stronger than below the umbilicus, thus forming a deeper and firmer canal; it is reinforced *in front and behind* by powerful fibrous aponeuroses, which tend to moor the stoma in place. This anchorage is further strengthened by the linea alba internally, and the lineae transversae, one of which should fall above and one below the stoma. Owing to the shorter fibres of the rectus lying between these latter, the grip of the "sphincter" at the stoma is much more efficient than in the iliac operation.

The situation is admirable for the fitting of a belt; for not only are the loins here of a shape to hold the belt without slipping, thus doing away with braces, bands, etc., but a degree of pressure can be supported here with comfort which would be impossible below the umbilicus, this pressure being rendered possible by the presence of the costal margins and the presence of liver and the firm nature of the abdominal wall here.

Prolapse I have already dealt with; I have never seen it occur in any of my cases.

The position of the transverse colostomy opening renders it extremely easy for the patient to cleanse and care for it; no matter how obese he may be, the opening is never overhung by fat, as may be the case with iliac colostomy. The skin here is thick and not easily excoriated by the moisture of the mucous membrane. The evacuation of the bowels is most simply accomplished, for it can be performed in the sedentary attitude, the body being inclined forwards and a receptacle placed over the stoma. Owing to the depth of the intramuscular canal and the length of the mesocolon here, an excellent spur can be made when the operation is done by Maydl's method. That this spur is *always* better than that of an iliac colostomy I do not claim, but I have already given my reasons for the occasional defects in the spur formation in the latter, which defects are invariably absent in the transverse operation.

Besides this latter question of spur formation, removal of the colostomy to a distance from the site of the growth offers one other great advantage; there is no little doubt that the offensive odour of a colostomy is largely due to the proximity to and the ease with which the foul debris of an ulcerating growth is discharged from the iliac opening. I have seldom, if ever, known a transverse colostomy to be in the least offensive, but I have never known an iliac one that was not.

There is one other point in which transverse has a great advantage over iliac colostomy—that is, in cases of intractable fistulae of the rectum and anus, where a cure has been effected by temporary colostomy; the ultimate reconstitution of the colon is effected far more easily and far more safely and certainly in the case of the former than in that of the latter operation.

I have then endeavoured to lay out the points which to my mind support strongly the adoption of this method as a routine practice; and finally I would consider the objections that have been raised by certain surgeons to its performance.

The objection has been made that the subcostal position of the stoma is a more unpleasant one for the patient. I can only reply to this that none of my own patients have ever complained on this score; and the greater cleanliness and better control which this position gives goes far to overcoming this objection.

Again, it is contended that control *must* be more difficult, since the motions in the transverse are more fluid than in the descending colon. This I can answer from my own experience: it is a purely theoretical objection; there is so little difference in the contents of the two sections that there is nothing to choose between them. It is quite obvious that the life of a patient, no matter of what variety his colostomy may be, can never again be regarded as normal. That is to say, he must always so regulate his diet and fluid intake as to favour constipation rather than diarrhoea, and so keep the excreta as firm as possible.

Mr. Paul has made the objection that the position is not a good one in view of the possibility of a subsequent laparotomy; neither is any colostomy, iliac, lumbar, transverse, or caecal. But since these operations are commonly reserved for patients who are already doomed, the prospect of their ever having to undergo such laparotomy must be very small indeed. Case xv is an exception—the only one I have come across in my practice.

Lastly, an objection from one of the highest authorities on rectal surgery made to me personally, is one which I mention merely to show the extraordinary attitude so often assumed by certain surgeons who, because they cannot themselves see any good in a new method, would deny the possibility of its existence, when expounded by others. It was that "iliac colostomy having served its purpose for so many years, there did not appear to be any obvious reason why it should be abandoned." On such an objection I leave the more progressive of surgeons to pass their own criticism. My cases are, as will be seen, comparatively few, and this is accounted for, first, by the fact that I have only used those of which accurate notes have been kept, many being hospital cases of which the notes have been found worthless, or have actually been mislaid; and, secondly, because I have never submitted any patient to colostomy who could by any means be safely tied on to the end without it; thus I have often avoided the operation where, with less trouble or more precipitate action, I might have performed it.

CASE I.

M. C., aged 60, married; has had three children; advanced carcinoma of second part of rectum; iliac colostomy by Maydl's method; bowel opened on third and divided on fifth day. Belt fitted on twenty-seventh day.

Patient survived eight months. Control seldom complete, and extravasation occasionally troublesome; complained much of her condition. Towards the end prolapse of mucous membrane with every evacuation, manual reposition being necessary. Could never leave her house for any length of time. Painful excoriation about anterior superior spine, she being a thin woman.

CASE II.

E. J., aged 52, married woman; three children; very stout; advanced carcinoma of first part of rectum with secondary deposits in liver, and malignant ascites. Iliac colostomy by Maydl's method; bowel opened on third and divided on fifth day. About an hour after division the divided ends suddenly receded into the abdomen. Laparotomy immediately performed, Paul's tubes in either opening; abdomen sponged out and drained.

Patient died forty-eight hours later from shock. The conclusions to be drawn from this case are that the fifth day is dangerously early for the division of the bowel; and that when ascites is present it is especially so, since the oozing of ascitic fluid between the bowel and the wound margins results in delay in the formation of plastic adhesions. Since this case was done I have made it a rule never to remove the rod or divide the bowel before the tenth day.

CASE III.

E. P., aged 18, unmarried girl, with a fistula in the left iliac region, following the opening of an abscess resulting upon left salpingo-ophorectomy performed by another surgeon. Every means had been tried in hope of closing this fistula without success. Transverse colostomy by Maydl's method done, with a view to resting the fistula and allowing it to close. Bowel opened fifth day and divided on tenth.

Result excellent; control perfect; no extravasation or prolapse. Although discharge from fistula not entirely stopped, latter reduced to fine probe sinns at end of ten weeks. Patient, when apparently in perfect health at end of three months, and while waiting for reposition of colon, was suddenly taken with signs of acute intestinal obstruction. Operation was refused by her parents and she died unrelieved. *Post mortem*: Ileum caught by the loop of a fine adhesion, stretching from right psoas muscle to umbilicus. Colon below the stoma shrunk to diameter of little finger. Fistula track Y-shaped and leading to both sigmoid and small intestine, 4 in. above ileo-caecal valve.

CASE IV.

J. B., aged 50, widow. Advanced carcinoma of second part of rectum. Much ulceration and bleeding and great pain, defaecation causing agony for one or two hours. Iliac colostomy by Maydl's method resulted in very great relief, the bowel being opened at end of forty-eight hours and divided on tenth day. This patient lived five months. Control was never complete, and extravasation, in spite of repeated fittings of belts and plugs and careful dieting, caused her much misery, and she was practically bedridden owing to this from the time of her operation.

CASE V.

F. D., man aged 25, admitted for intractable chronic dysenteric ulceration of rectum; his motions being mixed with blood and mucus, and defaecation being accompanied by intense aching pain. Patient rapidly going downhill. Transverse colostomy by Maydl's method resulted in complete cessation of pain and great improvement in general condition. At the end of a year patient, finding his control so good and colostomy so satisfactory, refused to have the colon replaced. Owing to the fear of a fresh outbreak and of the formation of a stenosis of the rectum which even now threatened, this was not pressed. Two years or more after his operation this patient contracted pulmonary phthisis, of which he died.

CASE VI.

K. C., woman aged 55. Advanced carcinoma of rectum, involving second part high up, threatening obstruction, nothing but fluid motion passing; tenesmus and dragging pains; blood in motions; discharge very foul. Iliac colostomy by Maydl's method; meso-sigmoid thickened and very short. Bowel opened in forty-eight hours, and divided on tenth day. Subsequent control very difficult, owing to slipping of belt, she being small in the waist and wide in the hips. Complained much of the discomfort, and never could regulate her actions sufficiently to trust herself out of doors; consequently had to lead the life of an invalid to the end, which came eight months after operation. There was always a tendency to prolapse, moisture, excoriation, and foul discharge from the distal stoma.

CASE VII.

H. B., aged 45, suffering from faecal fistula through old laparotomy scar and stenosis of rectum. Six months previously patient had apparently undergone operation for pyosalpinx; this was followed by pelvic peritonitis, the formation of an abscess which burst into the rectum, and a second one which burst through the old wound and very soon discharged solid faecal material. Several attempts were made to close this sinus without avail, nearly all her excreta passing through it. It was then found that the rectum passing through a mass in the pelvis was tightly stenosed. Transverse colostomy by Maydl's method. Belt fitted at end of three weeks. Patient is alive and well eight years after operation. She tells me she has no difficulty whatever with the colostomy. Her control has always been so perfect that she can frequently leave off the belt. She knows exactly when the bowel requires evacuation, and has trained herself to do this morning and evening. She has never had prolapse, and only on one or two occasions has there been the least tendency to extravasation when she has taken a purgative. She does not experience any unpleasantness from the high position of stoma, and finds access to stoma much easier than it was to the old fistula, which closed entirely six or seven months after operation. The patient has been so perfectly comfortable that she has carried out her work for the past seven and a half years without any difficulty.

CASE VIII.

K. B., 47, sent to me by Dr. Sidney Beauchamp for the cure of an umbilical hernia. During convalescence was discovered to be suffering from carcinoma of rectum. Seen in consultation with Mr. (now Sir Anthony) Bowlby and Mr. (now Sir Alfred) Pearce Gould, who advised against excision. Transverse colostomy done by Maydl's method. Bowel opened on fifth and divided on tenth day. Belt fitted twenty-fourth day. This patient travelled to Devonshire at the end of the fifth week, and dined the same night in evening dress with her family. This she continued to do, leading her ordinary life and frequently motoring many miles in the day, to within four months of her death, which occurred over three years from the time of her operation. So satisfactory was her condition through-

out that none of her household except her husband knew that such an operation had been done. She wrote to me many times saying how perfectly satisfactory she found the colostomy.

CASE IX.

P. C., married woman, aged 49. Advanced carcinoma of rectum in the second and third part, with secondary deposits in the liver and sacral glands. Could only pass flatus and fluid. Great pain and tenesmus, and occasional distension and partial obstruction. Linen always stained with foul bloody discharge, the sphincter ani being quite inactive. Transverse colostomy. Bowel opened at once on a Paul's tube and divided tenth day. From time of operation bleeding, discharge, and pain ceased entirely, and patient began to sleep well at night. She lived for fourteen months. During this time her colostomy worked perfectly. In less than two months she had almost complete control. From this time she never had the least difficulty; there was neither extravasation nor prolapse, and she herself said that had she realized how little inconvenience she was to have she would not have hesitated so long to have the operation done.

CASE X.

D. M., man aged 61, admitted with signs of acute intestinal obstruction, no obvious cause being present. Colon distended as far as the splenic flexure. Symptoms had been present for three days, and patient was very ill and feeble. Transverse colostomy was performed and a Paul's tube inserted. Immediately an enormous quantity of flatus and faeces passed, and patient was relieved. Four days later he again began to vomit and become distended, and although the signs were obviously those of general peritonitis, he was too ill to undergo any further operation, and died on the sixth day. *Post mortem* was found general suppurative peritonitis resulting from a perforating ulcer of the ileum just above the ileo-caecal valve, due probably to the preceding distension.

CASE XI.

J. A., married woman, aged 71. Advanced cancer of the sigmoid colon, chronic obstruction becoming acute. Patient very feeble. Refused operation till third day of vomiting, and then accepted. Transverse colostomy. Patient unrelieved, and died of ileus on the second day.

CASE XII.

M. L., married woman, aged 62, under care of Dr. Donkin of Bexley. Exactly similar case to the above, the obstruction being acute. Transverse colostomy: bowel opened at once, a large amount of faeces and flatus escaped. Union, however, was defective, probably owing to debilitated condition of patient, and leakage occurred into the perineum, causing patient's death from general peritonitis on the tenth day.

CASE XIII.

E. W., married woman, aged 47, under care of Dr. R. T. Smith. Carcinoma of uterus. The whole pelvis appeared to be filled with a mass of growth, the rectum being almost completely obstructed. Transverse colostomy. Bowel opened third and divided tenth day. Belt fitted twenty-fourth day. Patient died more than two years later. From the time this patient received her belt, she had no difficulty in controlling her motions with the usual restriction as to diet, she remained comfortable up to the end, the bowels being opened night and morning; there was neither extravasation nor prolapse.

CASE XIV.

J. D., man aged 41. Carcinoma of rectum in second part, with secondary deposits in liver and glands. The patient was so ill and wasted that the question of operation was deferred, but as obstruction threatened, and he began to vomit, an iliac colostomy was done. The sigmoid mesocolon was found much contracted, and the bowel was rather tense when the rod was passed beneath it. It was opened as in the last case, but the result was negative, little or nothing but flatus passing; the vomiting, however, ceased. As it was clear that there was some obstruction higher up, it was thought unwise to open the transverse colon, and therefore a caecostomy was done. This relieved the patient, who, however, died of asthenia on the fifteenth day.

CASE XV.*

B. C., married woman, aged 42. Carcinoma of sigmoid. Laparotomy. No secondary deposits found; growth quite free. Growth with meso-sigmoid everted and fixed in position of iliac colostomy. Proximal loop opened on fifth day, the whole mass being resected on fourteenth day, leaving the parts in the condition of iliac colostomy. The patient is still alive and well five years after operation, but has always had great difficulty in controlling her bowels. She can never depend on her belt although many varieties have been tried, and lately she has suffered from prolapse; her skin is consequently often tender and excoriated, and she has to allow herself to become constipated in order to be able to do her housework. She is at present considering the question of transverse colostomy in order to obtain relief. A year later I removed this patient's appendix, obtaining a primary union in spite of the colostomy.

* Since this paper was written this patient has undergone two further operations, first for a non-malignant tumour of the right ovary, during which operation I did away with the lower colostomy opening by implanting the rectum into the transverse colon; and, secondly, for closure of the upper colostomy opening. This patient is still in hospital, but is doing well and is passing everything per rectum. She shows no sign of any return of her growth.

CASE XVI.

S. C., married woman, aged 20. Extensive carcinoma of the whole abdomen, probably commencing in the pelvis. Early acute obstruction. Transverse colostomy. Colon found so bound down and the mesocolon so infiltrated that it could not be brought over the rod; it was therefore stitched to the skin margin and a Paul's tube inserted. Patient was relieved of vomiting and pain, but the absence of a spur permitted a good deal of faecal matter passing beyond to stoma. Patient died of exhaustion a fortnight later.

CASE XVII.

J. V., man aged 60. Carcinoma of third part of rectum and anus. No obstruction, but great pain and bleeding on defaecation; some small glands in both inguinal regions. Transverse colostomy by Maydl's method and removal of all inguinal glands. Bowel opened fourth and divided on tenth day. Excision of rectum and anus four days after colostomy by direct route. Patient is alive and well three years after operation. He has never had the least trouble with the colostomy, and has excellent control, knowing at once when the bowels require relief. Tells me he frequently discards his belt in the hot weather, as he never suffers from extravasation or prolapse. There is at present no sign of recurrence.

CASE XVIII.

M. H., 69, married woman. Under care of Dr. Sidney Beauchamp. Patient had an umbilical hernia, with symptoms of intestinal obstruction, which were thought to be the result of it. At operation no strangulation was found but a narrow ring cancer of the splenic flexure. Transverse colostomy by Maydl's method. Bowel opened on table and divided on tenth day. Patient relieved; good recovery. Patient lived eighteen months. Up to last two months of her life she had no difficulty whatever with her bowels, the belt being comfortable and controlling the motions perfectly. During the last two months the growth invaded the abdominal wall and broke down, an abscess discharging beside the stoma. This ceased to discharge for some time, but again broke down, and ultimately the patient died of asthenia. Had this patient not been so aged and corpulent, the case would have been better served with an ileo-sigmoidostomy.

CASE XIX.

L. C., married woman, 57 years of age. Inoperable carcinoma of rectum in the second part. Admitted with acute obstruction, vomiting, and distension. Patient very ill, and transverse colostomy done simply to relieve distress, bowel being opened on table. Immediate recovery took place and colostomy worked well, but patient died of perforating ulcer of caecum on the eighth day.

CASE XX.

M. S., married woman, aged 57. Inoperable carcinoma of sigmoid. Patient going gradually downhill with bleeding, pain, sleeplessness, and recurrent obstruction. Transverse colostomy by Maydl's method. Bowel opened third and divided tenth day. Bleeding and pain ceased almost entirely. Patient obtained complete control as soon as belt was fitted, and although more or less an invalid owing to her weakness, was able to get about with comfort for months after her operation, and was still alive when seen twelve months from that date. There was never either extravasation or prolapse, and patient expressed herself as perfectly comfortable.

CASE XXI.†

R. C., man aged 57, suffering from carcinoma of second part of rectum, with bleeding, pain, and incontinence of faeces. Growth was removed by abdomino-perineal excision. Transverse colostomy done by Maydl's method as a preliminary operation. Bowel opened in forty-eight hours and divided tenth day. Patient, in spite of *Bacillus coli* infection of superficial layers of abdominal wound, made an excellent recovery. He has never had any difficulty with his wound and has done his work without discomfort, extravasation, or prolapse for nearly two years, and says he is very satisfied with his operation. There is no sign of recurrence.

CASE XXII.

S. S., man aged 65, suffering from malignant growth of transverse colon at junction of middle and left third. Laparotomy done at site of transverse colostomy and growth found slightly adherent to stomach and omentum. The whole mass with its mesocolon everted and fixed outside abdomen. Bowel opened on fifth day and whole mass resected on fourteenth day, leaving him with the condition of a transverse colostomy. It is now two years and eight months since his operation, and he is alive and well; he has done his work regularly since convalescence, and so satisfactory has his colostomy proved that he tells me he has "discarded his belt as he has perfect control without it, and never uses it 'unless he has taken a purge.'" In spite of the absence of the belt there is no prolapse. He wears a pad of cotton-wool over the stoma to protect it.

CASE XXIII.

F. J., man aged 41. Similar case to No. 21; transverse colostomy preliminary to abdomino-perineal excision of rectum. Patient unfortunately suffered severely from *Bacillus coli* infection owing to the tearing away of growth in the pelvis, where it was slightly adherent to the sacrum. He died on the fourth day.

† This patient has died of a recurrence since this paper was written.

CASE XXIV.

E. S., married woman, aged 62. Extensive inoperable carcinoma of second and third parts of rectum, with enlargement of liver and secondary glands. Transverse colostomy by Maydl's method. Bowel opened fifth and divided tenth day. Patient had perfect control and lived three months without discomfort or prolapse. Bowels were moved morning and evening. She died of asthenia.

CASE XXV.

M. M., married woman, aged 60. Similar case in all respects to the above, and equally satisfactory; neither extravasation nor prolapse, and patient is alive and able to get about without discomfort.

CASE XXVI.

J. W., unmarried woman, aged 57, sent to me by Dr. Donkin of Bexley. Carcinoma of second part of rectum, no glands and no enlargement of liver. Transverse colostomy done as preliminary operation to abdomino-perineal excision of rectum, the two operations being done under spinal anaesthesia, with the exception of forty minutes light chloroform anaesthesia. Sixteen months since operation, patient well and no sign of recurrence. Colostomy works well, and with belt she has complete control, is comfortable, has no trouble with her bowels, and is able to get about as well as ever. She expresses herself as being very pleased with the result of operation.

Thus of these 26 cases 20 have been done by the transverse and 6 by the iliac method. Of the former 3 were done for non-malignant and 17 for malignant conditions. Of the non-malignant 1 died of strangulation at three months, and 1 of phthisis at two years from operation, the third is alive and well to-day.

Of the malignant cases 5 are alive to-day, 1 at three years, 1 at two years, 2 at eighteen months, and 1 at a year from the time of operation; and in all of these this method of colostomy has fully justified the opinion I have formed of it, as it has also done in all cases in which the patients have lived sufficiently long to allow of an honest judgement being formed.

URACHAL FISTULA.

BY

J. ELMSLY MITCHELL, M.D. ABERD.,
WEST HARTLEPOOL.

As is well known, in early fetal life the allantois, the pouch from the lower end of the primitive intestinal cloaca, projects through the umbilicus. At the seventh month the upper portion of the allantois becomes normally closed and forms a fibrous cord, called the urachus, extending from the umbilicus to the urinary bladder, which is derived from its lower portion. Now and then the upper part remains patent, as the so-called urachal fistula, from which a certain amount of urine escapes upon attempts at micturition. In such a case any of the following conditions may be observed:¹

(a) A button-like papillary projection at the umbilicus with an orifice at its summit, through which a probe may be passed.

(b) The urine may escape at several points of a hernial protrusion, covered externally by mucous membrane.

(c) The orifice may be a mere deficiency in the linea alba.

The abnormality may be said to be one of degree, the greatest deformity being fissure of the bladder, in which condition the allantois has failed to close completely inside the abdomen, so as to form the urinary bladder, and the lateral borders of the latter are adherent to the sides of the cleft, while the anterior wall is entirely absent. Again, the cleft may be confined to the upper part of the bladder, which presents itself as a red protrusion just beneath the umbilicus, the parts below being perfect.² Whichever condition exists, there is a greater or less amount of discomfort and danger.

The following case is interesting, because of the size of the projection, the presence of an apparent pouch, and the rapidity of closure with practically no interference of a surgical nature:

Mrs. W., primipara, somewhat neurotic, was confined on May 19th, 1912. Presentation was normal, and, on account of a prolonged second stage and the patient's temperament, delivery was accelerated by forceps under an anaesthetic.

The child (a male) was apparently healthy, presented no obvious signs of incomplete development, and shortly after birth weighed $7\frac{1}{2}$ lb. It may be noted that the umbilical cord contained a great excess of Wharton's jelly, its circumference being 6 in. at a point 7 in. from the child. It was tied and afterwards dressed in the ordinary way.

Four days later (May 23rd) the nurse reported that the state of the navel seemed unusual, and that the infant had not passed any urine. On examination the cord was found to be partially separated and particularly foul, the surrounding skin having an inflamed appearance. What remained of it was removed, and there was found at the umbilical region, projecting quite above the surface of the skin, a bright red mass of almost cauliflower appearance, having a circumference slightly larger than that of a penny. It was tender to the touch, and at two obvious points upon its surface small globules of urine oozed, while the child cried and struggled. On passing a fine probe into these openings it was found that one led straight into the cavity of the bladder without any obstruction; the second led into the first passage, about $1\frac{1}{2}$ in. from the entrance; there was a third opening on the surface into which the probe entered for only an inch, but when in this small pouch it could be moved easily from side to side. In no case could the probe be passed upwards.

The surrounding skin was smeared with a mild, unirritating ointment, and waterproof tissue, cut in such a way as to fit tightly round the base of the projecting mass, and so prevent the urine touching the skin, was applied, and on the top of this a thick pad of wool and binder, the wool being changed as frequently as was necessary. There was a slight degree of phimosis present, but when, two days later, a small catheter was passed, the urethra was found quite patent. The raw surface was dressed several times a day like an ordinary wound, and the child got frequent boric acid baths, as recommended by Vaughn,³ to aid normal micturition.

On May 30th, eleven days after birth, the nurse stated that normal micturition had begun, and on June 6th it was seen that the pad of wool was no longer wet with urine. The protuberance had diminished in size, and, on probing, though the main canal leading to the bladder was still pervious, the smaller one could not be found, whilst that connected with the small pouch would scarcely admit the probe. The whole surface was lightly touched with silver nitrate.

On June 12th the projection was only the size of a small nut, and pink instead of red in colour. The only canal pervious was the main fistula, and no urine was squeezed out even when the child struggled, or during micturition. It was again treated with silver nitrate, the entrance to the fistula being especially cauterized.

On June 24th the umbilicus still projected slightly, but had become the colour of the surrounding skin. Probe entered the fistula with difficulty.

On August 10th there was no apparent fistula left, and all the functions of the infant were normal.

At no time in this case was there any rise in temperature, nor was any faeculent material ever excreted at the fleshy protrusion. The child, with the exception of the first few days of its existence, steadily increased in weight, and on August 10th was 16 lb., and above the average weight at that age. There were no complications, and the progress throughout was not such as to warrant more energetic methods of treatment.

In some cases a slender electric cautery has been applied to close up a small urachal tract, but this is not without danger; in others, laying open the dilated urachus at the umbilicus, evertting its walls, and cauterizing the whole interior with zinc chloride, is successful even after plastic paring has failed.⁴

In cases simpler than that detailed above the application of a ligature around the base of the papilla which will dry up and fall off, leaving the fistula permanently closed, is sufficient. The choice of any of these methods of treatment, however, must depend not only upon the local conditions at the umbilicus, but also upon the circumstances associated with the abnormality, for urethral calculus, phimosis, and congenital stricture often accompany it, and unless these are treated with a certain degree of success, no attempt at closure should be made.

THE Royal Academy of Medicine at Turin reminds the medical profession in all countries that the thirteenth award of the Riberi prize of £8,000 for scientific work relating to medical subjects in the widest sense will be made on December 31st, 1916. For particulars application should be made to the Secretariat of the Academy, 18 Via Po, Turin.

ENCHONDROMA OF THE MANUBRIUM STERNI SUCCESSFULLY REMOVED BY OPERATION.

By W. G. RICHARDSON, M.B.DUNELM., F.R.C.S.,
SENIOR ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY,
NEWCASTLE-ON-TYNE.

A. C., aged 26, a healthy, well-developed, sea-going engineer, was sent to me on February 15th, 1913, by Dr. Baker, of North Shields. He had a swelling in the lower part of his neck, immediately above the sternum (Fig. 1), and he complained of difficulty in breathing when he exerted himself.

When I first saw him he had just arrived at the Royal Victoria Infirmary, having walked uphill from the railway station, a distance of less than a mile; he looked anxious and appeared to be distressed in breathing, and he told me that he always felt the same after exertion. With the exception of shortness of breath he had no complaint to make and he appeared to be in perfect health.

History.

He had known of the existence of a swelling above the sternum for years. It had never inconvenienced him by interfering with his employment and it had never been painful. Seven months previously he noticed that it was increasing in size, and shortly after that date he began to feel some shortness of breath during exertion, but he always found that he recovered as soon as he rested. The shortness of breath, however, had become distressing during the few weeks before he saw Dr. Baker, and on that account alone he sought medical advice.

Condition on Admission.

The swelling was in the mid-line of the neck, and in appearance it was indistinguishable from an adenoma of the thyroid gland. It was densely hard, uneven on the surface, and continuous with the sternum. The sternal head of each sterno-mastoid muscle passed in front of the tumour, which was not affected by the act of swallowing. Movements of the head and of the neck were natural. There was no cyanosis and no visible distension of the veins of either the head and neck or of the arms. The patient was not aware of any alteration in the tone of his voice, and there was no pulsation or bruit in the tumour.

He was admitted as an in-patient for observation, and during the few following days he showed no symptoms whatever.

The tumour, being of very slow growth, was thought to be innocent; but, in view of the fact that the difficulty in breathing was increasing rather rapidly, there was a suspicion that it might be sarcomatous. An x-ray photograph showed a shadow in the situation of the tumour, but it was ill defined and little more than enough to obscure the shadows of the vertebrae.

Diagnosis.

We had to deal with a tumour attached to the sternum which was narrowing the upper outlet of the thorax and implicating the trachea at such a low point as to render it impossible to perform tracheotomy, should that operation, as seemed probable, become necessary, and thus removal of the tumour was the only alternative. The question arose, Was removal practicable? Slow growth and the absence of any symptoms pointing to infiltration of adjacent structures made it probable that there was something in the nature of a capsule, and, if that were the case, removal would be possible. In that opinion I had the benefit of the concurrence of Professor Rutherford Morison.

Operation.

I operated on March 5th. The incision was in the line of a necklace with a pendant (Fig. 2). Both sterno-mastoid muscles were fully exposed in their lower portions, and so were the great pectoral muscles and the sternum to a point below the junction of the manubrium and the gladiolus. Each sterno-mastoid muscle was divided about $2\frac{1}{2}$ in. above the clavicle, but not completely, the outer part of the clavicular portion of each muscle being left. The sterno-hyoid and sterno-thyroid muscles were behind the tumour, and were divided at a late stage of the operation. Each clavicle was sawn through about $\frac{1}{4}$ in. from

its sterno-clavicular joint (Figs. 3 and 4). The portion of each great pectoral muscle which covered the first intercostal space was dissected up, and then the intercostal muscle on either side was separated from the sternum with a periosteal elevator. The sternum was sawn through immediately above its junction with the second costal cartilages, and an elevator being inserted into the saw-cut, the manubrium sterni was levered up. This latter procedure did not cause any increase of pressure upon the trachea. Each first costal cartilage was divided with bone pliers. It was found that there was a capsule over the posterior surface of the tumour, and thus the subsequent steps of the operation consisted in easing the underlying structures and the innominate veins over the irregularities of that surface—partly with the blade and partly with the handle of the scalpel. The wound was sewn up with interrupted silkworm gut sutures and a drain of iodoform gauze left in, chiefly for the purpose of checking haemorrhage from the cut ends of the clavicles: one end of the gauze was brought out at the lower end of the vertical incision.

During the operation it was found that though the growth sprang from a point towards the left side of the upper border of the manubrium sterni, the most prominent backward projection of the tumour almost reached the spine towards the right side of the neck, and the upper

opening of the thorax was in a large part occluded. The trachea was not recognized. Haemorrhage was slight. At the end of the operation the patient coughed, and the consequent distension of the veins in the floor of the wound was very alarming, as they swelled up to a degree which recalled the bulging of an abdominal ventral hernia. In the dressing a large pad of wool was retained in position by an elastic bandage to make good the absence of support normally given to the great vessels by the manubrium sterni.

Fig. 1.—Constitution on admission.

Fig. 2.—Three weeks after operation.

Nature of Tumour.

On section, the tumour appeared to the naked eye to be a simple enchondroma, and Professor Stuart McDonald has reported that

microscopic examination confirms that view.

After-History.

The wound was dressed on the fifth day, for the purpose of removing the gauze, and it was healed on the tenth

Fig. 3.—Photograph of the whole mass removed, viewed from the right side. rhage from the cut ends of the clavicles: one end of the gauze was brought out at the lower end of the vertical incision.

During the operation it was found that though the growth sprang from a point towards the left side of the upper border of the manubrium sterni, the most prominent backward projection of the tumour almost reached the spine towards the right side of the neck, and the upper

day. The patient was allowed to be out of bed on the sixteenth day, and he is now well.

The remaining portion of the clavicular head of each sterno-mastoid muscle acts strongly, and both arms can be raised from the sides, at full stretch, until the palms of the hands meet together high above the head, or are placed together straight out forwards.

A CASE OF ABDOMINAL ANEURYSM WITH UNUSUAL FEATURES, OPERATED ON BY MEANS OF COLT'S APPARATUS.*

BY

J. RUPERT COLLINS, M.A., M.D.DUB.,

PHYSICIAN, CHELTENHAM GENERAL HOSPITAL,

AND

C. BRAINE-HARTNELL, F.R.C.S.EDIN.,

SURGEON, CHELTENHAM GENERAL HOSPITAL.

C. P., aged 41, had all his life been a farm labourer, and had enjoyed good health with the exception of having attacks of "indigestion" and being subject to colds. During the past twelve months he had lost weight and had lately been troubled with obstinate constipation.

He was at full work up to the day of his present illness and was accustomed in the course of his work to carry a sack of meal weighing 2½ cwt. On March 26th, 1912, he was at his work as usual when he was seized with what he described as a pinching pain which doubled him up and caused him agony. He went home to bed; his wife applied hot fomentations and the pain became less. The next morning he was feeling so well that he started out to work, but as soon as he began to labour he was seized with the same pain as previously and soon after vomited some green fluid. He returned to bed, and on April 2nd was sent into hospital on an ambulance as a case of acute appendicitis. He was admitted to the surgical ward and on the following day we saw him together, and he was transferred to the medical side.

The man was very pale, sweating, and in considerable pain, which he located as gripping him right across the abdomen above the umbilicus and going into his back. The temperature was 100° and the pulse 66. The right side of the abdomen was contracted but was not hard. There was a little tenderness to palpation over the right hypochondrium, but no tenderness. Any attempt at deep palpation produced contraction of the abdominal muscles. The area of cardiac dullness was enlarged, the apex beat was in the sixth space in the nipple line, and the blood pressure was 115 mm. of mercury. The knee-jerks and pupil reflex were normal. The urine contained a few red blood cells. The leucocyte count was under 8,000 on the three occasions on which it was examined, the haemoglobin was 100 per cent.

He was ordered belladonna suppositories and hot fomentations to the abdomen. On the following day he was much easier and the abdomen less contracted. For the next few days he felt so much better that he asked each day to be allowed to go home and resume his work. On April 6th he passed some bright blood with a motion, and had a considerable amount of pain, for which he was

given morphine. The pains now were more severe, and occurred more frequently; they were always in the same region, and he thought that the pain in the back was worse than the pain in the abdomen. On admission he lay on his left side, but later preferred to lie on his right side or on his back. The abdomen was always flatulent, and palpation was accompanied by much gurgling. The stomach was dilated.

The least exertion, as turning in bed, was liable to evoke paroxysms of the most acute pain, which rendered him pallid and perspiring. On two occasions he was in a bad attack of pain when one of us entered the ward, and the pain ceased on palpating the abdomen. The pain would come on suddenly and leave him abruptly, and, though he was an extremely plucky man, he suffered at times severely, in spite of receiving one-sixth of a grain of morphine every six hours.

We could now make out a swelling in the right hypochondrium, below the ninth costal cartilage, and wholly to the right of the middle line; the tumour pulsated, and though it was difficult to say whether the pulsation was distensible, we thought it was. A loud single sound, systolic in time and impure in character, but not harsh enough to be termed a bellows murmur, was audible over the swelling and along the spinal column. We made an entry in the notes that we were surprised to find that the pulse in the dorsalis pedis, could not be felt on the right, but easily on the left. On the following day (April 14th) the right leg and foot became oedematous. There was no sign of oedema in the left foot until April 28th, two days before the operation, when it too became oedematous. On April 14th the collateral circulation was evidenced by the distension of the right epigastric vein and by little patches of dilated venules on the right side below the costal arch. The temperature continued irregularly febrile in character. Constipation was difficult to treat, as anything in the nature of laxatives by the mouth caused him much pain.

The diagnosis was beset with difficulties. Absence of tenderness in the right iliac fossa and on rectal examination seemed to exclude appendicitis. The finding of red blood cells on three occasions in the centrifugized deposit from the urine, the sudden paroxysmal pains, and the contracted right abdominal muscles, suggested a renal cause. The history of loss of flesh (the patient was clearly wasted), with recent obstinate constipation, a tumour to be felt, a considerable haemorrhage from the rectum, and oedema of the right leg suggested strongly the existence of a neoplasm of the bowel, with a deposit pressing on the right common iliac vein. The absence of all anaemia and of any leucocytosis was evidence against malignant disease. The expansile pulsation of the tumour, the delay in the artery of the foot, the bruit over the swelling and also over the spinal column, and the character of the pain, agonizing while it lasted and then ceasing, and readily evoked by movement of the bowels or of his position in bed, pointed to the presence of an aneurysm.

* Communicated in brief to the Surgical Section of the Royal Society of Medicine.

While fully recognizing that abdominal aneurysm is nearly always on the left side of the abdomen, and in spite of the fact that Stokes states "fever is rarely met with in any stage of abdominal aneurysm,"¹ and that he has never observed in cases of abdominal aneurysm "collateral venous circulation, as shown by the enlargement of the epigastric veins,"² we formed the opinion that we were dealing with an abdominal aneurysm. The patient urged us to do any operation which might ease his pain.

To a great extent encouraged by the successes of Mr. Wheeler of Dublin³ in operating on these cases, we decided to wire the aneurysm, and obtained Colt's apparatus for doing so. Before describing the operation there is one other point to which we would draw attention. Examining the patient every day in the ward, we found the aneurysm varied in the ease with which it was palpable, and on three or four occasions we were told by the house-physician that the tumour had disappeared. It certainly required at times much deeper palpation in order to feel it. This is worth recording, as it agrees with a note made by Stokes in regard to Case lxxiv, page 632 in his book, *Diseases of the Heart and Aorta*:

I had no difficulty in recognizing an aneurysm, for in addition to the evidences from the symptoms I found a large pulsating tumour in the epigastrium, having every character of abdominal aneurysm, and presenting a distinct bellows murmur. He was admitted into hospital, where, after two days had elapsed, I examined him a second time. To my surprise, the epigastric tumour which had been manifest had disappeared; so that I began to hesitate as to the correctness of the first opinion. The patient now mentioned that when he lay on his side he felt at ease, and the tumour disappeared, but that when he lay on his back the pain returned, and also the tumour. This singular experiment he performed in my presence on several occasions, and always with the above result.

I do not remember ever witnessing a more singular circumstance than the reappearance and as it were growth of the tumour under the hand when the patient continued on his back for a period certainly within two minutes.

Operation.

The operation was performed on April 30th. The patient was anaesthetized with chloroform by Dr. Tatham, Mr. Howell, our colleague, and Mr. Henry, the house-surgeon, assisting. A rubber air cushion was placed under the dorsal spines.

The abdomen was opened from the ensiform cartilage to below the umbilicus. On passing the hand in a large globular pulsating swelling about $4\frac{1}{2}$ in. in diameter, or the size of a large Jaffa orange, was found springing from the aorta, and extending over to the right hypochondrium. The tumour reached from below the renal artery to the bifurcation of the aorta. It was extremely tense. The transverse colon and the duodenum lay in front of it, the latter being adherent to the wall of the sac. The reflexion of the external peritoneal from the ascending colon was torn through, and the duodenum was with difficulty separated from the sac in an upward and inward direction. Colt's trocar was thrust into the aneurysm, and on removing the aspirator a jet of blood shot up 2 ft., and blood welled up by the side of the cannula. A cap packing containing 150 in. of wire with a surface area of $3\frac{1}{2}$ sq. in. was passed into the tumour. On withdrawing the cannula there was free bleeding from the side of the puncture, which stopped after ten minutes' pressure with a gauze sponge. The abdomen was closed without a drain.

The patient stood the operation fairly well, but had extreme pain afterwards, which $1\frac{1}{2}$ grains of morphine in the twenty-four hours following the operation failed to control. He complained even more bitterly of inability to sleep than of the pain. In addition, he caused grave anxiety by frequently vomiting large quantities of dark green watery fluid. In fact, this vomiting with inability to pass flatus or a motion for the first three days after the operation suggested that the irritation of the wire was reflexly causing a spasmodic intestinal obstruction; be this as it may, on the fourth day he passed a small partly formed motion, and the vomiting grew less. A few hours after the operation the dorsalis pedis in the right foot could be felt easily. The day following the left foot was observed to be more oedematous than the right, from which the oedema was disappearing; on May 3rd all trace of oedema had left both feet and legs. On auscultation on May 3rd the bruit was much coarser and was a definite bellows murmur.

It has already been shown that there was a definite relation between the condition of the bowels and the occurrence of pain in the aneurysm. Both constipation and the effect of purgatives evoked pain. We think this to be of importance as a diagnostic sign, as the same has been described in the classic case recorded by Beatty in 1829,⁴ and referred to in Stokes's book.

On May 5th the patient was still vomiting, though to a lesser extent, and said he felt much better. Thinking the vomiting might be due to dilatation of the stomach one of us tried to pass a soft tube to wash the stomach out, but this caused so much discomfort and retching that we deemed it wiser to stop lest the aneurysm should rupture. On May 6th the patient was distinctly weaker, the vomit a dirty brown colour but without faecal odour. We transfused 2 pints of saline, but the patient sank in the evening.

Post-mortem Examination.

There was no peritonitis. The aneurysm extended from the right renal artery to the bifurcation of the aorta. The sac came off the right side of the aorta, and lay wholly to the right of the middle line. The external measurements of the aneurysm were $4\frac{1}{2}$ in. in length by 3 in. in breadth. There was an oval opening from the aorta into the aneurysm, 2 in. by 1 in., on its right wall, filled with firm clot. There was a further opening on the left and lower extremity, directed down outside the bifurcation of the left common iliac, encircling three quarters of its circumference. The upper end of the wire was found projecting through a point $\frac{3}{8}$ in. above the centre of the oval opening on the right side, having torn its way through the aortic wall. The lower end of the wire was tucked away inside the aneurysm immediately outside the end of the liver, which tore on handling.

It was now seen that the wire had not opened into a cage form, but was lying with the component wires close together, embracing the anterior border of the opening into the aneurysm. The site of the puncture made by the trocar was $\frac{1}{2}$ in. behind the centre of the aneurysm.

The vena cava lay immediately below the aneurysm; on slitting it up, the union of the two iliacs was seen to be at the junction of the lower and upper three-fourths of the aneurysm. The way in which the aneurysm overhung the right iliac vein offered an explanation of the fact that the oedema of the right leg preceded that of the left. Small patches of atheroma were present in the aorta and common iliac vessels. The transverse colon was lying over the upper half of the aneurysm. The left renal vein was seen running just above the superior border. The duodenum and pancreas were very closely adherent to the sac.

It was interesting to note that, in spite of the fact that the man suffered from intense pain, there was no erosion of the vertebrae, and we suggest that the pain was caused by the dissecting aneurysm along the left common iliac artery. The stomach was very dilated, its lower border reaching to the umbilicus. The thoracic viscera were normal.

In criticism on this method of treatment we submit the following:

1. The wire did not form in a cage as it is supposed to do.
2. The wire that we used was too strong.

After seeing the result of the *post-mortem* examination we made some experiments on tennis balls with Colt's apparatus. We noticed that when the wire came in contact with the wall it failed to spread out in the same way as it had failed in the aneurysm. Apparently, in order that the wire should spread out into a cage form, it is necessary that it should have sufficient room to do so without encountering much peripheral resistance.

We suggest that it might be an advantage if the ends of the wires were turned in, forming when closed a cartridge resembling the folding of an umbrella probang; and, when opened out, a cage like a ball of string. We also suggest that if the component wires were roughened it would lead to more rapid clotting in the sac.

THE Russian Duma has petitioned the Government to establish some new medical faculties in different parts of the empire.

THE twelfth International Congress of Ophthalmology will be held at St. Petersburg in August next, under the patronage of the Czar. The official languages will be French, English, German, Russian, Spanish, and Italian. The subjects proposed officially for discussion are the etiology of trachoma and the nutrition of the eye.

CHEILO TOMY FOR CRIPPLING TRAUMATIC ARTHRITIS OF THE HIP-JOINT.

BY W. I. DE C. WHEELER, F.R.C.S.I.,
SURGEON TO MERCER'S HOSPITAL, DUBLIN.

I WAS much interested in the communication published under the joint names of Mr. Sampson Handley and Dr. Preston Ball which appeared under the above heading in the BRITISH MEDICAL JOURNAL of May 3rd.

I have many times, in common with other surgeons, operated upon cases of chronic rheumatic arthritis to relieve pain and deformity, but as my last case is identical in all essential respects with the two cases described in the communication, and as the operation was performed on the patient's hip on October 22nd last, three months before Mr. Sampson Handley operated upon his first patient, it may be of interest to mention the outstanding features, and thus put a third case on record. The question of priority is of no great importance, but Mr. Sampson Handley and Dr. Preston Ball are in error in thinking that the operation had not been performed prior to their first case in January, 1913.

Miss H. D., aged 21, residing in London, was sent to me in September last, the subject of polyarticular chronic rheumatic arthritis from which she had suffered from childhood. The left knee-joint, the right hip and the two wrists were disorganized with the changes characteristic of the disease. The left knee could not be completely extended without intense pain, and the right hip could bear no weight whatever, the slightest pressure on the heel causing pain in the joint. Locomotion was therefore only possible with the aid of crutches, and even then was attended with much suffering. She had been dependent on the use of crutches for seven years.

X-ray photographs, taken by Dr. Hayes on September 9th, showed tipping of the tibia to the outer side of the left knee-joint, which was the site of great tenderness. A ring of osteo-arthritic bone surrounded the right hip, impeding every movement of the joint, stretching the capsule, and on pressure evidently abutting against the rim of the acetabulum and the neighbouring bone.

The first operation was performed on the knee-joint on September 12th. (It should be mentioned that the shortening produced by the enforced flexion was corrected in London by raising the boot about 2 in.) Through an incision made along the outer side of the knee-joint the tipping of the tibia was removed with a gouge and chisel through a well-marked line of cleavage such as is seen in the new bone formed in connexion with a bunion. A weight and pulley was attached to the limb for about ten days to correct the flexion, and massage was applied for a short time subsequently. All pain disappeared immediately after the operation, and on removal of the weight and pulley the joint could be fully extended and flexed.

The result of this operation encouraged me to operate upon the hip of the opposite side on October 22nd. The joint was opened through Kocher's posterior incision. There was a well-marked "cornice" of newly-formed bone encircling the junction of the head and neck of the femur, giving it the mushroom appearance commonly seen in the specimens of chronic rheumatic hips found in the surgical museums.

The capsule having been freely opened, the hip was rotated in all directions by an assistant, and the new bone was chiselled away from about two-thirds of the circumference. The result of the operation surpassed all expectations. The following day pressure on the heel caused no pain. The stitches were removed in ten days and the patient was allowed up. She could now bear her entire weight on the right limb, and the movements of the hip-joint were free and painless. Subsequent progress was unevenful. I saw the patient when in London last week, and she is walking without crutches in absolute comfort after being a cripple for seven years. I can arrange for Mr. Sampson Handley to see the patient and the x-ray photographs if he is interested in the case.

I was glad to read the result of his two cases, which convinces me that my result was no exception, and that in selected cases the operation of "cheilotomy" is destined to give instant relief, and to change completely the outlook for a certain class of crippled patients. I think the

title of the paper would be better if the word "traumatic" were omitted; the etiology matters little if the pathological changes are the same.

I should mention that practically every form of treatment, including the use of vaccines and serums, had been tried in my case during the nine years she had suffered from the disease. The condition of the wrists has improved considerably since the patient has been able to discard the use of crutches.

THE INTERNEURONIC SYNAPSE IN DISEASE.

BY

B. HENRY SHAW, M.B.,

SENIOR ASSISTANT MEDICAL OFFICER, COUNTY ASYLUM, STAFFORD.

I HAVE long felt that the cell-exhaustion theory does not satisfactorily explain the pathology of acute delirium. Take, for instance, such a case as this: A young woman, while walking in her sleep, falls from a height, injuring herself severely, and at once becomes acutely delirious; or a girl, owing to a celluloid comb in her hair suddenly taking fire, immediately develops acute insanity; or a similar state results in an elderly widow on finding her sister dead in the same bed. Up to the occurrence of the shock, a state of mind entirely normal to the individual apparently exists, and almost immediately after we find more or less complete inco-ordination of the higher centres and mis-interpretation of stimuli. Inco-ordination of the higher centres is the outstanding result. To my mind, this suddenly developed condition, accompanied as it is by extreme motor restlessness, cannot logically be due to cell exhaustion. For purposes of comparison I have examined my records of 17 cases of insanity occurring after surgical operation in which the undoubtedly important factor producing the alienation was exhaustion—physical and mental—plus the slight shock of the operation perhaps, and contrasted them with 25 cases of insanity immediately supervening on sudden and violent mental shock, with the following results:

TABLE I.—The Types of Insanity Resulting.

| Type of Insanity. | Etiological Factor. | |
|---|---------------------|------------|
| | Shock. | Operation. |
| Acute delirium | 11 | 4 |
| Confusional insanity ¹ | 5 | — |
| Melancholia | 5 | 9 |
| Mania | 3 | 3 |
| Stupor | 1 | — |
| Delusional insanity (systematized) | — | 1 |
| Totals | 25 | 17 |

TABLE II.—Ages at Onset.

| Age. | Etiological Factor. | |
|-----------------------|---------------------|------------|
| | Shock. | Operation. |
| Under 20 years | 4 | 1 |
| 21 to 30 | 5 | 2 |
| 31 to 40 | 3 | 5 |
| 41 to 50 | 4 | 6 |
| 51 to 60 | 4 | 3 |
| 61 to 70 | 5 | — |
| Totals | 25 | 17 |

As regards predisposing causes, a family history of insanity was ascertained in 28 per cent. of the cases due to shock, and in 23.5 per cent. of those due to operation.

TABLE III.—*After-History.*

| | Recovered. | Died. | Permanently Insane. |
|------------------------------------|------------|-------|---------------------|
| <i>(a) Cases due to Shock:</i> | | | |
| Acute delirium | 6 | 4 | 1 |
| Confusional insanity ... | 3 | — | 2 |
| Melancholia | 3 | — | 2 |
| Mania | 1 | — | 2 |
| Stupor | — | 1 | — |
| <i>(b) Cases due to Operation:</i> | | | |
| Acute delirium | 2 | 2 | — |
| Melancholia | 4 | 3 | 2 |
| Mania | 2 | — | 1 |
| Delusional insanity (systematized) | — | 1 | — |

The average period required for recovery was in the cases due to shock 5.8 months, and in those due to operation 16.2 months, practically three times as long. In 50 per cent. of the cases resulting from shock which became chronic a definite family history of insanity was obtained. The average period of recovery of the deliriant cases was practically the same in both, namely, three to four months.

It will be noticed that the type of insanity resulting from severe shock is decidedly different from that produced when exhaustion is the important etiological factor. Acute delirium resulted in practically half of the former cases—and, indeed, the confusional cases were verging on delirium—melancholia in more than half of the latter. In other words, as a result of sudden and severe mental shock, the tendency is to acute delirium, and when prolonged exhaustion enters into the causation the tendency is to depression. From my cases, too, I am justified in saying that the greater the shock the more the tendency towards delirium. Now if this is sought to be explained by saying that the delirium is a more intense reduction, the fact that complete recovery is both more probable and more rapid in these cases than in melancholia must be reckoned with.

Again, the tendency in acute delirium is either towards rapid recovery or death. Only one out of the whole 15 cases became permanently insane, which is in marked contradistinction to other forms of insanity. In the one case, which became a secondary dement, there was a strong family history of insanity, and she was herself of a very low mental type. One would expect profound cell exhaustion to produce a depressive—almost stuporose—type of insanity, whereas what we apparently find as a result of intense mental shock is the opposite.

In cases due to shock the age has apparently no influence worthy of notice. This is quite different from what obtains in post-operative cases, among which 8 out of the 17 occurred between the ages of 40 and 50 inclusive. The fact that 11 of the whole 17 were operated on for uterine or ovarian trouble will throw some light on this.

I think it may fairly be assumed that the delirium resulting from sudden nervous shock cannot satisfactorily be explained by the theory of cell exhaustion.

Whatever be the nature of the nerve current, the cell has apparently the power of releasing energy on the reception of a stimulus corresponding in degree to the intensity of that stimulus. The balance of evidence appears to be in favour of the nervous impulse being a physical process, and it is, I think, satisfactorily established that resistance to its passage is principally met with at the inter-neuronic synaptic membranes and finer terminal arborizations.¹

It is a matter of common observation that minor degrees of shock are accompanied by a rigor-like thrill. A weird sound in the silence of the night, the presence of a human form at a time and place when and where it is not expected, will give rise to a "start" and a conscious sensation as of an electric-like discharge throughout the system. If this is a matter of common observation on the occurrence of slight or moderate degrees of shock, is it not probable that a very intense nervous discharge might cause serious damage to the finer nerve arborizations

and synaptic junctions, and that, just as under similar conditions electrically the fusion of a wire would take place, so here, as a result of intense shock, we may have some degree of what might be termed "synaptic fusion" of the higher neurone terminals and interneuronic membranes, causing dissociation of the higher centres and misinterpretation of stimuli? These higher associative neurones being the latest to develop their terminal arborizations, are probably the most delicate.

The effect of very intense nervous shock on the memory is similar to that occurring after severe concussion—namely, there is total lack of recollection of the shock itself and of events happening shortly before, or, at best, the recollection is very indistinct. A further point of interest is the fact that the average period required for recovery in acute delirium resulting from shock is identical with that required for nerve regeneration as a result of trauma—namely, three to four months.

In a few cases return to co-ordinated thought is apparently sudden. It seems probable that in these cases synapses of association fibres not in common use were probably uninjured by the discharge, allowing an almost sudden return to sanity once the current found a new path connecting up the higher centres. The tendency of the nervous impulse to revert to its accustomed course would account for the fact that such cases are very liable to slight relapses before ultimate recovery. In those cases which quickly result in death, may it not be due to the intensity of the discharge causing damage to many more axone terminals than would occur in a slighter degree of shock which in another case will terminate in recovery, given similar resistance at the synapses?

There are different degrees of synaptic resistances.² Sherrington states that "there is abundant evidence that synapses differ from one another" in this respect, and the action of strychnine and tetanus toxin affords further proof. Now, if in the same individual different degrees of synaptic resistance are met with, is it not probable that individuals will differ with regard to nervous irradiation, owing to the fact that in general their synaptic resistances are heightened or lowered abnormally? Strychnine and tetanus toxin have the effect of lessening synaptic resistance and of converting normal spinal inhibition into excitation.³

I have noticed that great susceptibility to the action of strychnine exists in hysteria, relatively small doses causing most unpleasant sensations, such as tachycardia and much mental uneasiness. Might not this indicate that in hysteria the neuronic trouble is synaptic—that there is normally in this affection too little interneuronic resistance, resulting in a constant leakage of current, so to speak, outside the area to which it is limited in the normal individual? Supposing this is so, what would we expect? "The hysterical temperament," to quote Starr, "is manifested by an abnormally keen sensibility to all external impressions and sensations, and a susceptibility to suggestions, by a manifest incapacity to exercise control over thought, emotion, and action, and by a tendency to act on sudden impulses."⁴ In other words, stimuli which normally would only take a certain definite course, owing to a lowered interneuronic resistance become diffused in their effects on the higher associative centres, and also concomitantly the ultimate stimulation is more intense than normal, hence hyper-ordinate and inco-ordinate reaction. The mental process resulting from sensory stimuli is in the normal person orderly, and in nine cases out of ten similar stimuli will result in a similar train of thought, but given a generally lowered synaptic resistance it is obvious that these same sensory stimuli will not confine themselves to the same orderly path, but that in addition other associated neurones will be affected, which in the normal individual would remain quiescent. Ideation is confused and chaotic and conduct illogical, distractibility is intense, the nervous mechanism is out of control and feels the need of a stronger mind, hence its susceptibility to suggestion and hence the ready obedience to the commands of one for whom the hysterical person feels respect and has confidence in.

This would probably be the result of an abnormally lowered synaptic resistance. Now imagine the opposite—an abnormally heightened resistance. Is it not possible that the periodical disorderly discharge of nervous energy in some cases of epilepsy may be due to certain neurones

acting practically as storage batteries owing to the fact that the synaptic membranes which separate them from contiguous neurones present an abnormally great resistance to the passage of the impulse, thereby practically insulating these neurones until such time as the resistance is overcome by accumulation of energy or by the reception of a violent stimulus?

An important etiological factor in the production of acquired epilepsy is alcohol. Now, alcohol spends itself principally on the interstitial tissue; it is therefore quite likely that its circulation through the nervous system will have a more injurious effect on the interneuronic junctions than on the neurones themselves; it is also quite probable that alcohol will have a selective action on different series of synapses in different individuals. A cirrhotic liver is rarely seen in the asylum *post-mortem* room, and the moral loss of tone so common in chronic alcoholics and the peculiar memory disorder may result from dissociation of the higher association centres, and consequent lack of orderly thought and judgement.

That a sudden fright is so frequently thought to be the determining cause of epilepsy is of much interest in the light of the suggestion that acute delirium as a result of shock may be due to what I have termed "synaptic fusion." It might be possible that this fright has caused minute structural change in certain synaptic junctions, perhaps in the way of upsetting the normal polarity or causing temporary insulation, if one might use the term, of neurones, and spasmodic and irregular nervous discharge as a consequence. The idea that epilepsy may be due to faulty synaptic conduction is a fascinating subject for speculation; for instance, if we suppose the channels connecting the cerebrum and cerebellum to be affected, then as a result of spasmodic action at these synapses, and consequent brief interruption of the normal inhibitory influence of the cerebrum, a condition analogous to decerebrate rigidity would result, and the clonic spasms succeeding the tonic are what we would expect to find before the establishment of association is again complete.

It is not, of course, suggested that in every case of epilepsy synaptic disorder is present; for instance, convulsions are readily produced in children by slight irritation of peripheral neurones (phimosi, etc.). This may be due to the distracting effect of these stimuli on cerebral neurones, resulting in temporary cessation of the normal inhibitory influence of the latter over cerebellar tonus.

My attention has been called to the fact that Dr. Stoddart has already expressed the opinion that there is increased synaptic resistance in acute confusional insanity. As his reasons, he gives the effect of repeated subliminal stimuli in overcoming the analgesia which is present, which he compared with Sherrington's experiments on the scratch reflex of a dog, and the fact that he has met with success in the treatment of some cases with strychnine.⁵ I have not found any benefit from the exhibition of strychnine in these cases; indeed, it was this fact which led me to think that some definite synaptic lesion had occurred. In epilepsy, on the other hand, I have found decided alteration, in the majority of cases, both in the number and intensity of the fits during the administration of strychnine—in 25 per cent. there was no apparent difference, in 50 per cent. the fits were decreased both in numbers and intensity, and in 25 per cent. they were increased. This inconstant effect is to be expected, as the pathological basis of epileptiform convulsions must undoubtedly vary greatly; for instance, it may be that the neurone is irritated through its blood supply either mechanically by vasomotor action or intravascular clotting, or by the direct effect of toxins, or it may be that the cortical neurones are themselves intrinsically abnormal. In any of these cases strychnine is not likely to have any definite effect; but if the sudden discharge of nervous energy is due to faulty synaptic action, either in the way of constant or spasmodic excessive resistance to the passage of the current, then it probably would have some effect on the number and intensity of the seizures. Bearing in mind Hughlings Jackson's speculation that post-hemiplegic muscular rigidity was due to the unantagonized action of the cerebellum, which is the centre for continuous (as is the greater brain for changing) movement,⁶ it seems possible that the convulsions resulting from excessive doses of strychnine may be due to some

kind of synaptic spasm affecting the cortico-cerebellar fibres. He says: "When the influence of the cerebrum is permanently taken off by disease of the cerebrum, as in hemiplegia from the parts which it most especially governs (arm and leg), the cerebellar influence is no longer antagonized, there is unimpeded cerebellar influx, and hence rigidity of the muscles which in health the cerebrum chiefly innervates."

In this connexion also the experiments of Ferrier on the electrization of the cerebellum of monkeys are of much interest; the ocular and other movements produced were similar to those occurring in epileptic convulsions. He found, on stimulating different portions of the cerebellum, backward, forward, and left or right movements resulted corresponding to certain definite cerebellar areas; also—an interesting fact in view of the involuntary cry so common in epilepsy—he found that irritation of the adjacent testes "invariably excites a sudden bark or howl." Now if we suppose faulty action at the cortico-cerebellar synapses to exist, allowing momentary unimpeded discharge from the cerebellar neurones, the result would be a tetanic seizure, becoming clonic as the cerebral influence resumed its sway, and the nature of the seizure would indicate which cerebellar area was primarily affected. Epileptics generally fall in each fit in the same way, so that when the eyes are moved upwards and the head thrown back the initiatory discharge would probably be in the menticulus cerebelli, as Ferrier has shown that such movements result from irritation of this area.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SUTURE OF TENDONS.

Owing to the relatively unsuccessful results frequently following the suture of tendons, especially when closely adjacent tendons and their sheaths are injured, I have adopted the plan, after suturing each tendon, of surrounding it at the line of suture with a wrapping of membrane taken from beneath the shell of an egg sterilized by boiling. The tendon sheath is then closed.

I have seen no mention of this material having been used for the purpose of preventing the formation of adhesions, and venture to bring this method to notice as one easy of application, and one from which I have obtained improved results.

T. T. JEANS,
Fleet Surgeon, R.N.

A CASE OF ACTINOMYCOSIS TREATED BY
A VACCINE.

The following case, although not unique, may help to emphasize the curability, even in advanced cases, of that somewhat rare disease, actinomycosis. As is well known, the outlook in advanced cases of this disease is particularly gloomy.

The patient, a schoolmaster, aged 40, chewed a stalk of corn whilst taking a country walk last June. Throughout July he noticed a gradual deterioration in health; in August a definite swelling appeared above the outer part of Poupart's ligament in the left groin; this was a hard, fixed mass; shortly afterwards swellings appeared also between the shoulders and at the back of the neck. The tumour in the groin was incised at the London Hospital, and was found to contain the fungus of actinomycosis. As further swellings appeared he was sent home, and the case was considered and treated as hopeless. Potassium iodide, which had been given freely, was wholly without effect.

As the condition was at one time alleged to be the result of an accident on duty, I was asked to see him and report to the London County Council. When I saw him on November 16th, 1912, he was confined to his couch; he was pale, emaciated, with a large suppurating abscess in the left iliac fossa, a second in the left costal margin in the nipple line, and a third between the shoulders. His mental

attitude and physiognomy reflected the pessimistic prognosis which his medical attendants had made, and of which, unfortunately, he had become aware. The outlook was indeed dreary, for he was rapidly and steadily wasting.

I induced his doctor to send him to Sir Almoth Wright, who kindly at once undertook the case, and to whom I am indebted for permission to publish it. Eleven days after I saw him he was given a vaccine injection from stock, the dose being $7\frac{1}{2}$ million. He at once improved, and by January 11th, 1913, the dose had been brought down to 5 million once a week. In February of this year an autogenous vaccine was for the first time used; this was administered regularly up to March 18th. He had in all some seventeen inoculations.

On April 30th he called on me and stated that he had returned to work. His groin trouble had entirely disappeared; two small healing wounds remained; both will probably heal in a few weeks; he has gained much weight, looks the picture of health, and is, and has very good reason to be, grateful that he lives in the days of vaccine treatment.

London, W.

JOHN COLLIE, M.D., J.P.

CARIES OF THE MILK TEETH.

THE reluctance of dentists to undertake conservative treatment of the teeth in school children is easily understood. Filling is very tedious and exhausting, and only work carefully done is of any avail in a young mouth.

The following few simple rules as to extraction may be of use:

1. Where the tooth is painful on mastication, either from pulpitis or periodontitis, extract.

Reason. The avoidance by the child of vigorous mastication will hinder development of the jaw, the latter not depending entirely, as is sometimes supposed, on the presence of teeth.

2. Where the tooth has an abscess or chronic sinus, extract.

Reason. The tooth is dead and will not be shed at the proper time. Although the patient may not complain of pain at the time of the interview, there are certain to be periods of subacute inflammation when vigorous mastication is suspended.

3. If the tooth has an interstitial cavity on the side near a permanent tooth, remove before the latter is affected. The most usual instance is that of a cavity in the distal surface of the second temporary molar infecting the first permanent molar.

Much may be done by breaking down cavity walls and rubbing with lunar caustic, a deposit of secondary dentine with complete repair of a carious surface being a frequent and happy result. To be successful with this, the tooth must be alive and have no gross exposure of the pulp.

The above hints are intended as guides for institutional and school work only.

Bury St. Edmunds.

H. E. H. TRACY, M.R.C.S., L.D.S.

** This memorandum was elicited by a question published in the BRITISH MEDICAL JOURNAL of March 29th, p. 696.

THE report for 1912 of the council of the Metropolitan Provident Medical Association shows that during the year it has devoted much time to anxious consideration of the new circumstances created by the Insurance Act. It hoped to be able to devise some plan by which the association would become part of the working machinery of the Act, but became convinced that no step in this direction was possible. The association will continue its work on the same principles and with the same aims as heretofore, though difficulties, it is expected, will ensue from the loss at every dispensary of the bulk of the insured persons; the council, however, feels that this loss increases rather than diminishes its responsibility towards women, children, old people, and other uninsured persons, and hopes that its endeavour to retain for them the fruits of thrift and self-dependence will be acknowledged by an increase in charitable contributions. The payment rates for provident members have been revised and have been accepted as fair by all parties concerned. Much gratitude is expressed towards the medical staff of the association for its loyalty and co-operation during a very trying period.

ON MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

UNION HOSPITAL, BRADFORD.

THE VACCINE TREATMENT OF ACUTE LOBAR PNEUMONIA.

(By W. C. LYONS, M.B., Ch.B., Assistant Medical Officer.)

(From the Department of Pathology, University of Leeds.)

THE following cases of acute lobar pneumonia which have been treated with a pneumococcus vaccine show results which indicate the value of the treatment in such cases.

A vaccine of the pneumococcus was prepared by inoculating a mouse intraperitoneally with sputum derived from a case of acute lobar pneumonia. The animal died from general pneumococcal infection and its heart blood was plated out on nutrient agar. An emulsion was made from the agar culture with normal saline and killed by heating to 56° C. for one hour, and $\frac{1}{2}$ per cent. phenol added, and the vaccine standardized.

The vaccine and method of dosage were the same for all four cases. In all, four injections were made in each case, twenty-four hours elapsing between each injection. The first dose contained 5 million organisms, the second and third 10 million each, and the fourth 15 million. The vaccine was given subcutaneously into the abdominal wall.

CASE I.

L. R., aged 34, male, was admitted on the third day of the illness, having well-marked signs of consolidation in the lower lobe of the left lung, with a typical pulse-respiration ratio. The sputum was rusty and viscid; pulse dicrotic; mild delirium. Twelve hours after the first dose the temperature fell from 102.4° F. to 100.4° F.; after the second it became 100.8° F., falling after the third dose to 99.2° F., and after the fourth dose, on the eighth day of the disease, it fell to 98° F., and remained about this level during the remainder of the stay in hospital. There was no change in the pulse or respiration rate until after the third dose, when they began to fall, and finally became normal on the tenth day of the illness.

CASE II.

F. S., aged 24, male, was admitted on the third day of the illness, with the usual signs of consolidation in the lower lobe of the right lung. Sputum viscid and rusty; pulse dicrotic. There was considerable delirium in this case, and a pronounced alcoholic history.

Twelve hours after the first dose of vaccine the temperature, which had been 103° F., fell to 101° F. Following the second dose it fell further to 100° F., rising to 101.2° F. in four hours. After the third dose it remained at 101° F., and fell after the fourth to 100.2° F.; six hours later it was normal, nor did it rise above this level during a brief convalescence. The pulse and respiration-rate began to fall after the third dose, on the seventh day of the disease. Sedatives were employed in this case on account of the delirium.

CASE III.

B. B., aged 37, male, was in hospital suffering from transverse myelitis, when he contracted acute lobar pneumonia. Pneumococci were found in the sputum, which was viscid and rusty.

In this case the temperature remained at 103.4° F. until after the third dose given on the fourth day of the disease, when it fell to 100.8° F. After the fourth dose it increased to 103° F., but came gradually to normal on the seventh day of the illness, and there were undoubted signs of resolution.

On the tenth day, however, the patient had retention of urine, and pus was found in the catheter specimen, and the temperature again increased to 101.2° F. By the fifteenth day all the signs of consolidation had apparently disappeared. The patient died on the twenty-second day from cystitis.

CASE IV.

J. T., aged 39, male, was admitted to hospital on the fourth day of the disease, with well-marked signs of consolidation in the lower lobe of the right lung. Pulse dicrotic; sputum viscid and rusty. History of alcoholism and considerable delirium.

After the first dose the temperature fell from 103.2° F. to 102.4° F., and fell further to 101° F. after the third dose, reaching normal after the fourth dose on the seventh day of the illness, and remained normal during convalescence.

It would seem that the advantages gained from this method of treatment are—a lessening of the toxæmia as evidenced by the gradual fall of temperature followed by a fall in the pulse-rate and respiration-rate, together with an improvement in the general condition of the patient, and an earlier abatement of the symptoms, lysis in each case appearing to supplant the crisis.

I am indebted to Dr. Coplans of Leeds University for the primary cultures of pneumococcus.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

BATH AND BRISTOL BRANCH.

THE sixth ordinary meeting of the session was held at Bath on April 30th. Dr. ROXBURGH, President, was in the chair, and twenty-eight members and visitors were present. Mr. C. E. S. FLEMING read notes of *Some cases of acute oedema of the lung*, and the PRESIDENT, Mr. PAGAN LOWE, Colonel LEE, Dr. NEILD, and Dr. KENNEDY added other instances. Dr. G. H. H. ALMOND read a paper on the *Urinary products of intestinal intoxication*, which was discussed by the PRESIDENT, Mr. PAGAN LOWE, and Dr. NEWMAN NEILD. Mr. T. PAGAN LOWE read a note on *The physiological action of radio-active water*, and the PRESIDENT made remarks upon it. Dr. R. WATERHOUSE described a case, and showed the skiagram, of *Cervical rib*. It was discussed by the PRESIDENT, Mr. COSTABADIE, Mr. LACE, and Dr. BOWKER.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

A CLINICAL meeting was held on April 22nd, when Dr. LYSANDER MAYBURY was in the chair and thirty-three other members were present. Dr. HILDA CLARK, in opening a discussion on *The practical application of tuberculin treatment*, emphasized the importance, in summarizing experience, of considering its relation to the natural production of immunity to tuberculosis and the influence of environmental factors, and suggested that this could best be done by grouping cases treated according to the clinical condition regarded as a whole, and not only by the anatomical extent of the disease. To this end she had tabulated a complete series of consecutive cases of adult pulmonary tuberculosis treated to a greater or less extent by the intensive dose method. Tubercle bacillus was present in 181 cases and absent in 210. Each set was subdivided after careful consideration of the history, the nature of the onset, and progress of the disease, and the condition, general and local, when treatment began. After an account of the preparations of tuberculin used—that is, PTO, PT, OT, TAF, PBE, and BE, and of the technique of administration—Dr. Clark gave an account of her experience and conclusions with regard to dosage, intervals, and special preparations in these different types of cases. The practical application of tuberculin treatment was first and foremost, in our present state of knowledge, to early cases, in the vast majority of which her experience showed that it could be used safely and successfully as the main method of treatment. She also showed that the temporary improvement obtained by tuberculin alone in many advanced cases, together with the complete arrest of the disease occasionally obtained even in severe cases, led to the conclusion, suggested by Koehl in 1890, that, combined with sanatorium treatment, if sufficient time could be given before the patient had to return to bad conditions, a higher percentage of cases of permanent arrest of the disease might be expected than with sanatorium treatment alone. She emphasized the necessity for allowing time for the completion of the arrest of the disease after the production of immunity had been initiated by any method of treatment adopted. A discussion followed, in which several members joined.

DR. W. BRYCE ORME, formerly medical officer at Larut, Federated Malay States, has been appointed P.M.O. to British North Borneo.

THE third international congress on cancer research will be held in Brussels in August (1st to 5th). The subjects proposed for discussion are: (1) The use of physico-chemical measures in the treatment of cancer and the use of chemical substances after radical operations; (2) vaccination treatment of tumours; (3) statistics of cancer, its local distribution; (4) organization of institutions where cancer patients can be treated; (5) nursing of cancerous patients and instruction in this subject; (6) report on the position of cancer research and the struggle against cancer in various countries, including special literature for doctors, leaflets of instruction for lay people, etc.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

RESUMED DEBATE ON ALIMENTARY TOXAEMIA.

Monday, May 5th, 1913.

Dr. AMAND ROUTH in the Chair.

PROFESSOR H. J. HUTCHENS (Newcastle) said he understood by the term "alimentary toxæmia" the circulation in the blood of certain poisons elaborated in the alimentary canal, which would combine with and to a certain extent injure the cells of the body for which they had a chemical affinity. These substances might be elaborated either chemically—by the action of digestive juices acting on the foodstuffs—or as the result of the activity of bacteria. The poisons produced by the bacteria in the alimentary tract might be of two kinds: (1) The specific poisons of the bacteria themselves; or (2) the non-specific products manufactured by bacteria. Outside the body the colon bacillus produced indol, which was not a specific toxin of the colon bacillus. There were two schools of thought: the one maintained that certain bacteria were essential to animal life, that they broke up the food so that it could be more readily absorbed, and that they protected the body against pathogenic species; the other school, led largely by the French, said that bacteria were altogether harmful, and that the digestive juices in the animal sufficed to elaborate the products necessary for the maintenance of life. They pointed out that it was mainly in the large intestine that bacteria were found, where practically no digestion took place, and the organisms found there were productive of the sclerotic changes characteristic of old age. These were largely hypotheses, and there were but few facts to support them. In many cases of gastric disturbance following alimentary toxæmia the colon bacillus was present in the urine when not suspected.

Sir JAMES GOODHART considered that more diseases were attributed to oral sepsis and pyorrhoea alveolaris than was justifiable, and he agreed with Professor Keith that the question of alimentary toxæmia centred round the nature and functions of the colon. But he did not consider the physiological arguments which had been used altogether sound. Though it had been shown that some people could apparently get along in comfort without the large bowel, he believed the colon had been gradually elaborated and was a great organ of digestion. It had been said that the colon absorbed little beyond water; but he believed that its function was to display to the food passing through it the greatest extent of surface possible. The colon should be full, not empty; satisfied, not hungry. Yet it had been grafted into the minds of the profession and the laity that the one object in life was to get the bowels opened once a day, and failing this, there would be poisoning by noxious products. But the function of delay to facilitate absorption must be borne in mind, and every kink in the large intestine must not be regarded as a source of pathological obstruction.

Mr. W. LANG's thesis, which he set out to establish by showing tables of large numbers of cases, was that pyorrhoea alveolaris and other septic conditions in the upper part of the alimentary tract were answerable for inflammations in every part of the eyes. In many of the cases he could not discover the nature of the poison, but the improvement which immediately followed upon removal of the septic source convinced him that his suspicion was correct. In some cases of choroiditis lost vision quickly returned when these measures were taken. He had notes of 10,000 private cases, the results in which were properly comparable, as he examined them all himself. Septic cases were, of course, very common among hospital patients, but even among private patients some of the results were striking. He showed photographs of septic gums, and described the *modus operandi* of the infection of the visual apparatus.

Dr. DAVID SOMERVILLE said that many people at and past middle age consumed excessive quantities of protein—that is, more than they could properly oxidize or assimilate. The lassitude, headache, drowsiness, irritability, etc., were accompanied by abnormal physical and chemical changes in the urine, and frequently by increased

arterial tension. The surface tension of the urine was lowered; it contained increased indol, skatol, and aromatic acids, and the proportion of ethereal to preformed sulphates was increased, as well as the ratio of the ethereal sulphates to the total nitrogen. Many patients were greatly improved when they substituted carbohydrates for proteins in their diet. The most important matter was not what happened in the alimentary canal, or what bodies were found in the urine, but what was constantly happening in the intermediate body tissues.

Dr. A. C. JORDAN again stated his position in regard to the question of ileal and other kinks and obstructions, and showed a number of striking skiagrams bearing on the subject. He insisted that his opinion, founded upon x-ray examination, was constantly being put to the test by operation, and it was the rule for his findings to be verified. He did not find ileal kinks except in patients whose duodenum was distended and who presented clinical evidences of toxæmia.

Mr. ERNEST CLARKE contended that the eye registered, in a delicate manner, certain conditions of the system, and intestinal toxæmia was one of them. The condition of the lens was a very good index, for the degree of its "squeezability" decreased not only naturally with age, but prematurely as the result of disease, so that more and more assistance was needed to enable the possessor to see near objects. He had records of over 3,000 cases, which he had plotted on a chart to show the age of the patient and the accommodative power of the lens. For instance, the lens of one man, aged 40, had the accommodative power of a man aged 55. Conversely, regular habits and a healthy life resulted in preserving the resiliency of the lens long beyond the normal period. He had marked in a number of cases a very distinct rejuvenation of accommodative power when intestinal stasis had been efficiently treated.

Dr. F. LANGMEAD dealt specially with the relation of the thyroid gland to the condition of alimentary toxæmia. Tetany was supposed to be due to toxins generated in the alimentary canal: it disappeared if the stomach were washed out. It was common in rickety children, in whom it was usual to find some dilatation of stomach. It was sometimes treated with success by the administration of thyroid extract. Infective arthritis was not uncommonly accompanied by enlargement of the thyroid, or by Graves's disease, or by tetany. In rheumatoid arthritis great improvement had been noted to follow short-circuiting, and also the giving of thyroid extract. He had observed great improvement in cases of enlargement of the thyroid from the use of a vaccine prepared from the coliform bacilli from the patient's own bowel. In one case the goitre entirely disappeared, and in all the others the gland had diminished in size.

Dr. J. M. H. MACLEOD observed that though many skin conditions had been attributed to food toxins and the aberrant products of digestion, the assumption was only warranted at present in respect to a few, including urticaria, toxic erythemata—that is, erythema multiforme, rosacea, and the acneiform eruptions of adolescence, especially in women. In many cases the harm resulting from the ingestion of certain kinds of food was due to the patient's idiosyncrasy. The primary attack of urticaria was often a sequel of gross dietary error, but thereafter a very small quantity of that food would cause a return of the eruption. The toxic erythemata were polymorphic, and their pathogenesis was not certain, though some thought they were a consequence of a toxin acting on the walls of the blood vessels.

Dr. E. VON OFENHEIM said that stasis caused bacterial poisons to be formed, which had a paralysing effect on the intestines. In stasis the organisms were in a condition which indicated that they were in an unusual environment, the changes being similar to those seen in overgrown cultures. Only about a fifteenth of the attempts to make cultures from the faeces in these circumstances were successful as compared with those from the faeces of normal healthy people.

Mr. S. H. BROWNING remarked that certain eye conditions were cured when certain alimentary conditions were remedied, and that seemed the only ground to go upon at present. Considering the wide prevalence of pyorrhoea alveolaris, it was surprising that such a small percentage of cases suffered from eye disease; he thought the reason

was that eye conditions occurred when a particular form of organism was present in the gum condition. He had been struck with the frequency of pneumococcal infections in this connexion, and this organism was the least common in pyorrhoea except *Staphylococcus aureus*. The treatment of pyorrhoea lay chiefly with the dentist, but cure could be greatly accelerated by the use of vaccines. He had noted the frequent association of asthenopia with pyorrhoea, and he regarded this as a valuable early indicator of alimentary intoxication. The tonsils were a frequent source of alimentary toxæmia, and the eye condition most often associated therewith was irido-cyclitis. Sometimes removal of the tonsils cured the eye disease. In many cases the result of treating the eye condition by means of attention to the intestinal canal had been unsatisfactory, but there was sufficient encouragement to warrant a systematic examination of the excreta.

CLINICAL SECTION.

At a meeting on May 2nd, Mr. WALTER G. SPENCER, Vice-President, in the chair, the following were among the exhibits:—Dr. F. PARKES WEBER: Old quiescent *Zoniform scleroderma* of the right lower extremity. The patient was a woman, aged 44, the disease having been first noticed when she was aged 11 or 12. There was a hard depressed band, feeling like a cicatrix, in the subcutaneous tissues. It partly encircled the upper part of the thigh and extended downwards to the inner side of the knee. Dr. FILIP SYLVAN: *Pulmonary tuberculosis after gymnastic treatment*. The man, aged 24, had extensive disease of the lungs, which Dr. Sylvan thought had been arrested after ten weeks' treatment. Dr. G. H. HUNT: (1) *Complete heart-block* in a woman aged 22. It had caused no symptoms. The pulse-rate was usually about 30 per minute. The etiology was uncertain. (2) A case illustrating *Prognosis of extra-systoles*. It was that of an athletic man aged 23. With a dilated heart, ventricular extra-systoles had been present. The dilatation improved and the patient returned to vigorous exercise. This caused the extra-systoles to disappear. Mr. PHILIP TURNER: *Renal calculi in both kidneys* of a woman aged 42. The left kidney had been exposed and a calculus weighing, when dried, 4 oz. and several smaller ones were removed. Four weeks later seventeen calculi and a number of small ones were removed from the right kidney. The patient made good progress. Mr. J. G. SANER: (1) *Congenital lipoma* of the sole of the foot with hypertrophy of the second and third toes in a child aged 2. (2) *Congenital hypertrophy* of the right leg with scoliosis in a girl aged 13. There was a general naevoid condition of the skin. Mr. R. J. PYE-SMITH read a short paper on *Arsenic cancer*, with notes of a case. It was illustrated by a photograph and microscopic slides. The case occurred in a woman who had been treated for some years for psoriasis probably by arsenic, hyperkeratosis resulted, and later epithelioma. The probable sequence in such cases was hyperkeratosis, fissuring of the heaped-up areas, and finally epithelioma. The condition had been described by Sir Jonathan Hutchinson.

SECTION OF DISEASES OF CHILDREN.

At a meeting on April 25th, Mr. A. H. TUBBY, President, in the chair, the following were among the exhibits:—Dr. J. L. BUNCH: Two cases of *Hereditary syphilis* treated by intravenous injections of salvarsan and neo-salvarsan—(1) A child, aged 2, who was given 0.03 gram of salvarsan at 8 weeks old; (2) a child, aged 3 months, to whom, when aged 5 weeks, 0.04 gram of neo-salvarsan was administered. Both had benefited considerably by the treatment. Dr. J. PORTER PARKINSON: *Tuberculosis of the kidney* in a boy aged 8. The diseased kidney was palpable. Tubercle bacilli were found in the urine. Mr. R. H. A. WHITELOCKE: A successful case of *Cerebral decompression* for convulsions. It was of a boy aged 4. The chief points were: (1) The unascertained cause of the illness, no lesion having been found; (2) the one-sided limitation of the spasms, with at first no loss of consciousness; (3) the complete cessation of the fits so soon as intracranial pressure was relieved by the operation; and (4) the complete and rapid restoration to health. Also *Enlargement of the thyroid gland* in a family of five

children—four boys and a girl. The disease existed in all the children of the family, the parents being exempt. One case was congenital. The thyroids enlarged in all the children, whether they lived on bracing and high ground or in a low-lying and damp watershed. Dr. H. MORLEY FLETCHER: *Cachexia strumipriva* in a girl aged 13. A small tumour had been removed from the neck, at the level of the thyroid cartilage, when she was aged 7. This proved to be thyroid glandular tissue. The physical evidences of myxoedema had not improved under thyroid therapy, but the mental state was good. Dr. E. A. COCKAYNE: *Distal myopathy* in a boy aged 6. The boy was small for his age and showed great wasting of the glutei and of the muscles below the knees. It did not fall in any definite group of the myopathies. Dr. E. BELLINGHAM SMITH: *Congenital absence of abdominal muscles* in a baby aged 2 months. The abdominal wall showed many linear grooves, and the navel was slit-like. The right leg was kept slightly flexed at the hip-joint and knee-joint. There were genu valgum and talipes calcaneo-vaigus on both sides. A faint systolic murmur was heard over the cardiac apex. Dr. J. D. ROLLESTON: *Diphtheria of the oesophagus*. A membrane was found about 1½ in. from the cardiac orifice and small patches below it. There was a membranous inflammation also of the naso-pharynx, larynx, and trachea. Mr. WHITELOCKE recorded two successful cases of operation for *Strangulated inguinal herniae in female infants* of the ages of 22 and 17 days respectively. The special features of interest were: (1) The early age at which strangulation occurred without definite cause; (2) the unusual hernial contents, in one case an ovary and tube as well as small intestine, in the other an unduly mobile caecum with a large appendix; (3) the successful issue in each case, even after the obstruction and symptoms of strangulation had lasted for over three days; (4) the absence of post-operative shock, after a general anaesthetic and herniotomy, and in the younger of appendicectomy also. Mr. Whitelocke also described a case of pseudo-meningitis, in which the symptoms were caused by the escape of threadworms into the peritoneal cavity through a perforated appendix.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION.

In the account of the discussion on the etiology and treatment and other aspects of high blood pressure, on April 17th, which was given at page 940 of our issue for May 3rd, Dr. Bezley Thorne was represented as having said that in the course of fifteen observations he had never known digitalis to raise blood pressure. In reality, however, he spoke not of fifteen single observations, but of fifteen years of observation.

MEDICAL SOCIETY OF LONDON.

Monday, April 28th, 1913.

Mr. A. E. BARKER, Vice-President, in the Chair.

The Treatment of Arterio-sclerosis and High Tension.

Dr. DE HAVILLAND HALL, in introducing a discussion on this subject, said that the Registrar-General's reports showed that among males 45 to 65 years of age there had been an actual increase in the death-rate of late years, and that between the ages of 55 and 65 one-third of the total deaths were due to diseases of the heart and blood vessels. Dr. Hall discussed the various conditions causing arterio-sclerosis, such as the increased physical and mental strain of modern life and the increase in the consumption of tea, coffee, and tobacco, and he alluded to the influence of alcohol and syphilis. Under the head of treatment the necessity of relieving mental strain was insisted upon. Auto-intoxication was considered to play a very important rôle in the production of arterio-sclerosis. Directions were given as to diet. In advanced cases meat and soups made from stock were prohibited; a milk and vegetable diet was recommended. Attention to the quantity as well as to the quality of the food was advised. Special directions were necessary should the patient be obese. The amount of tea, coffee, and tobacco consumed must be strictly limited. Alcohol was to be abstained from, if possible. An abundant supply of distilled water for drinking was recommended. Turkish and electric light baths had a beneficial action, but must be ordered

with caution. The desirability of exercise in the open air was insisted upon; failing sufficient exercise massage was a useful substitute. In the event of an enlarged prostate causing trouble prostatectomy was advocated. Oral sepsis required to be treated. Stress was laid upon the necessity for daily action of the bowels and of the advantage of an occasional dose of calomel or blue pill. Potassium iodide was stated to be the drug most generally useful in cases of arterio-sclerosis associated with high tension, and it might be necessary to continue its use in small doses even for years. The addition of bromide to the iodide was especially useful in the high tension so common at the menopause. Iodides were contraindicated in cases of low tension and failing compensation, and in these digitalis and strophanthus were useful. Small doses of thyroid extract had given excellent results in obese patients with high tension. Mention was made of the hippurates, guipsine, and Trunczek's serum (antisclerosin) in the treatment of arterio-sclerosis. The speaker was of opinion that in the past the more powerful vaso-dilator drugs had been indiscriminately and injudiciously employed. It must be realized that high pressure was an effort of Nature to maintain the balance of the circulation under adverse circumstances, and that it should not be interfered with, unless there were reasons, such as anginal pains or headache, to justify the employment of these drugs. The abstraction of blood by leeches or venesection was highly commended in suitable cases. Spa treatment and the Nauheim system of treatment were briefly alluded to.

Sir LAUDER BRUNTON said he had been accustomed to regard arterial tension as almost entirely depending upon the force of the heart in propelling blood and the resistance opposed by the capillaries to its onward flow, this resistance depending almost entirely upon the greater or less contraction of the arterioles or capillaries. He had, however, neglected too much the viscosity of the blood as a factor in raising blood pressure. It had been found by Determann and Weil that the viscosity depended upon the number of formed elements within it, and that its viscosity could be roughly estimated by their enumeration—a distinctly easier method than that of employing the viscosimeter. It appeared to him that in future they must direct their attention, not only to the power of the heart and contraction of the vessels, but to the viscosity of the blood.

Dr. A. P. LUFF referred to the relation of strain, increased pressure, and toxic agents to arterio-sclerosis and high tension. He drew attention to the fact that the two terms were not necessarily synonymous, as in many cases of gout in elderly persons arterio-sclerosis occurred without high tension, provided that contracted granular kidneys did not exist. On the other hand, the very highest pressure might be present with quite moderate thickening of the vessels. The most important factor in treatment was to diminish the production of toxins in the gastro-intestinal tract and their absorption therefrom, which was effected by ensuring a free action of the bowels and a reduced consumption of meat and alcohol. Potassium iodide and sodium nitrite were most valuable for the reduction of tension, but vaso-dilators should not be used in cases of advanced arterio-sclerosis, as in such a high arterial pressure was essential in order to maintain a sufficient circulation of blood through the tissues.

After further discussion by other members, Dr. DE HAVILLAND HALL replied.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on April 24th, Mr. ROBERT JONES, President, in the chair, Dr. GARDNER-MEDWIN described a case of *Malta fever* in a patient who had never been in Malta and who had no history of having taken goat's milk. The *M. melitensis* was isolated from the urine. The patient had jaundice. Mr. R. C. DUN recorded 220 cases of *Hernia* operated upon in the out-patient room, the children being sent home the same night. There had been no mortality, and in all cases under 1 year of age there had been healing by first intention. In two cases there had been suppuration; one had a stitch abscess; the other had broken down on the tenth day, apparently from infection, when the stitches were removed. For preparation of the skin 2 per cent. iodine in chloroform was used. He divided the sac

high in the canal and used a stitch to pull the pillars of the ring together. A mattress subcuticular suture was used to draw the wound together. There was no dressing beyond flexile collodion. The child was put on a Thomas's hip splint to keep it at rest. The operator thought 3 months the best age at which to operate. Professor J. M. BEATTIE, in a paper on *Relapses in acute rheumatism*, said some relapses were probably reinfections from the throat, but might be due to survival of the infection in the synovial membranes. In 89 *post-mortem* examinations in which the joints were examined bacteriologically, 60 had sterile joints. In 12 there were putrefactive organisms or staphylococci, in 17 diplococci or streptococci. Of the 10 streptococcal cases 9 had a definite rheumatic history. In all definite rheumatic cases an organism could be isolated from synovial membrane of joints; the organism could be grown outside the body, and was still capable of producing rheumatism if kept even for three years. Slides were shown illustrating the effect of the injection of cultures and of cold air on eleven rabbits that had been injected. The injection produced joint trouble which tended to disappear, but exposure to cold would cause relapses. Treatment by salicylates should be continued during the apyrexial period with a view to preventing relapses. Not much was to be hoped from vaccines during the acute periods, but they might be of service during the latent condition of the disease. Sir JAMES BARR considered mechanical strain was of importance in determining the site of the attack. Dr. T. R. BRADSHAW thought that treatment by salicylates was not pushed far enough nor continued long enough to prevent cardiac lesions. He agreed that vaccine treatment was of no use in the acute stage. Dr. PERCY MARSH had used an antistreptococcus vaccine in treating children, but had given it up. Dr. JOHN HAY found it hard to satisfy himself that there was any useful treatment except rest and the salicylates. Professor BEATTIE, in reply, said he had not treated rabbits with salicylates. He had seen chorea in one rabbit, and an organism had been isolated from the spinal cord. Watering the floor of the animal room produced relapses. He thought the organism was an inhabitant of the alimentary canal, and the infection probably came, in many cases, from the mouth and tonsils.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

At a meeting on April 18th, Dr. Dobson, President, in the chair, the following were among the exhibits:—Dr. WATSON: A case of *Heart-block* in a man of 60. For some weeks the condition had been looked upon as being one of complete heart-block. The pulse varied from 22 to 26 per minute, and was regular in rate and force. There were practically no symptoms beyond dyspnoea on exertion and dizziness. He was treated with potassium iodide in 7-grain doses with small doses of liquor morph. three times a day. After a few days the pulse-rate jumped to 44 per minute, and afterwards to 72 to 76 per minute. Whenever the pulse-rate altered in frequency the patient experienced a momentary sensation of faintness. Dr. WARDROP GRIFFITH: A woman in whom he had diagnosed *Patency of the ductus arteriosus*, and in whom the condition was complicated by acquired mitral disease. Mr. A. L. WHITEHEAD: A case of *Congenital "pit"* at the right macular region; he explained its developmental origin. Dr. R. A. VEALE: (1) A man with an *Arthritis of the elbow-joint* of doubtful causation, which had given rise to ulnar nerve paralysis. Rapid improvement was taking place with massage and electricity. (2) A case of *Hydroa aestivalis* in a boy aged 4 years. He pointed out the seasonal incidence of the disorder, and mentioned its rare occurrence. Mr. J. F. DOBSON: Two cases of *Intestinal stasis with rheumatoid arthritis* in whom he had performed ileo-sigmoidostomy. After the operation there was almost immediate improvement in both the general health and in the local condition of the joints. Dr. C. W. VINING: Two cases of *Para-syphilitic disease of the nervous system*. In his remarks Dr. Vining emphasized the importance of accurately differentiating between tertiary syphilis and para-syphilis. In the former case

treatment was necessary and usually effective; in para-syphilis, no treatment as a rule was of avail.

At a meeting on May 2nd, Dr. Dobson, President, in the chair, the following were among the exhibits:—Dr. J. G. GREENFIELD: Sections exhibiting *Subacute combined degeneration of the spinal cord*. Mr. S. W. DAW: (1) A case of severe *Ricketty deformity of the legs* in a girl of 17. The patient had been unable to walk up to the time of operation. Osteotomies of femur, tibia, and fibula on both sides were performed, followed by rectification and fixation in splints. Now, one year later, the patient could walk well and was able to earn her living. (2) A case of double *Congenital talipes equino-varus*, previously treated and relapsed. Over-correction with Thomas's wrench was performed, followed by fixation in plaster for many weeks. The patient can now walk well, correction being temporarily maintained by a simple apparatus. Dr. WARDROP GRIFFITH described the case of a young man with extensive *Sarcomatosis*. On admission there was a flaccid paraplegia, with abolition of superficial and deep reflexes, partial anaesthesia, and some loss of control over the sphincters. There was slight retraction of the head, with great stiffness of the neck. Facial paralysis of Bell's type on the left side, with some deafness, was present. There was enlargement of the liver and spleen and well-marked optic neuritis. Under the skin of the abdomen many small purple tinted growths, varying in size up to a small lentil, were found, and under the skin of the scalp a great many masses were found which were not movable on the cranium. The diagnosis of sarcomatosis, originating probably in one or other of the bones, was confirmed by Dr. Stewart's examination of the blood and cerebro-spinal fluid.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

At a meeting on April 16th, Mr. W. G. LAWS, President, in the chair, Mr. LYN DIXON read a paper on *Colloids in medicine and physiology*. Their absorption depended on surface and tension. Among other therapeutic cases they had been employed in the treatment of malignant disease. Mr. ALEX. R. TWEDIE gave a demonstration on the *Functions of the labyrinth and cerebellum*, based on the methods of Bárány and Ruttin, and illustrated by the diagram evolved by the former observer. The physiological phenomena associated with induced vertical nystagmus and the effect on vertical and horizontal co-ordination under the influence of rotation with the head erect were first shown in a normal subject. Two patients were then utilized to demonstrate the variations of these phenomena under pathological conditions, both the rotatory and cold caloric tests being employed. One of these patients had been operated on for caries of the labyrinth and the other for extensive suppurative disease of the middle ear coupled with cerebellar abscess. Incidentally the uses of Bárány's "noise apparatus" could be well shown in both these patients as in each the cochlear nerve on the diseased side was functionless. Allusion was also made to the puzzling transitory effects of disseminated sclerosis in simulating labyrinthine and cerebellar lesions in certain cases.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

At a meeting on April 9th, Dr. WALTER SWAYNE, President, in the chair, Mr. E. H. E. STACK, in a demonstration on some varieties of arm splints, advocated the use of a malleable metal anterior angular splint for the treatment of *Fractures of the forearm*. For all injuries about the elbow-joint he had found the position of acute flexion to give the best results, and demonstrated a simple method for putting up an arm in that position. He advocated the early use of active rather than passive movements, the patient being better able to judge the amount of movement possible without risk of damage. Mr. CHARLES CORFIELD, in a paper entitled *What is an accident?* pointed out that it was impossible to give a satisfactory definition, but that each case must be decided on its merits. Such diverse conditions as lightning stroke and anthrax had been adjudged to be accidents within the

Workmen's Compensation Act; on the other hand, a case of sewer gas poisoning was ruled to be outside it. Dr. PARKER suggested that as a doctor was only expected to use ordinary skill and care, so an accident should only be so adjudged if it would similarly have affected a person in an ordinary state of health. Mr. STUART V. STOCK related two cases in which death from heart failure occurred two or three days after an operation in patients the subject of fatty heart, although they had shown no bad signs during a prolonged *Administration of an anaesthetic*. Mr. A. RENDLE SHORT, in a paper on the nature of *Surgical shock*, pointed out that the two great objections to the generally accepted vasomotor fatigue theory of Crile and Mummery were that the peripheral vessels were found to be constricted and not dilated, and that the centre could be shown experimentally not to be exhausted. He had examined the venous blood of a number of patients the subjects of shock, but had been unable to confirm the theory of Yandel Henderson that shock was due to a deficiency of CO₂ in the blood. His own view was that the symptoms were due to a loss of fluid from the blood; it apparently passed out into the tissues and was possibly squeezed out by vasomotor reflexes.

LONDON DERMATOLOGICAL SOCIETY.

At a meeting on April 15th, Dr. M. DOCKRELL in the chair, Dr. KNOWSLEY SIBLEY, in a paper on *Electrical procedures in diseases of the skin and mucous membranes*, dealt with some of the more recent treatments under the following headings: (1) Electrolysis, in which connexion he described the process of removing sebaceous cysts by two copper needles; (2) ionization, especially for the cure of lupus vulgaris and the absorption of scar tissue; (3) high frequency currents for the treatment of pruritus ani et vulvae, haemorrhoids, etc.; (4) *x* rays, under which he described the most appropriate doses for the cure of many chronic skin diseases, such as eczema, psoriasis, lichen, etc.; and (5) radium, on which he spoke at greater length, giving the various methods of application and dosage, together with a description of some of the skin diseases which give the most satisfactory results from treatment by radium, such as rodent ulcer, naevus, keloid, etc. Finally, he compared the treatments by radium with those of *x* rays, and detailed the advantages and disadvantages of the one with the other. The cases shown during the evening included the following:—Dr. BUNCH: (1) A case of *Scleroderma* in a man aged 25, with marked keratosis of the palms, considered to be possibly due to arsenic. It was proposed to treat the case with thyroid extract. (2) A case of severe *Tertiary ulceration* of the buttocks in a married woman aged 25 years, who gave a history of considerable haemorrhage from these ulcers about each menstrual period, her normal catamenia being absent for fifteen months. (3) A case of *Pityriasis rosacea* in a man aged 35 years. Dr. SIBLEY: (1) A boy, aged 6, who had suffered since 8 months of age with a severe *Generalized irritable eczema*, accompanied with enlarged glands in the femoral region, and therefore resembling in some respects prurigo. (2) A boy, aged 6 years, sent him by Dr. McHugh, with apparently a very extensive psoriasis on an ichthyotic skin. Dr. GRIFFITH: Specimens of growths of two varieties of the fungus of *Ringworm* which varied in colour, some growing pinkish and some white.

It is stated by the *Journal of the American Medical Association* that a lady* has given £130,000 for social welfare laboratories to be conducted by the New York Association for Improving the Condition of the Poor. In the laboratory are to be studied questions relating to public health and hygiene, the welfare of school children, and the food supply. Among the subjects to be investigated are the ventilation of school and other public buildings, and for this purpose a committee of experts will be organized to conduct research and experimental work. The subcommittee on food supply will make investigations concerning the scientific production of various articles of food, its purchase in larger quantities, its scientific storage, its efficient and honest handling, and the latest facts as to relative food values, with the object of ascertaining how the cost of food to the consumer may be reduced and its nourishing qualities increased.

Reviews.

DISEASES OF WOMEN.

THE call for a new edition shows the attractiveness of the older form of the book which now appears as *Diseases of Women*,¹ by HERMAN and MAXWELL. This attraction—and it is a great merit—lay in the skill and emphasis with which Dr. Herman presented the subjective as well as the objective side of his cases. The intimate individual note struck in a book written from the personal experience of the author had also its advantages, but in the preface to this new edition Dr. Herman acknowledges that it has defects in the treatment of operative gynaecology, and he has called in the assistance of Dr. Drummond Maxwell whose name appears on the title page. The impression left on the mind, after comparing the methods of operation as described and illustrated in the older editions and in this, is that it would have been well to have given Dr. Maxwell rather more scope. The added figures and the descriptions of newer methods materially increase the value of the book as a general manual. In the description of abdominal hysterectomy for cancer the method given for recognizing the ureter is not so certain as its recognition by vision on the inside of the peritoneal flap when this has been incised and pulled inwards. The description of ovariectomy hardly differs from that of the first edition, and the dressing with iodoform is neither so simple nor so good as some of the modern methods. The "index of authorities" is not so useful as a moderate bibliography would be, and the preponderance given to the *Transactions* of the London Obstetrical Society lends a somewhat restricted air to the volume, which, though its descriptions perhaps represent the natural history of diseases of women before rather than after the present surgical era, is on the whole a very interesting and useful book.

The most recent appearance among the ranks of English authors on the subject of gynaecology has been made by Dr. T. G. STEVENS, who, in his *Diseases of Women*,² has produced a work which, without presenting any particularly striking feature, may certainly claim to be regarded as a good textbook, in which the student and practitioner will find much valuable information. The author points out that, as far as the present limit of knowledge allows, the subject is nowadays to be dealt with on a pathological basis and that it has been brought into line with other branches of surgery, with the result that much of the mystery which at one time appeared to surround diseases peculiar to the female has been dispelled. Perhaps the most noticeable feature is presented by the photomicrographs. The author has considered it necessary to apologize for these in the preface. To our mind no such apology is necessary, as they are excellent. They are obviously taken from actual sections and are not spoilt by any attempt to alter them into diagrams—a process which is frequently adopted, although the result of so doing is not always an increase of utility. The manual presents a genuine attempt to deal with the subject in an up-to-date manner. All prehistoric theories have been suitably treated by omission, and only such are put forward for consideration as have some support in fact. The chapters on menstruation and its anomalies are well written in a short space; much well worth reading is said. It is, however, difficult to be absolutely in agreement with the author as to the great importance to be attached to the part played in this connexion by the salts of calcium. In many gynaecological manuals it is the custom to regard an alteration in the position of the uterus as of such serious import that it might be gathered from them that most of the ills to which the female flesh is heir have their origin in such a malposition. The author has handled this subject rationally and the treatment suggested is well considered. The language of the

¹ *Diseases of Women. A Clinical Guide to their Diagnosis and Treatment.* By George Ernest Herman, M.B., F.R.C.P., F.R.C.S. Eng. Enlarged edition, revised by the author, assisted by R. Drummond Maxwell, M.D., F.R.C.S. Eng. London: Cassell and Company, Limited, 1913. (Med. 8vo, pp. 914, plates 8, figs. 292. 25s. net.)

² *Diseases of Women.* By T. G. Stevens, M.D., B.S. Lond., F.R.C.S. Eng., M.R.C.P. Lond. London Medical Publications. London: Hodder and Stoughton, and Henry Frowde, 1912. (Demy 8vo, pp. 445; figs. 202. 15s. net.)

book is concise; it is well printed and the text interspersed by numerous illustrations, which are not only interesting but useful.

Nine years have elapsed since the appearance of the sixth edition of LEWERS'S *Textbook of the Diseases of Women*.³ The seventh, as was only to be expected, contains much new matter, and is published in a well-printed volume. The author has added much matter respecting radical operations in cases of cancer of the uterus, and states that he has witnessed Professor Wertheim performing the operation with which his name is associated. Dr. Lewers figures the table and instruments rather than the stages of this procedure. He rightly warns the operator to set the ureters sufficiently free so as to permit of their being held out of the way as required, but not to strip them too clean, lest they should slough. It is questionable how far Wertheim's operation is suitable as a method to be taught in a textbook for "the beginner," who is mentioned in the second line of the author's introduction. Like some other experienced gynaecologists in this country, Dr. Lewers does not speak with enthusiasm about this radical method. He concludes that it is most successful in early cases, and admits that he has not had good results when the disease was advanced. More stress might have been laid on the danger of damage to the bladder, the results of which do not appear immediately. If free dissection be made beyond the immediate area of the uterus and appendages, it should be as much in the direction of the vagina as upwards. Dr. Lewers still prefers the supra-vaginal operation to panhysterectomy in the treatment of fibromyoma of the uterus. He rightly says little about myomectomy, which is a dangerous procedure unless the operator has special experience in operations involving the wounding of uterine tissue. Lastly, Dr. Lewers is quite to be commended in his observations on operations for the suspension of the uterus, most of which are unscientific and liable to prove complete failures. This distrust is supported, we may add, by much clinical and pathological evidence recently made public by M. Bazin in his article on the after-results of such operations in the *Revue de gynécologie*. Thus Dr. Lewers's new edition is quite up to date, and the author cannot be blamed for writing somewhat vaguely on the merits of certain new methods which are certainly radical but not so surely surgical.

MARTIN and JUNG are deservedly popular with teachers and students in Germany on account of their *Pathologie und Therapie der Frauenkrankheiten*. It is a concise sketch of its subjects. There is a great demand for German medical works in the United States, and Dr. Henry Schmitz has prepared a translation under the title *Pathology and Treatment of Diseases of Women*.⁴ Firstly and above all, as far as the British and American readers are concerned, it is published in the English language by a writer conversant with the German tongue as well. Thus an excellent textbook is available for those whose mother tongue is English. It is compactly bound in cloth boards, and the type is large and clear; the illustrations are not so satisfactory. There are a few fairly good coloured drawings in the original fourth edition (1907), such as Fig. 132, representing a surface carcinoma of the corpus uteri, and Fig. 185 showing a uterus presenting the changes due to perimetritis, but both, especially the latter, come out poorly in this translation. Moreover, some of the plain illustrations of diseased structures, which were rough in the original, are not improved in the translation. Fig. 181 representing a parovarian cyst, compares very unfavourably with the beautiful drawings of tumours of that type in certain well-known books published in the translator's country. Relatively speaking, the microscopical drawings come out better. The translation is a

faithful rendering of the original handbook, and will be of great use to those who, ignorant of the German language, desire to know the teaching of a distinguished German gynaecologist and his opinions on asepsis and radical operations.

MANUALS FOR HOUSE-SURGEONS AND DRESSERS.

THERE was a time when *Pye's Surgical Handicraft*⁵ was the only book of its kind, and many of us remember with pleasure its quiet, modest aspect, its rather crude illustrations, and its old-fashioned chapter headings. Of late years it has had many rivals, but after a careful inspection we venture to think that the sixth edition of "Pye" can safely be trusted to hold its ground. Mr. W. H. CLAYTON-GREENE is responsible for the editing and to a great extent the rewriting of the book. He is to be congratulated on producing a thoroughly up-to-date accurate work without losing sight of the main purpose of the original author in 1884, which was to inculcate the acquisition of manual skill or handicraft. There can be no doubt that students are apt to be carried away with enthusiasm for brilliant operative work, and to pay less attention to everyday routine care of patients. We are satisfied that there is real need for such a book as this, if only to give dressers correct ideas of the things they have got to know. These things cannot be learnt by reading, they can be learnt only by direct frequent and diligent contact with the patient, but this book points the way. In Mr. Clayton-Greene's work nothing has been omitted. But we venture to think that the illustrations and descriptions of the "capeline" and "knotted bandage" for the head should be expunged. Soft gauze bandages are now so easily obtained that the hard inelastic material so difficult to apply neatly should be relegated to the past. We must also point out an inaccuracy in the description of the Macewen method of controlling the abdominal aorta. We agree that there is none better. The proper way to do it, however, is for the assistant to stand on a low stool at the patient's left side, with his right closed fist pressing just immediately to the left and above the umbilicus, the right arm being straight and rigid; there is no muscular effort demanded; the attitude of the assistant is that of a public speaker standing easy on the right foot with the left leg crossed in front; the left hand is free to feel the patient's left femoral if required. The book is handsomely bound, well printed, and profusely illustrated.

The house-surgeon generally finds the first few weeks of duty a trying time. He is suddenly placed in charge of a position of responsibility, and he makes the discovery that there are a great many practical matters about which he knows nothing. He is confused by the multiplicity of his duties and embarrassed by the assumption of those in contact with him that he really does know what he is about. *The House-Surgeon's Yule-Mecum*,⁶ which Mr. RUSSELL HOWARD has written, will do much to relieve the fledgeling house-surgeon of his mental perturbation. If this little book lies handy he will find in it a short, succinct solution of every difficulty he is likely to meet with. The author is to be congratulated on the way in which he has contrived to include all the essentials of the really practical and everyday features of a house-surgeon's work and in resisting the temptation to flood the book with pathology and bacteriology. The chapter dealing with injuries and diseases of the urinary organs and the modes of handling them appeals to us as quite the best of its kind we have read. The section on septic conditions and burns is exceedingly well and concisely written. The author might have mentioned excision of carbuncle and the early removal under an anaesthetic of sloughs in cases of burns and scalds as methods of treatment which materially shorten the period of residence in

³ *A Practical Textbook of the Diseases of Women*. By Arthur H. Lewers, M.D., Lond., F.R.C.P., Lond., Senior Obstetric Physician to the London Hospital. Seventh edition. London: H. K. Lewis, 1912. (Demy 8vo, pp. 550, illust. 258, plates 18. Price 12s. 6d. net.)

⁴ *Pathology and Treatment of Diseases of Women*. By A. Martin, Professor and Director of the Universitäts-Frauenklinik, and Ph. Jung, Professor and Oberarzt to the Frauenklinik, Greifswald. Fourth edition. Only authorized English translation, written and edited by Henry Schmitz, M.D., Professor of Gynaecology, Chicago College of Medicine and Surgery, etc. London: Rebinman Limited, 1912. (Super. roy. 8vo, pp. 475; illustrations 187. 21s. net.)

⁵ *Pye's Surgical Handicraft*. Edited and largely rewritten by W. H. Clayton-Greene, B.A., M.B., B.C. Cantab., F.R.C.S. Eng., Surgeon to St. Mary's Hospital, Lecturer on Surgery in the Medical School. Sixth edition, fully revised, with some additional matter and illustrations. Bristol: John Wright and Sons, Limited; London: Simpkin Marshall. 1912. (Demy 8vo, pp. 611; figs. 329, plates 11. 12s. 6d. net.)

⁶ *The House-Surgeon's Yule-Mecum*. By Russell Howard, M.B., B.S. Lond., F.R.C.S. Eng., Surgeon to Poplar Hospital, Assistant Surgeon, London Hospital. London: Edward Arnold, 1911. (Post 8vo, pp. 526; figs. 142. 7s. 6d. net.)

hospital. The diagram illustrating the Fowler position does not represent the best way of using this important adjunct to the after-treatment of abdominal cases: a photograph of a patient in the usual sitting posture with knees flexed would appeal at once to the reader. In this connexion we would like to call the attention of Mr. Russell Howard to a bed frame suggested by Mr. P. Paterson of Glasgow; this is hinged in two places, so that the upper half supporting the upper half of the patient from the hip joints upwards can be screwed up to any angle, and the knees can be similarly flexed by a second screw; the mattress is not a special one, but bends with the angles made by the bed frame. The chapter on anaesthetics is by Dr. Ashley Daly, and maintains the same level of concise practical statement without embellishment found in the rest of the volume. We can heartily commend this book to the notice of chiefs to put into the hands of their house-surgeons. We are satisfied that on its own merits it will readily make a place for itself.

In all works on surgery *Modern Wound Treatment and the Conduct of an Operation*⁷ are subjects fully set forth, but Sir GEORGE BEATSON has been prompted to embody his views in a small handbook which is an expression of gratitude to Lister and reverence for his memory. The introductory chapter is a short outline of Lister's life and work. The principles of wound treatment are then discussed, and the various classes of organisms met with which the surgeon is most concerned are described. The plan of an operating theatre, the duties of the various people concerned with the operation, the preparation of dressings, the preparation of the patient and the operation area are all exhibited in accordance with everyday practice. Sterilization of the skin with iodine receives proper emphasis, but the other method described, requiring, as it does, no fewer than six steps, cannot be regarded as simple, and it might have been proper to mention that thorough scrubbing with hot soap and water of surgeon's hands and patient's skin is regarded by some operators as sufficient. In some hospitals the omission of a description of a method of preparing iodized or other form of sterile antiseptic catgut will be regretted, but as a whole this little volume is well suited for the use of house-surgeons and surgical nurses.

PHYSIOLOGY.

As Professor HOWELL says in his preface to the fourth edition of his *Textbook of Physiology*,⁸ any author who undertakes such a task is confronted with the enormous output of experimental work in physiology. "The ever widening boundaries of physiological literature make it more and more difficult for any one individual to gain a familiar knowledge, not only of the highways but of all the many byways along which enthusiastic workers are following their investigations." Yet the place of the textbook in the student's career cannot be filled by a series of monographs dealing with each separate part of the subject, and each written by an expert thoroughly up to date in his subject. These monographs are required, and the teacher endowed with the power of popular exposition must, using them as quarries, construct the edifice required; a textbook which will not merely catalogue facts, but arouse interest, excite imagination, and lead the student to further sources of knowledge. How well Professor Howell succeeds is shown by the wide popularity of this book on both sides of the water. He has produced a thoroughly sound book, interesting and readable, and has kept it up to the mark in each edition. One of the most interesting chapters is that on reproduction, growth, and senescence. He says:

The physiological evidences of an increasing senescence warrant the view that death is a necessary result of the properties of living matter in all the tissues, except possibly the reproductive elements; the course of metabolism is such that it is self-limited, and even if perfect conditions were supplied natural death would eventually result. We do not understand the nature of these limitations—that is, the ultimate causes of senescence.

⁷ *Modern Wound Treatment and the Conduct of an Operation*. By Sir George T. Beatson, K.C.B., B.A., M.D., Surgeon, Western Infirmary, Glasgow; Senior Surgeon, Glasgow Royal Cancer Hospital, Edinburgh; F. and S. Livingstone, 1913. (Cr. 8vo, pp. 106; figs. 10. 2s. net.)

⁸ *A Textbook of Physiology*. By Professor Howell. Fourth edition. Philadelphia and London: W. B. Saunders and Co. 1911. (Med. 8vo, pp. 1018; 306 figs. 18s. net.)

If the Bulgarians include some 70 per cent. of all the centenarians in Europe, is it because they live on sour milk? We think not, but rather because they come of a long-lived breed and live a simple open-air life. If one of a long-lived breed of Englishmen would seek out as a mate some fair Bulgar the daughter of a family of centenarians, he might endow his children with more than the threescore years and ten now allotted to man. Strange things will happen when men turn their attention to the selection and breeding of human beings in place of big gooseberries.

Mr. ERNEST EVANS, Natural Science Master at the Technical Institute, Bury, has written a volume entitled *The Student's Human Physiology*⁹—a first-year course in the practice and theory of the subject. He has also written *The Student's Hygiene and How to Study Geology*. What the value of the last of these books may be we do not know, but we cannot say that the volume before us shows the student rightly how to study physiology. A catalogue of facts may be crammed up, but is of little educational value. To write an elementary book of science is a most difficult task, and can, we believe, only be accomplished successfully by one who has worked as an investigator and learnt the breadth of view which comes from years of original work in his subject. Mr. Evans's book is suitable for a candidate to run through just before an examination. For ordinary examination purposes the information given is clearly set out. The illustrations are rather poor.

DISEASES OF THE MOUTH.

*Diseases of the Mouth*¹⁰ (syphilis and similar diseases) is a translation from the German of Professor Dr. F. ZINSSER by Dr. SREIN of the New York College of Dentistry. The book is really an atlas of mouth syphilis, and is intended to be an illustrated aid in stiddy and diagnosis; consequently the therapeutic side has not been taken up, nor have the diseases resembling syphilis received more than a short description dealing with the chief points in differential diagnosis. Since the main point of the book is to supply the need there exists for lucid and detailed instruction in the diagnosis of syphilis and similar diseases of the mouth, syphilis is accorded a far more detailed description. This includes introductory remarks on the *Treponema pallidum*, the Wassermann reaction, and spirochaetes which may be found in the sites of syphilitic lesions, and chapters on primary, secondary, tertiary, and hereditary syphilis, all written with special reference to the mouth. The two remaining chapters are devoted to diseases similar to secondary and tertiary syphilis in the mouth.

In reading those chapters one gets the impression that syphilis is very prevalent in Germany (p. 13). In Cologne, every year during the carnival time, the number of primary lesions in the mouth is especially great, and perhaps this accounts for the inclusion of all forms of hypoplastic teeth as syphilitic, and for the failure to recognize the septic element in the causation of leukoplakia buccalis. It is further suggested that numerous other irregularities in shape and position of the teeth (shark-like teeth, absence of teeth, microdontism, etc.) can be traced to hereditary syphilis. Certainly, if the same standard of diagnosis were applied here in England, many grievous errors in diagnosis would be perpetrated.

The author thinks the tooth-hypoplasia is not of a specific nature, since a local syphilitic process should produce asymmetrical lesions; this, in fact, does occur, and he seems to have overlooked Cavallero's sections showing the early stages of destruction of the tooth germ. He expresses the opinion that "deformities of the teeth following heredo syphilis are of quite frequent occurrence and of great importance," but we think he very much over-estimates their frequency.

The forty-six plates, containing seventy-three illustrations, are all of great merit. Most are coloured, and the

⁹ *The Student's Human Physiology*. By Ernest Evans. London: George Allen and Co. 1912. (Cr. 8vo, pp. 319; figs. 113. 5s. net.)

¹⁰ *Diseases of the Mouth: Syphilis, and Similar Diseases*. By Professor Dr. F. Zinsser, Dozent at the Academy for Practical Medicine, Cologne. Translated and edited by J. E. Stein, M.D., New York College of Dentistry. London: Rebman, Limited. 1913. (Imp. 8vo, pp. 285; illustrations 73. 30s. net.)

natural tints are well reproduced. Each illustration is accompanied by a short description giving the reasons for the diagnosis. A large number of the illustrations refer to syphilis, but every disease mentioned in the text as possibly resembling syphilis is also illustrated. It is doubtful whether Figs. 63 to 66 represent teeth of syphilitic origin. The price of the book (30s.) will put it beyond the reach of most students, but it should be kept in every reference library.

TASTE AND SMELL.

To the series entitled *Questions Biologiques Actuelles*, edited by Professor DASTRE, a volume on taste and smell has been contributed by L. LARGUIER DES BANCELS.¹¹ The subjects are treated in a readable and scholarly form. An interesting experimental observation quoted from Pavlov is that the sight of black may cause saliva to flow into the mouth of a dog if an acid solution coloured black has been put several times into its mouth; this sight reflex disappears if repeated frequently without being confirmed by the acid stimulus. The author quotes from Berthelot the curious calculation that if a gram of iodoform were enclosed in a tube communicating with a receiver of the capacity of 100 c.cm., it would scent every cubic centimetre of this perceptibly in one hour, but the amount lost by the iodoform is so small that if a fresh receiver were put in place every hour for a hundred years the iodoform would have lost only 1 mg. in weight; 0.01 mg. of mercaptan will scent 230 cm. of air, and 1 litre of air so scented will not contain more than 0.000,000,04 mg. of mercaptan. Odours spread as a gas diffuses, and the olfactory nerve endings are excited by the minutest quantity of matter. The fixation of odours by different substances is curious—for example, paint by wet hay, and tobacco by curtain materials; skatol is fixed by aluminium, musk by copper, tin, nickel, and lead, but not by aluminium or glass, and onions by steel. One of the most interesting ways of obtaining scents is *l'enfleurage à froid*; that is, simply putting the flower in contact with a layer of fat. The pomade so obtained when treated with alcohol yields up the scent.

PATHOLOGICAL INEBRIETY.

SHORTER than Dr. Hare's recent volume, Mr. J. W. ASTLEY COOPER's work on *Pathological Inebriety*¹² gives a lucid, workmanlike account of the pathology and treatment of inebriety. As Sir David Ferrier says in his introductory words of commendation, the book is characterized by sound sense, and bears the marks of ample experience. It is the work of an observer and thinker who writes well, but never permits temperance zeal to kill the scientific presentment of his subject. Mr. Cooper holds that all inebriates who come within the scope of the title of his book are psychoneurotics, and that, to be effective, treatment must be based on a recognition of this deficiency in their equipment. He employs a combination of isolation, drugs, and psychotherapeutics in the form of suggestion or other variety of hypnotism. The first stage is to withdraw the alcohol and suppress the desire for it; the second is the restoration of psychoneural integrity to enable the patient to realize his condition and the need for total abstinence. Mr. Cooper believes that the inebriate has the best chance of recovery in a well-managed retreat, and indulges in a friendly criticism of Dr. Hare's attitude towards these institutions. The pathology and treatment of the periodic and chronic inebriate are adequately dealt with, and the modern view that sudden stoppage of alcohol incurs the risk of delirium tremens is upheld. When once it has started, however, alcohol is said to do harm. Mr. Cooper pleads for preventive treatment in the shape of self-discipline of the young and the control of the inebriate, who both by precept and example is a potential manufacturer of inebriates. Chapters on inebriety and temperance societies,

drug treatment and secret remedies, conclude the book, which is a valuable addition to the accumulating store of reliable facts on the subject of inebriety, and can be heartily recommended.

MEDICAL JURISPRUDENCE.

IT is easy to see why GIFFEN and DUNDAS'S *Student's Manual of Medical Jurisprudence and Public Health*¹³ has reached a third edition in a comparatively short time. It is extremely handy in size, beautifully and clearly printed, and contains all essentials for a student arranged in such a way that reference is extremely easy, for the eye is easily caught by tables, headings, and subheadings in different type. All these points must naturally increase the popularity of such a book in the eyes of students, and we are of opinion that they really do constitute intrinsic excellence in themselves, for after all the most that any student of the subject can learn is its principles, real knowledge can only come by experience in courts and elsewhere. It is somewhat of a triumph of good packing to get the principles of forensic medicine and toxicology into 232 pages, and those of public health into 98. The worst feature of the book—it is not peculiar to this particular work, but applies to all small manuals for students—is that as the authors have to accept and teach one particular view of very disputable points, the student learns this view and very probably no other, and it remains with him through life, possibly to lead to trouble in cross-examination in court, where dogmatizing is out of place. Our meaning may be illustrated by referring to page 256, where it is asserted that the destruction of lecithin in fresh milk is *the* (the italics are ours) cause of the deterioration of milk from boiling or sterilization.

NOTES ON BOOKS.

THE number of textbooks on elementary biology is constantly increasing, and one is tempted to wonder for what purpose they are all written as so many of them cover the same ground, and with regard to most of the subjects treated there can be little new to add. An exception may, however, be made in the case of *Applied Biology*,¹⁴ by Professor MAURICE A. and ANNA M. BIGELOW, for while it is true that the animal and vegetable, dealt with in most textbooks are also included in this, it has the advantage of being a combined textbook and laboratory guide, and special attention is paid to the physiological and economic aspects of the science. There is also a part devoted to evolution and heredity in animals and plants. A student of general biology working conscientiously through this book will have gained a very considerable insight into the processes of Nature and a solid ground work upon which to base further studies. Towards the latter he is also helped, advice being given as to the more advanced works which may be consulted by those wishing to probe further into the subjects dealt with in the various chapters. While the book covers more ground than is required by the average medical student, except perhaps, in the case of candidates for certain university degrees, nevertheless the applications to man are so constantly referred to that the book may be recommended to all who wish to understand biology, and not merely to "cram up" the minimum amount for examination purposes.

It is only after reading a book like *The Cruelty Man*¹⁵ that one realizes fully the benefits of the age in which we live and which, in spite of its drawbacks, has yet grasped the fact that it has duties and responsibilities to discharge towards the weak and suffering. "The Cruelty Man" is the name by which the inspectors employed by the National Society for the Prevention of Cruelty to Children are known in certain districts to the people amongst whom they work, and the book contains an account of the actual experiences of one of these officers. No stronger proof could be given of the need for such a society than

¹¹ *Le goût et l'odorat*. By L. Farguier des Banceels. *Questions Biologiques Actuelles*. Collection de monographies publiques sous la direction de M. A. Dastre. Paris: A. Hermann. 1912. (Roy. 8vo, pp. 100, fr. 3.50.)

¹² *Pathological Inebriety, its Causes and Treatment*. By J. W. Astley Cooper, Medical Superintendent and Licentiate of Ghyllwood Sanatorium, near Cockermouth; with introduction by Sir David Ferrier, M.D., F.R.S. London: Baillière, Tindall, and Cox. 1913. (Crown 8vo, pp. 165. 3s. 6d. net.)

¹³ *Student's Manual of Medical Jurisprudence and Public Health*. By G. Heston Giffen, F.R.C.S.I., D.P.H. Camb., and James Dundas M.D., D.P.H., D.T.M. Third edition. Edinburgh: William Bryce. 1913. (Cr. 8vo., pp. 348. 5s. net.)

¹⁴ *Applied Biology*. By Maurice A. Bigelow, Ph.D., and Anna M. Bigelow, M.S. New York: Macmillan Company. 1911. (4p. 58s.)

¹⁵ *The Cruelty Man*. Actual experiences of an inspector of the N.S.P.C.C. graphically told by himself. London: National Society for the Prevention of Cruelty to Children. 1912. (Cr. 8vo, pp. 160. 1s. net.)

this matter-of-fact record of the tortures endured day by day by helpless children at the hands of those who ought to be their natural protectors. The author has been an inspector for many years and has seen many sad and dreadful sights, but he has managed to preserve his belief in the inherent goodness of human nature, and the gloom of his terrible story is lightened by his honest pride in his work and his tender pity for the miserable little beings he has helped to rescue from their wretched homes. His book is a mirror which faithfully reflects the hideous conditions in which thousands of suffering children are to-day leading their neglected lives, and its appeal on behalf of these innocent victims of parental vice and ignorance should go straight to the heart of every right-thinking man and woman.

In late years it has become a custom with some of the principal wholesale and manufacturing pharmaceutical houses to publish to the world much of the information which they obtain in the regular course of testing crude drugs, chemicals, and preparations made from them. Such a practice is entirely to be commended. The latest publication of this kind which has reached us is *Evans's Analytical Notes for 1912*, published by Messrs. Evans, Sons, Lescher, and Webb, Ltd., of Liverpool and London. It contains accumulated data of great value to all those engaged in the analysis of drugs, and not without interest to the medical practitioner, as showing the amount of trouble and of scientific work which has to be expended in maintaining the quality and purity of medicines for which the leading houses can now be depended on. In the introductory note it is mentioned that over 10,000 samples have been examined in this firm's laboratory during the year. Of the 2,400 samples dealt with in the *Notes*, 250 were found to be in some way below the standard; this fact well exemplifies the necessity for such testing, especially when it is borne in mind that the drugs tendered to a firm known to test samples thoroughly are likely to be distinctly above the average of all those in the market. The details of the notes are necessarily very technical and outside the scope of these columns. The fact is alluded to that "the researches of science are being employed in an illegitimate, as well as in a legitimate, direction"; it is evident, however, that in the perpetual competition between sophisticator and analyst the latter manages to maintain a good lead. The firm offers to send a copy of the *Notes* to any person interested.

English men and women are notoriously bad linguists; and even amongst the educated classes there are many who have considerable difficulty in making themselves understood when travelling in a foreign country. To such people the *Travellers' Practical Manuals of Conversation*,¹⁶ published by Marlborough and Co., should prove invaluable travelling companions. The second volume of this excellent series is designed to meet the needs of English tourists in France, Belgium, Switzerland, Austria, Germany, and Holland, and contains, besides the usual phrases and a full vocabulary of French, Dutch, and German words, much information that should be of assistance to the inexperienced traveller. The book, which has been very carefully compiled, is well printed, and has the additional advantage of being of a convenient size and shape for carrying in the pocket or handbag.

A third edition has appeared of Dr. PROUT'S *Lessons on Elementary Hygiene and Sanitation*,¹⁷ a composition which has already received very favourable notice in these columns. Its scope extends somewhat further than is indicated by the title, for elementary anatomy and physiology both receive considerable attention. Though written mainly from the point of view of the needs of dwellers in tropical climates, it would be a useful book to place in the hands of lay students anywhere.

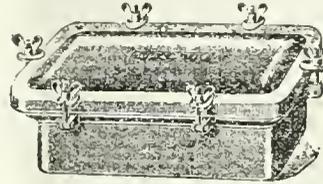

The volume entitled *Collected Papers by Officers in the Royal Army Medical Corps*¹⁸ consists of reprints of various communications appearing in the *Journal of the Royal Army Medical Corps* during the twenty months ending December, 1912. Numbering just two dozen, they relate largely to research work in connexion with venereal

disease, malarial fever, and other tropical diseases. The volume bears notable testimony to the scientific activity of the modern soldier-doctor.

MEDICAL AND SURGICAL APPLIANCES.

An Instrument Tank.

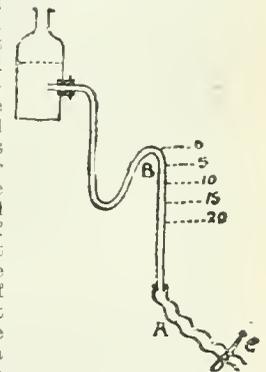

MR. W. SAMPSON HANDLEY (London) writes: The sterilization of instruments in private houses by a spirit lamp and boiling water immediately prior to an operation is an annoying and time-consuming process. Owing to the vagaries of spirit lamps, it is not unattended by risk of accident. The instrument tank represented in the figure

is of a size to hold all the instruments required for an ordinary abdominal operation. The instruments required are boiled at home in an ordinary sterilizer, dried (or dipped in methylated spirit), and placed in the tank immediately ready for use, immersed in methylated spirit, to which, if desired, a proportion of lysol can be added. Sharp instruments—such as knives, scissors, and needles—are kept in the tank permanently, and need not be boiled. Ligatures may also be kept in the tank. Once in two or three weeks the instruments should be taken out and cleaned, especially if lysol is used, since it causes a greasy deposit to form upon them. It is also important to see that no blood or water gets access to the tank, since in either case the instruments will rust. It should be noted that the tank is not intended for sterilizing instruments by heating. It is simply used as a container. It was made to my design by Messrs. Meyer and Meltzer, and has been tested by two years' constant use in practice. The top, sides, and bottom of the box are made of sheet copper. The whole strength of the box is concentrated in the circumference of the lid, which is a gun-metal casting, and the top edge of the box itself, which is also cast in gun metal, and has upon its upper aspect all round a deep undercut groove into which a ring of hard rubber is forced by pressure. This groove corresponds with a V-shaped ridge within the lid, which bites into the rubber and ensures a spirit-tight joint. The spirit should be changed whenever it becomes turbid.

Technique of Hypodermic Injection.

DR. H. POLLARD HACKER (London), writes: I recently devised an apparatus which enables nurses and others to test themselves in the technique of hypodermic injection. It shows at a glance whether the full dose has been delivered, and also whether any air has been admitted at the same time. It consists of a reservoir of coloured water connected to an arrangement of tubing as shown in the diagram. The dose prescribed is measured in ether and is injected through the rubber tubing at A. The ether will be seen to rise through the coloured fluid and can be measured off at B, and the actual amount delivered compared with the dose intended. Any bubble of air also admitted will be evident above the fluid injected. The clip C is then released for a moment, and the injection flushed out by fresh fluid from the reservoir. When the clip is reapplied the apparatus is again full, and is ready for the next trial. The apparatus can also be used to demonstrate the method of using Southey's tubes and the aspirating syringe.

THE first Italian congress of medical radiology, organized by the Italian society of medical radiologists, founded in January, will be held at Milan in October. The subjects proposed for discussion are intensive apparatus in *x*-ray technique, introduced by Professor Maragliano of Genoa; radiological investigation of the skull, introduced by Dr. Aristide Busi of Bologna; radiology of the bowel, introduced by Dr. Pasquale Tanjoda of Naples; Roentgen-ray and radium treatment in gynaecology, introduced by Professor Lario Bertolotti. Communications should be in the hands of the General Secretary, Dr. Felice Perussia, Foro Bonaparte 61, Milan, on or before August 31st.

FESTIVAL DINNER OF THE ROYAL MEDICAL BENEVOLENT FUND.

In the absence of Prince Arthur of Connaught, owing to the illness of the Duchess of Connaught, Sir JOHN TWEEDY, the President, occupied the chair at the festival dinner of the Royal Medical Benevolent Fund at the Hotel Cecil on April 30th. A numerous company sat down, and the guests included many ladies.

Sir JOHN TWEEDY, in proposing the toast of "The Fund," read a message from Prince Arthur of Connaught, who, after announcing that, in addition to conferring the title of "Royal," His Majesty had bestowed a still greater honour upon the fund by consenting to become its Patron, described the work of the fund, and continued:

I am not sure that we all realize what a debt we owe to the medical profession. The fact that its members are spending their lives in alleviating suffering and fighting disease must appeal to the imagination. Do any of us, whose business hours are from 10 to 4, ever think of the over-worked doctor, liable to be called out at any hour of the day or night to pass several hours at a bedside, while others, who have probably not spent nearly such a hard day in pursuit of their profession or business, are obtaining what they consider their well-deserved rest?

Great prizes in the way of fame and fortune are, no doubt, attained by a few members of the medical profession, but these must always be in a minority. When we consider the long and patient training needed for such a profession as medicine and surgery has become in these days of exact science, it is inevitable that amongst the rank and file some must go to the wall. Even those whose talent and industry give promise of a brilliant career may be struck down by illness, and it is to provide for the fatherless children of such that I plead this cause to-night.

As you are all aware, the Royal Family and myself have very special reasons for gratitude to the medical profession, by whose skill and care my beloved mother, the Duchess of Connaught, though passing through a very grave crisis, is being slowly restored to her normal health and strength. Consequently it is a great pleasure to me to subscribe to this fund and to hand over a cheque from my father as his contribution as a thank-offering and tribute of respect and admiration for the noble profession so largely represented at your gathering to-night.

Dr. SAMUEL WEST, the Treasurer, in responding, remarked that no one could fail to be touched by the sympathetic tone in which Prince Arthur of Connaught had written of the fund and its work. The announcement that the King had consented to become the Patron of the fund would render that gathering memorable. They would ask Prince Arthur to convey to His Majesty their grateful appreciation of the honour, and of the sympathy the King showed in the work of the fund. Dr. West went on to say that every profession had its woes, but upon the doctor's misfortune, when it came, laid a particularly heavy hand. If in the early years his health broke down, or should he die, there might be, owing to the expenses of the long training and the acquisition of a practice, no adequate provision for the widow and children. Dr. West described the methods by which the fund is administered, and alluded to the need for an emergency fund out of which pressing needs could be relieved with greater liberality than was possible out of the ordinary income. He also referred to the valuable work of the Guild of Lady Helpers in rendering the personal service which was no less important than the pecuniary assistance afforded by the organization.

Sir JOHN TWEEDY proposed a resolution of thanks to Prince Arthur of Connaught for his sympathetic interest in the fund, and for the earnest and eloquent appeal he had sent on its behalf. Sir John Tweedy remarked that never was medicine higher in the hierarchy of the sciences than at the present time, but, on the other hand, never were the prospects and status of the general practitioner more uncertain. The difficulties of medical practice were such that it was difficult for the majority of medical men to do more than earn a modest livelihood and secure sufficient means for the decent maintenance and upbringing of a family. He wished he could see any solid hope for improvement in the future, but he feared

that straitened circumstances and even actual poverty must be the portion of a large number of medical practitioners in this country.

Mr. PARKER YOUNG, Chairman of Committee, seconded the vote of thanks, which was carried with acclamation. Lord GOSCHEN proposed the health of the Chairman, who made suitable acknowledgement.

During the evening it was announced that subscriptions to the fund had been collected or promised to the amount of nearly £3,000.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, 1913.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

The President of the Section is Sir Francis Champneys, Bart., and the Honorary Secretary is Dr. Herbert R. Spencer (104, Harley Street, W.). The section will meet in the Chemistry Theatre of the Imperial College of Science. The following discussions have been arranged:

Thursday, August 7th.—A discussion will be opened by Professor Döderlein (Munich) and Professor Essen-Möller (Lund) on the treatment of hæmorrhage from the placental site (placenta prævia and accidental hæmorrhage) in the later months of pregnancy.

Friday, August 8th.—A discussion (jointly with the Sections of Diseases of Children and Hygiene and Preventive Medicine) on infant mortality in the first four weeks of life will be opened by Dr. A. K. Chalmers (Glasgow), Dr. Henry Koplik (New York), and Professor Wallich (Paris).

Monday, August 11th.—A discussion (jointly with the Section of Radiology) on Roentgen and radium therapy in gynaecology will be introduced by Dr. Fovcau de Courmelles (Paris), Professor B. Krönig (Freiburg), and Professor A. Schönberg (Hamburg).

Tuesday, August 12th.—A discussion on cancer of the uterus (body and cervix)—operative technique and results, will be introduced by Professor D. de Ott (St. Petersburg), Professor A. Pöllsson (Lyons), and Professor Wertheim (Vienna).

The afternoon sessions will be occupied with the reading and discussion of independent papers, which will be selected by the Council of the Section, and for demonstrations. The latest date for the reception of titles of papers is July 1st.

The department of the museum dealing with obstetrics and gynaecology will contain specimens illustrating the papers and discussions, and also other material either dealing with the subjects of cancer of the uterus and hæmorrhage from the placental site or illustrating other investigations and observations of current interest.

An exhibition of old obstetrical instruments will be a special feature of this department of the museum. It will contain the whole of the collection now preserved at the Royal College of Surgeons, which is being catalogued by Mr. Alban Doran, and, it is hoped, many other rare old instruments from British and foreign sources. Communications regarding the museum should be addressed to the Honorary Secretary of the Museum Committee, Mr. H. W. Armit, Ravenhurst, Talbot Road, Wembley.

On Saturday, August 9th, a dinner will be given by British members of the Section, at which foreign guests will be entertained.

SINCE antityphoid vaccination was introduced in the French Army, in January of last year, 62,788 men have voluntarily submitted to the treatment. No injurious effects have been observed, and the measure of protection afforded by the vaccination has been very marked. The official statistics show that in France no case of typhoid fever has occurred among the soldiers vaccinated, who, on December 31st, numbered 37,140. On the same date only one case was reported among the 13,290 vaccinated men in Algiers-Tunis; that was in a soldier who had come from Morocco. In Morocco the results were as follows: In Eastern Morocco the morbidity and mortality were nil, whereas among the non-vaccinated the morbidity was 38.23 and the mortality 5.51 per 1,000. In Western Morocco the morbidity among the vaccinated was 2.96 and the mortality 0.09 per 1,000, whereas among the non-vaccinated the morbidity was 168.75 and the mortality 21.29 per thousand. Taking the average typhoid statistics for the whole army it is estimated that antityphoid vaccination has, among the 62,788 men treated, prevented 2,101 cases of disease and 266 deaths during the year 1912.

NINTH INTERNATIONAL PHYSIOLOGICAL CONGRESS.

GRONINGEN, SEPTEMBER 2ND TO 6TH, 1913.

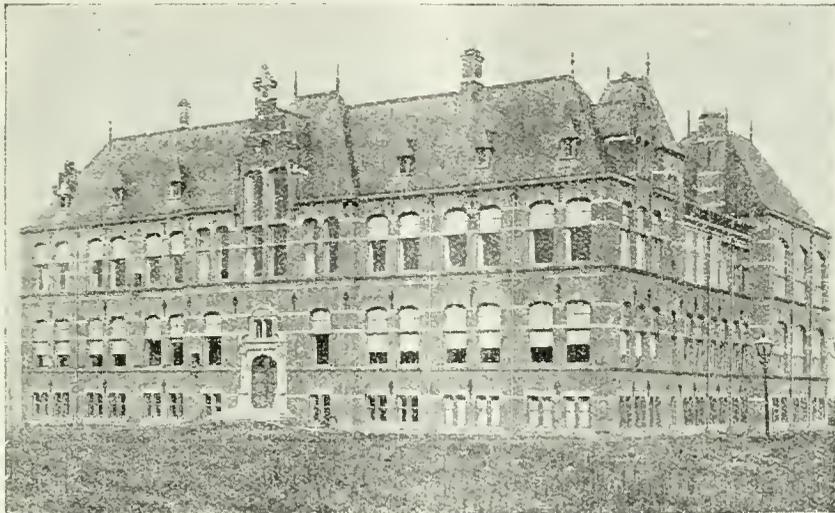

THE Ninth International Physiological Congress will be held at Groningen from September 2nd to 6th next, under the presidency of Dr. H. J. Hamburger, Professor of Physiology in the University of Groningen, and Director of its Physiological Institute. Previous congresses have been held in Bale (1889), Liège (1892), Bern (1895), Cambridge (1898), Turin (1901), Brussels (1904), Heidelberg (1907), and Vienna (1910).

Groningen was one of the first universities in Europe to be provided with a building specially designed to fulfil the purpose of a physiological institute. About the year 1863, the late Professor Donders induced the then Minister of the Interior for Holland to provide in the national budget a grant of money for the erection of physiological laboratories at Utrecht, Leyden, and Groningen. The first of these to be completed in Holland and the second in Europe was that at Groningen. It was fitted up under the direction of Van Deen in 1865.

The present building, which has replaced that erected in 1865, was completed and fitted under the direction of Professor Hamburger, and was opened on April 7th, 1911.

The main building forms three sides of a square, and

the illustration shows the main front. The building consists of a basement and two stories. On the first floor is a large lecture room fitted with a kinematograph, for which device Professor Hamburger foretels a great future in physiology, not only as a means of demonstrating movements to students, but also for research, and particularly for the analysis of

movements by running the machinery slowly. Adjoining the theatre are the preparation room and the private office and laboratory of the Director. On the same floor is a laboratory and reading room, a balance room, a "spectatorium" for demonstrations, a laboratory for candidates preparing their theses for the Doctor's degree, and a laboratory for assistants, a histological class-room with attached preparation room, and a drawing and photograph room.

On the ground floor are the rooms for practical instruction in physiology, a bacteriological laboratory, where in particular investigations are carried out with regard to enzymes and antibodies, for Professor Hamburger entertains the opinion that the essentials of serum therapeutics and immunity, since they are based on physiological reactions, concern the physiologist as much as the pathologist and hygienist. There is a large operating room for animals, with attached preparation room, observation room, and sterilization room. On this floor also are rooms for physico-chemical researches, and for optical and x-ray investigations.

In the basement there is a room for electro-physiology, a laboratory for low temperatures, another for investigation of the body temperature, a centrifugalizing room, a room for meters of gas, water, and electricity, and various offices.

The laboratory is surrounded by grounds, which are cultivated for green food and clover, and are used also as a meadow, which contains a natural pond, where fish can live through the winter. In the grounds there is also a stable.

The facilities afforded by the institute are placed at the disposal of competent investigators free of charge. Great pains have been taken in the arrangement of the details of the rooms, so that, with the help of an inventory, anything can be found at short notice. If an object is taken away, a printed card is put in the vacant place recording the name of the person who has borrowed it and the room to which it has been taken. In fact, Professor Hamburger has worked out with scientific precision the old injunction to find a place for everything and everything in its place.

The scientific staff of the institute consists of the Professor-Director and four assistants, whose duties are confined to giving assistance in the conduct of the practical classes. The rest of their time is at their own disposal for scientific work. One of the assistants, who has the title of Conservator, assists the Director in the management of the laboratory, and acts when necessary as his substitute. Every week the Conservator makes a report to the Director on what has been going on in the laboratory during the past week. In addition to the scientific staff there is a technical staff whose offices are permanent; the professor is assisted in his lecture experiments by the senior member, called the first amanuensis. The second amanuensis is responsible for the inventory, and both assist, not only the Director, but other members of the scientific staff in their experiments.

The chief instrument maker has a workroom and an apprentice, and there is a mechanic who attends to the larger engines for general use.

The Congress, as has been said, will begin on September 2nd, and the President in a recent circular emphasizes his approval of one of the rules of the Congress, which is: "Special value is attached to the demonstration of actual experiments, which will always take precedence of

merely oral communications." He invites physiologists to give demonstrations and experiments, even though they may already have been published. The business of the Congress will occupy from about 9 a.m. to 5 p.m. on Tuesday, Wednesday and Thursday. On Friday afternoon, September 5th, a closing meeting will be held in the aula of the University, when Professor J. P. Pawlow will give an address on the investigation of the higher nervous activities.

During the Congress there will be an exhibition of physiological instruments and apparatus. These will be exempt from all duty, and the cases containing them will only be opened in the laboratory at Groningen. A committee of ladies has been formed to arrange entertainments and excursions.

A tour has been arranged, starting on Saturday, September 6th, through some of the most interesting parts of Holland, including the northern part of the country, which, though known to few foreigners, is most characteristic and interesting.

THE Paris Academy of Sciences has awarded prizes of the value of £100 each to Dr. Carlos Finlay and Dr. Aristides Agramonte of Havana in recognition of their investigations on yellow fever.

A DEPARTMENT for treatment with radium emanation has been established at the New York Post-Graduate Medical School and Hospital. The department is intended for scientific investigation as well as for the treatment of disease.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

THE ADVERTISEMENT OF MEDICATED WINES IN THE MEDICAL PRESS.

ON May 1st the Chairman (Sir Henry Norman) announced that he had a further statement to make on the subject of the advertisement of Coleman's Wincarnis in the *BRITISH MEDICAL JOURNAL*. The Committee had received a letter from Mr. Rudderham, the general manager of Messrs. Coleman and Co., enclosing a copy of correspondence between Dr. Cox and himself on this matter. It did not appear necessary for the whole of the correspondence to be read; summarized, it was to the effect that Mr. Rudderham entirely repudiated the statement made by Dr. Cox that the advertisement of Wincarnis was refused by the *BRITISH MEDICAL JOURNAL*, and he declared that statement to be supported by the advertising agents of the firm. Mr. Rudderham suggested that possibly the British Medical Association might have considered the question of the advertisement of medicated wines after the advertisement by his firm had ceased, and he invited Dr. Cox to give him any documentary proof. On the other hand, Dr. Cox adhered strongly to his statement that on September 22nd, 1910, the Financial Secretary and Business Manager to the *JOURNAL* received an order for thirteen more insertions of the Wincarnis advertisements, and that this was not executed. There was, therefore, a complete contradiction of evidence between the parties and on neither side had any documentary evidence been placed before the Committee.

With reference to this matter, the Medical Secretary of the British Medical Association on May 5th addressed a letter to the Secretary of the Committee, in which, after recapitulating the Chairman's observation, he wrote as follows:

I have now the honour to send you the actual order, dated September 22nd, 1910, for further insertions of the Wincarnis advertisement in the *BRITISH MEDICAL JOURNAL*, on which document I based my case for challenging the accuracy of the statement made by Mr. Rudderham. I would ask you in due course to return this order.

I beg to state, in order that there may be no further doubt about the matter that the advertisement tendered was not inserted, that no correspondence took place on the matter, and that the advertising agents, on inquiring through the telephone why they had not received any communication respecting the advertisement, were informed by our Manager that we did not intend to insert it.

I note that according to the statement made by the Chairman of the Committee Mr. Rudderham has nothing to say in regard to the *Lancet*, and I would repeat that I have the authority of the Manager of that journal for saying that they definitely declined the advertisement of Wincarnis for reasons which I have previously stated, and that the Manager of the *Lancet* is willing to appear before the Committee if required.

It is obvious, therefore, that if the above statements are correct, and they are easily capable of being tested, Mr. Rudderham was not correct in stating that his advertisements were withdrawn from the medical press for commercial reasons.]

THE LIMITATIONS OF ANALYSIS.

Evidence was then given by Dr. Dobbie, who said he was head of the department organized by the Treasury about two years ago for the purpose of advising various Government departments on analytical questions and to do chemical work on their behalf.

In response to the Chairman's request, the witness first dealt with the limitations of analysis. He remarked that there was an important distinction between the terms "detection" and "determination," which were constantly used in connexion with chemical analysis. Detection of a substance meant proving its presence without regard for its quantity. Determination meant ascertaining the quantity. It might be quite possible to detect or identify a substance by chemical means in certain cases where there were no satisfactory chemical means of determining or evaluating it. For example, the presence of one or more of the constituents of digitalis in a medicine might be determined chemically, but there was no satisfactory chemical method of determining the proportion of the active ingredients in digitalis. In some cases the physiological test was employed; the drug was administered to animals. Thus, while the statement made to the Committee that only forty-four of the vegetable preparations

in the *British Pharmacopoeia* had definite chemical principles which could be determined might or might not be correct, it would not be correct to say that only forty-four could be recognized by such methods. Detection of a substance depended ultimately on obtaining it or some of its combinations or derivatives in a condition recognizable by some characteristic property—for example, form, colour, smell, taste, melting point, boiling point, solubility, miscibility, or alteration in colour or other characteristic, when brought in contact with chemical reagents. There was no essential difference in principle between the method of detecting a substance by ordinary analysis and those of the expert who judged chiefly by smell and taste. From some of the evidence it might appear that the one method of identification was essentially different from the other.

In reply to the Chairman, the witness said he did not disagree with the view that an expert who had spent years in the handling of drugs would have acquired a certain applied use of the senses in a special degree in detecting drugs.

Continuing, he said that the quantity of essential oil obtained in the ordinary analysis of medicine was often so small that it would be impracticable to determine its physical and chemical constants, such as specific gravity, boiling point, polarization, and so on; the odour alone had often to be relied upon. On the question of the trustworthiness of analysis when applied to medicinal preparations, when it was a question of a single drug, either as a solid or in solution, there would usually be no great difficulty in identifying the drug, provided that it was one of the official drugs or one the properties of which had been described in the ordinary chemical or pharmacological literature. In the large class of drugs included in inorganic substances, such as salts of bismuth, mercury, zinc, bromides, iodides, alkalis, acids, and so on, no difficulty would arise in analysis. The same could be said of substances of definite composition, either prepared synthetically or extracted from plants, such as acetanilide, salicylic and other acids and alkaloids; also plants or parts of plants, whole or powdered. Taking the whole range of medicinal substances, in regard to the great majority there would be no special difficulty in identifying the drug in question with certainty when the analyst was dealing with single articles, the properties of which had been adequately studied and described. When, however, the drug was a new one, or one not known to British pharmacists, or one which had no known characteristic, chemical or physical property, its definite recognition might be difficult or impossible. To that group belonged extracts from certain plants, obtained by maceration of the plant with alcohol or other solvent. The extract might only contain substances common to several plants and nothing characteristic of any one, and then it would be impossible to identify it positively by chemical means. Speaking generally, it was quite practicable for chemical analysis to deal with most of the mixtures of drugs prescribed in ordinary medicines, but when a number of drugs were mixed together the difficulty increased with the complexity of the mixture, and eventually the difficulties became so great that the complete analysis of the mixture was impossible. Even in such cases bodies of a distinct character might be separated from the mixture and identified, the organic from the inorganic, the volatile from the non-volatile, and so on. In many cases the constituents of a mixture could be detected directly and readily because they had characteristic properties. Broadly it might be said that the proportions of mineral drugs could be determined with no substantial error; organic bodies, however, presented a much wider range of variation, and, while some of them could be determined accurately, approximations only were possible in other instances. So far as a general opinion could be given, it would be safe to say that where the presence of an active organic drug in a mixture had been definitely ascertained, in the majority of cases the analyst by one means or another could obtain a fair idea of its proportions, although sometimes he must be content with a rough approximation only.

The Chairman: Speaking generally, the analysts who have appeared on behalf of proprietary medicines have told us that in very many cases it is practically impossible to detect or determine the composition of a medicine. On the other hand, the analyst who has appeared on behalf of

those who are criticizing proprietary medicines has told us that practically to all useful intents and purposes you can detect what is in a medicine. On which side do you range yourself?

The Witness: So far as I have read the evidence I do not think there is very much conflict between the analysts. I would say that some of the witnesses on one side would push the dividing line further than I should in one direction; on the other side the witnesses would push it further in the other direction. (Laughter.)

The Chairman: I am sorry you cannot range yourself a little more definitely on one side or the other.

The Witness: I am on the side of the chemists.

The Chairman: I am not sure we know which side they are on. (Laughter.)

Sir Philip Magnus: The dividing line to which you referred is a "movable fixture"?—Yes.

The Chairman: May we put it that, as a general rule, any drug with fairly active therapeutic effects can be detected?

The Witness: Not every drug, but most drugs.

Do you mean there may be a drug with fairly active therapeutic effects which cannot be determined by analysis?—If it is contained in a mixture, yes.

Then in that case, supposing a proprietary medicine owner says in his advertisements that his is a very valuable medicine, and no analyst can possibly tell what it is, that might be a correct statement in certain circumstances?—I think so. The witness added that the number of drugs which could not be identified was constantly diminishing as knowledge advanced.

Mr. Cawley: Is it correct to say that drugs which have a therapeutic effect have generally some known reactions which enable them to be discovered without much difficulty?—I think as a general statement that is correct.

THE ANALYSIS OF WOODWARD'S GRIPE WATER.

After the luncheon interval, Sir Philip Magnus, who was then in the chair, said he wished to ask the witness a question regarding the analysis of Woodward's gripe water. The Committee sent a sample of this preparation to the Government analyst, and when that analysis was read to Mr. Umney he said: "It is not more accurate than Mr. Harrison's; the particular ingredient (the ingredient stated by Mr. Umney to be present) has not been found, but certain ingredients not in it have been found, and I think practically it is a general confirmation of the statement that these things cannot be determined by analytical methods." Since then (proceeded Sir Philip Magnus) the Government analyst had again analysed the medicine, and he asked if the witness had anything to say on this.

The Witness: As regards the statement that certain ingredients that are not in the gripe water have been found, we see no reason whatever for modifying the terms of our report; we are not prepared to dispute the allegation that another extract is an ingredient of the article—if so its presence was masked by the capsicum.

DISCLOSURE OF FORMULAE: AN ANALOGY.

Dr. Dobbie went on to deal with the suggestion advanced by various witnesses that the formulæ of proprietary medicines should be registered with the Customs and Excise Department, with particulars of any poisons they contained. He thought it might be useful to the Committee to have some information as to the regulations adopted for the protection of the public in a case somewhat analogous to the sale of proprietary medicines. The Board of Agriculture, he explained, to secure that sheep dips should be efficient for the purpose, while at the same time securing that the various makers' formulæ should not be divulged to trade rivals, and that within certain limits freedom of competition and manufacture should prevail, made the stipulation that sheep must be dipped with a dip approved by the Board of Agriculture, and the dip must contain 1 per cent. or more of a disinfectant. Makers might include any other ingredients they wished, and the formulæ in fact varied considerably, but, in order to get a dip approved, the formula must be submitted to the Government chemist, an analysis being made to see that the manufactured product conformed to the formula. More than 1,300 samples had been examined in connexion

with the various formulæ submitted, but no complaint had been made that the makers' secrets leaked out, and the regulations had not destroyed competition in the production of dips. There was a somewhat similar procedure with regard to the strength of disinfectants used on board ship. He thought this procedure gave some hints as to a possible method of dealing with proprietary medicines; it showed it to be possible to have a disclosure that would protect the public and not injure the interest of the proprietor.

Mr. Bathurst suggested that it would be difficult to apply this procedure, because in the case of proprietary medicines more than one ingredient needed supervision. The witness thought that the method might be that before a proprietary medicine vendor could get a medicine stamp or licence he would have to disclose his formula to a public department and submit a sample for examination; if the medicine was found to contain the admitted remedy for the complaint which it purported to treat, then his view was that it would be accepted.

Mr. Bathurst: But who is going to decide whether the alleged remedy is a remedy?

Mr. Lawson: The British Medical Association, perhaps?

The witness replied that a public body would have to be given that function.

Mr. Glyn-Jones: If a man buys a dip, he has the Government guarantee that it is efficacious. Would the Government analyst like to be put in that position as regards the proprietary medicines?

The Witness: It would be a Government statement that the preparation did contain an admitted remedy for the complaint it claimed to cure.

You agree that it is much easier to act as a censor for a sheep dip than for a medicine?—Yes.

Mr. Lawson remarked that, although sheep dips were sold under a certificate by the Board of Agriculture, that sort of approval could not be applied to proprietary medicines. The witness thought that was for the Committee to say. In reply to a further question, he said that difficulties of analysis would be to a great extent overcome in this way; if the vendor were required to submit the formula, it would always be possible to check the composition, because the article could be made up in accordance with the list of ingredients, and it could be ascertained whether the article resulting agreed with the formula.

Mr. C. Simmonds, a first class analyst in the department of the Government chemist, then gave evidence. He put in, without reading, an elaborate statement as to the character of the drugs in the *Pharmacopœia* which might be determined by analysis. Mr. Glyn-Jones suggested that the fact that there were so many drugs outside the *Pharmacopœia* vitiated the figures given in the witness's statement of the drugs which could and could not be determined by analysis. The witness, however, thought that his list might be taken as fairly representative. Mr. Glyn-Jones further suggested that there were drugs for whose therapeutic action scientists could not account, and that therefore analysis would not have any bearing on their medicinal merit. The witness replied that this question was a medical one and was beyond his competence.

The Committee adjourned for a month for the Whitsuntide recess.

AN international conference for the biological and statistical study of alcoholism was recently held at Paris at which France, Great Britain, the United States, Austria, Italy, Russia, Switzerland, and Belgium were represented. The following list of questions was drawn up as an international programme of studies: (1) Does alcohol possess any alimentary property or not? (2) What is the relative influence of the forms and manner in which alcohol is consumed? (3) What is the alimentary value of the different alcoholic beverages? (4) What are the effects of pure alcohol and the extraneous substances produced by the distillation of fermented products? (5) What are the principal causes and effects of alcoholism? (6) What are the means employed against alcoholism, and with what results? (7) A critical investigation of the national statistics of the production and consumption of alcohol and alcoholic beverages; consideration of the effect of such production and consumption.

UNIVERSITY OF LONDON.

FINAL REPORT OF THE ROYAL COMMISSION.

[THIRD NOTICE.]*

THE ROYAL COLLEGES IN LONDON.

So far as we have been able to ascertain from a study of the report, the scheme propounded by the Commissioners contains no place for the Royal Colleges of Physicians and Surgeons in London. They would not be constituent parts of the University, and they would not be entitled to representation on the proposed Board of Medical Studies nor on the Medical Faculty should it be formed. Both of these bodies would consist wholly or mainly of direct representatives of schools actually engaged in teaching.

The Commissioners devote a section of their report to the consideration of proposals made to them by the Presidents of the Royal Colleges of Physicians and Surgeons in London and Mr. Hallett, the Secretary of the English Conjoint Board, for the purpose of establishing a single portal to the profession in England. The witnesses, it is stated, spoke in their private capacity, and not as representing the Royal Colleges.

The proposal was that all English students should enter the medical profession through the single portal of the final examination in medicine, surgery, and midwifery of the English Conjoint Board. A student who had passed the earlier examinations of a university and completed a five years' course would be admitted to the final examination, and, having passed it, would be entitled, upon payment of the fees required by the Royal Colleges, to the diplomas of L.R.C.P. and M.R.C.S. His university would require further study, and probably additional subjects, and might require additional examinations to entitle him to the medical degree of the university. A student who was not a member of a university but had passed a preliminary examination recognized by the Conjoint Board and a preliminary and intermediate science examination of that Board could obtain the diplomas of the Royal Colleges upon passing his final examination, but could not proceed to a university degree. It was proposed that the universities should either have three representatives on the Committee of Management of the Conjoint Examination, or should have assessors to be present during the examination of their own students, or should agree to accept, in lieu of their own examination in the final professional subjects, the examination of the Conjoint Board. The Board, on the other hand, as has been stated, would continue to admit to its final examination not only students who had taken the earlier part of their course in the University but also students who had passed the preliminary examination accepted by the Conjoint Board "which is of a lower standard than a matriculation at the universities," and had also taken the examinations held or accepted by the Conjoint Board in the preliminary and intermediate sciences. The Commissioners express the opinion that in view of the provision of Section 3 of the Medical Act, 1886, such a scheme would probably require the sanction of Parliament. The section of the Medical Act referred to defines a qualifying examination as follows:

A qualifying examination shall be an examination in medicine, surgery, and midwifery, held for the purpose of granting a diploma or diplomas conferring the right of registration under the Medical Acts by . . . (c) Any combination of any such university as aforesaid with any other such university or universities, or of any such university or universities with a medical corporation or corporations, the bodies forming such combinations being in the same part of the United Kingdom.

In view of subsection (c) the opinion that further authority from Parliament would be required is a little surprising.

The Commissioners state that the main argument in favour of the proposal was that the large number of medical students who reach the final examination for the degree of M.B. of the Universities of England have already passed the final examination of the Conjoint Board, and that it is a hardship that they should be compelled to pass two examinations in the same subject. The statistics given to the Commission were to the effect that about 87 per cent. of the university students who reached the

final examination of the university also took the final examination of the Conjoint Board. The percentage in the case of students of Oxford, Cambridge, and London universities was 82, while in the case of the northern universities it was not more than 40.

The Commissioners considered the question of the advisability of a single portal as the entrance to the medical profession to be beyond their reference, because they could not be in a position to form a considered opinion without ascertaining the views of all the universities and other licensing authorities whose consent and agreement would be required, and that to ascertain these views would have carried them beyond the scope of their inquiry.

On the other hand, they consider that it is within their reference to consider whether it may be desirable and feasible for the University of London to make an arrangement with the Royal Colleges with regard to the final examination. The Commissioners observe that if the University of London were to join in an arrangement between all the English universities and the Royal Colleges for the conduct of the final examination it might be possible for the Royal Colleges to require all candidates for their diplomas to take the courses and examinations of the University in the earlier part of their curriculum.

The Commissioners, however, hold that it is more important to raise the standard of entrance to the medical curriculum and to afford a more scientific foundation for the professional studies than to ensure a uniform standard of professional attainment for entrance to the profession, and believe that "the permanently open door of the Conjoint Board to a lower level of general education than the universities require, and an examination in the more purely scientific part of the medical curriculum which tends to hamper the teaching by the requirements of a prescribed syllabus is a greater disservice to medical education than any slight variation of standard in professional attainment which the final examinations of the universities may allow."

In their examination of the reasons given for the establishment of a single portal the Commissioners say: (1) That the contention that the number of licensing authorities has been largely increased by the creation of new universities would have more weight if there were any real danger of the standard being lowered, but they do not think it is suggested that the General Medical Council fails to perform its inspecting duties efficiently, and still less that the qualification granted by any university is at the minimum standard. (2) To the argument that the Government and municipal medical services are increasing the demand for official as compared with private medical practitioners, the Commissioners reply that what is specially required for a public medical service is the scientific training of a university education, rather than strict uniformity of professional attainment. (3) Another argument quoted is that the endowment of the medical departments of the universities and of independent medical schools by the State through the Board of Education entails a system of Government inspection, and that from inspection to control, dependent upon results of examinations, with a view to uniformity, is a short step. The Commissioners express their inability to understand this argument, and point out that the grants of the Board of Education to medical schools are university grants, and it is contrary to the declared policy of the Board to interfere with the educational freedom of the universities. If it were not so, the Commissioners state that they would be strongly opposed to such a method of subsidizing university education.

They declare themselves unconvinced by the contentions stated, and express the opinion that to make separate arrangements with the University of London would not improve the earlier Conjoint Board examination. On this point they say:

It would not be possible under a separate arrangement between the University of London and the Royal Colleges to insist on the Royal Colleges reciprocating by requiring a university standard of general education, and university courses and examinations for the earlier parts of the curriculum, because if such an arrangement were made with regard to London students, and did not apply to other candidates for the diplomas, all the purely Conjoint men would be driven out of the London medical schools—

* Previous notices were published on April 19th (p. 836) and April 26th (p. 835).

a result which the Royal Colleges would not face, and the University of London would not desire. Moreover, such an agreement might not be possible, as we were told that the northern universities had announced their intention of opposing any exclusive agreement between London University and the Royal Colleges.

In dismissing this subject the Commissioners state that, after careful consideration, they are not prepared to recommend the University of London to give up examining in the final subjects of medicine, surgery, and midwifery, and express their final views in the following sentences:

When great internal educational reforms are being proposed, it is hardly the time for the University to commit itself definitely to any system of examinations beyond its own control. We are satisfied by the evidence we have taken that the examinations of the Conjoint Board are admirably arranged and efficiently conducted. It is claimed as their chief merit that the examiners appointed are teachers, and teachers at their best; that they are chosen from all the London Medical Schools under conditions which ensure that they are men in the middle period of their career, whose powers are at their highest. This is as it should be, but we cannot tell what the state of things would be if any far-reaching change of the organization of clinical teaching, such as we have proposed, should be introduced; and in these circumstances we cannot recommend that the University should agree, perhaps irrevocably, to the examination of its students by examiners appointed by an external authority.

So far as we can gather, the idea of the Commissioners is that the Royal Colleges should continue as at present. If, therefore, the teaching university conceived by the Commissioners comes into existence, the position of the Royal Colleges in London will be very similar to that of the Royal Colleges in Edinburgh. We have already quoted (*BRITISH MEDICAL JOURNAL*, April 19th, p. 838) from their report the most important passages in which the Commissioners deal with the grievance of London medical students that they are debarred by circumstances from obtaining a university degree in medicine. The Commission recognizes that so far as entrance to the University is concerned the average London student has been under a real disadvantage in the past, partly because the present matriculation examination is not connected with a well-developed system of secondary education, and partly because the Conjoint Board and the General Medical Council accept standards of admission to the medical curriculum which the University will not accept, so that students do not realize until too late that they are excluded from the beginning of their course from taking a university degree. The Commissioners regret that so large a proportion of medical students in London do not graduate from its university, but state that the difficulty resolves itself into one of defective early school education, and that the true solution is to institute a proper system of school examinations.

THE ADMISSION OF STUDENTS TO THE UNIVERSITY.

We may now, in concluding these articles, give a short account of the scheme of the Commissioners for the admission of undergraduates to the University.

The Commissioners recommend that the normal qualification for admission to the University should be a school examination based upon the curriculum of the school, conducted in the interests of the school itself, and closely related to its curriculum.

The Commissioners consider that the study of the preliminary sciences should not be included in the medical curriculum, and an undergraduate should not be admitted to the Faculty of Medicine in the University until he had received thorough instruction in the principles of pure science, and that whenever possible the best time and place for this instruction is the last two years of a good secondary school course. A certificate of having passed such an examination, which should not be taken until the pupil has reached the age of about 18, should be the normal qualification for registration as an undergraduate. The Commissioners recommend that the first step the University should take should be to cease to admit pupils in schools to its own examinations, and that no student should be registered as matriculated until he has attained the age of 17. A boy intending to become a medical student who had passed the lower school examination at the age of 16 would remain at

school and continue the course of his general education, but during the last year and a half or two years would work at special subjects, physics, chemistry, and, "if possible," biology, for the higher school examination to be taken at 18.

The Commissioners do not recommend the continuation of the system under which the Conjoint Board in England and the General Medical Council have recognized secondary schools for the teaching of preliminary sciences; they consider that the responsibility of deciding what schools are efficient in this respect should lie with the Board of Education, which in estimating whether the teaching in any school reached the standard and character required would be guided by the opinion of the universities as to the standard of knowledge requisite. The Commissioners add the following very important qualifications of this opinion:

We do not know how soon the number of schools may become sufficient to give the necessary instruction to the majority of those seeking to enter the medical profession, but we are convinced that the aim should be to increase their number sufficiently for the purpose. Meantime the teaching of those candidates who have been unable to obtain the necessary instruction at school should be provided for either in the science laboratories of the University itself or in institutions recognized for the purpose by the University. There is another class of student who may desire to study medicine, and who has not reached the necessary standard in the Preliminary Science subjects at school because the course of his secondary education has followed other lines. This class of student will continue to exist after the provision of secondary schools is complete; but it will not be a large class, and for these it ought not to be difficult for the University to continue to make the necessary arrangements. But these arrangements will, as we have pointed out in paragraph 92, be incidental. We think, however, that neither class of student should be admitted to the regular undergraduate teaching and examinations of the Faculty of Science, but that they should be dealt with in special classes and examined at the close of the course by a general examination of the kind described below (see paragraphs 384, 385) as suitable for students in schools of the University.

With regard to biology, a further qualification is found necessary, inasmuch as the subject differs from physics and chemistry in more than one respect. Upon this point the Commissioners say:

In the first place, the number of schools teaching biology is far smaller than that of the schools teaching physics and chemistry, and is likely to remain so. Its teaching is much more expensive. A separate laboratory is required, specially arranged and exclusively reserved for this science: more trouble is involved in providing the necessary materials, and the number of pupils who wish to take the subject is small. Secondly, the study of this subject cannot be carried beyond the most elementary stages by the methods of instruction which hitherto have generally been employed in schools. Even in the case of physics and chemistry, some change in the method of instruction may be desirable, and is, in fact, being introduced. But biology must be approached with a certain independence of mind, and the better opinion is that it is more profitably studied under conditions of freedom and intellectual responsibility which are not commonly reached till the stage of pupilage is past. Nevertheless, we think that these conditions are present in the upper forms of the great public schools, and in some other schools in which special provision is made for the study of biology; and whenever this is the case it is a gain that this subject should be included in the school curriculum of boys who stay at school till the age of at least 18.

The prospective medical student would, therefore, have to pass two examinations at school. A lower school examination, planned for pupils of about the age of 16, which should be a test of general education; and a higher school examination, planned for pupils of about the age of 18, which should be suitable as a test for pupils whose course had to some extent been specialized. A student admitted on the higher school examination would, if the appropriate subjects had been taken, be excused from the Preliminary Science examination, and would be admitted direct to the Faculty of Medicine, his course in the university being shortened to four and a half years.

A student admitted on the lower school examination, and a student admitted on the higher school examination,

in which the science subjects had not been taken, would be required to pass a Preliminary Science examination before admission to the Faculty of Medicine.

The Matriculation examination (to which pupils in schools would not be admitted) would be retained for those students who did not approach the university through the normal avenue of the secondary school. Students of mature age desiring admission to a constituent college or university department would be submitted to a special test approved by the Senate and conducted by the Faculty he desired to enter.

Nova et Vetera.

THE LEGEND OF THE ENGLISH TAIL.

IN THE BRITISH MEDICAL JOURNAL of October 17th, 1908, we discussed the meaning and origin of the epithet *Caudatus* (tailed), which was applied to Englishmen as an opprobrious nickname all through the Middle Ages. It was concluded that the clue to the meaning was to be found in a tradition that the fishermen of the English coast received St. Augustine and his fellow missionaries with insults, in particular fastening fish tails to their garments. For this a curse was laid upon them by the saint that their descendants should be born with tails. On the Continent this legend grew into a popular belief, especially among the French, who avenged their many defeats by their hereditary foes by calling them *cotés* (tailed). With the notion of an actual physical deformity was mingled the idea of want of courage, the French *coward* and the Italian *codardo*, from which the word "coward" is derived, being connected with *cauda* or *coda*, the tail. In heraldry a lion *coward* has his tail between his legs. M. Louis A. Barbé has recently discussed what he calls The Story of the "Long-Tail" Myth, in a chapter of his interesting book entitled *In Byways of Scottish History* (Blackie and Son, Ltd., 1912). He produces an abundance of evidence from mediæval literature showing that the belief that Englishmen had tails was accepted in a literal sense. A typical example occurs in a mediæval poem communicated by Professor Wattenbach to the *Anzeiger für Kunde der Deutschen Vorzeit* (1874). There the Englishman is described in the following unflattering verse:

Anglicus a tergo caudam gerit : est pecus ergo ;
Cum tibi dicit " Ave," sicut ab hoste cave.

M. Barbé traces the legend through chronicles and popular literature from the twelfth to the seventeenth century. Only two or three instances need be cited. When Richard Cœur de Lion was betrayed and brought as a prisoner before the King of Alençon he represented himself and his companions as pilgrims, but the king replied with a jeering allusion to their tails. A poem, dated about 1430, celebrating the exploits of Joan of Arc, opened with the words *Arrière, Englois coués, arrière!* When, in 1436, the English evacuated Paris, which they had held for sixteen years, the inhabitants shouted after them in derision, "Tails, tails!" In the sixteenth century the English king is described as wearing a tail. By the seventeenth century the tradition had almost died out, and when allusion to the *quoucz* English was made in a French poem, a footnote was appended to the passage explaining that the epithet was justified by the fact that in most Englishmen the end of the os sacrum, called "coccyx," actually protrudes and forms a tail!

Even at the present day, says M. Barbé, the old cry has not died out. In Guernsey, where it was once so frequently heard, the country children have a custom of throwing at passers-by a hairy, clinging weed which grows abundantly by the wayside. If any of this sticks to the victim's clothes, he is assailed with cries of "La Coué!"

The legend of the tail seems to have long persisted in Cornwall. Mr. Baring Gould, in his *Myths of the Middle Ages*, says that, as a child, he firmly believed, on the authority of his nurse, that all Cornishmen were born with tails.

It was natural that the Scots should adopt the taunt which they had learnt from their Continental allies.

Many examples of allusions to the supposed tails of Englishmen, taken from Scottish literature ranging from the thirteenth to the sixteenth century, are given by the author. The festivities accompanying the christening of the infant son of Mary Queen of Scots on December 17th, 1566, included a masque written by George Buchanan, in which figured satyrs wearing tails. As the mummers passed the English guests they put their hands to their tails and wagged them, thus nearly causing a brawl.

The earliest account of the origin of the legend is given by Goscelin, a monk of Canterbury, who wrote a life of St. Augustine, based on older records and embodying local tradition as it existed before the Norman Conquest. Two versions of the life of Augustine are given. Both agree that the outrage on the saint and his companions occurred in Dorsetshire. The episode reappears about the middle of the twelfth century in the *Gesta Pontificum* of William of Malmesbury, who names as the scene of the event Cerne, a village where a ruined abbey now exists, about seven miles north of Dorchester, while Robert Wace, the Anglo-Norman poet, in his *Brut* says it happened in Dorchester itself, which is five or six miles from the sea; otherwise the legend is substantially the same. Layamon, who translated, or rather paraphrased, Wace's poems in old English, states that foreigners by that time attributed to all Englishmen indiscriminately the tails with which only the actual offenders and their posterity were afflicted. He says the tails were called "Muggles" and the men who wore them "Mugglins." The scene of the insult to St. Augustine was in course of time transferred to Strood near Rochester, where, it was alleged, "tayles of thorn-back or like fishes" were attached to St. Augustine and his brethren. It may here be stated that Æneas Sylvius, afterwards Pope Pius II (1405-64), who was in England in 1435, on his way to fulfil a secret mission in Scotland, mentions Strood, "whereof the natives are reputed to be born with tails."

It would seem that two legends became confused, the original story about St. Augustine being replaced or supplemented by a tradition that the docking of the tail of St. Thomas à Becket's horse by the people of Rochester was punished in the same way as the insult to the older saint. From the middle of the sixteenth century the legend begins to die out. Writers mention it only to scoff at its absurdity. In the seventeenth century, however, a trace of it is found in the attribution of tails to the men of Kent. Andrew Marvel, in his *Loyal Scot*, says:

For Becket's sake Kent always shall have tails.

In his *Worthies of England*, Fuller, discussing the origin of the nickname, states that the saying is "first of outlandish extraction and cast by Forrainers as a note of disgrace on all the English, though it chanceth to stick only on the Kentish men at this day." He thinks the nickname arose from the fact that the county of Kent lies nearest to France, and the French were the originators of the calumny. Barbé concludes that the actual possession of tails by Englishmen was accepted as a fact from the outset. His explanation is that the insult offered to St. Augustine, about which there is no ground for scepticism, was believed to be worthy of punishment in the same way as the disrespect of the children who called the Prophet "bald head" was visited upon them. The conviction that this ought to be the case easily led to the assumption that it actually was. The nature of the punishment was suggested by the offence. The legend found ready acceptance in a credulous age, and with the various connotations of "tail"—"beast," "coward," and so forth—supplied a term of insult of which "our fair enemy France" and her ally Scotland were glad to avail themselves.

The belief was, however, by no means confined to these countries. Fazio degli Uberti, an Italian poet of the fourteenth century, refers to England as an island where people are born with short tails, such as are seen in stags and other beasts. Boccaccio also mentions that certain Englishmen are born with tails. The legend is a striking example of credulity accepting as true a statement the falsity of which could so easily have been ascertained. But it must be remembered that even at the present day there are among us many people who seriously believe that a man

has one rib less than a woman because a rib was taken from Adam to form Eve. Perhaps the tail legend should be taken as an unintended compliment implying that English warriors did not show their backs to their enemies. All nations, even at the present day, are too ready to believe the most absurd things about foreigners. The ease and rapidity of communication nowadays has led to the decay of such superstitions as that Frenchmen feed on nothing but frogs and Germans on sauerkraut. But there still remains the general idea that a foreigner is somehow differently constituted from ourselves. This makes the ridiculous legend that Englishmen bore about them the mark of a beast in the shape of a tail all the more amusing.

LITERARY NOTES.

La Revue Mensuelle de physiothérapie pratique is the name of a new periodical devoted, as its title imports, to physical methods of treatment. The journal is intended for practitioners, and it therefore deals with essentially practical subjects. The editorial secretary is Dr. Dahain, of Lille.

In an article which appeared in the BRITISH MEDICAL JOURNAL of May 3rd (p. 959) we referred to "Tom Sawyer, late Nockemorf." We have to entreat forgiveness for a momentary aberration which led us to give the immortal "Bob" the Christian name of Mark Twain's delightful creation. At the same time we apologize for having inserted a superfluous apostrophe in the name of Sawyer's predecessor in the Bristol practice, "Nockemorf," especially as the superior literary person now *naso suspendit aduoco* the author of *Pickwick*. But we are sure that many of our readers are lovers of Dickens, and to them the mistake in Bob Sawyer's name must have come as a painful shock.

Messrs. Jack announce *The Battlefields of Scotland*, by T. C. F. Brochie, F.S.A.Scot. During the summer of 1912 Mr. Brochie, in the course of a tour over all the Scottish battlefields, from Culloden in the north to Flodden in the south, made a number of crayon drawings. These drawings, which are included in the present work, form a valuable record of this phase of Scottish history. The book also contains a map showing the sites of the various battles.

A volume entitled *Matriculation Albums of the University of Glasgow, 1728 to 1858*, has just been issued by Messrs. MacLehose. It was compiled by the late Mr. James Addison, Registrar of the University. For a long time matriculation was compulsory only on "gown" students whose intention it was to proceed to a degree, and those who wished to have a vote on the election of the Lord Rector. Till 1843 the lists cannot be taken as complete. Mr. Addison tried to trace the after-career of the students whose names were entered on the matriculation roll, and in this laborious task he met with a "gratifying measure of success."

Visitors to an exhibition held some years ago at Earl's Court will doubtless remember a room containing a quantity of Nelson relics, amongst which was the first letter written by the hero of Trafalgar after the loss of his right arm. Nelson was not naturally ambidextrous as this irregular straggling writing testified; but that he quickly gained a certain amount of facility in writing with the left hand is proved by the signature reproduced in the April number of *The Child*, to which Dr. H. Macnaughton-Jones has contributed an interesting article on ambidexterity. According to Dr. Macnaughton-Jones the modern system of teaching children to write and draw with either hand is by no means a new one. Apart from the warlike Scythians, who are said to have been ambidextrous from birth, there is reason to believe that the ancient Egyptians were trained to use both hands, whilst ambidexterity has been a common trait amongst the Japanese of both sexes ever since Japan has had a history. In Persia at the present day a large proportion of workmen are ambidextrous, whilst the signing of letters and documents is usually done with the left hand. In Europe the teaching of ambidexterity has only in recent years found its way into the schools. It is interesting to find, however, that several famous artists, including Leonardo, Holbein, and, in our own day, Landseer, used the left hand freely when painting. Landseer, indeed, has even been known

to draw different objects with either hand at one and the same time. Dr. Macnaughton Jones strongly advocates the training of children in the use of the left hand from their earliest infancy, regarding it not merely as a useful accomplishment, but as an excellent mental and moral discipline. The same number of *The Child* contains a short article on the hygiene of the ear by Mr. C. A. Adair-Dighton, and an interesting description by Mr. G. C. Brown of the College for the Higher Education of the Blind at Worcester, the only public school for blind boys in the kingdom.

In the *Chronique Médicale* of May 1st we find the following story which shows how unalarming was treated in the Reign of Terror. The painter David had a particular affection for his pupil Gérard. Wishing to give the young man a proof of his sympathy and esteem, the famous Republican painter caused him to be chosen a member of the jury appointed to try Queen Marie Antoinette. Gérard was by no means anxious for the "honour" thus thrust upon him, but timidity and the fear of offending his master prevented his declining the nomination. Seeing no other way of getting himself exempted from service, he pretended to be lame, and, shutting himself up in his studio, practised walking on crutches. David came several times to stimulate the zeal of his pupil, which was too lukewarm to please the *atrox animus* of the revolutionary. Gérard pleaded the pain in his leg as an excuse. This state of things lasted several days, when one of the most noted leaders of the Revolution came to see Gérard, whose talent he greatly admired. The young painter escorted his visitor to the bottom of the stairs, pretending to walk with great difficulty. When he was alone, however, he put his crutches over his shoulder and quickly ran up the stairs, on a landing of which he was met by Madame Fourcroy—probably the wife of the famous chemist. He hastily attempted again to play the cripple, but the lady said, "Do not be alarmed, sir. I have guessed the motives of your action, and respect them too much not to keep silent." David, too, had suspected the truth. The next day he called on Gérard, when the following significant conversation took place: "You don't wish to be on the jury?" "No, I can't. They would be obliged to cut off my leg if I did so." "Ah, really! Well, something else will be cut off." "What is that?" "There is a rumour about that you are an aristocrat, and if you don't come you will be guillotined." These words wrought a miraculous cure. Gérard threw away his crutches, and took his place in the jury-box.

In his delightful book, *A Wanderer in Florence* (Methuen and Co., 1912), Mr. E. V. Lucas refers to a curious piece of medical folklore which still survives at Florence. When Pazzo de' Pazzi, a founder of the family, was in the Holy Land during the First Crusade, it was his proud lot to set the Christian banner on the walls of Jerusalem. As a reward Godfrey de' Bonillon gave him some flints from the Holy Sepulchre. These he brought back to Florence, and they are now preserved at SS. Apostoli, the little church in the Piazza del Limbo, off the Borgo SS. Apostoli, and every year the flints are used to kindle the ritual fire for Easter Day. Gradually the ceremony was expanded until it became a great spectacle, which was for centuries under the direction of the Pazzi family. A car containing explosives, after being drawn in procession through the streets by white oxen, is ignited by the sacred fire borne to it by a mechanical dove liberated at the high altar of the Duomo. With its explosion Easter begins. "This," says Mr. Lucas, "is a great moment not only for the spectator but for all Florence, for in myriad rooms mothers have been waiting, with their babies on their knees, for the first clang of the bells, because if a child's eyes are washed then it is unlikely ever to have weak sight, while if a baby takes its first steps to this accompaniment its legs will not be bowed."

The fame acquired by the Italian shrine of Loreto led to the opening of what may be called branch establishments in other countries. Of such shrines Scotland, we learn from Mr. Louis A. Barbé's *Byways of Scottish History*, possessed at least two. One was in Perth, the other, of greater reputation, was beyond the eastern gate of Musselburgh on the margin of the links. This was founded in 1533 by one Thomas Douchie, or Duthy, who had long been a captive in the hands of the Turks. There is a charter of James V, dated July 29th, 1534,

confirming the grant by the bailies of a "petra" of land in the territory of Musselburgh to Thomas Duthy of the order of St. Paul, first hermit of Mount Sinai, for the erection of a chapel in honour of Almighty God and of Blessed Mary of "Laureto." The king also gave a quantity of vestments and altar linen for the use of the chapel, and himself went thither as a pilgrim when he made further gifts at the shrine. The foundation throve under this royal favour, and Sir David Lyndsay testifies to the crowd which went

Under the forme of feinzzeit sanctitude,
For till adore ane image in Laureit.

Against the hermit himself he brought the charge that:

He pat the common peple in beleve
That blynd gat seycht and crukkit gat their feit,
The quihilk that patyard no way can approve.

The popularity of the shrine was increased by the claim put forward that, in addition to its general healing powers, it possessed a special obstetrical virtue. The success of Duthy's venture naturally excited jealousy. In his *History of the Scottish Kirk*, Calderwood relates how one John Scott, "a landed man," having failed to get himself accepted as a partner in the enterprise, set up in competition. He erected an altar in a chamber near Edinburgh, whereon he set his daughter, a young maid, and wax candles about her burning, to be worshipped in place of the Virgin Mary. This did not prove successful. Scott seems to have been an early hunger-striker, though, it would seem, not to escape punishment but to demonstrate that he was a special object of heavenly protection. Calderwood says:

Before his departure out of this country he had succumbed in an action of law, and because he was not able to pay the sum which the other party had evicted he took sanctuary at Holyrood House. There he abstained from meat and drink certain days. The bruit of his abstinence coming to the King's ears, the King caused put him into David's tower in the Castle of Edinburgh and bread and water to be set beside him. He abstained from eating and drinking thirty-two days. When he was let forth the people came flocking to him. He uttered many idle speeches, and among the rest that by the help of the Blessed Virgin he could fast suppose never so long time. He went to Rome, where he was committed to prison by Pope Clement till trial was taken of his abstinence.

After he had given a similar exhibition at Venice he got 50 ducats to pay his expenses to Jerusalem. Passing through London on his return, he was imprisoned for a harangue against Henry VIII, "but was set at liberty after he had been kept fifty days, all which space he abstained from meat and drink."

SCIENCE NOTES.

At a recent meeting of the Royal Society, Professor J. H. Priestley and Mr. R. C. Knight communicated the results of some curious observations on the nature of the toxic action of the electric discharge upon the *Bacillus coli communis*. They found that the electric discharge in air was fatal to bacteria, and that the effect is due to the products of the interaction of the constituents of the air—namely, nitric and nitrous acid and ozone. Discharge in air-free hydrogen had no deleterious effect on the organisms, but the presence of small quantities of air allowed the formation of a toxic substance, probably hydrogen peroxide, which exerted a bactericidal action. It therefore followed that electric discharges in which the current density did not exceed 10^{-5} ampères per square centimetre did not exert any directly toxic action upon micro-organisms, a result contrary to statements made by some previous investigators.

Schryver and Singer have shown that in cases of simple ulcer on the lesser curvature of the stomach the analysis of the stomach contents after a test meal is often almost identical with that given in the case of gastric carcinoma; but when the lesion is situated in the pylorus, be it simple or cancerous, either a normal analysis or hyperacidity is obtained. In duodenal ulcer there is almost always hyperacidity. In cancer of the body of the stomach it is usual to find a condition which may be described as achylia, and this is indicated not only by the absence of hydrochloric acid, but also by the very low amount or practical absence of pepsin and the

small amount of total chlorides. In healthy gastric juice they find that about 2.4 is the "nitrogen factor"—that is, the ratio of difference to titration to methyl orange and phenolphthalein divided by the amount of nitrogen—and any increase of this factor above 2.8 is diagnostic of delayed emptying of the stomach.

Dr. Wheeler has carried out at the Home Office Experimental Station at Eskmeals a series of experiments¹ called for by two dust explosions—one at a provender mill in Glasgow and the other in an oil-cake factory in Liverpool—each attended by serious loss of life. In these experiments several kinds of dust were dealt with so that the degree of their inflammability should be determined as well as their capacity to transmit explosions. Dust was taken at random from the beams and crevices in factories. In all sixty-six samples were taken. Attention was in the first place directed to the separation of harmful and harmless dusts and to the temperatures at which the dangerous dusts readily took fire. Some dusts readily ignite and propagate flame, the source of the heat for ignition being small, such, for example, as that from a lighted match; other dusts become readily ignited, but for the propagation of flame there is required a source of heat of large size and high temperature (an electric arc) or of long duration (the flame of a Bunsen burner); and there are also dusts which are incapable of propagating flame under any conditions likely to obtain in a factory. Sugar, starch, and the ground grain of many cereals come under the first class of dusts; oil products, sawdust, and leather under the second. Sugar, dextrine, starch, and cocoa are the most dangerous, sugar exceptionally so. It ignites when projected as a cloud against a surface heated to below red heat, and when ignition takes place the flame travels with great rapidity through the dust cloud. The temperature at which ignition of the different kinds of dusts takes place varies. Dr. Wheeler reduced the various kinds of dust as far as possible to the same degree of fineness by passing them through a 200-mesh sieve. For the sake of comparison the temperature of bituminous coal dust was determined and found to lie between 1000 C. and 1100° C. Some dusts of a fluffy nature could not be passed through a sieve. The ignition-temperature of briquette dust was found to be 1090° C., chicory 1070°, flour 1060°, starch 1035°, tea 1010°, oil cake 945°, and dextrine 940° C. The inflammability of combustible substances is regulated by the rapidity with which oxidation can be effected so as to produce flame. It is therefore a question of the affinity of the combustible material for oxygen. Physical conditions, too, are not without influence, a circumstance which explains the greater inflammability of coal dust than coal in the lump. The finer the dust the greater is its inflammability. From such dusts as those alluded to inflammable gases are evolved which form with atmospheric air inflammable mixtures. Should such a mixture of gas and air become ignited, sufficient heat would be provided to cause inflammation of an adjoining layer of air and dust, and thus initiate an explosion. In a series of tables Dr. Wheeler gives the lowest temperatures at which ignition can be effected. The report is an interesting and valuable contribution to an important subject.

¹Report on the Inflammability and Capacity for Transmitting Explosions of Carbonaceous Dusts, etc. By R. V. Wheeler, D.Sc. 1913. Price 13d. (Cd. 6562.)

DR. HEARSEY, P.M.O. of the Nyasaland Protectorate, in his *Sleeping Sickness Diary*, Part XIX, states that during the preceding quarter 15 additional cases of human trypanosomiasis were reported; of this number 12 were found by Dr. Shircore and 2 by Dr. Conran in the sleeping sickness area; the remaining case was notified by Dr. Morgan from the Marimba district; these added to the cases previously reported made a total of 108. Dr. Hearsey points out that so far some 10 cases of trypanosomiasis have been discovered in or found to be derived from the districts lying to the north and south of the proclaimed area. This indicates that the factors necessary for acquiring infection are not limited to the Dowa subdistrict. Much difficulty has been experienced by medical officers owing to the natives refusing to present themselves for examination and also hiding their sick. This, however, had been to a great extent overcome in the proclaimed area of the Dowa subdistrict by the employment of special police.

British Medical Journal.

SATURDAY, MAY 10th, 1913.

THE SITUATION IN SOUTH WALES.

THE acuteness of the situation in South Wales, where the relations of the medical profession to the Insurance Commissioners and certain organized bodies of workmen are strained almost to breaking point, affords good reason for dealing at some greater length with the position than was possible last week. If there was a part of the kingdom in which it might have been prophesied that the National Insurance Act might work with the minimum of friction the industrial areas of South Wales would probably have been selected. Medical practitioners there had for generations been accustomed to work on a contract system, and, indeed, in some districts practically no other kind of practice was known. The special needs of the poundage contract systems seemed to be met by that otherwise objectionable subsection of Section 15 of the Act known best as the Harmsworth amendment. Wales is believed to be strongly Radical in its political tendencies, and it might naturally be supposed that every effort would be strained by the administrators of the Act, paid and honorary, to make it a popular success in the home of its author. The Act has more than once falsified expectations, but never more than in this case. While it may be said that over Great Britain generally it is working with less friction than might have been anticipated we find that in the mining and industrial areas of South Wales apparently nobody is pleased. The public, the Commissioners, the Committees, and the doctors are all dissatisfied.

As regards the poundage systems, which have in many areas supplied medical attendance for workmen and their families to the general satisfaction of all concerned, an unexpected obstacle arose when the Welsh Commissioners declined to approve their continued existence under Subsection 15 (4) as institutions existing at the time of passing of the Act, unless a committee were set up whose duty it would be to receive the money of the workmen, pay the doctors, submit audited accounts, and perform other functions which would doubtless in time extend to the complete control of the doctors unfortunate enough to be in their employment. It did not matter that the schemes had worked perfectly well for years in most cases without any such committee; that the deductions had been made at the office of the mine or works and paid direct to the doctor; that unless the new committee was to prove superior to the temptation of making deductions for various purposes from the workmen's contributions the only items on the balance sheet would be, on the one side—collected so much; on the other—paid to the doctor the same amount. The vested interests of the doctors who had been making their livelihood through these schemes were apparently also deemed to be of no consequence, though we know that it was the vested interests of the friendly society medical aid associations which led to the insertion of the Harmsworth amendment in the

Insurance Bill. In spite of the protests of the doctors, and also of the workmen in some of the areas where they are quite content with the old arrangement, the Commissioners have insisted on the institution of committees of workmen. The medical men in these areas, to their great credit, have for the most part flatly declined to have anything to do with such committees. They have proved them to be unnecessary, and they know from sad experience what it means to members of the profession to put themselves under their yoke.

But there were areas where such schemes were not in operation at the time of the passing of the Act, and where, in consequence, it appeared they could not now be set up. The ingenuity of some of the Welsh Insurance Committees, encouraged it appears by the Welsh Commissioners, has proved equal to the emergency. Why not try Subsection 15 (3) of the Act, which allows persons, with the permission of Insurance Committees, to make their own arrangements? It is true that Dr. Addison, the author of this subsection, never dreamed of its being used to set up what amounts to a new creation of "Harmsworth institutions," nor was it suggested to Parliament when the matter was being debated that the subsection was intended for this purpose. But such small obstacles as these could not be allowed to stand in the way of large bodies of workmen who saw the chance not only of getting their dependants attended cheaply by the aid of the money allowed for attendance on insured persons, but saw in it an opportunity for getting the local profession under lay control in a manner much more effective than anything possible under the panel system. Accordingly a considerable number of "schemes" have been floated in Monmouthshire and Glamorganshire in which it is proposed to offer an inclusive sum to the doctor for attendance on a number of insured persons and their dependants, the funds being obtained by pooling the 6s. 6d. of the insured person, plus small extra contributions on behalf of the dependants. Several of these schemes have already been approved by Insurance Committees.

A very interesting feature about these schemes is that, unless they are entirely *ultra vires*—an opinion which we strongly hold—they only need the approval of the Insurance Committee, and do not require that of the Commissioners. That is to say, that a scheme which, had it been in operation at the time of passing of the Act, would, if it sought approval under Section 15 (4), have been restricted in the most careful way by the Regulations of the Commissioners, is under Subsection (3) to be allowed to be established without any of these safeguards. Take an instance which is quite within the bounds of probability. A scheme is set up consisting of 1,500 insured persons with their dependants, and pays its doctor £700 a year. If we assume that the dependants average two to each insured person the doctor of the scheme will be required to attend 4,500 persons. The committee working the scheme would receive from the Insurance Committee 6s. 6d. for each insured person—that is, £487 10s.; therefore, the 3,000 dependants would only need to find £212 10s., or 18. 5d. a head per annum. Now, it is obvious that the person who gets his or her attendance for 18. 5d. per annum is getting it at a rate which is ludicrous. The inevitable result of a system under which insurance funds were used to subsidize a system of this kind would be to depress the standard of medical attendance on the whole 4,500. We have no hesitation in saying that any Insurance Committee which permits its money to be used in

this way is guilty of aiding and abetting the defeat of the ends aimed at by Parliament in granting the rate of 6s. 6d. a head for insured persons. We go further and say that, in spite of the fact that Subsection 15 (3) leaves the right of allowing persons to make their own arrangements in the hands of the Insurance Committees, and apparently does not contemplate any supervision on the part of the Commissioners, any body of Government officials which acquiesces in the institution of such schemes is guilty of a dereliction of duty to the State and to the insured persons for whose medical treatment they are responsible.

It is instructive to note the difference between the action of Insurance Committees in Wales in connexion with this subsection and that of the Committees in England and Scotland. It has only been with the greatest difficulty in most insurance areas in England and Scotland that even thoroughly deserving cases have been allowed to "make their own arrangements." In Wales the Committees are apparently willing to allow it on a wholesale scale and the Commissioners look on with complacency. The whole situation appears to us to be a grave public scandal. In protesting against it the profession in Wales will receive the sympathy and the whole-hearted support of the Association. In resisting the imposition of lay control in its most repugnant form they are doing a service to the profession and to the public. We would say again that the case is eminently one for the exercise of the powers of co-ordination in regard to medical benefit which are possessed by the Joint Commissions. If there is ever to be a case for their intervention, this is one. We understand, indeed, that the points at issue have been brought prominently before Ministers and the Joint Commission, and are receiving their serious attention, so that it is not likely that a decision will be arrived at without a full consideration of all sides of the case. Parliament rose for the Whitsuntide recess last Thursday, and it is not anticipated that an announcement will be made on the subject for two or three weeks.

THE CONDUCT OF LABOUR WITHOUT INTERNAL EXAMINATIONS.

CAN confinement cases be conducted safely and efficiently without vaginal examinations? If they can be so conducted, then internal examinations should be abandoned, for it is easy to show that they introduce an element of risk into labours which apart from them would be free from danger. The risks are nowadays well known. There is, first, the introduction of infection from without, and even the expert obstetrician occasionally, with all his aseptic precautions, may carry into the vagina, on his fingers, gloves, or instruments, microbes of diseases with which he has been in touch. How much more the midwife or the inexpert or incautious! There are also microbes in the vagina or near to it which, whilst they are confined to that canal and its surroundings, seem to be less virulent than usual, but become dangerous when they are carried up by examinations to its upper part and into the neighbourhood of cervical cracks or erosions. They constitute a second risk, that of infection from within; and this risk is intensified by vaginal examinations. Professor Charles M. Green, of Harvard University, who has been writing on this subject,¹ states another objection to internal examinations in midwifery—

namely, that they are distasteful and even painful to the parturient woman, especially when she is a supersensitive primipara.

Now the real question to be settled at the present time is this: Granting that internal examinations in labour, even when practised by obstetric experts, introduce an extra risk into the management of confinements, is there any way in which the diagnostic and prognostic purposes for which they are made can be obtained otherwise? Professor Green and a good many other teachers think that the external examination, which is free from risks, may be safely regarded as a sufficient substitute; and it is true that if it be carried out as these obstetricians advise, and with the *tactus eruditus* which they possess, it must be ranked high both in diagnosis and prognosis. But it is not everyone who can by noticing the movements of the unborn infant "map out the fetus by sight," detect by palpation "the presence of a complicating neoplasm and locate the placenta," or gauge the normal amount of liquor amnii after the rupture of the membranes. Further, we fear the practice of the "Pawlik grip" would upset a supersensitive primipara as much as, if not more than, a vaginal examination. These, however, are objections which it is safe to say may be largely overcome by proper teaching and by persistent practice, but there are others which are not so easily disposed of.

How, for instance, is progress in the dilatation of the cervix to be measured if not by internal examination? How are pelvic contractions, still more vaginal septums and bands, the presence of a dermoid cyst in the pelvic cavity, and such anomalies as prolapse of the cord in labour, to be discovered so as to allow of proper treatment being instituted at a suitable and sufficiently early time? It may be urged—and this is the view which Professor Green apparently takes—that if labour goes on normally and terminates within reasonably normal limits of time, there is no need to know about the dilatation of the cervix. But the detection of the pelvic and other anomalies is a more difficult problem, and it is just here that we are in cordial agreement with the Harvard professor. He says, "Let every pregnant patient be under the care of her medical attendant from the early months of her pregnancy; let the pelvis then be measured externally with care, and search made for any existing condition likely to make the future labour abnormal; nay, more, let a thorough bimanual examination be made. But why should an internal examination be advised in the early months and forbidden at the time of labour? Will the supersensitive primipara be likely to submit more willingly at the former than at the later time? No; but the reason, of course, is that in the former case there are no abrasions and tears in the cervix and vagina, and the uterine cervix is closed, and the risks of bacterial infection very small. This is a very important point, and it is well to emphasize it; in order to enable us to conduct labours without internal examinations in labour we must make these examinations in early pregnancy. To what, then, does this conclusion lead but to the value of diagnosis in pregnancy, and through it we reach the prematernity ward or pavilion about which we have spoken more than once (*vide* JOURNAL, February 3th, p. 297)? Curiously enough, Professor Green has apparently reached the prematernity ward himself, although he gives it no special name, for here is what he says: "Even in my hospital more and more women have year by year been led to make early application for pregnancy care and observation, until finally a clinic has been established, with a special staff, to carry on this work for

¹ *Boston Medical and Surgical Journal*, vol. clixviii, April 10th, 1915, pp. 52, 530

hospital patients and out-patients alike, and the same advantages are extended to the poor as to the private patient." Assistance may be forthcoming from the radio-scopic investigation of pregnancy and labour. At first much was expected from this means of diagnosis and yet comparatively little was obtained on account of technical difficulties, fetal movements (which the x rays seemed to stimulate), and the deep breathing of the mother; now, however, the radiographers of some of the Parisian hospitals seem to have surmounted all obstacles and are able to give reliable skiagrams of obstetric conditions and even to show the fetus at the fourth month.

Whilst all these things are true—whilst, by making use of careful external inspection, palpation, and pelvimetry in labour, and whilst, by carrying out internal examinations in the early and even in the later months of pregnancy, there will be less need of the vaginal examination in actual labour, yet it cannot be dispensed with altogether in all cases. Even Professor Green accepts this conclusion, for he enumerates *ante-partum* haemorrhage, eclampsia, prolapse of the cord, long delay in labour, and the complications rendering operation necessary, as conditions warranting vaginal examinations during labour. We cannot therefore answer in the affirmative the question asked at the beginning of this article; we cannot say that confinement cases can be conducted safely and efficiently without vaginal examinations. We can well agree with Professor Green when he says that "the common custom of making frequent vaginal examinations during labour is a bad one," and it deserves the name of "vaginal invasion" which he has given to it. We can go further, and look forward to the time when the doctor, by his earlier acceptance of responsibility for supervising his obstetric patients, will be able to dispense more and more with vaginal examinations at the time of actual confinement. The general institution of prematernity institutions will help also. Still, the conclusion must be that vaginal examinations cannot be entirely abolished in labour.

SCHOOL BOOKS AND EYESIGHT.

THE report of a special committee on the influence of school books upon eyesight, issued recently by the British Association,¹ is a sign of a revival of interest in the ancient and honourable craft and mystery of printing. In the beginning almost all books were beautifully printed, for the type makers gave their characters bold forms, taking the work of the manuscript writers as their model. They considered all the factors in the legibility of the page which the report we are considering enumerates, and paid regard also to the form and balance of the mass of type, to the size and shape of the page, and so got a beautiful and gracious effect. Until almost the other day, all printing was done from the actual type and on hand presses, but the hunger for knowledge and the growth of the habit of reading produced a demand for cheap books which was met at first by using cheap paper and small type, and so cramming as many words as possible on to as small a page as possible. For generations things have been going from bad to worse, for to the earlier defects have been added those due to the practice of stereotyping or casting, and the use of rapid mechanically-driven printing presses. There have always been a few

printers who have kept a higher standard in view, and there have always been the old books to remind us of what a well printed book is. But until lately the general tendency has been downwards.

This has been due to the spirit of competition in commerce and the assumption that the public would prefer quantity to quality in the matter of paper and printing, and would be certain to choose the book that supplied the largest number of words for sixpence. Bargains in books would often be found to be no gain to the reader if the sum total of the effects of the reading were ascertained, and there are signs that the public are beginning to find this out. School books ought not merely to share in the improvement, but to lead the way, for only school children, students, and reviewers are compelled to read books they find trying to the sight.

The report commences with a statement of the results of the committee's inquiries into the present practice of local education authorities under the authority of Circular 596 of the Board of Education. The conclusion arrived at is that "practically no systematic attention is given to the influence of school books upon eyesight."

Four pages of the report are given to a report of the oculist subcommittee, consisting of Dr. H. Eason, Mr. Bishop Harman, and Professor Priestley Smith. This report is really the answer to the question set before the committee. The surgeons state categorically the effects that reading is likely to have on the children who read too much or begin too early. The warning given in the report of this subcommittee as to the grave danger incurred in overworking the immature eye of the young child is worthy of the most serious attention from every one concerned. No amount of provision and care in the production of school books will make up for the lack of recognition of this one point. If the report does no more than drive this simple fact home to those who are responsible for the training of the young, it will have earned the thanks of the next generation. Equally wise and cautious are the remarks of the surgeons concerning the production and increase of myopia. These four pages should be in the hands of every one who has educational charge of children. They are certain to be helpful, and technical terms which might confuse the understanding of the layman are avoided.

The third section of the report deals with the hygienic requirements with which school books should conform. The several conditions that go to make up good printing and their relation to the psychology of the reading process are set out. Similarly the requirements of special subjects such as music, mathematics, and foreign scripts are set forth. The report ends with an appendix, a glossary of technical terms, and ten pages of specimen types suitable for children's use at various ages.

The general findings of the committee as to the conditions a book which shall be "good" in the sense of legibility must fulfil may be summarized as follows: (1) The size of the type must conform to the age of the child. (2) The width of each character must be proportionate to its height. (3) The outline to the type must have sufficient strength. (4) The space between the lines, termed the "leading," must be sufficient. (5) The length of the line must be reasonable. (6) The ink must be black. (7) The paper must be white, or nearly white, hard, opaque, and without gloss.

The practice of printing has changed greatly of recent years. The extended use of machinery, "fashion," and improvements in the arts of manu-

¹ Report on the Influence of School Books upon Eyesight, by the Special Committee of the British Association appointed to inquire thereon. Pp. 34. Price 4d., from the offices of the Association, Burlington House.

facture, have changed the prevailing style of type, not always for the better. The skill of the type-founder has led him to produce founts that are a marvel of accuracy and delicacy of moulding, with hair lines that would have been the wonder of earlier printers. But the value of these improvements so far as the comfort of the reader is concerned is *nil*, rather they are a drawback. The introduction of rapid machines for printing has had even greater effects. It was unavoidable that the hand press should go, but it is a thousand pities that the bold emphatic impressions which came forth from those presses should go with them. The expression "damp from the press" tells of the way in which the old printers got their fine effects: they damped the paper. To-day most printing is more or less dry, and dry paper and thin-faced type give an effect that is not impressive to the eye of the reader, and causes fatigue and weariness. The conditions become worse when the requirements of illustrations of modern style—commonly photographs reproduced by photography—are met by the use of a highly-glazed "art" paper for the text also.

The legibility of print depends upon effective contrast. The contrast cannot be effective when the paper shines, or when it is so thin and wanting in opacity that the print of the other side shows through, or when the lines are so close that the eye is confused by their nearness. Further, the salient points of letters are mainly along their tops, so that to enlarge a letter by increasing its height is not to make it more legible: breadth is equally necessary. The point can be well seen by reference to the specimens of type given in the report. No. 1 is a large type of "modern face": No. 3 slightly smaller type of "old face," yet the latter is legible at a greater distance than the former. The committee had evident leanings toward the superior legibility and artistic merit of the "old face," or "old style antique," and there can be no doubt of the truth of its recommendations. A page of old face type has an air of distinction that is a dignified introduction to what we may hope are pearls of wisdom in the text. For school books it should be the standard style of type. Examination of recent elementary school books shows that publishers are already turning their attention once more to this style, which seems to be the only style that can successfully counteract the evil effects of rapid machine printing on dry paper.

The report is not without defects in detail. No note was made on the binding of books—a very necessary point since the introduction of the machine staple. If these are set in from side to side, as is too often the case, the book cannot be opened flat, and therefore becomes unreadable. The Stationery Office sets a deplorable example in this respect. The scale of "leading" is inaccurate for the younger years. In school books the minimum space between the lines made by the short letters should not be less than twice the height of these letters. Some of the specimens are examples of that which should be eschewed rather than that which is commendable. No. 4 is a beautiful style of type ruined by lack of "leading." No. 5 seems to pass muster on the soft paper of the report, but on a hard paper it has an unpleasing effect like the dazzling produced by viewing a long row of palisading. The hair lines are too fine in comparison to the down-strokes—the common fault with "modern face" style. No. 6 shows a type that conforms to standard measurements in size and leading, but there is a want of strength of line, and the whole effect is "pale faced." On harder paper this would be more marked. These errors in the

report show how necessary it is that printers and writers should come together again as no doubt they did in former days. If the printer knows nothing of the ideas and intentions of authors, how can he be an artist in type?

The report ends with a severe but thoroughly justified criticism on the printing of Bibles, prayer-books, and hymn-books. For the most part these books are not fit to be put into the hands of young children, because the elders who produce, vend, and buy these books are greedy. They are not content with a book of modest contents, of the size that a child can handle, done in type that a child can see. They must needs cram into that same sized book enough material to fill half a dozen, with the result that the paper is thin, the type small, and the book unreadable. So far as the Bible is concerned there is no necessity for this. The issue of the several books of the Bible in well printed volumes of convenient size is merely a matter of arrangement; the "parts" at present on sale are too cheap and poor for school use.

The whole moral of the report of the Committee of the British Association may be summed up in the words—less material and better quality.

THE AMENDMENT OF THE INSURANCE ACT.

A NUMBER of statements have appeared in the press as to the lines of the bill to amend the Insurance Act now under consideration, but we believe that they mainly represent the kind of guesswork with which we are familiar on these occasions. When the additional money was provided for medical benefit it was understood that the use of this money as a supplement to the two-ninths otherwise contributed by the State towards the cost of benefits would have to be regularized in an amending Act, and, as we suggested in a recent issue, the difficulties presented by casual labour are so great that they can scarcely escape attention during the present session. It will be remembered also that an undertaking was given by the Chancellor of the Exchequer that the Government would give attention to the contention put forward by medical men in respect of insured persons who subsequently become well-to-do. Under Section 1 (3) (b) such persons may continue as voluntary contributors if they have been insured for five years. The point of the medical objection is that thereby a number of well-to-do persons with incomes of more, sometimes far more, than £160 a year might be able to take advantage of the State-aided insurance. We should certainly anticipate that the Government will see to the fulfilment of that promise in the forthcoming amending bill. The grant of money made to assist in providing medical benefit for those who are insured under the Act, and were 65 years of age at the appointed day, will also probably require embodiment in the forthcoming bill.

INTERPRETING THE INSURANCE ACT.

The case *Heard v. Pickthorne*, which was decided by the Court of Appeal on May 1st, settles a point of considerable practical importance both to insured persons and to members of the medical profession. A friendly society had refused to accept the certificates of a medical man as evidence that the applicant was entitled to sick benefit on the ground that the signature was not that of a doctor on the panel. It appeared that the society had adopted a resolution "that in every instance a certificate from a panel doctor must be sent." The case was brought to the notice of the London Medical Committee, and an application was made to Mr. Justice Bucknill for an interim injunction against the defendants on the ground that the resolution and the consequent refusal were *ultra vires* and not enforceable. The judge did not issue an

interim injunction, on the ground that the matter was one which should be tried in court. It accordingly came before Mr. Justice Baillache, who dismissed the action with costs, on the ground that the point was one which ought to be decided by arbitration under Section 67 of the National Insurance Act. The National Medical Guild, the body which has developed out of the London Medical Committee, took steps to ensure that an appeal was entered against this decision, and the hearing was expedited in view of the importance of the matter. The Court of Appeal was unanimous in holding that the action of the friendly society was *ultra vires*, inasmuch as its resolution had stated that the only proof it would accept of incapacity for work was a certificate signed by a panel doctor. The Court held that the society had no right to limit beforehand in this way the kind of evidence it would accept. When the Insurance Act was hurriedly completed in December, 1911, it was prophesied by many that it would afford a great deal of work for the lawyers and the law courts. This case is one of the earliest proofs of the truth of this prophecy, and the importance which the Courts attach to speedily settling doubtful points at rest is shown by the almost unexampled celerity with which this particular matter had been dealt with. There is, we are afraid, no doubt that the friendly societies, and at least some of the authorities created by the Act, are disposed to interpret any point in doubt to the disadvantage of the medical profession. The result in this case will encourage the profession, where it feels that it is being unjustly treated and the terms of the Act are being strained to its disadvantage, to bring the matter promptly to the arbitration of the Court of King's Bench. The Court of Appeal in this case has shown itself jealous of its authority, and has very definitely indicated its opinion that the case was one which fell within the jurisdiction of the courts of law, and was not a matter to be settled by arbitration.

ATTENDANCE ON AGED AND DISABLED MEMBERS OF FRIENDLY SOCIETIES.

THE issue by the Insurance Commissioners for England of the Memorandum (155/A.S.), which is reproduced in the SUPPLEMENT, raises once again the question of the rate of remuneration for the attendance on those members of friendly societies who, because they were over 65 or were permanently disabled, did not become entitled to medical benefit under the ordinary arrangements made between Insurance Committees and doctors on the panel. The circular repeats, and emphasizes, that reading of the Section 15 (2) (c) of the National Insurance Act to which the Association has taken strong exception, and for which we can find no foundation in the wording of the section, and certainly none in the code of honour which regulates ordinary dealings between man and man. As we have repeatedly pointed out, the Association made a bargain with the friendly society representatives that if they on their part would abandon their proposed campaign in favour of inducing Parliament to reverse its decision to put the administration of medical benefit in the hands of the Insurance Committees and not into those of the friendly societies, the Association on its part would undertake that the class of members of friendly societies with whom we are now dealing should be attended at the same rate of remuneration as applied to insured persons. The Association was, of course, ready to carry out its side of the bargain, and, being unaccustomed to deal with people who hold that whether they do so or not depends on whether it pays them, ingenuously imagined that when the terms of the bargain were incorporated in the Act the last word had been said. But it did not reckon on the ingenuity of the friendly societies, or rather some of them, for they have not all tried to evade their obligations. Nor did it reckon on having the dice loaded against

it by the active partisanship of the Chairman of the Joint Commission, who by official action, by innuendo, and by direct accusations of meanness against the medical profession, has done his worst to keep alive a quarrel which without his intervention would, in all probability, by this time have died a natural death. In the memorandum now under consideration an official document is used to dot the i's and cross the t's of Mr. Masterman's misreading of this subsection. We are told that the Exchequer grant of 2s. 6d. will be available for all the insured persons over 65, though not for the permanently disabled members of friendly societies who were thereby prevented from becoming insured persons. But the societies are told that if they are able to make a contract with doctors at less than 8s. 6d. for attendance and medicines, they will be able to give the contributor the advantage, by giving him an increase of his sick pay—at the expense of the doctor! But the most amazing part of the document is contained in paragraph 8, where the societies are told that the doctors on the panel can be *required* (this word is italicized in the memorandum) by the Insurance Committees to attend these classes of friendly society members at the same rate as the insured, but that the duties of the Insurance Committees "are limited to enforcing upon doctors upon the panel, if called upon to do so, one of the conditions of these doctors' contract with the Committee." In plain English this means that the doctors can be held by official machinery to *their* side of the bargain, but that the friendly societies are at liberty to do all in their power to evade their obligations and are to have resort to the compulsory powers of the Committees only if they find the doctors are not so foolish as it is hoped they will be. It is as well to have the matter thus plainly stated, and we hope the eyes of the medical profession will be fully opened to the unscrupulous nature of the opposition they have to encounter on this subject. The duty of the profession is quite clear. In spite of any leanings its members may individually have towards dealing on charitable terms with the old and disabled members of friendly societies, it must remember that on its behalf a bargain was made that medical practitioners would attend this class at the same rate as was paid for insured persons generally. The efforts of the other parties to the bargain to escape their lawful obligations, backed as they have been by official and officious interference, should only make the profession more determined that the bargain shall be kept by both sides. The problem which the friendly societies have to solve is a very small one. They now, by the terms of the circular under consideration, have 2s. 6d. towards the payment for the medical attendance on each of their members who were 65 at the passing of the Act, so that no difficulty should arise as to these. As regards their permanently disabled members who could not become insured, all the societies have to find is the difference between the old rate of payment to the doctor and the 8s. 6d. now paid for the attendance on insured persons. It must be remembered that these members have for years been insured by the medical profession for their medical attendance at a rate which the Government has admitted was inadequate even for ordinary healthy employed persons. How even Mr. Masterman can contend that that inadequate rate should be continued for the worst class from an insurance point—the class the Government refused to insure because the risk was too great—passes our comprehension, and may well pass the endurance of the medical profession.

A NEW TYPE OF CONSCIENTIOUS OBJECTOR.

DURING the passage of the Insurance Bill through the House of Commons Mr. McKenna gave an assurance that the case of those who conscientiously objected to receiving treatment from qualified medical practitioners should be considered. Their case was mentioned also in the

discussion of the amendment to Section 15 of the Insurance Act, under which certain persons might be allowed to make their own arrangements for medical attendance and treatment. A deputation on this subject was received by Mr. Masterman on May 6th, and it was promised that the Government would endeavour to see that in some way or other those persons who did not believe in the orthodox system of medicine, and were willing to make a declaration as insured persons that they wished for some other form of treatment, should be allowed to have that treatment and should not on that account lose the proportion of the money allotted to them for medical benefit. It is understood that applications have been received from different parts of the country from insured persons who wish to be treated by herbalists, Christian Scientists, and others, and it seems to be considered that the only way in which the Government promise to this class of person can be redeemed will be to devise some scheme by which they will be allowed to use the money set aside for providing medical benefit to help them to pay for "the treatment" they desire to receive. The administration of sickness benefit according to their rules is wholly in the hands of the societies. The Insurance Committees have nothing to do with the payment of sick benefit, and it will remain for the societies to decide whether they will accept certificates for sickness from herbalists and Christian Scientists. There is no indication at present that the societies are willing to accept certificates from any persons other than qualified medical practitioners.

SCHOOL MEDICAL OFFICERS IN CONFERENCE.

If anything were required to show how far the profession has travelled in the subject of the medical inspection and management of school children during the past twenty years, it is furnished by such a conference as that which met in Edinburgh last week; a brief report of it is published elsewhere. The single fact that ten years ago there was at most only one medical inspector of a school board school in the whole of Scotland and that now there are 105 such officers is sufficient to set in a high light the revolution which has taken place in this department of medical practice. Formerly the schoolmaster ruled over the school and the scholar, with the inspector exercising periodic discipline over the schoolmaster; but now the medical man has stepped upon the scene, and with him has come the realization of the paramount importance of the second part of the old adage, *Mens sana in corpore sano*. As was being said in Edinburgh last week, "physical culture is to come before the Humanities, and hygiene is to be reckoned of greater importance than higher mathematics." It looks as if it were to be a stiff contest between the leech and the dominie, with the advantage of attack on the side of the former. That one out of the four sessions into which the conference was divided was held in Dunfermline furnished the delegates with an object lesson which will not be lost either upon them or upon the profession and public generally. In the ancient Fifeshire royal burgh, the scene of many stirring historic events, the birthplace, in 1837, of Dr. Andrew Carnegie, and now a busy manufacturing town, the Carnegie Dunfermline Trustees have since 1903 made provision for the bodies as well as for the minds of the school children within the bounds. As Dr. Ross (Chairman of the Trust) told the visitors, the Dunfermline Carnegie Trustees began their interest in physical training by providing on a humble scale for gymnastic exercises; then they extended the work to the teaching of physical culture in all their public schools; then they passed to medical inspection of all school children, and eventually were further led to the creation of a College of Hygiene and Physical Training, where students, after pursuing a suitable course of study, became qualified as teachers to communicate what they had gained by their studies to the children in the public

schools throughout the country. Still further, medical inspection had led the way to its natural and indispensable sequel, medical treatment. In all these advances the Carnegie Trustees, with it can well be believed the full approbation of the trustee, tried to act as pioneers, and their success can now be recognized. Further, the delegates not only heard of these things—they saw the training lessons for children of various ages going on, and witnessed an exhibition by the students of the College of Hygiene. The conference was notable for other things, however, as well as the visit to Dunfermline. Dr. Campbell Munro, the County Medical Officer for Renfrewshire, carried the sense of the gathering with him when he advocated simple and inexpensive buildings and condemned the palatial schools—costly solid stone structures—put up as if they were to last for ever. Inexpensive buildings, well heated of course, well lighted, and well ventilated, were what were needed; they would serve their day and could then be razed to the ground when new ideas perhaps demanded a different type of structure. Dr. Leslie Mackenzie touched upon another difficulty when he asked the conference how far they could, without danger to the boy or girl, require the industrial worker to remain at school. This was the medical problem of the continuation schools. Was it medically right to permit a boy or girl to work eight or nine hours a day, and then to require two or three hours of intellectual labour at an evening school? There were several other matters of no little moment discussed, such as the difficulties of the medical treatment of school children in the rural districts, on which Dr. Maxwell Ross spoke helpfully and suggestively. Touching upon the problem of the teeth, especially between the critical ages of 6 and 8, Dr. Maxwell Ross, we notice, recommended the appointment of a whole-time dentist for such a county as Dumfries. One of the most interesting events of the conference was the visit paid to one of its sessions by Sir John Struthers, K.C.B., Secretary to the Scottish Education Department. In an address he expressed what was probably in the minds of all the delegates, the thanks they owed to Dr. Leslie Mackenzie, to Dr. Cruickshank, and others for making the conference possible and for carrying it through so successfully. Very significant, too, was Sir John Struthers's remark that he was entirely with Dr. Campbell Munro in his desire for improvement and economy in the building of schools. Taking it altogether, this conference, the first of its kind held in Scotland, must have lasting effects. The school medical officer is a growing power in the land; and with the help of such conferences to enable him to see his subject "steadily and see it whole," and with such special training as can now be got from post-graduate courses on the diseases and defects of children, he ought to be a beneficent force likewise.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE extensions in progress at the London School of Tropical Medicine are approaching completion and will materially increase its resources. The new general laboratory, which is beautifully lighted from the north, will provide bench room for seventy-two students, or, indeed, more if necessary. Separate laboratory accommodation on a generous scale is also being provided for a suggested new department of tropical sanitation and for an insect room, a preparation room, and a director's room. All these are in addition to the existing helminthological, protozoological, and entomological laboratories. The residential accommodation has been extended, and now comprises twenty-seven bedrooms, while a new mess-room and serving-room are nearly completed. Suitable accommodation is being provided also for ladies, a considerable number of whom attend the classes. The necessity for this general increase in the workrooms and residential quarters is due to the gratifying growth in the number

attending the three sessions of the school which are held each year. Last year the total number attending the three classes was 194. The school draws its pupils from all parts of the British Empire and not a few from other countries. The visitor to the school cannot fail to be impressed by the way in which the institution is organized, and especially, perhaps, by the high standard already attained by the comparatively new special departments of helminthology, protozoology, and entomology. It is probable that the extension of the school will be opened with some ceremony during the summer, and in any case everything will be ready for the work of the next autumn session. The hospital is in immediate connexion with the school; both occupy a site close by the entrances to the largest docks on the Thames, and there are projects for adding to the docks at least one still larger. In the wards of the hospital may be seen, in the course of a month or two, seamen and others of almost every nationality suffering from those exotic diseases to the study of the prevention and treatment of which the whole institution is primarily devoted.

GRAND OLD MEN.

Thus is usually said to be the day of the young man, and in business at least the phrase "too old at forty" is supposed to express the truth. Undoubtedly, the pushful young man is very much to the fore, but in the higher spheres of activity where judgement and ripe experience are more valuable than adventurous energy, old men still do more than hold their own. The question of a retirement age for judges has recently been discussed, and Lord Alverstone is reported to have said that a judge is at his best from 65 to 80. Mr. Justice Phillimore, again, is reported to have delivered himself of the apparent paradox that the work he now does is so hard that if he was a younger man he could not do it. This, we take it, means that the larger experience he has gained with increasing years has made him more capable. But it is not only on the bench that we see octogenarians full of intellectual vigour, and there are among us several nonagenarians who are far, indeed, from the second childishness and mere oblivion of the last act of Jaques's drama of life. Lord Wemyss at 94 still wields a slashing pen in the advocacy of his opinions, and Lord Stratheona at 92 continues active in public life. We are proud to claim as one of our grand old men of medicine the Right Hon. Sir Charles Tupper, now aged 91, who sailed from Canada for England on May 2nd. He is a Doctor of Medicine of Edinburgh, but is best known as a politician. He was Premier of the Province of Nova Scotia at the time of the Confederation in 1867, and has held nearly every great office of State in the Canadian Government. He was President of the Privy Council in 1872, Minister of Inland Revenue (1872-3), Minister of Customs (1873), Minister of Public Works (1878-9), and Minister of Railways and Canals (1879-84), High Commissioner for Canada in England (1883-7 and 1888-96), and Minister of Finance (1887-8). He was one of His Majesty's Plenipotentiaries on the Fishery Commission at Washington in 1887-8, and Commissioner for the negotiation of a treaty between Canada and France, 1893. He became Prime Minister of the Dominion of Canada in 1896 and was Leader of Opposition in the Canadian House of Commons from 1896 to 1900. He was created a baronet in 1883 and was named a Privy Councillor in 1909. Few men's lives have been so full of work useful to their country and to mankind as that of Sir Charles Tupper.

SIR JAMES PORTER.

SURGEON-GENERAL SIR JAMES PORTER, K.C.B., who retires from the office of Director-General of the Medical Department of the Royal Navy, which he has held for exactly five years, has had a very distinguished career

since he entered the service as Surgeon in 1877 as the first man of his year. He served as Surgeon to H.M.S. *Orontes*, which was employed as a hospital ship during the Egyptian war of 1882, and received the medal and Khedive's star. From May, 1884, to May, 1885, he was Surgeon of the Royal Marine Battalion engaged in the defence of Suakim and in the operations in the Eastern Soudan. He took part in the action at Hashien, ToFrek, the attack on the convoy of Guards and Marines, and the taking and burning of Tamai; for these services he received the two clasps—Suakim, 1885, and ToFrek. In 1889 he was promoted Staff Surgeon, and in 1898 Fleet Surgeon. He served in the South African war from an early period. He was Senior Medical Officer of the Naval Brigade landed for the defence of Stormberg, and subsequently joined Lord Methuen's (the first) division of the army, taking part in the actions at Belmont, Graspan, with storming party of naval brigade, Modder River, and Magersfontein. He then joined the sixth division under General Kelly Kenny, and took part with it in the relief of Kimberley, including the action at Klip Drift, engagements at Paardeburg from start to finish, Poplar Grove, Dreifontein, and the entry into Blomfontein. Later he joined the eleventh division under General Pole-Carew, and served with it from Blomfontein to Belfast, being present at the following engagements during the advance: Vet River, Zand River, Johannesburg, Pretoria, Diamond Hill, and Belfast. Afterwards he joined the cavalry division under General French and proceeded with it to the capture of Barberton. He received the South African medal with eight clasps and was specially promoted to Deputy Inspector-General in 1900 for his South African war services. He received the military C.B. in June, 1902, and was promoted to Inspector-General, the rank now called Surgeon-General, in 1906. In addition to these war services he has held many appointments, having been in medical charge, among other establishments, of Gibraltar, Chatham, and Haslar Hospitals. His tenure of office as Director-General has been marked by the same administrative abilities as distinguished the other stages of his career, and his nomination to be K.C.B. in 1910 was felt to be a fitting recognition of his loyalty to the premier service and to his own department. Recently he was appointed Honorary Physician to the King. He will be succeeded by Surgeon-General Arthur William May, C.B., who entered the service in 1873 and served in the Egyptian war of 1882, the Suakim expedition of 1884, and with the Camel Corps of the Nile expedition for the relief of General Gordon. He acted as Deputy Director-General from 1905 to 1909, and was recently in charge of the Royal Naval Hospital, Chatham.

THE ROYAL SOCIETY CONVERSAZIONE.

THE Royal Society held its annual conversazione on May 7th at Burlington House. Owing to the celebration of the 250th anniversary of the foundation of the society last year, there was a considerable change then in the character of exhibits, but this year the demonstrations given were of the usual type, forming, as on previous occasions, for the most part, the usual synopsis of the year's advance in science. Naturally, this was shown most strikingly in the number of exhibits illustrating the new forms of apparatus, or new means of determining principles connected with the science of aeronautics. There was little in the exhibits having a direct bearing on medicine. An exception, however, must be made in the case of the demonstration by Mr. H. G. Plummer of blood parasites that were either new to science or had been found in new hosts. The most remarkable of these, which were mounted with characteristic skill, were a new type of haemogregarine in the blood of a Bengal monitor, a trypanosome that had been found in the blood of a Malay parakeet, though it had hitherto been

believed that there were no trypanosomes in that country, and the presence of *Spirochaeta pallida* in the lung of an embryo whose mother was infected. There were many exhibits bearing indirectly on medical science. The most remarkable of these, and one of the most interesting in the whole collection, was the collection of living crustacea from the neighbourhood of Plymouth shown by the Marine Biological Association of the United Kingdom. The principle of the arrangement was to illustrate the modification in living crabs and their allies. Among the specimens shown were good examples of the spider crab, which decks itself out with all sorts of foreign material and small "parasites," so as to make itself resemble its environment; of the hermit crab, which, not content with living in a shell that it has commandeered, joins forces with an anemone, the advantage gained being that whereas the crab is a favourite prey for fish, the anemone is avoided on account of its powers of stinging; and of the crustacean in which the female, after being parasitic on a fish, drops to the bottom of the ocean and converts the whole of its body material into eggs to carry on the race. Among the many exhibits was one of certain crabs that had come from a tropical port, sheltering themselves beneath the shell of the barnacles fastened on the ship's bottom; they were eventually discovered when the vessel was dry-docked in Plymouth. The Curator of Geology at the British Museum, Dr. A. Smith Woodward, showed the famous Piltdown skull of the species named *Eoanthropus dawsoni* and with it a number of plaster casts, some showing the exact remains as they were discovered, and others illustrating how it had been possible to reconstruct the skull of the species. It was perhaps unfortunate that this exhibit was not placed side by side with that shown by Professor Elliot Smith, who had a number of casts of the brain of the species and of other primitive brains in primitive man, anthropoid apes, and other mammals supposed to be near the line of human ancestors. The series illustrated the interpretation of the distinctive features of the most primitive human brain, and elucidated to some extent the nature of the evolutionary process by which the human brain has been derived from that of the early mammal. Professor E. B. Boulton showed a number of moths illustrating points in heredity, and Mr. L. Doncaster by a series of six generations of the moth *Abraxas grossulariata*, in which families consisting solely of females had appeared. Usually, the exhibit demonstrated, unisexual broods are the offspring of females which belonged to such broods; but not all such females have only female offspring, and in some cases unisexual broods had been produced by females of bisexual broods immediately descended from unisexual families. Professor Collie and Mr. H. F. Paterson gave a demonstration of the neon and helium they have found in hydrogen after the passage of the electrical discharge through the latter at low pressure. An ultra-condenser for the observation of ultramicroscopic particles, greatly simplifying the apparatus necessary for this class of work, was shown by Messrs. Leitz and Routh. In the evening special demonstrations were given on "The Motion of Viscous Fluids," by Mr. Leonard Baird, and on "The Discovery of a Paleolithic Skull and Mandible at Piltdown, Fletching, Sussex," by Dr. A. Smith Woodward.

THE RECENT ACTION AGAINST THE "PALL MALL GAZETTE."

A LETTER signed by 148 representatives of the medical profession and teachers of medical sciences has been sent to Mr. W. W. Astor, proprietor of the *Pall Mall Gazette*, congratulating him on the result of the recent libel action against that paper, and thanking him for the public service which he has rendered to the medical profession in this matter. The letter was in the following terms:

"We desire to congratulate you on the result of the action recently brought against the *Pall Mall Gazette*, and to thank you for the public service which you have rendered to our profession. You have enabled all men to understand more clearly the principles of our science and practice, the absolute necessity for research into the problems of disease, and the profound significance of the discoveries made during the past thirty years. You have spared neither time nor trouble nor money to bring home to the public the truth about experiments on animals in this country, and to expose the errors of antivivisection. We thank you, in the name of our profession, for the very important work which you have thus accomplished."

THE spring session of the General Medical Council will begin on Tuesday, May 27th, when the chair will be taken by the President, Sir Donald MacAlister, K.C.B., at 2 p.m.

The Presidency of the Section of Ophthalmology of the XVIIth International Congress of Medicine, which became vacant by the lamented death of Sir Henry Swanzy, has been accepted by Sir Anderson Critchett.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Parliamentary Grant to Universities.—A considerable number of questions on this subject have been addressed to Mr. Pease, the President of the Board of Education, in connexion with questions relating to the administration and management of the University of Bristol. In one of his replies, Mr. Pease said that he was informed by the Advisory Committee, presided over by Sir William McCormick, that the educational work was efficiently carried on, and laid down the general principle by which he was guided in the allocation of parliamentary grants to universities as follows: "Power is given, through the Sovereign, to the President of the Council and the visitors to make inquiry if one is needed. But my duty is to see that the parliamentary grant is efficiently administered in connexion with education, and I am satisfied that the educational efficiency is satisfactory at the present time."

Milk Preservatives (Boron Trioxide).—Mr. Charles Bathurst asked the President of the Local Government Board whether, in the opinion of his expert advisers, the use of less than 0.20 per cent. of boron trioxide as a preservative in cream was injurious to the health of infants, pregnant women, and invalids; whether the new milk and cream regulations of his Department permitted its use for that purpose, and, if so, in what quantities. Mr. Burns said that there was no exact consensus of opinion as to the amount of boron trioxide which might be necessary to produce injurious effects in different persons. The regulations to which reference was made were not intended to control the amount of preservative which might be added, but only to secure that no preservative should be added to cream without declaration on the label as to the amount. The provisions of the Sale of Food and Drugs Act, 1875, were available for preventing the use of preservatives to an extent such as to render any article injurious to health.

Tuberculosis Order, 1913.—Mr. C. Bathurst asked the President of the Board of Agriculture whether, seeing that under the Dairy, Cowsheds, and Milkshops Order of 1885 compulsory veterinary inspection of cowsheds and notification of bovine tuberculous disease was now required by those district sanitary authorities only which had adopted that Order and would continue to be required by them until uniformity of action was secured as the result of the

passage into law of the Milk and Dairies Bill, and seeing that under the Tuberculosis Order of 1913 such inspection and notification would be optional throughout the greater part of the country, he would facilitate local procedure and secure simultaneous uniformity of tuberculosis administration, as contemplated in 1909, make the commencement of the operation of the Tuberculosis Order contemporaneous with that of the Milk and Dairies Bill. Mr. Runciman said he had considered the suggestion, but he saw no good reason for postponing the operation of the Tuberculosis Order.

Air Space in Cowsheds.—In reply to Mr. Charles Bathurst, Mr. Burns said that no decision had yet been arrived at in regard to the prescribing by Departmental Order the minimum cubic air space for cows beyond the 500 cub. ft. commonly accepted as sufficient. He added that in framing the regulations care would be taken to see that any requirements which were prescribed were reasonable and practicable.

Lind v. Saleeby and the "Pall Mall Gazette."—Sir J. D. Rees asked the Attorney-General if the attention of the Government had been directed to the case of *Lind v. Saleeby* and the *Pall Mall Gazette*, which had occupied a judge and jury sixteen days; what had been the cost to the State of this trial and how much would be recovered from the plaintiff, who herself occupied several entire days; and whether any means existed or would be devised by the Government to make it impossible to convert the Courts of Justice into theatres for the discussion of abstract issues and places of advertisement for the professors of particular scientific or other beliefs.—Sir Rufus Isaacs said he had seen the reports of the trial in the public press. No extra cost had been caused to the State by the trial. If the court had not been occupied with that action it would have been engaged in the trial of other cases. It was for the learned judge who presided at the trial to decide whether the opinions of professors were relevant to the issue and should be given in evidence.

Lead Poisoning in the Potteries.—In reply to Mr. Noel Buxton, Mr. McKenna said that the number of cases of lead poisoning in the Potteries reported up to date was twenty-six, of which four were fatal; the number for the corresponding period in 1912 was the same, five, however, being fatal. The new Regulations were only made on January 2nd last, and entailed a great deal of work, both on the occupiers and the Department, to give effect to the requirements. It was too early yet to look for any substantial change in the figures of lead poisoning.

School Medical Officers.—In reply to Mr. Leach, Mr. Pease stated that the latest complete figures were those given in the chief medical officer's report dated October, 1912, in which it was stated that the total number of medical officers in the School Medical Service in England and Wales was 943.

Sleeping Sickness Commission.—In reply to Dr. Chapple Mr. Hareourt said that the Commission of Inquiry appointed last autumn by the British South Africa Company when it was found that a case of sleeping sickness had occurred south of the Zambesi, was constituted as follows: Dr. Fleming, the Medical Director; Mr. Carbutt, of the Native Department; Mr. Jack, the Government Entomologist; and Dr. Stohr, of the Northern Rhodesian Administration, who had been engaged in sleeping sickness work in North-Eastern Rhodesia.

Motor Ambulance Wagons: Petrol Duty.—In reply to Dr. Chapple, Mr. Lloyd George said that he was considering, in connexion with his forthcoming Revenue Bill, the question as to the possibility of exempting from duty the petrol required by ambulance wagons used in accident and sick transport work.

Housing of the Working Classes (Ireland) Act.—In reply to Mr. William O'Brien, Mr. Birrell said that from the information furnished by local authorities it would appear that the average weekly rent charged for houses erected since the passing of the Housing of the Working Classes (Ireland) Act, 1908, was 3s. 4d. Twenty-eight houses were let at rents under 2s. a week.

Housing of the Working Classes Bill.—At the meeting of Grand Committee last week, the bill introduced by Sir Randolph Baker, commonly known as the Boscawen Bill, was under consideration. The President of the Local Government Board announced his intention of refusing to bring in a resolution to make the necessary financial provision. On this announcement Mr. Long advised the promoters to withdraw the bill, and this was accordingly done, but the action of the President of the Local Government Board has evoked emphatic protests from members of the Conservative, Liberal, and Labour parties. In view of the attitude adopted by Mr. Burns, it is certain that very considerable pressure will be exercised on the Government to introduce alternative proposals of their own.

Treatment of School Children (Scotland) Bill.—A short bill has been presented by Mr. McKinnon Wood, the Secretary for Scotland, which consists of one operative clause, the effect of which is to give to the education authorities in Scotland the same powers and duties with reference to the provision of medical treatment for children attending schools within their districts as they have with reference to the provision of sufficient and proper food or clothing or necessary personal attention under the provisions of Section 6 of the Education (Scotland) Act, 1908.

Bill for the Abolition of Vivisection.—A bill has been introduced by Mr. Chancellor, supported by Mr. Black, Mr. Hodge, Sir John Rolleston, Mr. Parker, Mr. William Thorne, Mr. John Wilson, Mr. Tyson Wilson, Mr. Thomas, Colonel Lockwood, Mr. Keir Hardie, and Mr. Snowden, the effect of which would be to prohibit the performance on any live animal, with or without the use of anaesthetics, of any experiment or demonstration or inoculation of a nature to give pain or suffering, either directly or in its after-effects, for any pathological, surgical, or any scientific purpose, or for the acquirement of manipulative skill. Whether this bill is or is not a product of a recent case in the Court of Queen's Bench it is difficult to say, but it is fairly safe to suggest that it has not much chance of obtaining a second reading.

Infanticide Bill.—A bill has been introduced by Sir William Byles the object of which is to abolish sentence of death in cases of infanticide by mothers where the infant is under the age of 4 weeks. The sentence which the bill proposes to substitute is detention during His Majesty's pleasure.

Capital Punishment (Age of Liability) Bill.—Another bill has been introduced by Sir William Byles on a subject similar to the foregoing, the object of which is to abolish sentence of death where the criminal is under the age of 21 years. The sentence which the bill proposes to substitute is detention during His Majesty's pleasure. The present age of liability to capital punishment is 16, such liability having been abolished as regards "children" and "young persons" by the Children's Act, 1908.

Whitsuntide Recess.—The House adjourned on May 8th for the Whitsuntide recess. It will reassemble on May 27th, and on that day the Mental Deficiency Bill, the Elementary Education (Defective and Epileptic Children) Bill, and the Milk and Dairies Bill have been put down for a second reading.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

CONFERENCE OF SCOTTISH SCHOOL MEDICAL OFFICERS IN EDINBURGH.

THE medical event of the week in Edinburgh was the holding of a two days' conference (May 1st and 2nd) of Scottish school medical officers. At the first session Dr. Carstairs Douglas presided, and in his opening remarks referred to the state of things as it was in 1891-2 and as it is now; a great evolution had, he said, taken place, and it was to be remembered that school medical officers were not merely examining children, but were rendering a great service to their country. Dr. Leslie Mackenzie dealt with the social significance of medical inspection, and pointed out that ten years ago there was no medical inspector in the whole of Scotland or perhaps only one, whilst now there were 105 medical men engaged in the work; there were various departments, including the hygiene of the school, medical research, medical examination of teachers, recuperative residence schools, the tuberculosis school, and medical conditions in the continuation school. Dr. Campbell Munro contributed a paper on the hygiene of the school, in which he protested against palatial school buildings which would be antiquated long before they were worn out. Dr. Rose spoke upon school medical research, and emphasized the importance of the investigation of the colour sense and the practice of physical culture.

The second session took place in the afternoon of May 1st at Dunfermline, where the delegates were received by Dr. Ross, the chairman of the Carnegie Trust. Dr. Ross pointed out how Dunfermline had, by its College of Hygiene and Physical Training, led the way in physical culture and medical inspection of school children and its necessary consequence—medical treatment. A visit was paid to the Women's Institute, where an address was given by Dr. L. D. Cruickshank on the organization of physical education as an integral part of the work of the school medical service. He urged that a broad general system of constructive hygiene should form the basis of the entire work of the medical inspector: the child not the disease should become the main point of interest; there was need for the correlation of the work of the expert in physical culture and the medical officer. The delegates also saw typical physical training lessons for children of different ages in the institutions under the Carnegie Trust, as well as an exhibition by the students of the College of Hygiene in the Carnegie Gymnasium. Altogether the visit to Dunfermline was a most interesting part of the conference's work.

The second day the conference had a morning session, over which Dr. A. E. Scougal, formerly H.M. Chief Inspector of Schools for Scotland, presided, and at which Sir John Struthers, K.C.B., of the Education Department of Scotland, gave an address; in the course of it he expressed his personal strong belief in the importance and value of the system which had now been initiated, and his fervent hope for its further advancement. It was, he said, beginning to be realized that all educational theorizing was more or less futile unless it started from the physical basis. Where the medical officer was convinced that improvement in school premises was needed for the health of the scholars, and where the local authority was reluctant or recalcitrant, he strongly suggested communication with the inspector of schools in the district, who had very definite powers under the Code. Dr. Alister Mackenzie, Principal of the Dunfermline College of Hygiene and Physical Training, read a paper on the medical and physical examination of candidates for the physical training profession, dealing with the qualifications for women students only. The candidates underwent searching examination, and the attempt was made to select such as would be not only suitable physically, but who would surround their pupils with a good intellectual, aesthetic, and moral atmosphere. A paper by Dr. Darling, the medical officer of the Edinburgh Provincial Committee, on some typically difficult cases which come under the medical examination of candidates in the teaching profession, was read in his absence by Dr. Isabella Cameron, lecturer on hygiene to the Edinburgh Provincial Com-

mittee. Legal means and extreme persuasion should be used to compel attention to all remediable and arrestable morbid conditions. In some cases the medical officer should have power to recommend the granting of a temporary certificate.

At the afternoon session, which was presided over by Dr. James Ritchie, Medical Officer, Heriot's Hospital, Dr. J. Halley Meikle, Chief School Medical Officer, Edinburgh, read a paper on the medical treatment of school children in towns, in which he dealt with the management of such defects as blindness, deafness, epilepsy, and various maladies (tuberculosis, skin diseases), and of such other conditions as defective eyesight and teeth. Dr. Maxwell Ross (M.O., Dumfriesshire), considered the same matters as they called for attention in rural districts, specially emphasizing the dental problem, which he regarded as the most pressing. He favoured the plan of the appointment of a whole-time dentist for such a county as Dumfriesshire. A discussion of these papers brought the conference to a close, but not before Dr. Cruickshank (who along with Dr. Leslie Mackenzie had done so much to bring about the conference) had made the important suggestion that steps might be taken to hold a three weeks' course of physical training for medical officers in Edinburgh during the summer. The suggestion was favourably received.

COUNTY COUNCILS AND SANATORIA.

At the annual meeting of the Association of County Councils in Scotland on April 24th the question of the erection of sanatoria and the treatment of tuberculous patients was considered. The committee expressed the view that Scottish county councils should proceed with the erection of sanatoria in terms of Section 64 of the National Insurance Act for all areas for which such institutions had not already been provided.

The Chairman (Sir Charles Bine Renshaw) said it was very important that county councils should act on parallel lines in regard to sanatoria, and suggested that the Secretary for Scotland should be asked to introduce a short bill providing that the borrowing powers which the county councils enjoyed under the Local Government Acts were, to the extent necessary, available for the purpose of providing sanatoria.

This suggestion was unanimously adopted, and the Chairman said that a condition precedent to any action by the county authorities should be that the cost of treatment of insured persons should be borne by the Government. In Renfrewshire there was a deficiency of £600. The treatment of dependants and others was also important. Mr. Shaw, County Clerk, Ayr, said that in Ayrshire the Insurance Committee had adopted a resolution to meet the expenditure upon uninsured dependants, and had submitted through the National Insurance Commissioners an estimate of the deficiency, which amounted to £11,600, which included the treatment of tuberculosis other than phthisis. The general situation was serious. If the Insurance Committee, which did not represent the ratepayers, could call upon the County Council, which did represent the ratepayers, for a large sum of money, it was time the county councils had a larger representation on these committees.

After discussion it was agreed that county councils should undertake the erection of sanatoria, that the association should make a representation to the Treasury with regard to the cost of providing sanatoria for insured persons, and that no discrimination should be made between those counties which had and those which had not already provided sanatoria.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

TUBERCULOSIS SCHEME FOR BELFAST.

THE Belfast Public Health Committee has, after considerable discussion and deliberation, formulated a tuberculosis scheme, which will be laid before the City Council and the Local Government Board. The scheme is comprehensive and includes both the insured and the uninsured. The total cost is estimated to amount to over £42,000 a year. To meet this liability about £8,000 is

expected from insured contributions and half of the balance will be paid by the Exchequer. The Abbey Sanatorium, which at present costs the ratepayers already £12,000 per annum, is to be taken over from the Poor Law Guardians, so that no further taxation will be required to meet that item. The Corporation already pays to the Forster Green Sanatorium some £3,000 a year, so that, unless things are managed on a much more expensive scale, only an extra £1,000 a year or so will be required, and a clear sum of £42,000 a year will be available for use in the prevention and treatment of consumption.

There will be two branches of work—the sanatorium and the dispensary. Several dispensaries may be required. The Abbey Sanatorium will be enlarged by the addition of 100 beds. Belfast's share of the £140,000 to be provided by Government for buildings will be £10,000 or more.

OPERATIONS IN WORKHOUSE HOSPITALS.

Among the reports received at a recent meeting of the Lurgan Board of Guardians was one which this board requests the medical officer of its workhouse, Dr. J. S. Darling, to make annually on the surgical operations performed therein. It was published in the local papers in a subsequent account of the meeting, and is worth attention as an indication of the wide field covered by the work of a medical man in this position, and of the amount of skill which he must possess for its successful performance. The operations performed during the year totalled 274, and included 35 appendicectomies, with 1 death; 7 gastro-enterostomies, with 1 death; 3 excisions of the rectum; 10 operations for repair of ruptured perineum; 5 prosta-tectomies, with 1 death; 5 cases of strangulated hernia, with 2 deaths; 17 cases of radical cure of hernia; 14 operations on malignant growths, with 1 death; 4 ventri-fixations of the uterus, 11 plastic operations, and 8 major amputations. Taken together, the 274 operations cover fairly well the whole field of modern surgery, and give a total mortality-rate of only 4.3 per cent. This would seem to be a very satisfactory figure, especially when it is borne in mind that the conditions for operative work—though through Dr. Darling's efforts they have been greatly improved, and as may be seen provide some of the essentials for success—can hardly be as ideal as those at the great hospitals in large centres, and that there must be little opportunity for the selection of cases. In the fever block of the same workhouse, there were over 369 cases, with 12 deaths, these including 7 deaths from scarlet fever on a total of 240 cases, and 3 from diphtheria on a total of 33. Dr. Darling in his report gracefully expresses his indebtedness to Dr. Pedlow, Dr. Laird, and his other colleagues for assistance rendered to him in his work.

THE MENTAL DEFICIENCY BILL.

A special meeting of the Joint Committee of Management of the Richmond District Lunatic Asylum was held last week for the purpose of considering the provisions of the Mental Deficiency Bill now before Parliament, and whether it would be advisable to make application that the Act should apply to Ireland.

The Resident Medical Superintendent stated that the Royal Commission had reported that of the feeble-minded in Ireland 66 per cent. were urgently in need of attention; in England 44 per cent. and in Scotland 34 per cent. were similarly circumstanced. Ireland had no institutions open to the poorer class defectives, while across the water private charity had done a good deal to help these pitiable outcasts of society—in fact, about 25 per cent. were already provided for. From the ratepayers' point of view the Act should be distinctly beneficial, as it contemplated a contribution of as much as half the cost of maintenance, thus to some degree making good the deficiency from the local taxation account. A deputation from the Medico-Psychological Association had waited upon the Chief Secretary, who had expressed his willingness to draft an amendment extending the Act to Ireland, and that if the Irish members approved it would go through. Resolutions in favour of its extension to Ireland had been passed by the Irish Workhouse Reform Association, Philanthropic Reform Association, the State Medicine Section of the Royal Academy of Medicine, the Medico-Psychological Association, and the Committees of

the Down District and several other asylums. The following resolution was proposed and seconded:

That in the opinion of the Joint Committee of Management the Mental Deficiency Bill now before Parliament should be extended to Ireland, and that we request the Irish representatives to see that the provisions of the Act are extended to Ireland, and that proper safeguards are inserted in the bill with reference to an adequate Treasury grant in aid of the rates.

The motion was opposed on the ground that one of the first things to be undertaken by the new Irish Parliament would be the reform of the whole system of charitable relief, and that the extension of this Act to Ireland would be only a patching up of the present system, and that it would be better to see how the Act worked in England before adding a further burden to the ratepayers. On a poll the motion was lost, 5 voting for and 7 against.

SEVERE EPIDEMIC OF MEASLES.

A serious epidemic of measles prevails in Wexford, and it is estimated that at the present moment there are 250 cases in the town. During the past seven weeks an average of about twelve young children have died per week from pneumonia or bronchitis supervening on measles.

England and Wales.

(FROM OUR SPECIAL CORRESPONDENTS.)

LEEDS.

RETIREMENT OF MR. LITTLEWOOD.

To the great regret of every class in Leeds, and in a very special degree to the regret of his colleagues on the staff of the infirmary, Mr. Littlewood has decided, not only to resign his position as Senior Surgeon to the infirmary, but to retire from practice and to leave Leeds. Mr. Littlewood, who was educated at University College, London, was appointed Resident Surgical Officer to the General Infirmary at Leeds in 1886. This position he held for about four years, and shortly after he ceased residence he was appointed to the assistant staff, on which he served for six years, when he was promoted to the full staff. During the earlier years of his teaching he acted as honorary demonstrator of surgical pathology at the School of Medicine, was afterwards lecturer on practical and operative surgery, and then succeeded Mr. Edward Ward as professor of surgery, from which position he retired in 1909. Mr. Littlewood held many other honorary appointments, but it is, of course, as a teacher, both at the medical school and at the infirmary, as a distinguished member of the staff, and as a deservedly popular consulting surgeon, that he will longest be held in remembrance. It would, indeed, be difficult to over-estimate the value of the work which Mr. Littlewood has done for the welfare of the university and the infirmary. His teaching has always been of the highest order, and he always seemed to succeed in getting the best work out of those who were privileged to work under him. At a meeting of the weekly board of the infirmary the following resolution was passed:

That the Board of the General Infirmary desire to record their deep regret at Mr. Littlewood's resignation and their appreciation of the great services which he has rendered to the patients and to surgery.

During his whole connexion with the infirmary, and particularly during his twenty-three years' service as assistant surgeon and surgeon, he has gained the confidence of his profession and extended the fame of the institution.

The Board wish him much enjoyment in his well-earned leisure.

Every one who knows Mr. Littlewood will cordially join with the board in the good wishes which they express for his happiness in his retirement; Mr. Littlewood has been a most strenuous worker, and many will fully understand his desire to return to his native county of Norfolk while still in the zenith of his fame as a surgeon.

MANCHESTER AND DISTRICT.

THE MANCHESTER ROYAL INFIRMARY.

At a meeting of the board of management of the Manchester Royal Infirmary, held last week, it was announced that Dr. A. T. Wilkinson had intimated his intention to resign his position as Honorary Physician to the infirmary from May 24th. Dr. Wilkinson has been a member of the staff for upwards of thirty-three years—twelve years as a member of the resident and non-resident junior staff, and twenty-one years as a member of the honorary staff. The board passed a resolution expressing regret that the time had arrived for his retirement from the active work at the infirmary, and its high appreciation of the services he had rendered to the institution. It is understood that retirement from the work at the infirmary does not involve retirement from private work as a consulting physician. The board further decided to appoint Dr. Wilkinson Honorary Consulting Physician to the Infirmary from the date of his retirement. Dr. E. N. Cunliffe, who is now Senior Honorary Assistant Physician, succeeds to the vacancy caused by Dr. Wilkinson's retirement.

LONDON.

METROPOLITAN ASYLUMS BOARD.

Appointment of Research Pathologist.

DR. WILLIAM MAIR, M.A., B.Sc., M.D., Ch.B. Edin., and D.P.H. Camb., for seven years Lecturer in Pathology at the Manchester University, and Pathologist to the Manchester Children's Hospital and the Salford Royal Hospital, has been appointed research pathologist to the Metropolitan Asylums Board.

Recognition of Medical Services.

The Asylums Committee reported that in view of the greatly altered conditions at the Darent Industrial Colony it had had under consideration the salary of the medical superintendent, Dr. Rotherham, who had been in receipt since 1908 of his maximum remuneration of £800 with emoluments. The changes in administration had involved the removal from Darent of the unimprovable imbeciles, who merely required housing, and the aggregation there, in two separate sections, first of the highest grade, or improvable imbeciles, and, secondly, of the non-certified feeble-minded. The Committee quoted favourable reports upon the institution by the Lunacy Commissioners, and said that the work which had elicited so many commendations had been carried out under Dr. Rotherham's personal direction and supervision. The Board approved a proposal which would have the effect of increasing the salary of the medical superintendent by about £40 per annum.

The Board also approved the increase of the salary of Dr. W. T. Gordon Pugh, Medical Superintendent of Queen Mary's Hospital for Children, from £600 with emoluments, to the maximum of £700 in one increment. The committee in this case noted that the development and organization of the work of the hospital, the introduction of many up-to-date forms of treatment, and the widespread reputation the hospital had gained in the eyes of visiting deputations from all parts, were attributable to the great initiative and resource of the medical superintendent. Side by side with this, due regard had been paid to economical management, and the Finance Committee had noted the comparatively low cost.

LONDON COUNTY COUNCIL.

The London County Council at its meeting this week received a report from the Public Health Committee advising that, in order to allow a comprehensive scheme for the treatment of tuberculosis in London to be evolved, and in view of the fact that the Council has hitherto not been an authority providing treatment for tuberculous patients, and that the Metropolitan Asylums Board has available the machinery necessary for the provision of residential treatment, the Board should be enabled to become an authority providing institutions for residential treatment for tuberculous

persons of all classes. After some discussion, the Council instructed its Parliamentary Committee to take the necessary steps to place the Metropolitan Asylums Board in a position to form an active unit in any scheme that may be framed by the Council for the treatment of tuberculosis. It will be observed that the Local Government Board has already notified its intention to recognize the London County Council as the central organization for the provision of institutional treatment.

NEWCASTLE-UPON-TYNE.

BANQUET AND PRESENTATIONS TO PROFESSOR DRUMMOND AND PROFESSOR SIR THOMAS OLIVER.

ON May 6th, in view of their retirement as honorary physicians from the Royal Victoria Infirmary, Professor Drummond and Sir Thomas Oliver were entertained to dinner by the past and present students of the University of Durham College of Medicine, and were made the recipients of very handsome presents in silver. Old students came from a considerable distance to do honour to the guests of the evening, and altogether about 100 were present. The occasion will be memorable in the history of the infirmary in so far as two of its best known men have retired from the active staff. Their retirement is a loss to the infirmary and to the clinical teaching of the university. Mr. H. B. Angus, Professor of Surgery in the College of Medicine, and one of the surgeons of the Royal Victoria Infirmary, occupied the chair. To Dr. Nathan Raw was entrusted the task of making the presentation to Professor Drummond and of proposing his health. In a manner and in language appropriate to the occasion he discharged the task uncommonly well. As one of his old house-physicians, Dr. Raw could speak from experience of the ability of Dr. Drummond as a physician, of the interest he took in the students generally, and of the value of his contributions to the study of diseases of the nervous system. Equally happy, but with evidence of a feeling of regret at his severance from an institution with which he had been connected for thirty-five years, was Dr. Drummond in his reply. A note of sadness ran through the earlier part of his speech, and he was speaking to an audience which was in sympathy with him. When he passed to the story of his early years spent in Trinity College, Dublin, and spoke of his association as house-physician with Sir William Stokes, he warmed to a subject which riveted the attention of those assembled, and drew forth expressions of their appreciation. In a peroration at once graceful and dignified, he thanked the past and present students for the handsome silver tray and salver which had been presented to him.

Professor Beattie, in submitting the health of Sir Thomas Oliver, and in presenting to him a silver tray, salver, and centre piece, spoke of the lengthened service which he had rendered to the infirmary, and of the successful part he had played in the clinical instruction given there. He also dwelt on the work which Sir Thomas has done in the field of industrial diseases, and reminded his hearers that long before the Gulstonian Lectures on Lead Poisoning were delivered he, as one of his old students, had listened to clinical lectures on occupational disease by the guest whose health he had the honour of proposing. Sir Thomas Oliver, in accepting the gifts, after thanking Dr. Beattie for the compliments paid him, said that the mirror was held up to their gaze as well as to his own, and that on it was reflected the word *failure* in bolder letters than the word *success*. No man's life could be regarded as a success, for it was a question whether man's work was ever accomplished, since fulfilment could never transcend aspiration. Becoming reminiscent of his early association with the infirmary, he drew a picture of the great changes which had taken place in administration and progress. Listerism had just come into being when he joined the infirmary staff. Its adoption generally had changed the whole practice of medicine and surgery. Sir Thomas Oliver sounded no note of sadness on his retirement from the active staff of the infirmary, but said he looked forward to carrying on investigations which were waiting for him.

In a happy speech intermingled with anecdote Professor Stuart McDonald proposed "Past and Present Students," which was acknowledged by Professor Bolam and by Mr. J. M. Pirie.

The toast of "The University of Durham" was given by Dr. William Martin in an excellent speech, and responded to by the Vice-Chancellor of the University, Professor Sir George Hare Philipson. Dr. Parker submitted the health of the Chairman, and spoke of the interest Mr. Angus always took in sport and in all that concerned the welfare of the student.

During the dinner music was rendered by Mr. Robert Smith's band, and later on the harmony of the evening was much enlivened by the songs given by Dr. Abraham and Mr. Natrass. It is seldom that such a successful medical gathering has taken place in Newcastle. Much of the success of it was due to the honorary secretaries, Messrs. C. S. Woodman and F. J. Natrass.

Australasia.

CONSUMPTIVE IMMIGRANTS.

ATTENTION has been drawn to the fact that there is a relatively large proportion of cases of tuberculosis among the immigrants who have come out to New South Wales from the Old Country during the last few years. Dr. Richard Arthur, M.L.A., the President of the Immigration League, has on several occasions called attention to this matter both in the press and in Parliament, and some months ago he wrote to the leading London journals pointing out the cruelty of persons in England sending out their relatives who were suffering from advanced phthisis. The vice-president of the National Association for the Prevention of Consumption, who is also one of the physicians to the Tuberculosis Dispensary, states that he has lately come across several cases in the last stages of consumption among immigrants who have only recently arrived from the Old Country. While it is impossible at present to state the actual increase in the number of these cases, the Commonwealth statistics for 1910 give some idea of the number of advanced consumptives who came into the Commonwealth during the previous few years. In that year exactly 100 consumptives died who had been in Australia four years or less, while 43 died who had been in the country from five to ten years. Of these, 29 had been in Australia less than twelve months, while 27 had been there for one year, 21 a couple of years, 16 three years, and 13 four years. Increased care in the future is to be exercised in the selection of assisted immigrants. It is, of course, recognized that the dry and warm atmosphere of some parts of Australia is especially good for cases of early pulmonary tuberculosis, but the profession in England should be particularly careful in advising consumptive patients to come to Australia unless they have independent means.

THE LATE SIR JAMES GRAHAM OF SYDNEY.

Sir James Graham, M.A., M.D. (Edin.), died in Sydney on March 8th in his 56th year. He went out to New South Wales in 1880, and was appointed superintendent of Royal Prince Alfred Hospital. In 1889 he was elected assistant physician to the hospital, and on the death of the late Dr. Chambers was appointed lecturer in obstetrics in the University of Sydney, a position which he held till the time of his death. He was awarded the gold medal for his thesis on hydatid disease in Australia presented for the degree of M.D. at the University of Edinburgh. He founded the Surgical Appliance Aid Society, and was a Director of both the Sydney and Royal Prince Alfred Hospitals. In 1893 he was elected an alderman of the City of Sydney, and was the leader of the Municipal Reform party. He was president of the Citizens' Vigilance Committee when the first epidemic of bubonic plague occurred in Sydney. He was elected Mayor of Sydney in 1901, the year in which King George V, then Duke of York, visited Australia, and this was the occasion of his receiving the honour of knighthood. For several years he was a prominent figure in politics. He was elected a member of the Legislative Assembly for Belmore in 1894,

and represented that constituency for six years. He was Vice-President of the Liberal Association and was a strong supporter of the Liberal party. In 1890 he married Miss Millard, who was at that time a nurse at the Prince Alfred Hospital. He is survived by his widow and one son, who is at present a medical student at the Sydney Medical School. The funeral service was held at St. James's Church, King Street, Sydney, and was attended by a large and representative gathering, and the interment took place at Waverley Cemetery.

A CAMPAIGN AGAINST SYPHILIS IN VICTORIA.

When the Australasian Medical Congress met in 1908 the following resolution was carried after prolonged discussion:

That syphilis is responsible for an enormous amount of damage to mankind, and that preventive and remedial measures directed against it are worthy of the utmost consideration.

The congress took place in Melbourne and public interest being aroused by the resolution, a deputation of the clergy waited on the Premier of Victoria and asked that some action should be taken. The Victorian Government later consulted its medical officer, Dr. Barnett Han, who advised that a comprehensive inquiry into the extent of the prevalence of venereal disease should be made by utilizing the Wassermann blood test. The details of the inquiry were arranged by Dr. Ham with the assistance of an advisory committee of medical practitioners, and of what followed an account is given in the April number of *Bedrock*, by Dr. James W. Barrett, C.M.G. For twelve months syphilis was made a compulsory notifiable disease within a radius of ten miles from the General Post Office, Melbourne. No names were given, but the age, sex, and clinical conditions were to be accompanied by a specimen of blood which was submitted to the Wassermann test, a special staff being employed for the work. The profession, on the whole, responded well to the appeal, although Dr. Barrett thinks that probably only a small proportion of cases were caught in the net. At the end of the year about 5,500 cases had been reported and tested. Of these, 3,167—or the equivalent of 0.5 per cent. of the population—were definitely proved to be syphilitic. Simultaneously two other lines of investigation were followed up. At the Victorian Eye and Ear Hospital, during a period of four months, 550 patients were submitted to the Wassermann test, without regard to the condition which had caused them to visit the hospital. Of the eye cases 13 per cent. were found to be syphilitic, and of the ear and throat cases 15.8, giving a total percentage for all the 550 of 13.3 per cent. At the same time, at the Children's Hospital, a pathologist examined the tissues of those who showed signs of syphilis, whilst the blood was independently examined, the results going to confirm the observations already cited. In addition, a little later on, the staff of the Women's Hospital informed the Government that, in their opinion, half of their operative work was due to gonorrhoea, that much sterility was due to that cause, and that if an attempt were to be made to suppress one venereal disease, it would be better in the public interest to deal with all such diseases. Finally, this first committee presented a report, which was handed by the Government to the daily press for publication, with the object of convincing the public that action for the suppression of venereal diseases was imperative.

The Victorian Government next appointed, under the presidency of Dr. Ham, a permanent advisory committee of medical men and women, which at once made it known that whilst its members would informally support any moral campaign, its business in a corporate capacity was to teach people how to prevent infection, and to render those infected no longer dangerous to others. This was to be done by open educational means. The aid of influential ladies was then sought, and the National Council of Women was informally approached. This council convened a meeting of its members, and after hearing statements of fact from medical women passed a resolution offering to co-operate with the Government in any reasonable steps which might be taken to diminish suffering, though it would oppose the passage of a Contagious Diseases Act unless it applied to men as well as to women.

The passage of no such Act, however, was really contemplated, for the committee itself considered that the problem could be better attacked by other means. Newspapers were asked to publish official and unexpurgated accounts of the steps taken, to call these diseases by their proper names, and in general to abandon the ostrich-like attitude usually adopted in regard to them. This request was agreed to, and such reports have since been regularly published.

The Victorian Government then decided to equip a ward in the Alfred Hospital and the Women's Hospital, at Melbourne, for the treatment of persons of any class suffering from venereal diseases, except prostitutes, for whom other arrangements exist, and the profession was asked to send such cases for indoor treatment. These wards are specially staffed, and the Government defrays the cost of maintenance. The object of this measure was to prevent further infection and to give opportunities for advice to the patients. The Government has further arranged with the University of Melbourne for the free application of the Wassermann test to 2,000 hospital cases a year, and to all other cases at a low rate of payment. Lastly, it is proposed to introduce a modification of an Act which is in force in a sister State of the Australian Commonwealth, so as to provide that any person sentenced to a term of imprisonment for any cause can, if found to be suffering from contagious venereal disease, be detained until he can be released without risk to others.

The campaign against venereal diseases in Victoria is, therefore, founded on the rational basis of a comprehensive investigation as to the extent of their distribution, followed up, when this has been ascertained, by a combined attack on medical lines. In this work Dr. Barrett says the clergy have been of great service. They have had the facts placed fairly before them and have opened their pulpits to medical men who are prepared to state the facts in a temperate manner. Dr. Barrett thinks the elimination of venereal disease by such measures quite possible, and if the problem is faced straightforwardly, not very difficult. It will be interesting to watch the results of the experiment which every lover of his kind must fervently hope will be successful.

British Guiana.

THE report of the Surgeon-General, Dr. Godfrey, for the year ending March 31st, 1912, has recently been issued.

Hospitals and Asylums.

The Public Hospital, George Town, has accommodation for 291 males and 245 females; 11,149 patients were admitted during the year, and there were 496 patients in hospital on April 1st, 1911. The number of out-patients treated was 44,958, being an increase of 3,050 on the previous year. There were 1,265 deaths; this gives a death-rate of 10.8 per cent. of the total number treated. The deaths amongst children under 5 years of age were 235, or 18.5 per cent. of the total deaths; this percentage is high, and is to a large extent due to malnutrition consequent on improper feeding. The gross cost (medical attendance excepted) was 50.17 cents, and the net cost 43.8 cents a head a day. In the Public Hospital at New Amsterdam 3,867 patients were treated and 27,372 out-patients, with a death-rate of 10.2 per cent. on the cases treated. In the three other hospitals in the colony 2,277 in-patients and 4,609 out-patients were treated. There were 469 male and 299 female lunatics under care in 1911, and 75 males and 56 females were admitted. In the Leper Asylum there were 306 males and 134 females; the percentage of mortality on the total number of inmates was 13.

Public Health.

Glycerinated lymph is imported for the use of the public vaccinators, to whom it is supplied free of charge; 1,284 successful vaccinations were performed during the year.

The colony was free from plague, yellow fever, and small-pox.

The death-rate of the colony was 31.7 per 1,000 as against 34.4 per 1,000 for the previous year; the birth-rate was 28.8 per 1,000 as against 27.5 for the previous year. Pneumonia still claims a large number of victims. At the Public Hospital, George Town, 388 cases were treated with a death-rate of 32.2 per cent. There was also a large increase in the number of cases of enteric fever treated at the Public Hospital—108 cases with 37 deaths, against 60 cases with 19 deaths for the previous year. The mortality amongst children under 1 year was 235 per 1,000 in 1910 and 229 per 1,000 in 1911. The mean rate for the past five years was 223 per 1,000. Tuberculosis was the cause of 7.3 per cent. of the total mortality of the colony; in the previous year the rate was 6.8 per cent.

The number of cases of malarial fever treated in the city hospitals shows a slight decrease. In 1906-07 it was 33,748, in 1910-11 they had fallen to 21,063, while the number of cases in 1911-12 had fallen to 15,169. The decrease is attributed to the antimalarial measures which have been adopted on the estates, consisting of the abolition of mosquito breeding grounds, including the screening of tanks, baths, and other receptacles for storing drinking water, removal from the yards of old tins, bottles, etc.; and keeping the drains and trenches clean and free of grass, so as to allow small fish to get at the mosquito larvae. Quinine was distributed free to the resident labourers, and especially to the children.

Ankylostomiasis.

In connexion with this disease preventive measures which have for some time been advocated by the department have been continued on the different sugar estates. These measures consist of (1) the erection of latrines; (2) the systematic examination of all newly arrived emigrants, and of all persons suffering from anaemia or who show the least sign of being infected with the parasite; (3) the treatment and constant observation of all known infected cases. The introduction every year of a large number of infected East Indian immigrants is a serious factor in preventing not only much better results but the eradication of the disease.

Bacteriological Department.

In connexion with the Government bacteriological department much important work was done during the year. Over 5,000 specimens were dealt with, and various reports were issued by the bacteriologists. The bacteriologists completed their investigations of the use of nastin in leprosy. Their conclusions were as follows: (1) That nastin has apparently very little beneficial effect on cases of leprosy; (2) a solution of benzol chloride in oil shows a higher percentage of improvement than nastin; (3) anaesthetic cases of leprosy run a definite course, after which the disease seems to die out, leaving the patient no longer infected.

Noguchi's Observations on Treponema Pallidum in the Brain in General Paralysis.—The Functions of the Cerebellum.—Cerebral Surgery.—The Results of Nephrectomy.—Communication of Syphilis to Rabbits.—A Diphtherial Vaccine.

THE hypothesis that general paralysis of the insane, tabes, and allied affections of the central nervous system are parasymphilitic or metasyphilitic in their relation to the original infection has been rudely shaken by Noguchi's latest researches.¹ This renowned investigator recently sent to Ehrlich in Frankfurt, and to Hoffmann—the lamented Schaudinn's co-worker at Bonn—some sections of the brain from cases of general paralysis stained by a modification of the Levaditi method. The spirochaete of syphilis is present in every section, and both Ehrlich and Hoffmann have testified to their conviction by demonstrating the specimens on the same evening at their

¹ BRITISH MEDICAL JOURNAL, March 1st, 1913, p. 461.

respective medical societies. The organisms were more numerous in the cortex cerebri than in the medulla, and the nerve cells infected by them presented obvious signs of degeneration. Noguchi stated that he had been successful in finding the spirochaete in 14 out of 71 cases of general paralysis of the insane—that is, in 20 per cent. of all examined. As a result of his findings he has suggested that the disease is a lues cerebri; but Hoffmann, in the absence of any histological evidence to this effect, said that he was unable to accept this view, although he fully acknowledges the great importance of the discovery, which was bound to modify present views on the nature of a whole series of hitherto so-called parasyphilitic affections. At the close of his demonstration at Frankfurt Professor Ehrlich brought forward the following interesting theory to explain the frequent and well-known occurrence of lucid intervals in the course of the disease: When the spirochaetes in the brain have reached a certain number an antibody is produced which fixes the majority of them, and thus produces an intermission of the symptoms. A relapse would follow as soon as the organisms that had escaped fixation had reproduced themselves in sufficient number. On similar lines the fact that only 20 per cent. of Noguchi's cases yielded a positive result might, he thought, be explained, for the examination probably took place at a time when the majority of the spirochaetes had been destroyed. It must, however, be admitted that the comparative inefficiency of all therapeutic measures in this dark chapter in the history of the disease had been rendered even still more difficult of explanation by this discovery. Ehrlich believed that, although it was very doubtful if it were possible to eradicate the spirochaete completely from the brain in these cases, energetic administrations of a combination of arsenical compounds should at least be attempted, and would offer the best chance of success. Hoffmann took the same view, and urged resort to such measures, especially in early cases. Their opinions, however, are not shared by Westphal (Bonn), who, writing in the *Berliner klinische Wochenschrift* after the Ehrlich-Hoffmann demonstrations, and in reply to their statements, gave a warning that for the present we are still bound to the old symptomatic treatment, and rather resignedly bade us beware of too much optimism in our immediate therapeutic outlook.

At a joint sitting in Berlin of the Surgical Society, the Society for Internal Medicine and Pediatrics, the Otolological and the Neurological Societies, an important discussion was held on the functions of the cerebellum. The anatomy and physiology of the subject were respectively represented by Professors Edinger of Frankfurt and Bárányi of Vienna, whose recent work on the relations of the vestibular apparatus to cerebellar function and localization in the cerebellar cortex has given rise to so much interest amongst neurologists. Dr. Rothmann, a member of the Berlin Physiological Society, read a paper in which, after referring to the recent cerebellar experiments on dogs, he stated that he had established the presence of special centres in the cerebellar hemispheres for certain attitudes of the fore and hind extremities respectively. Stimulated by Bárányi's work he had been able to demonstrate the existence of other centres in these, for the alteration of both fore and hind leg postures. Whilst single extremities were separately represented in the cortex of the cerebellar hemispheres, it was important to note that ablation experiments on the median lobe—the so-called vermis cerebelli—constantly produced co-ordinated disturbances of the trunk and extremities, disturbances of Edinger's "statotenus," a name devised by him to express the muscular and articular co-ordination (controlled through the labyrinth) which makes walking and standing possible. The functional importance of the cerebellum was further emphasized by the case of a woman aged 30, presented conjointly by Oppenheim and Krause. The former had diagnosed a tumour of the left cerebellar hemisphere, and Krause had operated and removed it from its place of origin in the roof of the fourth ventricle, whence it had grown upwards between the vermis and the left cerebellar hemisphere. It proved to be a lymphangio-sarcoma, and the interest and importance of the case lay in the fact that its ablation necessitated the removal of the roof, and the complete exposure of the floor of the fourth ventricle with its vital cardiac, respiratory, and vasomotor centres. The patient

had completely recovered, and during her convalescence and in the two years which have passed since the operation had presented no symptoms assignable to disturbances of any of these centres. The result is a veritable triumph of surgery, and disposes once and for all of the old conception that surgical interference in the neighbourhood of the fourth ventricle can hardly be countenanced.

At the annual Surgical Congress, held shortly after Easter in Berlin, a discussion on cerebral surgery was opened by Professor Eiselsberg, of Vienna, whose statistical results on 162 operated cases are of great interest. Of these, 69 had been diagnosed as cerebral tumours; 20 cases were trephined without discovering anything, and 7 cases subsequently died. The cerebral tumours were removed in 40 cases with a direct mortality of 9; of these deaths, 4 were due to meningitis, 3 to shock, and 1 to pneumonia. In 9 of the remaining 31 cases there was a recurrence with fatal termination in the course of a few months. Of the 22 remaining cases, 6 were improved by the operation, 3 remained *in statu quo*, and 9 were cured. He was able to publish better results from his operations on 16 cases of tumour of the hypophysis cerebri. There were 4 deaths and 12 cures or improvements. Of 33 cerebellar cases, 9 died after the first operation, and the tumour was found in only 8 cases. Among 17 cases of tumours in the acusticus region there were 10 deaths, which suggested thereby that this localization has the worst prognosis. Küttner of Breslau presented his results on 92 cases. The immediate mortality of the operations worked out at 30.5 per cent., and he gave the same percentage of successful results, a percentage which in the case of his private patients rises to 55 per cent., owing, probably, to earlier interference. The surgery of the spinal cord as reported from the Eiselsberg clinic showed a mortality of 30 out of 40 cases operated upon. Oppenheim called attention to the fact that in late years the prognosis of operations for the relief of cerebral tumours appeared to have become less favourable. He was of opinion that the indications for intervention had become too broad, and urged that in cases in which the diagnosis was at all uncertain surgical intervention should be withheld, as spontaneous cure or alleviation occasionally took place.

The result of nephrectomy was another subject discussed at this congress. It was introduced by Kümmell of Hamburg, who published the after-history of 386 cases. There was complete cure in 80 per cent. of the tuberculous cases, in 40 per cent. of the malignant tumours, 90 per cent. of the cases of pyonephrosis, and in 98 per cent. of those of hydronephrosis. The prognosis was excellent in unilateral traumatic cases, but it was the reverse for cases of nephritis. A great many nephrectomized patients died within the first year. Pregnancy and parturition did not seem to be attended by special risk in such individuals. In 17 such cases there was 1 of nephritis and 1 of miscarriage. The Berlin University clinic reported the results of 100 nephrectomies. Of these 9 died as a direct sequel to the operation, and 28 of intercurrent disease, and 60 are still living. Among 18 cases of malignant disease of the kidney there was no successful case; all had since died from recurrence or metastatic deposits.

A report of some recent experiments by Uhlenhuth and Mulzer on the infectivity of human syphilitic blood and other tissue fluids for the rabbit has been published in the *Berliner klinische Wochenschrift*. Blood from patients in various stages of the disease was injected into the testicles of rabbits, and although spirochaetes were never demonstrable by examination of the blood by the dark ground illumination, a typical syphilitic orchitis set in, on an average within sixty days of the injection, and in the syphilemata thus produced spirochaetes were frequently found. There were 19 inoculations from typical primary syphilis, and 16 positive results (84.2 per cent.) were obtained. Of 36 inoculations from patients with secondary syphilis the results were positive in 27 (75 per cent.). In 4 cases of late tertiary cases only 1 yielded a positive result. At the time of writing, these investigators were experimenting with milk, urine, semen, and sputum from infected cases, and had obtained positive results in a few, whereas all attempts to convey the disease from the cerebro-spinal fluid of recent syphilitics, tabetics, or paralytics had been fruitless. These results might, they thought, have considerable value clinically, in cases of

doubtful or latent syphilis, and might solve the vexed question of the meaning of a positive Wassermann reaction in cases of latent syphilis, where it was doubtful whether virulent syphilis was present in the organism and potential for harm, or whether the reaction was merely proof of a previous and possibly unobserved infection. Furthermore, these infected rabbits would afford most valuable material for the observation of the therapeutic results of various antisiphilitic remedies.

Dr. Hahu had some interesting reports to give at the last meeting of the Medical Congress at Wiesbaden on his results with Behring's new prophylactic vaccine for active immunization against diphtheria. The protection given by the old serum only lasts a few weeks, and repeated injections carry with them the danger of anaphylaxis. Neither of these disadvantages could be urged, he said, against the use of the vaccine, which is a bacterial emulsion, and confers an immunity to the disease lasting for several months. One or two injections are required, and the active protecting bodies are produced in from three to five weeks after inoculation.

PARIS.

Medical Students and Military Service.—Treponema in General Paralysis.—Radioscopy of the Fetus in Utero.—Oculo-cardiac Reflex.

The proposal to extend the term of compulsory military service, which is now two years, to three will of course apply to medical students. In order to obviate as far as possible delay in their studies, while at the same time enabling them to serve their country as other men do, the staffs of the Schools of Medicine and Pharmacy recommended the adoption of the following resolutions:

Every Frenchman must serve his country when physically fit for a period of three years.

The students of medicine and pharmacy must be under strict military discipline for the same prescribed period as other men.

As the Army Medical Corps is not so efficient as might be in time of peace, and would possibly be inefficient in time of war, it is thought wise that the medical students should serve their time in this corps in the twenty-three towns in which medical and pharmaceutical schools exist. By these means they will be enabled to serve as male nurses in the hospitals and at the same time continue their medical studies.

At a recent meeting of the Society of Biology, Drs. Levaditi, Marie, and Baukowski communicated the results of the examination of the brain in 24 cases of general paralysis. In 2 cases they found the *Treponema pallidum*, thus confirming the findings of Noguchi in such cases. The parasites were found in the cortex of the frontal lobes. In one patient, in whom the disease had lasted seven years, the *treponema* was found in the brain substance. With the ultra microscope the parasites were demonstrated to be alive and active. The results were confirmed by different methods of staining and also by the Chinese ink method.

At a recent meeting of the Medical Society of the Hospitals, Drs. Potoelki, Delherm, and Laquerrière reported results obtained by the radioscopy of the fetus *in utero*. Thanks to the perfect equipment of the department at the new Pitié Hospital, the radioscopic results obtained were useful and interesting; in one case the fetus was photographed as early as the fourth month. Before making such an examination, a purgative must be given and the bowels thoroughly cleared out. The patient lies on her back on the table and the bulb is placed under the table, the plate being fixed on the abdomen. During the exposure the patient must not breathe deeply, or the photograph will be blurred. The time of exposure found necessary was about two and a half seconds. By this means the various presentations could be made out and useful information obtained regarding the probability of a normal labour.

Drs. Loeper and Mongcot made a communication recently to the same society on the "oculo-cardiac" reflex. They found that the cardiac rhythm might be affected by pressure on the eyeballs. In the normal subject the pulse-rate decreased by some six beats a minute. In nervous disorders of the stomach the reflex was exaggerated when

the symptom-complex pointed to over-excitability of the pneumogastric nerves; it was diminished when the sympathetic was involved. In a case of ulcer of the lesser curvature of the stomach marked slowing of the pulse due to irritation of the vagus nerves was observed.

RESEARCH DEFENCE SOCIETY.

Special Appeal.

SIR,—We have carefully considered what course our society ought to pursue in view of the recent exposure of antivivisection. We are of opinion that the society ought to maintain for some years in London a place of its own where it could put before the public, every day and all day long, the truth about experiments on animals in this country. We have tried this method in temporary premises and have found it abundantly successful, and we now have the opportunity of acquiring a small ground floor and basement at a moderate rent in one of the more important thoroughfares admirably suited for our work. It is the plain duty of all who desire the prevention of disease among mankind and among animals to help "the man in the street" to arrive at a right judgement in this matter. We are convinced from experience that the best way of dealing with antivivisection methods at the present time is to maintain a bureau where all passers-by can read and learn for themselves the truth about experiments on animals, and can obtain pamphlets and leaflets and ask for further information.

We therefore appeal for generous contributions towards a special fund for this one purpose. It is the especial business of the Research Defence Society to dispel the ignorance, or worse than ignorance, which still exists as to the character and object of experiments on animals in this country; and the maintenance of a bureau in London would be of an immense advantage to the work of the Society. All donations and subscriptions should be sent to the Honorary Treasurer, 21, Ladbroke Square, London, W. All cheques should be crossed Messrs. Coutts and Co.—We are, etc.,

May 5th.

THE OPERATION OF "CHEILO TOMY."

SIR,—The operation of trimming an osteo-arthritis cornice from around a joint margin, described by Mr. Sampson Handley, has no doubt occurred to and been performed by others, who, however, have not been able to invent an appropriate name.

In November last I performed this operation for the removal of a ridge around the anterior, upper and lower margins of the head of the femur in a patient with coxa vara; I had previously, in common, I believe, with many others, performed similar operations on the great toe for hallux rigidus.

Mr. Handley, unfortunately, gives no details of his operative methods. The real difficulty in the case of the hip is the inaccessibility of the joint. In my case I was obliged to approach the joint by an anterior incision, and the chief difficulty was found to consist in the overhanging of a somewhat highly developed iliacus muscle. I opened the joint by a V-shaped incision, the apex of the V being at the root of the neck of the femur, the other ends of the incision being respectively immediately below the anterior inferior spine, and at the lowest accessible part of the acetabular margin. A flap of capsule was turned inwards, good exposure of the joint being obtained. The capsule was sutured with chromic gut, and I allowed the patient to stand without support after a fortnight.

Mr. Handley was fortunate in the amount of movement he obtained. In my case the amount of ligamentous and

muscular contraction has rendered it extremely difficult to maintain the increased mobility which the removal of the bone allowed.

It is to be hoped that Mr. Handley will give us further details of his operative methods; and skiagraphs of the patients after the operation, to illustrate the extent to which the head of the femur was trimmed, would also be of much interest.—I am, etc.,

London, W., May 5th.

R. C. ELMSLIE.

RHEUMATOID ARTHRITIS.

SIR,—Sir James Barr admits that no doubt "many organisms set up a monarticular or polyarticular arthritis," also that "certain cases of arthritis are associated with pyorrhoea alveolaris, etc., and have been cured by a vaccine," and then states these cases are "not what we designate rheumatoid arthritis." That is to say, he makes his assertion (that rheumatoid arthritis is simply due to "a mild chronic acidosis") more probable by arguing that any case of monarticular or polyarticular arthritis which can be proved to have a microbial origin is therefore not rheumatoid arthritis.

He defines the disease as "a low chronic polyarticular inflammation," etc., and proceeds to describe it. If an inflammation, why due to acidosis rather than microbe or toxin? Its characteristics being so similar to arthritis due to the latter causes, why refuse to admit any cause but "a chronic acidosis"? Decalcification of bone cannot be admitted as a proof, for it is a common accompaniment of any bone inflammation; skiagraphs show it in tubercle, after fractures in the bone-ends, in whitlow, in terminal phalanges, etc. In the first and third cases one would not suggest acidosis, and they are due to microbial infection.

The wasting of articular cartilages, occurring early and seen as a constant feature in skiagraphs of joints affected by rheumatoid arthritis, seems to me much more possibly due to inflammation caused by microbe or toxin; its irregularity in incidence, attacking cartilages, first one then another, and one part of a cartilage before another part, suggests a series of local infections rather than a general acidosis.

However, until either theory of causation—acidosis or microbe—is proved (which seems well nigh impossible) cases have to be treated empirically, and some will find lime most successful and some iodides. I believe in antibacterial treatment, and consider, with Dr. Luff, that iodides (or iodine) are valuable in causing arrest of the disease.

I am strongly of opinion that the influence of continued cold and wet as a predisposing cause is very great. This disease attacks women in such very different positions in society, who, curiously, give a history of exposure to cold and wet. My cases include, for example, among hospital out-patients, laundry workers, scrubbers, workers in aerated water factories, and, in private, hunting ladies who have had wet gloves on for long together, amateur lady gardeners, ladies who spend much time in washing laces, etc.; some very poor, some wealthy, yet all affected similarly, all with history of exposure to cold and wet.

In a paper on treatment locally by radiant heat and iodine ionization¹ I gave my early experience of the results of a treatment which is now largely used in fibrositis and rheumatoid arthritis. There is no doubt in my mind that, properly carried out, as a local treatment, it has a real value. By this combined method cases of fibrositis can as a rule be cured absolutely, with perseverance for a sufficient time; perhaps Dr. Craig has given ionization up too soon, and that accounts for his failure with it. Treatment daily for a month, or on alternate days for two months is not too long; of course, many cases are cured in a fortnight. "It is," as Dr. Reginald Morton, stated in his presidential address on arthritis this year in the Electro-Therapeutic Section of the Royal Society of Medicine, "not enough to get a few ions through the skin, we must endeavour to suffuse the joint with ions, and thus render the site unsuitable to the development of the organism" (he is referring to the

bacillus of Schuller as the possible cause of rheumatoid arthritis).—I am, etc.,

C. FRED BAILEY,

Brighton, April 25th.

Royal Sussex County Hospital.

SIR,—I have read with much interest Sir James Barr's address upon this subject, and also his reply to what appeared to me a very fair criticism of his views by Dr. Luff.

Rheumatoid arthritis is a disease in which I have long been interested, and I think I may claim to have some knowledge of the subject, for I have been attached to the Royal Mineral Water Hospital almost continuously for the past twenty-three years, and during that time I have, both there and in private practice, seen and treated a very large number of cases.

First, I would like to say that the more I see of this disease, the less inclined I am to dogmatize about it. A few years ago I made bold, in a paper I read before our local Branch, to assert that there was no such disease as rheumatoid arthritis, but that what we call by that name was in part a bastard form of rheumatism or of gout, and in part an infective arthritis the result of many and different organisms. Granting, however, that there is in this great group of joint affections an inner group which may fairly be regarded as a distinct disease, I will take Sir James Barr's definition of rheumatoid arthritis as applying to this inner group, so that there may be no doubt as to the class of cases I am considering. Sir James Barr defines this disease as "a low chronic polyarticular inflammation with frequent acute exacerbations," etc.¹ I would point out that this definition rests entirely upon clinical features, and I suggest that there should be stronger grounds for establishing rheumatoid arthritis as a distinct and separate disease.

Sir James's definition, of which I have only quoted the first sentence, gives an excellent picture of a typical case of rheumatoid arthritis, and he says that, even in its later stages, "it is still possible to cure the disease, though not the deformities," presumably by administering sufficient lime salts. "If, however," he goes on, "you keep hunting after the germ and its toxin, the patient as well as the joints will become a hopeless wreck."

Sir James dismisses the idea of rheumatoid arthritis being an infective disease as not worthy of consideration. But I have seen cases of undoubted infective origin, from which Sir James's own clinical picture of the disease might have been drawn—cases, for instance, due to pyorrhoea alveolaris and the gonococcus, cases which, according to Sir James, are only associated with these infections, but in which a cure followed the removal of the centre of infection and the use of the proper vaccines. I am more justified in asserting that these cases were due to infection than is Sir James Barr in claiming that they were caused by a decalcifying agent supposed to exist in the blood. Has Sir James Barr tested his theory as severely as he tells us that those who believe in an infective arthritis should test theirs? If in those cases of which I have spoken I had waited to apply the tests of Koch, of which he speaks, both I and my patients would still be waiting for the happy results which followed the, possibly unscientific, use of the remedy.

After all, what evidence is there that Sir James Barr's views as to the causation of this disease are correct? He claims that rheumatoid arthritis is due to a deficiency of lime salts in the body caused by a "mild chronic acidosis," but he does not tell us to what this "mild chronic acidosis" is due. He is met at the outset with the difficulty of explaining the later osteo-arthritic forms of the disease, for he says, "It is true that the deposit of lime salts may take place in the final stages of rheumatoid arthritis," and adds that this is "Nature's clumsy method of effecting a cure." In such a case as this, will Sir James Barr tell us when the change took place in the "mild chronic acidosis" so that the extracting of the lime salts from the bones and tissues ceased and their deposit began? Are we to understand from Sir James Barr that Nature, after extracting the lime salts and recognizing that she has gone rather too far, begins in a "clumsy method" to lay them down again? In his letter in the

¹ BRITISH MEDICAL JOURNAL, 1910, pp. 518, 519.

¹ BRITISH MEDICAL JOURNAL, D. 753.

JOURNAL of April 26th, he says if Dr. Luff has any doubt about the extraction of the lime salts from the bones he had better look at some skiagrams. I think Dr. Luff's doubts upon this point are well founded, and I suggest that something further than the evidence from skiagrams is needed to prove this point. During recent years I have taken a large number of skiagrams at the Royal Mineral Water Hospital, and the conclusion I have come to is that in rheumatoid arthritis, and in other diseases where the tissues are wasted, the bones are more translucent than is normal, but that no reliance in diagnosis could be based upon this method.

According to Sir James Barr, rheumatoid arthritis begins in the larger joints and spreads to the smaller. This is entirely contrary to my experience. It is in the smaller joints, especially of the hand, that it first begins, and often, as Dr. Kent Spender pointed out, in the joint and muscles of the thumb.

That it is more common among the poorer classes I quite allow, but it is also seen only too often among the well to do. If the poverty of the one causes the "mild chronic acidosis," does the plenty of the other do the same?

As to the dilated stomach which Sir James Barr says is "almost invariably" present, and the albuminuria of the later stages accompanying the effusion into the joints, my experience and his do not at all agree, though of course either of these conditions may be present in special cases.

With regard to diet, and remembering the "mild chronic acidosis," Sir James Barr said acid fruits and sugar are to be avoided, though a little marmalade may occasionally be allowed. I have always understood that in a pound of marmalade there is more than half a pound of sugar and the rest is made up of the acid fruits that he says should be avoided.

That cases of this disease are benefited by the drugs that Dr. Luff advises, and upon which Sir James Barr pours such contempt, I am sure, and I have equally no doubt that in Sir James's hands good results have followed the use of lime salts, though their administration is based upon a theory that he has not proved.—I am, etc.,

Bath, May 4th.

PRESTON KING, M.D.

SIR,—The general practitioner in these days of specialism is not credited with knowing much about anything, but if there is one class of ailments of which he may claim some knowledge, it is rheumatoid arthritis and "rheumatic" affections. An experience of thirty years' practice in health resorts, during which period I have seen scores of cases of rheumatoid arthritis proves that Sir James Barr's statement about potassium iodide, arsenic, etc., is correct. The most absolutely useless drug to administer in this disease (or any other disease) is guaiacol carbonate. It has no influence either in mitigating the symptoms or moderating the course of the disease. What it does is to upset the patient's digestion, causing continuous disgusting eructations and adding generally to already existing miseries. I have asked many brother practitioners if they have ever tried it, and they all answered in the negative, and a leading chemist recently told me that he did not even stock it, there being no demand for it. There are one or two useful remedies for rheumatoid arthritis, but guaiacol carbonate is not one of them.—I am, etc.,

Margate, April 27th.

PERCY NEWELL.

SIR,—Dr. Luff's tale of injured innocence will deceive no one. He should remember that when he enters the pages of the BRITISH MEDICAL JOURNAL he is not lecturing a class of students who must accept his statements as gospel truth. The only effect which his letter has on me is to make me take off the gloves, and I shall not put them on until I have not left him a leg to stand upon.

The rarefaction and even in extreme cases crumbling up of the ends of the bones; the thinning and erosion of the cartilages; the effusion into the joints; the swelling of the fibrous tissues; the wasting, weakness, and increased irritability of the muscles with frequent effusion into their fibrous sheaths; the neuralgia and neuritis in cases of rheumatoid arthritis afford no proof to Dr. Luff of the extraction of the lime salts from these respective tissues. What, then, does he imagine that these allied

phenomena prove? If he be not satisfied with the skiagrams which he sees, surely out of his thousands of cases he will have an opportunity now and again of making a *post-mortem* examination. He will then be able to examine these tissues both physically and chemically. When he can show me anything else except an acid which will extract the fixed lime from these tissues, I shall reconsider my position. In the meantime, while he is waiting for the autopsy, as something which will readily come within his cognizance, he might study the extraction of the lime salts from a carious tooth.

I have shown that with the phenomena which constitute rheumatoid arthritis there is an excessive excretion of lime and phosphates; that the normal amount of lime in the tissues is diminished, and in the case of the ends of the bones entering into the affected joints this is apparent to the most casual observer; that nothing will extract these fixed salts of lime but acids; and that again you can induce the phenomena of rheumatoid arthritis by the free administration of phosphoric acid and citric acid, especially when you cut the lime salts out of the diet. There is another experiment with the lime salts which I would advise Dr. Luff not to try; a person can readily and rapidly kill himself by converting the lime salts in the blood into the insoluble oxalate. I must apologize to the intelligence of your readers for this verbose explanation, which, however, seems to be necessary.

Dr. Luff apparently does not take kindly my prescription for sharpening his wits, but I can assure him there is nothing heroic or new, and the experiment is well worth trying. In 1910 I said, If you want to think quickly, speak quickly, and act quickly you had better not have too much lime in your nervous tissue.

I tried to lay my hands on a few of Dr. Luff's thousands of cases of rheumatoid arthritis, but I failed, as St. Mary's Hospital, which used to be considered a very important teaching centre, does not publish any statistics of the cases treated there. My countryman, George Bernard Shaw, says that every one should be required to prove the necessity for his existence at least every ten years, and I certainly think that a specialist who has had thousands of cases of rheumatoid arthritis under his care, and has got no "forrader" with the treatment than an abominable and useless mixture of guaiacol carbonate and potassium iodide is on his defence.

I may now in as serious an air as I am capable of assuming assure Dr. Luff that the best treatment for rheumatoid arthritis is to prevent its occurrence. This is the end of the second round and I am still smiling. By the time we get to the fifth or sixth round the subject of rheumatoid arthritis will be getting very interesting.—I am, etc.,

Liverpool, May 3rd.

JAMES BARR.

ADRENALIN IN CHLOROFORM ANAESTHESIA.

SIR,—The thanks of the profession, and of anaesthetists in particular, are due to Mr. Depree for publishing his fatality after the injection of solution of adrenalin chlorido during light chloroform anaesthesia.

The importance of the paper read by Dr. Goodman Levy at the annual meeting at Liverpool cannot be overestimated nor the results of his experiments too widely known in order that these fatalities may be avoided in the future. Clinical experience has unfortunately confirmed Dr. Levy's results, though against them it has been urged that adrenalin has been injected during light chloroform anaesthesia in hundreds of cases without any untoward results. The reason is, I think, obvious—namely, that danger only arises in cases where some small blood vessel has been pierced, and the solution has found its way directly into the blood stream, an accident that can neither be foreseen nor prevented.

Of all the excellent work done in the Anaesthetic Section at Liverpool, two papers made an indelible impression on me—the one referred to above, and a paper by Mr. R. E. Apperly, in which, *inter alia*, he brought forward experimental proof of the increased risk of fatal acidosis after the administration of chloroform in the presence of abdominal sepsis. This is a digression, but I refer to the matter in the hope that catastrophe from this source also may be avoided in the future.—I am, etc.,

London, W., April 26th.

G. A. H. BARTON.

SIR,—The thanks of all who are interested in the subject are due to Dr. Deprez for his report (p. 879) of a death under chloroform anaesthesia following the submucous injection of a solution of adrenalin. I may, perhaps, be permitted to refer to three points in connexion with the case that appear to me to be of interest from the point of view merely of those who are frequently called upon to perform the operation of submucous resection of the nasal septum: (1) I think a 1 in 1,000 solution of adrenalin is too concentrated for submucous injection. (2) A general anaesthetic is, I think, rarely required for the operation in question in a man aged 26. If a method such as that of Freer be employed, perfect local anaesthesia can be obtained. (3) I do not consider submucous injection of adrenalin solution necessary as a preliminary to submucous resection of the nasal septum under general, or, for that matter local, anaesthesia. I have always obtained satisfactory haemostasis by the surface application of strips of gauze soaked in a solution of cocaine (10 per cent.) in adrenalin chloride 1 in 1,000, for from three-quarters to one hour before the operation.—I am, etc.,

Liverpool, April 29th.

THOMAS GUTHRIE.

SYPHILIS AND CANCER OF THE TONGUE.

SIR,—Your correspondent, Dr. Aston Key, says Mr. Clement Lucas used to teach that the three great causes of cancer of the tongue were syphilis, smoking, and mercurial stomatitis. I think it was Alfred Fournier who first emphasized the importance of syphilis as a primary and tobacco as a secondary cause of lingual cancer. As regards mercurial stomatitis as an exciting cause of cancer of the tongue, the evidence is rather against this view, because under modern mercurial treatment stomatitis is, or should be, either mild or absent, while the incidence of cancer of the tongue apparently has not diminished. In this connexion it will be interesting to see whether this incidence will be diminished by salvarsan treatment. As regards the Wassermann reaction, perhaps it may be positive in the majority of cases of lingual cancer, but so is a history of syphilis; and, as Mr. Ryall wisely remarks, a positive Wassermann reaction does not exclude cancer. It might be added that it does not exclude any other disease. The main point is that Mr. Ryall, by his series of cases of cancer of the tongue, has confirmed the doctrine of Fournier—that syphilis is the primary cause of lingual cancer.—I am, etc.,

London, W., April 28th.

C. F. MARSHALL.

SIR,—I have to thank Mr. Ryall for his courteous reply to my letter relating to cancer of the tongue and the percentage of cases resulting from active syphilis.

Mr. Ryall indicates that, because a history of syphilis is obtainable in 82 per cent. of cases, syphilis is an active factor in the development of this condition, and in his lecture that "The thorough treatment of syphilis would well-nigh abolish cancer of the tongue." Mr. Ryall's argument very much resembles *post hoc, ergo propter hoc*. One might as truly say that because a patient has been taking mercury by the mouth for so many years therefore cancer of the tongue is due to the stomatitis associated with the too free ingestion of this metal. In this connexion one remembers the statement, due, I believe, to Mr. McDonagh, that on the Continent cancer of the tongue is rarer than in this country, where internal administration is much more largely used than the other methods of administering this metal.

The Wassermann reaction appears to have been tested in seven cases. I maintain, however, that if the reaction be applied to a large number of cases the percentage of cases in which one can definitely say that a syphilitic process plays an active part will be very much smaller.

In view of Mr. Ryall's association with the Lock Hospital as well as with the Cancer Hospital, is it not possible that an unduly large proportion of the tongue cases have first been met with at the former hospital?

Dr. Leitch has overcome the supersensitiveness of his complement by using two serums. I overcame that objection by testing the strength of complement previously, by testing each patient's serum on more than one occasion,

and by testing them along with serums which I had had under observation on many previous occasions.

It is useless to argue that one method is better than another unless the same serums are used in a large number of cases. I am anxious to investigate this question to the utmost, not only in cases of cancer of the tongue, but also by means of the Wassermann reaction to ascertain the relationship of syphilis to cancer in other situations. If Mr. Ryall will further extend his courtesy, I would suggest that the serums from such cases be exchanged between the two hospitals, that Dr. Leitch check my results by his methods, while I for my part will undertake to test most carefully any serums he will be good enough to forward to me.

I have the consent of Dr. Wild, the Chairman of the Medical Board at the Cancer Hospital in Manchester, to exchange serums for this purpose, and I can assure Mr. Ryall and Dr. Leitch that so far as I am concerned I am prepared to investigate the matter most fully.—I am, etc.,

Manchester, April 29th.

ARNOLD RENSHAW.

EVIDENCE FOR AND AGAINST THE USE OF TUBERCULIN.

SIR,—I should like to congratulate Dr. H. Batty Shaw on the prominent position which he assigns to Nature's efforts in the cure of tuberculosis. If therapeutics is ever to be raised to a satisfactory scientific level, the enthusiasm of the therapist must not be permitted to obscure this cardinal fact to which Dr. Shaw directs attention. The crucial experiment, however, of leaving Nature entirely alone in one series of cases and introducing this or that factor in other series cannot, for obvious reasons, be made. It seems to me, therefore, that in this, as in most other departments of medical work, the verdict must ultimately rest on a consensus of opinion of careful clinical workers of wide experience. To expect cures in the sense that the man in the street expects cures is, I think, to expect too much. The question is not so much whether we can make absolute cures in that sense, as whether we can to any real extent assist Nature's efforts, as distinguished from mere routine medicine.

After a number of years' constant use of tuberculin I am convinced clinically (1) that in the doses suggested by Sir Almroth Wright it does no harm in febrile cases; and (2) that in a very considerable percentage of such cases real good is effected. I may say that the pulmonary cases upon which I base my conclusion as to the value of tuberculin were not early cases, but I may add that they were not continuously febrile. In this latter class I have failed to do any perceptible good, possibly because here Nature fails to do her fair share of the work. I do not suggest that specific treatment in this type of case is absolutely valueless; all I say is that it has failed in my hands, even in cases in which some evidence of immunizing response (evidenced by improvement of appetites and general feeling of well-being) was obtainable. On the other hand, to any one who has treated a moderate number of gland cases, for example, with secondary infections by means of tuberculin and autogenous vaccines, the question as to the value of such treatment is no longer open. It rests with the sceptic either to remain a sceptic or convert himself by practical experience.

Dr. Shaw admits that "all vaccine treatment is capable of effecting a change in the aspects of disease." Whether that is strictly true as a general proposition, I am not prepared to say; but I think that there is now available a large amount of evidence that in many chronic ailments there is such a change and, if the method be properly employed, that the change is in a curative direction.

In conclusion, I should like to add that some individuals of a neurotic type seem to be abnormally sensitive to tuberculin, and for this reason, if for no other, any uniform or rule-of-thumb method of using it appears to me objectionable. Tuberculin is a remedy, I think, which demands the most careful consideration of each case on its merits.—I am, etc.,

J. STAVELY DICK,

Honorary Clinical Pathologist, Northern Hospital,
Manchester, May 6th.

EXISTING UNSATISFACTORY CONDITION OF THE SCHOOL MEDICAL SERVICE.

SIR,—May I be allowed to call attention to the existing unsatisfactory condition of the school medical service of this country, both as regards organization as well as regards the future prospects held out to those desirous of devoting their lives to this branch of medical work?

In the larger centres there are at present two systems of organization of the school medical service. Under the first the medical officer of health has also been created school medical officer; under the second, the two offices are held by different individuals, assistance being given under both systems by a staff of subordinate officers known as school medical inspectors. Considering the ever-increasing number of duties imposed on medical officers of health, it is practically impossible for them to take any active part in the work of the school medical department; moreover, the duties of a school medical officer include many matters, such as the diagnosis of mental deficiency and its educational treatment, the examination and educational treatment of the blind and deaf (both total and partial cases), and a host of other matters too numerous to mention, which find no place either in the training or experience of medical officers of health as such. Practically the whole of the work, therefore, passes into the hands of young and inexperienced assistants, who, in the absence of any hope of future advancement in the service, are constantly coming and going, and consequently never become really experts at their work.

The second system could undoubtedly be developed into a highly satisfactory and efficient national service, the school medical officers being selected from the more experienced and efficient of the subordinate officials—the school medical inspectors. By this means the placing of the control of the service in thoroughly experienced and competent hands would be assured.

There are at present twenty-two county boroughs where the school medical officer is an official distinct from the medical officer of health. There appears, however, to be a movement in many of these cases on the part of directors and secretaries of education to assume control over these school medical officers and their work, a movement which, if not promptly nipped in the bud, will result in the spectacle of laymen assuming direction of the work of medical departments.

The result under either system has been to make members of the service either assistants to the medical officer of health, or, in the case of those that are not, the penalty is incurred of being classed on the same level as regards both salary and status. Of the twenty-two county boroughs above referred to, in six instances only does the salary of the school medical officer amount to £500 a year; in most it appears to average about £300, and in some even less. The usual salary of a medical inspector is £250. These figures refer entirely to full-time appointments. A condition of things which holds out no better prospects to would-be entrants into the service than that of remaining for life in the position of assistants and drawing the salaries of assistants must not only prove a barrier against any further development of its efficiency, but must also inevitably result in its early and rapid deterioration.—I am, etc.,

ROBERT HUGHES, M.B.Lond., etc.,
School Medical Officer.

Stoke-on-Trent, May 3rd. County Borough of Stoke-on-Trent.

THE PARISH DOCTOR AND HIS OPPORTUNITY.

SIR,—I quite agree with Dr. Morley Lynch's letter of April 12th. It is high time that the Poor Law medical officers struck for better pay. Speaking generally, the pay is not half as good as that obtained from insurance work, which is generally considered inadequate.

In my own particular case, for a workhouse with some 270 inmates, with 125 sick beds in the infirmary, I am paid £60 a year and have to supply drugs, whereas 270 insured, healthy people at 8s. 6d. a head (being beyond the three-mile limit) would give £114 15s. My salary works out that for 7s. 6d. I have to drive six miles, see 125 sick persons, supply all drugs, etc., which is less than 1d. a patient and is just the cab fare to see the patients and back.

As district medical officer I am paid at the rate of 8d.

a visit with medicines, and I often have to drive 18 miles, as my district is a wide one.

Surely united action on our part would stop this sweating.—I am, etc.,

DUDLEY W. BOSWELL, M.D.,
Medical Officer, Mutford and Lotheringland Union
Lowestoft, April 29th. and Workhouse.

TRADE UNIONISM AND MEDICINE.

SIR,—The medical profession is to be congratulated on the success of the appeal in the case of Heard v. Pickthorne and others, and the case seems to show the necessity for the existence of a strong body, whose primary object shall be to watch over the position of medical men in relation to the Insurance Act. The British Medical Association found itself unable to advise action in the matter, but the National Medical Guild decided to take up the case, and, notwithstanding the reverse suffered in the King's Bench, pressed the matter to appeal, and has succeeded in maintaining due recognition of medical certificates, whether panel or non-panel.

Dr. Gordon Ward has ably shown reasons why the body to deal with Insurance Act questions should be registered as a trade union, notably in order to be free from liability to libel actions, and with a view to obtaining in the future representation in Parliament. In the meantime it would be well for the attention of the Divisions to be drawn to a proposal from Leicester which is on the agenda for the Representative Meeting. It is suggested that the Association should recognize a trade union, working apart from the Association but under its aegis. Such a body might very well be developed from a federation of trade unions already formed or in process of formation. It should aim at representing the whole profession, and, while demonstrating that it does not exist for the purpose of "smashing the Act," it should press forward a policy for restoring the freedom of the profession while safeguarding the interests of the community. As outlines of such a policy may I suggest the following?

1. Ultimate abolition of the "panel" in the future.
2. Fullest possible measure of "contracting out" in the present.
3. Abolition of lay control in medical matters.
4. Substitution of medical referees in place of the proposed medical inspectors.
5. Recognition of wage limit.
6. Curtailment of unnecessary forms and records.

In addition to advocating these improvements in the Act and Regulations, the trade union would take up any question of arbitrary action such as that involved in the case of Heard v. Pickthorne, and numerous other points that are bound to arise in the administration of an Act which makes great inroads on the freedom of the public.—I am, etc.,

London, W., May 5th.

CHAS. BUTTAR.

THE ETHICS OF ANTIVIVISECTION.

SIR,—You have done me the honour to devote five and a half columns of your issue of May 3rd to what I am sure you intend for an attack upon me. But as a considerable portion of your article consists of verbatim reproductions of what you describe flatteringly as my rhetoric, I can view with more complacency the remainder written by yourself.

I see no ground for your pleasantries in the matter of my phrase "ocular demonstration." In its place as I used it, the expression was felicitous and appropriate. I had already received auricular evidence of the presence of dogs in pain at the laboratory at University College; what I sought for was confirmation or confutation of that auricular evidence by the use of my eyes. If I had seen the dogs with the wounds in them after vivisections performed on them under Certificate B, and observed with my eyes that their howls were induced by those wounds, I should have come away, as I remarked, "armed with ocular demonstration that the dreadful cries which I had heard emanated from dogs whose dolorous clamour was caused by the wounds in their bodies inflicted on them under Certificate B."

I entirely appreciate why you imagine you can with safety represent me to your readers as an illiterate person. The absorption of many of them in the pursuit of some

confined corner of science precludes them from a study of the classics, which alone could make them capable of perceiving the absurdity of your efforts. In your concluding paragraph you recommend me "not to rush into print again with descriptions of delirious clamour caused by wounds inflicted under Certificate B, till he has had ocular demonstration that the dreadful cries do not emanate from untouched dogs protesting that they are debarred from following the instinct of Nature, 'red in tooth and claw.'" It is idle to upbraid me in this manner for not doing exactly what I endeavoured to do. You bid me go to the laboratory and see for myself. That is precisely what I did, and was refused admission.

As to the silly anonymous letter which you think it worth while to reproduce in facsimile across two whole pages of your JOURNAL, I know nothing about it. I myself, like most public men who advocate anything with firmness, am constantly subjected to every sort of filthy anonymous communication. But I do not publish them in the *Zoophilist*; if I did, I dare say my opponents would accuse me of writing them to myself for the purpose of creating prejudice. I make no such accusation against Professor Starling; I simply think him foolish to take any notice of such things.—I am, etc.,

London, S.W., May 6th.

STEPHEN COLERIDGE.

MEMORIAL TO MR. ETHERINGTON-SMITH.

SIR,—At a meeting held at St. Bartholomew's Hospital on May 1st it was decided to open a subscription list for a memorial to the late R. B. Etherington-Smith.

It is suggested that the memorial should take the form of providing and endowing separate sick quarters at St. Bartholomew's Hospital for the use of the medical, surgical, and resident staff, and of providing a suitable memorial at Cambridge.

Etherington-Smith's life-work was so bound up with St. Bartholomew's that this form of memorial will doubtless commend itself not only to his colleagues in the profession, but also to the larger body of men who knew and admired him as an oarsman and friend.

The scheme has received the cordial approval of his family.

Subscriptions will be received by the Honorary Treasurer, Dr. T. W. Shore, Dean of the Medical School, St. Bartholomew's Hospital, E.C., or they may be sent to the "Etherington-Smith Memorial Fund" at the Bank of England.

(Signed) ANTHONY A. BOWLBY, C.M.G., Senior Surgeon to St. Bartholomew's Hospital.
W. B. CLOSE, C.U.B.C.
G. ACORN DAVIS, Acting Treasurer, St. Bartholomew's Hospital.
J. H. GIBBON, C.U.B.C.
HARCOURT GOLD, O.U.B.C.
W. P. HERRINGHAM, Senior Physician to St. Bartholomew's Hospital.
R. C. LEHMANN, C.U.B.C., Secretary to the Fund.
HOWARD MARSH, Professor of Surgery, Cambridge University.
S. D. MUTTEBURY, C.U.B.C.
GUY NICKALLS, O.U.B.C.
G. D. REWE, O.U.B.C.
H. T. STEWARD, Leander R.C.

THE eighty-fifth annual meeting of German scientists and medical practitioners will be held at Vienna in September (21st to 26th). Among the communications to the medical section will be one by Professor von Behring on the prophylaxis of diphtheria.

A NUMBER of medical charities benefit under the will of the late Colonel Frank Shuttleworth, of Bedford and Lincoln, among them being Lincoln County Hospital, £2,000; Lincoln Dispensary, £500; Bedford County Hospital, £3,000; Bedford Dispensary, £500; Middlesex Hospital, £1,000; the Cancer Hospital, £1,000; and the Great Northern Central Hospital, £500.

THE Corbett Hospital for Children, Amblecott, near Stourbridge, in Worcestershire, is the recipient of a sum of £5,000 under the will of the late Mr. Edward Webb. The sum is bequeathed in memory of the testator's wife, and is to be used for the building and equipment of a new wing.

Obituary.

JOHN CHARLES THOROWGOOD, M.D., F.R.C.P.,
CONSULTING PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF
THE CHEST.

THERE passed away last month at Bognor, in the person of Dr. J. C. Thorowgood, a fine representative of the transitional period of medicine and a physician who at one time played a very active part in the professional life of London. He had been living at Bognor since his retirement from practice some twelve years ago, and died in the eighty-first year of his age, on April 25th, after a very short illness.

Dr. Thorowgood was the son of a schoolmaster, and received his general education at his father's school at Totteridge, in Hertfordshire, then quite a small village. He completed it in the Art Faculty of University College, where he was a prizeman both in Latin and Greek. Subsequently he joined its medical faculty, and evinced therein the same aptitude and industry that he had displayed as a student in arts. Eriksen, who was then the professor of surgery, awarded him the silver medal, and subsequently the Fellowes medal for clinical work also fell to his lot. He fared equally well at the hands of the London University examiners, winning gold medals both in chemistry and medicine at his M.B. examinations. These he completed in 1855, and became about the same time L.S.A. A year previously he had been admitted M.R.C.S. Eng., and in 1857 graduated M.D. Lond. Meantime he rounded off his work by acting as assistant to his sister's husband, who was in general practice in the provinces, and then, after spending some time in the South of France in charge of a patient, returned to London to start a career as a consultant.

His first success in this direction was his appointment as physician to the Royal General Dispensary in Bartholomew Close, an ancient institution which has been the early training ground of many distinguished men, and where he had as colleague the late Dr. James Andrew, afterwards senior physician of St. Bartholomew's Hospital. Next came his appointment to the assistant staff of the City of London Hospital for Diseases of the Chest, a post for which he qualified by becoming a Member of the Royal College of Physicians. Here, too, he had James Andrew as a colleague, for there were two vacancies for an assistant physician at this hospital, and both received appointment on the same day. This appointment assured Thorowgood's success, and little by little he attained the prominence in the medical life of London to which his personal qualities and professional abilities certainly entitled him.

His connexion with the City of London Hospital lasted to the end of his life, for on his retirement from the post of senior physician under the age clause in 1885 he was elected consulting physician. His connexion with the West London Hospital, where he was physician, was almost equally long. He also served the Middlesex Hospital, though not as a member of its staff. His work there lay in the school, where in 1872 he succeeded Sir Lauder Brunton as lecturer on materia medica and therapeutics, and in the same year delivered the introductory address at the beginning of the winter session.

To the Fellowship of the College of Physicians he was elected in 1874, and during the last year of his life in London he served on its Council. The Medical Society of London was also indebted to him, for he acted as one of its honorary secretaries for some years, and at the time when Sir Erasmus Wilson was president delivered the Lettsomian Lecture. He was also one of its vice-presidents. More important still, perhaps, was the work that Dr. Thorowgood did at the Society of Apothecaries. He became one of its examiners at an early date, and for four years was chairman of its board of examiners. He was also a member of the Society and filled the office of Warden. In the natural course he would have served a year as Master, but when the time came the condition of his health necessitated his refusal of the honour. Other offices which he held were those of consulting physician to the Royal National Hospital for Consumption and the presidency of the West Kent Medico-Chirurgical Society.

Unlike many of his contemporaries, Thorowgood did a good deal of writing on professional subjects. Apart from contributions to the medical journals he published several

books. His *Notes on Asthma*, which contained a good deal of the material on which his Lettsomian Lecture was based, went through three editions; while two appeared of a book on *materia medica* which he wrote for students. Curiously enough, the least successful of his publications was the one which in many respects is of the most permanent interest; this was a book entitled, *The Climatic Treatment of Consumption*; it was written by him quite early in his career and put forth views which are in consonance with present conceptions. He combated the notion that phthisical patients should be sent to mild climates, and argued that, on the contrary, bracing resorts must be best for them, since they would have a tonic influence and improve digestion and the constitutional strength of the patient.

Dr. Thorowgood married in 1863 Miss Ashwin, of Bourton-on-the-Water, Gloucestershire, by whom he was predeceased, but he leaves several daughters.

PROFESSOR JACCOUD,

SECRETARY OF THE FRENCH ACADEMY OF MEDICINE.

DR. S. JACCOUD, Perpetual Secretary of the Academy of Medicine and former Professor of Clinical Medicine in the Paris Faculty, has recently died at the age of 83. He was born in Geneva and received his literary education in that city. He went to Paris in 1849 with only a few letters of introduction, and at first, while studying medicine, he had to make his living by giving lessons in literature and music. He also put his talent as a violinist to use in the orchestras of the Odéon, the Gymnase, and the opera balls. Later he taught anatomy. He had a brilliant career as a student. He gained the coveted post of *interne*, coming out first on the list. Four years later he was awarded the gold medal of the *internat*. He took his doctor's degree in 1860 with a thesis on the conditions producing albuminuria. He won the appointment of physician to the hospitals in 1862 at his first trial, again being first among the candidates; the following year he became *agrégé*, also at the first trial, and again with the first place. These successes are said to be almost unparalleled. His thesis for the position of *agrégé* was written and printed in less than a fortnight; it shows a deep knowledge of the history of medicine, whilst the point of view is entirely modern. In 1876 he became professor of internal pathology. In 1883, after the death of Lasègue, he was at his own wish transferred to the chair of clinical medicine at the Pitié Hospital, where he remained during the rest of his teaching career. Jacoud was elected a member of the Académie de Médecine in 1877; he was president in 1898, and became its perpetual secretary in 1901. Among his works are an annotated translation of *Graves's Clinical Medicine* (1862); *Paralysis and Atony of Movement* (1864); *A Treatise of Medical Pathology* in two volumes (1870-71), the last (seventh) edition in three volumes appeared in 1882; clinical lectures delivered at the Charité Hospital (1867); and the *Lariboisière* (1873); a monograph on the curability and treatment of pulmonary phthisis (1881); and *La clinique médicale de l'hôpital de la Pitié* (vol. iv, 1883-1888). To foreigners his name is perhaps best known in connexion with the *Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques* (1864-1886), a medical encyclopaedia in many volumes published under his direction, to which he contributed a number of articles dealing with albuminuria, diabetes, endocarditis, and other subjects. He had a wide acquaintance with foreign medical literature and was thus able to put before his pupils and readers very complete accounts of the actual state of medical science. His vast knowledge, together with the precision and clearness of his ideas, and his great gift of expression, made him a first-rate teacher. In his work he opened up new paths and was looked upon as one of the most advanced among his contemporaries. He scorned popularity and never stooped to the mean arts by which it is acquired. He was a man of austere integrity, and when his conscience showed him his duty he followed its dictates with a firmness which often seemed opposed to his own interests. His independence made him hold himself aloof from all coteries. Those admitted to his intimacy knew the goodness of his heart and the affectionate sympathy which he could display when the occasion called for it. The dignified aloofness in which he lived, however, served to hide those amiable qualities.

E. J. W. CARRUTHERS, M.D. EDIN.,

CONGLETON.

THE death of Dr. Edward John Walter Carruthers, of Congleton, which was briefly noted in our columns at the beginning of last month, has removed from the ranks of medicine at an early age a man who had the gift of winning the warm affection, as well as the respect, of those who came in contact with him. He received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1891, proceeding to the M.D. some four years later. In the meantime he had obtained a wide knowledge of his profession by institutional work, among the posts that he filled being those of senior resident medical officer to the Hospital for Sick Children at Pendlebury, and resident physician to the Royal Infirmary at Edinburgh. For a considerable period also he assisted his father-in-law in the conduct of the Wye House Asylum at Buxton. At Congleton he settled in practice some sixteen or seventeen years ago as successor to the late Dr. Moss, and at the time of his death, which occurred in the 46th year of his age, he was honorary surgeon to the Congleton Cottage Hospital, and medical officer to the Congleton Union. Some of his characteristics, both as a practitioner and as a man, are well brought out in a letter from another medical man who at one time served him as an assistant. After expression of his sympathy with Dr. Carruthers's family and of his own sense of loss, and some references to Dr. Carruthers's skill as a practitioner and the position he held among his fellows, he writes as follows:

My sojourn with him was the happiest time of my life. He was a splendid man for a young graduate to go to, and many of his assistants must, like the writer, have a lot to thank him for. One got well grounded not only in diagnosis and treatment, but in the general routine of practice. He taught you things that the textbooks do not and cannot teach. He was particularly strong on the duties of a medical man towards his brother practitioners and on questions of medical etiquette, and for many acts of kindness towards myself and my family my heart is truly grateful to him.

Dr. Carruthers, in short, was one of those general practitioners who form the real backbone of the profession, bringing to their work as they do not alone up-to-date book knowledge, but clinical experience and the power of correct observation and the influence of high ideals. As might be expected of such a man, Dr. Carruthers was a staunch upholder of the British Medical Association, and held the view that every young man should join its ranks as soon as he is entitled to do so. Dr. Carruthers was married, and is survived by his wife and several children.

WE regret to announce the sudden death of Dr. ROBERT HOPETON BROWNE, Medical Superintendent Officer of Health for the Rathmines Township, on April 29th. His father was one of the first Township Commissioners elected after the incorporation of the district in 1847, and his brother, the late Mr. Vere Ward Browne, was for many years a member of that body. Dr. Browne was educated at Trinity College, and as a student of the Royal City of Dublin Hospital gained the Purser Studentship. He took the degree of M.B. in 1868, and that of M.D. in 1871. For some time he studied in Paris. He took the Fellowship of the Royal College of Surgeons in Ireland in 1876. He early gained a considerable practice, and was elected to the Board of Commissioners of Rathmines. He relinquished this position when he became medical officer of the dispensary. He was appointed medical superintendent officer of health in January, 1898, and discharged the duties of that post with conspicuous ability. Though for the last twelve months he had been in bad health, it was only recently that his illness took a serious turn. He was an enthusiastic golfer and vice-president of the Rathfarnham Club. At a special meeting of the Rathmines Council, the following resolution was passed:

That this meeting has heard with the deepest regret of the death of Dr. Browne, with whom we have been associated so long as medical superintendent of health. The loss of one who has been for so many years closely associated with everything tending to the advancement of the township is keenly felt by us, and we desire to express our deep sympathy with Mrs. Browne and the other members of his family.

THE announcement of the sudden death of Dr. MacCORMAC was received in Belfast with much regret, and great sympathy is felt with his widow and family. Dr. MacCormac was in his usual health and was taking a quiet walk after dinner on April 20th on one of the country roads in the neighbourhood of the city; when opposite the gates of the Forster Green Consumptive Sanatorium he became suddenly ill and fell; the resident physician was immediately summoned and rendered such aid as the emergency demanded, but death supervened. Dr. MacCormac, who took the diplomas of L.R.C.P. and S. Edin. in 1867, graduated M.D. Durh. in 1885. After a short residence in Belfast, he practised for a time in England, but returned to Belfast nearly twenty-five years ago, and specialized in nervous diseases. He was mainly instrumental in starting the Hospital for Diseases of the Nervous System, Belfast; at the same time he opened a private institution for the same class of disease. He made several contributions to the journals and medical societies.

Medico-Legal.

MEDICAL CERTIFICATES UNDER THE INSURANCE ACT.

THE case, *Heard v. Pickthorne*, which came before the Court of Appeal on May 1st, raised the question whether a friendly society is entitled to refuse payment of a claim on its State sick fund unless the certificate in support of the claim is signed by a medical man on the panel, and the three Judges of Appeal unanimously decided in the negative. In other words, they ruled that a certificate signed by a non-panel medical man is valid for the purposes of the National Insurance Act. The facts in the case had already been considered on two occasions by judges of the High Court, and the hearing of the appeal was expedited in view of the public importance of the matter. For the same reason the proceedings were reported in detail by the *Times* and the *Morning Post*. We derive the following summary of matters from the former paper:

The plaintiff in the original action—that is to say, the appellant in the appeal action—is a member of a London branch of the Ancient Order of Foresters, and brought an action against the administrators of that society on behalf of himself and all other members other than the administrators on the following ground: Having been ill, he claimed an allowance out of the sick fund, presenting a certificate signed by his own medical man, but the defendants declined to pay it unless the plaintiff obtained and presented a certificate of sickness from a doctor on the panel. This refusal was based on a resolution of the society which affected all its members, and which resulted from a discussion on the question of what medical certificate should be accepted to place members on the State sick fund. The resolution was "That in every instance a certificate from a panel doctor must be sent." The plaintiff, believing that this resolution and the consequent refusal of his claim was illegal, *ultra vires*, and not enforceable, applied in the first instance to Mr. Justice Bucknill for an interim injunction against the defendants. This being refused he made a request for a declaration to this effect in an action before Mr. Justice Bailhache. The defendants met it by asserting that the resolution was not illegal and that the dispute as to the granting of the sick pay ought to be decided by arbitration under Section 67 of the National Insurance Act. Mr. Justice Bailhache dismissed the action with costs. Thereon the appeal followed.

After setting forth the general facts of the case, counsel for the plaintiff indicated the following as the questions to be determined: Was the resolution passed by the society illegal? If any illegality existed, could it be restrained by a court of law, or was the dispute between the plaintiff and the defendants one which ought to be settled by arbitration? He then set forth the law in regard to friendly societies. If they made rules or amended rules, they must register such rules or amendments with the Registrar of Friendly Societies. There was a penalty for not registering rules, but no penalty for not registering amendments. The rules of this particular society had been approved by the Insurance Commissioners, and one of them disentitled a member to sickness benefit unless he sent to the secretary of the society a declaration of incapacity for work in the form required and a medical certificate or other evidence of incapacity and the cause thereof. The society now purported to have amended that rule by the resolution in question, and this, counsel maintained, was illegal. The resolution imposed upon an insured person an obligation which was not an obligation allowed by the Insurance Act or by the rules. He submitted that an insured person might offer any sort of proof of sickness that he thought fit. No doubt in any particular case the society could say that the proof offered was not sufficient, but it had no right to lay down beforehand any arbitrary rule imposing a condition which was not allowed by

the Act. Nor was the dispute one which should go to arbitration. There was a clear distinction between cases in which dispute arose as to the internal management of a society and those in which a member complained that the society had done something illegal or unconstitutional. The former cases the court ruled had to be matters for arbitration, but in respect of the latter it had allowed injunctions to be issued.

Counsel for the defendants said that the resolution was passed on the day on which the benefits of the Act came into operation, and was passed in consequence of a warning which the society had received from the Insurance Commissioners to the effect that they must not make out of the State funds any payments which were not authorized by the Act or by their rules. If they did so they would be surcharged on audit. The resolution consequently adopted was not a new rule, merely an instruction to an officer of the society. It contained nothing *ultra vires*, and any dispute regarding it was a dispute under Section 67 of the Insurance Act.

Junior counsel on both sides having further argued the matter, Lord Justice Vaughan Williams said that by the resolution in question the society had said that the only proof it would accept of the incapacity for work on the part of an insured person was a certificate signed by a panel doctor. In his opinion the society had no right to limit beforehand in such way the kind of evidence it would accept. In each case the society was bound, he thought, to consider the evidence of sickness offered, whether it was the certificate of a panel doctor or the certificate of any other qualified medical man, or whether, indeed, it was any other sufficient evidence of sickness. It was not disputed that there were cases in which an injunction might properly be obtained against a society, or that there were other cases in which an injunction ought not to be granted, the complainant being left to resort to arbitration; but the present case seemed to him one in which a friendly society was interfering with the rights of those entitled to its benefits, and he thought the court had the right and duty to prevent such *ultra vires* action. The matter at issue was whether it was a legal condition to the right of an insured person to receive sickness benefit that he should produce evidence of a particular kind—namely, the certificate of a panel doctor—or whether it was sufficient for him to produce any other kind of medical certificate. In his opinion such a question ought to be decided not by arbitration, but in the courts. He held that the resolution was illegal and *ultra vires*, and that the plaintiff was entitled to a declaration to that effect and to an injunction with costs both in the Appeal Court and in the court below.

The other two Judges of Appeal delivered judgement on the same effect, Lord Justice Hamilton, according to the *Morning Post*, stating that it seemed to him that the resolution was an attempted evasion of the rights of the plaintiff to get his compensation under the Act, and Mr. Justice Bray stating that the resolution was not, as was suggested, a mere instruction, but a new rule which sought to impose a very grave restriction on a member of the society in regard to the rights given him by the Act.

Earlier in the case Lord Justice Vaughan Williams asked counsel for the defendants whether it did not seem to him that it was contrary to natural justice that a man who was ill and who was attended by his own duly qualified doctor should nevertheless have to get a certificate from a panel doctor before he was paid sickness benefit.

The Services.

ROYAL ARMY MEDICAL CORPS.

THE King has granted permission to Captain William Byam, R.A.M.C., to accept and wear the Imperial Ottoman Order of the Medjidich (Fourth Class) conferred upon him by the Khedive of Egypt in recognition of valuable services rendered.

INSURANCE ACT: CONTRIBUTIONS OF MEMBERS OF THE TERRITORIAL FORCE.

A MEMORIAL signed by some 150 members of the House of Commons has been presented to the Prime Minister and Colonel Seely suggesting that as an encouragement and as a help to members of the Territorial Force, the contributions required of them under the Insurance Act should be defrayed by the State. Colonel Seely, on receipt of the memorial, stated that the Government would give careful consideration to the proposal, and that it would be discussed with the Treasury authorities.

THE TRAINING OF THE SPECIAL RESERVE AND EPIDEMICS.

AT the meeting of the county council of Inverness, held on May 1st, Dr. Jno. Macdonald, the chief medical officer of health, called attention to a statement in a report by the district medical officer in North Uist to the effect that serious loss was occasioned through school closures and in other ways in the island by the introduction of diseases annually by the men attending the special reserve training, and suggesting that when an epidemic occurred in the battalion the men should be kept in quarantine long enough to make it certain that none of them would be carriers of infection. Dr. Macdonald suggested that in conjunction with Ross-shire a representation should be made

to the War Office regarding these matters. Cameron of Lochiel, who commands the Special Reserve Battalion of the Cameron Highlanders, and is a member of the county council, said that it would require a special Act of Parliament and a supplementary vote in the House of Commons to keep the battalion one day longer in camp than the date allowed for the closing of the training. He did not believe the county council would pass any resolution until the army medical authorities had an opportunity of replying to the accusations in the report, and suggested that the statement should be sent to the Principal Medical Officer of the Scottish Command for his remarks. This suggestion was adopted.

SIXTH LONDON FIELD AMBULANCE, R.A.M.C.(T.F.), SECOND LONDON DIVISION.

Two vacancies exist for a senior and junior officer in this unit. Applications should be addressed to the Officer Commanding, Duke of York's Head Quarters, Chelsea, S.W. Hours and days for attendance are so arranged that interference with private work is reduced to a minimum. Transfers from other corps can be arranged if deemed expedient. The vacancy for a junior officer would suit a member of the junior staff of a hospital, or a young medical man who is practising, or intends to practise, in the London District.

HIGHLAND FIELD MEDICAL UNITS.

It is now officially notified that the three Highland Division Field Medical Units, the 1st and 2nd Field Ambulances from Aberdeen and the 3rd Field Ambulance from Dundee, will undergo their annual training in camp at Boards, near Stirling.

INDIAN MEDICAL SERVICE.

THE Government of India has sanctioned a limited number of officers of the Indian Medical Service, not exceeding four in a year, being attached, while on leave in the United Kingdom, to the staff for periods of one month each for the purpose of undergoing a course of training in medical work in the field and medical organization generally.

Universities and Colleges.

UNIVERSITY OF LONDON.

FACULTY OF MEDICINE.

At a meeting of the Faculty of Medicine, held at the University of London on Friday, May 2nd, Sir Alfred Pearce Gould, Dean of the Faculty, in the chair, Mr. H. J. Waring, M.S., was appointed to represent the Faculty on the Senate for the period 1913-17.

The constitution of the Board of the Faculty was approved as follows: Sir Alfred Pearce Gould, *Dean*; Dr. C. Wall, *Secretary*; Dr. Herringham, Professor Crossley, Dr. Eason, Sir Rickman Godlee, Dr. Graham Little, Dr. Senter, Professor J. H. Thomson, Professor Waller, Mr. H. J. Waring (members of the Faculty who are also members of the Senate). The chairmen of the following boards of studies: Preliminary Medical Studies, Professor Womack; Intermediate Medical Studies, Professor Halliburton; Advanced Medical Studies, Sir Francis Champneys; Hygiene and Public Health, Professor Kenwood; Physiology, Dr. Pembrey; Human Anatomy and Morphology, Professor Wright. Professor J. P. Hill and Mr. J. A. Gardner, nominated by the Board of Preliminary Medical Studies; Professor Parsons and another, nominated by the Board of Intermediate Studies; Dr. H. D. Rolleston, Mr. Stanley Boyd, Dr. Herbert Tilley, and Mr. S. G. Shattock, nominated by the Board of Advanced Medical Studies; and the following members appointed by the Faculty: Mr. Raymond Johnson, Mr. A. Macphail, Mrs. Scharlieb, Dr. T. W. Shore, Dr. T. G. Stevens, and Dr. H. Tooth.

The sum of £100 for advanced lectures in the Faculty of Medicine was allocated in the proportion of £55 to the Board of Intermediate Medical Studies, and £65 to the Board of Advanced Medical Studies.

The Faculty requested the Board of the Faculty to consider the position of the Faculty of Medicine in view of the publication of the report of the Royal Commission on the University of London, and to present a report.

KING'S COLLEGE.

The course of four lectures on the physiology of absorption to be given by Professor T. G. Brodie, F.R.S., will begin on May 28th, at 4.50 p.m., instead of May 21st, as originally proposed. The lectures, which will be continued on the three following Wednesdays at the same hour, are free to all medical students in London medical schools, to internal students of the University, and to medical men on presentation of their card.

VICTORIA UNIVERSITY OF MANCHESTER.

Appointments.

THE following appointments have been made: Dr. C. P. Lapage to be Lecturer on Diseases of Children, Dr. G. H. Lancashire to be Lecturer on Skin Diseases, and Dr. N. William Ingalls to be a Research Fellow in Anatomy.

UNIVERSITY OF DURHAM.

Installation of Chancellor.

THE Duke of Northumberland was on May 3rd installed Chancellor of the University by Sir George Hare Philipson, Vice-Chancellor.

After the newly elected Chancellor had given a short address a number of honorary degrees were conferred, including that of D.Sc., upon Sir Archibald Geikie, President of the Royal Society; Sir William Ramsay, K.C.B.; Sir T. Clifford Allbutt, K.C.B., Regius Professor of Physic at Cambridge; Sir J. A. Ewing, Director of Naval Education; Sir William Crookes, O.M.; Sir J. J. Thomson, O.M., Cavendish Professor of Experimental Physics at Cambridge; and Dr. E. B. Poulton, Hops Professor of Zoology at Oxford.

Afterwards a thanksgiving service was held in the cathedral, at which the Dean of Durham preached a sermon, in the course of which he said that the university owed its origin largely to Van Mildert, who, when Bishop of Durham, conceived the notion of appropriating some of the revenue of the cathedral for the establishment of a university in the north of England, where the first signs of the immense industrial development, which had since taken place, were becoming apparent. Durham thus shared with Oxford and Cambridge an ecclesiastical origin.

UNIVERSITY OF GLASGOW.

THE following were among the degrees conferred at the spring graduation ceremony:

D.Sc.—Williamina Abel, M.D. Aberd.; G. H. Edington, M.D. Glas.
M.D.—J. Taylor, A. R. Carmichael, J. H. Douglas.
M.B., C.M.—A. P. Aitken.

M.B., CH.B.—J. S. K. Boyd, H. S. Banks, W. C. Davidson, W. M. Howells, F. M. Robertson, R. A. Barlow, Cecilia S. T. Anderson, Janet R. Anderson, W. L. Anderson, J. L. Brownlie, A. G. Buchanan, W. L. Cassells, J. Connel, R. Craig, W. E. Elliot, J. Fraser, W. Fraser, A. Glen, J. L. Gregory, J. M. Grier, D. M. Hunter, Jane K. M. Hunter, J. F. Hutton, T. P. Inglis, C. J. Kirk, Mary A. Kirk, P. A. McCallum, J. M'Ghie, Margaret H. M'Killip, M. H. MacLeod, J. H. Magoveny, W. E. Matland, W. Montgomery, J. M. R. Philip, Sarah A. J. Radkin, A. W. Russell, J. J. Sinclair, N. I. Sinclair, J. A. Smith, R. A. Steven, G. Taylor, E. G. Y. Thom, A. Walker, J. C. Watt, J. Whiteside, A. M. Young.

[†] With honours.

[‡] With commendation.

On the same occasion the following prizes were also handed to the winners of the competitions involved: The Arnott Prize for Physiological Physics, J. W. Moffat; the Bellahouston gold medals for eminent merit in a thesis, J. S. Dunn, W. Gilmour, Ivy McKenzie; the Asher Asher gold medal for laryngology and rhinology, D. K. Adams.

Inclusive Fees.

At the statutory half-yearly meeting of the General Council of Glasgow University, held on April 30th, a report was submitted from the Business Committee dealing with the representations made to the University Court on the subject of inclusive fees in medicine and applied science. The report stated that the circumstances had been considerably altered, for the Treasury had agreed to make the full grant for this year. The Committee adhered to the view that sufficient experience of the working and effect of an inclusive fee in other faculties had not been gained to warrant its adoption in the difficult case of medicine, and that an inclusive fee in medicine would exercise an adverse influence on extramural teaching.

Public Health

AND

POOR LAW MEDICAL SERVICES.

MEDICAL INSPECTION OF CHILDREN IN SCOTLAND.

THE Committee of Council on Education in Scotland has issued a minute requiring that the medical inspection of children in schools within the area of every school board shall be conducted in accordance with the regulations embodied in the department's memorandum on the medical inspection and supervision of school children, bearing date March 31st, 1909; and also, that in cases where such inspection is not provided for under a scheme approved under Section 17 (6) of the Education (Scotland) Act, 1908, it should be conducted by a medical practitioner who (a) holds the diploma in public health or possesses other qualifications which are accepted by the department as equivalent thereto; and (b) is not engaged in private practice; but that nothing in the minute shall prejudice the right of any school board to institute a supplementary scheme of medical inspection for the children attending schools within their district, provided that any such supplementary scheme has been submitted beforehand to the department for approval.

HEAVY FINE FOR MILK ADULTERATION.

LAST week, in the Dublin Southern Police Court, a woman was summoned for selling milk adulterated with 28 per cent. of water. It was mentioned that there were several previous convictions against her, and that she had been fined £25 on the last occasion. The magistrate said he would now impose a fine of £100, to be reduced to £10 if the woman, who is old and in feeble health, discontinued the business within three months.

Medical News.

SIR LAUDER BRUNTON has been elected an honorary member of the Imperial-Royal Medical Society of Vienna.

THE Congress of the Alliance of Social Hygiene will be held in Paris (5, rue Las Cases) on May 14th and 15th.

THE Master and Wardens of the Society of Apothecaries have issued invitations to a *conversazione* on Friday, May 23rd.

THE house of the Royal Society of Medicine will be closed for Whitsuntide from Saturday, May 10th, to Tuesday, May 13th, both days inclusive.

DR. R. PRICHARD, M.O.H. Llandaff and Dinas Powis Rural District, has been granted an increase of salary of £50 per annum in view of additional work imposed by recent legislation.

MISS N. M. BASCHMAKOWA, of St. Petersburg, the oldest sister of the Red Cross in Russia, who worked under Pirogoff in the Crimean war, has recently died at the age of 103.

H.R.H. PRINCESS CHRISTIAN OF SCHLESWIG-HOLSTEIN will lay the foundation-stone of the Helena Building (new out-patient department), Royal Free Hospital, on Monday, May 19th, at 2.45 p.m.

THE Durham University Medical Graduates' Association will hold a dinner at the Criterion Restaurant, Piccadilly Circus, on Friday, May 30th, when the President, Dr. F. Edridge-Green, will take the chair.

DR. ALEXIS CARREL, well known for his experiments on the survival of tissues and other researches, for which last year he was awarded the Nobel prize in medicine, has been made a Knight of the Royal Order of Isabella the Catholic by the King of Spain.

THE annual oration before the Medical Society of London will be delivered by Sir William Whitla, M.D., on Monday evening, May 25th; the subject will be recent advances in therapeutics. Subsequently a smoking *conversazione* will be held.

THE sixth International Dental Congress will be held in London in August (3rd to 8th), 1914, under the patronage of His Majesty the King. The President of the Congress will be Mr. J. Howard Mummery, and the joint General Secretaries are Mr. Norman G. Bennett and Mr. H. R. P. Brooks. Mr. H. Baldwin is Honorary Treasurer. The offices of the Congress are at 19, Hanover Square, London, W., to which address all communications should be sent.

THE Central Committee for Medical Post-graduate Education in Prussia has arranged a series of medical courses, including all branches, to be given from June 19th to June 28th. The course is primarily intended for German practitioners, but foreign physicians will be admitted at a higher fee as far as space permits. Further particulars can be obtained from the Bureau of the Kaiserin Friedrich-Haus at Berlin, N.W. 6, Luisenplatz 2-4.

THE usual Friday evening discourse at the Royal Institution was given last week by Mr. H. G. Plimmer, who gave his audience a rapid birdseye view of the whole field of blood parasites, and, as he modestly suggested, gave them at least some idea of its extent and of the great gaps which still await the investigator's spade. He did not attempt to follow a biological order, but dealt first with the blood parasites which live in the plasma and those which enter the corpuscles. The address was very fully illustrated by lantern slides.

THE Hunterian Society's medal, awarded this year to Dr. Graham-Stewart, of Margate, was presented to him at a meeting on April 23rd. On the same occasion he read an abstract from the essay for which the medal was awarded. It dealt with hyperpiesis, and urged the desirability of measuring the blood pressure in all cases of illness. A theory of autoinoculation was put forward in regard to etiology, and it was contended that the common belief that digitalis should never be administered to persons whose blood pressure was high was ill founded. Since digitalis was incapable of raising pressure which was already high, its use was legitimate if other symptoms in the case called for its employment.

AT a meeting held at the house of Dr. Clement Cleveland of Philadelphia on April 22nd it was decided to organize a national anticancer association and to begin a campaign of education as to the means to be adopted for the prevention of cancer. An organizing committee was appointed. The main object of the association is to educate the public to recognize the early symptoms of the disease by means of magazine articles, leaflets distributed through boards of health, social workers and women's clubs, special instruction in nurses' training schools, and public lectures.

The campaign of education is addressed chiefly to women. Two committees already appointed for the consideration of such an organization were represented at the meeting, one formed at the annual meeting of the American Gynaecological Society in May, 1912, the other at the surgical congress held in September.

THE Historical Medical Museum, organized by Mr. Henry S. Wellcome, to which reference was made in a recent issue of the BRITISH MEDICAL JOURNAL, is to be opened in London towards the end of June. Mention has already been made of some interesting exhibits. Among the others there will be a large collection of the original apparatus used by Galvani in his first experiments. Ancient microscopes and optical instruments, gathered from all quarters of Europe, will form another feature, and a selection of surgical instruments used by famous surgeons when operating on historical personages is promised. A large collection of votive offerings will also be exhibited; it will include Graeco-Roman *ex-votos* in silver, bronze, marble, and terra cotta, together with a number of similar objects used to express thanksgiving for recovered health in the Middle Ages and in modern times. A number of amulets and charms used in English folk-medicine will also be shown. A collection of early medical medals and coins from the Graeco-Roman period, ancient manuscripts, and early printed medical books will also be exhibited.

THE second Guildhall School Conference of the Food Reform League will be held on June 30th and July 1st. The opening session will be devoted to a discussion of papers on the working of the English and Scottish Acts governing the provision of meals for necessitous school children. At the second the educational aspect of the problem, the meals of country school children, and the relation of school and home will be considered. The morning of July 1st will be taken up with a discussion of the teaching in public elementary schools of personal hygiene, food values, catering and cookery, while the concluding session will be devoted to the consideration of diet, cookery, and hygiene in day and residential institutions for children and adolescents, both public and philanthropic, including open-air and special schools, reformatories, industrial schools, and Poor Law institutions. Full particulars will be sent to any one forwarding a stamped addressed envelope to the Secretary, National Food Reform Association, 178, St. Stephen's House, Westminster.

A DINNER of the Brussels Medical Graduates' Association, in connexion with the forthcoming congress in Paris of the Royal Institute of Public Health, was held at the Trocadero, London, on April 22nd. In the unavoidable absence of the president, Dr. Arthur Haydon took the chair, and, after the usual loyal toasts, gave the toast of "The Visitors." The object of the dinner, he said, was to bring together the members who were interested in the Paris Congress, and to appoint delegates to represent the association. If possible, he hoped to be able to organize another river party next July, on the same lines as the successful party last year. The association was making good progress, and quite a large number of candidates were working for the degree, both at home and abroad. Dr. Ettles then proposed the toast of the "Brussels Medical Graduates' Association," and Dr. James Metcalfe suitably responded. The following were elected officers for the year: President, Dr. Harold S. Sington; vice-president, Dr. Howard Humphris; honorary treasurer, Dr. Major Greenwood; honorary secretary, Dr. Arthur Haydon; Members of council, Drs. Wilkinson, Callender, Smallwood, Fielden Briggs, Dutch, Bryce Macaulay, Bruce-Porter, Robinson, and Gibbon.

THE third of the Chadwick lectures by Dr. J. T. C. Nash was read for him by Professor R. T. Hewlett, the author being unfortunately still indisposed. In this lecture the consideration of the evolution of epidemics, of which an account appeared in our issue for April 12th, was concluded by a discussion of the question of whether pathogenic micro-organisms are not only specific but immutable in structure and powers. He concluded that this was not the case, and that, like the higher organisms, bacteria were likely to be affected by their environment. Hence the conclusion was drawn that to combat pestilences successfully the measures taken must be aimed at the common environment alike of mankind and of pathogenic organisms, improving it for the former, rendering it less favourable for the latter. This conception involved direct sanitation such as the destruction of vermin, purification of water, and the prevention of contact between the defective and the sound, and justified the "sanitary idea" of Chadwick, Richardson, Alfred Carpenter, and other of the older pioneers of the science of public health.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

TELEGRAPHIC ADDRESS.—The telegraphic address of the **EDITOR** of the *BRITISH MEDICAL JOURNAL* is *Atiology, Westrand, London*. The telegraphic address of the *BRITISH MEDICAL JOURNAL* is *Articulate, Westrand, London*.

TELEPHONE (National):—

2630, Gerrard, **BRITISH MEDICAL ASSOCIATION.**
2634, Gerrard, **MEDICAL SECRETARY.**

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

PARALYSIS AGITANS.

G. F. P. asks for advice or references which would help him in treating a case of paralysis agitans in an elderly lady in whom the constant flow of saliva is a distressing symptom.

LETTERS, NOTES, ETC.

THE TREATMENT OF LIVER ABSCESS BY INJECTIONS OF EMETINE.

MAJOR F. J. W. PORTER, D.S.O., R.A.M.C., writes: I have recently treated a native of Hyderabad, Deccan, by injections of emetine. There was a definite history of a liver abscess, which had burrowed into the right lobe about a month before I saw him. Physical signs of consolidation and softening were present, and there was much wasting. The temperature ranged between 101° and 103°. Expectoration (containing typical liver pus) was about 2½ pints in the twenty-four hours. Within three days the temperature was normal, and the amount of expectoration was only half a pint. There was no pain in the chest after the first day. Convalescence was very rapid, and there has been no relapse. Nine injections were given in all, and the remedy acted like a charm.

HERPES ZOSTER AND VARICELLA.

DR. B. JONES (Boscombe) writes: In the Epitome of January 11th there is an annotation ament "Herpes Zoster and Varicella" in which particulars are given of many cases of shingles being followed by chicken-pox in other members of the family about a fortnight after the shingles appeared in the first patient. In *Guy's Hospital Gazette* of Saturday last there is a further case, reported from Rhodesia, of this disease followed after a fortnight by three cases of chicken-pox in the family. As the affected house was three miles from the nearest farm and nine miles from a railway station and every inquiry failed to discover any possible source of infection, the matter is certainly very curious. Years ago, when medical officer to a workhouse, I was frequently puzzled by the causation of shingles which occurred from time to time, generally in twos or threes, but did not give much thought to what was always, in my experience, in young people a trifling disorder. I have nothing to add to the subject, but it is one of those cases worth noting.

IS TUBERCULIN A FAILURE?

DR. J. REID (London, W.C.) writes: In 1884 I had occasion to make a *post-mortem* examination on a young man in a room lighted with one candle, where there was a very limited supply of water. Both lungs were full of cavities, hard. I accidentally cut two fingers with a scalpel. The cuts were on the back of the fingers, on the second phalanges of the left hand. I treated both alike, but one became erysipelatous and healed in a few days, although it gave me a great deal of pain. The other refused to heal under compresses and various germinicides, including corrosive sublimate. In about six weeks I used balsam of Peru—it was then still troublesome and ulcerating—and it healed speedily. A writer in the *JOURNAL* proposes experiments with pneumococcus and tubercle. If he looks round he will find many in man, which recover and leave the tubercle to run its course. I am now in good health in spite of the tubercle inoculation.

RHEUMATOID ARTHRITIS.

DR. LIONEL CALTHROP (Woodhall Spa), writes: The fact that it is possible for two such teachers and leading men in our profession as Sir James Barr and Dr. Luff to differ so widely both as to the etiology, pathology, and treatment of so important a disease as rheumatoid arthritis, as shown by their articles and correspondence, must inevitably cause confusion in the mind of the rank and file. One hoped that we were gradually approaching more precise and reliable knowledge on the subject, but apparently this is not so. Has not the time now arrived when it is advisable that a representative committee should be formed thoroughly to investigate all the

points at issue and at least report for the guidance of the profession as to which of the many methods of treatment now in vogue produces the most successful results?

DECIMAL WEIGHTS AND MEASURES.

THE annual report of the Decimal Association contains a good deal of encouragement for those who are anxious to see the British practice of returning weights and measures in all kinds of ancient terms replaced by the decimal or metric system. The fact that the General Medical Council has decided to employ the metric system in the next issue of the *Pharmacopœia* has attracted considerable attention, and the gem dealers of London are now agitating for the introduction of an official metric carat. In South Africa likewise matters are trending in the same direction. The Union Government introduced last year a bill for the consolidation of the various acts of the four States relating to weights and measures, and in the schedule to this bill the metric system was adopted. The bill did not reach a second reading last year, but it is not anticipated that when reintroduced there will be any serious opposition. In Malta an Ordinance on the subject was promulgated in 1911, and, when it comes into operation next year, will have the effect of rendering the metric system compulsory in commerce. Russia is the only European country besides the United Kingdom in which the decimal is not the sole official standard; the decimal system is there used, among others, and the Duma has now passed legislation which will encourage its use. In China also there appears to be a strong disposition towards the introduction of the metric system as one of the outcomes of general reform. The Advisory Council has passed a measure on the subject, and the Government proposes to send Commissioners to all the provinces to arrange tables for the conversion of the old weights and measures into those of the decimal system. If and when this reform takes place it will be a matter of considerable importance to this country, more especially when it is taken in conjunction with the fact that in the kingdom of Siam a metric system is also now in use. One of the arguments which principally led to the rejection of the Decimal Bill introduced in the House of Commons in 1907 was that the Lancashire cotton manufacturers and merchants would suffer if they were forced to adopt a metric system, because the conservatism of their customers in the Far East was so great that they would regard any change in the dimensions of the fabrics offered to them with extreme suspicion. If native merchants in the Middle East were themselves obliged to use decimal measures, and thus became accustomed to them, arguments of this character would lose their force. Though the main arguments in favour of the general adoption of the decimal system are commercial, it might be contended also that if a child can be rendered fit to conduct the ordinary business transactions of life without being forced to learn a confusing series of tables of weights and measures it would have more time to learn other subjects. The offices of the Decimal Association are at Finsbury Court, Finsbury Pavement, E.C.

WARNINGS.

A MAN, presenting the appearance of a workman—brown hair, thick set, 6 ft. in height—wearing a suit of dark material, called recently on a medical man; when asked for his insurance card he said that he was not insured. In payment of the fee he placed what appeared to be half a sovereign on the writing table. We are informed that a person answering this description is wanted by the police at Willesden Green, N.W., for passing counterfeit coin.

THERE is reason to believe that an individual is now visiting medical men in London and seeking from them monetary assistance. He has stated that he was an American medical man stranded in London, and so hard up that he had had no food for hours. He has produced a copy of a telegram addressed to a person of position in America, asking for the remission of funds, and stated that pending their receipt he required a little assistance. He has also alleged that he has just been discharged from a certain hospital in London after a serious operation. One medical man to whom he applied investigated this particular point, and could find no evidence that it was true. The individual in question was sturdily built, about 5 ft. 3 in. high, clean shaven, and had curly hair, and there was evidence that he was a heavy smoker. His general appearance suggested a Jewish origin.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

THE INTERNAL SECRETIONS IN RELATION TO DERMATOLOGY.

BY

SIR MALCOLM MORRIS, K.C.V.O.,

SURGEON TO THE SKIN DEPARTMENT, SEAMEN'S HOSPITAL,
GREENWICH.

Nearly twenty years have passed since Byrom Branwell reported to the Newcastle meeting of the British Medical Association (1893) the results which he had obtained in cases of psoriasis, lupus vulgaris, and acute eczema by the internal administration of thyroid extract.¹ This was the beginning of organotherapy in connexion with dermatology. Thyroid treatment had already been successfully used in myxoedema by G. R. Murray, Hector Mackenzie, Arthur T. Davies, and others; and it was now employed on an extensive scale in the therapeutics of skin affections. But, as was perhaps inevitable, it was administered with too little discrimination, and, though it found enthusiastic advocates, signs of reaction were not long in declaring themselves, and after a while it was neglected and almost forgotten. Of late years, owing in part to the light that has been thrown upon the physiology and pathology of the ductless glands by a multitude of investigators, there has been a revival of interest in the subject, and the more discriminating use of animal extracts in many chronic skin diseases has yielded results more favourable than those at first obtained. The time seems, therefore, to be appropriate for considering in some detail the influence of the internal secretions upon the skin and its appendages, and attempting an estimate of the value of organotherapy in the treatment of cutaneous affections.

HISTORICAL NOTES.

It may not be without interest first to note the chief landmarks in our knowledge, so laboriously acquired, of the internal secretions, one of the most obscure and complex, and at the same time one of the most fascinating branches of medical science. In his textbook of physiology, published in 1776, Haller² grouped together the thyroid, the thymus, and the spleen as glands which, though ductless, secrete fluids that find their way into the general circulation. Thenceforward the glandular character of the thyroid body was generally accepted, though it was not until many years later that any serious attempt was made to investigate the nature and function of its secretion. In 1844 Johannes Müller³ included among secretory as distinguished from excretory glands, the spleen, thyroid, suprarenals, thymus, and placenta. But it was in connexion with a gland that is not ductless that the action of an internal secretion was first experimentally proved. In 1849 A. A. Berthold, of Göttingen,⁴ published his famous experiments in the transplantation of the testicles of cocks, showing that after the transplantation the animals retained their male characters in voice, reproductive instinct, fighting spirit, and growth of combs and wattles. Thus he demonstrated the influence exerted through the blood upon the economy by an organ through which the blood stream circulates, and to him, as Biedl⁵ remarks, belongs the honour of having first proved the existence of an internal secretion and seized its immediate significance.

The demonstration, however, passed unheeded; the time was not yet ripe for a recognition of its far-reaching import. In the following decade came the classical investigations by which Claude Bernard⁶ proved that in addition to its external secretion—bile—the liver forms an internal secretion—glycogen—which, he held, passes into the blood stream as sugar. But it was reserved for Brown-Séquard⁷ to formulate (1869) the theory that all glands, whether furnished or unfurnished with ducts, contribute to the blood substances of physiological utility. Some years earlier,⁸ prompted by Addison's discovery of the connexion between the suprarenals and the disease which now bears that great physician's name, he had experimentally investigated the action of those bodies, and had come to the conclusion that in certain animals their extirpation caused rapid death, which could be postponed by the injection of suprarenal extract. Finally, in 1889,⁹ he related the experiments which he had been conducting for twenty years with the subcutaneous injection of

testicular extract, and thus, whatever view may be taken of the value of that series of experiments, became the founder of modern organo- or opo-therapy, so like, yet so unlike, the organotherapy of primitive medicine.

The importance of the thyroid was first revealed by the results of the operations undertaken by the Reverdin and by Kocher for the relief of goitre. The keen observation of Sir William Gull¹⁰ had already detected the resemblance to cretinism of the condition afterwards known as myxoedema, and he had characterized it (1874) as "a cretinoid state supervening in adult life in women"; and when (1883) the Reverdin and Kocher described the symptoms produced in goitrous patients by removal of the thyroid their identity with the symptoms described by Gull was recognized by Sir Felix Semon,¹¹ and the Reverdin styled the condition they had unwittingly created "*myxoedème postopératoire*." Next, it was found *post mortem* that myxoedema is associated with degeneration of the thyroid. The brilliant experimental work of Schiff, Sir Victor Horsley, G. R. Murray,¹² and many other observers that followed these discoveries has not, it must be admitted, finally solved the problems to which it was directed, partly because the gland functions differently in different animals, but also because at first the influence of the parathyroids was not recognized. These bodies were only discovered in 1880 by Sandström, and it was not until 1892 that their importance was insisted upon by Gley,¹³ whose view, elaborated by Vassale and Generali, is that their secretion is even more essential than that of the thyroid itself.

To the pituitary body, which has functional relations with the thyroid, a glandular character had from time immemorial been ascribed. It was the view of Galen, and long afterwards of Vesalius, that it secreted a mucous fluid, which escaped through the nose, while Magendie, in times nearer our own, held that its office was to collect the cerebral lymph and pour it into the circulation; but it was so recently as 1889 that Pierre Marie,¹⁴ by associating it with acromegaly, suggested the real nature of its function as influencing the development of the body and furnishing the explanation of gigantism, infantilism, and other abnormalities of growth.

Of the thyroid and its functions our knowledge is still defective. The most diverse views are taken of its relations with the parathyroids, and all that can be regarded as certain on this point is that the relationship is of the most intimate character. This inference would appear to be irresistible from the hypertrophy which the parathyroids undergo when the thyroid is extirpated, and the thyroid when the parathyroids are excised.

To these historical notes it may be added that it was Starling¹⁵ who proposed the term "hormones" (from ὁρμή = I excite or arouse) for the chemical stimuli, or, to use his own expression, "chemical messengers," which are "carried from the organ where they are produced to the organ which they affect by means of the blood stream." The word met with general acceptance and is frequently used as a synonym for "internal secretions."

CUTANEOUS SYMPTOMS OF MYXOEDEMA.

How the thyroid and the other ductless glands influence each other and the body generally—whether the secretions elaborated from the blood and then, directly or indirectly, returned to it, stimulate metabolism and growth, or neutralize the toxins of metabolism, or exercise an inhibitory effect upon organs whose activity requires to be controlled, or whether there is a combination of these processes, is a question still involved in obscurity. Nor is the difficulty of determining the functions of the thyroid lessened by the interaction that takes place between this gland and others. But however the thyroid does its work, and whatever its relations with other glands, it is certain that degeneration of this organ is causally connected with the changes in the integuments which enter into the myxoedema syndrome. It is probable also, though the evidence is less conclusive, resting as it does upon purely clinical grounds, that in irregular functioning of the thyroid is to be found in many cases, though not necessarily in all, the explanation of cutaneous changes similar to those met with in myxoedema. In this disease the skin is cold, dry, and rough, seldom or never perspires, and may take on a yellowish tint; it presents swellings, and the mucous membranes

also may be swollen. There is a bright-red flush in the malar region, due to dilatation of capillaries and veins. Swale Vincent¹⁶ has found that the elements of the connective tissue of the derma are torn asunder, while the fibres are the seat of a hyperplastic process, and the cell nuclei and the fibrils of the gelatinous substance between the fat lobules are multiplied. The skin as a whole looks transparent, as though saturated with a semi-fluid substance. The hair of the scalp becomes scanty, the pubic and axillary hair, with the eyelashes and eyebrows, often falls out; in many cases the teeth are brittle and carious. As these signs disappear under the administration of thyroid preparations, there is *prima facie* ground for expecting benefit from the same treatment in conditions presenting more or less resemblance to them, but not associated with myxoedema, such as psoriasis, alopecia, ichthyosis, and xeroderma. That expectation has been abundantly justified by experience. So often, indeed, have I during the last two years found the use of thyroid extract followed by improvement in these and other conditions that I now make it a routine practice, in examining patients suffering from chronic skin affections of which the causation is not known, to palpate the thyroid. If the gland be smaller than usual a trial of thyroid extract is suggested; if there be marked hypertrophy, thyroid medication is contraindicated. It has, however, to be remembered that thyroid insufficiency may be due not to atrophy of the gland but to replacement of the vesicular substance by interstitial growth. Moreover, it is probable that thyroid hypertrophy is sometimes compensatory rather than morbid, the result of an effort to restore secretory equilibrium that has been disturbed by failure of some other ductless gland. Cases are recorded in which thyroid treatment has abolished cutaneous symptoms associated with thyroid excess; such cases are examples of what French authors designate *l'instabilité thyroïdienne*. It is necessary, therefore, to be on one's guard against hastily concluding that a moderate degree of thyroid hyperplasia is an indication against the use of thyroid extract.

ITCHING AFFECTIONS.

In no skin affection has thyroid medication given better results than in *psoriasis*. The failures that have been reported by myself and others are explained by the fact that formerly there were no data for determining the cases to which the remedy was appropriate. My recent experience has led me to the conclusion that one of the secrets of success in the employment of thyroid extract, as of other ductless gland preparations, consists in selecting for its administration cases in which the skin affection complicates other conditions in which this remedy is indicated. In obesity, in infantile wasting, in a certain type of chronic rheumatism, both articular and muscular, in osteomalacia, rickets, and delayed union of fractured bones, in haemophilia, etc., thyroid preparations are of proved utility, and whenever cutaneous affections are found associated with such conditions as these, there is a presumption in favour of thyroid treatment. The association may, of course, be fortuitous, but on the whole it is more likely that the morbid process in the skin is an expression of the constitutional condition. Thus I have found thyroid extract specially efficacious in psoriasis associated with adiposity. In the case of a woman aged 32, who also displayed the mental symptoms of myxoedema, under a course of thyroid extract and arsenic the psoriasis entirely disappeared, the adiposity diminished, and the mental symptoms and general health were greatly benefited. Arsenic alone had been employed without avail; there can be no doubt, therefore, that the improvement was due, mainly at any rate, to the thyroid extract. This is but one of a series of somewhat similar personal cases in which the treatment has proved to be successful. Léopold-Lévi and de Rothschild¹⁷ report cases of psoriasis associated with chronic rheumatism in which the psoriasis completely disappeared under thyroid treatment. In psoriasis generally my experience is that the treatment is more suitable for chronic than for acute cases; and I agree with Radcliffe Crocker and with C. E. Sajous¹⁸ that thyroid extract should not be exhibited until the eruption is fully developed. Stelwagon,¹⁹ while holding that it has but a limited sphere of usefulness in psoriasis, allows that it has

been of service in a few instances in which other agents had failed, and he regards it therefore as a reserve remedy for trial in rebellious cases. In one such case in which it was employed with little hope of success, Sir Clifford Allbutt was agreeably surprised to find that it produced rapid and complete cure. The effect produced consists not only in lessening or abolishing the irritation, but also, it would seem, in stimulating the epidermal layers, so that the degenerate epidermis scales off and is replaced by healthy epidermis.

This is not the only itching affection in which thyroid treatment has been used with success. Obstinate cases of *pruritus* have proved amenable to its influence. In *eczema* I am able to report most encouraging results. Unlike psoriasis, this affection responds to it not only in chronic but also in acute forms. The most responsive cases are those in fat subjects, and those, again, in which the eczema is associated with xeroderma. In cases belonging to both these groups I have found it to answer exceptionally well. Léopold-Lévi and de Rothschild record three cases of eczema associated with thyroid symptoms which were cured or ameliorated by thyroid treatment; they also refer to a case reported by Parhon and Papinian in which eczema complicating chronic rheumatism disappeared under the same treatment. Marbé²⁰ reports two cases of eczema cured by thyroid. Eason²¹ has successfully treated cases of eczema in young children with thyroid, and I have employed it with advantage in such cases. In several cases of infantile eczema, especially in fat babies, I have had equally satisfactory results. Moussois²² has found the treatment answer well in seborrhoeic eczema of the scalp.

DYSTROPHIES OF THE SKIN.

Ichthyosis, a malformation of the epidermis, was one of the affections in which thyroid extract was used with advantage in the early days of cutaneous organotherapy by Byrom Branwell and by Arthur T. Davies.²³ Darier²⁴ counsels its prudent use in such cases. Stelwagon can only say that it deserves a trial. My own recent experience has been distinctly more favourable. I have used this agent in a number of cases, and in none without benefit. One in particular may be cited because of its inveteracy. The patient was a lady of 25, who had long-standing xeroderma of the palms, elbows, and knees, with severe seborrhoea of the scalp, scanty hair, and dry skin, the general picture resembling that of myxoedema. Under a combined course of thyroid extract and arsenic all the symptoms, notably the seborrhoea of the scalp and the dryness of the skin, were much abated, and the general health strikingly improved. Favourable results are also reported by Weill, Monriquand, and Barth.

In *Darier's disease* there is ground for believing that thyroid is indicated, since it is associated with cellular degeneration, and is not improbably, as Audrey and Dalous hold, an expression of dystrophy of the whole epidermis. Darier himself has suggested that this remedy be tried, though not to the exclusion of local measures.

In *scleroderma*, again, there is a presumption in favour of the efficacy of thyroid, for it has been held that the changes in the derma are the result of perversion of nutrition analogous to myxoedema, and Ehrmann has advanced the view that they are the response to an autoinfection commencing in the thyroid body, while Pedrazzini found that of 5 cases the thyroid was small and atrophied in 4. Sir William Osler, in 1898, did not go beyond saying, from his own experience in 6 cases and from results recorded by others, that thyroid treatment in this condition might "be tried without harm." Later reports are by no means unanimous, but there is a rather considerable body of testimony in its favour, among others from Lancereaux and Panlesco, Lustgarten, Ménétrier and Bloch, Picko, Jakimoff, Schamberg, and McMaster. Grünfeld and de Kornfeld have found thyroid treatment beneficial in scleroderma, even when associated with Graves's disease. Léopold Lévi and de Rothschild explain this result by the suggestion that Graves's disease and scleroderma sometimes evolve upon a *terrain* of thyroid insufficiency. Of 9 cases of scleroderma which they themselves submitted to thyroid medication the treatment was finally successful in 5, but it had to be perseveringly applied.

C. J. White of Boston²⁵ has reported great improvement from thyroid treatment in a case of *acanthosis nigricans*.

This affection, of which the pathology is not understood, may be referred to here; for although it is sometimes included among new growths, it was first designated, by Darier, *dystrophie papillaire et pigmentaire*.

CHELOID.

Cheloid appears to have been first submitted to thyroid treatment in the United States, by J. William White, who observed a lessening of the growth under its influence. Stelwagon employed it in several cases, in one of which there was material diminution of the growth. In my experience, it is distinctly useful in this affection, and I have been especially struck by its influence in alleviating the pain which is not infrequently a symptom of cheloid.

WARTS, ACNE, AND RHINOPHYMA.

Occurring as they do most commonly in children, and tending to disappear at puberty, *multiple warts* are possibly an error of development. Whether this be so or not, I have repeatedly found them disappear under thyroid medication. *Acne vulgaris* is another affection of childhood or adolescence which, in my experience, responds well to thyroid extract. In one case, that of a boy of 16 who had overgrown his strength, after a month's treatment the acne was considerably less, while the accompanying seborrhoea of the face and scalp had entirely cleared up and the general health had much improved. I have had equally satisfactory results in a number of other cases. Thyroid treatment is obviously indicated in *acne rosacea* occurring as a result of flushing in what, for lack of a better designation, I may term the pseudo-myxoedema sometimes associated with the menopause in fat women, who become dull and lethargic and depressed. In such cases I have found that the adiposity, the mental symptoms, and the rosacea have all alike responded to the treatment. Léopold-Lévi and de Rothschild report several cases of *acne rosacea* and *acne vulgaris* which were cured by thyroid treatment. In one, in which the skin affection was associated with menstrual irregularity, corpus luteum extract was combined with the thyroid treatment. A remarkable ease of cure of *rhinophyma* after three months' thyroid treatment is reported by Dyer of New Orleans.

CUTANEOUS TUBERCULOSIS.

Lupus vulgaris is one of the affections in which thyroid treatment was first employed by Byrom Bramwell. In 1898 Pearce Gould²⁸ exhibited to the Clinical Society of London a woman of 47 in whom long-standing lupoid ulceration of the face, with tuberculous lesions in other parts, had completely healed over after three weeks' administration of thyroid colloid. Radcliffe Crocker is another of those who have reported favourably of thyroid medication in lupus. Pringle²⁷ has declared that it produces results little short of marvellous. According to him the cases which make the best response are those in which there is marked hyperaemia or inflammation. Both in lupus and in tuberculosis of the skin (*scrofuloderma*) I am able to report favourably of the treatment.

CUTANEOUS SYMPTOMS OF GRAVES'S DISEASE.

In exophthalmic goitre, generally held to be due to excessive or perverted functioning of the thyroid, the cutaneous symptoms are the reverse of those met with in myxoedema: instead of coldness, dryness, and scaldiness there are heat and moisture; pigmentary changes are not infrequent; and there may also be pruritus, factitious urticaria, and purpuric erythema; but in both conditions there may be loss of hair and atrophy of the nails. In Graves's disease thyroid treatment is, of course, contra-indicated; but there are cases on record in which cutaneous symptoms associated with some degree of overaction of the thyroid have been benefited by the judicious administration of thyroid extract. Those are cases, probably, of the "thyroid instability" referred to above, in which the thyroid makes an effort to compensate the defective action of some other gland.

AFFECTIONS OF THE HAIR.

The influence of the thyroid gland upon the growth of hair is unmistakable. In myxoedema, as already noted, the hair of the scalp becomes scanty, and the eyelashes

and eyebrows, the pubic and axillary hair, often fall out, while under thyroid treatment there is a return to the normal. Hertoghe²⁹ records a case of entire baldness in myxoedema, followed by complete restoration of hair after the use of thyroid. On the other hand, in cases of thyroid excess there is sometimes hypertrichosis, manifesting itself in superabundance of growth, exaggeration of length, and growth in unusual situations, although in Graves's disease the hair often falls out, as in myxoedema. The hair of the face also may be affected by thyroid irregularity; with thyroid insufficiency the hair of the beard and moustache may fall, or its development may be retarded; with thyroid excess, spontaneous or due to medication, there may be growth of hair on the face in women, or black hairs may appear in the light-coloured beards of men. The colour of hair, too, is influenced by the thyroid, as is proved by return to the normal under thyroid treatment in cases of premature greyness. Examples of the effect of thyroid treatment upon the growth and colour of the hair in such affections as chronic rheumatism, scleroderma, neurasthenia, migraine, and asthma, associated with various degrees of thyroid irregularity, are reported by Léopold-Lévi and de Rothschild.

There is reason to believe that the pituitary and the adrenals take part in the trichogenic function. Thus in hyperpituitarism there is marked hypertrichosis, while in hypopituitarism, though the hair of the scalp may not be affected, except in cases commencing in adult life, that of the axillae and pubes may be almost entirely lacking, or in males may conform to a feminine type of distribution. A case reported by Bulloch and Sequeira²⁹ seems to support the view that there is some relation, stimulative or inhibitory, between the functioning of the adrenals and the growth of hair. The patient was a girl of 11, who, normal up to the age of 10, then began to show precocious general sexual development, evidenced by increase in her size and bulk, by the onset of menstruation, by rapid maturation of the mammary glands, and by the growth of hair on pubis and face and axillae. All this time a tumour was growing in the abdomen, which was found *post mortem* to be a malignant hypernephroma. Their researches brought to light a number of similar cases, in which carcinoma or hypertrophy of the suprarenals was attended by precocious sexual development, and also cases in which suprarenal atrophy was associated with non-development or disappearance of pubic hair and by genital hypoplasia.

It has long been known that the growth of hair is also influenced, directly or indirectly, by the sexual glands. Arthur Keith,³⁰ in his masterly little book on *The Human Body*, remarks that in elderly women the withdrawal of the sexual secretion seems to allow the forces of growth to assert themselves: hence the growth of hair on the faces of elderly women. This ingenious suggestion finds support in the fact, observed by Aristotle, and confirmed by Sabouraud as the result of inquiries made in Constantinople and Cairo, that eunuchs do not become bald. Léopold-Lévi and de Rothschild incline to the view that the thyroid chiefly influences the hair of the scalp, and the sexual glands the pubic and axillary hair, and the beard. The whole subject needs much further investigation.

AFFECTIONS OF THE NAILS.

Both in myxoedema and in Graves's disease, and also in the intermediate degrees of thyroid disorder, the nails, as well as the teeth, undergo degenerative changes. Cases in which thyroid treatment exerted a favourable trophic influence upon the nails are recorded by Léopold-Lévi and de Rothschild. The new part of the nail, nearer the matrix, became normal in colour and thickness and texture, and, as is observed in convalescence from some acute affections, there was a furrow between the old part and the new. The number of such cases is not considerable, but they are sufficient to encourage the use of thyroid treatment wherever ungual affections not known to be of parasitic origin are associated with thyroid disturbance.

In hypopituitarism also there is dystrophy of the nails. They are frequently small, thin, and imperfectly developed; and Crowe has noticed that they do not show the crescents at their base.

PIGMENTATION.

There can be little doubt that the coloration of the skin is influenced by several of the internal secretions, and

also, it may be, by the liver and the abdominal sympathetic. It is significant that, as Rolleston³¹ has noted, the pigmentation in Addison's disease is an exaggeration of the normal, and occurs, therefore, on the face, the neck, the hands, the anterior folds of the axillae, the nipples, the perineum, and the genitals, while in more advanced cases the mucous membranes may become pigmented. There is pigmentation also in hyperpituitarism, but it is often accompanied with asthenia and low blood pressure, which suggests that it may be due to adrenal insufficiency rather than to excessive functioning of the pituitary. The familiar pigmentary signs of pregnancy suggest that the sexual secretions may be concerned in normal coloration. There is evidence also that the thyroid is not without influence in this process. One of the signs of myxoedema is the yellowish tint which the skin may present, and Lancereaux and Paulesco, and others, have found that abnormal pigmentation is beneficially affected by thyroid treatment. In leucoderma favourable results from thyroid treatment are recorded, but the negative results recorded by other authors suggest that a careful selection of cases is necessary. The treatment appears to answer best in diffused cases.

Indications are not wanting that the rôle of the thyroid in coloration is of a regulative character. Arbuthnot Lane³² has described the pronounced pigmentation met with in cases of alimentary toxæmia, beginning in the eyelids and thence spreading gradually over the face. The neck becomes first brown and then almost chocolate-coloured. The skin of the abdomen, the thighs, the axillae, and that covering the spinous processes of the vertebrae grows progressively darker, and on these surfaces areas of a still darker staining may develop. This observer also calls attention to the changes the thyroid undergoes in cases of intestinal toxæmia. In one case, in which the patient had for eight years suffered from an enlarged thyroid, it was obvious a few days after resection of the large intestine that the gland was diminishing in size, and by the time she left the hospital it was but little larger than usual. The case does not stand alone, for he had noticed the complete disappearance of symptoms of thyroid excess in other patients after operation for intestinal stasis. Such cases suggest that the thyroid may hypertrophy in its effort to antagonize the intestinal toxins to which in these cases the abnormal pigmentation is probably due. Possibly it is in this way that the effect of thyroid medication in improving the complexion is to be explained.

THYROID DOSAGE.

So powerful an agent as thyroid extract must obviously be used with great caution, and its effects closely watched. As a rule I begin with a 2½ grain tabloid, to be taken at bedtime, and after a few days double the dose; then, if the remedy be well borne, a tabloid of the same strength is taken, in addition, after breakfast, and, later, another after dinner, and so gradually a maximum of 10 grains per diem is attained. For infants I begin with ½ grain a day, increased to 1 grain, and occasionally to 1 grain. Experience is proving that small doses are as efficacious as the larger doses formerly given, and it is obviously desirable to run no avoidable risk of evoking symptoms of thyroidism, such as rapid pulse, nausea, headache, lumbar pain, restlessness. On the appearance of such symptoms the treatment must be at once suspended or the dosage diminished.

In cases treated with thyroid in which arsenic would be used, as in psoriasis, I usually employ the two agents together, and have found the combination answer admirably. I am glad to find myself in agreement on this point with Ewald and with Gauthier.

THE PITUITARY BODY AND THE SKIN.

That the skin and its appendages are subject to the influence of other ductless glands than the thyroid might have been anticipated from the interaction that has been proved to exist between these bodies, as well as between them and certain organs of external secretion—the testis and the ovary, for example—which also form internal secretions. As the result of this interaction there may be simultaneous functional disturbances in several organs of internal secretion, and thus may arise the clinical picture which has been designated pluriglandular or polyglandular insufficiency. In seeking for the causes of cutaneous affections the dermatologist must be prepared to take account

of the pituitary body. The thyroid is so often and so greatly affected in acromegaly, and the pituitary in myxoedema and after experimental thyroidectomy, as to suggest not merely a complementary relation between these glands when either is the subject of disease, but even some measure of normal interaction—a suggestion which finds support in their histological resemblances. Harvey Cushing,³³ in considering the relations between the pituitary and the thyroid, points out that definite alterations in the thyroid have been reported by many observers in animals from which the hypophysis had been experimentally removed, and that in 24 acromegalics Farnival found only 5 thyroids that were normal, while Schönemann, in 85 cases of goitre, observed marked alterations of the pituitary in 84. In acromegaly there is increase in the size of the hair follicles and of the papillae, and, as the result of enlargement and abnormal activity of the secretory glands, the skin becomes moist and greasy. There is also hyperplasia of the connective tissue of the subcutis, which may involve the muscles, and while the process of hyperpituitarism is active there is, as is mentioned in an earlier paragraph, an unusual degree of hypertrichosis, strikingly exemplified in one of Cushing's illustrated cases. The transition from hyperpituitarism to hypophyseal insufficiency is attended by a very slow but unmistakable retrogression of the cutaneous symptoms. Just as the condition of the skin in Graves's disease is the exact reverse of that in myxoedema, so in primary hypopituitarism the cutaneous changes are the opposite of those in acromegaly. Cushing found that in all his patients affected with primary hypopituitarism, except the older ones, the skin was "smooth, transparent, and notably free from moisture." In some it had an infantile smoothness, such as might suggest a subcutaneous oedema, though there was no pitting on pressure.

In connexion with the pituitary I may refer to the rapid growth of the long bones which often follows typhoid and many other infections in young adolescents, and which comes under the notice of the dermatologist, because of the patellar and other striae produced by the tension to which the skin is subjected. In one of my own cases—that of a girl of 15, who had had scarlet fever—there were linear streaks on the thighs, abdomen, and breast, suggesting a general skeletal overgrowth. Jean Chanal³⁴ has suggested that the skeletal over-development is due to bacillary stimulation of the epiphyses, but I agree with Cushing that it is more likely to be the result of a functional hyperactivity of the pituitary, which sets free in unusual quantity the hormones that stimulate growth.

THE THYMUS AND THE SKIN.

In view of the relation subsisting between the thymus gland and the sexual system, it is possible that to irregularity in the functioning of this gland may be due some affections of the skin that occur specially in childhood and adolescence. There is now reason for believing that the thymus continues to function regularly until puberty, and it has been found that in castrated animals the gland does not at puberty undergo hypoplasia. Although its secretion has not been definitely isolated, there is much to be said for the view that the thymus furnishes a secretion which is of service to the economy while the reproductive organs are undergoing development. Some cases of acne, therefore, may possibly be due to insufficiency or excess of its secretion. Similarly there appears to be some connexion, as Sabouraud has suggested, between large and active sebaceous glands and over-activity of the testicle; this may account for the frequency of scborrhoea in virile and hairy men and its rarity in women, who, when the subjects of it, are generally of the masculine type. It is significant that acne in women often coincides with the menstrual periods.

THYMUS, PITUITARY AND SUPRARENAL EXTRACTS IN SKIN DISEASES.

Neither thymus nor pituitary nor suprarenal preparations have yet been extensively used in dermatology. But I have employed thymus gland extract with advantage in acne associated with enlarged thyroid and rapid heart, and have had encouraging results from pituitary gland extract, and also from suprarenal extract, in persistent urticaria and angio-neurotic oedema, conditions in which Ravitch and other French authors report improvement

under thyroid treatment. I have also found benefit to follow the use of suprarenal extract in *lupus erythematosus*, possibly owing to its influence upon the vaso-motor centres. This condition is amenable to physio-therapeutic methods to radium and carbonic acid snow; but it is not a merely local affection, and when the lesions disappear under local treatment there is always the possibility of recurrence to be reckoned with. It is desirable, therefore, that farther trial be given to any agent which holds out the promise of beneficially affecting the constitutional condition.

UNSOLVED PROBLEMS OF DERMATOLOGY.

The influence which the thyroid, the pituitary, the thymus, and other glands exert on metabolism and growth, and so on the nutrition of the integuments and their appendages, suggests that farther knowledge of their nature and functions will help to solve some of the many perplexing problems of dermatology. Bacteriology has accounted for not a few skin diseases, and vaccine-therapy and serum-therapy have now a recognized place in dermatological therapeutics; but there is still a disconcertingly long list of skin affections of which the cause is unknown and the treatment purely empirical. May it not be that of some of these the explanation will be found in overaction or underaction of glands that form secretions at once so potent and so difficult of analysis? The facts that animals from which the hypophysis has been partially removed betray diminished power of resistance to infections, and that pituitary hyperplasia has been found associated with bacterial intoxications, may possibly prove to be charged with significance. It is conceivable that irregularity of this or of other organs of internal secretion may be the direct cause of certain obscure skin diseases, and that in others it may induce the predisposing condition which is the opportunity of bacterial or other pathological influences. Thus, too, may possibly be explained the tendency of so many skin affections to recur after the lesions have disappeared under empirical treatment.

I will not pursue these speculations, tempting as they are. But I venture to think that the results yielded by organotherapy in a considerable number of skin affections are sufficient to warrant a more extensive use of this method of treatment in dermatology. It was by the experimental use of thyroid extract, for example, in such affections that we acquired the knowledge that now enables us in some measure to select the cases suitable for its exhibition, and only by the further use of this and other preparations in the same spirit, guided largely by the principle of analogy, will our knowledge be extended. That animal extracts must be employed with circumspection need not be said; but their effects are now tolerably well understood, and those who are practised in their use will be at no loss to recognize the conditions in which they are contraindicated.

A Lecture

ON

SOME POINTS IN THE EARLY DIAGNOSIS OF CANCER OF THE STOMACH.

DELIVERED AT THE CANCER HOSPITAL, BROMPTON,

BY

THOMAS J. HORDER, F.R.C.P.,

PHYSICIAN TO THE HOSPITAL AND ASSISTANT PHYSICIAN TO ST.
BARTHOLOMEW'S HOSPITAL.

It may possibly seem to some that as my contribution to this course of lectures I have chosen to speak on an unattractive subject. "What is the good," it may be said, "when you have diagnosed cancer of the stomach? You have diagnosed an incurable disease." There are three important considerations, however, a proper appreciation of which shows the subject to be one of great consequence.

1. *The incidence of the disease is high.* Cancer of the stomach is a very common disease, and it is becoming more common still. Half of all cancers originate in the stomach, and in men a larger proportion even than this. Whether a disease is, in its ultimate issues, incurable or not, if it is a common ailment and if it entails much suffering, it is essential that we should study it minutely and be able to recognize it at its earliest inception.

2. *The question of curability is probably in large degree a matter of early diagnosis.* This consideration not only holds good to-day, when the radical treatment of all cancers is by their surgical removal, but will no doubt hold good if and when the treatment of cancer proceeds along other than surgical lines.

Whatever chemical, physical, or biological principles govern the future treatment of cancer, it will be as important to begin the treatment at the earliest possible moment as it is now important to subject the patient at the earliest moment to a surgical operation.

3. *The differential diagnosis between cancer of the stomach and some other important, but less serious, malady is often extremely difficult.* The thorough investigation of a case of suspected cancer of the stomach provides the best possible exercise of the clinician's powers, because of the large number and the great variety of observations that must be passed in review.

I do not intend to deal to-day with purely pathological points, such as the morbid anatomy or the histology of the disease, nor shall I treat of the help in diagnosis derived from chemical investigations made upon the stomach contents after giving a test meal. I shall confine myself to the purely clinical aspects of the disease—to the symptoms and signs that can be made out without the aid of special apparatus.

Briefly put, the problem is usually as follows: A man, about 40 years of age, consults us on account of dyspepsia. What are the conditions of his illness which lead us to suspect, and eventually to diagnose, gastric carcinoma?

I. HISTORY OF THE PRESENT CONDITION.

In the history there is one very material point that quite often emerges: it is that the dyspepsia has arisen, as it were, in the midst of health. The man is not, as a rule, a chronic dyspeptic. This is rather a striking fact. There seems no doubt at all in many situations as to the predisposing effect of chronic irritation in causing cancer; but chronic gastritis does not seem to lead to new growth in the stomach. Certainly, for one case in which this sequence is observed there are a dozen in which it is absent. The rule is that patients developing gastric carcinoma have, until the beginning of the disease, enjoyed good digestion. The exception that proves the rule is the passing of a chronic gastric ulcer into carcinoma, but this, though definite enough at times, is not at all a common event. A close analogy exists between this fact in the history of cancer of the stomach and a fact so often seen in the study of intestinal cancer—the difficulty with the bowels complained of by patients with this disease is very frequently their first experience of constipation. Chronic constipation does not lead to cancer, despite the theorists.

who lay so much stress upon "intestinal stasis" as a cause of malignant disease. To summarize this point: as we should be very suspicious of constipation arising in a patient of 60 whose bowels have moved "like clockwork" until recently, so we should strongly suspect the state of affairs leading to dyspepsia of gastric type in a man of 40 who has formerly had no indigestion.

II. SYMPTOMS.

1. *Anorexia*.—This is an extremely common symptom, too little emphasized by the textbooks. For a long time it may be the only symptom of actual gastric origin; it may be quite unassociated with pain or vomiting. Its degree may be very marked, amounting to a positive loathing of food rather than a merely passive lack of desire for food. I recently saw a patient who said that to hear the rattle of the tray as the servant brought the meal upstairs, before the smell of the food was apparent—and the smell often causes distress—created a most unpleasant feeling of loathing. This anorexia, with the loss of flesh and strength accompanying it, is itself enough to raise suspicion of cancer of the stomach if no other cause is found. The anorexia may be for all kinds of food; at times it is for meat only. It contrasts with the state of the appetite in most cases of simple ulcer; here the appetite is seldom lost, and is often excessive or capricious.

2. *Flatulence and Heartburn*.—Symptoms common to various stomach disorders, and to some that are trivial in their nature. They help little in the diagnosis of the case. There is, however, one point worth mentioning—that the feeling of distension, in the case of cancer, is but little relieved by careful choice of food. Removal of sweet stuff, and perhaps of all carbohydrates, from the diet, usually serves to diminish, it may be completely to abolish, the gastric distension present in ulcer or dilatation. This is rarely seen in carcinoma.

3. *Pain* is a very variable feature, perhaps the most variable of all. Occasionally it is quite absent, even throughout the whole illness; it is sometimes a matter for surprise to see a patient with a large gastric tumour and extreme wasting quite free from pain. Unfortunately the contrary is the rule; cancer of the stomach is usually a very painful malady. The character of the pain differs from that of chronic simple ulcer; it is more constant, though it rarely rises to those severe heights of extreme and acute suffering seen in the hyperchlorhydria of ulcer. It is generally present as a persistent intractable ache—the worst sort of stomach-ache in fact. The pain more often involves the back in cancer than in simple ulcer and the radiation of the pain commonly suggests widespread gastric adhesion. "Hunger pain" is uncommon, food seldom giving complete relief, as is often the case in ulcer.

4. *Vomiting*, again, is a variable symptom, but it is more constantly present than in ulcer. When it occurs it less often brings relief of pain than in simple ulcer. And careful dieting less often checks it.

5. *Haematemesis*.—A frank bleeding—that is to say, the vomiting of a good quantity of fresh or recently clotted blood—is distinctly uncommon in cancer of the stomach. When it occurs it is often a terminal event, and is due to the ulceration of quite a large vessel, such as the splenic artery or the pancreatico-duodenal artery, the vessel having been caught up into the base of the malignant ulcer. A patient who faints, or who is left blanched, as the result of a severe haematemesis—or of a severe melæna, for the same argument holds good—is much more likely to be suffering from a simple ulcer than from a carcinoma. This point in differential diagnosis is not altered by the fact that the patient's age is over 40; chronic ulcer is not uncommon round about the age of 50, and occurs even later than this. It is not a single large hæmorrhage but steady slight oozing that characterizes cancer. This oozing shows itself, by careful inspection of the vomit, in two ways: (a) By the so-called "coffee grounds," a sediment of dark brown material, sometimes only distinguishable from the dark residue of gastric stasis by spectroscopic examination; (b) by small black specks or shreds which are in reality small clots altered by the action of acids in the stomach. The identification of one or of both of these forms of blood is of the utmost importance. Single findings are not, of course, of nearly such significance as repeated findings.

6. *Loss of flesh*.—Despite the fact that some patients with gastric cancer lose no weight, or actually gain weight under preliminary treatment, the fact remains that the great majority progressively lose weight, and this in spite of treatment. In almost every wasting disease the patient may come under observation in a condition when the general nutrition is below that degree necessarily imposed by the extent of his lesion. No conclusion, therefore, should be deduced in this respect until he has been at rest and under treatment for about fourteen days. If, at the end of this time and despite treatment, the weight still falls, a case of stomach disease is almost certain to be either cancer or extreme pyloric stenosis, or, of course, a combination of both of these—that is, the observer is dealing either with a condition of relative starvation from mechanical obstruction at the pylorus or with progressive malignant disease. And it is not very difficult to decide between these two states. In connexion with chronic diseases of the stomach, therefore, careful periodic weighings are of the utmost importance.

7. *Loss of Strength*.—Asthénia is significant, but not very helpful in diagnosis, unless associated with definite evidence of stomach disease.

III. PHYSICAL SIGNS.

1. *Local Signs*—that is, signs elicited on examination of the abdomen and adjacent parts. These signs are found almost entirely by inspection and palpation.

(a) *Inspection* of the abdomen is of great importance, and is too often slurred over. For efficient observations a good light is essential, and the position of the observer should for preference be at the head and at the foot of the bed rather than at the side. In this way any asymmetry, however slight, or anything unusual in the curves of the abdomen, may be quickly detected. The effects of respiration upon the lines of the abdomen are carefully watched. It may be advisable to inspect the abdomen again after inflation of the stomach by gas. It is convenient to remember that the two common situations of gastric cancer are (1) the region of the pylorus and (2) the region of the lesser curvature and body of the organ. (Growth at the cardiac orifice and diffuse infiltration of the whole organ are types of cancer of much less frequent occurrence.) These two common forms present two different pictures: (1) Pyloric cancer leads to dilatation of the stomach—it may be great dilatation—with (at some time or other) a small tumour in the right hypochondrium. Here the signs of dilatation are seen, and usually of gastroptosis also. (2) Cancer of the body of the stomach leads usually to early fixation of the organ in a more or less normal position, with (at some time or other) a tumour in the epigastrium. In (1) there is apt to be a depressed epigastrium and a full hypogastrium; in (2) the epigastrium is apt to be full, the hypogastrium (relatively) depressed.

(b) *Palpation* of the abdomen is no less important than inspection. Here a warm hand is as much a desideratum for successful examinations as a good light was in inspection. The position of the patient is that in which the muscles are most relaxed. It is sometimes helpful to palpate the abdomen whilst the patient is in a warm bath. Palpation possibly discovers five things: (1) The position and size of the stomach if this is dilated; (2) the presence of a tumour; (3) rigidity of muscles; (4) tenderness; and (5) enlarged glands or secondary masses in other organs than the stomach. It is well to emphasize the importance of localized rigidity of muscle—a finding that is only secondary in importance to the discovery of a tumour. Constant rigidity of certain areas of the rectus abdominis, such as the upper part of the left rectus, in a case of suspected cancer on other grounds, is probably sufficient to justify operative procedure. For it must be remembered that this rigidity may conceal a tumour, and even if this be not the case, it is important to operate on gastric cancer before the growth is so large as to yield an abdominal tumour on examination. When rigidity is definite it is well to examine under chloroform; the absence of a tumour in these circumstances raises the question of chronic simple ulcer. In palpating for enlarged glands the region of the supraclavicular triangles must not be omitted.

2. *General Signs*.—These include some very important features.

(a) *Anæmia*.—Blood examination yields definite differential help between cancer and simple ulcer. For if considerable hæmorrhage be excluded, the presence of any degree of anæmia greatly favours cancer—or, to be more accurate, it should be said that the absence of anæmia is much against cancer. In pyloric stenosis due to simple fibrosis, as from an old healed ulcer, wasting may be extreme, and yet there may be little or no anæmia; the condition is largely one of starvation, and in starvation the blood suffers relatively little. Whereas oftentimes a patient in whom the degree of wasting is less, but who suffers from gastric cancer, yields a red blood count and hæmoglobin percentage considerably below normal. Too much importance can scarcely be attached to this point.

(b) *Fever*.—When fever is present in a chronic case of stomach disease, the nature of the disease is more likely to be malignant than simple ulcer. It is not, however, common—it is not nearly so common as in cancer of the large bowel.

(c) *Cachexia* is a late sign, and therefore one I will not dwell upon.

(d) *The tongue* gives very little, if any, help. Its state is very dependent upon local conditions, as of the teeth, pharynx, etc.

The data obtained as the result of all these considerations is supplemented by observations of the stomach contents removed after giving a test meal. It is important that more than one such observation should be undertaken. In some cases a series of *x*-ray pictures after a bismuth meal will still further assist the diagnosis. As the result of all these methods, and not as the result of any one alone, a diagnosis of cancer of the stomach should be arrived at as early as possible. In concluding, let me draw your attention to these two specimens in our museum; they both illustrate successful operations upon cases of cancer of the stomach. In the first the growth which you see was removed seven years ago; in the second, two and a half years ago. Both patients are today alive and quite well. Such results as these, albeit not common, should stimulate us to active and thorough efforts at early diagnosis of this important disease.

AN INSTANCE OF LARGE URETERAL CALCULUS AND SOME OTHER CASES OF CALCULI.*

By GEORGE WHERRY, M.C. (CANTAB.), F.R.C.S. (ENG.),
LECTURER ON SURGERY, UNIVERSITY OF CAMBRIDGE.

I RECORD my five cases in which calculi have been removed by operation. Four were renal or ureteral, and in one a stone was excised from the perineum. In the cases of renal and ureteral stone the *x*-ray photographs proved very helpful.

CASE I.

The first case is that of a girl, aged 16 years, from whom large calculi were removed from the pelvic portion of the right ureter by intraperitoneal operation. The patient was admitted to Addenbrooke Hospital under the care of Dr. Bradbury, by whose kindness I was called in to consider the case. It should be noted that there was very little in this girl's condition to call attention to her real malady. She was admitted with pains in the joints and epigastric pains; there was some swelling of the knee-joints on both sides; she had pain in the right side of her chest, aggravated by coughing, and had not felt well for a month. There was a history of pneumonia and pleurisy two years before, and frequent sore throat. The urine was acid, free from albumen and sugar. She was watched during five weeks until an access of fever and abdominal pain led to further examination of the urine, in which pus and blood were found, and some crystals of oxalic acid. Digital examination by the rectum detected a hard mass on the right of the uterus; under an anaesthetic this mass was felt to be fixed, but not connected with the uterus. The *x* rays made it almost certain that there were calculi in the ureter; a clear space was to be seen around the stones inside the ring of the true pelvis. As the patient's condition was certainly growing worse it was decided to operate. Her temperature varied from 101.4° on the day of admission to 104.2° on the day of operation.

Operation.—Through a median incision the abdomen was opened, and then with the patient in the Trendelenburg position two large calculi were found in the pelvic portion of the ureter. The stones were fixed and could not be pushed

upwards or downwards. The ureter was clamped above, an incision was made, and the stones removed; about two ounces of purulent urine was swabbed out. The ureter was sewn up with catgut, using a harelip needle. The patient was then placed in the horizontal position and the suturing tested, so that the pressure in the ureters was tried in two positions. The clamp was removed and the abdomen closed in the usual way without the use of drainage.

In this case the calculi were so deep in the pelvis as to make it a question whether it would not be better to pursue the bolder course of operating through the peritoneum rather than by the usual extraperitoneal route. In the latter procedure the consideration of the large size of the wound, the difficulty of suturing the ureters, and the certainty that a drain would have to be used, with long delay in healing, decided me to venture on the operation above described, in spite of the very real risk of leakage of purulent urine into the peritoneal cavity. However, a good recovery was made, the temperature came down at once to normal, and except for washing out the bladder with boric lotion there was no trouble with the nursing. In textbooks the extraperitoneal method is recommended. But it is obvious that methods may be combined of operating through the peritoneal cavity and then making a drain from the pelvic basin to the exterior, directed from within by a limited incision. There is the possibility also of pushing the stone upwards to the pelvis of the kidney or downwards to the bladder. The two narrow points where stones commonly lodge are just below the kidney and, lower down, some two inches above the bladder. In the pelvic end of the ureter stones are fortunately not so often found.

It has chanced to many surgeons, as it has chanced to me, to cut through a healthy ureter which has become involved in a tumour, and on the ureter being carefully stitched no trouble beyond anxiety to the surgeon has resulted. But in dealing with pathological cases in which the ureter is dilated and contains urine loaded with bacilli, the risks must be serious. With regard to the technique of the operation, there is much to be said in favour of an intestinal needle instead of a harelip needle unless the tissues are very thick, but in any case catgut, not silk, should be used lest a crust should subsequently deposit on the silk. The stones removed from Case I were of large size. Together they measured 2½ in. by 1 in. diameter, and their weight when dry was 226 grains and 91 grains = 317 grains.

CASE II.

The next case is that of George S., aged 23, who had calculi in both kidneys. The stone in the right kidney was first removed. In this operation there was nothing unusual and a good recovery was made, but on the left side there was a great collection of pus, and as the stone in the ureter could not be reached from the loin, a large drainage tube was put into the abscess cavity, and when a certain stage of recovery had been reached and the cavity had contracted, an abdominal intraperitoneal operation was planned and the stone pushed into the kidney. This done, the incision in the loin was enlarged along the drain tube, and the stone extracted with a scoop. The patient made a good recovery, and wrote to the hospital on May 23rd to state that he was well and about to start work.

CASE III.

This was a chauffeur, aged 28, who had continued his work until his admission to hospital under the care of Dr. Bradbury. He had pain in the left loin, which had begun only about five weeks previously. He had passed blood on one occasion only; it was after taking urotropin. About a year previously he had an attack of appendicitis, but recovered without operation; thirteen years ago he had had a vesical calculus removed by lithotomy. On admission there was tenderness over the left renal area; the urine was loaded with pus, but showed no blood or casts, and a skiagram demonstrated calculi in the left kidney. At the operation were removed masses of phosphatic debris too friable to hold together in the scoop, and the whole kidney was distended with purulent urine and in a state of phosphatic pyelonephritis. Thorough douching was used to clear the cavities of crusts as well as possible, and a large drainage tube inserted.

The patient did well, but there was pus in the urine for some weeks, and an *x*-ray photograph taken since the operation still shows the shadows of phosphates. His general condition is excellent.

CASE IV.

This was a countrywoman, who, though stout, looked pale and feeble; she had been ill and in great pain for many months past, and had constantly passed large quantities of pus with the urine. Finally, when absolutely obliged by her malady, she sought relief at the hospital. With all her stoutness it was

* Read before the Cambridge and Huntingdon Branch of the British Medical Association.

possible to make out a swelling and a dull area at the seat of her pain in the left lumbar region, and a skiagram showed a collection of stones. It was evident that an operation was her only chance. Despite her wretched condition it was undertaken. An incision resulted in the removal of a quantity of stones and of a large amount of pus from an enormous loculated abscess. She rallied somewhat and gave hopes of recovery, the pus draining well from the inserted tube, but after a week the struggle proved too much for her enfeebled powers, and she gradually sank and died nine days after the operation.

There was no fair chance for surgery in this case, the patient having delayed too long. The operation was borne fairly well, but there seemed no recovery power, and probably there was very little actual kidney tissue left remaining.

The last case to which I propose to draw attention was one of calculus in the perineum.

CASE V.

The patient, a labouring man aged 33, came under my care in the hospital on April 24th, 1912, with a sinus in the left side of his scrotum, which discharged pus and urine. The left testis was absent, and he had a right scrotal hernia. He had been at work up to the end of 1911, when he had an attack of influenza; and it was only since then that he had noticed discomfort and discharge. A catheter passed into the urethra struck a stone about the position of the triangular ligament; and two days after his admission an incision down to this point was made and the stone removed. It measured $1\frac{1}{2}$ by $1\frac{1}{2}$ in., and must have been forming for a long time. It was very firmly impacted in the perineum under the pubic arch, and projecting into the urethra, and thus blocked it. The septic condition of his scrotum prevented me from examining the bladder lest it should be tainted by the catheter or sound. During his convalescence from the operation the sphincter of the bladder worked perfectly, the patient passing water like a woman, until the wound had granulated and healed up; he recovered without the recurrence of any cystitis.

This, therefore, was an extravescial stone when extracted, but had its origin in the kidney or bladder, whence it had travelled into the urethra, and there ulcerated through the mucous membrane, and gradually grew into the perineum along the lines of least resistance to its present size. The patient did all the work of a labourer on the land until shortly before the operation, but never rode a bicycle.

The x-rays proved a very valuable help in the diagnosis of these cases, as also in their operative treatment; and I am grateful to Dr. Scales for his co-operation, especially for the picture of the large pelvic stone in the young female.

TREATMENT OF CONGENITAL DISLOCATION OF THE HIP.

By A. S. BLUNDELL BANKART, M.C.CANTAB.,
F.R.C.S.ENG.,

Surgeon to the Royal National Orthopaedic Hospital, etc.

[WITH SPECIAL PLATE.]

SINCE Lorenz, in 1895, first introduced his operation of "bloodless reduction" of congenital dislocation of the hip, treatment of this affection has become well established in orthopaedic practice, and it is attended, in the majority of cases, with the happiest results.

Many surgeons, however, have not made themselves acquainted with the progress of this branch of surgery during the last eighteen years, and even now one hears the old objection that in congenital dislocation treatment is useless, and that the acetabulum is absent, or at least so small that the head of the femur cannot be placed therein. But orthopaedic surgeons know that an acetabulum of some sort is always present, except in some old untreated cases in which, in the course of years, it becomes obliterated; and the argument that it is too small is a relic of obsolete pathology, for, however rudimentary it may be, it is still sufficient. It is many years since we were taught to believe that bone is a rigid, unalterable structure. We know now that bone, like other tissues, is capable of undergoing plastic changes in obedience to forces acting upon it; an angular deformity in fracture becomes buttressed by new bone on one side and rounded off on the other; the bones of the foot become changed in shape, both in the development and in the cure of deformities; similar

changes occur in the spine, the chest, in fact in any part of the skeleton. It is proved beyond question that in congenital dislocation of the hip, if the head of the femur is placed and retained "in," "on," or "against" the acetabulum, the bone grows out around the head, the acetabulum becomes deeper and the head better developed, so that a joint is formed which is anatomically and functionally sound.

The majority of surgeons who deal with these cases have adhered more or less closely to the technique described by Lorenz; indeed, many still follow his original teaching in every detail. But it must not be supposed that the surgery of congenital hip has stood still for eighteen years. Many modifications have been introduced during that time—some good, and some bad—and, while the general principle of Lorenz's pioneer work remains the same, there is no doubt that just as good results—and in many cases, I am convinced, much better results—can be obtained by a technique which differs in many ways from the original.

I do not propose to describe the details of Lorenz's procedure here, but some criticisms of the method must be made.

I.

As every one knows, the first step in Lorenz's "bloodless" operation is to stretch or tear the soft parts around the joint; the adductor muscles are ruptured by forcible abduction and hacking with the hand; the parts behind and in front are stretched by forced flexion and hyperextension, and those above by traction on the limb. It is taken as an axiom that the hip cannot be properly reduced until all the soft parts are so stretched as to offer no resistance. This is not true; for in the majority of cases the hip can be reduced without any of these violent preliminaries, which are responsible for most of the shock and for nearly all the accidents of the Lorenz operation, and which, in addition, greatly weaken the muscles of the thigh.

The constant pull of the muscles upon the femur is the most important factor in bringing about the development of the joint, and, provided that the head of the bone is in place, the more powerful the muscular retraction the better. The muscles should therefore be damaged as little as possible.

II.

Many surgeons do a preliminary tenotomy, sometimes an extensive division, or even partial excision, of the adductors, in order to facilitate stretching. This, I am convinced, is a great mistake. I have seen a number of cases in which there was a wide gap where the adductors had been divided. Some of these cases had been successfully reduced and had good hip-joints, and yet they walked very badly. The disability in many of these cases is, I believe, due to permanent weakness of the adductor muscles, the gait being comparable in every way to what is often seen in cases of infantile paralysis when the adductors are affected, and the child, to compensate for the weakness, throws himself on to the head of the femur at each step, so that he sways from side to side. Simple tenotomy of the adductor longus is sometimes necessary in old and resistant cases; as a routine it is to be condemned. When a congenital hip is reduced and fully abducted, some muscles are bound to give way, but the damage should be limited to this, and unnecessary interference avoided.

III.

In the earlier attempts to treat congenital hip, the great difficulty was the tendency to redislocation of the head of the femur backwards. To overcome this, Lorenz introduced his "frog" position, in which the thigh is fixed in right-angled abduction and external rotation, the knee being actually behind the plane of the hips, and this position is still used in the majority of cases immediately after the hip has been reduced.

But the fear of relaxation has been exaggerated. In the Lorenz position the head of the femur is thrust forwards and tends to project in front; often it passes in front of the acetabulum, and an anterior transposition is the result. Anterior transpositions are so common after the Lorenz technique that some surgeons have even counted them among their "successful" results! It is

true that, compared to an untreated dislocation, the functional result of anterior transposition is often very good, but it cannot for a moment be compared with that of true reposition. The head should be placed in the acetabulum, and nothing short of that can be called a success.

When the Lorenz position is maintained too long, the retraction of the soft parts behind is so great that the thigh cannot be rotated inwards. Consequently after this treatment one sees many cases of persistent external rotation (often associated with anterior transposition), which gives rise to great disability, and is most difficult to treat. The Lorenz position should be employed until the tendency to backward displacement is overcome—that is, a comparatively short time—after which the thigh should be placed in a position of *internal rotation*, which gives a much more perfect apposition of the head of the femur and acetabulum, and which also allows retraction to take place more equally all round the joint.

IV.

When the hip is successfully reduced, there is considerable tension on the muscles of the thigh, especially on the hamstrings, which keep the knee tightly flexed. Great stress is laid by Lorenz and his followers upon the stretching of these muscles by daily extension of the knee soon after reduction. I believe this to be absolutely wrong. The surest way to induce redislocation of the hip is to stretch the hamstrings early by extension of the knee. The force of such stretching acts obliquely upwards on the femur, and if there is any possibility of the head slipping sideways from the acetabulum, it will be made to do so. The fear of permanent flexion of the knee is unfounded. Personally I make a point of including the knees, flexed, in the first plasters, so as to ensure that they are left alone. I have had them fixed in this position for upwards of eight months, and I have never had any trouble in getting them straight afterwards. In the second position of the hip it is necessary to include the knee in order to secure internal rotation.

V.

Another fallacy of the Lorenz after-treatment is the alleged importance of "grinding" movements of the head of the femur in the making of a new acetabulum. To this end the child is encouraged actively to use the limb within the restrictions imposed by the plaster. The knee being left out, some rotation of the femur is possible, and it is a common practice to put the child astride on a low chair or hobby-horse, and to let her push herself about with a leg on each side; then she is taught to walk, and the activity such patients display in their plasters is often surprising. All this, as I have said, is to encourage "grinding" of the joint. It is thought that the grinding or boring motion of the head of the femur is a most important factor in deepening the acetabulum and in promoting the formation of new bone around it.

I believe this is a notion derived from a false analogy. We know that in certain fractures which fail to unite, constant movement is a factor in preventing repair; and that when a false joint forms the opposed ends of the bone become smooth, rounded, and to some extent mutually adapted by friction and pressure; friction, too, is mainly responsible for the development of a false capsule to the joint. But in congenital dislocation of the hip totally different conditions obtain. The head of the femur and the acetabulum are both covered by cartilage, and all the elements of a joint are present. The aim of treatment is to secure *stability*. The changes in the bones are brought about, not by friction, but by constant unchanging *pressure*. The source of this pressure is the pull of the thigh muscles upon the femur, and this pull is constantly acting when the head of the bone is in place. Under the influence of this force, if the limb is left absolutely undisturbed, the acetabulum can be seen (by *x* rays) to become deeper, the head of the femur is better developed, and a buttress of new bone grows up from the margin of the acetabulum around the head until a secure joint is formed (Fig. 2). Then, and not till then, should the child be allowed to use the limb. Activity before this stage can only make for instability. By movement the pressure is distributed over a wider area, instead of being concentrated on the centre of the joint; the acetabulum becomes wide

and shelving instead of steep and abrupt; the capsule is looser all round than if the joint had been kept still, and, lastly, movement is a potent cause of redislocation.

VI.

Ultimately, when the plaster is removed and the child is allowed full freedom, she rapidly regains her strength and normal use of the limb, *provided that the hip has been properly reduced*. I have never found it necessary to order special exercises, massage, or manipulations to strengthen the muscles or to obtain movement in these cases. Children do not waste to a skeleton through mere inactivity. In cases of tuberculous disease of the spine or hip we see children immobilized, sometimes for years at a time, and yet, as soon as they get about, they pick up all they have lost. During recumbency they are for the most part plump, and merely "out of condition" in the athletic sense. In congenital dislocation of the hip persistent weakness after reduction is due to gross injury of muscles; restricted movement is due to faulty reduction.

The Reduction of Congenital Dislocation of the Hip.

By far the best method with which I am acquainted is that of reduction over the *inferior* border of the acetabulum, advocated by Ridlon. It is performed in the following way: In the case of a left hip the knee is grasped with the right hand, and the limb is fully flexed both at the hip and the knee; the head of the femur is thus directed downwards. Pressure—and, if necessary, great pressure—is now made straight downwards upon the knee, so that the head of the femur is driven down below the acetabulum; counter-pressure is made by the other hand upon the tuberosity of the ischium, and the position of the femoral head is made out by the fingers of that hand feeling in the buttock. The descent of the head is increased by internal rotation of the thigh, but, as Ridlon has pointed out, it may even descend too low for easy reduction. When the head has thus been brought below the acetabulum, the thigh is slowly abducted; the head then passes upwards over the lowest part of the rim into the acetabulum.

The simplicity, rapidity, and ease of this reduction, as compared with the Lorenz method, is often surprising. In the latter the hip is reduced over the *posterior* margin of the acetabulum, with the thigh abducted to a right angle. To do this successfully, the head of the femur must first be brought down to that level by tearing and stretching the soft parts. But in reduction over the inferior border no preliminary violence is employed; the limb is not previously pulled about in any way; descent of the head is secured by the position of the limb and by direct pressure downwards on the femur; when the thigh is abducted the muscles aid rather than oppose reduction.

The elimination of unnecessary violence is a great advance in the treatment of congenital hip. Shock is infinitely less; the risk of accident—fracture, paralysis, etc.—is reduced to a minimum; permanent weakness of the muscles is avoided, and their important action during after-treatment is better preserved.

One other advantage must be specially mentioned. In the treatment of congenital hip it is generally agreed that there is an age limit beyond which it is inadvisable to attempt reduction—usually about eight years in bilateral, and about ten years in unilateral, cases. This restriction is imposed on the Lorenz operation on account of the great violence required to stretch the soft parts in older patients, whereby the severity of the operation is proportionally increased, and the risks of serious accidents are very much greater. But, as I have already said, in reduction over the inferior border, these preliminary forcible manipulations are avoided, so that the same objections do not apply to this method. Accordingly, the scope of the operation has been considerably extended in recent years, and many older patients are treated now than formerly. It is not to be denied that the difficulties increase with age, but provided that they can be overcome, there is *no age limit*, as such, to reduction of congenital dislocation of the hip. The limit is reached, in an individual case, when the operator ultimately fails to get the hip in. I have emphasized this point because many surgeons maintain that it is unjustifiable to attempt reduction over a certain age. Many patients are, therefore, passed over who at the present day certainly ought to be

given a chance. The ideal of treatment is to benefit the greatest possible number of patients, and if there is any possibility of getting a hip in without serious injury to the patient, it should be attempted. It may be said in passing that the age of a patient is not always a sure guide to the difficulty of reduction; a case of 14 or 15 may prove to be easier than one of 4 years old; often in bilateral cases one side is much more difficult than the other; some of the most difficult cases are in quite young children.

Treatment after Reduction.

As soon as the hip is reduced it is put up in plaster-of-Paris while the child is still under the anaesthetic. At this stage the Lorenz position—that is, abduction to a right angle and external rotation—is adopted, but it should be seen that the head of the femur is not displaced too far forwards. Both sides should be put up, even when the dislocation is unilateral; though in the latter case the sound hip need not be forced into full abduction, but should be put into as nearly a symmetrical position as it will go. A unilateral plaster is unsatisfactory, as it does not fix the hip properly. Also, I always make a point of including the knees in the plaster, so that no stretching of the hamstrings is possible.

Skiagrams should be taken before and throughout the treatment, and the position of the head of the femur should be checked by them. The position is often spoken of as being "good," "fair," or "nearly in." But there are no degrees in reduction of congenital hip—the hip is either in or it is out. If it is in, well and good; if it is out, the plaster must be cut off and one must begin again by reducing it.

One is often asked how long the first plaster should be left on, but it is impossible to give a fixed time for all cases. It is determined in each case by the conditions found at operation and after. In an average case, where there is fair stability on reduction, it is left on for three or four months, and at the end of that time the hip is examined, and according to the degree of stability present it is decided whether to change the position or not. The hip should never be allowed to redislocate in order to estimate its stability. Cases which are very difficult to reduce, and also cases which are very easy, as a rule require longer fixation than others. Often the more easily a hip slips in the more easily will it slip out and the longer will be the time required to make it firm. In some very mobile cases—especially in some which had been unnecessarily stretched—I found that the only way to prevent redislocation was to keep the hip in the first position for a year. On the other hand, it must be remembered that fixation for too long a time in one position may give rise to difficulty later. The time must be separately determined, not only for each case, but, in bilateral cases, for each hip.

When sufficient retraction has occurred in the soft parts behind the hip, the position of the limb should be changed.

The second position is one of slightly diminished abduction with about 45 degrees of *internal rotation*. This brings the centre of the head of the femur into more perfect apposition to the acetabulum; it removes the tendency to anterior transposition; and it allows a more equal retraction of the soft parts around the joint. An anaesthetic is necessary for this change, and the position is secured by a plaster which again includes the knee, flexed. In a bilateral case each hip is treated according to its own indications; so that either the position may be symmetrical, or one hip may be in the second position while the other is still in the first. In a unilateral case the sound thigh is brought down straight, and the upper part of it is included in the plaster.

This plaster is left on as a rule for four or five months, after which a fresh one is put on in still further diminished abduction, and this time leaving the knee out. In a unilateral case, only the affected side need now be put up. If there is any contraction of the knee it is soon overcome; and then, provided that the hip is firm, the child is allowed to walk, the sole of the boot on the affected side being raised about 2 in. to keep the limb abducted. In a bilateral case if one side is more advanced than the other, it must wait until both are ready for the child to walk, and of course no raising of the boot is necessary.

When I first adopted fixation of the knee in the plaster

I expected that some contraction of the hamstrings would follow, and I was surprised, on cutting off a plaster after eight months' continual flexion, to find that the knee could be straightened at once without any force. This I have since found to be common, and when slight contraction does occur it is always easily worked out in a few days by ordinary manipulations. I have never had any difficulty in getting the knees straight, and as I believe that it is important to leave the muscles alone until the hip is firm, I never have any hesitation in fixing the knees during the earlier stages of the treatment.

The last stage of the treatment consists in gradually reducing the amount of abduction and in deciding when to allow the child to go free. The skiagrams should now be showing a well-marked formation of new bone above the acetabulum, the cavity of which is better developed, as is also the head of the femur. These changes indicate that redislocation will not take place, and the child may safely be allowed to go without plaster. The last remnant of abduction is left for the child to get rid of, and, if a good joint has been formed, she quickly does this, and in addition recovers full use of the hip.

Naturally, plastic changes occur more readily in the growing bones of young children than in the denser, more mature bones of older patients. The fact that reduction may be attempted at a later age in *neglected cases* must not be taken to mean that treatment may safely be deferred while the child is young. To obtain the best results congenital dislocation of the hip must be treated in *early childhood* while the growing bones are soft and readily adaptable. Only in neglected cases does the question of late treatment arise, and in these cases it is determined by (1) the possibility of getting the hip "in," and (2) the probability of a stable joint forming within a reasonable time.

It has been shown that, if time is no object, bone changes similar to those which occur in children may be brought about, even in adults, by a constantly acting force. Thus in the old days of exclusively instrumental treatment of deformities, extreme cases of genu valgum, etc., were *cured* by apparatus which was worn sometimes for any period up to fifteen or twenty years. Such slow progress is not tolerated at the present day, and, of course, it is out of the question in the case of congenital hip, where the patient cannot get about until the joint is firm. The example merely serves to show that plastic changes can be brought about in a mature skeleton, though much more slowly. In late cases of congenital dislocation of the hip the question is whether sufficient stability can be secured within a reasonable time. If there is a fairly good acetabulum and fair stability on reduction the ordinary routine treatment may be successful, but failing this the only alternative is an open operation to make an acetabulum—that is, by cutting it out. The open operation has given good results in a number of selected cases, but it is exceptional treatment to be reserved for old cases, and its performance as a routine in young children is to be absolutely condemned. The best results in congenital dislocation of the hip are obtained by manipulative reduction in early childhood, and they are incomparably superior to those obtainable by any other method of treatment.

In a speech recently delivered at the general meeting of the Society of Preservation against Tuberculosis, the French Minister of the Interior supplied the following figures as to tuberculosis which he said no one could dispute. Of the total number of deaths in France a proportion of 12.07 per cent. is due to definitely recognized tuberculosis, a figure higher than that of all other diseases. The proportion is higher in France than anywhere else. Moreover, during a period of three years 217 deaths per 100,000 inhabitants have been recorded, as compared with 139 deaths in Belgium, 166 in Italy, 146 in England, and 168 in Germany. The evil appears still more serious when it is considered that it is especially in persons between the ages of 20 and 40 that tuberculosis is particularly frequent. Of 100 French men and women who die at that age, 42 die of tuberculosis. In Paris the mortality from tuberculosis in 1909 was 44 per 10,000 inhabitants. The proportion was 33 for the department of the Seine, 30 for the Seine Inférieure, 27 in the Cotes-du-Nord, 26 in the Finistère, L'Ille et Vilaine, Loire Inférieure, and the Rhone. In the Hautes Alpes it fell to 10.

CONGENITAL DISLOCATION OF THE HIP (MR. A. S. B. BANKART).

FIG. 1.—Congenital Dislocation of Left Hip. Boy aged 3½ years. Before treatment. B, Upper epiphysis of femur. (Skiagram by Dr. Stanley Melville.)

FIG. 2.—Congenital Dislocation of Left Hip. Same case as Fig. 1, ten months after reduction. A, Buttress of new bone at upper margin of acetabulum. B, Upper epiphysis of femur.

PAROTID TUMOURS (PROFESSOR A. STREET, L.M.S., BOMBAY).

CASE I. Hindu, aged 48. Tumour had existed since childhood. Weight, 7 lb. 3 oz. Perithelioma.

CASE II. Hindu, aged 35. Weight, 5 lb. 4 oz. Ten years' history. Endothelioma.

CASE III. Hindu, aged 40. History, 5 years. Weight, 6 lb. 8 oz. ? Round-celled sarcoma.

CASE IV. Hindu, aged 25. Weight, 2 lb. 12 oz. Ten years' history. Myxoma.

A SERIES OF CASES OF PAROTID TUMOUR.

[WITH SPECIAL PLATE.]

By LIEUTENANT-COLONEL A. STREET, M.B.,
F.R.C.S., I.M.S.,

PROFESSOR OF SURGERY, GRANT MEDICAL COLLEGE, BOMBAY.

The following cases were reported by me at the meeting on June 20th, 1912, of the Bombay Branch of the British Medical Association, but as there was a full account of one such case reported in the JOURNAL of June 8th from China I think these, with the accompanying photographs, may be considered of sufficient interest to be published in the JOURNAL.

They were all operated on by me at the Jamsetji Jeejeebhoy Hospital, Bombay, and all recovered without any troublesome symptoms. The four operations were all performed under chloroform, and the dragging and weight of the tumour in no way caused difficulty in its administration. During the removal of the tumour very little difficulty was experienced, and afterwards the main trouble was that nearly all the veins required ligation, the walls being too thin to stand torsion, and if only clamped were liable to restart bleeding when sponged. The amount of skin that needed removal was more than one would have expected at first, and owing to only a small piece having been removed in the first case there was some bagging and collection of serous fluid which delayed healing till it could be drained away. The duration and the weight of the tumour had completely destroyed the elasticity of the skin, and the amount of stretching it had undergone is well shown in Fig. 2 by the distance between the pores.

The clinical history was much the same in all: one had existed for forty years, two for ten, one for five. The growth of the tumours had been slow and even, except in No. 3, which had spurted the last year. The tumours were painless, not tender, freely movable, and the skin was only adherent in places where cauterization and then healing had taken place; but the skin in all showed where cauterization as applied by the native Hakims had been tried. One man came from Ratnagiri in the south, one from Poona in the east, one from Surat, and one from Cutch in the north. They were all Hindus and males. They gave their ages as 48, 40, 35, 25. Two, at all events, confessed that the reason they wanted operation was that they were waiting to get married. Their clinical history and description was practically the same, and the naked-eye section did not reveal much difference, some being more nodular both on the surface and on section than the others; very few, and small, cysts were found in all. No glands were found enlarged in any case.

A portion of each growth was sent to the pathologist of the hospital for examination, with the statement that it was part of a parotid tumour. His report, however, showed very considerable difference. No. 1 was stated to be perithelioma; No. 2, endothelioma; No. 3, round-celled sarcoma; No. 4, myxoma—a mixed tumour. No. 1 weighed 7 lb. 3 oz.; No. 2, 5 lb. 4 oz.; No. 3, 6 lb. 8 oz.; No. 4, 2 lb. 12 oz.

This series seems interesting on account of the large size of the growths, and the fact that they should come from north, east, and south within a period of six months.

PROFESSOR BLANCHARD reported recently to the French Academy of Medicine the occurrence of a tapeworm in man previously known as infesting the orang-outang only. It was passed by a girl aged 8 in Mauritius. It belongs to the genus *Bertiella* (now *Bertiella*) formed by Professor Blanchard in 1891 to receive two cestodes of the anthropoid apes, *B. stuederi* of the chimpanzee, and *B. satyri* of the orang-outang. Apart from the interest of the communication due to the addition it makes to the ever-growing list of human parasites, it raises a curious point in zoological distribution. This parasite has now been found on opposite sides of the Indian Ocean, in the ape in Borneo and in man in Mauritius, and so far in these localities only; but Professor Blanchard points out that this is not a solitary instance of the wide distribution of a cestode. *Darained madagascariensis* (a parasite of man) first identified in the Comoro Islands north-west of Madagascar, has also been found by Leuckart in Siam, and by Daniels in British Guiana.

CHRONIC ARTHRITIS:

THERAPEUTIC EVIDENCE OF THE INCIDENCE
OF STREPTOCOCCAL INFECTION.

By D. W. CARMALT JONES, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN AND DIRECTOR OF THE DEPARTMENT OF
BACTERIO-THERAPEUTICS, WESTMINSTER HOSPITAL.

It is a commonplace that accurate bacteriological diagnosis is essential to the successful treatment of bacterial infections by specific therapy. Yet in many cases this diagnosis is so difficult that it is abandoned, and frankly empirical methods of bacterio-therapeutic treatment are adopted, with necessarily variable results; still, some information of diagnostic value may be gathered from the results obtained in a series of empirically treated cases.

In practice, bacteriological diagnosis for therapeutic purposes is made by direct or indirect methods, or a combination of the two. The direct method consists in the recovery of bacteria of known infective nature, such as the *Bacillus tuberculosus*, from any part of the body, or of bacteria of any kind from sites normally sterile, such as the blood stream or the joints.

The indirect methods consist in the estimation of "reactions," either "immunity reactions" or "constitutional reactions." The "immunity reactions" depend on the power of the tissues to elaborate antibodies to any foreign albuminous substance introduced into them which is capable of solution in the body fluids. The antibodies are produced in excess of the amount required to neutralize the foreign substance, and the residue passes into the blood and can be demonstrated by suitable methods in the drawn blood serum. The bactericidal, bacteriolytic, or agglutination reactions are those most generally available. The opsonic reaction is similar, but presents certain differences.

The "constitutional reactions" depend on the peculiar sensitiveness of a person suffering from certain specific diseases to inoculation with minimal doses of the infecting organism or its products, a rise of temperature and local signs at the site of inoculation occurring in a susceptible person which do not arise in healthy people; this is the basis of the various tuberculin tests.

These two methods are applicable to infections with bacteria of known virulence, and are comparatively straightforward procedures, but much of the difficulty in bacteriological diagnosis is due to the fact that many organisms are only potentially infective, since they are constantly present on the mucous surfaces of quite healthy persons as harmless parasites, and only occasionally give rise to disease. When definite pathogenic bacteria cannot be found, organisms of potential infectivity may be taken from any breach of surface or from one of the mucous membranes, and the immunity reactions of the patient's blood may be investigated. Instructions to carry out these tests so often turn out to be a counsel of perfection, that treatment is frequently invited with a general recommendation to do the best one can.

To do this it is necessary to hazard a bacteriological diagnosis on clinical grounds, and in these circumstances it is as well to give a guarded prognosis, nevertheless the clinical diagnosis of some bacterial infections is made every day with tolerable accuracy. Such a diagnosis, however, can only be made on the strength of numerous previous observations, in which a group of symptoms and physical signs have been demonstrated by recognized bacteriological methods to be constantly associated with a certain infection. Any bacteriological evidence, therefore, which associates a disease of obscure causation with a definite infection is an addition of some value to the knowledge of the etiology of that disease.

In reviewing the indirect methods of bacteriological diagnosis, mention was made of "constitutional reactions," meaning general and local disturbance set up in susceptible subjects by small doses of bacterial substances. Another form of constitutional reaction is complete or partial recovery from a given disease under treatment by specific antibacterial methods, but since diagnosis should precede treatment this method is not available for purely diagnostic purposes. However, the records of results of similar cases treated empirically by the same specific remedy afford

bacteriological evidence which may be of value for clinical diagnosis.

This paper is a contribution to the bacteriological diagnosis of arthritis based on the results of such empirical therapeutic measures. It contains the records of twenty consecutive cases in private practice suffering from arthritis of various types, in all of which a tentative clinical diagnosis of streptococcal infection was made, and which were treated with vaccines of streptococci derived from different sources. They do not go to show that all cases of arthritis are due to streptococcal infection, nor is that the least likely, for the *B. tuberculosis*, gonococcus, and pneumococcus are all well known to infect joints, which indicates that joints are susceptible to a considerable variety of bacterial infection. If, however, therapeutic results can be accepted as a basis of bacteriological diagnosis, these cases indicate that streptococcal infection is frequently concerned in cases of chronic arthritis.

The cases were, in the majority of instances, of long standing, they had resisted general therapeutic measures, and no source of infection was clearly indicated. Effusion into joints was rare, and the fluid when removed by puncture was invariably sterile. Blood cultures were also sterile whenever investigated. For various reasons streptococcal infections were suspected, and the patients were accordingly treated with vaccines made from streptococci obtained either from the mouth, in cases of oral sepsis, from the urine, or from the faeces. The patients have, in most instances, remained in the charge of their own medical men, whose reports are here quoted, so that any prejudice on the part of the writer, and any suggestion to the patient arising out of the employment of a new doctor and a supposedly scientific method of treatment have been, as far as possible, excluded.

CASE 1.

Seen with Dr. Luff, under the care of Dr. Johnson, Richmond. A lady, aged 70. Arthritis of many years' duration; bedridden.

Possible Site of Infection.—Mouth; gums retracted.

Bacteriological Examination.—Blood culture, sterile; urine, sterile; faeces, *B. coli* and *Streptococcus faecalis*; gums, streptococcus, *Micrococcus catarrhalis*. Vaccine of *Streptococcus faecalis* prepared.

Inoculation followed immediately by subjective improvement. Duration of treatment six months. Dr. Johnson reports: When first inoculated, sallow, almost yellow, with the usual toxic stain of skin, and anaemic. Pains in all joints, notably shoulders, elbow, and knee. Finger-joints and knee-joints much swollen. Nights bad, unable to turn herself in bed, appetite nil, bowels constipated. Pulse 90 to 96. Now extremely well in herself, excellent colour, pink and clear. Pulse 70 to 76. Temperature normal. Great abeyance of pain, though every now and then a fair amount in hands (finger-joints) and knees. Anxious to try to walk; appetite excellent, bowels regular. Joints very little swollen, though considerable joint destruction and tendency of fingers to ulnar side.

CASE 2.

A lady of 60, seen with Dr. Luff, under the care of Dr. Christopherson, St. Leonards. Rheumatoid arthritis, duration six years (since menopause). Joints affected—cervical, shoulders, wrists, hands, knees, ankles.

Possible Focus of Infection.—Gums; teeth began to "dissolve" some years before arthritis was felt, many had been extracted, and of the few left the incisors were much worn away at the necks.

Bacteriological Examination.—Blood culture, sterile; urine, sterile; gums, streptococcus, tetrad, *Micrococcus catarrhalis*. Vaccine of streptococcus. Inoculated six months. Dr. Christopherson reported that he was unable to see any improvement. The patient ultimately died of abdominal neoplasm.

CASE 3.

A lady of 50, seen on the recommendation of Dr. Luff, under the care of Dr. Halley, of Fulham. Duration twenty-four years. Joints affected: nearly all joints of limbs, great disorganization of metacarpal-phalangeal joints of hands with forward dislocation.

Suspected Cause.—Septic absorption from intestine. Gums sound; no oral sepsis.

Bacteriological Examination.—Blood culture, sterile; urine, numerous diphtheroid bacilli; faeces, *B. coli* and *Streptococcus faecalis*. Vaccine of streptococcus; after six inoculations Dr. Halley reported she had less pain in joints, and was decidedly stronger, but the improvement was not maintained.

CASE 4.

Seen on the advice of Dr. Williams, Harrow. A lady aged 45. Arthritis affecting many joints, with effusion into wrists, and sometimes other joints. No evidence of bony change. Duration several years. Exciting cause unknown.

Possible Source of Infection.—Teeth, well cared for, but considerable retraction of gums.

Bacteriological Examination. Fluid from wrist-joint, sterile; urine, coliform bacillus giving reactions of *B. acidilactici*; faeces, coliform bacilli only; gums, *Streptococcus salivarius*. Vaccines: (1) *B. acidilactici*, four inoculations given with little change; (2) after this, mouth streptococcus for about eight weeks; massage was employed at the same time. There was marked subjective improvement both in general health and in the joints, with decrease of pain and increase of power, and considerable decrease in swelling, though the joints were still liable to effusion.

CASE 5.

Seen on the advice of Dr. Luff, under the care of Dr. Fox-Symons, South Kensington. Gentleman, aged about 50. Had an attack of gonorrhoea, followed by septic conditions of the throat, and some angina. After this had acute pains in various joints, with temperature up to 103°. Joints hot, swollen, and painful.

Bacteriological Examination.—Blood culture, sterile; urine, numerous diphtheroid organisms; faeces, *B. coli* and *Streptococcus faecalis*. Vaccine of latter. Two inoculations were given.

Dr. Fox-Symons reports that the temperature rose to nearly 102°; there was a general lighting up of pains all over the body. After an interval another dose was given; all acute symptoms recurred, and inoculations were discontinued. The patient had had inoculations of the stock vaccine previous to this, and probably an error was made in starting the autogenous vaccine with too large a dose.

CASE 6.

Seen on the recommendation of Dr. Luff; under the care of Dr. Murray, of Hornsey. A lady of about 60. Severe polyarthritis of sudden onset, six months' duration.

Possible Site of Infection.—Gums; much pyorrhoea, lower incisors loose. Patient refused to have efficient treatment for the mouth.

Bacteriological Examination.—Gums: Profuse and nearly pure streptococcus. Vaccine of same. Dr. Murray reports that after four or five injections the patient had derived no benefit, and refused further treatment.

CASE 7.

Under the care of Dr. Earle, Hyde Park. A lady of about 65. Arthritis two and a half years, following prolonged fatigue. Joints affected numerous, especially hands and knees. Much deformity of fingers, shortening of tendons, but no bony changes detected.

Possible Site of Infection.—Mouth; much gingivitis and pyorrhoea, which remained untreated.

Bacteriological Examination.—Mouth, streptococcus; urine, diphtheroid bacillus and streptococcus. Vaccine of streptococcus. Treatment about three months.

Dr. Earle reports that the treatment seemed to give some slight subjective relief at the time; no objective improvement.

CASE 8.

Lady of 30. Tonsillitis for many years, subject to acute attacks; recent acute attack followed by arthritis in knees, ankles, and arm joints.

Bacteriological Examination.—Throat: *Streptococcus brevis*. Vaccine of same. Inoculated six weeks. Made good recovery.

CASE 9.

Seen on the advice of Dr. Luff, under the care of Dr. Cathcart Bruce, Kensington. Lady of 28. Acute illness clinically resembling rheumatic fever several months before treatment began. Many joints involved. Condition had apparently become chronic. No oral sepsis.

Bacteriological Examination.—Blood culture, sterile; urine, sterile; vaginal discharge, diphtheroid bacilli; faeces, *Bacillus coli* and streptococcus. Vaccine of *Streptococcus faecalis*.

Dr. Bruce reports that after fourteen weeks' pain, with temperature ranging high during which many joints were affected enlarged and painful, the vaccine treatment was started. This had an almost immediate effect, and at the end of three months there was no sign left of the trouble, and no recurrence at the end of eighteen months.

CASE 10.

Seen on the recommendation of Dr. Luff, under the care of Dr. Earle, Hyde Park. Lady about 60. Arthritis of about two years' duration. Many joints affected, especially knees. No evidence of bony change. Teeth well cared for. Abscess of one tooth had affected the gums of some of those adjacent.

Bacteriological Examination.—Urine contained streptococcus. Vaccine of same.

Under treatment for several months. Great subjective improvement with occasional slight relapses.

CASE 11.

Lady aged 60. Seen on the advice of Dr. Luff, under the care of Dr. Schacht, Kensington. Arthritis of two or three years' duration following severe mental and physical strain; bedridden. Joints affected: Small joints of fingers, elbows, ankles, and other joints. No fluid, no bony change detected. Gums retracted.

Bacteriological Examination. Blood culture, sterile; urine, sterile; faeces, *B. coli* only; gums, streptococcus. Vaccine of streptococcus.

Dr. Schacht reports that the patient's general condition gradually improved in the summer and autumn to a marked degree; was able to attend an "at home." Less nervous and irritable, and sleeping well; pain in shoulders and joints less;

wrists and finger-joints smaller and more mobile. Some months later there was a recurrence, and further inoculations were given. It is difficult to estimate the fluctuations, but "There is no doubt she is distinctly better again."

CASE 12.

Under the care of Dr. Earle. Lady aged 50. Chronic rheumatic pains in various joints. No oral sepsis.

Bacteriological Examination.—Urine, numerous diphtheroid organisms; faeces, *B. coli* and *Streptococcus faecalis*. Vaccine of streptococcus. Duration of treatment about six months.

Dr. Earle reports both subjective and objective improvement during and for some time after treatment. There has been a relapse since. On the whole the treatment seemed to do good.

CASE 13.

Seen on the advice of Dr. Luff, under the care of Dr. Wood, Bloomsbury. Lady aged about 50. Arthritis two years. Right knee, left wrist, many finger-joints affected; changes chiefly polyarticular; no evidence of bone affection. Slight gingivitis; no other obvious source of infection.

Bacteriological Examination.—Blood culture, sterile; urine, *B. coli*, staphylococcus; mouth, many organisms, chiefly coliform and *Micrococcus catarrhalis*; faeces, *B. coli* and *Streptococcus faecalis*. Vaccine of *Streptococcus faecalis*.

The patient went abroad and reported after about a month: "The treatment is doing me a lot of good, and I think when I have my teeth seen to I shall soon be able to walk as I used to."

CASE 14.

Seen on the advice of Dr. Luff. Gentleman aged 51. Joints affected; temporo-maxillary, shoulders, elbows, distal joints, three ulnar fingers, hips, knees; feet flat, hammer toes. A little fluid and slight grating in several joints, especially hips. Teeth few and bad; receding gums. Completely crippled. Five years previously had slight injury to a knee, followed by sudden hydrarthrosis. Had bath treatment and massage, which led to an attack of "rheumatic fever." In bed five months; joints began to swell. Progressive arthritis ever since. Distinctly worse after bath treatment. Had gonorrhoea fifteen years before, but no evidence of gonococcal infection could be obtained by autoinoculation experiment.

Bacteriological Examination.—Teeth, diphtheroid bacillus, tetrad; urethral discharge, diphtheroid bacillus; faeces, *B. coli* and streptococcus. Vaccine of gonococcus was tried without result. He has had inoculations of streptococcus vaccine for the last two and a half years. The disease is progressing, but the patient thinks he gets slight relief from the inoculations.

CASE 15.

Under the care of Dr. Tyson, Folkestone. Lady aged about 45. Arthritis, duration several years. Joints affected generally, especially hands. Enlargement of joints, interphalangeal joint left hallux destroyed, with hyperextension. Left temporo-maxillary joint sometimes affected.

Site of Infection.—Lower gums considerable swelling, no definite pyorrhoea.

Bacteriological Examination.—Urine and faeces similar streptococcus; mouth, *Micrococcus catarrhalis*, coliform bacillus. Vaccine of streptococcus.

Dr. Tyson reports: Inoculated two months, but "I cannot say that there were changes subjective or objective noticeable either for better or worse."

CASE 16.

Seen on the advice of Dr. Luff. Lady of about 50. Arthritis twenty years' duration. Sudden onset in left index finger; all joints affected since, varying in degree. Right knee much distended and stiff, hands deformed.

Possible Site of Infection.—Mouth, slight pyorrhoea.

Bacteriological Examination.—Synovial fluid in knee, sterile; gums, streptococcus. Vaccine of streptococcus. Inoculated three months; no improvement.

CASE 17.

Seen in consultation with Dr. Farquhar Buzzard, under the care of Dr. Payne, Torquay. Lady aged about 35. Joints affected, fingers, knees, ankles, and others. Slight limitation of movement. No bony change detected. Duration eighteen months. Teeth and gums sound and well cared for with the exception of an abscess at root of one tooth. Chronic vaginal discharge.

Bacteriological Examination.—Gums, *Streptococcus salivarius*; vaginal discharge, diphtheroid bacilli in pure culture; urine normal; faeces, *B. coli* and streptococcus. Vaccines of *Streptococcus faecalis* and *Streptococcus salivarius*. Under treatment nine months.

Dr. Payne reports the amount of pain very variable; sometimes quite free when at rest, but comes on with movement. Finger-joints smaller, wrists and ankles markedly improved. Knees and neck most troublesome. Still fluid in left knee. Shoulders better; pain chiefly felt in knees and neck. After the first two months in Torquay the *Streptococcus salivarius* vaccine was commenced; up to that time the joints and other symptoms were getting much worse. The chief improvement has taken place since very good Swedish massage was started three months ago.

CASE 18.

Under the care of Dr. Turner, Ryde. Lady aged 33. Duration two years; stated to have followed septic condition of mouth. Joints affected: Right wrist slightly swollen, right knee swollen, left elbow flexed; great loss of power in all limbs. Possible site of infection month; slight gingivitis.

Bacteriological Examination.—Synovial fluid from knee, sterile; mouth, *Streptococcus salivarius*; urine, sterile; faeces, *B. coli* and *Streptococcus faecalis*. Vaccine, *Streptococcus faecalis*.

Dr. Turner reports: Duration of treatment six months; during last months of treatment improvement has taken place in pain and swelling, which continued steadily until six months after discontinuance. Both pain and swelling have now disappeared, leaving nothing but ankylosis.

CASE 19.

Lady of about 60. Under the care of Dr. Male, Croydon. Joints affected, fingers; Heberden's nodes on fingers; synovial crackling right knee, thickening of synovial membrane left knee. Possible source of infection, rheumatic fever twenty-seven years before. History of endocarditis. Aching pains on and off ever since in legs and arms. Joints very recently affected.

Bacteriological Examination.—Urine, streptococcus. Vaccine of same.

Dr. Male reports that vaccine was injected for four months. Marked subjective improvement during treatment, but relapsed later towards the end of treatment. On the whole condition now is better than formerly. Does not complain of knee. Temperature has tendency to rise at night. Nervous symptoms predominate. Still has occasional bouts of rheumatism at times.

CASE 20.

A medical man. Seen on the advice of Dr. Luff. Acute arthritis of some months' duration. Double flat feet, especially on the right; severe pain in tarso-metatarsal joint; fusiform swellings of all finger-joints. Mouth sound, slight gingivitis only.

Bacteriological Examination.—Blood culture, sterile; urine, sterile; faeces, *Streptococcus faecalis*. Vaccine of latter. Duration of treatment, three months. Slight improvement, probably not referable to vaccine.

I wish here to record my thanks to the various gentlemen who have assisted me with these reports and for their permission to publish them.

These results may be analysed as follows. One case, No. 9, is cured. Six cases, Nos. 1, 4, 8, 10, 11, 18 are much improved. Six cases, Nos. 3, 7, 12, 13, 17, 19 have shown some improvement. Six cases, Nos. 2, 6, 14, 15, 16, 20 are unchanged. One case, No. 5, was much worse.

From the point of view of bacteriological diagnosis, the cases cured and much better afford strong evidence of streptococcal infection, and No. 5—the case in which there was marked increase in symptoms—points equally in the same direction. The six cases which were quite unchanged are evidence against such infection, and the improvement in the six cases described as slightly improved cannot be separated from accessory treatment such as the massage adopted in Case 17, or from the psychological influence inherent in any form of treatment which is new to the patient. It is, however, a reasonable conclusion from this series of cases that eight out of twenty unselected cases have given strong therapeutic evidence that their arthritis was due to infection by streptococci chiefly derived from some part of the alimentary tract.

THE Governments of Norway and of the Principality of Monaco have given their adhesion as from January 1st, 1913, to the arrangement signed in Rome on December 9th, 1907, by which the international office of public hygiene was created in Paris. The number of countries which now take part in the work is twenty-nine.

At the last meeting of the Roentgen Congress, held at Berlin under the presidency of Dr. Immelmann, it was decided to establish a system of tours for the purpose of seeing radiographers in different places at work and studying their methods. A large number of heads of laboratories have already expressed their willingness to receive the members. The first tour is to take place from September 15th to 20th, when the visit will be made to Vienna. For the second tour the week before Whit-Sunday of next year has been suggested. A round of visits will then be paid to Bremen, Hamburg, Altona, Cologne, Bonn, Frankfurt-on-the-Main, Nuremberg, Erlangen, and Munich. A special subcommittee has been formed from the committee of the German Roentgen Society, consisting of Drs. Eberlein, Levy-Dorn, and Immelmann. Communications should be addressed to this subcommittee, Lutzowstrasse 72, Berlin.

SEQUEL OF A CASE OF CARDIOLYSIS.

BY

SIR ROBERT SIMON, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

IN THE BRITISH MEDICAL JOURNAL of December 14th, 1912, was published a case of cardiolysis.

A boy of 15, who appeared to be at the point of death from cardiac failure, supposed to be secondary to adhesions of the pericardium to the heart muscle and to surrounding tissues and organs, was operated upon by Mr. Barling on June 17th. Every method of treatment had previously been tried but had failed to relieve him.

At the operation about 14 in. of ribs over the præcordial region were removed and adhesions to the sternum and ribs were broken down. Good results were almost instantaneous; four days later the pulse, which had always been from 100 to 120 per minute, fell to 60. Diastolic bruits which had been audible could no longer be heard, and the only systolic murmur audible was over the mitral orifice.

Three weeks later it was noted that, though his pulse was irregular, he was comfortable and much less cyanosed than formerly. His breathlessness had vanished, he was able to walk up and down stairs, oedema had disappeared from his legs, and the marked ascites was no longer existent. The improvement was quite remarkable, and continued until the end of October, when he gradually began to fail.

All the old symptoms reappeared, and, though he was treated continuously either in the General or the Jaffray Hospital, nothing could be done for him. Death occurred at the end of March. A very careful *post-mortem* examination was made for me by Dr. Parsons and Mr. Hayeraft, and the result of their examination, for which I am greatly indebted to them, is as follows:

POST-MORTEM NOTES BY LEONARD G. PARSONS, M.D.,
AND J. B. HAYERAFT, F.R.C.S.

External Appearances.—The body was very thin and wasted. The face was cyanosed. The abdomen was distended and discoloured, and there was some oedema of the legs, chiefly on the left side. Over the præcordium there was a large depression and a semilunar scar where the ribs had been resected by surgical operation.

Thorax: Universal adhesions; many of the adhesions were oedematous, broke down easily, and looked fresh; others were dense and firm. The heart and pericardium were extremely large, measuring 6 by 5½ in., with marked recent and old adhesions to the chest wall, to the operation scar, and to the lungs. The pericardium is universally adherent to the heart, and can be separated in patches only, and that with the greatest difficulty. The heart cavities are considerably dilated. There is a slight thickening of the mitral cusps (some functional regurgitation). The other valves are quite normal in appearance. The heart muscle is quite pale and very flabby, and showed marked hypertrophy. Left ventricular wall ¾ to 1 in. thickness. The pericardium is very adherent to the diaphragm, and there are marked adhesions around the inferior vena cava and round the superior vena cava and the venae innominate. All these veins, together with the jugulars, were very distended with blood. The left internal jugular measured 1 in. in width. These veins were traced along their whole extent, and no constriction or stenosis was found, even where they were enveloped in fibrous tissue. The left lung was considerably retracted. There was a fair amount of straw-coloured fluid in each pleural sac, and there were many adhesions. Both lungs showed marked oedema, and the lower lobe of the right lung was consolidated. The pulmonary veins throughout the lung seemed distended, and their walls showed up very distinctly; they did not appear to be distended.

Abdomen: On opening the abdomen there was an escape of a large amount of clear, yellowish-coloured fluid. The inferior vena cava was full of blood and markedly distended. The renal veins were in a similar condition. The stomach and duodenum were healthy. The intestines were normal.

Liver: There is some perihepatitis, and on section there is a definite, although small, increase in fibrous tissue. The liver on section shows a well-marked nutmeg character. It is free from adhesions to other organs and to the diaphragm.

Pancreas: Healthy.

Kidneys: Right, 3½ oz.; left, 4 oz. They showed some congestion.

The *spleen* was enlarged, firm in consistence, of a dark red colour, and congested and also showed a mild degree of peri-splenitis.

The *suprarenals* were enlarged and of a purplish colour.

The inferior vena cava showed the smallest calibre when passing through the diaphragm. There was no stenosis beyond that point, and it opened into the auricle by a very large mouth. The Eustachian valve was very prominent, and the right muscle very dilated.

Microscopical Examination.

Liver: The capsule showed some degree of thickening, and there was a slight increase of fibrous tissue round the portal tracts with some spread into the lobules. In a few places there was some small-celled infiltration, and the liver columns were separated by oedema and congestion.

The *kidneys* showed some degeneration of cells of the convoluted tubules, and some early fibrous change affecting the vessels and glomeruli.

Spleen: Definite fibrosis of capsule, trabeculae, and vessels.

The *suprarenals* showed patches of small-celled infiltration, and the medulla was of more open structure (oedema) than normal.

So far as I know this is the first time the sequel of a case of cardiolysis has been recorded, and the results are not only very interesting but may have also a very important bearing upon treatment. In addition they do, to a certain extent, justify the opinions I hazarded as to the causation of symptoms when the pericardium is adherent to structures in the mediastinum.

They show, moreover, the accuracy of the observations of Sir Thomas Barlow, who had noted the dilatation of the jugulars in similar cases, and of Professor Keith, who suggested that the symptoms were largely due to the posterior adhesion. To both of these gentlemen I am greatly indebted for their letters and their interest in my case. They justify, I think, my guess that the ascites and the cyanosis might be due to the nipping of the inferior and superior cavæ respectively, for though no stenosis of the former was found, it is expressly stated that the smallest calibre of the vein was found in its passage through the diaphragm.

The disappearance of practically all the bruits which had been audible over the whole cardiac area was remarkable, and justified the opinion that they were due not to endocardial changes but to distortion of the relations of the valves and the heart cavities.

What the bearing of the *post-mortem* evidence on future surgical methods may be I cannot say, and perhaps it would be unwise to generalize from a single case, but it is difficult not to think that, if there are evidences of pathological adhesions to the diaphragm, it would be wise to try to divide some of them. It is, I think, material to this point to remark that the operation has been always done in cases in which there is no possibility of improvement by means other than surgical, and that if death results, as, so far as published cases show, it never has resulted, from operation, it will anticipate by only a few days or weeks death with all the distressing symptoms of breathlessness, sleeplessness, and mental misery.

There can be no question that in my case the operation was worth doing, for it gave the patient a good six months of pleasant life and comfort before the recurrence of distressing symptoms began.

AN ANALYSIS OF A SERIES OF CASES OF HYPERTENSION AND HYPOTENSION TREATED AT VITTEL.

BY

H. J. JOHNSTON-LAVIS, M.D., D.Cr., M.R.C.S.,

PROFESSEUR AGRÉGÉ; SENIOR CONSULTING PHYSICIAN, QUEEN VICTORIA HOSPITAL, NICE; BEAULIEU.

I look upon the sphygmomanometer as just as important an instrument in the diagnosis and treatment of chronic ailments and diseases as is the thermometer in acute ones. The interpretation of blood-pressure readings, however, is a far more complicated problem than is that of making one's deductions from the varying height of the thermometric column.

My first experiences of the use of instruments for measuring the hydraulic phenomena of circulation were those early investigations of Dr. George Oliver. From that time onwards I employed at irregular spells one or another of the numerous instruments for measuring arterial tension. In 1903 I was driven by a very serious attack of cyclic synovitis for treatment at Vittel, where I entirely recovered, and since 1904 have reversed my condition from patient to physician at that spa. During the last nine seasons, therefore, a large number of patients have passed through my hands.

At about this time—1904—I realized that a large proportion of ailments attributed to varied and multiple causes could be grouped together as due to different forms of chronic toxæmia. The writings of Huchard and others were directing attention to the importance of hypertension as being most frequently the preliminary phenomenon that eventually led up to "heart disease." They furthermore assigned to most hypertension and eventual arterio-sclerosis a toxi-alimentary origin. Their teaching had a marked influence upon our ideas of the whole question, and did much to modify our views of treatment. I was much struck by these writings, and my old interests in blood pressure were again thoroughly revived, all the more so because Huchard had chosen Vitte! as being the ideal place for the treatment of hypertension.

Two or three years' experience convinced me, however, that although a toxi-alimentary origin formed a large proportion of predisposing causes, there were also others at work, and that not infrequently several causes were combined. In fact, I now think that there are many conditions which favour this ailment, some of which we do not know, while of others we have but the faintest inkling.

I have chosen at random some 456 cases of all kinds which have resorted to Vitte! for treatment, the only conditions I have observed in the selection of them being that I was in possession of full records of each case, consisting of two complete quantitative analyses of the urine made under my supervision in my own laboratory both before and after the cure, and of the determinations of blood pressure, capillary reflux, pulse, weight, etc., taken before, during, and after the cure.

Normal Blood Pressure.

For the moment I do not propose to touch upon the arterial tension of children, of which I know little, but upon which some interesting researches have lately been published. Limiting the discussion, therefore, to adults, we are still met by a number of difficult problems. I have further circumscribed this study to maximum or systolic pressure only. The minimum or so-called diastolic pressure is still too problematical, and, although in most of these cases minimum pressures are recorded, yet I am so dissatisfied with the uncertainties of the readings that I postpone drawing conclusions therefrom to a later date. Most of the pressures here quoted were those recorded by a mercurial manometer. A large proportion were taken by my secretary, who has no medical training, and therefore no theoretical ideas by which to be influenced, but has great technical skill, and a large number were confirmed afterwards by myself.

In giving my experiences with Pachon's oscilometer¹ in a cursory way, I stated in outline only an empirical method which I have adopted, fixing upon average normal blood pressure, but with the desire to limit my letter I did not give collateral details and reservations. I here repeat the method: For every year of age after 15 I allow 1 mm. Hg. and add 100 to the number. Thus a person of 15 years of age should have 115 mm., one of 35 years 135 mm., one of 60 years 160 mm., etc.

The first qualification I would make to this is that these figures represent a *safe maximum*. The second is that for persons over 60 years of age there should not be a uniform rise in the systolic thrust, as somewhere about this time a markedly less strenuous mode of living is followed, and also the heart muscles begin to show the first indications of senile enfeeblement. As a third qualification I would say that, as the general muscles, glands, nerves, etc., vary in different people, so, no doubt, their heart, blood vessels, capillaries, etc., also vary, and even vary amongst themselves. A powerful heart with weak arteries and perhaps inefficient kidneys will give us a normal average blood pressure for such a person very different from that which a reverse condition would register. Many physicians know of people with permanently high blood pressures who have lived for years in good health, whilst others with relatively low blood pressure have died of apoplectic hæmorrhages or failing hearts.

Analysis of Cases.

These 456 patients include persons resorting to the cure for all sorts of ailments, but chiefly those who owed their ill health to some form of chronic toxæmia.

The largest number are those of the "gouty" nature—visceral, articular, and nervous. Next come those with the dominant phenomena of hypertension and heart troubles. After these follow albuminurics and other renal and vesical sufferers, while lastly we may place glycosurics, hepatics, etc. As may be observed, these are mostly ailments in which we expect to find some alterations in blood pressure.

Age.

From this total of 456 persons, then, we get an average age of 53.78 years—which will, no doubt, be inferior to the truth, since a considerable proportion were ladies—and an average blood pressure of 151 mm. Hg. evidently a far higher maximum blood pressure than we should obtain from the same number of persons of the same ages not requiring a cure. The average blood pressure on departure was 138 mm., which affords us a mean diminution indiscriminately for each person of 13 mm. But of the 456 patients there were 75 whose blood pressure rose and 36 with no variation. This leaves us 345, or three-fourths of the total, whose blood pressure went down in consequence of the cure. The calculated average age of these 345 was 54.1, while their blood pressure was 156 mm. before and 136 mm. after the cure, giving an individual mean reduction of 20 mm.—a striking demonstration of the good effects of the Vitte! treatment.

The next thing to select was all those whose blood pressure on arrival was over 160 mm., my maximum safe limit for any age. These attained the number of 154, the larger proportion of whom were sent to Vitte! for the purpose of reducing their hypertension. The average age of these was 59.75 years, with a mean tension of 182 mm. before and 159 mm., or a reduction of 23 mm., after the cure.

I then proceeded to make a selection of those over 60 years of age. Taking their averages once more I got 66 years, with blood pressure at 161 mm. before and 146 mm. after, or a reduction of 15 mm.—that is a gain of 14 mm. below the maximum safe normal for their ages.

It will be observed that those above 60 years of age had on arrival an average lower tension than the others of all ages who had a blood pressure above 160 mm. This would lead us to infer that in these younger patients we had further special causes for increased arterial degeneration, such as syphilis, nephritis, adrenal excess, capillary spasm, higher blood viscosity, etc., than in those over 60 years of age, where we have to look more to the true senile wear and tear of the arteries. In the group of those over 60 years no doubt a less strenuous mode of living would keep the heart at a lower level of activity, and our average may be vitiated by a certain number of failing heart muscles.

Passing now to the consideration of the 36 patients whose blood pressure remained unaltered during the cure, we obtain a mean age of 55 years and blood pressure of 144 mm., which, I think, will give us an absolute normal for persons of their age, and therefore it is to be presumed that as no reduction was necessary in such cases the cure did not act in this direction.

Effect of Vitte! Treatment on Abnormal Tension.

In the last group of the 456 we have 75 whose blood pressure was raised during the cure, their mean age being 51.6 years and their blood pressure before the cure 131 mm. and after 142 mm., or an augmentation of 11 mm. It may be noticed how very near were the final readings of these hypotensionists to the normal blood pressure of those who remained unaltered during the cure—that is, 142 and 144 mm. Obviously, 131 mm. is a decidedly low blood pressure for people averaging 51.6 years. If, however, we examine individually this group of 75 persons, we find many of them with blood pressure below or near 100 mm. In the statistics, however, the results are marred by a certain number whose blood pressure was fairly high and rose during the cure. Why this increase took place I am unable to say in some cases, but in others, as seen by their history and the analyses of their urine, we have to deal with hypertensionists from chronic nephritis. In these patients their kidneys are just able to perform the ordinary daily work, but when the renal structure has to deal with the large extra amount of fluid,

the actual volume of blood is temporarily increased. If one is able to watch these cases for several days after the cure, one may see that several of them come down finally to below the blood pressure they had on their arrival, and show permanent improvement. One well-known man illustrated this admirably. He had had blackwater fever four times. During the cure his blood pressure went up somewhat, but finally came down with a considerable margin to the good, and marked improvement in health. In these cases we ought to be allowed much longer for the cure, in order that we may push water-drinking so much less in proportion. All practitioners know, however, the meanness of patients in the question of time given to any course of treatment.

If we get a prolonged spell of cold and damp weather such as we had last year (1912) blood pressure often goes up, and then drops when warm weather comes, and the capillary reflux oscillates in accordance, showing that the hypertension is due to capillary spasm. The mechanism of this is, I think, fairly clear. I should like to know if any other physician has observed this fact. At any rate, it points to the great advantage of dry, warm weather for hypertensionists in general. I have frequently observed this favourable influence in such cases that come to me in my winter practice on the Riviera.

I am often asked by my medical colleagues whether, over and above the relief of the symptoms that usually accompany hypertension, the reduction or increase of blood pressure towards normal is permanent. The reply to this question must be qualified. I have no hesitation in saying that in most cases the improvement is not evanescent. On the other hand, if no intermediate care as to mode of living is taken, or no lixiviating treatment followed from time to time, the blood pressure again gradually rises. This rise, however, is far and away more gradual than after treatment by drugs, most of which I have used with very indifferent success, and which, I am convinced, are more dangerous—excepting as a temporary measure—than the hypertension which they are intended to reduce. Drug treatment in such cases is neither more nor less than superposing or replacing one toxæmia by another. In consequence of the length of this study, I propose to postpone to a future paper an investigation on these lines of a number of annual *habitués* to Vittel, who well illustrate this point.

Classification of Patients.

Experience has taught me to classify persons suffering from increased blood pressure into three classes. In the first group are those persons "who are never still"—I mean those who work, worry, play, etc., very hard. Their heart is always in an overstrained and excited condition, and pumps too hard. These may or may not have a minimum arterial-capillary spasm from their vessels carrying and being fed by a toxæmic blood in ratio to the nature of their diet and the efficiency of their excretory organs. In the second group are those where a toxæmic blood, setting up capillary and arterial spasm, has persisted until the arteries have advanced more or less towards permanent reduction in calibre by arterio-sclerotic changes, just as a long restrained limb becomes permanently a rigid one. The earlier these cases are treated, the greater and easier is the fall of blood pressure coincident with an increase in capillary permeability.

If we measure the capillary reflux in these cases we often find it fall during the cure from five to ten or more seconds to three or even less, and simultaneously the systolic blood pressure will diminish 30 to 50 mm., the heart regains its exhausted forces, the aortic clang is no longer audible, and cold extremities are replaced by warm ones. Even in the last stages of arterio-sclerotic disease, with a dilated and failing heart and fallen blood pressure I have seen great improvement; but, of course, here the cure must be very gentle, carefully watched, and prolonged over several weeks.

In taking the averages of our records of capillary reflux we obtained an average of 3.7 seconds before the cure and 3.5 seconds after. Taking 3 seconds as the average normal, it will be observed that all the patients had slow capillary circulation, showing that the average high tension was to no inconsiderable extent due to capillary spasm and high blood viscosity.

It is interesting, though to a less extent, to investigate

the total effect on the pulse, which often increases as blood pressure is reduced in ordinary conditions. This occurs when the pressure descends from normal or above it to below normal, the heart making an effort to keep up circulation, and so equalize nutrition in distant parts of the organism. Our pulse records give us a mean of 75 per minute on arrival and 73 on departure. Although the mean reduction is only two, yet the approach to average normal is marked. But what is of greater interest is that, notwithstanding the marked reduction in the blood pressure of these patients, not only did no increase of pulse-rate occur, but on the contrary a slight reduction, demonstrating that the improvement of the hydraulics of the circulation was a real and substantial one.

In the third group we must place the renal cases. Here great complexity arises. Complete twenty-four hour urine analyses help us a good deal, but are often deceptive as to the amount or advance of the kidney lesion. Many of these cases come year after year to wash their blood and tissues, clear their urine of casts, diminish or get rid of their albumen, if they have any, and to reduce their arterial tension. Some cases get quite well, and remain so for years; others wind up their clock of life for some months; but, year by year, as they return, a morbid, degenerative action, although greatly reduced in the speed of its progress, eventually leads to a fatal termination. In two of the cases recorded a patient and his wife came each winter to Beaulieu and each summer to Vittel. They were both cases of chronic nephritis. The wife, step by step, for three consecutive seasons at Vittel, quite recovered her health, but her husband, though he improved considerably each season, yet each year on his arrival had lost during the eleven months' interval more than he had gained during his previous cure. Eventually, after a number of renal and other small hæmorrhages, he died in London of uræmia. This man, two seasons before his death, arrived at Vittel with the phenomenal blood pressure of 290 mm., which fell during the first five days of the cure to 245 mm., and at the end of it to 215 mm. I have selected these two as illustrations, as they lived inseparably for many years, and therefore were exposed to identical surroundings, and ate the same food, etc.

Another question I am often asked is whether the reduction of hypertension in old people is brought about by a cure at Vittel. The answer to this is already given in the statistics for those over 60 years of age, as also for those with blood pressure over 160 mm. on arrival. Both results—the former showing a reduction after the cure of 17 mm. as the average per head, and the latter one of 23 mm.—are speaking enough. No more striking demonstration could be offered, I think, of the remarkably practical, positive, and fairly permanent results of proper treatment by a non-chloride bearing, slightly hypotonic water, in which we introduce into the organism no substance that does not enter into the composition of the human frame to a greater or less extent, a method of treatment incomparably superior to any employment of drugs.

REFERENCE.

¹ BRITISH MEDICAL JOURNAL, JANUARY 13th, 1912.

THE Principal Medical Officer (Dr. Sanson), in his annual report for 1911, states that the estimated population of the Federated Malay States was 1,045,947, being an increase of 44,690 over the number for 1910. The birth-rate was 19.41 per 1,000 of the estimated population—a slight decrease on the rate for 1910, which was 21.39. The death-rate for 1911 was 37.03, as against 32.16 for 1910. Malaria caused 45.02 per cent., and dysentery and diarrhoea 19 per cent. of the total deaths. The infantile mortality was 170 per 1,000. There are forty hospitals and nine gaol hospitals, and in these 97,162 in-patients were treated during the year, and 232,506 out-patients. An Advisory Board has been appointed (1) to collect and distribute information regarding malaria; (2) to advise how anti-malarial measures could be most advantageously carried out in each district; (3) to encourage and advise local bodies in their efforts towards extermination of mosquitoes; and (4) draw up appropriate legislative measures. There were 6,042 cases of beri-beri treated in the hospitals, with 695 deaths. The Government has had under consideration several proposals for preventing or limiting the use of an unsafe rice and encouraging the use of a safe rice.

X RAYS IN THE TREATMENT OF DISEASES OF THE PALM.

By HALDIN DAVIS, M.R.C.P., F.R.C.S.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE SKIN,
BLACKFRIARS.

VERY soon after their discovery the therapeutic value of x rays in the treatment of skin diseases became manifest, and a proper knowledge of their powers has become increasingly necessary to the dermatologist. As is well known, they are extremely valuable in the treatment of rodent ulcer, lupus, mycosis fungoides, and other serious diseases of the skin, and in this country, at all events, the attention of the profession seems to have been concentrated on this aspect of their utility to the exclusion of the advantages they possess in dealing with such conditions as chronic eczema and psoriasis. There are very few references to this branch of the subject to be found in English; the earliest I have been able to find is a paper by Biddle.¹ Other earlier but Continental papers are by Albers-Schonberg² and Hahn, who published a series of 35 cases with uniformly good results. Wettcer³ in 1908 stated that he had treated several hundred cases of chronic eczema with x rays which without exception did well. In America, Williams⁴ in 1904 published several cases of eczema cured with the rays.

The best account of the treatment of eczema with x rays will, however, be found in a book recently written by Dr. Schultz,⁵ which has been translated into English. The whole subject of x -ray therapy is excellently and impartially treated in this work, and it is a great misfortune to the science and art of radiology that Dr. Schultz has recently died. Very little has been published in this country on the treatment of eczema with x rays, although as early as 1899 Thurstan Holland published in this JOURNAL a case of eczema of the hand cured in four sittings with x rays. This is almost the only paper on this branch of radio-therapeutics which has been published in this country. In *Light and X-Ray Treatment*, by Sir Malcolm Morris and S. E. Dore, the question is dismissed in about three lines, and about the same space is devoted to it in the last edition of the same authors' textbook and also in that of Dr. Sequeira.

Perhaps more attention has been given to the radio-therapeutics of psoriasis, no doubt because that complaint is more often refractory to the older methods of treatment. Still there are many cases of chronic eczema persisting over long periods which may almost without exception be cured with x rays. Among the most obstinate forms, often quite uninfluenced by the ordinary treatment with ointments and lotions, are those which affect the palms of the hands. In these cases the skin of the palms is thickened, the horny layer is much changed and exhibits both the phenomena of hyperkeratosis and parakeratosis, and as a consequence the natural lines of the palm are much deepened, and often become the sites of painful and troublesome cracks and fissures. The patients complain as a rule of great irritation, which is occasionally sufficiently severe to disturb their sleep. Psoriasis of the palm does not, perhaps, cause the patient so much discomfort, but it is equally refractory to treatment. It consists of sharply defined areas of scaling, sometimes accompanied by changes in the nails, but by no means always associated with typical psoriatic lesions on other parts of the body. In the absence of psoriasis on other parts of the body the diagnosis may be very difficult. I have lately had the opportunity of treating some cases falling into the above categories, and in view of the fact that so little attention has been directed to this method of treatment I think they are worthy of publication.

CASE I.—Palmar Eczema.

G. G., a gentleman aged about 48, a patient of Dr. Stocker. He had suffered for two years from typical palmar eczema with well marked fissures and much hyperkeratosis. The subjective symptoms were not very severe—in fact, he was able to play golf in comfort when wearing gloves, but he complained of the unsightliness of the condition and the constant necessity for using lubricant applications to prevent the hands becoming stiff. He had used various plasters and ointments without much relief. The whole of the patient's skin was somewhat dry and he had a poor circulation, as was shown by the prominence of the venous network on his limbs. The eczema

had been supposed to be gouty, although there was no other sign of that condition, and otherwise he enjoyed excellent health. The examination of the urine disclosed nothing abnormal.

He was treated with x rays in the following manner: On September 2nd the left hand was exposed for seven minutes to a tube of equivalent spark-gap of 4 in. with 5 milliamperes of current passing through it, while the right hand was exposed for five minutes with the current gradually increasing from 0 to 1 milliampere. The distance of the anticathode from the skin was 8 in., and from measurements previously made with the same tube the whole dose was calculated to be about half a pastille dose.

On September 10th both hands were somewhat improved, especially the right. Each hand was given another half-pastille dose. On September 17th the hands were still more improved. Each palm received only a very small dose—about one-third of a pastille. On September 24th the palms were practically well, but some new cracks had appeared on the left thenar eminence, and this part, which had not previously been exposed to the rays, received half a pastille dose. On October 1st and on October 8th the left thenar eminence received about one-third of a pastille, and since then the patient has been quite well.

CASE II.—Palmar Eczema.

A lady, aged 68, who had definite articular gout, had suffered from fissured eczema of the palms for thirty years. When first seen on December 12th she had, in addition, patches of vesicular weeping eczema on the backs of the hands and also on the dorsal aspect of the third finger of the left hand just underneath her wedding-ring. She also had a patch of irritable erythema on the forehead.

The backs of the hands and the forehead were treated with zinc and ichthyol for a month and got quite well. On January 9th the palms were first x -rayed. They were given a dose of about two-thirds of a pastille each, and the same dose was repeated on January 23rd. On February 6th, except for being a little dry, the palms were quite well, there were no more fissures, and the patient said that the irritation had practically disappeared, so that she was able to sleep better than for many years. She said, however, there was still a little itching on the backs of the hands, and they therefore received half a pastille dose.

CASE III.—Palmar Psoriasis.

M. H., a woman aged 58, first came under my care at the Hospital for Diseases of the Skin, Blackfriars, on May 17th, 1912. She exhibited on the palms of both hands large peeling areas with well-defined margins. The natural lines were deeply cut, and in some places fissures had developed. The diagnosis of psoriasis was made because the condition was strictly confined to the palms, and there was not, as is usually the case in eczema, any inflammatory condition of the dorsal aspects of the phalanges. The nails, however, were, as is common in psoriasis, slightly pitted. The patient had suffered from this condition for eighteen months, although she had had much treatment.

She was treated at the Skin Hospital at first with tar and salicylic acid ointment, and for the first month made good progress, but afterwards relapsed. Various applications were tried without much success. Ultimately, however, on September 20th, 1912, she had a full pastille dose of x rays to both palms. On October 4th they were already much better, and on October 25th they were quite well, the first time for two years. Since then they have remained well.

As has been stated above, x rays are extremely useful in treating chronic eczema in most situations, but they are especially advantageous in the case of lesions situated upon the hands, because it is obviously very inconvenient to keep those almost indispensable appendages continually swathed in bandages, as is necessary if treatment with ointments is to have a fair chance of success.

THE Maryland University School of Medicine has instituted a course of tropical medicine, under the direction of Surgeon J. A. Nydegger, of the United States Public Health Service, with the assistance of Dr. C. W. Stiles and other members of the same service.

PROFESSOR SHERIDAN DELÉPINE, in a paper on post-graduate teaching in tuberculosis, published recently in the *British Journal of Tuberculosis*, urges that tuberculosis officers selected by authorities should be allowed after their appointment to devote a part of the first year to the study of the special pathological, administrative, and clinical work to which they will have to devote themselves in the service of the public. This proposal seems to be on all-fours with the regulations which already exist with respect to the medical services of the army and navy.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CHICKEN-POX DURING INTRAUTERINE LIFE.

I HAVE been unable to find in the literature any account of a case resembling the following:

I was called to see an infant some four hours after delivery. The child was apparently healthy, except for the presence of a rash distributed generally, but more marked on the scalp, face, and trunk. The palms of the hands and soles of the feet were also affected, as was also the mucous membrane of the mouth. In character the eruption was identical with that which obtains on or about the fourth day in varicella, that is, macules, vesicles, vesicles with turbid fluid contents, pustules, ruptured pustules, and scabs, were all present, indicating that the eruption must have begun whilst the infant was still unborn. There were no further signs of disease, and the eruption disappeared in a few days without a further crop appearing.

The mother of the child was apparently unaffected with the disease, but in the same house there had been cases of chicken-pox fourteen days previously, disinfection of the room having taken place, however, in the interval between that time and the birth of the child. The history of the illness of the other children was as follows: About twenty-five days before the confinement one child was removed to the fever hospital with measles and bronchopneumonia. Four days later a second child developed measles and chicken-pox, and a third followed with measles, and this last child developed chicken-pox in the fever hospital, incubation period having begun at home. In the interval between the removal of the last child and the birth of the infant—that is, fourteen days—no illness could be traced in the house, neither could any contact with infectious disease be discovered, except for the fact that the mother visited her children at the fever hospital.

Hirst, in his *Textbook of Obstetrics*, gives an account of various infectious diseases occurring in the fetus, and the following remarks are extracted in the main from that work. At first it was thought that the transmission of organisms into the placenta from the maternal blood was impossible, the ground for such belief lying in the results of experimental inoculation of animals with the tubercle bacillus, with the anthrax bacillus, and with pathogenic organisms. In the fetuses of animals injected with these micro-organisms, although the latter were found in the maternal blood in large numbers, none were ever discovered in that of the fetuses. Later, however, the observers responsible for the foregoing conclusions, as a result of further experiment, stated that micro-organisms and colouring matters, when injected into the maternal blood, could be discovered in that of the fetus. In a human fetus removed by Caesarean section from its mother, dead of septicaemia, numbers of micro-organisms were found in the blood.

Koubasoff¹ stated that he had always found anthrax bacilli in the blood of fetuses born of mothers infected with the disease except in one instance, where, in a twin birth, one fetus was macerated and its placenta the site of haemorrhages, the other being healthy and its placenta unaffected. In the blood of the former organisms were not isolated, whereas in that of the latter they were numerous; this seems to suggest that a pathological condition of the placenta is necessary to prevent the transmission of organisms, and is one which alone offers resistance to microbial invasion of the fetal blood.

The list of infectious diseases affecting the fetus *in utero* is lengthy. Variola is a well recognized entity. A child may be born covered with pustules or even scars, and the mother may or may not be affected with the disease. As a general rule, however, the fetus of a small-pox patient is born unaffected. The mother has in some cases been vaccinated during pregnancy in order to see if immunity may be produced in the fetus; a positive result occasionally obtains, but the reverse is the rule.

McDonald² has reported intrauterine measles, and scarlatina has been noted in many cases. Hirst quotes a case reported by Leale³ in which a child was born with a "strawberry" tongue and a red coloration of the skin,

the latter remaining for seven days, and on the tenth day albuminuria and oedema appeared.

Other diseases are also reported in the new-born fetus. A child has been born with consolidation of its lungs, the mother herself being affected with pneumonia. The organisms of septicaemia, cholera, malaria, typhoid, and erysipelas are reported to have been found in the blood of the new-born fetus.

All these facts are interesting in the light of the above case, which was clinically a definite but mild attack of varicella, as evidenced both by the eruption and the history of illness in the house, together with a satisfactory incubation period, although disinfection had taken place. If, then, small-pox and other infectious diseases may and do occur in the fetus, their origin taking place *in utero*, there is no reason why, in virtue of this case, chicken-pox may not be added to the list.

I must express my indebtedness to Dr. J. Prescott Hedley for advice and permission to publish this case.

Darlington.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.

RUPTURED SPLEEN IN A BOY: SPLENECTOMY: RECOVERY.

(By HOWARD H. C. DENT, M.B., F.R.C.S., L.R.C.P.,
Honorary Surgeon to the Hospital.)

On January 3rd, 1913, a boy, aged 14, was admitted under my care. He had been walking along a pit "way" without his light when he was run into by a tub coming towards him and thrown violently against a "prop." He felt a blow in his abdomen, suffered great pain internally, and vomited.

When I saw him he was blanched, very restless, and had great pain and distension of the abdomen. The urine contained blood, and he had bruises over his left shoulder and left ribs. The temperature was 97° F., the pulse was 108 and increasing in rate, and the respirations 28.

Internal haemorrhage was diagnosed, and the abdomen was opened in the middle line. It was found full of blood. The bleeding came from the splenic region. In order to gain more room a transverse incision was made across the left rectus. With considerable difficulty the spleen was pulled up for examination, and was then found badly crushed and lacerated posteriorly. I did not think it possible to suture the tears, and therefore decided that the safest course was to remove the organ. Clamps were put on the vessels close to the spleen and the latter cut away. The vessels were then tied with difficulty, owing to the depth, the shortness of the pedicle, and the difficulty of pulling the latter into the wound. It was also necessary to take care not to include any portion of the pancreas. After the ligatures had been tied there was still some small amount of oozing, and as the boy's condition demanded speed, the region was packed with gauze, the end of which was brought out at the lower angle of the transverse wound. During the operation 2 pints of saline solution were put into the median basilic vein.

The after treatment consisted of continuous salines per rectum, pituitrin every four hours, and morphine hypodermically, as there was great restlessness. The morphine had to be used for four days. After the operation there was no further haematuria. During the next week the temperature ranged from 98.4 F. to 100.5 F., the pulse from 100 to 120, and the respirations from 30 to 40. The gauze was removed on the third day.

On January 12th—nine days after the operation—the temperature went up to 102° F., and kept at 101 for the next three or four days. The respirations varied from 40 to 46; the pulse was 120. Signs of fluid were found on the left side of the chest, the side that was bruised; 10 oz. of bile-stained fluid were withdrawn by aspiration, and the temperature, pulse, and respirations rapidly improved, and the signs of fluid disappeared. The boy

³ *Medical News*, 1884, p. 636.

was allowed up on January 30th, and on February 15th was only waiting for an abdominal belt before discharge. He was very fit and well. He had been taking a mixture since February 1st containing liq. arsenicalis and ferri et ammon. cit. An examination of the blood at this stage by Dr. Ratray, the Resident Medical Officer of the hospital, gave the following result:

| | | | | |
|--------------------------|-----|-----|-----|-----------|
| Haemoglobin | ... | ... | ... | 80% |
| Red corpuscles | ... | ... | ... | 5,066,000 |
| White corpuscles | ... | ... | ... | 9,600 |
| The latter consisted of: | | | | |
| Polymorphs | ... | ... | ... | 22% |
| Large lymphocytes | ... | ... | ... | 13% |
| Small lymphocytes | ... | ... | ... | 64% |
| Eosinophiles | ... | ... | ... | 1% |

The lymphocytes being mainly of transitional type—that is, with large numbers of basophile granules and kidney-shaped nucleus.

This boy came to my out-patients on March 3rd, 1913, feeling remarkably fit and well. A blood film was taken, and Dr. Gordon Ward, who kindly examined it for me, reports as follows:

“There is slight eosinophilia and marked lymphocytosis, as is commonly found after splenectomy.

“Slight changes in the red cells of little significance, and commonly found in children.

“Increase in the platelets of doubtful significance.”

Differential Leucocyte Count.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

THE third general meeting of the session of the Branch was held at Wolverhampton on April 24th, when the chair was taken by the President, Mr. E. C. STACK, F.R.C.S.I.

Mr. E. DEANESLY showed the following patients: (1) *Two Cases of Facio-hypoglossal Nerve Anastomosis for Facial Paralysis.*—The first, now a girl of 14, was admitted nine years ago with facial paralysis on one side and double mastoid suppuration. Radical mastoid operation was performed on the paralysed side, but two months later the facial paralysis was still complete. The facial nerve was therefore exposed as it emerged from the stylo-mastoid foramen and the hypoglossal nerve at the hypoglossal border. The latter was divided, turned back, and anastomosed with fine silk into a longitudinal slit in the undivided facial nerve. The second case, a girl of 16, underwent a similar operation two years ago on account of facial paralysis following a radical mastoid operation. In this case both nerves were divided, and the distal end of the facial nerve anastomosed directly to the central end of the hypoglossal. Both cases now showed identical results. In repose the face showed no difference in the two sides; there was no flaccidity on the affected side or overaction on the opposite side. A smile, however, at once showed a marked difference, the mouth being drawn strongly towards the unaffected side. On making a strong voluntary effort to frown and screw up the eyes, the brow muscles, the orbicularis, and the muscles of the angle of the mouth all contracted visibly, though less strongly than on the opposite side. Voluntary action of the affected muscles was, however, much stronger when associated with voluntary movement of the tongue, for when the latter was protruded and withdrawn the action of all the muscles on the affected side was almost equal to that on the sound side. The half of the tongue on the side of the anastomosis was completely paralysed and wasted. (2) *Two Cases of Paralysis of the Arm from Injury of the Brachial Plexus at Birth.*—The first, a child of 8 months, which was awaiting operation, showed the ordinary type of birth palsy described by Duchenne—namely, paralysis of the deltoid, spinati, biceps, brachialis

anticus, and supinators of the radius. The arm hung helplessly by the side without power to flex the elbow or perform any shoulder movements except adduction (pectoral muscles) and slight elevation of the scapula (serratus). The second case was in a similar condition on its admission to hospital seven years ago at the age of 10 months. The site of the nerve injury was indicated by a cicatricial ball at the junction of the fifth and sixth cervical nerves to form the highest primary cord of the brachial plexus. This node was excised and the divided ends of the cord reunited with fine silk. The affected muscles responded to faradic stimulation of the divided nerves. Recovery was now practically perfect, save for slightly less power of supination on the affected side. The arm could be raised above the head, and all the previously paralysed muscles could be seen to be plump and well nourished. (3) *Cancer of the Rectum.*—A man, aged 50, from whom a cancerous reatum had been removed by the abdominal route. He was now soundly healed, and had normal actions of the bowel through the anus. The operation performed was not the combined abdomino-perineal operation; the whole operation was carried out in the Trendelenburg position through a median hypogastric incision. The operation was not applicable to cases in which the anus was involved in the growth, or so near it as to necessitate sacrifice of the anus, but it was applicable to all cases not less than 2 in. above the anus. After mobilizing the sigmoid and dividing the superior haemorrhoidal artery, the rectum was detached from the sacrum behind and the bladder in front until it could be cut off well below the growth and immediately above the anus. The upper section was made at the lower end of the sigmoid flexure and the length of bowel removed measured 9 or 10 in. The end of the sigmoid was then passed through the anus from above and sutured to the cut edge of the remaining anal segment of bowel. The peritoneum was carefully closed over the pelvic floor and the wound closed. Performed in this way there was no haemorrhage and remarkably little shock.

The Nutrition of Elementary School Children.—Dr. W. SPENCER BADGER, in a paper on this subject, discussed the various methods of assessing nutrition, and pointed out that clinical examination afforded the only reliable means of estimating its value. The popular belief that the nutrition of slum children was good was controverted. Among the common characteristics of malnutrition were expressionless countenance, mental dullness, mouth breathing, blepharitis, loss of muscular tone, half-open eyes, blueness of the extremities, and a harsh dry skin. The frequency of bronchitis and nasal catarrh in school children was commented upon. One-fourth of a series of 700 scholars were reported to be subject to night sweats. Malnutrition had a close association with disease, sometimes preceding and sometimes following it. Heart disease, particularly, was a nutritional disorder in school children. Dental caries had a widespread influence in producing malnutrition, and insufficiency of sleep was one of the prime preventable causes. The harmful effect of overwork operated mainly by reason of the work outside school hours being undertaken by the least fit and worst fed children. Malnutrition was frequently associated with poverty, but in such cases the poverty was commonly found to be accompanied by thriftlessness, ignorance, dirt, or neglect. It was remarkable how little alteration the nutrition of the children of thrifty and sober parents underwent. In the face of such abundant evidence of neglect as existed in the elementary schools it was regrettable that national philanthropy consisted so exclusively in giving assistance. While there were various agencies for the relief of destitution, there was a conspicuous disinclination to apply the proper remedies for the prevention of neglect. Drs. LILA GREIG, LOWE, GALBRAITH, and Mr. STACK discussed the paper, and Dr. BADGER replied.

Thrombosis and Embolism after Pelvic Operations.—Dr. FREDERICK EDGE suggested the prophylactic fixation of the thrombus by injections of antistreptococcal serum, the administration of horse serum, calcium lactate, and potassium iodide by the mouth. The volume of blood should be increased by copious saline solutions. Messrs. ALCOCK, DEANESLY, and STACK took part in the discussion which followed, and Dr. EDGE replied.

Intestinal Obstruction.—Mr. DEANESLY read a paper on this subject.

Exhibition of Pathological Specimens.—Mr. DEANESLY showed several specimens of cancerous rectums removed by abdominal operation. Also a cancerous stricture of the transverse colon removed twelve months ago, the operation being completed by end-to-end suture of the divided bowel. The patient had recovered and was still in good health. Dr. EDGE showed: (a) A uterus with chorion-epithelioma following a hydatidiform mole successfully removed by abdominal hysterectomy. (b) A uterus with soft degeneration of a small myoma. Dr. CODB showed a specimen of cerebral tumour from a girl aged 8. The chief symptoms were headache, blindness, optic atrophy, conjugate deviation of head and eyes to the left, Babinski's and Kernig's signs, progressive drowsiness, and at the last very profuse purulent nasal discharge. The tumour appeared to originate in the left crus and invaded the right crus, the third ventricle, the infundibulum, and perhaps the pituitary. The sphenoidal sinus was full of pus, but the floor of the sella turcica appeared to be intact. There was much calcareous change and cystic degeneration; the tumour was a psammoma.

YORKSHIRE BRANCH.

At a meeting of this Branch on April 16th, Dr. GIBSON (Harrogate), President of the Branch, in the chair, Mr. PRIESTLEY LEECH (Halifax) showed some *X-ray photographs* of fractured heads of humeri and of early bone tuberculosis. Mr. BASIL HUGHES (Bradford) read a paper on the utility of *Autogenous vaccines in the treatment of chronic joint affections*, notably rheumatoid arthritis and gonorrhoeal arthritis. Dr. MAXWELL TELLING drew attention to some points in the management and treatment of cases of grave or *Pernicious anaemia*. In the first place, he emphasized the necessity of the most scrupulous attention to the mouth to eliminate any source of oral sepsis, for certain cases of grave anaemia arose from this cause and could be cured by its removal; in true pernicious anaemia, however, some other factor was present, and the results of treatment on these lines were not so striking, though the treatment was not less necessary. The difficulty in feeding these patients was mentioned. In pernicious anaemia oro-gastro-intestinal attacks not infrequently occurred, often associated with pyrexia; the treatment was not, as a rule, to stop the administration of arsenic, but to continue it and to bring the alimentation down to the patient's powers of assimilation. The occurrence of mental disturbances and pyrexia was also discussed.

Election of President and New Members.—At a meeting of the Council on the same day Dr. Stanger (Wakefield) was unanimously appointed President-elect, and thirteen new members were elected.

AN international exposition of town hygiene will be held at Lyons in 1914, from May 1st to November 1st. One of the objects is to show the organization of a modern city, especially from the sanitary point of view. The exposition will be divided into forty-two sections: Statistics and demography; administration of streets, roads, waterways, and other channels of communication; transport; drinking water; sewers and the purification of waters that have been used; disposal of solid residues; dwelling; furnishing; lighting; ventilation, heating, and refrigeration; alimentation of animal origin; milk and its derivatives; alimentation of vegetable origin; hygienic drinks; adulteration of foodstuffs, investigation of frauds; mineral waters; chemical products; protection of infancy and preiculture; school; military hygiene; care of the body and cleanliness; primary and secondary education; superior education; technical, professional, and household education; hygiene and protection of labour; social economy; police of cities and police lavatories; infectious diseases (parasites, microbes, fungi); disinfection; organization of public hygiene in States; departmental and municipal services of hygiene; public assistance and hospitals; the struggle against tuberculosis; the struggle against alcohol; touring; physical culture and sports; arts; photography; industries of the book, the advertisement and the newspaper; horticulture; electricity; posts, telegraphs, telephones. Professor Commont, who is general commissioner of the exposition, has made it a condition that no alcoholic drink, with the exception of hygienic beverages, shall be admitted to the exposition.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

DEBATE ON ALIMENTARY TOXAEMIA (*concluded*).

Wednesday, May 7th, 1913.

Sir FRANCIS CHAMPEYS, Bart., M.D., President, in the Chair.

DR. H. D. ROLLESTON, in reopening the debate, said that the alimentary was not only much the largest mucous tract of the body, but was the most exposed to infection and intoxication. Though it was protected by the acid gastric juice against microbial activity, and by the liver against poisons, these lines of defence could be broken down. It was, however, possible to attribute too many disorders to intestinal toxæmia; many of the defects assumed to be toxic might be due to the passage of micro-organisms in small numbers into the circulation, and so into the tissues, as was shown by Adami's subinfection with *B. coli*, which he held played some part in cirrhosis and pernicious anaemia. Toxaemia and bacteriaemia might occur simultaneously, as was evidenced by the frequent association of chronic pancreatitis and portal cirrhosis. The digestive processes might be so modified or the circumstances so altered by a change in the intestinal flora, as to produce poisons out of ordinary food. Heister and Kendall had found that intestinal infantilism was associated with large numbers of *Bacillus infantilis* in the stools. The view that exophthalmic goitre might, in some instances, be due to alimentary toxæmia was supported by the facts that digestive disturbances were frequent, that a protein diet usually aggravated the symptoms, and that indicanuria was common. The relationship between arthritis and alimentary toxæmia afforded scope for discussion; chronic rheumatoid arthritis might be secondary to a focal infection in various parts of the alimentary canal. It seemed clear that the intestinal tract was primarily at fault in enterogenous cyanosis, and it was difficult to avoid the conclusion that in young children intestinal toxæmia was sometimes the cause of anaemia. It had long been known that indiscretions in diet and overeating caused chronic arterial and renal disease. The mechanism by which alimentary toxæmia might cause arterio-sclerosis was not yet proven; but it might do so by inducing thyroid insufficiency.

DR. DOUGLAS WILSON (Harrogate) based his views on the subject upon observation and treatment of 800 cases in which he believed the colon to have been the seat of toxic absorption. Practically all the cases were treated with colon irrigations of mineral water and other spa methods; 43 per cent. of the cases were males, 57 per cent. females. The condition occurred in families, and sometimes two or three generations had been affected. The onset was insidious. The patient usually sought advice at about 40 years of age, when the wear and tear of life were beginning to be felt. Constipation was present in most of the cases, and sometimes colon irrigations brought away hard old scybala. These subjects often had lax abdominal walls, though the remaining musculature of the body was vigorous and good. It was common to find the sigmoid spasmodically contracted. Usually the subjects of colon intoxication were depressed, irritable, and worried by small causes; there was difficulty in concentration and the memory suffered. It was a not sufficiently recognized cause of insomnia. There might be acute neuralgia and persistent hemicrania, as well as irregularity of pulse, both as to time and force. Fibrositis, gout, rheumatoid arthritis were other sequelae of intestinal derangement.

DR. F. W. BROOK said that he had for a long time examined the faeces of all cases of neurasthenia which came under his care, and had details of 54 cases, all showing an abnormal condition of the flora. He gave autogenous vaccines, commencing with very small doses, so as to minimize constitutional reactions, and found that patients expressed themselves as feeling better when the motions were found to be acid. Intestinal antiseptics were given from time to time, but only beta-naphthol and sulphur were found to be serviceable. A vegetarian diet was useful in rendering the stools acid.

Dr. ARMSTRONG (Buxton) believed that dental sepsis originated or kept up gastric disturbances and in some cases arthritic mischief, though recently there seemed to be a tendency to over-rate this cause for joint trouble. The treatment was divisible into three heads: (1) methods of emptying the stomach, (2) strengthening the atonic gastric wall, (3) measures to control the poisonous fermentation.

Dr. W. KNOWSLEY SIBLEY said that a system saturated with the toxins absorbed from an overloaded intestine was by no means an uncommon cause of a large number of apparently very different skin diseases. Psoriasis he regarded as often the result of the influences of toxins derived from the alimentary canal, and a change to a vegetarian diet would often cure an old-standing case. Many of the drugs useful in skin diseases—arsenic and quinine were good cases in point—were also intestinal disinfectants.

Dr. H. D. McCULLOCH emphasized the fact that the localities where microbes were most prolific were those in which lymphatic channels and glands were most numerous. It was the lymph which most needed protection from microbial and toxic contamination.

Dr. J. F. BRISCOE commented on the rarity of gross intestinal lesions, such as appendicitis, in mental hospitals. Dr. Mott, pathologist at Claybury, had stated that there had not been a case of appendicitis found on the *post-mortem* table out of 2,000 deaths since he had held the post. Constipation was a link in the series of causes and consequences arising from the disturbed abdominal viscera; it encouraged irritability, perverted moral feelings, and melancholia; while physically it led to emaciation, rheumatism, and many other conditions. Sometimes a copious motion dissipated an attack of insanity. Stasis was a less formidable condition when the food had been thoroughly triturated before being swallowed. In the ten years 1902-11 the English Commissioners in Lunacy recorded only 75 deaths from appendicitis, typhlitis, or perityphlitis, ascertained in most cases by *post-mortem* examination.

After some remarks from Dr. ROBERT BELL and Dr. RALPH VINCENT the discussion was wound up by Dr. HALE WHITE, who began his reply by observing that it was obviously impossible to present, in a quarter of an hour, any adequate summary of a debate in which sixty speakers had taken part. Probably poisons were continually being formed from the contents of the alimentary canal, or they might be endotoxins derived from dead bacteria, but no harm followed so long as the constantly active defences of the body against such poisons were in full play. A great step forward would be made when experimental pathologists were able to say which cases of supposed alimentary toxæmia were really caused by disease of the liver, disease of thyroid, or disease of some other organ, or which were due to the formation of abnormal poisons or to an excess of normal poisons in the alimentary canal. There seemed to be a consensus of opinion that the phrase "alimentary toxæmia" should be limited to the absorption of chemical poisons, and should not include the passage into the blood of bacteria themselves, although this probably occurred more often than was usually thought. The discussion had shed very little light on the bacteriology of alimentary toxæmia originating in the gastro-intestinal tract. Probably among the intestinal bacteria the *Bacillus aminophilus intestinalis* and its allies would most repay research, but it certainly appeared that many of the statements of the French school on the intestinal flora needed serious revision, and that the case against indol had not been proved. In the clinical part of the discussion the dental surgeons seemed to be on surer ground than other speakers. Disease of the gums leading to periodontal disease was by far the most fruitful source of oral sepsis. Mouth breathing in children led to persistent marginal gingivitis, which was more intractable and serious in its results in mouth breathers. It followed that not only must teeth be treated, but that often it was necessary to treat nasal obstruction also. Probably the most important part of the treatment was local, but in the more severe examples the intelligent use of autogenous vaccines might be of distinct help. It was possible that in a few cases pyorrhœa alveolaris was secondary to a toxæmia arising from some other parts of the alimentary tract,

or, at any rate, that the pyorrhœa was increased by the fact that the general resistance of the body was lowered by an alimentary toxæmia of other origin. The discussion had been of great use in directing attention to the fact that some diseases of the eye might be due to pyorrhœa alveolaris; what others were due to other forms of alimentary toxæmia could only be decided by future clinical observation. The extremely interesting question whether failure of accommodative power might not often be due to intestinal toxæmia needed further investigation. The urticaria which followed the ingestion of shellfish, copaiba, etc., in some persons was most likely an example of anaphylactic phenomena following the absorption of foreign proteins, and therefore not an instance of alimentary toxæmia. The purpura often associated with cirrhosis of the liver was probably an alimentary toxæmia in which the poison absorbed from the intestine was able to act, because the protective influence of the liver was in abeyance. Henoch's purpura might be an example of alimentary toxæmia, and the dark-blue tint of the skin in enterogenous cyanosis was almost certainly due to alimentary toxæmia, and the brown cutaneous pigment so often seen in disease of the intestines might have a like cause: It had been urged that in consequence of the erect posture of man the intestines tended to drop: that to overcome this peritoneal bands were evolved; that they produced kinks; that these led to stagnation of the intestinal contents and increased putrefaction, and this was followed by the formation of poisons, which, passing into the general circulation, caused definite symptoms, and predisposed to many diseases. The question would have to be solved by anatomists. Were these bands to be found in all animals in whom the body was usually vertical—for example, in apes, gibbons, and penguins? were there evidences of them in animals whose bodies approached the vertical—for example, giraffes? and were there what might be called reverse bands in bats that spend so much of their time head downwards? if present in animals that adopted the erect posture, did such animals have intestinal stasis? Those who laid great stress on an ileal kink as a cause of intestinal stasis did not seem to have estimated at its full value the strength and activity of the ileo-caecal sphincter; much of the holding back of the intestinal contents at the end of the ileum was normal, and when abnormal was often due to spasm of the ileo-caecal muscle. Many of the statements about kinks and stasis claimed support from x -ray examinations after bismuth or barium sulphate, but it had been urged on the other hand that sometimes food was given too soon after a bismuth meal; that sometimes so much bismuth was given that its weight might invalidate the observations; that allowance was not made for normal variations in the average time taken in the passage of a bismuth meal, anything differing from the average being taken as abnormal; that sometimes the bismuth mixture lagged in the stomach because it was nasty, although in the same patient a meal would leave the stomach normally if palatable; that the so-called writhing of the duodenum was nothing else than the normal peristalsis and segmentation rendered more clearly visible than usual by the great quantity of bismuth-containing chyme present; that the x rays did not show the duodenum to be dilated in cases of duodenal ulcer; and that many of the kinks which the x rays were supposed to show depended upon the fact that the x -ray picture was taken in a single plane. As the x -ray work on this subject had been so severely criticized, it should be repeated by independent observers. Those who believed that evolutionary peritoneal bands often led to intestinal stasis because they produced kinks, especially a kink at the last part of the ileum, thought that as a further result a kink formed at the end of the duodenum, and this and the stomach dilated, and either might become ulcerated. The debate had not provided any statistical evidence to show in what proportion of sufferers from duodenal or gastric ulcers such kinks were found, nor had any experimental evidence been brought forward to show that in animals such ulcers formed as a result of an artificially induced ileal kink. It seemed that the onus of proving their contention lay with those who believed that these phenomena followed intestinal stasis. It was agreed that in the vast majority of cases medical treatment sufficed. If the cases that now

seemed to some to justify surgical treatment had been treated in the first stages by proper medical means surgical interference would not be necessary, so that, when this was widely appreciated, cases ought never to become so ill that surgical treatment would be contemplated, and it might be hoped that one result of the discussion would be that "the drainage scheme" of patients would be kept in sufficiently good order to render surgical interference unnecessary.

SURGICAL SECTION.

At a meeting on May 6th, Mr. G. H. MAKINS, President, in the chair, Mr. J. HUTCHINSON, in a paper on *Aberrant renal arteries*, said that it might have been thought that symptoms would be caused more commonly in females with movable kidney, and would come on early in life, and be produced by an artery lying in front of the ureter. But in the 21 cases seen at the London Hospital between 1904-12, 15 were in males, 6 in females, and the right kidney was affected twice as commonly as the left. It was usually fixed in position, and the aberrant artery lay posterior. The onset of symptoms was always sudden, commonly between the age of 15 and 25; in only 4 of these cases did they develop after 30. In 2 the kidney had already been fixed by operation, and the true condition was not diagnosed. It had to be diagnosed from duodenal ulcer, gall stones, renal colic, etc. He thought the main points in diagnosis to be periodic attacks of right renal pain followed by a dull aching in males between the ages of 15 and 25. The patients lay on the side of the pain, it was unrelieved by lying down, and was accompanied by sweating and vomiting; the vomiting often relieved the pain. The cystoscope might show congestion of the ureteral orifice, and the *x* ray the absence of a calculus. Albuminuria and haematuria were occasionally present. With these signs a provisional diagnosis could be made and the lumbar region explored. The aberrant artery often produced a narrowing of the ureter and distortion of the pelvis. In these cases removal of the artery might be insufficient, and he was tempted to perform a plastic operation, and sew up a longitudinal incision transversely. The published records of this plastic operation were bad; he could not advise it. If necessary, he performed nephrectomy, all but two of the recorded cases being one-sided. Mr. F. KIDD said a positive diagnosis could be made by intra-ureteral injection of 8 c.cm. of a 5 per cent. solution of collargol. A pyelograph could then be made and a dilated pelvis seen. Mr. A. JOHNSON said that 15 per cent. of renal arteries were abnormal, and the veins still more frequently. Pyelography after a collargol injection would show a dilated pelvis, and in the absence of a movable kidney, stone, or tumour, an aberrant artery should be diagnosed. Mr. McADAM ECCLES recorded a case of intermittent hydronephrosis due to an aberrant vein. The vein was tied, and the hydronephrosis at once disappeared. Mr. F. KIDD recorded two cases of *Splenectomy*. One was in a patient who four years previously had been sent to a fever hospital with a diagnosis of typhoid fever; the Widal reaction was negative and Banti's disease diagnosed. She was of a dirty yellow colour, had had haematemesis for one year, her periods had ceased; the liver was small and the spleen large; the blood showed a typical anaemia. She suddenly developed ascites and was tapped. Splenectomy was performed. The veins were much enlarged and caused trouble; the liver was hard and cirrhotic. A good recovery was made, and menstruation recommenced and her blood returned to normal. The second patient gave a three months' history of pain in the left hypochondrium relieved by vomiting, and referred to the left shoulder-joint. The spleen, which was enlarged, was removed, and it was found to be in a condition of hypertrophy, both macroscopically and microscopically. The pain in the left shoulder-joint was caused by irritation of the fifth cervical root; it gave origin to both the phrenic and the suprascapular nerves. He thought splenectomy should be performed in all cases where the liver was cirrhotic and the spleen enlarged. It was best done through a 4-inch incision through the left rectus: a 2-inch transverse incision could be added to it if necessary. Mr. J. HUTCHINSON recorded a case of splenectomy for splenic anaemia with haematemesis and marked failure of mental development. After the operation there was great improvement in mentality. Sir JOHN BLAND-SUTTON stated that he had performed splenectomy

in 10 cases for wandering spleen, injury, tubercle, and Banti's disease. One was eighteen years ago. He thought the after-effects—thirst, restlessness, and pain in the bones—was due not to overaction of the bone-marrow, but to sepsis of the splenic pedicle. He was sure there was a great future for splenectomy. The PRESIDENT showed a case in which splenectomy had been performed fifteen months previously for splenic anaemia. The white corpuscles rose to 43,000 on the second day after the operation, and fell to 12,000 on the ninth day.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

At a meeting on May 7th, Mr. J. M. COTTERILL, President, in the chair, Dr. H. M. TRAQUAIR, in a paper on *Bi-temporal hemiopia* (postponed from March 5th), described the condition as occurring in two types: the *scotomatous type*, where there was a scotoma occupying part or all of the area between the fixation point and the blind spot, associated with a varying degree of defect of the temporal field, and the *non-scotomatous type*, where the defect diminished in intensity from the periphery to the centre of the temporal field. For the detection of these defects the ordinary examination was often inadequate, and the use of small and large objects of known diameter and of different colours, and the additional employment of a large Bjerrum screen (2 metres) were necessary. Following this special technique the author gave details of his examination in a series of cases of hemiopia. Of those of scotomatous type, one was a case of acromegaly with pronounced neighbourhood signs (Cushing's Class I), and the other of maxillary emphyema with ocular disturbance. Some of the chief points elicited by a long series of vision fields were the peculiar regular progress of the field defect, the sharp vertical and horizontal edges of the scotoma representing the apices of several quadrants, the appearance of vertical splitting in the fields, and the great power of recovery (apparently spontaneous) in both cases. This recovery seemed to indicate rather a vascular congestion or oedema in the region of the chiasma than a tumour pressure. The examples of non-scotomatous type were three cases of acromegaly with absence of neighbour signs but predominant hypophyseal symptoms. These like those of the first group showed defects of low intensity, which were only revealed by the use of the special methods of examination employed. It seemed probable, therefore, that such defects of low intensity were really commoner than was indicated by present records. Thus the records of a large number of cases of acromegaly show such field defects in only 50 per cent., while he, in a small series of seven acromegalics, had found field defects in all. The scotomatous type was associated as a general rule with an active lesion and a short case-history, and if other evidence, such as the enlargement of the pituitary fossa on *x*-ray examination, pointed to tumour, it indicated a malignant rather than a benign tumour. The non-scotomatous type was associated with the opposite conditions. Dr. LEWIS THATCHER described a case of congenital *Malformation of the urinary apparatus* with absence of the abdominal wall musculature in a male child which came under observation at the age of 3 weeks, and died when aged 2 months. There was some asymmetry of the skull, and flattening of the pinnae of the ears. The chest was markedly prow-shaped (a deformity absent at birth). The abdominal wall showed a remarkable wrinkling and redundancy of the skin, which was also sunk in and showed clearly the outline of liver, spleen, kidneys, and a greatly enlarged and thickened bladder. Long deep longitudinal furrows scored the surface, and at the foot of one of these lay the umbilicus, in normal position, but firmly attached to the apex of the bladder. The cause of death was bronchopneumonia. The autopsy showed an absence of the recti and of the greater part of the oblique and transverse muscles. The urethra was patent and healthy, but the bladder wall was thickened to three-quarters of an inch, and the ureteral openings were almost obstructed by this hypertrophy, leading to great dilatation and hypertrophy of the ureters and to some hydronephrosis of the kidneys. Both testicles were undescended. Dr. Thatcher analysed 11 similar cases which he had found in the literature. All were in males, and showed close agreement both in

the external picture and also in the condition of the internal organs. Various explanations had been put forward, but the most probable was that of Stammé. He ascribed it to an increase of intra-abdominal tension caused by enlargement of the bladder. This took place at an early period before the muscles of the abdominal wall had developed, for the condition was one of muscular aplasia and not of atrophy. The thickening of the bladder accounted for the blocking of the ureteral openings and the secondary dilatation of the ureters. This theory made the change in the bladder the primary one; and this had been suggested by Dr. John Thomson as due to an inco-ordination of the vesical sphincter, analogous in its origin and effects to congenital hypertrophy of the pylorus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

At a meeting on April 11th, Dr. T. P. C. KIRKPATRICK in the chair, Dr. T. T. O'FARRELL urged the desirability of the hospital statistics of Dublin being all returned on the same basis, and described the system in use at St. Vincent's Hospital, which was found to work satisfactorily. It was based on the card-indexing system, and distributed the work over a number of people. The registrar's work was confined to keeping the admission and discharge book, filing the case sheets and cards, and at the end of the year drawing up a digest of the cases in an analysis book. Its details were briefly as follows: (1) Cases are divided into males and females, the method of registration for each being the same. (2) Each patient on admission is provided with the usual history sheets, etc., together with a "coloured card"—red for males and blue for females. (3) At the end of each week the "coloured cards" of each new patient, containing preliminary details, are sent to the registrar, who copies them into the admission and discharge book, and having given the card its registration number, returns it to the ward. (4) At the end of each case all the notes are completed and sent up to the registrar. (5) The registrar then enters the date of discharge, diagnosis, date of operation, if any, and result in the book, together with any short comment necessary in the observations column. He also fills in the number of the disease as it appears in the College of Physicians' *Nomenclature of Diseases*. (6) The registrar then files the charts and coloured cards as follows: (a) History sheets and other notes according to registration number in serial order in batches of ten, each batch being enclosed in an open stiff paper pocket, special indicators of a remarkable colour being placed at the hundreds intervals; (b) the "coloured cards" are filed alphabetically, according to the surname of the patient. Both these files are in the form of drawers in a cabinet, and worded according to the card-indexing system. At the end of the year these files are cleared, the contents being placed in boxes, numbered according to year, and stored on shelves in an easily accessible place. (7) At the end of the year the "analysis book" is drawn up, which is a rearrangement of the cases according to disease. The register number of each case is marked down, so that all the cases of any one disease treated can be seen at a glance and their case-sheets easily referred to if required. (8) The final report is drawn up from the analysis book, the total number of cases of each disease, with their results, being set down.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a meeting on May 2nd, Dr. G. P. SHUTER, President, in the chair, Professor FREDERICK HOBDAY, F.R.C.V.S., read, by invitation, a paper concerning *Diseases communicable from animals to man*. In regard to glanders he said that until about ten years ago it was a most unusual thing for a day to pass without several fresh glanders cases being reported, and the veterinary inspector was only permitted to interfere with the clinically glandered cases, and not to enforce the mallein test. Now, however, when an outbreak occurred in a stable the test was applied and all reactors were valued and slaughtered. Although not a common disease in man, glanders used to be sufficiently

often met with in all large cities to be of interest to medical men. The absence of definite and differentiating symptoms made it necessary to bear the disease in mind when treating stable hands. In one of the cases he had seen the patient had been ailing off and on for ten months without a diagnosis being made, and at the *post-mortem* examination the lungs were found full of glanders nodules. In the year 1901, 2,370 horses were reported in Great Britain as suffering from the disease. Last year the numbers had been reduced to only 504 individual horses for the whole of Great Britain. In the horse, dog, and cat, tuberculosis was well recognized, and in connexion with the latter two this fact ought to be kept well in mind on account of their constant presence in the house as pets. With regard to mange every species of domesticated and many wild animals might become the subject of an attack. It was always caused by the presence of a parasite caught from somewhere, and was contagious to man as well as to other animals. The parasite did not of necessity find its new host, when transmitted to man, as comfortable and convenient a resting-place as its original host, and as a rule lived its life but did not propagate. Mange as acquired from dogs and cats was sometimes unrecognized, and was treated unsuccessfully either as pruritus or eczema. It was manifested by a troublesome irritation and vesicular eruption, with small black spots at the places where the heads had been removed by scratching. In reply to various questions, Professor Hobday stated that in the cases of ringworm infection caught from horse or calf which he had seen himself, the persons had been infected on the face or arms and not on the head. He had no personal experience of the ophthalmic reaction, either with mallein or tuberculin, and could not say whether damage occurred to the eyesight as was sometimes the case in human subjects. It was not generally admitted by veterinarians that cats were the subjects of scarlet fever, or of true diphtheria, nor were they especially susceptible to glanders, although under certain circumstances they might of course become the carriers of the contagion. The disease known as bird diphtheria, and commonly met with in wood-pigeons and other birds, had no analogy with the disease known as diphtheria in the human species.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

At a meeting of the Northern and Midland Division on April 24th, Dr. J. G. SOUTER, President, in the chair, Dr. CASSIDY gave an account of the history of the Lancaster County Asylum. The accommodation provided in 1815 was for 150 patients; in 1824 the number had risen to 250, and in 1913 to 2,450. Among methods of treatment in vogue in the early days of its work was the warm room and the whirligig chair, and the restraining of patients by fastening them to the wall. All the windows in the wards were kept carefully shut, and an attendant was reported if he left one open. Dr. DOUGLAS, in a paper on the Mental Deficiency Bill, 1913, defined the different classes of persons deemed to be defectives within the meaning of the bill, distinguishing between idiots, imbeciles, feeble-minded, and moral imbeciles. He then mentioned how these cases had been dealt with up to the present time. He said that it was by careful classification alone that one could hope to obtain any tangible result from the education and training of the different classes of persons deemed defective within the meaning of the bill. A combination of counties, forming associated areas, aided by institutions already in existence, should be able to deal with the matter. Each of the voluntary institutions might be used as a centre or filtering ground through which all defectives in the area would pass before being drafted to the other homes or colonies. Dr. BLAIR showed a case of *Catalepsy* in one of three sisters, all of whom had been treated at Lancaster Asylum, and she was there first from the beginning of 1906 to the end of 1908. She was admitted again in January, 1910, and for the past three years had been insensible. She gave no response, or very slightly at times, to stimuli, and had to be forcibly fed. At present she showed slight indications of returning sensibility. Dr. Rows gave a demonstration of interesting objects and processes in the pathological laboratory of Lancaster County Asylum, where the meeting was held.

Reviews.

INSECTS AND DISEASE.

WITHIN the past few years the important part played by insects and other animals in the transmission of disease has become more and more realized. Not only is this true of the mosquito and other tropical insects, but even our common house-fly cannot be exempted. A popular account of the way in which insects may spread or cause some of our common diseases has been given in a little volume entitled *Insects and Disease*,¹ by Mr. R. W. DOANE, Assistant Professor of Entomology in the Leland Stanford Junior University. The volume is one of the American Nature Series. The title does not sufficiently indicate the contents, since insects are not the only parasites dealt with. There is a chapter on bacteria and protozoa, and another on ticks and mites, these latter being frequently regarded as insects by the uninitiated. The general principles of parasitism are also briefly treated. The author claims it only as a "popular account" and as such it must be judged. From this standpoint it may be stated that the author has been successful in his attempt. The book is written in a popular style and is not without humour. It is illustrated by a series of admirable and instructive photographs. To the systematist or to the student of tropical medicine, whether human or veterinary, the book will yield little that is new, but the general reader will no doubt find in it much to interest him, and it is to be hoped that many belonging to that class will read it. Men of science are too prone to hide their light under a bushel, with the result that all too little is known of the economic value of much of the work which is being done. The inevitable effect of this is the lack of funds in this country to assist in carrying on work of this nature. If only the intelligent person with means at his command could be made to realize the importance of much of the good work now being unostentatiously carried on, they might be stimulated to give money for its furtherance. A book like the one before us enables them to become acquainted with some of the results already achieved. Or, again, the importance of flies in the dissemination of such diseases as enteric fever or even of the summer diarrhoea of children, is not yet appreciated by the public at large. These are some of the facts to which the author draws attention, and sufficient evidence is detailed to justify the conclusions which have so far been made. As a work of the missionary type the book is to be commended. There is also a good bibliography which will materially assist those desirous of seeking for further information.

Another book, which has just been published, *The Reduction of Domestic Flies*,² by Dr. E. H. ROSS, may be commended as making to the same end. It discusses the life-history and habits of domestic flies, both in this country and in warmer regions; the egg, larva, and chrysalis are described, the flies' enemies are enumerated, and a campaign against these pests is first outlined and then worked out in detail. A chapter is devoted to the justification of expenditure of money and energy in suppressing the plague of flies, and there is another chapter, written in very popular style, tracing the life-history of a female fly from her birth in a manure heap until her death by fungus infection, leaving a numerous progeny behind her. The book is well illustrated by photographs of larvae and flies and diagrams showing their anatomy and habits. Its publication at this season of the year is opportune even in this country, and it will be found extremely useful by residents in the tropics and subtropics.

ORTHOPAEDICS.

IN a book on orthopaedics for the general practitioner, Dr. GEORG MÜLLER³ of Berlin sets out to supply post-

graduate instruction on orthopaedics to those who cannot leave their practices or for other reasons cannot attend a university or hospital course of instruction on the subject. The book has no pretensions to the completeness of a full treatise on the subject, and the author, as he says, only treats of anatomical, physiological, and pathological-anatomical relations so far as they are strictly necessary for understanding practical treatment. The work is divided into a general and a special part. In the former, after a short historical review, the various materials for making temporary and permanent appliances, such as plaster-of-Paris and celluloid, Hessing's apparatus and artificial limbs, massage, gymnastics, hydropathic treatment, diet, Bier's hyperaemic treatment, and the serum therapy of surgical tuberculosis are dealt with at moderate length. In the special part the conditions, including joint diseases, usually treated of in books on orthopaedics are considered briefly. In a book of this sort nothing very novel is to be looked for. The author briefly describes the morbid conditions, gives an adequate account of the usual methods of treatment, and indicates briefly those which he recommends as best or most expedient. Although we have not the pleasure of Dr. Müller's acquaintance, yet after looking at the illustrations of this book we feel that his genial personality is familiar to us, for his likeness appears in twenty-one of them.

The good opinion expressed five years ago of the first edition of Dr. LOVETT'S book upon *Lateral Curvature of the Spine*⁴ (BRITISH MEDICAL JOURNAL, 1908, vol. i, p. 992, April 25th) has not been altered by the lapse of time, and we now welcome the second edition. The form and scope of the book are unchanged, but it is a good deal more than a mere reprint, for the whole has evidently been carefully revised and brought up to date. The number of illustrations has been increased, and a chapter has been added on school life and scoliosis. These changes are all for the better, and we can but repeat and emphasize the recommendation made in 1908. Dr. Lovett does not claim to be able to work miracles upon deformed spines, but the moderation of his statements and the good sense of his reasoning are far more convincing than the extravagant promises made on behalf of some methods of treatment. Particularly interesting, as showing the importance of unremitting and thorough treatment, are the illustrations on page 167, which show the progress of a case during seven years from bad to worse, owing to discontinuous and inefficient treatment.

TEXTBOOKS OF OPHTHALMOLOGY.

A VOLUME recently issued by the University of London Press cannot fail to be a boon to every student and general practitioner into whose hands it falls. There are so many excellent manuals on ophthalmology written in the English language that it seemed as though there could be no place for another, and yet, now that we have the latest book in our hands, we feel that it has given the student exactly what he requires. Mr. DEVEREUX MARSHALL has compiled a modest volume on *Diseases of the Eyes*,⁵ which contains the clinical teaching the ophthalmic dresser needs to supplement his practical work at the hospital. He will here find the most modern practice, and will not have to wade through pages of mathematical optics or of abstruse pathology to discover the exact symptoms of a disease and the best means of treating it. Mr. Marshall rightly assumes that every student has already had a course of optics and physiology and is acquainted with the simple dioptries of the eye. He proceeds at once to practical teaching. The chapters upon refraction and upon the examination of the eye are admirable, and inculcate that good style which is as essential to the oculist as it is to the cricketer. The correct method of refraction is to perform an accurate retinoscopy and then to proceed with the trial lenses and test types. Every student should realize that unless he can use the retinoscope he cannot refract. Mr. Marshall's

¹ *Insects and Disease*. By Rennie W. Doane, A.B., Assistant Professor of Entomology, Leland Stanford Junior University. London: Constable and Co. (Demy 8vo, pp. 241. Price, 8s. net.) *American Nature Series*. Group ix, Working with Nature.

² *The Reduction of Domestic Flies*. By E. H. Ross, M.R.C.S., L.R.C.P. Lond. London: John Murray. 1913. (Med. 8vo, pp. 111; illustrations 18. 5s. net.)

³ *Die Orthopädie des praktischen Aerztes*. By Dr. Georg Müller, Berlin. Berlin and Vienna: Urban and Schwarzenberg. (S. roy. 8vo, pp. 258. Mk. 10.)

⁴ *Lateral Curvature of the Spine and Round Shoulders*. By Robert W. Lovett, M.D. Boston. Second edition, revised and enlarged. London: Robman Limited. 1912. (Demy 8vo, pp. 202; 171 illustrations. 7s. 6d. net.)

⁵ *Diseases of the Eyes*. By C. Devereux Marshall, F.R.C.S., London Medical Publications. London: University of London Press, Hodder and Stoughton, and Henry Frowde. 1912. (Demy 8vo, pp. 316; figs. 95. 10s. 6d. net.)

views upon the treatment of lacrymal obstruction are thoroughly modern; in this respect, as in many others, he has discarded methods which, though of respectable antiquity, are founded upon a false pathology, and can only bring discredit upon the surgeon and his art. The chapter upon colour blindness is exceedingly valuable. Tests founded upon the Young-Helmholtz theory of colour vision are justly condemned, and the Halmgren test, which has been repeatedly shown to be valueless in this country and in Germany, is utterly discountenanced. Instead, the Edridge-Green lamp is recommended, and methods which really unmask the dangerously colour blind are carefully explained. Judging the book by the standard necessary for the student and the general practitioner we can give it the highest praise, and can confidently recommend it. It is, however, capable of improvement in some respects. "Myosis," although often spelt with a "y," should be "miosis." The author might reconsider his doubts about the etiology of episcleritis, for the evidence brought forward by Verhoeff and others points very strongly to a tuberculous origin. It should be noted that Paton's researches convinced him that it was impossible to decide upon which side of the brain a tumour was situated from a study of the discs. The cases in which the tumour was found to be situated on the same side as that on which the oldest or most intense optic neuritis was present were about equally balanced with those in which the tumour was on the opposite side. Nyctalopia is not mentioned as a symptom of tobacco amblyopia. These and some other minor points are all the defects noted in a book which is admirably adapted to the use of students.

The appearance of a second edition of Professor RÖMER'S *Lehrbuch der Augenheilkunde*⁶ is a proof that it has been successful in Germany, and the fact that the first volume of the American translation has been published points to its popularity outside Germany. We reviewed the first edition at considerable length, pointing out that it represented the complete course of lectures given by the author at the University of Greifswald. The old bulky volume has now been divided, and the present edition is sold in two volumes. An attempt has been made to make the diction in places more concise, and the space so gained has been utilized for more illustrations and coloured plates. A marginal analysis has been added, so that it is comparatively easy for the reader to find the paragraph relating to the subject he is searching for. The university eye clinic has been able to train its own ophthalmoscopic artist, who has contributed some excellent plates to the new edition. Some of these represent the external diseases of the eye, others retinal conditions. The two volumes contain 32 coloured plates and 268 illustrations. Although the subject is presented in the form of lectures, the arrangement of the book is of the usual kind. The first chapter deals with the clinical examination of the anterior part of the eye, and is followed by one upon the diseases of the conjunctiva and cornea. The iris and lens are next considered, and then the vitreous and the optic nerve. The retina and choroid occupy Sections VII and VIII. The first volume is ended by chapters upon the sclera and the eyelids. The second volume treats of diseases of the lacrymal apparatus, of the orbit, of injuries to the eyes, glaucoma, the pupil, strabismus, paralysis of the ocular muscles, ocular neurology, and of the functional investigation of the eyes, in the order named. The index, as is usual in German books, is not very elaborate, only one, or at most two, references being given under each head. When we last reviewed the book we concluded that it was a very good one, but pointed out certain imperfections here and there; these have not been removed; thus, under "glaucoma" very little information is given about the newer operations for glaucoma which seek to establish a filtration scar. Elliot's trephining operation, Holth's punch method, and Herbert's flap operation are not even mentioned. The whole question of the ocular circulation and the theory of glaucoma is exhaustively treated and has been brought up to date, but the valuable anatomical discoveries made by Thomson Henderson with reference to the action of

iridectomy and sclerosis of the pectinate ligament are not mentioned. In fact, for Römer, British ophthalmology seems hardly to exist, for, as far as we can see, Priestley Smith is the only English ophthalmologist mentioned in the book. We find the same thing when we come to the article on colour-vision tests. Edridge-Green's theory and his lantern are not mentioned. Even the Young-Helmholtz theory escapes notice, whereas two pages are devoted to Hering's theory of colour vision, a theory which is now much discredited. In spite of small defects Römer's book is a valuable addition to ophthalmic literature, and the English translation may be commended to the general practitioner, for whom Römer wrote the book.

THE SURGEON'S WORKSTEAD.

IN the preface to his book on the working-place, or to coin a word, the "workstead," of the surgeon and orthopaedist,⁷ Dr. OSCAR LANGEMAK says that its object is to show how with comparatively scanty means the objective necessities of surgical and orthopaedic practice may be provided; what they are and what they cost. Dr. Langemak takes nothing for granted, and begins with the waiting-room. This should, if possible, be remote from the consulting-room, so that the waiting patients may not be disturbed by the cries of pain from the patient under treatment, and that the latter, on leaving, need not pass through the waiting-room. The word-picture which he draws of some surgeons' waiting-rooms is far from pleasant, nor are the illustrations which he prints of the waiting-room as it ought to be, very attractive. This will, perhaps, be understood when it is noted that he allows only £5 15s. (Mk. 115) for the purchase of furniture. Almost every imaginable detail of apparatus useful in the examination and treatment of private patients is mentioned. Many ingenious contrivances are of the author's own invention. Various methods of preparing sutures and ligatures and dressings are considered, and the best method of preserving rubber goods is not forgotten, nor does the author omit prescriptions for ointments to be used in the surgery. X-ray apparatus, fittings and chemicals for the pathological laboratory, methods of lighting, case-books, machines for mechanical treatment, plaster-of-Paris—all are considered, and advice is given as to where to buy everything and what to pay for it. In the section on the installation of a private hospital the same thoroughness is manifest. Lists of bed-linen and nurses' clothing, discussions of all the details of ward furniture down to spittoons and towel-horses here find places, as well as full lists for instruments for anaesthesia and all operations. The book will probably be of considerable use in Germany, but its value in this country must be seriously reduced by the fact that many of the appliances of the patterns recommended are not obtainable in England, and that the firms named and prices quoted are of course German.

NOTES ON BOOKS.

FOR those who love children there is, perhaps, no more fascinating occupation than to watch from day to day the gradual awakening of the mind of a little child. The "new-born denizen of life's great city" has been a source of inspiration to innumerable writers, amongst whom must be reckoned the German poet, OTTO ERNST, whose charming study of his little daughter *Roswitha*⁸ has recently been translated into English by Mr. A. C. CATON. Herr Ernst is well known to his fellow-countrymen for his exquisite portrayal of the short joys and sorrows of childhood; and he has given here a delightful picture of a German home and the doings of his five children, the youngest of whom gives her name to his book. There are few of his readers, we imagine, who will not fall under the spell of this pet and plaything of the whole household and the queen of her learned father's heart. *Roswitha* is a wonderfully close and subtle analysis of child nature; and English readers owe a debt of gratitude to Mr. Caton for his admirable translation of a most interesting and

⁶ *Lehrbuch der Augenheilkunde in der Form klinischer Besprechungen*. Von Dr. Paul Römer. Erster und Zweiter Band. Zweite Auflage. Berlin und Vienna: Urban und Schwarzenberg, 1913. (Sup. roy. 8vo. Vol. i, 396, Tfn. 21, Mk. 16; Geb., Mk. 13. Vol. ii, pp. 381-828. Tfn. 22-32, Abbn. 162, Mk. 8.)

⁷ *Die Arbeitsstätte des Chirurgen und Orthopäden (mit Hinweisen für Einrichtung)*. Von Privatkliniken von Dr. Oscar Langemak. Spezialarzt für Chirurgie und Orthopädie in Erfurt. Jena: Gustav Fischer, 1912. (Med. 8vo, pp. 189; Abbn. 45. Mk. 5.)

⁸ *Roswitha*. Being leaves from the life of my little daughter. By Otto Ernst. Translated by A. C. Caton. London: A. C. Caton, 1913. (Cr. 8vo, pp. 322. Price 5s. net.)

attractive book. The grace and innocence of early childhood have seldom been more delicately or more lovingly described; and the baby girl to whom they are dedicated is worthy to rank beside the nameless child who inspired one of the most beautiful of Longfellow's poems:

On thy head
The glory of the morn is shed,
Like a celestial benison!
Here at the portal thou dost stand,
And with thy little hand
Thou openest the mysterious gate
Into the future's undiscovered land.

At a time when research is vigorously attacked as being productive of no useful results a book which deals in popular language with the progress and attainments of modern medicine should be welcome. Such a book is *Bacteria*,⁹ by Dr. MAX SCHOTTELIUS, written with the object of promoting an understanding of the responsibility of medical action in the fight against disease. The ground covered is comprehensive and includes a chapter on protozoa, which, though outside the scope of the title, is quite germane to the theme. With so rapidly moving a science as bacteriology a book on the subject soon becomes out of date, but at this time of day one does not expect to find the statement that, "if tuberculosis is conveyed to man, and especially to children, by milk, it is by human tubercle bacilli which have got into the milk." That is a particularly unfortunate statement in a book designed to popularize preventive medicine. In other respects the views adopted are as recent as can reasonably be expected. With so much good material and so fascinating a subject, it is a pity that a little more care has not been taken with the English translation. There is much good stuff in the book, and it should appeal to the laity and to such members of the profession as require a brief summary of the subject. Ten excellent coloured plates atone for a number of split infinitives.

A Roosevelt Hospital Graduate Nurse has written under the title of *A Stitch in Time*¹⁰ a kind of first-aid guide to the common emergencies, accidents, and every-day troubles. By using clear terse descriptions much more has been included than in the average first-aid guide, and the book contains excellent hints on the preservation of health, the treatment of minor ailments, and a useful list of invalid foods. It is essentially a practical book, useful to the householder, and one from which the medical man can glean a few wrinkles.

The failure to obtain a sufficient number of recruits for the Territorial Force, and the want of interest and even dislike manifested by so many of the younger generation for any form of military service, has given rise to much discussion as to the merits and demerits of conscription in this country. One of the most ardent supporters of compulsory military service is General Sir IAN HAMILTON, whose stirring speech on *National Life and National Training*,¹¹ which was delivered at Birmingham in September last, has just been published as a pamphlet. Sir Ian Hamilton, foreseeing a time when the great European Powers will "Cry havoc! and let slip the dogs of war," suggests the adoption of enforced military training in every boys' school in the kingdom as the most effectual means of preparing for the conflict which he regards as almost inevitable. He states his reasons for this proposal very clearly and temperately. His sympathy with boyhood has given him a thorough understanding of the mental and physical needs of the average English boy; and his pages are characterized by a good humour and common sense that should do much to reconcile to his opinions even the most confirmed antimilitarists amongst his readers. His words are at once a warning and an appeal on behalf of that boyhood upon whose well-being and efficiency the future welfare of the race depends, and should be read with attention by all those into whose hands the destinies of the British Empire have been confided.

⁹ *Bacteria*. By Max Schottelius. Translated by Staff Surgeon Herbert Geoghegan, R.N. Second edition. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. (Cr. 8vo, pp. 336; figs. 33; plates 10. 8s. 6d. net.)

¹⁰ *A Stitch in Time*. Simple and practical remedies for use in emergencies. By a Roosevelt Hospital Graduate Nurse and a Grateful Patient. New York and London: G. P. Putnam's Sons. 1912. (Crown 8vo, pp. 20. 3s. 6d. net.)

¹¹ *National Life and National Training*. By General Sir Ian Hamilton, G.C.B. London: F. S. King and Son. 1913. (Cr. 8vo, pp. 55; 6d. net.)

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of the above society was held on Tuesday, May 6th, Sir Thomas Boor Crosby, President, in the chair. Twenty members were present. The Secretary read the following report for 1912, which was adopted:

Since the last report eight new members were elected; seven died and three resigned. The society consists at the present time of 1 honorary member, 152 life, and 149 ordinary members, making a total of 302, which, considering the number of medical men who are eligible for membership, is but a very small proportion.

The advantages of the society, and the very great amount of good which it does, cannot be better shown than by a short study of the balance sheet for the year. The invested funds amount to £101,600, from which was derived in interest the sum of £3,180 5s. 9d.; £361 3s. was received in subscriptions and donations. Amongst the annuitants of the charity—namely, 46 widows and 11 orphans, the sum of £3,065 was distributed, each widow receiving on an average £50, besides an additional £10 as a Christmas gift, and each orphan £15 and a gift of £3 at Christmas. The grants to orphans have been increased from £15 to £25 per annum.

The Copeland Fund is a special fund which enables the society to grant to any widow or orphan already in receipt of the society's ordinary relief, extraordinary assistance in special circumstances of unusual distress, such as blindness, paralysis, insanity, severe disabling accident or grave permanent disease, and to continue such extra relief in the case of orphans beyond the age of 16 or 18 years (at which under the society's existing by-laws, the ordinary relief ceases) for such further period as the Court of Directors may think fit.

One widow and five orphans were elected on to the funds during the year, and on December 31st there were 46 widows and 11 orphans in receipt of grants. One of the widows has been on the books since 1854, and has already received over £2,420.

Relief is only granted to the widows and orphans of deceased members who have paid their annual subscription for three years, or who are life members. During the year thirty-two letters were received from widows of medical men who, in many instances, had been left practically penniless, asking for relief, but this had to be refused, as their husbands had not been members of the society. An application for relief was received from the widow of one of the members on behalf of herself and five orphans; her late husband had paid in subscriptions £16 lfs. The court voted a grant at the rate of £50 per annum for the widow and £20 per annum for each orphan, making a total grant of £150 per annum. In addition, the widow will probably receive at Christmas £10, and each orphan £3, bringing the total amount she will receive from the society up to £175 per annum. A more striking example of the advantages of joining the society can hardly be shown.

The directors would bring to the notice of the members of the medical profession, especially the younger, the advantages of joining the society. Membership is open to any registered practitioner who at the time of his election is resident within a twenty mile radius from Charing Cross. Should any member remove beyond the limits of the society he nevertheless continues to be a member. The annual subscription is two guineas; every member who has paid this sum for twenty-five years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant.

Further particulars and application forms may be obtained from the Secretary at the offices of the society, 11, Chandos Street, Cavendish Square, W.

The acting treasurer, Dr. F. de Havilland Hall, reported that the society would shortly benefit under the will of the late Mr. James Brickwell to the extent of over £36,000. Mr. Brickwell was elected a member in 1833 and died in 1893. By his will he made the society his residuary legatee, his son, however, having a life interest in the money.

A RADIUM hospital has recently been established in Tokio under the direction of Dr. K. Watanabe, formerly Surgeon-Lieutenant-Colonel in the Japanese Army.

THE German society for the prevention of venereal diseases will hold its annual meeting this year on June 20th and 21st at Breslau, on the occasion of the centenary exhibition there. The programme includes a number of important questions of wide interest. Dr. Julian Marcuse and Professor Blaschko will present reports introductory to a discussion on venereal diseases and social problems. Professor J. Heller will deliver an address on venereal diseases and the right to marry. Dr. Chotzen will present a report on the action taken by the society in regard to instruction in sexual matters. The discussion will turn largely on the expediency of further action in this direction being taken by the society.

THE REPORT OF THE ROYAL COMMISSION IN REFERENCE TO MEDICAL TEACHING IN LONDON.

By ERNEST H. STARLING, M.D., F.R.C.P., F.R.S.,
JODRELL PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE.

I.

REGRET has been expressed that there was not included among the Commissioners a medical man, preferably a London graduate, who should be acquainted at first hand with the conditions of medical education in London. Such an inclusion would, however, have been in contradiction to the spirit underlying the appointment of the Commission. Its labours included the consideration of the teaching of arts, science, and engineering, as well as of medicine. No teacher of these subjects or engineer was included, the Commission being made up entirely of administrators and business men (with one judge)—that is to say, of men whose life business it has been to act or to devise policies after taking the opinion of experts on the different problems involved. It would have been hard, therefore, to make an exception in favour of medicine, and still more difficult to choose a representative medical man who, though interested in the matter, had taken no side in the interminable discussions which have occurred during the last twenty years of the University. The advantage of having no such man on the Commission is that the Commissioners have come to the burning questions which have divided medical opinion in London—for example, the concentration of preliminary and early medical studies—with an entirely open mind. As a result they have left some of them entirely on one side and have indicated new policies, which may indeed not satisfy any particular party in the University, but represent, at any rate, an unbiassed attempt to create a London Medical School which shall be second to none in the world. It behoves every medical teacher, therefore, to try and approach the recommendations of the Commission with an equally open mind, and to ask himself whether, although his pet scheme is not advocated, the actual recommendations may not be, if not in his opinion equally effective, yet a considerable advance on present conditions, and whether they may not contain the possibilities of a right development in the future.

The recommendations in the Report fall under two headings:

1. In the first place suggestions are framed which will enable the work of medical education in London to go on with the present machinery, while removing many of the hindrances which medical schools have experienced in their work.

2. In the second place, a plan is sketched out by which the new University, when it is constituted, may establish, either *de novo* or preferably out of the present machinery, a University Faculty of Medicine under the control of the University and with full control of academic matters affecting medicine, which, while preserving all the advantages of the present English system of medical training, may provide, as has never yet been done, for the carrying out of the other function of a university—namely, the *advancement* of learning. This act of creation cannot, however, be immediate, since it awaits the formation of a new university by Act of Parliament, and in all probability also the voluntary sacrifice of autonomy on the part of one or more of the present medical schools. It will be convenient, therefore, to deal first with the situation which will present itself directly the new University is constituted.

THE PRESENT MEDICAL FACULTY.

At the present time the Medical Faculty is a large unwieldy body composed of practically all the teachers in the London Medical Schools. It has no powers except the election of three representatives on the Senate, representatives who as soon as they enter on their duties find themselves enmeshed in a great cobweb of red tape which renders them practically powerless for good or for evil. The Faculty has no power to appoint Boards of Studies,

to propose the curricula, and to nominate examiners. The proposals of the Boards of Studies are subject to alteration and amendment by the Senate, and have to be approved both by the Academic Council and by the Council for External Students. No change in the curricula has any chance of approval unless it is equally adapted to the needs of London students and students in the provinces.

THE PROPOSED BOARD OF MEDICAL STUDIES.

In the scheme proposed by the Commissioners the Senate becomes a small body of men occupied with finance and general policy, who will therefore not interfere in academic and professional questions. All the present Medical Schools will be continued as Schools of the University, and their teachers, who at present form the Faculty of Medicine, will lose this name and be entitled the "Board of Medical Studies." This Board will have power to appoint any committees it may wish, and these committees will play the part at present appertaining to the Boards of Studies. These committees, however, will be appointed by the body of medical teachers, and will have to report to this body before any recommendation is sent up to the Senate. The Board of Medical Studies can determine also what committees it is advantageous to appoint. It will directly or through its committees draw up curricula, nominate examiners, and determine conditions of the examinations. The examinations, as now, will be general, but open and common only to students in the London Schools, the external student in the Faculty of Medicine being abolished.

There is apparently no suggestion to interfere with the present grants of the Board of Education to the London Medical Schools, and it is to be presumed that these grants, as now, will continue to be awarded on the amount of professional training of sufficient quality which is given in the schools.

These changes are none of them very revolutionary, but are improvements on present conditions, and probably represent a large part of what would be regarded as desirable by those teachers who are strongly attached to the principle of autonomy of the separate schools.

EARLY EDUCATION.

More fundamental proposals are made with regard to the studies and examinations which are antecedent to the professional curriculum. It has long been felt that one of the chief bars to any increase in the number of medical students in London taking a university degree has been the exclusive character of the matriculation examination. In its older form, with a number of compulsory subjects, it might have served as a test of a good secondary education; but, owing to the fact that only a small number of schools regulated their courses of studies in accordance with the requirements of the London University, most boys who wished to take a London degree had after, or just before, leaving school to take special classes, or go to cramming to be prepared for this examination. Changes which have been introduced into the examination during the last ten years have, indeed, rendered it easier, but have robbed it of most of its value as an incentive to a properly balanced secondary education.

The Commissioners regard the whole examination as a mistake, and propose that admission to the University should be determined on the basis of a school examination, which should be passed by the scholars in all secondary schools of the country at about 16 or 17. The examination will probably be under the general supervision of the Board of Education, acting in concert with the local university, and with the school teachers, and will be based on the school curriculum. If this school-leaving examination is made a necessary requisite for entrance to all professions, as is the case with the Abiturienten examination in Germany, every medical student in the country will finally be qualified to pass to a degree in the University of London. Until such action is taken by the Board of Education it would seem that some examination like the present matriculation must be continued by the University. But it does not appear likely that the newly constituted University will place the captious difficulties in the way of recognizing the entrance examinations of other universities as has been the case with the present University.

EDUCATION IN THE PRELIMINARY SCIENCES.

The proposals of the Commissioners with regard to the preliminary scientific education and examination are more revolutionary, or, at any rate, unexpected, and suffer from the objection that, however desirable they may be in themselves, many years must probably elapse before they can come into effect to any large extent or influence any considerable majority of the London students. The Commissioners adopt the view which has long been maintained by the Royal Colleges, namely, that preliminary science should be learnt during the school years. They therefore recommend that a *senior* school examination be held in all secondary schools, more specialized than the examination mentioned above, and varying in type according to the subsequent aims of the pupil. In the case of the pupils who propose to proceed to medicine this examination will include physics, chemistry, and biology, and should be passed by the pupil about the age of 18, so that the last one and a half to two years at school will be spent in the study of these subjects. Until this examination is not only instituted but becomes general, the University will have to continue its Preliminary Scientific examination, and not until this examination is passed can a student enter the University as a student of medicine. Probably the nature of this examination, and the method of holding it will be largely influenced by the representations of the Board of Medical Studies, that is, the body corresponding to the present Medical Faculty. But it is a weak point in the Report that no clear account is given of the long transition period which must elapse before the recommendations can become effective, and it would seem that the Medical Schools may have to provide teaching for the subjects of this examination for a considerable time to come. The Report draws attention to the greater difficulty of teaching biology in schools as compared with physics and chemistry. The changes recommended by the Commissioners would be certainly easier to bring about if this subject were dropped for the Preliminary Science examination and the training in general biological principles transferred to the teachers of anatomy and physiology in the Medical Schools. Such a change would meet with the approval of many of the teachers of the professional subjects, but it is not clear from the Report that any such change is contemplated by the Commissioners. Certainly most Medical Schools would feel it a relief to receive the students already well grounded in the elements of general science by a two years' course of physics and chemistry taken while they are still under school discipline and during their most receptive years.

THE NATURE AND FUNCTIONS OF UNIVERSITY EDUCATION.

These proposals, however, do not make a University Faculty of Medicine, they simply provide for an improvement in the examinational test of knowledge acquired at a number of hospital schools, and ensure some correlation between the examinations and the average teaching carried out in the different schools.

The fundamental idea underlying the present Report is that university teaching can be given only by men who are actively and systematically engaged in the advancement of knowledge in the subject they teach. It is the association of such men which forms the university and creates an atmosphere in which the student not only learns to earn his living but acquires also the training of mind which will fit him to take part in or to avail himself of every advance in the knowledge of his subject. "He learns to weigh evidence, to follow and criticize argument, and put his own value on authorities."

Hitherto there has been no means of organizing either teaching or research with a single eye to the interests of medicine as a whole. It was these considerations which led the last two Royal Commissions to advocate the concentration of preliminary and early medical studies in university institutions, so that London men should have the advantage, at present enjoyed by Oxford and Cambridge students, of a university training during the first three years of their medical course, and the institutions, being under the direction of professors appointed by the University, could have been freed from the hampering effect on their education which is at present exercised by the system of external examinations.

In the last University Commission the subjects of pathology and hygiene were grouped with those of the

intermediate studies, anatomy, physiology, and pharmacology. Until recently no one has ventured to suggest that the professional subjects of medicine, surgery, and gynaecology were equally susceptible of treatment as subjects in a university curriculum, or that the university spirit was as necessary in the pursuit of these studies as in that of physiology and anatomy. We have been apparently so deeply impressed by the system in which we have been brought up, derived from the century-old method of apprenticeship, that we have regarded the main object of medical education in the later years of the curriculum as a training in a craft. As Mr. Flexner rather unkindly says, "Such medical teaching regards itself as preparing the student to be a higher sort of artisan." Curiously enough this attitude of mind is peculiar to England, and its long survival and its strength at the present day are probably due to the first-rate quality of the technical training which is given, especially in London, and to the high personal character of the men who are responsible for the training. But its effect on the advance of medicine and surgery in this country can only be regarded as disastrous. In the advances of the last twenty years our clinical teachers have taken little part. The English schools of physiology and pathology, and of tropical diseases, have acquired a high reputation in the civilized world, but reference to the authorities quoted in any textbook of medicine shows that, with but a few honourable exceptions, the recent advances in the science of medicine, when not due to pathologists or physiologists, are accredited to some foreign school. Nor are our clinical teachers to be blamed for this condition. Many, perhaps most of them, take up medicine or surgery from a love of the subject, and the question of professional success—that is, the acquisition of a large practice—may be at first an entirely subordinate consideration. But it has to be taken into account that at the present time "there is no place in the sun" for the man who would give his life to medicine or surgery. Unless he has a considerable private income he must practise or starve. Nor are the chances of advancement in his profession determined by his powers and work as an original investigator. It is more important that he should work for the school to which he is attached than for the subject which he professes. It is twenty years since I was told authoritatively that "a medical school is not the place for research," and since that time conditions have altered considerably, but even now organized research is regarded as something fitting for the scientific teachers in the school rather than for the clinical teachers attached to the hospital staff.

The complete lack in London of teaching of university rank in the professional subjects of the medical curriculum was brought clearly before the Commission by Flexner, not only in evidence, but also in his reports to the Carnegie Institute on the conditions of medical education in the States, Canada, Germany, and France, as well as in this country. If a real University Faculty of Medicine is to be created in London it must be made possible, in Flexner's words, "to import into London the scientific producing clinician—devoted to teaching and research—from any place in which he may be found; and younger men must be taught that their chances of higher appointment depend, not on using themselves up in tutorial coaching, not on faithfully stepping into the breach when the superior is absent nor following in his footsteps when he is present, but on the development of their own powers along genuinely productive lines. . . . The first step in the direction of modernizing medical education would appear to lie in the total conversion of an existing school or in the creation in London of a new school, the clinical Faculty being selected upon precisely the same lines as the scientific Faculty, the entire body of teachers animated by one ideal and working as an organic unit towards a single end. The clinician's relation to the hospital must reproduce the chemist's relation to his laboratory."

UNIVERSITY COLLEGES OF MEDICINE.

Evidence to somewhat the same effect was given before the Commission by Sir William Osler, by Dr. Head, and, with reservations, by the staffs of St. Bartholomew's and of the London Hospitals, with the result that the Commissioners have been convinced of the feasibility of creating a University School of Medicine in London which

will include all subjects of professional study, and which will conform to the ideals of a university which are generally accepted for the Faculties of Arts, Science, and Technology. The Commissioners therefore propose that, as in the other Faculties, one, two, or three University Constituent Colleges of Medicine be instituted in connexion with hospitals. In these colleges the financial and academic control of the schools must be in the hands of the University, the local management of each being carried out by a delegacy appointed by the Senate of the University. Each of these Colleges will include departments representing all the subjects of the medical curriculum subsequent to the Preliminary Scientific examination. Only University students, that is, those who are qualified for registration as matriculated students in the University, will be admitted to these Colleges, but it must be remembered that most students of Oxford and Cambridge, and probably of other universities, will be capable of being so registered. All the teachers in the Colleges will finally be appointed by the University, using the mechanism of Boards of Advisors as at present, as professors, associate professors, or readers. The "Faculty of Medicine" of the University will be composed of these teachers appointed by the University. Since these teachers will be selected and appointed by the University, they will be trusted to develop their teaching along their own lines, and to determine—subject to the general approval of the whole Faculty, and in the qualifying examinations to inspection by the General Medical Council—the nature and extent of the examinational tests to be applied. It is laid down, however, that assessors must be appointed to aid the professors in their public examinations.

It will be noted that the Commissioners thus accept the argument insisted on during the concentration discussion of a few years ago, especially by the teachers of the Medical Schools of London and Guy's, as to the great advantages connected with the close association of all subjects in the medical curriculum, intermediate and advanced, in the same educational institute. By throwing over "concentration," however, the Commissioners have had to abandon a principle on which much stress was laid by the advocates of concentration and of which they themselves approve in the early part of their Report—namely, the advantage to the student of an education in an institution where many Faculties are represented, so that he can broaden his mind in directions other than the immediate subjects of his studies. Both advantages are real ones, and I am inclined to think that if choice has to be made between them the Commissioners have taken the right course. Moreover, it is possible that the mixture of students of many Faculties may be effected to a considerable extent by the institution of hostels connected with the University rather than with any given College or School, whether of one or more Faculties of the University.

The most important innovation in this scheme, and the one which promises most for the advancement of medicine in this country, is the recommendation that University professors shall be appointed to deal with the clinical subjects. These professors are to have charge of wards and of laboratories attached to the wards. They will have a number of paid whole-time assistants, in addition probably to half-time unpaid assistants. They will have charge of an out-patient department connected with their wards. They will receive a salary of £1,000 to £1,500 a year, and will be expected to devote all their heart and the greater part of their time to the work of teaching and research in their department. They will, however, be allowed a certain limited amount of private practice—for example, two or three afternoons a week.

There is no question that these proposals of the Commissioners will meet with much criticism. Mediocrity is certain to be up in arms at the institution of any system which promises to pick out and place in a superior position the talented, the enthusiast, or the man of genius. But it must be distinctly pointed out that no proposal is made to abolish the present system of clinical teaching in London—namely, teaching by appointments. All the witnesses examined before the Commission were unanimous on the advantages of this system; and Flexner in his book on *Medical Education in Europe* expressly shows that the great lack in German medical education is some system

like this, in which students obtain direct access to the patients during the whole of their professional studies. There is no doubt that in London the art of medicine and surgery is taught to the ordinary student better than anywhere else. This system, however, will not be any the worse for having added to it instruction by skilled teachers who are giving their life to their subject instead of by men in active practice who can spare a few hours a week for their hospital wards, but have no time either to carry out investigations for themselves or even to keep themselves abreast of the modern developments of science.

At the present time it is the training rather than the teaching which is the strong point of the London schools. The most important teaching that a medical student in London gets he receives from himself and from his fellow students, especially those holding senior appointments, as he passes through the various positions in the hospital with their graded responsibility. Much of the teaching by the staff is recognized by the students themselves as out of date. The actual instruction imparted in a school is largely directed to passing the students through their examinations, the most sterile form of instruction possible, since knowledge gained solely in preparation for an examination is apt to be thrown away and be lost a very short time after the examination is passed. In a real University the passing of the examination is not the end of the training, and should hardly bulk at all in the mind of the student. The whole aim of his education should be to fit him for his future work, to render him mentally alert and resourceful, keen to avail himself of the advance of knowledge, and prepared by scientific training to distinguish the true from the merely specious among the various modifications in the theory and practice of medicine which are being continually brought before the public.

The recommendation of the Commission that a certain limited amount of private practice should be allowed to clinical teachers will hardly count as an attraction to the right kind of men for the post, but it will be useful in furnishing a bridge by which a professor who is tiring of his earlier aims, or losing his enthusiasm and is beginning to be attracted by the more lucrative rewards of practice, may be enabled to give up his post and devote himself entirely to practice, his place being taken by some younger man with his enthusiasm for medicine and medical research still hot upon him. In this way a constant succession of the right class of man should be assured, and it must be remembered that these men will be drawn not from any given Medical School or College, but from the whole Empire.

FINANCIAL.

It is evident that no step can be taken in the creation of a Medical College or Colleges of this type until the new University is established. The Report suggests that one, two, or three of the existing medical schools might be taken over by the University. In each such Medical School the buildings and funds available for medical education should be vested in the University and be administered by a delegacy appointed by the University.

Suggestions are made in the Report for the manner in which adequate arrangements might be made between the University and the hospital with regard to the use of the wards for teaching, but this I need not go into.

It is calculated that in a School with an annual entry of about seventy students the income from fees, endowments, and grants from the Board of Education would amount to about £12,000 to £15,000, and would be sufficient for the requirements of the departments of Anatomy, Physiology, Pharmacology, and Pathology. To this the University would have to add another £12,000 for the service of the three units of clinical study—medicine, surgery, and gynaecology. Additional provision would have to be made, either in the school or elsewhere, for the special departments of clinical study, which would require further expense. Thus the University would have to be founded and provided with funds before it could carry out the negotiations necessary for the conversion of one of the present Medical Schools into a constituent College of the University. It is impossible at present to say which, if any, of the schools would be willing to accept the terms suggested. Although the School itself would gain enormously in prestige and usefulness, considerable sacrifice

would be required from the individual members of the present staffs; for the change would mean not only the sacrifice of their present autonomy and patronage, but also the admission of a new order of men who would be academically, though not necessarily professionally, of a higher grade than the present clinical teachers.

The change would also involve the transference of the whole future of the School into the power of a new and unknown body, and necessitates, therefore, considerable faith in the adequacy of the statutes made for the government of the new University, and in the quality of the men selected in the first place as members of the Senate.

It would be impossible, for instance, to imagine any Medical School daring to entrust its fortunes to the guidance of the present Senate.

I believe, however, that the principles laid down in the Report will be found adequate, and that if the right men are chosen by Government to guide the fortunes of the new University through the first six years of its life, there is a prospect of having after these seventy-five years of struggle a University worthy of London and a Medical School in the University inferior to none.

Those who oppose these changes will have to show that their opposition is really based on a consideration for the welfare of medicine and the medical sciences, and is not directed by a regard for the private interests of themselves or their Schools. The Report points out that the public are alive to the fact that hospitals founded and supported by charity should be used to the fullest extent for medical education and the advancement of medical science. If hospitals "are required for a University Faculty of Medicine in London which has no end in view but medical education and the advancement of medical science, the public interest must be considered, and the question of the privilege of access to the great London hospitals cannot be treated as a matter of private right, or decided as if they were the private property of the existing Medical Schools."

SPECIALISM IN THE GENERAL HOSPITAL.

THE Phipps Psychiatric Clinic in connexion with the Johns Hopkins Hospital, Baltimore, was opened with the customary ritual of "exercises," speeches, and banqueting on April 16th.

It owes its establishment to the liberality of Mr. Henry Phipps of New York, who some years ago gave a large sum to Johns Hopkins in furtherance of the knowledge of tuberculosis. The cost of the building of the Psychiatric Clinic is estimated at £200,000, and Mr. Phipps has further undertaken to provide for its maintenance during the next ten years and has endowed a professorship. The director is Dr. Adolf Meyer, who during the last three years has been engaged in organizing the clinic, which is now ready for the reception of patients; his staff will consist of ten physicians and some fifty nurses.

Of the addresses delivered at the opening of the new foundation, the most notable was that of Sir William Osler, who discoursed on specialism in the general hospital. He said that, although in 1889 the Johns Hopkins Hospital seemed to many the last word in hospital construction, year by year since then new departments had been added, new lecture rooms, operating rooms, laboratories, and so forth. He recalled the fact that in the address delivered by him when he was leaving Johns Hopkins in 1904 he spoke of the need of special departments, expressing the hope that within twenty-five years they would have a psychopathic institute, a children's hospital, a genito-urinary clinic, and a special building for diseases of the eye, ear, and throat. Two of these were already in existence—the department for sick children, and now the psychopathic institute. Money had been furnished for the new genito-urinary clinic. Others would follow rapidly, and it was safe to say that within a dozen years there would be as many special departments, semi-independent units in a great organization. Each of these units was a place where sufferers received the best skilled help that could be given; each was a place where students were taught, and each was also a centre of study and research. Each unit represented a technical school linked to the university by the Medical Faculty. They differed from the more purely scientific departments of the medical school in one important particular. The

hospital units minted for current use in the community the gold wrought by the miners of science. That was their first function. "Only a cold-hearted, apathetic, phlegmatic, batrachian, white-livered generation, with blood congealed in the cold storage of commercialism, could not recognize the enormous debt which we owe to these self-sacrificing miners of science; and yet there are to-day sons of Belial, brothers of Schemel, daughters of Jezebel, direct descendants of the scribes, pharisees and hypocrites in the time of Christ, who maligned these prophets and wise men, winners in a fight for humanity, unparalleled in the annals of the human race." Dealing more particularly with the new institute, Sir William Osler went on to say that the progress in the rational treatment of insanity was a bright chapter in the history of the past century. On the other hand one of the tragedies of the subject had been its dissociation from centres of active professional and university life. A department of medicine with the closest affiliation with the life of the community had been segregated and stamped with a taboo of a peculiarly offensive character. At Johns Hopkins it would take its proper place as a unit in the work of the medical school of the university. A new atmosphere would be diffused, a new group of energy and activity would come into the hospital which could not but be helpful. The medical student, living as he did in close fellowship with the hospital staff, would be influenced in this way by the very presence of the institute. It was to be hoped that time might be found for general instruction of the senior students in the elements of neuro-psychology. To a large class outside the institute it should prove immensely beneficial. He estimated that there must be a thousand or more assistants in the asylums of the United States whose pineal glands were not yet crystallized, and who should find there inspiration and help. He expressed the hope that room would be found for the general practitioner, through whom more than any other group the benefits of the institute would be distributed. The doctor in general practice needed enlightenment as to the vast importance of early deviations from normal mental states, instruction in new methods of diagnosis and treatment, and encouragement to feel that in the great fight for sanity in the community he was the man behind the guns. Men talked a great deal about the human mind, and when cornered quoted Hamlet to cover an unpleasant ignorance of its true nature. The modern student, like the ancient, took his stand either with Plato and compared the mind and brain to a player with his musical instrument, or with Lucretius to a musical box wound up for so many years to play so many tunes. Modern authorities leaned to one or other of these views. Three things they did know: Departures from normal mental states were extraordinarily common; they were the most distressing of all human ills, and they should be studied systematically by experts with a view to their prevention and cure. A widespread feeling had arisen that the hygiene of the mind was just as important as the hygiene of the body, that they must return to the Greek ideal of the fair mind in a fair body. He was afraid several generations must pass before they saw any practical result of the present active eugenic crusade. But there was an immense and hopeful work to be done in educating parents in training-stable methods. The orator expressed his confidence that the psychopathic institute would play its part in the national campaign of prevention of mental ill health through education, a campaign as important to the public as the great struggles against tuberculosis and infant mortality. It would be helpful, too, to study in a sane, sober, and sympathetic way epidemics of mental, moral, and even economic folly as they swept over the country. The present outbreak had not been equalled since the capture of the Roman world by oriental cults. The same old-fashioned credulity existed that enabled Mithras and Isis, Apollonius and Alexander, to flourish then as the new cults did to-day, and for the same reason. There was still potency in the protoplasm out of which arose in primitive man magic, religion, and medicine. So recent was the control of the forces of Nature that even in the most civilized countries man had not yet adjusted himself to the new conditions, and stood only half awake rubbing his eyes outside Eden. Still in the thaumaturgic state of mental development 99 per cent. of their fellow creatures when in trouble, sorrow, or sickness, trusted to charms,

incantations, and the saints. Many a shrine had more followers than Pasteur, many a saint more believers than Lister. Mentally the race was still in leading strings, and in the childhood of the world they could not expect people yet to put away childish things. These were some of the hopes that filled their hearts as they thought of the future of the new department.

Dr. W. H. Welch delivered an address, in which he said that Mr. Phipps wished the clinic to be for the "ameliorated treatment of the insane." There had been no branch more in need of close association with the medical school and hospital than psychiatry. The general practitioner as a rule lacked opportunities for study and investigation in this line of medicine.

Dr. Stewart Paton, of Princeton, in a speech on the clinic and the community, said that institutions of that kind were intended for the study of man on broad biological grounds. The patients presented themselves for treatment as victims of imperfect adjustment to life's problems. That clinic should be considered an important link among many other links—the home, the school, the university, and others.

Dr. Mott paid a warm tribute to the value of the new clinic, which he said was one of the most prominent, if not the leading, institution of its kind in the world.

Dr. Meyer pointed out that the institution had a great educational value, and should aid in bettering civic conditions. Now that the North and South Pole had been found, it was time for the public to take an increased interest in exploring the great field of the nature and function of the brain.

Three hundred and fifty guests, some of them of world-wide fame, sat down to the ceremonial banquet in the evening. Dr. William H. Welch was in the chair. Among those present were Sir William Osler, Dr. F. W. Mott, and Dr. William McDougall of Oxford, besides many American leaders in psychiatry and neurology.

THE BIOLOGICAL PROPERTIES OF MILK.

In the report of Dr. Janet E. Lane-Clayton to the Local Government Board the biological characters of human and cow's milk are considered largely from the standpoint of infant feeding, and an extensive literature on this subject comes under review. The subject is considered under two main headings:

- (a) The ferments in milk and their mode of action.
- (b) Those protective substances in milk similar to the bodies found in normal or immune serums which play a part in immunity.

The literature dealing with the individual substances is passed in review and the present position of knowledge considered.

The report should appeal both to the research worker and to all dealing with the questions of infant feeding and public health; for although the value to the infant of the substances reviewed would not appear to be great, to reach this conclusion has required an amount of critical reading and research on the part of Dr. Lane-Clayton not possible to many who are interested in all phases of the milk problem. Unfortunately, many of the earlier workers did not sufficiently realize the importance of employing only sterile milk, and hence it is not surprising to find that several of the enzymes originally stated to be present in milk are really derived from bacterial contamination.

Oxidizing Ferments.

The enzymes which receive most attention in the report are the oxidizing and reducing ferments and catalase. With regard to the former it was at first considered that two enzymes were concerned, one, an oxidase, giving a direct action; the second, a peroxidase, acting only in the presence of a peroxide, such as hydrogen peroxide. More recently, however, it has been shown (Moore and Whitley, Bach, and others) that the first of these is not an enzyme but a peroxide, so that only one enzyme need be con-

sidered—namely, the peroxidase; a direct action merely indicates that a peroxide is already present. In using the peroxidase reaction as a test for boiled milk it must of course be remembered that the addition of a small quantity of raw milk to a boiled sample will again make the test positive. In order to overcome this difficulty attempts have been made by Van Eck and others with a certain amount of success to carry out the test in a quantitative manner. Peroxidase appears to be always present in cow's milk, even when this is entirely free from bacteria. The enzyme can be precipitated from the whey by saturation with ammonium sulphate, and is probably associated with the lactalbumin. It is destroyed by heating to a temperature of about 75°.

In human milk its presence is less certain; it is, however, nearly always found in colostrum, and also in inflammatory conditions, such as mastitis. It would, therefore, appear to be derived from cellular elements, such as the leucocytes. The mechanism of the peroxidase reaction is not fully understood, but it seems likely that it depends on the presence in the milk of small quantities of metals or metallic salts in the colloidal state. This theory receives support from the work of Sarthou, who has shown that very minute traces of colloidal iron and manganese—two metals almost always present in milk—can bring about the reaction.

Reducing Ferments.

Passing next to reducing ferments, we have again to consider a direct and indirect action. The reagent usually employed to detect reducing enzymes is a solution of methylene blue, either alone or with the addition of formaldehyde (Schardinger's reagent). The work reviewed shows quite conclusively that milk free from bacteria does not reduce methylene blue alone—that is to say, the direct action, when it occurs, is due to bacterial contamination. It has even been suggested (Bartel) that this reaction might be used as a test for contamination. With Schardinger's reagent, on the other hand, reduction is brought about by cow's milk, even when sterile, though not by human milk, which contains, therefore, no reducing ferments. The mechanism of this reaction has received much attention from Bach, and an interesting review of this worker's chief results is given in the report. Bach suggests the name "perhydridase" for the enzyme acting in the presence of formaldehyde, and considers that its action is analogous to that of the metallic sols, which have been shown by Bredig and Sommer to possess similar properties. He thinks that scission of the water by the oxidizable substance (formaldehyde) takes place under the influence of the enzyme, which then forms a strongly reducing compound with the hydrogen. At the same time Bach calls attention to the analogy between the action of perhydridase and of peroxidase, which is indicated by the following equations:

Prolonged boiling of milk also leads to an increased reducing action, but this is probably due simply to the formation of reducing bodies in the process of boiling and cannot be caused by ferment action.

Catalase, the enzyme which destroys H_2O_2 , appears to be nearly always present in cow's milk even when sterile. It is, however, much increased by bacterial contamination, many organisms such as *B. pyocyaneus*, *Protens vulgaris*, and *Oidium lactis* being able to produce this ferment. The catalase reaction has, therefore, been suggested as a means of measuring the degree of contamination and several forms of apparatus have been devised for this purpose. In this connexion, however, it is pointed out that Schroeter found no connexion between the amount of oxygen evolved from H_2O_2 and the bacterial count, and hence it is obvious that the test cannot be applied in a very stringent manner. Catalase is usually present in human milk, but the amount is extremely variable. It is more plentiful in colostrum, and is also increased as a rule in ill health or where the gland is acting badly.

Other Enzymes.

The other enzymes have received very much less attention, but it would appear that sterile milk contains neither proteolytic nor lipolytic ferments, while the presence of

* Reports to the Local Government Board on Public Health and Medical Subjects. New Series, No. 75. Report to the Local Government Board upon the "Biological Properties" of Milk, both of the Human Species and of Cows, considered in Special Relation to the Feeding of Infants. By Janet E. Lane-Clayton, M.D., D.Sc.Lond.

lactase is doubtful. Amylase, however, is present in small quantities both in human and cow's milk, and it is interesting to find that, according to most observers, the hydrolysis of starch proceeds no further than to dextrin. It is difficult to see what use such a limited action could be, and further experiments are desirable to examine the correctness of this view.

Action of the Enzymes in Milk.

The enzymes usually present in fresh human milk are therefore catalase, amylase, and peroxidase, while cow's milk contains in addition perhydridase. A considerable amount of evidence is, however, brought forward to show that the presence in the milk of these ferments can be of little biological value to the infant. Peroxidase, for example, is rapidly destroyed by acid, and would therefore be inactivated on reaching the stomach, while amylase is already present in the saliva of newly born infants, and hence cannot be required in the milk. These ferments are probably derived for the most part from the blood, and their presence in the milk is therefore probably more or less accidental.

Protective Substances.

The protective substances dealt with in the report are such as have been directly demonstrated in the milk or have been investigated from the standpoint of infant feeding.

As to complement in milk, the work up to date has been carried out largely by the use of the haemolytic test. The chief points of interest elucidated are that complement is present in cow's milk in the colostrum period, but that later it is absent or the quantity is so small as to be negligible. Some evidence, however, has been brought forward to show that it becomes substantial in amount in early mastitis. The complement of human milk requires a sensitive system for its demonstration.

Haemolytic amoceptor is found in normal cow's milk only in the early colostrum period, and apparently not later. Balloch was also able to demonstrate *specific amoceptor* in the milk of immunized rabbits. The results which have been obtained with haemolytic amoceptors probably indicate the type of behaviour of other specific immune bodies in the case of milk.

Bactericidal substances have been investigated by considering the growth of the organisms found in milk itself, and also the growth of organisms added to approximately sterile milk, the samples being kept at different temperatures. The growth was determined by plating out samples of the milk at stated intervals. The results of this method have been attacked by Rosenau and McCoy, and others who account for the apparent inhibition or bactericidal effect by agglutination. They have shown that slight traces of serum added to boiled milk produce the same effect; further, by breaking up the clumps of bacteria in fresh milk and counting, they proved that the inhibition was apparent rather than real. The work of Bab on this subject supports the contention of Rosenau and McCoy. Inhibitory and bactericidal action against *B. coli*, *B. typhosus*, *B. pyocyaneus*, *V. cholerae*, and the organisms found in ordinary milk, have for long been attributed to fresh milk, but most of the work on this subject requires repetition of the experiments under conditions which avoid the errors introduced by agglutination.

The *precipitins* in milk seem to have received little study. The account of Langer's work in this connexion is not stated in very clear terms.

The *agglutinins* of milk have already been noted as complicating and vitiating many of the experiments on the bactericidal properties of milk. The natural agglutinins are present in greater quantities in colostrum. It has been shown, however, that artificial agglutinins also pass out into the milk, and diphtheria antitoxin behaves in a similar way.

The general conclusion is that if specific immune substances are present in the blood of the mother they will pass out in small amount into the milk, in which they are present in the whey.

The value of protective bodies in the milk to the infant largely depends on whether they can be absorbed into the blood stream. The effect of digestion on these protective bodies is discussed. Complement appears to be destroyed in the stomach in the course of a few minutes, but the

work of Ehrlich, Römer, Hamburger, and others shows clearly that some passive immunity can be conferred on the young of the species by the *milk* of a protected mother. The question as to the absorption of foreign protein through the mucous membrane of the infant's alimentary tract is discussed at great length, and much evidence adduced to show that it can be absorbed during the first few days of life, but in the case of the homologous whey proteins it appears possible that the absorption can go on for a longer period. Disturbance of the alimentary canal and excess of protein may also result in absorption of foreign protein in older animals. Specific agglutinin, according to the work of various observers, is not absorbed from the intestinal tract of sucklings, but apparently the subject has not been studied in the very young. The mouth feeding of young animals with dead vaccines, however, gives rise to marked formation of agglutinins in the serum.

The type of feeding seems to have some effect on the antibody content of the serum of infants. Pfandler and his school have shown that the complement content of the serum at birth is high, that it falls after birth, and rises subsequently at a rate depending on the character of the infant's food. There seems some evidence to show that amoceptor for sheep's red cells, which is a normal constituent of human blood, appears earlier in the case of infants artificially fed than in those which are breast-fed. It has been suggested that this difference is due to infection, but the point has not yet been decided.

Finally, in a short addendum to the report, attention is called to the recent work of Schumann and Funk on beri-beri,¹ and the bearing of this on the question of infantile scurvy is discussed.

Conclusion.

Dr. Lane-Clayton's main conclusion alone remains to be considered, and this can best be given in the author's words: "The weight of evidence suggests the absence of any direct value in the biological substances *per se*, but it also most decidedly shows the paramount importance of providing breast milk for the young animal. It would seem impossible to emphasize this fact too strongly, and all those concerned in the health of infants should aim at obtaining satisfactory breast feeding for all infants during, at any rate, the early weeks of life."

INTERNATIONAL CONGRESS OF MEDICINE.

LONDON, AUGUST 6TH TO 12TH, 1913.

IN the advertisement columns of to-day's issue a list of subscribers to the International Congress of Medicine to be held in August next will be found. A further sum of £2,500, which is the minimum required to cover the necessary expenditure, is asked for. This method of appeal has been adopted in order to avoid the very large expenditure entailed by a fresh general issue of circulars to members of the profession.

The expenses of this great meeting have in this country to be met entirely by private subscription, since the actual membership fees do not more than suffice to pay for the copy of the *Transactions* supplied to each member.

It will be noted that less than 600 members of the whole profession are at present represented in the list of subscribers, and that upon many of these will fall the further expense of private entertainment of guests during the course of the meeting.

We earnestly support the request for further subscriptions. It is expected that at least 7,000 persons will attend the Congress, an estimate which is fully corroborated by the entries which have been received up to the present time, and, further, that the meeting will be fully representative of the profession in the various European countries, America, and the British dominions beyond the seas. It may be pointed out that in the matter of private hospitality the executive will receive support from His Majesty King George, and from many prominent men, such as Lord Strathcona, the Hon. W. F. D. Smith, and Mr. Astor, as well as from the medical corporations and some of the City Livery Companies, and that the subscriptions asked for will be mainly

¹ BRITISH MEDICAL JOURNAL, April 5th, 1913, p. 722.

devoted to the scientific objects of the meeting. As the Congress is an international engagement, the larger the number of the names which appear upon the list, independently of the amount subscribed, the greater will be the compliment to our colleagues from abroad and from the Dominions who are visiting us upon this occasion.

Subscriptions may be sent to the Treasurer, International Congress of Medicine, 13, Hinde Street, London, W.

SECTION II.

Physiology.

The President of this Section is Professor E. A. Schäfer of Edinburgh; the Vice-Presidents, Professors Brodie, Gotch, L. E. Hill, McKendrick, Sherrington, Starling, Stirling, and Waller. The Secretaries are Dr. Edkins and Professors Halliburton, Nool Paton, and W. H. Thompson.

The number of set discussions is three; the one which appears to be exciting most interest, to judge by the number of those wishing to take part in it, is that on Internal secretions, which will be held jointly with the Section of Medicine. The Reporters in this discussion—Professor Gley of Paris and Professor Biedl of Strassburg—have been nominated by the physiologists. To introduce this subject a discussion on Endogenous protein metabolism, to be held in conjunction with the Subsection of Chemical Pathology, will be introduced by Professor Abderhalden, Dr. H. D. Dakin, and Professor G. Embden. The third discussion will be confined to the Section of Physiology, and will deal with the question of Reciprocal innervation: it will be introduced by Professors Sherrington and Max Verworn.

Perhaps the most interesting meetings of this Section will be three laboratory meetings, at which demonstrations will be given. These will be held in the Physiological Laboratories of the University of London, University College, London, and King's College, London, respectively. The remaining sittings of the Section will be occupied by the reading of papers; the number of titles sent in so far is not great, but they include communications from Professor Lendemann of Kiev, Professor Sivén of Helsingfors, Professor Graham Lusk, Professor N. Zuntz, and Dr. Iscovesco.

The meetings of the Section will take place in the rooms of the Physiological Laboratory, University of London.

The following is a provisional programme:

- Wednesday, August 6th.*—Morning: Demonstrations. Afternoon: Papers.
- Thursday, August 7th.*—Morning: Papers. Afternoon: Laboratory Meeting. University of London.
- Friday, August 8th.*—Morning: Discussion: Internal Secretions. Afternoon: Laboratory Meeting at University College followed by a Physiological Society Dinner.
- Saturday, August 9th.*—Morning: Papers. Afternoon: Garden Party at Professor Bayliss's.
- Sunday, August 10th.*—Morning: Picnic Party on the Thames.
- Monday, August 11th.*—Morning: Discussion: Reciprocal Innervation. Afternoon: Laboratory Meeting at King's College.
- Tuesday, August 12th.*—Morning: Discussion: Protein Metabolism. Afternoon: Papers.

The acting secretary is Professor W. D. Halliburton, King's College, London, to whom titles of papers and demonstrations should be forwarded without delay.

The entertainments arranged include an excursion on the Thames on the Sunday, a garden party kindly given by Dr. and Mrs. Bayliss at Hampstead, and an informal dinner given by the Physiological Society after one of the laboratory meetings.

THOSE in search of information with regard to Buxton can obtain it from a handbook recently issued. It contains a full account not only of the provisions made for the treatment of disease, but of the opportunities offered for motoring, golfing, and angling, and the enjoyment of music and picturesque scenery. There is also ample information as to hotels and lodgings. Special attention is drawn to the fact that this spa now has a winter as well as a summer and autumn season, and that during the former prices are somewhat reduced. Copies of the booklet can be obtained on application to the Bureau of information, Buxton.

VACCINATION INQUIRY IN THE ISLE OF MAN.

SEVERAL months ago the Manx House of Keys passed a Vaccination Acts Amendment Bill, the object of which was to secure exemption from vaccination by means of a conscience clause. Before becoming law it was necessary for the bill to be submitted to the Legislative Council for consideration and adoption or rejection. The Legislative Council decided to take expert evidence and conducted an inquiry. Dr. Hadwen (Gloucester) gave evidence against vaccination on March 1st; Dr. Drury (Halifax) and three resident doctors gave evidence in favour of vaccination on March 10th. At a meeting of the Legislative Council on April 21st the subject was further discussed and the Amendment Bill was unanimously rejected.

The evidence given at the inquiry has been published in a Blue Book. Dr. Hadwen first dealt with the question from a moral and political standpoint, and urged that it was absolutely wrong for any Government to embody a medical prescription—even supposing that prescription were a right one—among its legal enactments. Whatever might have been the conditions formerly, they did not now warrant any such enforcement, because small-pox had gone the way of the black death, sleeping sickness, and the plague. This was due to sanitary improvements. The State gave no guarantee that vaccination would effect the purpose it professed to accomplish. Vaccination was a cause of injury and death. Surveying the historical aspect of vaccination, Dr. Hadwen submitted that Jenner got £30,000 for the so-called discovery (which Jenner himself had not made) without presenting one atom of solid proof of what he professed to have accomplished. The whole great system had been built up on one solitary fictitious case. The medical men of Jenner's time accepted vaccination without any evidence whatever beyond Jenner's statements. Dr. Hadwen next dealt with the statistical side of the question. After thirty years of compulsory vaccination, the small-pox deaths increased. It was not until the passing of the Public Health Act that small-pox commenced to go down. At the present time, when half the population had not been vaccinated, there was practically no small-pox. He considered the Gloucester epidemic was due to the insanitary state of Gloucester. On the south side the whole area was in an insanitary condition, and the people were living practically over a huge cesspit. The main sewer was broken in every direction. The year was exceptionally dry, and the water supply ran short. He did not know about the necessity for the introduction of small-pox virus. It was constantly being said in these days that there must be an importation of small-pox. Cases had arisen in previous years which showed no connexion whatever with one another. He did not think there was any evidence that small-pox must be caught or that it must be introduced from elsewhere. His figures regarding the Gloucester epidemic did not agree with the official figures of Dr. Coupland. He could not conceive how such blunders were made. The alleged condition of the hospital at Gloucester was described in detail by Dr. Hadwen. It was said that the wards were undermanned, the nurses mostly untrained, and the earliest cases not properly attended by a medical man for days and weeks together: "the patients must have been simply choked with filth." He was a strong antivivisectionist. He would not say that cow-pox was syphilis, but cow-pox could not be distinguished from syphilis. Dr. Hadwen repeated this statement many times. He did not believe in the germ theory of disease in any form. It had never been proved that a specific germ produced a specific disease. The percentage of unsuccessful vaccinations in the West End of London was far larger than in the East End. This led him to suppose the West End doctor vaccinated with an exceedingly light hand, because he got his fee whatever might be the result. Regarding the dangers of vaccination, even the recorded cases of death did not include all, because it stood to reason that medical men would not like to give certificates condemnatory of their own acts. The majority of the profession believed in vaccination because the medical profession were more ready than any other profession to follow the fashion of the day. The medical profession had seldom been unanimous except when it had been

unanimously wrong. With regard to the practice of vaccination the medical profession had been misled by prejudice. Most of the doctors would admit there was no science for it. He did not believe in the use of antitoxins, in anti-septic surgery, or in any of Pasteur's works. Asked if he could give the names of any men in the front rank of the profession holding the views that he did, Dr. Hadwen mentioned the names of Dr. Charles Creighton, Professor Crookshank, Sir William Collins, and Dr. Tebb. There were, he said, a good many more. There was no widespread uneasiness whatever among the profession caused by the great diminution of vaccination. No medical man troubled himself about it. The only people who were troubling themselves about it were the public vaccinators because they were losing their emoluments. He would like to see the Legislature of the Isle of Man set an example to the whole of England, and not merely grant exemption to the conscientious objector, but wipe out compulsory vaccination altogether from the island.

Dr. Drury commenced his evidence by reference to the Royal Commission on Vaccination, its constitution and conclusions. The seven conclusions in par. 377 of the final report were read and emphasized. Diagrams suspended on the walls showed "The mean annual deaths from small-pox at successive life periods per million living at each such period (1847-87), England and Wales." After the introduction of vaccination there had been an enormous fall in the deaths from small-pox at the age under 5 years. This fall commenced long before the Public Health Acts and continued after. The antivaccinator would not consider the points "when" vaccinated and "how" vaccinated in dealing with the subject. The provaccinist considered this of great importance. The witness detailed the mortality-rates from small-pox in recent epidemics at Sheffield, Dewsbury, Halifax, Bradford, and Oldham. The marked difference between the mortality in the vaccinated and unvaccinated illustrated in these and other epidemics was most significant. He did not wonder at antivaccinators talking about colossal collusion when they deal with this aspect of the subject, because the figures worked out so uniformly in one direction, and that was practically the only explanation the antivaccinators could give. It was, however, nonsense to suggest that the medical officer of one town was in collusion with another to produce a uniform set of figures. After demonstrating the effect of vaccination in reducing the liability to death, Dr. Drury proceeded to show how vaccination effected a mitigation of small-pox in persons vaccinated long before. A table calculated on the cases in epidemics at Sheffield, Leicester, Warrington, and Dewsbury showed the proportion of mild and severe cases among the vaccinated and unvaccinated respectively. The figures were almost exactly reversed in the two groups. In Sheffield, for example, among the vaccinated at all ages the percentages of mild cases were 82.8; severe, 17.2. Among the unvaccinated the mild cases were 18.5, and the severe 81.5. He thought the statistics told rather unfairly in favour of the antivaccinators because of the large number of cases of imperfect vaccination, and these were put down as vaccinated. Small-pox was not absent from the country. There were cycles of epidemics almost rhythmic in their regularity. In November and December last there were 42 cases at Kirkcaldy; since then cases had appeared at Basford, Lydbrook, Bristol, Ayr, Cardiff, and Grangemouth. Quite recently between 20 and 30 cases were notified at Newhaven. As to the alleged dangers of vaccination, they were, in his experience, due to preventable causes. He had vaccinated between 8,000 and 10,000 persons, and had never seen a case that could be confused with syphilis. He proposed to hand to each member of the Council a copy of Dr. John McVail's review, which was a complete answer to Dr. Creighton's views regarding vaccination and syphilis. It had been suggested that syphilis increased during a period corresponding with increased vaccinations. The antivaccinator quoted from official returns to show this, but omitted to mention that the whole of the increase referred to was in infants under 3 months old—under the vaccination period. Further, the increase in syphilis was greater in the same period in Leicester than in England and Wales generally, vaccination being at the same time reduced to a minimum. The names of Dr. Creighton, Dr. Crookshank, and Sir William

Collins were constantly being used by antivaccinators. Of these, Dr. Creighton told the Royal Commission vaccination afforded no protection at all. Dr. Crookshank admitted there was evidence to show a temporary antagonism between cow-pox and small-pox, and that for a period of two or three years small-pox, by the test of inoculation, would not take after an attack of cow-pox. The third—Sir William Collins—was not in reality an antivaccinator. He supported the unanimous decision of the Royal Commission that the State should continue to provide vaccination. It was a misstatement of fact to say there was no widespread anxiety in the profession. The persons who should be concerned were really concerned. He had collected about 150 "warning notes" from medical officers of health published in their annual reports recently. Examples were read from Ipswich and Liverpool. Dr. Drury handed to the Council the most recent book on the subject of vaccination and small-pox in Liverpool by Dr. Hanna. A communication which appeared in the BRITISH MEDICAL JOURNAL from the medical officer of health at Ossett (Yorks) was read by Dr. Drury dealing with an outbreak of small-pox among school children. This "unpremeditated experiment" brought out precisely the points with which the conclusions of the Royal Commission began, and the case for vaccination ended. The epidemic at Gloucester and the "Leicester method" of dealing with small-pox were discussed by Dr. Drury; also the recent outbreak at Newhaven, where three exempted children in one family died from small-pox on consecutive days in January. On the subject of compulsion he did not think the first conscience clause in England did much harm, but the second (1907) had brought about an enormous increase in exemptions. The Legislature would be justified in increasing the certainty, by any means possible, of getting the people properly vaccinated.

Dr. Thomas Mackenzie and Dr. Pantin of Douglas and Dr. Barbour of Ramsey gave important evidence on the subject, and urged the Council not to relax the vaccination laws.

As previously stated, the Council announced its decision on April 21st by unanimously rejecting the Amendment Bill.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

The annual general meeting of the London and Counties Medical Protection Society, Limited, was held on April 30th, at the offices of the society, 32, Craven Street, W.C. Dr. G. A. HERON, chairman of council, presided, and before submitting the annual report suggested that the meeting should send to Sir Jonathan Hutchinson a letter conveying the society's warm greetings and good wishes. He had been its president ever since its foundation twenty-one years ago, and was still keenly interested in its doings. The suggestion was adopted unanimously.

The report submitted stated that the past year had been one of prosperity, despite many dangers and difficulties. Not only had the society, as usual, many battles to fight for its members, but it had itself been assailed in the law courts, an effort being made to apply the old enactments against Maintenance so as to hinder its work. The society, however, had been as successful in its own defence as it had in nearly all the cases it had taken up for its members. The fortunate results of the legal proceedings during the year had enabled it to save a substantial balance out of the moneys provided for the protection of its members against adverse verdicts in the courts. The council had watched very closely during the year the questions arising out of the National Insurance Act, but had felt that while the British Medical Association was conducting negotiations in the name of the medical profession any independent public action on its part might do more harm than good. In regard to the future, the council felt that in the new conditions of medical practice it would be more than ever necessary for medical men to provide by the help of the society against numerous possible and even probable dangers to their reputation and position. The plan adopted of providing against damages and costs of the other side in unsuccessful actions had worked very successfully. By undertaking the risk up to the extent

of £2,000 per annum, and reinsuring against anything in excess of that sum up to £20,000 per annum, the council had succeeded in retaining for the benefit of the society a considerable part of the money subscribed by members for insurance purposes. The report also supplied details of a number of cases in which the society's advice and assistance had been sought during the year, and concluded with a financial statement covering the work of the past seven years. The latter showed that, after valuing investments at their market value on December 31st, 1912, instead of at their cost price, and making all other due reductions, the society at that date had at its command for the work of the coming year resources equal to £36,568, in addition to annual subscriptions which would be received during its course. During the expired year 350 new members had been admitted, and 4,762 members were in benefit, in addition to 141 who, being in arrears with their subscriptions for more than a month, were for the time being out of benefit.

In moving the adoption of the report, Dr. HERON reviewed the early history of the society. It had risen from a very small beginning to one which, as the report showed, possessed a very substantial financial basis. It had seemed originally that a subscription of 10s. a member was a very small sum on which to start life, but the work done with that subscription had given results on which every man connected with it must look with satisfaction. Little by little money had been saved, thanks partly to careful management, partly to the fact that practically all the officers of the society did their work without pay, while those who were paid were remunerated on a very low scale. General expenses were still met out of the original subscription of 10s., the additional 10s. now paid being reserved exclusively for the purpose of insuring members against every possible risk of legal actions. The insurance was effected at Lloyd's, which, as it possessed no data for an estimation of risks, was only willing to undertake the work on a yearly contract. Hence, as also with the object of saving the premiums paid, it was desirable that the society should endeavour to accumulate an insurance fund of its own, say a sum of not less than £20,000. The general business of the society was increasing, for members had got to know that it was ready to help them in various small matters as well as in big ones, and sought advice in all sorts of predicaments. Most of such work was done by Dr. Woods, but when he did not feel equal to dealing with any given matter, he, with the consent of the council, handed it over to the society's solicitors, Messrs. Le Brasseur and Oakley, who did their work in a way which entitled them to the gratitude of the members of the society. The National Insurance Act would certainly give the society a great deal more work to do: as that meant increased expenditure, it was very desirable that every member of the society should do his best to increase its roll of membership, for although there was a reserve fund it would not be sound policy to allow general expenses per member to exceed the aggregate amount of the proportion of each annual subscription devoted to them.

The report having been adopted, the business concluded with the election of officers and a vote of thanks to the chairman. The president (Sir Jonathan Hutchinson), the vice-presidents, the treasurer, and the secretaries were re-elected, and the vacancies on the council caused by the annual retirement in rotation of a third of its members were filled by the re-election of Drs. Atkinson, Spriggs, and Stowers, and the election of Mr. Raymond Johnson.

MR. EDGAR JONES, F.R.C.S., of Great Burstead, Essex, who died on August 24th, in his 103rd year, left estate of the gross value of £14,981, of which £12,458 is net personality.

AN addition has been made to the number of journals produced for the benefit of those who for one reason or another take an interest in horseless vehicles. This is the *Motorist*, a weekly paper whose distinctive features externally are a blue cover and its low price of one half-penny a copy. It is freely illustrated, and proposes to cater more especially for the needs and tastes of the owner-driver, who is presumed to find too much purely technical matter supplied by the older motor journals. Should the standard of this first issue be maintained, the new journal is likely to become popular.

LITERARY NOTES.

MESSRS. T. C. AND E. C. JACK announce the publication of a new book entitled *Insects: their Life-Histories and Habits*, by Harold Bastin. It is a popular work, embodying in plain language all the latest knowledge regarding insects. The book is illustrated in colour and half-tone.

The name of Sbetland, to most people, is usually associated with the manufacture of a certain kind of wool; but probably few of the present generation are aware that the neighbouring islands of Orkney were once almost equally well known for the exportation of imitation Leghorn straw for ladies' hats. Mr. John Firth, writing in the April number of the *Old Lore Miscellany of Orkney, Shetland, Caithness, and Sutherland*, says that straw-plaiting was introduced into the Orkneys by an English company about the beginning of last century, and for many years was a favourite occupation among the younger women, particularly with those whom some physical disability had rendered unfit for heavy outdoor labour in the fields. In those days almost every hamlet had its "plaiting-house," where the young men and girls of the district spent the long winter evenings, the latter busily plaiting straw by the light of the peat fire and a single "cruzie," whilst the former alleviated the monotony of their toil with songs and story-telling. Straw-plaiting was well paid, and the Orkney plait was, for a time, very popular in the south; but the reduction of the duty on foreign straw paved the way for a change of fashion that ultimately resulted in the extinction of an industry which had once given employment to nearly 7,000 women. The Orcadians themselves, however, put down its decline to another and quite different cause. "A story current in Orkney, and generally believed," says Mr. Firth, "was that Her Majesty Queen Victoria, on being presented with a straw bonnet, laughed derisively at it, and then placed it on the head of her pet dog; and that on hearing of this action of the Queen all the ladies in the south gave up wearing straw hats," probably one of the most remarkable explanations ever given of the vagaries of "Fashion, leader of a chattering train, whom man, for his own hurt, permits to reign." The same number of the *Old Lore Miscellany* contains a description of the early Christian monuments of Caithness, and some natural history notes on the habits of the sea-eagle, a species once common in the Western Highlands, but now, unfortunately, showing signs of dying out.

The horrors of war have been well described by many writers; but none, perhaps, have drawn a more moving picture of the sufferings of the rank and file than the famous collaborators Erekmann and Chatrian, whose novel *Le Conscrit* enables the modern reader to realize the miserable plight of the wounded during the Napoleonic campaigns. The rough-and-ready treatment meted out to patients in a field hospital less than a hundred years ago is now, happily, a thing of the past, and to-day no effort is spared to ensure the comfort and safety of the sick and wounded after a battle. An interesting proof of the enormous improvement in military hygiene is given in the April number of *L'Hygiène*, which contains an account by Dr. Rebreyend of his experiences with the Red Cross Ambulance sent from France to Philippopolis at the beginning of the Balkan war. It supplements the more severely professional accounts of ambulances in the Balkan war given by Laurent of Brussels, and Monprofit of Angers, noted in our issue of March 22nd, p. 623. The French ambulance was established in an empty college belonging to the Assumptionist Fathers, whose pupils had deserted them as soon as war was declared, and the new arrivals found themselves well received by the Bulgarians, whose confidence and affection they quickly gained. His touching belief in the infallibility of the French doctors and the dauntless courage that seems to be a characteristic of his race made the Bulgarian soldier an ideal patient, and Dr. Rebreyend and his colleagues had the satisfaction of seeing many men leave the hospital restored to health and activity after injuries that a century earlier would either have killed them outright or disabled them for life. An interesting pendant to Dr. Rebreyend's experience of modern warfare has been contributed to the April number of *L'Hygiène* by M. Pasteur Valléry-Radot, who has had frequent opportunities during the last few months of observing the effects of gunshot wounds in the hospitals

of Constantinople. The same number of our excellent contemporary also contains the first instalment of a series of articles by Dr. Cabanès on the hobbies and amusements of European royalties; and some useful hints from Mme. Augusta Moll-Weiss on the diet of young children.

Questions of "purity" of speech have always excited a good deal of interest among readers of the JOURNAL. We have always contended that philological pedantry must not be allowed to hamper the growth of language. It is related that Lord Thurlow was once waited upon by a deputation of Nonconformist divines, who asked him to help in the redress of certain alleged grievances and disabilities. The Lord Chancellor told them he could do nothing for them unless they got their "d—d religion" established by law. This irreverent expression applied to language seems to state the true principle, which is that whatever gets itself established is right. In an excellent article on the *Oxford English Dictionary* which appeared some little time ago in the "Literary Supplement" of the *Times*, it is pointed out that the problem of "purity" of language confronts Frenchmen and Germans as well as ourselves. M. Henry de Gourmont, in his *Esthétique de la Langue Française*, says "purity" consists in assimilation. He holds that the French words are pure which have undergone those modifications and changes by which the French language has been created out of Latin and given its French character and sound. On the other hand, "impure" words are those which have been imported by scientists and scholars unchanged from the classical languages, or have come in from modern tongues unassimilated in sound and form.

As English is partly Teutonic and partly French in origin and character, it is in a combination of the German and French ideals of purity that we shall find the soundest basis for our conservatism. From the Germans we may learn to encourage native terms and from the French to assimilate our borrowings and make them conform to native ways.

The writer goes on to explain that by the "Anglicity" or integrity of the English language is, or should be, meant the harmony of our new terms with the real core or central part of the language. Those which are out of harmony with this should be regarded as "impure," and we should endeavour to modify them or cast them out. But, as we have insistently urged, language is a living, ever moving thing, the advance and expansion of which cannot be controlled by artificial restrictions. As the writer from whom we have quoted puts the matter:

We cannot "shut up the sea with doors or draw our Leviathan with a hook," and it would seem as if the individual must struggle in vain against the great collective will of the community.

That collective will, it is added, is not altogether a blind force; it is ultimately governed by a confused sense of what the language ought to be. More and more the soundness of this speech-feeling depends upon the taste of the educated classes. If they encourage the right fashions, the set of the language will be guided in the right direction. The writer goes on:

But something the individual can do towards forming a healthy state of public opinion; and in cases of undecided usage he can give his vote (which may be a casting vote) for the purer and more English form. He can help to wear off the awkward newness of new and native compounds; and when foreign words appear in two forms (*foet* and *focusses*, for example) . . . he will have a sound and definite principle to direct his choice. And if he be a fanatic in the cause of purity he can easily attain to martyrdom by attempting to naturalize the large and increasing number of our unassimilated terms. He will be committing a solecism but committing it in a good cause; and our usage, which has already discarded so many foreign pronunciations and so many pedantic plurals—*asyla, idææ, chœri, nautææ, splingææ*—may come round to him in the end.

We do not, however, allow that he is guilty of a solecism when he gives the adopted word an English dress; he is doing his best to maintain the "purity" of our speech by promoting the assimilation of foreign words. The "martyrdom" to which he may attain by this would scarcely entitle him to a place in the *Acta Sanctorum*. We have ourselves been through it in respect of such plurals as "serums," "sanatoriums," and we have had the satisfaction of seeing them already almost as firmly established as "eucommiums," "eulogiiums," and so forth.

Doubtless there were some who felt their sense of philological propriety outraged when Matthew Arnold wrote of "Cerb-ruses," but the author of *Friendship's Garland* is not one penny the worse in literary reputation for the "solecism."

SCIENCE NOTES.

As a result of research work carried on by the National Fruit and Cider Institute at Long Ashton, in Somerset, it has been demonstrated that the blackening of pear blossom and foliage, resulting in the withering of the fruit, is due to a specific bacillus, and not to frost and cold winds, as is commonly supposed. In reply to a question in the House of Commons, however, the President of the Board of Agriculture has stated that the Board is not at present in a position to issue a leaflet on remedial measures.

At a meeting of the Roentgen Society, on May 5th, Dr. F. Hernaman-Johnson, in a paper mainly on the subject of the secondary radiation obtainable from metallic and other substances when excited by a primary x -ray beam, mentioned that divergent results were forthcoming from the electroscope on the one hand and the photographic plate on the other when employed to measure this secondary-ray effect. In discussing the paper, Mr. J. H. Gardiner, F.C.S., said that a little thought made it clear that the difference between the indications given by the electroscopic and by the photographic method was inevitable. The action on the photographic plate was cumulative, while that on the electroscope was instantaneous; further, the photographic emulsion itself acted as a screen, and this introduced another variable element. Mr. C. E. S. Phillips said that attempts to measure secondary radiation by means of the photographic plate were necessarily vitiated by the scattered primary rays. An interesting suggestion was put forward by Mr. F. H. Glew, who had attempted to obtain the photographic effect of the secondary radiation proceeding from gold, silver, and copper. Using a hard tube, he had found that the silver gave an entirely abnormal effect, its image being disproportionately intense, and he thought it quite possible that the silver in the photographic plate itself acted selectively, having a preference for its own radiation, so that in the case of a silver medium an x radiation was excited to which the silver in the photographic plate was specially responsive. The photographic effect might therefore be due to an ionization action on the silver and not to a wholly chemical action, nor to a physical one, save so far as ionization was physical. If this were the case, photographic effects obtained in many investigations of the kind were open to error.

The murexide reaction is the standard test in use for the presence of uric acid in the blood, but it is merely a qualitative test, and as it is liable to confusion with the xanthoproteic reaction, owing to the presence of various protein materials and phenol compounds in the blood, it is probable that many of the positive results that have been reported were erroneous. The methods devised for quantitative estimations are either not sensitive enough or demand a very large quantity of blood for their application. Folin and Denis use a phosphotungstic acid solution (*Journal of Biological Chemistry*, January, 1913) which is capable of detecting 1 part of uric acid in 1 million parts of water. The blue colour obtained from $\frac{1}{2}$ mg. of uric acid is adequate for a quantitative estimation, and this amount has been found to exist in from 15 to 25 c.c.m. of normal blood. A weighed volume of blood is oxalated, and after treatment with five times its volume of boiling acetic acid solution is filtered and the residue refiltered after treatment with boiling water. The combined filtrates are further acidified and evaporated to a small volume. The uric acid is precipitated from this concentrated mother liquid by alkaline silver lactate solution, and after treatment of the precipitate with hydrogen sulphide the uric acid is obtained in solution. The blue colour produced by the addition of the phosphotungstic reagent is estimated approximately by dilution to the tint of one of the standard solutions, and then accurately determined by comparing it with that standard in the colorimeter.

British Medical Journal.

SATURDAY, MAY 17TH, 1913.

PSYCHIATRY AND THE GENERAL HOSPITAL.

ELSEWHERE will be found a report of the opening of a special department for the study and treatment of mental diseases in Johns Hopkins Hospital, Baltimore. The Phipps Psychiatric Clinic owes its existence to the enlightened liberality of a wealthy citizen of New York who sees in it a means of improving the treatment of the insane. How much has been done in that direction by the combined efforts of physicians and philanthropists in modern times can be learnt without laborious research by a glance at Hogarth's picture of Bedlam, which represents the last of the phases of the "Rake's Progress," or at Goya's still more dreadful picture of the Casa de Locos.

The clinical study of insanity has shed much light on the manifestations and course of insanity, and in recent years the investigation of its pathology by the scientific methods of the laboratory has led to the discovery of the physical basis of certain forms of the disease. But the immense importance, not only to the insane themselves but to the community, of a knowledge of mental disorder is still imperfectly recognized by those entrusted with the management of public affairs, and not at all by the people who place it in their hands. To this cause, combined with a short-sighted economy, is due the amazing apathy which so long delayed the realization of Dr. Maudsley's scheme of a hospital for the treatment of the insane in London, and at one time threatened to defeat the object of his princely munificence. As has repeatedly been pointed out, institutions on hospital lines where cases of acute insanity and those in the incipient stage can be promptly dealt with, where cases on the borderland can be watched, and where chronic cases can be weeded out and drafted to asylums, are essential if really satisfactory results are to be obtained. It is obvious that the indiscriminate herding together of masses of mad folk in huge barracks does not place them in conditions favourable to recovery.

Magnificent as are many of our asylums, we are sadly behind Germany and the United States in the matter of hospitals for the scientific study and treatment of mental diseases. In Germany every city of more than 50,000 inhabitants has a small hospital for acute cases and a colony for chronic lunatics in the country. Dr. Peterson of New York has strongly advocated this as the ideal system. In the United States emergency cases of insanity are, we believe, treated in the Bellevue Hospital, New York, and in the Blockley Hospital, Philadelphia. Bellevue has a separate pavilion for the purpose, with thirty beds and a resident medical staff. Some years ago the general hospital of the city of Albany, New York, built a model pavilion for the exclusive care of the insane, and a mental hospital was constructed by the State of Michigan in connexion with the State University at Ann Arbor.

Until lately insanity has been looked upon as altogether different in kind from other diseases, and the medical student has had very limited opportunities of studying the phenomena that indicate a disordered mind. The subject has to a large extent been isolated, and as a necessary consequence has been neglected by all but specialists. In Germany, indeed, psychiatry has been kept in touch with general medicine by the establishment of clinics in connexion with the universities. Every university has a psychiatric clinic, with pathological, chemical, and psychological laboratories. Special mention may be made of those of Giessen, Berlin, Kiel, Munich, Breslau, and Greifswald. Of the scale on which these institutions are built a notion may be formed from the fact that the one in Munich cost £120,000. Dr. Peterson, in his article on the hospital treatment of insanity in the *Encyclopaedia Britannica* (1902), says that the mental hospital should, if possible, be associated with a university or medical school; and Sir Thomas Clouston recently stated that this view is now accepted by all medical psychologists.

The Phipps Psychiatric Clinic is not only a university clinic; it is also a special department of a general hospital. This is a great advance which will bring the study of mental disease out of the seclusion in which it has hitherto been forced to dwell into free commerce with other provinces of medical activity. Psychiatry, instead of being, in the words of Sir William Osler, stamped with a taboo of a peculiarly offensive character, will, at Johns Hopkins, be in organic relationship with the clinical study of other diseases, and the student will realize that it is not an art or mystery standing by itself, but a living branch of the great tree of medicine. The Clinic will be a centre from which knowledge will be diffused among assistants in asylums and also among general practitioners. We need not labour the point that it is vitally important that doctors in general practice should be able to recognize the signs of oncoming insanity, and should be fully acquainted with the relations between mental disease and heredity. On them often depends the hope of cure for the patient, while to society they are the first line of defence against the spread of insanity. They will have a much better chance of obtaining the necessary knowledge in a hospital clinic than in the wards of an asylum.

Sir William Osler speaks of a national campaign against mental ill health through education. By "education" we take it that Sir William Osler means the education of the public mind in a rational system of eugenics. But there is another way in which insanity may be to a considerable extent prevented. Dr. Mott and others have shown that certain forms of insanity are caused by syphilis, and are therefore for the most part preventable. The diminution of syphilis would therefore entail a corresponding diminution of insanity. A campaign for the prevention of syphilis has recently been organized in Australia, and is said already to give good promise of success.

Sir William Osler concluded with the pregnant suggestion that a study, at once critical and sympathetic, of the epidemics of mental, moral, and economic folly which sweep over classes of people and whole nations, would be helpful. Certainly nothing would be a greater benefit to society in these days of superstition, credulity, sentimentalism, and contagious hysteria, than the discovery of means of conserving sanity in the individual and the community. To this end the human mind must be

closely studied in all its vagaries: the source of these must be traced, the conditions that favour or check their development determined, and the means of turning the perverted energies to which they may be due into right channels if possible discovered. This will be the work of the Phipps Psychiatric Clinic, and we heartily share Sir William Osler's hope that it will be successful. It is to be wished that the example of Mr. Phipps may be imitated by some philanthropist in this country. There is a large field for the study of the pathology of the mind, and, although much may be expected from the establishment of the Maudsley Hospital, there is abundant room for the psychiatric clinic.

THE CAROTID BODY.

ALTHOUGH this little bilateral structure was found by Haller so long ago as 1766, it is only quite recently that attempts have been made to apply the test of experiment to the question of its possible functions. The carotid body is present in all mammals; according to some writers it is found in birds; its presence in reptiles has been proved by Trinci (1909, 1912), and by de Gaetani (1912); Maurer describes it as present in amphibia but absent in fishes; it does not appear to have been found in cyclostomes. In man it is situated most commonly on the inner side of the common carotid artery close to the bifurcation—the site in which de Gaetani has found it in *Lacerta viridis* and *muralis*. The human carotid body is a greyish or brownish-red ovoid body, measuring from 5 to 7 mm. in length, $2\frac{1}{2}$ to 4 mm. in breadth, and 1.5 mm. in thickness; it is sometimes bilobed. It is highly vascular—a fact which tends to prove that it is not a rudimentary and functionless organ. Its arterioles come from the common carotid artery or its two main branches. It has an extraordinarily rich supply of nerves, chiefly non-medullated; these were described by Luschka fifty years ago as coming from the plexus intercaroticus, which is formed by fibres from the glosso-pharyngeal nerve, branches of the vagus nerve, and communicating twigs from the superior cervical ganglion of the sympathetic. This very rich nervous plexus contains some very small ganglia. Kohn describes a close relationship between the nerve fibres of the carotid body and its specific cells. He recognizes four histological types of the mammalian carotid body: (1) The compact circumscribed form in which the connective tissue of the organ is finely divided so that the cellular character of the tissue stands out prominently, a type seen in the cat; (2) the lobular type with much connective tissue, as in the monkey; (3) the insular type seen in man, the organ being divided into separate islets by connective tissue; (4) the diffuse type, consisting of scattered islets, as in the rabbit. As a rule the cells of the carotid body are large. Their shape varies considerably: they have a large granular nucleus, and one, or even sometimes two, nucleoli.

Various opinions have been held as to the nature and the morphological position of the carotid body. The earlier anatomists looked on it as a nerve-ganglion; Luschka considered it to be of glandular nature, resembling the pituitary and the adrenals. Its developmental origin was held by Stieda to be from the epithelium of a branchial cleft. Some observers derived it from the parathyroid bodies, which are themselves of branchial origin. Yet others claim to have proved that it arises from a thickening of the internal carotid artery at its point of origin, and that its elements are not epithelial, but

perithelial. Modern embryologists for the most part accept the teaching of Kohn that it is derived from the embryonic sympathetic system. Kohn regards it as a part of the chromaffine system, and gives it the name of paraganglion intercaroticum; yet he admits that its cells, even when fixed with the mixture of potassium bichromate and formol (which gives a marked chromaffine reaction in the case of the true paraganglia), do not for the most part take the yellowish-brown coloration well, while some fail to take it at all. But he claims that even these uncoloured cells show by their form, size, and disposition, the characters of chromaffine cells. Still, we do well to bear in mind that mere cell-characters form a very unsafe basis on which to found a morphological classification. It is important to note that Pende (1909) failed to obtain the chromaffine reaction by Kohn's staining methods in the case of the carotid bodies of newly-born children, whilst he got it readily in the case of the ganglia of the solar plexus, the adrenal medulla, and the paraganglion of Zuckerkandl (the temporary aortic bodies found in the newly-born child). Again, Tarozzi failed to get the reaction in the carotid body of human adults; and lastly, Vassale (1911) failed also in the case of the cat's carotid body, while he obtained an intense chromaffine reaction from small punctiform paraganglia found in these animals in the course of the abdominal sympathetic. He notes also that in the cat he never got the perchloride of iron reaction of Vulpian, which is characteristic of the vaso-constrictor principle of paraganglins, the secretory product of the paraganglia. Vassale therefore concluded that the carotid body could not be included in the paraganglia, and that it was an organ whose nature still remained to be determined. The tumours of the carotid body, which occasionally occur in man, have received attention from many pathologists, and they have even formed the subject of a thesis by M. Pagès (Montpellier, 1911); but up to the present, however, clinico-pathological studies have quite failed to throw any light on the functions of the carotid body.

The earliest experiments were apparently those of Scalfidi; it is stated by Vassale that Pende mentions that Scalfidi got entirely negative results from bilateral extirpation of the carotid body in guinea-pigs. Similar extirpation experiments were attempted by Vassale in 1911 in cats; but he found that in them complete extirpation was difficult, if not impossible, on account of the great risk of injury to the carotid artery. He chose the cat for his inquiry because, as was first pointed out by Kohn, that animal's carotid body is a compact parenchymatous organ, is clearly delimited from neighbouring structures, and is composed of numerous cell groups with little connective tissue. Vassale failed to completely extirpate the cat's carotid bodies, and adopted the method of their destruction by the cautery. He carried this out successfully in thirteen cats and kittens. In all the animals glycosuria appeared in the first urine voided on coming out of the chloroform narcosis; this disappeared usually on the fourth day. Albuminuria was generally absent; when present it appeared as only a trace on the first day. During the period of temporary glycosuria the animals were depressed, their hair was bristly, and their voice was raucous; but appetite remained good and recovery was perfect except in the case of two kittens, which were kept under observation for five or six months; although they ate voraciously and showed no glycosuria after the first three days following the operation, yet they became cachectic, showed alopecia of the head, neck, and body, emaciated greatly, and died from asthenia.

Vassallo does not believe that the post-operative glycosuria is due to a lesion of the very abundant nerves of the carotid body, for in one case of attempted bilateral extirpation he found that a small piece of one carotid body was left, and yet glycosuria followed. In another case avulsion of the nerves entering the carotid body was followed by only minimal traces of glycosuria. With reference to these experiments it must be remembered that the cat is specially apt to show temporary glycosuria after any operative procedure. We cannot, therefore, admit that Vassallo's experiments materially help us to understand the nature of the functions of the carotid body, and still less the mode of their action.

The recent experimental studies of Frugoni (1912) have added facts of positive value which help towards a better understanding of this question. He has approached the subject by means of the extract-injection method. He prepared extracts from the carotid bodies of young calves by a special method, so that 4 c.c.m. of the extract represented one carotid body. He found that 4 to 6 c.c.m. usually proved rapidly fatal when injected intravenously into rabbits. Changes were found in the blood, heart, and respiration, but he established the interesting fact that, by diminishing the interval between small doses, which were well borne, and by gradually increasing the dose, he was able to set up such a tolerance that even many times the ordinary fatal dose was easily borne. Small doses of carotidin gave rise to moderate vascular hypertension followed by fall of pressure, which was considerable and prolonged; it was proved that this hypotensive phase was not due to a modification of tonus of the bulbar vasomotor centre; it was shown that carotidin had a definite vaso-dilator property, and that the hypotension was, at any rate, largely subordinated to this vaso-dilator action. Experiments on the isolated hearts of rabbits showed that the vascular hypotension was not due to cardiac weakness; the extracts, indeed, tended to strengthen the heart. Frugoni did not observe changes in the blood vessels following repeated carotidin injections, such as are produced by adrenalin, lead, or tobacco. He further demonstrated the interesting facts that adrenalin when injected in the complete hypotensive phase of carotidin, gave its usual blood-pressure effects; that carotidin, when injected in the hypertensive phase of adrenalin, gave some hypotension, but only in large doses; and finally that, when adrenalin, and carotidin were injected simultaneously, the effects of adrenalin were always obtained, but possibly with a slightly less abrupt rise of blood pressure than that produced by adrenalin alone. Frugoni concluded that the carotid body probably possessed a true internal secretion, but that its existence could not at present be categorically affirmed. These experimental studies of Frugoni will, of course, be repeated, amplified, modified, and added to. One application is sorely needed: we need to know what histological changes, if any, occur in the endocrine glands of both young and old animals which have been previously injected with carotidin, from young and old animals, both in the case of the large, rapidly fatal dose, and in the case of smaller, long-continued doses.

In view of the conflicting opinions as to the genetic origin of the carotid bodies, and the absence of all chromaffine reaction in at least some of their cells, it seems quite possible that these little bodies may prove, on renewed embryological study, to be of double ontogenetic origin; in that case, they would be brought into line with the adrenal glands whose double genetic origin has been proved by many

observers. Be that as it may, we now have definite proof that the carotid body has an action on blood vessels; and we must class it among those many small gland-like bodies which have an action on body metabolism, an action which is as yet by no means nearly fully understood. One important point concerning the carotid body which seems not to have been studied is whether it remains of constant size throughout life or becomes smaller or larger during post-natal life. Even if it becomes smaller, we should not be justified in saying that it is useless, or is even becoming useless. Who will to-day be so rash as to say that the adrenals are becoming useless? And yet the fetal adrenals are much larger absolutely, and enormously larger relatively, than in post-natal life; and they go on diminishing in size in relation to the body weight of their possessor during the passage from early life to maturity. This question of the gradual changes in the size of organs, and the probable gradual change in functions that accompanies them, is one of the greatest physiological problems waiting for solution. It seems probable, in the light of Darwin's work, that all organs are always changing, the only difference being that some change very slowly—that is, the testes, etc.—and others more quickly and more radically. Any one who may be inclined to sniff contemptuously at the bare idea of such an insignificant looking organ as the carotid body possessing functions may be advised to remember that, if Maurer be right that these organs exist in amphibia, the history of the carotid body goes back to the Permian period of the Palaeozoic era when amphibia first made their appearance. And when we have got back so far as that we have gone a long way indeed! And yet here is this small body still "going strong" and showing no signs of any intention to disappear in any animal that is known to possess one. It may play one of the small parts in the physiological drama, but that it does its part well we cannot doubt.

HOUSING REFORM.

AN important statement was made by the Prime Minister on May 7th, in reply to Sir A. Griffith-Boscawen, who directed his attention to the speech made by the President of the Local Government Board in Standing Committee A on May 1st, in which he stated that the proposed grant-in-aid of housing was wrong in principle, and that it would deter private enterprise and discourage local authorities. It was asked whether in this matter the President of the Local Government Board was speaking for himself only or for the Government, and whether the Government had definitely decided against State grants-in-aid of housing.

The Prime Minister said that the remarks of the President of the Local Government Board were directed to criticizing the financial proposals of the bill under consideration, and that he agreed with him that in that particular case they would have been wasteful and unjust. The Prime Minister, however, added that the Government certainly had never said, and did not say now, that the question of grants-in-aid was excluded from consideration.

Other statements also recently made by the Prime Minister indicate that the representations which are being made from all quarters of the House on this subject are receiving the attention of the head of the Government, whose public utterances afford a welcome contrast to the attitude adopted by the President of the Local Government Board. It must

be plain that, whilst under the existing law considerable clearances of insanitary dwellings may be made, the difficulty of rehousing the displaced occupants is not being overcome, and that the whole subject of the character, powers, and duties of the local authorities, the security of tenure of their medical officers, and the rehousing at economic rents of displaced tenants are all so inter-related and involved that simple and effective reform, coupled with State aid, are essential if progress is to be made. It would appear, however, that he would be a sanguine person who looked for such undertakings whilst the policy of the Local Government Board, as defined by its President, remains as it is at present.

THE NATURE OF THE WASSERMANN REACTION.

THAT the Wassermann reaction for syphilis is not a true example of the Bordet-Gengou phenomenon was early demonstrated, but the real nature of the reaction still requires elucidation. Recent researches by Thiele and Embleton¹ with the object of discovering the true nature of the antigen and antibody, throw some further light on the subject. They conclude that the antibody so-called in the Wassermann reaction is not a true antibody, and is not characteristic of syphilis, but is probably only a stage in the formation of an anti-complementary combination which develops when there is rapid tissue destruction, as in acute infections, narcosis, and death. In all these processes proteins and their cleavage products are set free, and phosphatids are liberated. The latter form new combinations of the nature of non-specific antibody and antigen. In syphilis the process of destruction is slow, and the anticomplementary combination is not complete until an active lipoid has been added. The tissue destruction occurring in acute infections, after narcosis, and during and after death accounts for the apparent Wassermann reactions reported in such cases, but the authors do not regard these as true Wassermann reactions. Again, as regards the antigen, these observers find that the complement-fixation property is independent of the number of spirochaetes, their products, or changes due to their presence, and that there is no evidence that syphilitic organ extracts bind antibodies which cannot be bound by non-syphilitic extracts. They draw attention to the errors which may occur in carrying out the Wassermann reaction. In the first place, the antigen itself may be anticomplementary, and "an antigen can cause relatively and absolutely quite a large absorption of complement before any trace of inhibition of lysis becomes evident." Secondly, serums often contain anticomplementary substances which increase on standing. They also state that if two anticomplementary substances are mixed together, the complement-binding power of the mixture is much greater than the sum of the quantities bound by the separate components. In this way the mixing of an anticomplementary substance such as cholesterol with the antigen in the Wassermann reaction causes an increased absorption of complement, much greater than the sum of the quantities which are bound through the reaction, and through the anticomplementary power of cholesterol. The reaction is thus made more sensitive, while much more complement is absorbed. This is, however, in no way a property of syphilitic serum, but always occurs when two anticomplementary substances are brought together. This power they call the adjuvant phenomenon. They conclude, finally, that a true Wassermann reaction is only produced by injection of tissues of homogeneous origin. Thiele and Embleton's researches are no doubt of much interest from the biochemical point of view, but it can hardly be said that they add much support to the

diagnostic value of the Wassermann reaction, for it appears that not only does the reaction bear no relation to the presence of spirochaetes, but also that, unless the test is performed with definite quantities of reagents (themselves more or less unknown quantities), an apparent Wassermann reaction may be produced by anti-complementary substances present in the antigen or serum.

ACTION OF NORMAL PRODUCTS OF METABOLISM ON THE CIRCULATION.

IN a thesis for the degree of M.D., E. L. Backman¹ has given an account of work done by him at the Physiological Institution at Upsala and elsewhere between the years 1905 and 1912, as to the action, if any, of the products of metabolism, particularly the nitrogenous decomposition products, on the normal circulatory system. The experiments on the heart and blood pressure were carried out on rabbits, and the substances tested included ammonium carbonate, sodium hippurate, creatin, hypoxanthin, xanthin, and allantoin. The dilution of these bodies corresponded as closely as possible to that in which they may occur in the blood in health or disease. It was found that a 0.16 per cent. solution of creatin increased the contractility of the isolated heart, and that an intravenous injection of creatin solution, constituting 0.18 per cent. of the blood, caused a marked and continuous rise of blood pressure and a transitory increase in the pulse-rate. Many of the other substances had a somewhat similar action, but the rise of blood pressure varied considerably in character. He describes four types of pressure curve. In one the variations were slight but well maintained; in another the pressure fell to a marked degree, but rapidly rose again; in a third, when sodium hippurate was given, large oscillations of blood pressure were observed over a long period; in a fourth, when ammonium carbonate, creatin, hypoxanthin, or allantoin were given, the pressure fell rapidly, and then rose slowly to normal. The author concludes that, in certain strengths, all the substances he has tested increase the work done by the isolated heart. Several of the substances, when injected into the blood, increase the pulse-rate and raise the blood pressure. Many, too, are powerfully diuretic, and he credits them with the power of stimulating the circulatory system, and thus effecting their own elimination. Whether they also act directly on the renal epithelium, and thus hasten their excretion, is not clear. The thesis contains no promiscuous speculations about the conclusions to be drawn from the experiments as applied to man, and even as applied to the experimental animal Backman is guarded. He is honest enough, in fact, to admit frequently that his work is incomplete, and that further investigation is required.

THE ORIGIN OF A BACTERIOLOGICAL CHAIR.

IN addition to the Moncrieff Arnott Chair of Clinical Medicine, the regulations for which were approved at the meeting of the University Court on May 7th (see page 1089), another medical professorship in the University of Edinburgh—that in Bacteriology—is now about to be founded. The circumstances which make this foundation possible are somewhat peculiar: indeed it may be said without much exaggeration that bacteria have had a good deal to do with this chair of bacteriology. There is an island, about twelve miles long and nine miles broad, lying some two hundred miles to the south of Java in the Indian Ocean, which is called Christmas Island. It was visited in 1688 by Dampier, who found it to be uninhabited by man but swarming with sea-fowl. Exactly two hundred years later (in 1888) it was annexed by Great Britain, chiefly as a result of the repre-

¹ *Bidrag til Fragan om Normala Anneseomsättningsprodukters Verkan på Hjärta och Blodtryck.* Af E. Louis Backman. Upsala: Almqvist and Wiksell. 1912. (Demy 8vo, pp. 232.)

¹ *Zeitschrift f. Immunitätsforschung*, Bd. vi, Heft. iv, p. 430.

scatations of Sir John Murray (of the *Challenger Expedition*) and by the influence of the late Duke of Argyll. Sir John Murray had found that the island contained valuable deposits of phosphate of lime, and, according to a writer in the *Encyclopaedia Britannica* (vol. vi, p. 234), this phosphatic deposit had doubtless been produced by the long-continued action of a thick bed of seaweed dung (this is where the bacteria come in), which had converted the carbonate of the underlying limestone into phosphate. Sir John Murray obtained a lease of the island and formed a small company to develop its resources. In this company the late Robert Irvine, a Fellow of the Chemical Society, held 230 shares of £10 each, and at his death he bequeathed his interest in the company for the purpose of establishing a Chair of Bacteriology in the University of Edinburgh when the interest from these shares should reach the sum of £25,000 or £30,000, as the trustees might determine. Doubtless it did not appear very likely at the time that shares to the value of £2,300 would yield £30,000 within anything like a short term of years; but those persons who were sceptical have been pleasantly disappointed, for in eleven years from the death of the donor, so lucrative has the undertaking turned out to be and so busy in shipping the phosphates have the few hundreds of Chinese and Javanese workmen on the island been, that that large sum of money is available. Indeed, there will be enough to equip class-rooms and laboratories also, and to aid research, whilst, in accordance with Mr. Irvine's wishes, a merely nominal fee will be charged to those attending the lectures or working in the laboratories. The surviving trustees, who are Professor Sims Woodhead, Dr. David Patrick, Dr. David S. Jordan, and Mr. William Maxwell, are now about to hand over to the University Court the sum named for the founding of the chair. But this is not all, for the remaining interest in the shares is ultimately to pass in equal lots to the Edinburgh Royal Infirmary, the Royal Edinburgh Hospital for Incurables, and the Dunlop Cancer Fund. In this curious way has Christmas Island with its accumulated stores of phosphates, the deposits of countless generations of seaweed, and the results of their internal metabolic processes, come into the history of the founding of a chair of bacteriology. "Truth is stranger than fiction," as Byron sang; and "truth makes all things plain" and easy, as Shakespeare said.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

ONE of the most interesting medical words in the present instalment of Sir James Murray's great lexicographic achievement¹ is *Sore*. As a noun it has had three meanings, two of which at least are now obsolete, namely, bodily pain, disease, and mental suffering. As an instance of the first Dr. Craigie (who edits this part of the *Dictionary*), gives the sentence from *Cursor Mundi*, "Ute of his side . . . wit-oten sare a rib he tok"; of the second, "S. Anthonis Sore, called the Rose," forms an example; and Chaucer furnishes an illustration of the third usage in his question, "Who feelth double soor and heynesse But Palamon?" A fourth meaning of *sore* is almost obsolete, namely, a bodily injury or a wound, for Dr. Craigie has to go back to 1785 for the quotation, "He'll suck the poison frae the sair, An' be a noble leech." The only meaning of *sore* which has, so to say, held its own is "a place in an animal body where the skin or flesh is diseased or injured so as to be painfully tender or raw"; of this there are numerous instances, such as bring "a salve for that sore," and such compounds as *bed-sore* and *saddle-sore*. *Sore*, the adjective, has also had meanings which are now obsolete or nearly so; for instance, a

sore head, signifying a headache, is often quoted as a Scottishism, but it is really a survival of the word *sore* in the sense of pain. Indeed, *sore throat* and *sore spot* do not necessarily imply any ulceration of the mucous membrane or skin. But we must pass on to some other medical terms, for there are many of them between the words *snuggle* and *sorrow* with which this section begins and ends. There is the obsolete *sordis*, meaning filth, with its not-naturalized relative *sordes* and its little family of *sordid*, *sordidness*, *sordidly*, and *sorditude*. *Sordes*, which, by the way, may be construed either as singular or plural, signifies either filth or faeculent matter, or, more particularly, impure matter collecting about the teeth and gums, especially in typhoid fever. We use *sordid* so often in its application to habits and character that we are surprised to find that it is still employed in a strictly pathological sense; at any rate, the late Dr. Matthews Duncan wrote of "sordid epithelial detritus." A somewhat rare medical term is *sorbefacient*, derived from the Latin *sorbere*, to absorb, and meaning a substance which causes or promotes absorption; thus, mercury and iodine have been supposed to act as sorbefacients. *Sopor* is used itself to express deep sleep, and from it come *soporose*, *soporation*, *soporative*, *soporiferous*, *soporific*, *soporose*, and *soporous*; but it is not at first sight clear why *soporale* should be a synonym for carotid until we read Dr. Craigie's illustrative quotation from Phillips, "the Carotid Arteries, so call'd because if they be tied, they immediately incline the Person to Sleep." In this, as in other parts of this dictionary which have been commented upon in this JOURNAL, the reader will be struck by the care expended in giving the medical senses in which ordinary words are occasionally used. Instances of this minute and vigilant care are found under such terms as *soothing* (for example, syrups and applications), *solvent* (a laxative), *solution* (for example, in "solution of continuity" and as meaning the crisis of a disease), *solicit* (in the sense that aperients sollicit peristalsis), and *snuffles* (meaning the malady of children in which respiration is hindered in the nose). The mysterious word *soeterkin* is fully illustrated; it seems first to have signified a sweetheart (*soetkin*, *dulcis amica*), and then, wonderful to relate, an "imaginary kind of afterbirth" associated in some recondite manner with Dutch women sitting over lighted stoves, and finally a literary composition of a supplementary or imperfect character. We may assure the editor that the *New English Dictionary* at any rate runs no risk of having this quaint term applied to it.

TRIALS OF A COURT PHYSICIAN.

A PHYSICIAN who has the keeping of a sovereign's health enjoys the advantages of a conspicuous position, but against this must be set the heavy burden of responsibility which he has to bear. He may also have difficulties with his angust patients; even Louis XIV. the most doctor-ridden of monarchs, resented an expression which seemed to imply that he was under a physician's "orders." Dr. Barthez was in 1856 attached to the person of the Prince Imperial, then an infant of 3½ months. The doctor's letters to his wife from Saint-Cloud have recently, we learn from the *Chronique Médicale*, been published in a book entitled *La Famille Impériale*. Barthez, who was evidently a close observer, gives a picture as detailed as a Dutch painting of the Emperor and Empress and of the Imperial Court. The physician had to use a good deal of diplomacy in the exercise of his functions. Neither Napoleon III nor the Empress Eugénie had much faith in rational medicine. The Empress professed to believe that all doctors were ignorammuses who never worked. She scoffed at their endeavours to cure diseases and prevent death, a thing which she declared to be impossible, since when the hour had struck the player on

¹ A *New English Dictionary on Historical Principles*. Sniggle-Sorrow (vol. 13). By W. A. Craigie, M.A., LL.D., Oxford: At the Clarendon Press, Henry Frowde. Double Section. Price 5s. (1 dol. 25c.). April 1st, 1913.

the stage of life must make his exit. This fatalistic attitude, though unreasonable, is at any rate intelligible. But it is not easy to understand how Her Majesty could have been led to say that doctors never gave a thought to the relief of suffering! This statement is all the more amazing since the Empress who—wrongly as it turned out—believed herself to be pregnant, expressed a wish that she should be chloroformed when the expected hour of sorrow arrived. "It is even possible she may compel Jobert to give her the anaesthetic without cause, solely that it may be ascertained whether she could be pregnant." The Emperor thought there was an immediate remedy for every pain. Induced pain he bore with stoical fortitude. He rode on horseback with sores on the thighs and legs caused by recently applied blisters. He did not complain of the production of pustular eruptions on the back by the use of irritants. It was even believed that he applied moxas to himself. To all this he submitted with such patience that no one about him was aware of his sufferings. This recalls the heroic endurance which he showed at Sedan, when, with a stone in his bladder, he remained on horseback throughout that fateful day. But of "spontaneous pain" Barthez says he was very intolerant. He was subject to cutaneous neuralgia, which made him "indescribably impatient." He reproached the physicians for the failure of their remedies and was inclined to put his trust in any quack he came across. Barthez gives an example of the methods that had to be adopted by an official doctor to make his services acceptable to capricious royal personages. He says: "The Empress was pleased the other day to wet her feet badly. She lunched without changing her shoes, and after lunch did not wish to disturb her attendants, who were reposing. So she kept on her wet shoes, with the result that she caught a tremendous cold, which starting from the nose descended to the throat, then to the bronchi." With some difficulty Barthez induced her to interrupt her course of sea bathing, but she insisted on accompanying a water party on the Nive. There was first a drive in an open carriage, then a sail lasting two good hours, and finally the return in the evening in an open carriage from Bayonne to Biarritz after sundown. Barthez forbade the trip, and even threw himself in mock-heroic style at the feet of the Empress. She raised him up, punctuating her refusal to obey with a playful slap on the face. Barthez was forced to go in one of the boats. He salved his professional conscience by having a sedative potion made up; this he gave to a gentleman who was to be in the Empress's boat, begging him to make her take it on the way. He thought it likely, however, that the physic was thrown into the river. Barthez, it may be added, was a physician of the highest distinction, who long afterwards ministered to M. Thiers in his last illness. He announced the death of the ex-President to the widow in the graceful phrase, *Madame, votre illustre mari a vécu.*

ANTIQUITY OF THE HUNGER STRIKE.

THE hunger strike is not an invention of the suffragists, although they may, perhaps, claim the introduction of it as a means of release from prison. In the *JOURNAL* of May 10th (p. 1010) we cited the case of John Scott, who in the sixteenth century, while confined in David's Tower in Edinburgh Castle, abstained from meat and drink for thirty two days in order to show that he was under the special protection of heaven. But hunger striking is a custom of great antiquity. In a letter published in the *Tablet* of May 10th a writer, who signs himself "Anglus," points out that in an article on the "Ascetic Traditions of the Celtic Church," which appears in the current number of the *Irish Eccles Record*, Dom Gougand, of Farnborough, mentions "a legal institution of ancient Ireland—the procedure of fasting. Having exhausted all legal means to conquer the resistance of a powerful doctor, his creditor

had only one means of constraint left to him—that of standing before the door of the debtor and of refusing to take nourishment till the debt had been paid. If the debtor allowed the person fasting to die of hunger he was responsible for his death and had to pay his family a considerable indemnity in addition to the original debt. This was called 'fasting *against or on a person.*'" Dom Gougand adds that in no Christian society to his knowledge has there been made such frequent and daring use of this curious process as in mediæval Ireland. The custom is frequently mentioned in the Breton laws. Fasting seems to have been practised when it was desired to turn a heathen king into a Christian, and the monarch, if hard of heart, counterfasted as a means of protecting himself against conversion. It is recorded that St. Patrick "fasted upon" Loegaire, the heathen over-king of Ireland, until the latter embraced Christianity, and in accordance with the superstitions of the times the king and his family felt it incumbent upon them to fast at the same time until this test of endurance was won by the saint. The custom of hunger-striking for the same purpose was formerly common in India, but it is now almost obsolete. It is known in the East as *dharna* (or *dhurna*) *baithna*, or "sitting *dharna.*" It was chiefly resorted to in order to force payment of a debt. The creditor would sit at the debtor's door and taste no food until his claims were satisfied. If the debtor allowed the creditor to starve, it was believed that he laid himself open to supernatural punishment, especially if the starver happened to be a Brahmin; accordingly, Hindus of lower caste would sometimes engage a Brahmin to starve for them. The custom was much abused, being utilized to levy blackmail upon persons who were not debtors at all.

THE PASSING OF THE CHINESE OPIUM TRADE.

WE have repeatedly pointed out in these columns that the time was at hand when the Government would be compelled by the force of circumstances to announce a new departure in the matter of the Indo-Chinese opium trade. The debate in the House of Commons on May 7th furnished the occasion, and Mr. Montagu, the Under Secretary for India, made what had become the almost inevitable announcement that the Indo-Chinese opium trade is to be brought to an end. Still, under the treaty of 1911, Great Britain has the power, if she had the will, to sell China many thousands of chests of opium up to and including the year 1916. But, as was pointed out in the *JOURNAL* of January 18th, there is at the present time in the Chinese ports a glut of Indian opium, the profits from the sale of which by the Indian Government have gone to swell the record surplus of the Indian budget. Meanwhile the Chinese Government, recovering from the dislocation of the revolutionary period, is pursuing a policy of suppressing both poppy-growing and opium-smoking with sincerity, and indeed with Draconian severity. With a falling demand and huge accumulations in the market, it was idle to pursue the policy previously announced by the Government of maintaining 200,000 acres under poppy cultivation in India. A virtue has accordingly been made of necessity, and after the present stocks have been—as it is euphemistically put—"absorbed" by China, at the rate of 2,000 chests a month, and if China continues steadfast in well-doing, not a single ounce of the product of the Indian poppy is ever again to be sold to the citizens of the young republic. But for this new announcement some 43,000 more chests of Indian opium would have been sent to China under the rather illogical provisions of the treaty of 1907 as revised in 1911. This passing of the opium question, while removing a long-standing reproach from our Indian policy, will give additional point and importance to the steps which we

understand are now being taken towards ratification of the International Opium Convention of 1912. Evidence abounds to show that the vice of morphine taking, the Western analogue of the opium smoking of the East, is only too readily accepted as a substitute for the latter when active suppression of that practice has been attempted among Oriental nationalities. The imports of morphine and cocaine into China and India, both licit and illicit, are of a magnitude quite incompatible with any medical or legitimate use. Statements recently published have shown that on the Continent of Europe and in America far more stringent control in the traffic of these and other "drugs of addiction" is imperatively demanded. The shutting down of the Indo-Chinese opium trade will doubtless make more profitable than now the traffic in these alkaloids which is devastating the bazaars of the East. The International Convention drawn up at the Hague in 1912 by the twelve Powers which participated in the conference provides for the necessary international arrangements to secure a world-wide co-operation with a view to restrict to legitimate uses the manufacture and distribution of drugs thus liable to abuse. It is reported that next month representatives of all the Powers which have since January, 1912, signed the Convention will meet at the Hague, at the invitation of the Netherlands Government, with a view to proceeding as speedily as possible to ratify and give effect to that Convention. The new policy of Great Britain in the Far East just announced will be an earnest of the seriousness of her purpose, and at the same time will render more necessary than ever that international co-operation which it is the main object of the Opium Convention of 1912 to secure.

THE HARD CASE OF THE MANX CONSCIENTIOUS OBJECTOR.

A NOTABLE victory for vaccination has been achieved in the Isle of Man. The Legislature of the island consists of a lower chamber, the House of Keys, and an upper chamber, the Legislative Council. Early in the year a Vaccination Amendment Bill, allowing exemption on grounds of conscience, passed the House of Keys, and, in accordance with ordinary procedure, was sent to the Legislative Council, which decided to hold an inquiry for the purpose of taking expert evidence. Dr. Hadwen (Gloucester) attended on behalf of the antivaccinators and Dr. Drury (Halifax) for the defence of vaccination. Three doctors resident in the island also gave evidence. An official report of the whole of the evidence has been issued and will be found useful and instructive to all interested in the controversy, as the case for vaccination and the case against it are clearly stated. The examination of the witnesses by the members of the Council showed the earnestness and ability with which the inquiry was conducted. By a unanimous vote the Council rejected the bill. Judging from the reports in *The Isle of Man Examiner* and *The Isle of Man Times* no one of the speakers appeared to have had any difficulty in arriving at the decision to vote against the bill. The Attorney-General is reported to have said, "Taking the evidence of the strong witness on the antivaccination side—Dr. Hadwen—it convinced him that there was absolutely nothing in the case against vaccination." Dealing at length with Dr. Hadwen's evidence regarding vaccination and syphilis, the Attorney-General said, "If this inquiry had served no other purpose it had been well worth undertaking in that it had dispelled such a hideous bogey. There was not the slightest vestige of evidence to show that there was any such danger. . . . Not a case of syphilis being caused by vaccination with calf lymph could be produced, and the danger alleged entirely broke down." The Governor (Lord Raglan) made some severely critical allusions to Dr. Hadwen's evidence. He is reported in the papers mentioned to have said "that he had heard with the

greatest possible regret expression given to sentiments which he could not allow to pass." He referred to the very unfair and what he ventured to think was the extremely unwarranted attack made by Dr. Hadwen on the medical profession. "There was no profession in the world—there was no class of men in the world—so conscientious, or that did so much to assist charity or the poor as the medical profession. . . . To say that there was a conspiracy among the doctors to bolster up vaccination solely in view of the fees to be derived from vaccination seemed to him (the Governor) to be utterly unworthy of a man in Dr. Hadwen's position, and it was with the greatest possible regret he (the Governor) heard him make such a statement." The inquiry provided Dr. Hadwen an opportunity to distinguish himself, and advance the case against vaccination. What actually happened is reflected in the remarks of the Attorney-General and the Governor just quoted. On page 1069 a relatively brief epitome is published of the evidence of Dr. Hadwen and Dr. Drury taken from the official report (published by Messrs. Brown and Sons, Ltd., "Times" Buildings, Douglas, Isle of Man). Gratitude is once more due to Dr. Drury for the public spirit which induced him to give the Legislative Council of the Isle of Man the assistance which his unsurpassed acquaintance with the history of vaccination and with the methods of antivaccinists so well qualified him to afford. His action on this occasion involved not only large expenditure of time but a certain risk to health, as he was at the time suffering from an attack of indisposition which would have more than justified him in declining to make the journey at a rather inclement season. Fortunately no ill effects ensued and he has the satisfaction of feeling that he has discharged a public duty with complete success.

THE FEELING OF UNREALITY.

THAT descriptive master of morbid psychology, Edgar Allan Poe, has done much to reveal in flashes of genius many of the dark places of the human soul, and the tortures endured by a diseased imagination. But we are only now becoming fully alive to the fact that these things are not bodied forth from the imagination of the poet alone; they are daily facts with which the physician in ordinary practice has to deal. We can look for no assistance from the result of ordinary physical examination in these cases, and almost invariably the systemic examination is negative. Courtney¹ of Boston in this connexion quotes the case of a Russian Jewess, aged 25, who suffered from a condition which may be best described as "a feeling of unreality." There had been no actual insanity in the family, although a brother had been the victim of a variety of "phobias" and obsessions. The condition appears to have developed after the operation of encephalitis following a miscarriage, and rendered the life of the patient a burden to her. She felt as if her body had been entirely transformed. From morning to night she had to keep up an argument with herself to prove to her satisfaction that it was "her voice with which she talks, her hands with which she grasps things, and her legs which carry her about." There was a numbness of all the faculties of sensibility, and she asserted that she never felt cross, tired, or hungry. An examination of the nervous system showed that the ordinary reactions were normal and sensibility well preserved. The latter fact has been seized upon by some psychologists to affirm that this feeling of unreality is purely ideational in its action. The author criticizes Janet's view that this uncanny feeling results from the loss of a special intellectual operation—"the function of the real." The first form of this function of the real allows us to deal with external objects and metamorphose reality: its last form is concerned with the constitution of time—the formation in the

¹ *Boston Medical and Surgical Journal*, February 6th, 1913.

mind of the present moment. Courtney criticizes this theory severely. According to him it means "that the highest grade of intellectual activity is required to be able to realize that one is awake and thoroughly prepared at all times to cope with the ever-changing social complexities of everyday life." To the victims of the feeling of unreality the present is by no means vague. His difficulty with regard to time lies rather in the realm of feeling. He may know that it is noonday, but he cannot feel that it is. That the function of the real is, as claimed by Janet, of high intellectual value is disproved in these cases by the fact that such patients are by no means intellectually defective. It is in the unequal struggle between the intellect and the emotions, in which the latter are nearly always victorious, that the patient's failure to respond to the call to action lies. The expressions, "I feel like myself," or "I don't feel like myself," suggest, says the author, a contrast between the totality of bodily sensations which constitute "the ego" of the moment and a standard feeling of self-reality. Courtney regards the feeling of unreality as arising from "a lack of vividness and coherency of relation in the primary sensory and sensorial elements which in their totality constitute the ego—the personality—of the individual. Examination of the individual sensory and kinaesthetic elements of feeling, even if the result is normal, is no argument, according to him, against this view, as it is impossible to judge of any complex associative affect by the primary sensational elements composing it. The "feeling of unreality" is not itself a clinical entity, but constitutes a symptom of that complex adynamic state of the nervous system which is termed psychasthenia.

OPHTHALMIA NEONATORUM.

A MEMORANDUM has been published by the Medical Officer of Health of Glasgow submitting a report by Dr. Florence Mann on the recent experience of the department in dealing with ophthalmia neonatorum. The report covers a period of seventeen months, during which time 341 cases occurred; this is equal to 9.4 per 1,000. In only 31 per cent. of the cases was the gonococcus recovered, but as the taking of swabs becomes more usual it is thought that a higher percentage will be obtained. It is usually regarded as being present in about half the affected cases. In at least 9 per cent. of the cases syphilis was also present, and in contrasting the results of the eye affection in children with and without syphilis Dr. Mann shows that of the non-syphilitic cases 81 per cent. made an absolute recovery, but of the syphilitic cases only 48 per cent. Total blindness followed in 1.2 per cent. of the former and 8 per cent. of the latter. This observation is most significant. In 3.5 per cent. the symptoms developed within twelve hours of birth, 56 per cent. occurred within the first four days, 3.2 per cent. after the fourth day, and 8.5 per cent. after the eighth day. Treatment at home was found to be unsatisfactory in many instances, and such cases were admitted to the reception home. Dr. Mann came to the conclusion that it was wise and even advisable in many instances to take the children into the home without the mothers. Under these conditions the children did well. Written directions are issued by the department for the guidance of the nurses attending the cases. The report brings strongly into view the fact that the disease is very amenable to treatment, and that if this be commenced early enough few cases will be lost. If, however, in the early stages treatment be inefficient there is no disease more liable to produce permanent blindness.

UNUSUAL SOURCES OF POLLUTION OF WATER.

In the majority of instances there is not much difficulty in locating the source of gross pollution of public water supplies, but instances occur from time to time

which puzzle even the most careful investigators. Examples of some unusual causes of pollution were lately given by Dr. J. C. Thresh in a contribution to the Institution of Water Engineers. In one case in the water from a deep well in the new red sandstone *B. coli* were found in 10 c.cm. An examination of the surroundings did not suggest a solution, but the source of the pollution was eventually found to be in an iron tank under the engine-house floor, into which the water was first pumped and then forced to the reservoirs. The water in the tank was covered with dust, and appeared greasy, and the sides of the tank were coated with slime, which on examination bacteriologically was found to be a mass of bacteria of objectionable type, including myriads of *B. coli*. In another case, in which the water taken from a house tap was found to contain *B. coli*, the pollution was shown to be in the tap itself, which was placed over the kitchen sink; when the finger was placed in the nozzle of the tap it brought away a slimy mass of filth resembling sago, which proved to consist almost entirely of bacteria. The filthy condition of hydrant boxes was responsible for the pollution of particular mains in one district and bird-droppings from trees surrounding a reservoir in another. The leaking tank of a gas-holder situated 100 yards from deep wells, giving a large public supply, was considered to be the cause of pollution in another district. A peculiar odour was observed in the water when large quantities were drawn, but this entirely ceased, and the water became normal after the gas-holder had been put out of use.

A MEDICAL SKYSCRAPER.

THE doctors of New York are to have a skyscraper of their own. It is to be a structure of thirty-five stories, and will consist mainly of suites of offices for physicians, surgeons, and dentists. On the top floor will be a fully equipped operating room for the common use of the tenants. There will be vacuum cleaning throughout, together with an ample electric service for medical apparatus. Four lifts will be installed, and on the ground floor will be found waiting-rooms and shops for druggists and purveyors of other medical supplies. There will be an inner court with a turntable for ambulances. This skyscraper is to be known as the Professional Building, and will be situated at the south-east corner of Seventy-Second Street and West Avenue. The building is to be begun in June and finished by the spring of 1914.

THE STAFFING OF TUBERCULOSIS DISPENSARIES.

WE notice in the *South-Eastern Herald* of May 9th a letter from Dr. J. H. Keay on the appointment of a tuberculosis officer to the Greenwich Tuberculosis Dispensary. He points out that it was unanimously agreed at a meeting of the medical men practising in the district that the dispensary should be staffed by the medical men in the neighbourhood who had experience in the use of tuberculin, and that the general administration should be in the hands of the medical officer of health. The borough council unanimously adopted the findings of the meeting. The Local Government Board, however, in its craze for whole-time officers, stepped in and gave it to be understood that the work of the tuberculosis dispensary must be done by a whole-time officer, and refused to receive a deputation from the medical men in the neighbourhood to discuss the matter. The borough council meekly submitted to the Local Government Board, and, if Dr. Keay's information be correct, is about to advertise for a whole-time tuberculosis officer for the dispensary at a salary of £350 a year. The line taken by the medical men at Greenwich is in the main consonant with the tuberculosis scheme set out by the British Medical Association; since that was adopted the capitation fee of 6d. for all tuberculosis cases has been propounded by the

Treasury, so that the whole question of the treatment of tuberculosis is now in the melting-pot and in a very chaotic and unsatisfactory condition. If the salary of the whole-time officer is to be £350 we feel sure that a man of the high standing and special experience necessary for undertaking this work in sympathetic agreement with the medical men of the neighbourhood will not be found. The minimum salary suggested by the Association is £500 per annum, and this sum has been generally accepted throughout the country as a reasonable commencing salary. There is no good reason why the Local Government Board and the Greenwich Borough Council should endeavour to get a good man for less.

SCIENTIFIC ALLIANCE OF THE LATIN RACES.

AN association, called the Union Médicale Franco-Ibéro-Américaine has recently been formed in Paris for the purpose of uniting the doctors of the Republics of Central and South America with Spanish and French physicians in a scientific alliance of Latin races. From the initial letters of its title it is called for shortness "Umfia." The president is Dr. L. Dartigues; the general secretary is Dr. Gaullier l'Hardy; the vice-presidents, Drs. Bandelac de Pariente (physician to the Spanish Embassy in Paris), Manrique, and Delamuy. Among the members of the honorary committee are the Spanish Ambassador to the French Republic; Professor Ortega Morejon, member of the Spanish Academy of Medicine; Dr. Pulido, senator of Spain; Dr. Risquez, sometime rector of the University of Caracas, together with the Dean of the Paris Faculty, Professor Landouzy, and Professors Ch. Richot, F. Widal, A. Robin, Pozzi, Pierre Marie, Pinaré, Legneu, Doléris, and Bazy, and Dr. Roux, Director of the Pasteur Institute. Membership is open to all doctors throughout the world who speak Spanish or Portuguese. At present there exist more than twenty autonomous nations of Spanish speech, and it is estimated that the language is spoken by more than a hundred million persons. It is proposed to establish a Hispano-American Hospital, to arrange scientific tours, and to make summaries of all medical papers written in Spanish available for members. The objects of the Umfia are to make its members known to each other, to establish relations, social and scientific, with the doctors of every country where Spanish is spoken; to establish an information bureau for Spanish or Portuguese doctors who go to Paris to pursue clinical work and research; to arrange courses of instruction, lectures, meetings, festivities and congresses, and to organize means of assistance to foreigners of Spanish-American origin settled in Paris who may be in need of help. Almost all the doctors of France who speak Spanish are members, and already the Umfia has official representatives in all the principal cities of Spain and South America. It is hoped that the association, which has been in existence only a few months, will before long have a membership of many thousands.

WE understand that the proposal recently made for the issue of half-yearly insurance cards is receiving sympathetic consideration, and may quite likely be adopted for considerable classes of cases.

ON April 25th a meeting was held in New York to take steps for the commemoration of the work of Dr. J. S. Billings. Dr. Weir Mitchell recited Dr. Billings's services as a surgeon in the United States Army during the Civil War; Sir William Osler spoke of his work in the library at the Surgeon-General's Office, and Dr. W. H. Welch dwelt on his ability as a hospital organizer. A tribute was also paid by Mr. Andrew Carnegie, who was for many years associated with Dr. Billings in the work of the New York Public Library.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Asylums Officers' Superannuation Bill Amendment.—This bill, to which reference was made in a recent issue, was introduced under the ten minutes' rule by Sir John Jardine on May 6th, and read a first time. It has been put down for second reading on May 29th. The Home Secretary has stated, in reply to Mr. Rowlands, that the Commissioners in Lunacy reported that the total number of day and night attendants and nurses, exclusive of head attendants and assistant head attendants, employed in the county and borough asylums in England and Wales on December 31st, 1912, was 12,337 (5,762 males and 6,575 females). Of that number, the proportion under one year's service was 23 per cent. (namely, male attendants 17 per cent., and nurses 29 per cent.); and the proportion over five years' service (excluding six asylums open less than seven years, where 655 attendants and nurses were employed) was 37 per cent. (namely, male attendants 52 per cent., and nurses 24 per cent.).

Feeble-Minded or Epileptic Poor. Mr. Staveley-Hill asked for the names of the counties in which guardians had made application to the Local Government Board for Orders for the formation of joint committees of boards of guardians for the purpose of provision and special accommodation for, or special treatment of, the feeble-minded or epileptic poor.—Mr. Burns said that an Order had been issued for a joint committee of guardians in the county of Wiltshire. Orders were in preparation for the counties of Cornwall, Essex, Glamorgan, Salop, Staffordshire, and Warwickshire, and applications had been made by the counties of Kent, Suffolk, and Surrey. It was understood that schemes of combination were also under consideration in several other counties.

London Hospital: Employment of Nurses.—Dr. Chapple asked whether the Prime Minister intended to introduce legislation to prevent the London Hospital from sending out nurses one year before the expiry of the normal course of training required by every other great metropolitan hospital at the rate of 11s. 6d. a week while they earn £2 2s. a week for their hospital? Mr. Harry Lawson asked the Prime Minister whether he was aware that Mr. Sydney Holland, chairman of the London Hospital, flatly contradicted the first part of the statement when it was first made; whether he knew that the London Hospital trained its nurses free of charge or premium for two years and made a large loss on the whole transaction; and whether, when the nurses were properly equipped, they were able to earn a livelihood for themselves at the expense of the hospital.—The Prime Minister said: "I have not heard; and, with all respect to my hon. friend, I rather deprecate questions of this kind relating to a great London hospital, to which the metropolitan community is under a deep debt of gratitude. I am not aware of any grounds for legislation."

Forcible Feeding.—In reply to Mr. Thomas, Mr. McKenna stated that prison medical officers did not receive extra payment for operations performed in His Majesty's prisons, and that the question of additional payment for forcible feeding did not arise.

Sewage and Trade Effluents Bill.—In reply to Mr. Sherwell, the President of the Local Government Board said that he hoped to be able to introduce the proposed bill for dealing with the question of sewage and trade effluents during the present session.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

MR. WILLIAM M'EWAN AND THE M'EWAN HALL.

THE great memorial of the late Mr. M'EWAN's interest in the University of Edinburgh, and of his princely generosity to it, is the hall in Teviot Place which bears his name, and which completes the massive pile of buildings known as the Medical School. Here, on the site of the house in which Dr. Archibald Tait, one time Archbishop of Canterbury, was born and brought up, there now stands the M'EWAN Hall, in which graduation ceremonies and other academic functions are celebrated. Mr. M'EWAN, whose death took place in London on Whit Monday (May 12th), was born at Alloa in 1827, was educated in Alloa Academy, and, after that period of years (which seems to be almost essential to the great success of a Scotsman) in which he was thrown on his own resources, he found himself in his uncle's brewery business in Edinburgh (that of Messrs. John Jeffrey and Company). Soon, however, he ventured to start brewing on his own account, and with a capital of £2,000, one half of which was a cash credit from the bank, he founded the great brewing concern in Fountainbridge, Edinburgh, which is now known well nigh over all the world. In 1886 Mr. M'EWAN was returned to Parliament for Central Edinburgh, as a Liberal supporting Mr. Gladstone's Home Rule policy; and he represented that division of the capital of Scotland until 1900, when in consequence of failing strength he did not seek re-election. It was during this term of years that Mr. M'EWAN made his great gift to the University. In the early eighties of the last century the new Medical Buildings, made necessary by the rapid increase in the number of medical students attending the classes at Edinburgh, were completed at a total cost of £245,000, a large part of which was raised by public subscription. No graduation hall, however, was forthcoming, and it was felt that the public ought not to be again approached for financial aid so soon. It was then that Mr. M'EWAN came forward and agreed to defray the whole expense of the hall. It was designed by Dr. Rowland Anderson, in the Italian style of Cinque Cento period, with an interior fashioned in the form of a Greek theatre, and with wonderfully fine mural decorations by Palin of London; it cost, not £40,000 as was expected, but £115,000, but the whole amount was cheerfully given by Mr. M'EWAN. It took ten years in the building, and was opened in 1897. At this time also the freedom of the city was conferred upon Mr. M'EWAN, and some years later (in 1907) he had the honour of being made a Privy Councillor. For many years he had resided in London, and since the death of his wife, in 1906, his Edinburgh residence in Palmerston Place had seen him hardly at all. His name, however, is indissolubly linked with that of Edinburgh University, and his gift stood out in 1897 as the greatest benefaction that institution had received from any one man by his own act and in his own lifetime.

FIFESHIRE MEDICAL ASSOCIATION.

The spring meeting of the Fifeshire Medical Association was held at Dunfermline on May 9th, Dr. Alan Tuke, Dunfermline, presiding, when Dr. Edwin Bramwell, Edinburgh, gave an address. Thereafter, permission having been granted by the Admiralty and by Messrs. Easton, Gibb and Son, the contractors, the members were conducted over the works at Rosyth Dockyard. On returning to Dunfermline the party dined at the Royal Hotel.

Ireland.

FUNDS OF DUBLIN HOSPITALS.

AT the recent annual meeting of the Meath Hospital and County Dublin Infirmary it was reported that owing to the increase in the indebtedness of the hospital either some of the invested funds would have to be sold or some of the beds closed. The income from legacies was practically sufficient to cover the excess of expenditure over the income from the subscribers, but last year there was

a drop in the legacy income from £1,000 to £500. Many of the other Dublin hospitals are finding the same shrinkage in their funds, and one of them is just about to issue a special appeal, as it finds that many of its usual subscribers are failing to send their subscriptions this year. In a "boom" year, when charitable subscriptions might be expected to be heavy, there can be only one explanation for their extraordinary smallness, and the explanation is the Insurance Act. The Act appears to be destroying the system of voluntary charity. If all employers are compelled to insure their employees against sickness, few will care to make a second payment to the voluntary institutions which wage war on sickness. The decline in charitable legacies is probably in part due also to the heavy increase of death duties in recent years.

ST. JOHN AMBULANCE BRIGADE.

A meeting of the St. John Ambulance Brigade was held in Dublin last week to consider the arrangements for the Dublin Ambulance Challenge Cup Competition. It was decided to hold the competition on June 21st in Lord Treagh's gardens, which he kindly offered. It was announced that Messrs. Jacob had offered to present medals to the winning team. It was also announced that with the object of promoting ambulance work amongst women resident in Ireland, the Hon. Mrs. Ernest Guinness had promised to present a silver challenge cup to the St. John Ambulance Brigade to be called the Irish Women's Ambulance Challenge Cup for annual competition between teams of four women who are holders of the first aid and nursing certificates of the St. John Ambulance Association and who belong either to the St. John Ambulance Brigade, Voluntary Aid Detachments, or St. John Ambulance Centres. It was decided to hold this contest also on June 21st.

INSANE PATIENTS IN WORKHOUSES.

IN view of the action, reported last week, of the Committee of Management of the Richmond Asylum with regard to the Mental Deficiency Bill, the memorandum of inspection forwarded to the South Dublin Union by the Local Government Board is of special interest. The memorandum stated that notwithstanding the transfer of 58 patients to the Richmond Asylum since May, 1912, the number of patients in the lunatic wards of the workhouse had increased from 198 to 202. It was incumbent on the guardians to consider without delay the serious state of dilapidation into which many of the buildings had fallen. Apart from their unsuitable character and overcrowded state, and the risk of fire, they were in such a condition structurally as to involve danger to life in the event of a high wind. Since the last inspection 233 patients had been admitted to these wards and 100 discharged, in addition to those transferred to the Richmond Asylum, while 71 had died; and of those remaining, 15 were classified as insane epileptics, and 43 were stated to suffer from congenital mental weakness.

England and Wales.

MANCHESTER AND DISTRICT.

NEW SANATORIUM FOR SALFORD.

THE Salford Health Committee has issued an important report with reference to the provision of sanatorium accommodation for tuberculous cases. In order that no time might be lost in providing hospital and sanatorium treatment for insured persons and others suffering from tuberculosis, the town council some months ago resolved to utilize the Drinkwater Park Hospital, which has in the past been used only for cases of small-pox. It was fully recognized at the time that the situation of Drinkwater Park, in the valley close to the river Irwell, was not an ideal one for tuberculosis, and some strong criticism was directed against it which would have been fully justified if it had been intended as a permanent sanatorium. But the Health Committee and the Insurance Committee felt bound, owing to the number of applica-

tions for sanatorium treatment, to make some temporary arrangements, and the Drinkwater Park buildings being unoccupied were altered and adapted and pavilions erected at a cost of several hundred pounds. A few weeks ago the institution was visited and inspected by the Insurance Committee, and the opinion was expressed that everything was being done to meet immediate requirements. There was accommodation for thirty-five beds, and at the time of the committee's visit thirty patients were in residence, and the report of the medical officer as to their progress was most satisfactory. In the meantime the Health Committee has been in search of a better site for the erection of a permanent sanatorium, and the report just issued states that it has now had the offer of a freehold site known as Rab Top Farm, Rose Hill, Marple, for the sum of £2,500 with £100 for expenses. As the site contains about 65 acres this is at the rate of about £40 an acre, and the site lends itself readily to the erection of a sanatorium of a hundred beds. The committee thinks that such a sanatorium could be erected for about £15,000, and it is expected that the Local Government Board might contribute out of the fund set aside for this purpose by the Treasury between £8,000 and £9,000 towards the capital cost. The cost of maintaining such an institution is estimated at about £7,700 per annum, and towards this the committee expects to receive about £2,000 from the Insurance Committee and about £2,850 from the Hobhouse grant. This leaves the corporation to provide out of the rates about £2,850 a year. The Health Committee therefore recommends the council to accept the offered site, and to proceed as early as possible with the erection of a sanatorium. The proposal will be considered at the meeting of the town council to be held next week.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

SANITARY EDUCATION IN BOMBAY.

An appeal for funds towards the establishment of an Indian sanitary institute in Bombay has been published, the idea being to develop the admirable work done by the Bombay Sanitary Association for the past ten years by building a suitable institute in Princess Street. It is to form the head quarters of the association, and house a health museum and library on the lines of the Royal Sanitary Institute in London, providing also lecture and class rooms where courses of lectures and practical demonstrations of elementary sanitary science will be given.

THE HEALTH OF THE CITY OF BOMBAY.

The population of Bombay was ascertained by the census of 1911 to be 979,455, an advance of 1,623 (1.5 per 1,000) on the census of 1906. The proportion of females was 35 per cent. The conditions of the year 1911 were favourable to health. The birth-rate—21.8 per 1,000—was the highest on record. The number of stillbirths registered was 1,759. The death-rate was 35.6 per 1,000, which is considerably below the average of the previous decade. Infantile mortality was 379.8 per 1,000 of births, against 413.9 in 1910. Ten visiting nurses and midwives are employed by the municipality for purposes of aid and instruction, with excellent results. The diseases to which mortality is mainly due are, in order: Plague, respiratory diseases, fevers, tubercle, bowel complaints, small-pox, measles, and cholera. As compared with the preceding decade, there has been a saving in 1911 of 9,889 lives, a decrease under the headings of plague, fevers, bowel complaints, tubercle, small-pox, and cholera, but an increase under chest diseases and measles. The visit of the King caused for a time a great overcrowding, but no evil result followed. The report of the health officer, Dr. J. A. Turner, D.P.H., is very elaborate, and gives evidence of good and progressive sanitation.

SANITATION IN DELHI.

The difficulties in the way of the sanitarian in Delhi are very great, and a leading Indian journal points out that, whilst New Delhi is prominently in the public eye, it is well that Old Delhi should not be overlooked. A campaign against the uncleanness and unhealthiness of this walled

city and its suburbs has already been organized. The death-rate of the city exceeds the birth-rate—in the year just closed the former was roughly 50 per 1,000 and the latter 45. If there was no flow of immigration, the population of the city would be on the decline. Moreover, last year 37 per cent. of the 10,974 children born died before they were 12 months old. In this connexion it might be urged that the ignorance of mothers has more influence on the death-rate than a lack of sanitation, but it is significant that in the healthiest ward the infant death-rate is comparatively small. If more were needed to emphasize the case for reform, one has not far to look. The flies that abound, not only in the city, but overflow into the Civil Station, are testimony that cannot be shaken—flies cannot exist without dirt. To a sanitarian desirous to demonstrate the value of his science, the problem of Delhi, despite its magnitude, must present many attractions. Here is virgin soil—if the associations permit such a figure of speech—offering unlimited scope for work. The reformer will start with the advantage that the influence of a supreme Government urging haste is on his side, and that it will not be his lot to be standing impatient whilst a sceptical municipality doles out much-grudged funds.

HAND TRANSPORT FOR SICK AND WOUNDED IN THE INDIAN ARMY.

There is good reason to be proud of the organization of the army in India, but no one would contend that in some directions there is no room for improvement. One particularly glaring defect is the hopelessly inadequate number of trained dhooly-bearers. At present on manoeuvres or mobilization a large proportion of the men enlisted, or rather hired, as dhooly-bearers are absolutely raw coolies, often the riff-raff of the bazaar. In physique and character these men are entirely unsuited to the work, and their discipline is *nil*. During the recent medical manoeuvres they proved hopelessly inefficient, several deserted, and on the final day, when it rained hard, the whole of the men attached to two field ambulances disappeared *en masse*. We believe that in the final conference General Sir James Willcocks commented strongly on the unfitness of the men for the duties they were expected to perform, and it is to be hoped, therefore, that steps will now be taken to provide properly trained dhooly-bearers in adequate numbers.

THE HEALTH OF CALCUTTA.

The census of 1911 revealed an increase of 5.7 per cent. in the population of Calcutta. Of the 896,067 inhabitants 68 per cent. were males, and 32 females. The increase of the male population was 8.2 per cent., and of the female 1.1. The increase was entirely due to immigration, as the death-rate habitually exceeded the birth-rate. The birth-rate of 1911 was 21.7 per 1,000 of the population—the highest ever recorded. Vaccinators are now employed as sub-registrars of births and deaths with advantage. Stillbirths numbered 1,216, against 1,033 in the previous year. The death-rate was 27.2, the lowest hitherto recorded. Infantile mortality was 251 per 1,000 of registered births—a decrease attributed to the increase of registered births. "The city suffered considerably less from epidemic diseases than in previous years." There were only 41 deaths from small-pox and 88 from measles; cholera and malaria were less fatal, but plague, bowel complaints, and tuberculous diseases showed a slight rise. There were only 20 deaths from epidemic dropsy, which in recent years has been so severely prevalent. The health officer, Dr. Pearse, remarks: "There is no evidence that the diet of the people has been changed, and milling of rice goes on exactly as before."

Jamaica.

IS YELLOW FEVER ENDEMIC?

DR. ANGUS MACDONALD, Medical Officer of Health for Kingston, Jamaica, in a paper read before the Jamaica Branch of the British Medical Association, discusses the question, "Is yellow fever endemic in Jamaica?"

His paper appears to be a reply to the report of Captain Potter, who maintains that yellow fever was endemic in

Jamaica and expressed the opinion "that there is no justification for the use of the term 'vomiting sickness'; it is not a separate clinical entity. I am of the opinion that the majority of deaths ascribed to the so-called 'vomiting sickness' are due to yellow fever."

Dr. Macdonald analyses Captain Potter's report to show that this has not yet conclusively been proved. Out of 73 cases personally investigated by Captain Potter 35 are admittedly cases of some other condition, while of the 38 cases left Dr. Macdonald considers that there was not one in which the *post-mortem* evidence was typical of yellow fever. Of 73 cases of vomiting sickness investigated 35, he maintains, were due to some definite condition other than yellow fever, and the conclusion is drawn that medical men should be chary in making a diagnosis in any case of vomiting, especially in childhood.

Dr. Macdonald's reasons for his conclusion that yellow fever is not endemic in Jamaica are:

1. In the absence of definitely typical cases for a period of years it may be that all cases have been stamped out and reimportation has not taken place.

2. The nature of the shipping of Jamaica in recent years and the quarantine methods in force render the importation of yellow fever difficult. The possibility of the introduction of infected *Stegomyia* is so remote as to be negligible; the seasonal prevalence of vomiting sickness in the cold months is marked, while the *Stegomyia*, though certainly more abundant after rains, is met with all the year round. According to records of epidemics, the seasonal occurrence of yellow fever has been in the hot months.

The few cases recorded in Kingston in 1904 were typical yellow fever in adults, imported probably from Central America and limited to a group of young adult males. That yellow fever is not now endemic in the island may require to be proved; but its absence in typical form from Kingston, where there must be thousands of susceptibles resident, and where thousands more migrant susceptibles yearly still get bitten by *Stegomyia*, is suggestive of, at any rate, extremely limited endemicity.

Correspondence.

RHEUMATOID ARTHRITIS.

SIR.—In reply to Dr. Bailey, I may say that I have given what I consider a perfectly clear verbal picture of rheumatoid arthritis, which I believe to be a distinct entity, and one which can be easily differentiated from other affections of the joints, an entity which can be prevented, and which can be easily cured if early recognized. I do not propose to go over this ground again; that it is not always differentiated from other forms of arthritis is a concern which should trouble the patients rather than myself. The other day I saw an extremely well marked case of osteo-arthritis affecting one hip and one knee-joint; the patient had a magnificent set of teeth, every one his own, and not an unsound one in his head, yet two London physicians had recently recommended the extraction of nine of these teeth for a supposed pyorrhoea alveolaris, which was not present when I saw him, or, at least, I failed to discover it. As they would not guarantee a cure, the patient wisely declined the operation. I was rather surprised that the less heroic treatment of a vaccine had not been suggested.

Dr. Bailey says "decalcification of bones is a common accompaniment of any bone inflammation; skiagraphs show it in tubercle, after fractures in the bone ends, in whitlow, in terminal phalanges," etc. It is plain enough what he wants to imply, but what does he prove? Does he confound disorganization of the joints with decalcification? Does he confound the relative transparency of cancellous tissue with decalcification? Decalcification "after fractures in the bone ends" is certainly a bad look-out for bony union; it is the kind of thing surgeons would rather not see. A bone may be destroyed without an acid, and, I may add, even without a microbe; the pressure of an aneurysm may make a big hole in the spinal column; a sarcoma, or the growth in myelopathic albumosuria may eat up the bone, but here we may

possibly have to consider the electrical potential between the ions within and without the cells.

He is quite at liberty to believe that microbes may eat up the cartilages, and that "antibacterial treatment" is the correct card to play, but I can also exercise my right to estimate his beliefs at what I may consider their value—*nil*.

I do not question that many "laundry workers, scrubbers, workers in aerated water factories, hunting ladies, amateur lady gardeners, ladies who spend much time in washing laces" may get rheumatoid arthritis, but at the same time I have not the slightest doubt that hundreds of thousands of such individuals (though my practice and observation are not so extensive) never get and never have any intention of getting rheumatoid arthritis. When will medical men drop this *post hoc propter hoc* argument? I saw a man fall through a trap-door and break his neck after his breakfast, but I never thought that his breakfast had anything to do with the fracture.

"Treatment locally by radiant heat and iodine ionization for a month or on alternate days for two months" seems to me a laborious employment; it is, however, one which does not strongly commend itself to me. But why only two months? Why not as long as the patient's purse will hold out? The disease will certainly survive much more than two months of such treatment.

Dr. Preston King begins his letter with a testimonial to himself as to his large experience and interest in the subject, from which I in no way wish to detract, but he must excuse me if I refuse to discuss seriously with him his hypotheses about conditions concerning which he has even written a paper "to assert that there was no such disease as rheumatoid arthritis." Why, then, waste your space and your readers' time about a non-existent disease? He then proceeds to jumble all the joint affections together, and is willing to grant that there may be "in this great group of joint affections an inner group which may fairly be regarded as a distinct disease." Having set up this inner group, he then proceeds to mix it with pyorrhoea alveolaris and the gonococcus, so that we do not know where we are, and I must leave him to get out of his own muddle.

He quotes my statement that in the later stages the disease is curable, though not the deformities, and then adds "presumably by administering sufficient lime salts." What right has he got to saddle me with his presumption? If he would only take the trouble to read my address with an ordinary amount of attention, he would find that the first part of the treatment is to remove the cause, and until this is accomplished it is often very difficult to get lime into the tissues.

At this stage I think it would serve no useful purpose to enter into any discussion with him as to the passage from rheumatoid arthritis into osteo-arthritis, as it is evident that at the very outset we would differ as to what is meant by nature. I may, however, say that many cases of rheumatoid arthritis are cured by the removal of the cause in spite of treatment.

I cannot attach much importance to his interpretation of his skiagraphs, seeing that he does not clearly differentiate between the different affections of the joints. I have not laid down any hard and fast rules as to which joints are first affected; and, again, if he takes the trouble to read my address carefully, he will find that the joint affection is only a part of the disease. He talks about poverty and plenty as causes of mild chronic acidosis. How is it possible to have patience with such a travesty of my statement? The following similitude may make the matter clear to him: Drunkenness is usually preceded by the absorption of alcohol, but it is not necessarily associated with either poverty or wealth. His remarks about marmalade and acid fruits may seem to him spicy, but no fair-minded critic would ever attempt to divorce this matter from its context. He talks as if my treatment consists solely in the administration of lime salts.

I must express my thanks to Dr. Percy Newell for his kind appreciation of my address and for his whole-hearted condemnation of the drugs which I, it appears, boldly ventured to ostracize in this disease. In my presidential address last year I predicted a bright future for the general practitioner: "In my opinion the future of medicine will rest with enlightened and highly educated general

practitioners—men who will look after the health of the community, who will see that mechanism of a high order is produced, and who will see that the machinery of the individual is properly lubricated, and not subjected to any unnecessary friction or strain. The enlightened public will look to their medical attendants as guides, philosophers, and friends both in health and disease." The sooner we cease to batten on disease and go in for prevention the better for the public.

Professor W. E. Dixon has drawn my attention to an article on The Pathology of Chronic Fluorine Poisoning, by Dr. Fritz Schwyzer.¹ Schwyzer records a case of chronic fluorine poisoning in a man, aged 33, brought about by taking up the poison in his food. He also conducted experiments on rabbits, guinea-pigs, and pigeons. He concludes as follows:

In summing up, I wish to state that the main symptoms of chronic fluorine poisoning in man and animals so far experimented upon are the same. Abnormal increase of the myelocytes in the blood at expense of the number of the other leucocytes, partial change of the yellow bone marrow into red (so far seen only in animals, as my patient did not die), pain in the bones and joints, increased coagulability of the blood, and great deficiency of chlorine in the body.

That there was an enormous increase in the output of calcium could be shown directly in man through the analysis of the urine and faeces, and in animals by determining the specific gravity of the bones.

As sodium fluoride is used as a preservative it may be as well to be careful about its employment. It may be within the recollection of many of your readers that many years ago hydrofluoric acid was highly vaunted in the treatment of exophthalmic goitre, but its uselessness in that disease was soon recognized. It may possibly have done some good in cases of fibrocystic endemic goitre.

The well-known decalcifying effects of oatmeal I have ascribed to silicic acid.

I wish now to draw the attention of your readers to an able paper in the *Lancet* of May 10th by Professor W. E. Dixon, being his contribution to the discussion at the Royal Society of Medicine on alimentary toxæmia—an extraordinary title, by the way, for which Professor Dixon is in no way responsible, but which cannot reflect much credit on those who gave it birth. Professor Dixon says:

It is true that under certain conditions a kind of toxæmia may be induced from carbohydrate metabolism; for example, in certain conditions of the bowel an excess of lactic acid may be found leading to an excess of ammonium salts in the urine, and some four or five times the normal excretion of calcium; the result may be calcium starvation, of which one symptom is probably joint trouble.

—I am, etc.,

Liverpool, May 10th.

JAMES BARR.

SIR,—Most clinicians who have paid special attention to the subject will agree with Sir James Barr as to the inefficacy of guaiacol carbonate and other drugs in this disease. At the same time considerable difficulty will be felt in accepting the view suggested by Sir James Barr—that the cause of the disease is a mild chronic acidosis which extracts the lime salts from the fibrous and other tissues. For my own part a close study of the disease has led me to accept as most likely the view condemned by Sir James Barr—that the disease is a toxic arthritis of bacterial origin. Sir James Barr brushes this view aside as resting on no firmer foundation than the imagination of some writers, and he goes on to deprecate hunting for the germ and its toxin. A study of the later part of Sir James Barr's admirable article presents what appears to be a curious inconsistency in his position. We find, for example, that the principles for successful treatment are laid down by him as follows:

(1) Attention to be directed to the *prima via*, all sepsis to be eradicated. (2) All acid fermentation in the stomach to be eliminated. (3) The administration of medicinal substances, such as olive oil at night, and the regular administration of an aperient to keep the bowels open. (4) Leucorrhœa, if present, to be treated, and any infection of the urinary tract to receive attention, vaccines often proving useful in this class of case.

Now, taking these points seriatim, it seems clear that, consciously or unconsciously, the toxic or bacterial origin of the disease bulks much more largely in Sir James

Barr's mind than he would have us believe. A bacterial origin of the disease is clearly suggested by his first principle; since acid fermentation in the stomach and bowel is most commonly the result of abnormal bacterial activity, an *a priori* case for the germ origin of the disease is established by his second principle. Further, since a very large proportion of the faeces consists of bacteria, it will be readily understood that drugs which accelerate the passage of the faeces through the alimentary canal will diminish the amount of putrefaction which takes place in the bowel from these organisms, and also limit the absorption of their toxic products; and, lastly, Sir James Barr's personal experience of vaccines often proving useful in cases of rheumatoid arthritis associated with infection of the urinary tract, is itself a proof of the value to the patient of the physician hunting for the germ and its toxin.

I entirely share the view put forward by Sir James Barr that rheumatoid arthritis as a prolonged disease is a standing disgrace to the medical profession, and if the principles of treatment so well laid down by Sir James Barr were universally recognized (and this involves a careful bacteriological examination along modern lines), this unfortunate position of affairs would soon be corrected.—I am, etc.,

Edinburgh, May 10th.

CHALMERS WATSON, M.D.

SIR,—I often think that when writing on the etiology and treatment of rheumatoid arthritis we would do well to confine our observations to the disease as it is seen in young women. Then we should clear the ground.

Later on in life other varieties of chronic arthritis are met and often confused with the disease under consideration. This is hardly excusable even without the assistance of skiagrams, and yet how often we see osteo-arthritis and rheumatoid arthritis mistaken for each other. Thus it happens that treatment which may be of service for one of these diseases is extolled for both. We speak of iron anaemia and arsenic anaemia to distinguish between the remedies best suited for chlorosis and pernicious anaemia, so to-day we might borrow from that therapeutic definition and speak of iodine arthritis and calcium arthritis.

Those who have the patience to try iodine tincture in increasing doses for long periods in the treatment of osteo-arthritis (nodular rheumatism), as recommended by Trousseau in vol. iv of his *Clinical Medicine*, published as far back as 1872, will not be disappointed; but this treatment is perfectly useless in rheumatoid arthritis. Whether or not a mild acidosis is responsible for the decalcification of bones so often observed in rheumatoid arthritis I am unable to say, but I do know that this disease in young women is frequently benefited in no small degree by adding large quantities of milk to their diet.

In my own practice I endeavour to get these patients to take 3 or 4 pints daily in addition to their ordinary food, and I have seen the disease entirely disappear under this treatment.

What the prime cause may be we do not know, and whilst our ignorance is so colossal we must do the best we can, guided by the experience of those who have had most opportunity of studying the disease, but we have a right to expect that two entirely different pathological conditions should not be treated as one and the same malady.—I am, etc.,

Bath, April 28th.

T. PAGAN LOWE, M.R.C.S., L.R.C.P.

SIR,—Sir James Barr, in his letter in the *JOURNAL* of May 3rd, although professing to reply to my questions, fails to answer any of them. If Sir James Barr has no knowledge of the subject, may I tell him that the thermo-penetrating current has been in common use in Germany, Austria, and France for rheumatoid arthritis for many years? I have myself used it or seen it used many thousand times during the last five years, both in this and other diseases, with excellent results. The hot seaweed or other alkaline bath is, I fancy, almost as old as the employment of lime in the treatment of this disease. The hot alkaline bath is of itself of some value, and also, probably by increasing the absorptive powers of the skin, increases the value of the inunction when administered while the patient is still warm and damp after leaving the bath. Suitable inunctions to the spine and affected parts

¹ *Journal of Medical Research*, vol. x, p. 301.

are also very valuable when applied to the spine and affected joints, either when the parts are heated before a fire or even when applied at the normal temperature of the body. The best ointment to employ to the spine must vary. I may, however, say that I find milder counter irritants give much better results than the actual cantery or strong blisters, and have the further advantage that they can be almost continuously used; the patient in this way derives great benefit from the long-continued absorption of the medicament employed. Antirheumatic serums have been in use for over twenty years.

My objection to the employment of the calcium salts in rheumatoid arthritis is that they are neither good nor new. I remember in the year 1873 the late Sir Robert Christison gave his class a list of the various reasons different writers gave for using calcium salts in rheumatoid arthritis. He pointed out that some of the reasons were both plausible and ingenious, others rather stupid, and ended by telling us that after a prolonged trial his experience was he might as well have given his patients an infusion of straw. After forty years, in the *Medical Annual* for 1913, I notice that Hirschberg gives as his experience of treating a number of patients suffering from rheumatoid arthritis with a diet deficient in calcium, "that in a certain proportion a notable degree of improvement is obtained both in the mobility of the joints and in the relief of pain." I tried this treatment some years ago, but failed to notice any improvement.

I gathered from the cursory glance I gave Sir James Barr's address some weeks ago that he had either read about or employed vaccines in some forms of this disease, but I failed to notice any mention of antirheumatic serums.—I am, etc.,

Llandudno, May 4th.

JAMES CRAIG.

THE INTERNEURONIC SYNAPSE IN DISEASE.

SIR,—Dr. Shaw's suggestion that in hysteria the neuron trouble may be synaptic opens out one of the ways in which it may still be possible to bring into line the physiological and psychical conceptions of that disease.

Is it not more probable, however, that increased rather than diminished synaptic resistance is the cause of hysterical symptoms. The statement that "the hysterical temperament is manifested by an abnormally keen sensibility to all external impressions and sensations" is open to serious question. It is not in accord with the anaesthesia, loss of memory, paralysis, and diminished field of vision, which hold such an important place in the hysterical symptom complex. In the severe hysterical paroxysm the patient is often completely oblivious of her surroundings.

These facts are more in agreement with Janet's theory that hysteria is due to a diminished field of consciousness, and such a diminished field would be more likely to be brought about by increased synaptic resistances isolating more or less completely certain areas of the mind than by diminished resistances allowing impulses to run riot in all directions. The susceptibility to suggestion and lack of control are undoubtedly facts of the hysterical state, but these may be due to the cutting off of the higher controlling functions of the mind, reason, and will, and so are quite compatible with Janet's theory and increased synaptic resistance. Further, Dr. Shaw gives epilepsy as an instance of increased synaptic resistance causing an accumulation of energy which eventually bursts its bounds, causing an epileptic fit. This explanation has many facts to support it, but the phenomena of hysteria and those of epilepsy show several parallel features. In both we have fits characterized by an abnormal output of nervous energy, and in both we have an interparoxysmal period. The same explanation could therefore equally well be applied to both—namely, an undue accumulation followed by a sudden and violent output of nervous energy.

It is true that the phenomena are in detail very different, but this could be explained by assuming that different areas of the brain are involved.

Shock, which, as Dr. Shaw suggests, often appears to be a determining cause of epilepsy, is often also an important factor in the etiology of hysteria. If, in the case of epilepsy, the shock acts by causing "synaptic fusion"

and consequent increased resistance, is it not possible that a similar process may be at work in hysteria?—I am, etc.,

Sheffield, May 12th.

ARTHUR G. YATES, M.D., M.R.C.P.

THE FORM AND POSITION OF THE STOMACH.

SIR,—I had feelings of great astonishment and disappointment when I read Dr. A. E. Barclay's letter on this subject in your issue of May 3rd.

My quotations from his most recent writings on x-ray appearances of the stomach under varying conditions were surely extensive and consecutive enough to prevent any suggestion of misquotation. My previous communications on this subject indicate definitely where I locate the "middle sphincter." Dr. Barclay merely throws dust in the eyes of the reader and confuses the issue by saying that "apparently Mr. Gray claims all these sites as his middle sphincter." These sites are described by Dr. Barclay as "half-way down the stomach," "the lowest part of the organ," and "the middle of the body," and I interpreted these expressions as referring to one and the same situation. If this is not what Dr. Barclay meant then he is particularly unhappy in his choice of terms and in his descriptive powers. After all, the truth appears to be that he and I agree as to radiographic appearances presented in the stomach, but differ, widely it is true, as to the interpretation of these appearances. Nobody should be more willing than Dr. Barclay to admit that there is room for such disagreement, because his own writings indicate how frequently, in his own experience, operative findings show that his interpretations of the x-ray pictures have been delusive.

During this correspondence I have endeavoured to show (1) that the adoption of Dr. Hertz's suggestions regarding operative procedure in cases requiring gastro-enterostomy would entail retrogression, and (2) that the findings of radiographers of repute in different parts of the world are neither consistent nor conclusive.

Dr. Barclay, who has taken upon himself to reply to my letters, has entirely ignored, as has Dr. Hertz also up to this time, the very definite questions I put (1) with regard to discrepancies as to the positions accorded to the pylorus by himself and Dr. Jordan, to say nothing about the pelvic position given to it by Drs. Maclaren and Daugherty; and (2) with regard to the explanation of certain well-known clinical phenomena in the light of Dr. Barclay's "gravity theory." These are most important points, and I hoped that they would be taken up and answered without divergence into side issues. In the absence of such answer, I agree that "it is simply waste of time, ink, and paper" to attempt to forward the discussion, because it is apparent from Dr. Barclay's letter that "the subject lends itself to distortion," not merely "by those who are not familiar with normal appearances," but also by those who professedly are.—I am, etc.,

Aberdeen, May 10th.

H. M. W. GRAY.

EXISTING UNSATISFACTORY CONDITION OF THE SCHOOL MEDICAL SERVICE.

SIR,—I had occasion recently to circularize a number of school medical officers in reference to the subject of salary, and I could not help being impressed by the large number of private communications I received from all parts of the country, in addition to the answers to my circular, expressing views almost identical with the letter published in the *BRITISH MEDICAL JOURNAL* of May 10th.

The manner in which the school medical service has been organized bids fair to create a most practical system for bringing about an almost ideal method of preventive medicine, which is certainly the common-sense way of dealing with disease. Moreover, it has apparently attracted many very able men to join its ranks, but unless there are some prospects of a fair living wage, similar to that of tuberculosis medical officers, it is more than probable the service will rapidly deteriorate.

There is a feeling among some people, who have little or no practical experience of the work, that any one who has a qualification to practise is competent to do it, but owing to its special and far-reaching nature this is by no means the case.—I am, etc.,

Hastings, May 12th.

O. POLHILL TURNER, D.P.H.,
School Medical Officer.

SIR,—The remedy for the exceedingly unsatisfactory state of affairs in the school medical service described by the S.M.O. of Stoke-on-Trent in your issue of May 10th is indicated by the minutes concerning salaries of school medical officers contained in the SUPPLEMENT of May 3rd. No one can reasonably object to the commencing salaries of £500 and £250 laid down therein as the minimum salaries proper to be paid for senior and junior posts respectively. Unfortunately, however, the Association has not been able to secure the adoption of these salaries in practice. As a matter of actual fact, some responsible school medical officers were appointed at salaries that were the minimum proper to be paid to their assistants, and after four years they are still paid the salaries of junior officials, notwithstanding the responsibilities of their office and the fact that more than sufficient time has elapsed to make the necessary adjustments.

Under these circumstances the development referred to by your correspondent is not to be wondered at. In practice the status of the school medical service cannot be considered altogether apart from the salaries paid to its officials. If the school medical officer receives—as he frequently does receive—a salary utterly inappropriate to the importance of his work and to his responsibility, it is not surprising that the direction of his work tends to pass into the hands of laymen who happen to be better-paid officials.

Local authorities cannot, however, be altogether blamed in the matter, for the burden of medical inspection was thrust upon them at a time when they were most unwilling to incur any further financial obligations. But the fact remains, unfortunately, that the school medical service has been starved in consequence.

The Board of Education makes insistent demands upon education authorities for the efficient performance of medical inspection; and further, indicates the desirability of school hygiene being dealt with in its broadest aspect. The burden of all this falls upon the school medical officer, the chief concern of his committee being to limit the expenditure of money under this head. Among the economies thus practised, the school medical officer's salary is frequently the first to suffer.

It is earnestly to be desired, therefore, that school medical officers will themselves draw attention to the existing sweating of the school medical service. But it is not only in their own interests that complaint should be made of inadequate salaries. It is a matter of national importance that the status of the school medical service should receive adequate recognition by local authorities. Failing such recognition the service will almost inevitably suffer serious deterioration in the near future.—I am, etc.,

W. SPENCER BADGER,

May 13th.

S.M.O., Wolverhampton.

DEATH VACANCIES AND THE PANEL SYSTEM.

SIR,—May I make to you and your readers, with the hope that it may be eventually considered by the various Branches, what appears to me to be a practical and valuable suggestion?

It is only too true that the average practitioner, if stricken down in his earlier and responsible years, leaves behind him very little provision for the protection of those nearest and dearest to him. Prior to the incidence of the Insurance Act there was always a provision, small or large—unfortunately often small—derived from the sale of the death vacancy. With the incidence of the Insurance Act this provision may become very small indeed, for death will terminate the contract between the insured and the late doctor, and the former will be at liberty to go wherever he pleases, and I fear this will be seldom to the buyer of the death vacancy, and thus death vacancies will be valueless.

My suggestion is that, if a scheme were developed whereby the purchaser of a death vacancy was assured for twelve months of the possession of the panel patients of a deceased medical man, the provision for the widow and children would at least be a sum equal to the annual value of the panel patients—that is, at the present rate £350 a thousand.

All that should be necessary would be to bind all the panel men not to accept, under a penalty of £10, a patient the client on the insured list of a deceased colleague for

twelve months after such a colleague's death. The carrying out of such a proposal would be equivalent to each man insuring himself to the amount of the annual value of his panel practice, and should find ready acceptance by all. There appears to me to be no difficulties in putting such a proposal into practice, as the means of discovering what the list of a deceased colleague was will be in the possession of his executors and in the Insurance Office.—I am, etc.,

Plymouth, May 12th.

H. B. PALMER.

THE PARISH DOCTOR AND HIS OPPORTUNITY.

SIR,—It appears to me that the crux of the whole matter is that these appointments are made by men who for the most part are entirely incapable of forming a just opinion on the merits of the different candidates, and they are often made a matter of—shall I term it—"expediency" between the different parties on the boards of guardians.

The remedy seems to be in the appointments being made by a select committee who would not be parties to the sweating principle that most boards adopt. Whilst agreeing that united action on our part is desirable, much also may be done by educated laymen on the board, and our influence should be brought to bear to support those men at election times, who are willing to serve from the highest motives of public spirit.—I am, etc.,

F. BRYAN,

Late Medical Officer and Public Vaccinator,
Bastford Union.

Ipswich, May 12th.

LECTURES TO VOLUNTARY AID DETACHMENTS.

SIR,—The British Medical Association has passed a resolution that the minimum fees paid to doctors for giving first aid or nursing lectures should be 5 guineas for each course, and some of the Divisions of the Association, including York, have recently passed similar resolutions.

Whilst fully agreeing that doctors should be paid a fixed uniform fee for these services to the general public, to railway companies, county councils, and factories, I strongly feel that services voluntarily given to a voluntary and patriotic movement in preparation for the defence of this country in time of peril and need should be given gratis—first, as an example to our fellow countrymen and countrywomen; and secondly, because there are no funds to meet these fees, and this good and useful work will be absolutely crippled and will consequently fall to pieces, and the profession blamed for it. Some form of compulsory service, combatant and non-combatant, may be necessary for the defence of this country, but until that becomes law we must not imperil the safety of our country by refusing to volunteer our services and discouraging others to volunteer.

I do not know whether the officers of the R.A.M.C. in time of peace would be allowed to do this work for the medical practitioner, or if they have the time and willingness to undertake it. But I am surgeon to a voluntary aid detachment, and in absence of funds I shall continue to volunteer my services to this company rather than see it disbanded for want of a lecturer or instructor. In order to keep these companies or sections up to strength recruiting has to be done, and for this it is necessary to give a course of lectures every year in first aid and nursing, and if there are no funds I cannot charge a fee. It has been suggested that the county councils would pay these fees if approached. I do not know if they would, but that would lay the classes open to all, whether they joined these voluntary aid companies or not, and in this neighbourhood we generally form these classes only for those who are willing to enlist in the company.

It is an important question, and I should like the views of others. I feel quite sure that the profession does not wish to stand in the way of a patriotic movement.—I am, etc.,

Green Hammerton, York, May 7th.

J. A. BENSON.

MEMORIAL TO MR. ETHERINGTON-SMITH.

SIR,—As a friendly opponent may I be permitted to add my encomiums to the memory of one who, by his tactful and manly bearing, has endeared himself not only to his colleagues, but to his rivals in work and sport?

Some years ago while judging an international boat-race in Cork for the O'Brien Trophy an unfortunate and unforeseen (inter-national) point arose which demanded prompt decision, and but for the courteous and charming personality of our departed friend serious difficulties might have occurred. His influence will be long felt by the rising generation.

The form the memorial has taken and the sad circumstances of his death should appeal to all.—I am, etc.,

SHEPHERD BOYD,

President, Harrogate Medical Society.

May 12th.

Obituary.

JOHN HERBERT HAWKINS MANLEY, M.A.,
M.D. (LOND.).

M.O.H., WEST BROMWICH.

On May 4th occurred the death of Dr. Manley at his residence, New Street, West Bromwich, in his 57th year. He had been in failing health for some considerable time, and recently a severe operation became necessary, from which he appeared to be on the way to recovery, when hæmatemesis occurred, to which he succumbed.

Dr. Manley was the only son of the late Mr. John Manley, who was medical officer of health for West Bromwich for over seventeen years. He was educated at Winchester, Cambridge, and Guy's Hospital, and graduated M.B., B.C. in 1884, and proceeded M.D. in 1902. He took the diploma of L.S.A. in 1882, and that of M.R.C.S. Eng. in the following year. After holding the appointment of resident obstetric physician at Guy's Hospital he returned to West Bromwich about twenty years ago, and joined his father in private practice. He obtained the Diploma of Public Health in 1899, and in the following year succeeded his father as medical officer of health for the borough.

Dr. Manley was a barrister-at-law of the Middle Temple, and at one time thought of practising in this profession, but on his appointment to be school medical officer he devoted all his time to his official duties. He was also medical officer of the Infectious Hospital, examiner in lunacy for the West Bromwich Union, examiner of the St. John Ambulance Association, and a Captain in the Royal Army Medical Corps (T.F.), being a sanitary officer whose services would be available on mobilization.

West Bromwich owes a great deal to Dr. Manley, for he was indefatigable in his work, and instituted a large number of sanitary reforms. He was held in high esteem by his medical colleagues, not only for his great professional abilities but also for his charming personality. He was a man who had many true friends, for he could always be relied upon. He was a prominent Freemason, and one of the founders of the Lewisham Lodge at West Bromwich. He did excellent work in connexion with the Incorporated Society of Medical Officers of Health, being for some years secretary; he had also held the office of President of the Birmingham and Midland Branch.

He was ex-president of the Birmingham Branch of the British Medical Association, vice-president of the Section of State Medicine at the annual meeting at Leicester in 1905, vice-president of the Medical Defence Union, a Fellow of the Royal Sanitary Institute, honorary associate of the Midland Counties Veterinary Medical Association, and a member of the Medico-Legal Society. He had also been president of the Birmingham Graduates' Club, and a vice-president of the Birmingham Medical Benevolent Society. He was the author of a Legal Appendix to *Practical Sanitation* (1906), and contributed many articles to the medical and public health journals.

Dr. A. G. BATEMAN (General Secretary of the Medical Defence Union) writes:

Dr. Herbert Manley has for many years been a vice-president and member of the Council of the Medical Defence Union, taking the deepest interest in the work. During the last year he was too ill to attend, but, as soon as his almost miraculous recovery occurred, he at once took up his duties again, and as late as April 21st was present at the last monthly Council meeting. His legal knowledge as a barrister and his practical experience as a medical officer of health afforded to the Council great

assistance in dealing with public health matters, and his advice was constantly called for and placed most fully at the services of the executive officers. Dr. Manley was a classical scholar of the first rank, of keen intellectual powers, and a valued friend. The Council will ever retain a high regard for his memory and regret his loss with sincerity.

SIR JOHN WILLIAM TYLER, a well-known Anglo-Indian medical officer, died at his residence in London on May 12th, aged 73. He was educated at the Devon College in Calcutta, and at the medical college in that city, and in 1861 came to England and took the diplomas of L.S.A. and L.R.C.S. and L.R.C.P. Edin. In 1862 he graduated M.D. St. Andrews, and in 1870 became F.R.C.S. Edin. In 1863 he was appointed to the Uncovenanted Medical Service in the North-West Provinces, and joined as civil surgeon of Ebal District. In March, 1866, he was transferred to Manipuri. In April, 1873, he entered the Gaol Department as Superintendent of Meerut Gaol, and in April, 1876, took over charge of the Agra Gaol, which he held for fourteen years. Under Tyler this gaol became known as a great manufacturing gaol, its special line being Indian carpets of the best quality. He was employed on special duty in England at the Colonial and Indian Exhibition of 1886, and for his services on that occasion was given the C.I.E. In December, 1886, he was deputed on special duty in the Dholpur State, and in 1887 came to England again on the staff of the Maharaja of Bhartpur for the jubilee of Her Majesty Queen Victoria. In 1888 he received the honour of knighthood, and in September, 1890, was appointed Inspector-General of Prisons in the North-West Provinces, now the United Provinces of Agra and Oudh. He retired in July, 1896, after a career which may be said to be the most successful of any officer who ever served in the Indian Uncovenanted Medical Service.

LIEUTENANT-COLONEL ALEXANDER WILLIAM MACKENZIE, Bengal Medical Service (retired), died suddenly at Plymouth on May 11th. He was born on October 23rd, 1853, educated at Aberdeen, where he took the degrees of M.B. and C.M. in 1876, and entered the Indian Medical Service as surgeon on March 31st, 1887. He became surgeon-major on March 31st, 1889, and surgeon-lieutenant-colonel on March 31st, 1897. He served in the Afghan war of 1878-80, when he took part in the action at Chihil-dakhteran, and in the march from Kabul to the relief of Kandahar, and in the battle of Kandahar, gaining the Afghan medal with a clasp and the bronze star given for the march to Kandahar. Subsequently he served in four expeditions on the North-West Frontier of India, the Mahsud Waziri expedition of 1881, the two Miranzai campaigns of 1891, receiving the Frontier medal with a clasp, and in Waziristan in 1894-95, gaining another clasp.

MAJOR CHARLES FREDERICK WEINMANN, Indian Medical Service, died in London on May 4th. He was born on July 2nd, 1871, and was by extraction a Ceylon "burgher." After taking the degrees of M.B., C.M. at Aberdeen in 1896, he entered the Indian Medical Service as lieutenant in 1899. He became captain in 1902, and major in 1911. He served in Waziristan, on the north-west frontier, in 1901-2, receiving the frontier medal with the clasp for that campaign. For the past six years he had been in civil employment in Bengal, and since October 3rd, 1912, on furlough. Major Weinmann was civil surgeon of Midnapur at the time of the sedition trials at that station, a few years ago, and also at the same time was acting as superintendent of Midnapur Central Jail, in which a number of prisoners who were being tried for sedition were confined; this was a very onerous charge for a young officer who had lately taken up civil employment. Subsequently he appeared as a witness in the notorious Midnapur conspiracy case in the Calcutta High Court. He had complained that his life had been threatened by members of the anarchist party in Bengal, owing to his having given evidence in that case on behalf of Government. Such threats to witnesses, police officers, and magistrates in Bengal have been numerous during the

past few years, and in several cases the threats have been carried to the extent of political murders. His mind gave way under the strain. On March 1st last, while staying in a Bloomsbury boarding-house, he was found in bed suffering from eight wounds, inflicted by a surgical lancet. He was then suffering from a delusion that the servants in the house were trying to poison him. He was removed to the Royal Free Hospital, and there recovered from his injuries. Subsequently he greatly improved, both mentally and physically, and seemed to have made a complete recovery. Unfortunately his delusions returned, and on the morning of May 4th he threw himself from a third-story window of the house in which he was staying, and so put an end to his life.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Bastian, lecturer in the University of Geneva, one of the founders of the Société Romande de Gynécologie et Obstétrique, President of the Geneva League against cancer; Dr. Julian Count de Calleja, Dean of the Medical Faculty of the University of Madrid, and President of the Spanish Academy of Medicine; Dr. Ch. H. Ali Cohen, formerly lecturer on hygiene in the faculty of medicine of Groningen; Dr. John H. Droge, chief laryngologist to the German Hospital, Brooklyn, of which he was one of the founders, aged 53; Dr. A. P. Co Korkanoff, former professor of therapeutics in the University of Tomsk; Dr. T. H. Perrin, lecturer on urology in the medical faculty of Lausanne; Dr. Hugo Schmeilka, professor in the veterinary university of Vienna, formerly assistant in Professor Albert's Surgical Clinic; and Dr. Paul Yvon, co-founder with Bourneville of the *Archives de Neurologie* and the *Progrès Medical*, author of a handbook of urine analysis, commentaries on the Pharmaceutical Codex (1908), in the preparation of which he had taken a leading part, and in collaboration with Professor Gilbert of a *Formulaire pratique de thérapeutique et de pharmacologie*, a work now in its twenty-fifth edition, aged 65.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

The following degrees have been conferred:

M.D.—H. T. Ashby.
M.B.—G. V. Bakewell, T. H. G. Shore, H. K. Waller, H. F. Wilson.
B.C.—T. H. G. Shore, H. K. Waller.

UNIVERSITY OF EDINBURGH.

GENERAL COUNCIL.

Decrease in Number of Medical Students.

THE statutory half-yearly meeting of the General Council of the University of Edinburgh was held on May 7th. It was intimated that whilst there was an increase for the year (1911-12) in the total number of matriculated students attending the University there was a decrease in the number of medical students (1,326 as against 1,374 in the previous year).

The Inclusive Fee.

Reference was made to the question of the inclusive fee in medicine in several of the reports presented. Thus the Finance Committee noted with interest that "My Lords of the Treasury are giving directions for the payment of the additional grant of £12,500 for the current financial year, stipulating as a condition of receiving payment of the full amount that an inquiry shall be made as to the difficulties in the way of instituting an inclusive fee in applied science and medicine." Mr. J. B. Clark, Convener of the Business Committee, also referred to the action of the Treasury, which he regarded as an ample vindication of the attitude which the University Court had taken up on the subject, and consistently maintained, and Principal Laurie, Heriot-Watt College, believed that the General Council had made good their point not to allow the Treasury to interfere too much with the freedom and autonomy of the university. An appendix to the report contains the minute of the Conference of Representatives of the General Councils of the Universities of Glasgow and Edinburgh on March 22nd, when the effect of the inclusive fee in medicine upon extramural students was specially considered, and a subcommittee was appointed to prepare a reasoned statement. Meanwhile Principal Laurie moved that the General Council represent to the University Court the desirability of amending the regulations for the payment of inclusive fees in such a way that extramural students might be placed at no disadvantage; and this was agreed to.

Moncrieff Arnott Chair of Clinical Medicine.

The draft ordinance for the foundation of the Moncrieff Arnott Chair of Clinical Medicine was approved. The chair is intended to perpetuate the memory of the late James Moncrieff Arnott, of Chapel, in the county of Life, a graduate of the University of Edinburgh, and a medical practitioner of distinction, and also the memory of his daughter, the late Miss Jane Moncrieff Arnott, benefactors of the university. The Professor of Clinical Medicine is to be a Professor in the Faculty of Medicine, and is to be paid as an annual income the interest of £15,000, and if this does not amount to £600 a year the salary is to be made up to that sum out of the General University Fund. Further, on due cause being shown, the University Court shall have power to increase the emoluments. The University Court also shall from time to time, after consultation with the Senatus, define the duties of the Professor; and the patronage of the Professorship and the right of presentation or appointment shall be vested in and exercised by the University Court after consultation with the Managers of the Edinburgh Royal Infirmary for the time being. An important clause is that which provides for the contingency arising should the Professor of Clinical Medicine cease from any cause to have charge of clinical wards which in the opinion of the University Court are well fitted for the efficient teaching of his subject, then the Court shall have power to terminate his tenure of office as Professor of Clinical Medicine, and to determine the amount of pension, if any, which shall be granted to him—that is to say, if the contingency arise before he is entitled to a pension in the ordinary course.

Appointments.

The Business Committee reported that the following appointments had been made: Frederick Gardiner, M.D., an additional Lecturer on Diseases of the Skin. R. Chapman Davie, M.D., B.Sc., Lecturer on Botany in room of R. Stewart MacDougall, D.Sc., resigned. W. G. Sym, M.D., Lecturer on Diseases of the Eye. David G. Hogarth, M.A., Fellow of Magdalen College, Oxford, and Keeper of the Ashmolean Museum, Munro Lecturer on Anthropology and Prehistoric Archaeology for 1914. A. Ninian Bruce, M.D., D.Sc., Lecturer on the Physiology of the Brain and Nervous System. Professor Henri Bergson, Collège de France, Paris, Gifford Lecturer in Natural Theology for 1913-15.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on May 8th, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair.

Admission of Fellows.

The Members who were elected to the Fellowship at the last meeting were admitted Fellows.

Diplomas in Tropical Medicine and Hygiene.

Diplomas in Tropical Medicine and Hygiene were granted in conjunction with the Royal College of Surgeons of England to the following: P. P. Connor, Captain, I.M.S.; C. A. Gill, Captain, I.M.S.; Frances M. Harper.

A report was received from the Censors Board recommending that the following clause in a report of the Committee of Management be adopted. This was agreed to. The clause was as follows: "The attention of the committee has been called to the fact that the short title of the Diploma in Tropical Medicine and Hygiene—namely, 'D.T.M.England'—is not sufficiently descriptive, and that it is desirable to add a reference to hygiene in the title. The committee, therefore, recommend that the short title of the diploma be altered from 'D.T.M.England' to 'D.T.M. and H.England.'"

Alteration in By-laws.

An alteration was made in By-law CXXIV relating to the examination for the Membership. Candidates who have not been approved by the Censors Board can now be readmitted to examination after the lapse of six months, instead of a year as heretofore.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on May 8th.

Grant of Diplomas.

Diplomas of Membership were granted to eighty-nine candidates found qualified at the recent examination. Diplomas of the Licence in Dental Surgery were granted to five candidates found qualified. Diplomas in Tropical Medicine were granted conjointly with the Royal College of Physicians to three candidates.

Honorary Fellow.

Surgeon-Major Henry Benjamin Hinton was made an Honorary Fellow. An account, written by our South Australian correspondent, of the life of this retired officer, who attained the centenary of his birth on March 7th, was published in the BRITISH MEDICAL JOURNAL of March 15th, p. 559.

Vacancy on Board of Examiners.

The vacancy on the Board of Examiners occasioned by the retirement of Mr. W. F. Haslam will be filled in June. Mr. Haslam is not eligible for re-election.

Resignation from the Council.

The resignation of Mr. Bruce Clarke from the Council was

accepted with regret by the Council. The vacancy will be filled up at the annual meeting of Fellows in July.

Letter from the Home Office.

Mr. Richardson Cross was nominated to give evidence before the Home Office Committee on Factory Lighting.

CONJOINT BOARD IN ENGLAND.

At a meeting of Comitia of the Royal College of Physicians on April 24th, and of the Council of the Royal College of Surgeons on May 8th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following candidates:

C. B. Alexander, J. Appleyard, J. S. Arkle, R. A. Banbury, M. Barker, H. G. Barrie, H. J. Bates, R. S. De C. Bennett, E. W. Blake, T. D. J. Bowen, B. J. Brewitt, R. C. Briscoe, W. H. Broughton, P. P. Butler, P. N. Button, L. D. Cohen, F. Collar, G. D. Compston, E. R. C. Cooke, H. D. Cowper, W. Dale, A. C. E. D'Arifat, A. L. Davies, H. W. Davies, R. D. Davy, H. P. Dawson, S. A. Day, E. L. Dobson, J. D. Driberg, E. L. Z. Fickling, G. Garland, A. Goodwin, A. O. Gray, J. L. Green, A. Griffith-Williams, J. L. A. Grout, D. M. Hanson, J. S. Higgs, W. H. S. Hodge, *Elsie M. Humpherson, G. B. H. Jones, J. E. T. Jones, W. E. Kingdon, G. Laurence, G. A. Lilly, W. M. Lupton, J. D. Lyle, G. R. D. McGeagh, P. McRitchie, E. M. Mahon, H. Y. Mansfield, S. H. Marcus, G. S. Mather, W. J. Morris, H. H. P. Morton, W. H. Ogilvie, H. F. Overend, J. Owen, R. C. Parry, J. R. Payne, W. A. Pocock, R. C. Poyser, N. P. Pritchard, A. L. H. Rackham, W. A. Rail, C. G. Reinhardt, J. E. Rivera, G. M. Roberts, G. F. Rodrigues, A. B. Rosher, W. Salisbury, E. L. K. Sargent, A. W. M. Sawyer, R. S. Scott, D. N. Seth-Smith, A. K. Sinha, J. G. Sleet, J. S. Souttar, W. C. Spackman, D. B. Spence, E. J. Staddon, A. J. C. Tingle, E. W. Twining, E. H. Udall, A. Viney, I. L. Waddell, G. Whittington, R. F. Wilkinson, H. Wilks.

* Under the Medical Act, 1876.

Public Health

AND

POOR LAW MEDICAL SERVICES.

TUBERCULOSIS (IRELAND) ORDER.

ARRANGEMENTS have now been made with the Treasury and the Irish Department of Agriculture have issued a Tuberculosis Order on the same lines as that operating in Great Britain. Every person having in his possession or under his charge (1) any cow which is, or appears to be, suffering from tuberculosis of the udder, indurated udder, or other chronic disease of the udder; or (2) any bovine animal which is or appears to be suffering from tuberculosis with emaciation shall, without avoidable delay, give information of the fact to a constable of the police force for the area wherein the animal is, and the constable shall transmit the information (a) to the local authority, who, if not the sanitary authority, shall inform that authority; and (b) to the department. The milk from such a cow must not be mixed with other milk until the cow has been examined by a veterinary inspector; it must be boiled or otherwise sterilized forthwith, and any utensil in which such milk is placed before being so treated shall be thoroughly cleansed with boiling water before any other milk is placed therein. The animal must be kept isolated as far as practicable from other bovine animals. By this order a veterinary inspector shall be authorized to visit and examine all suspected animals, and if necessary and with the consent of the owner apply the tuberculin test; he may also require the cow to be milked in his presence, and take a separate sample of milk from any particular teat. Authority is also given for the slaughter of all such animals as are reported by the veterinary inspector to be diseased, except in the case of animals valued at over £50, so long as the animal is detained and isolated and the milk of any is sterilized. When a veterinary surgeon in his private practice is employed to examine an animal, and is of opinion that the cow is tuberculous, he must notify the case. Authority is also given to make *post-mortem* examinations of all animals slaughtered under this Order, and to require suspected animals to be removed from markets or sale yards, and any cow which is or appears to be suffering from tuberculosis must not be brought to any port for shipment. Provision is also made for the cleansing and disinfection of premises and sheds in which tuberculous cows have been recently kept.

This Order applies to the whole of Ireland, and is to come into operation on June 2nd.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Guildford Rural District.—Based on an estimated population at the middle of 1912 of 18,420, the net birth-rate was 19.4 per 1,000 and the net death-rate 8.9 per 1,000. The infant mortality-rate was equal to 48 per 1,000 births. Although out of the 172 houses inspected under the regulations of the Housing, Town Planning, etc., Act, 1909, 16 were considered to be unfit for human habitation, no steps were taken to close them owing to the reluctance of the district council to make closing orders until all other means had failed to make the houses habitable, for cottages are very scarce in the district. Dr. Pierce, the medical officer of health, describes a method which has been adopted with success for dealing with the drainage of cottages otherwise than by means of cesspits. A small pit or detritus chamber has been constructed at a distance

of not less than 20 ft. from the dwelling, and radiating from it are rows of end-to-end agricultural pipes laid within a foot or so of the surface whereby subsoil irrigation is carried out. By-laws with respect to tents, vans, and sheds are in force, and Dr. Pierce considers they have been of considerable service. For the effective control of persons occupying these places he considers further legislation may be necessary. He is not altogether in favour of the formation of recognized encampments, as his experience of two such has shown that the aggregation of large numbers on small areas of ground, especially when in a low-lying locality, leads to a deplorably insanitary condition of the ground, and that nothing short of the provision of a hard dry surface with suitable drainage for surface and waste water, and periodical scavenging will prevent such places from becoming insanitary in course of time. By-laws with respect to slaughter-houses are in force in the district, but they do not apply to farm premises upon which sheep and swine, but not cattle, may from time to time be slaughtered, provided that such sheep or swine are not conveyed to a farm specially for the purpose of slaughter. The Local Government Board was asked whether the by-laws would apply to cottagers who occasionally slaughtered an animal, but would express no opinion on the matter, merely stating that each particular instance must be considered on its merits.

Barry Urban District.—Dr. George Neale states that the net birth-rate during 1912 was 23.9 per 1,000 and the net death-rate 10.4 per 1,000 of the population, which was estimated at 33,767. The infant mortality-rate was equal to 60 per 1,000 births. Although there are in Barry nearly 6,500 houses, only about forty of them were built prior to the year 1885, and these are mostly well-constructed farmhouses on the outskirts of the town. The governing body of the town has always been alive to its responsibilities so that it is not surprising to learn that there are practically no slums. What may be described as the municipal equipment of the town is very complete. The sewage is discharged by two outfalls into the sea below low-water mark, and there has never been any evidence of any of it being returned by the incoming tide. About twelve years ago a destructor was erected at a cost of £9,000; it is capable of destroying 30 tons of refuse daily. The power generated is used for providing electric light for the destructor works and for the adjoining public abattoir and for giving steam to the latter for water-heating purposes. There are separate hospitals for small-pox and for other infectious diseases. The latter institution does not seem to be very much used, for only 1 of the 63 cases of scarlet fever, 2 of the 47 cases of diphtheria, and 6 of the 25 cases of typhoid fever notified during the year were treated in the wards of the hospital. A qualified veterinary inspector is employed by the district council to inspect the dairy cows in the town. In the course of his inspections in 1912 he discovered two cows with tuberculosis of the udder, and his diagnosis was confirmed by bacteriological examination of the milk. The cows were isolated and the owners were requested to destroy them. In one case the request was complied with and general tuberculosis was found to be present. In the other case the owner refused to destroy the animal unless he was compensated, but in a short time it died. Dr. Neale includes in his report a very useful table giving the rateable value and the amount of the district rate since the year 1889, from which it appears that the rateable value has increased from £18,000 to £186,000. The district rate, which was 3s. 6d. in the £ in 1912, has been as low as 1s. 8d., and only in one year has it been as high as 4s. in the £.

LOCAL GOVERNMENT BOARD REPORTS.

East Stow Rural District (New series, No. 75).—Dr. Wilfred Fletcher's report to the Local Government Board on the rural district of East Stow, in East Suffolk, is the result of an inspection of the district made in consequence of doubt having been raised as to the sufficiency of the arrangements for the discharge of the duties of inspector of nuisances. Dr. Fletcher appears to consider those arrangements adequate, and formed the opinion that the district council had for some time displayed little desire to secure improvements in the sanitary circumstances of the district, though he recognized that it was now making real efforts to do so. The housing accommodation is described as fairly good, but there seems to be a deficiency of accommodation for agricultural labourers, whose weekly wage of 12s. is insufficient to enable them to pay an adequate rental for good dwellings. There are no by-laws in force in the district, so that the deterrent effect of stringent regulations is not a determining factor in the failure to erect cottages in East Stow. Of the dairies and cowsheds in the district there is little adverse criticism. Regulations concerning them have been in force since 1907, and are apparently enforced. Dr. Fletcher takes occasion to point out that a district council's duties with respect to cowsheds are not limited to those cowsheds which are in the occupation of cowkeepers and purveyors of milk who are registered, but extend to those occupied by "any person following the trade of cowkeeper and dairyman," and, therefore, to such as carry on the trade of cowkeeper for the manufacture of cheese, butter, or for other purposes. The population of the rural district is over 6,000, and has increased in the past ten years, but no provision has been made for isolating cases of infectious disease, except that for small-pox purposes a small portable building is stored in sections. The district council would be well advised to combine with one or more adjoining districts in making the necessary provision for other infectious diseases.

CONDITIONS OF SUPERANNUATION ALLOWANCE.

A RETIRED Poor Law medical officer, who is in receipt of a superannuation, has been succeeded by his partner. He wishes to know if his superannuation would be forfeited if he were to give an anaesthetic for his partner when operating on a Poor Law patient.

We are advised that superannuation would not be forfeited in the circumstances he describes. Under Section 6 of the Superannuation Act of 1895, if he were to accept another Poor Law office the emoluments from which exceeded his superannuation, the latter would be suspended so long as he continued to hold that office. But the superannuation would not be affected by his acting as deputy for his partner, or assisting him in his Poor Law work.

Medical News.

THE Post-Graduate College, West London Hospital, will give a conversation at the hospital, Hammersmith Road, on Wednesday, May 21st, at 8.30 p.m.

DR. ARGYLL CAMPBELL, assistant to Professor Schäfer, University of Edinburgh, has been appointed Professor of Physiology in the Medical School at Singapore.

THE Bakerian Lecture before the Royal Society will be delivered by Professor Sir J. J. Thomson, O.M., at 4.30 p.m. on Thursday next. The lecture will deal with rays of positive electricity.

THE annual general meeting of the Asylum Workers' Association will be held at 11, Chandos Street, W., on May 28th, when Sir Robert Jardine, K.C.I.E., M.P., President of the Association, will take the chair at 3 p.m.

THE Glasgow University Club, London, will hold its annual spring dinner at the Trocadero Restaurant, Piccadilly Circus, on May 30th, when the Right Hon. A. Birrell, M.P., Lord Rector of the University, will take the chair at 7.30 p.m.

A NOAH'S ark fair and variety show in aid of the London Hospital Quinquennial Appeal Fund is to be held at the Albert Hall on June 11th and 12th, under the patronage of H.M. Queen Alexandra, who has consented to be present on June 11th.

THE annual general meeting of the Medical Defence Union will be held on May 29th at 4 p.m., at the New London Hotel, Exeter, when the usual statutory resolutions will be placed before the members, together with the annual report and balance-sheet.

THE annual conference of the British Hospitals Association will be held at Oxford from June 20th to June 28th. Papers dealing with the Insurance Act as affecting voluntary hospitals, the treatment of tuberculosis, and the upkeep of hospitals will be read and discussed.

THE first of the summer course of lectures at Brompton Hospital for Consumption will be delivered next Wednesday at 4.30 p.m. The lectures are free to all registered medical practitioners and senior students, and will be given by different members of the staff on Wednesday each week.

THE British Fire Prevention Committee's testing station, near Regent's Park, was opened, after the recent extension and alteration, on May 7th. The testing arrangements for the day comprised high-temperature fire tests with fire-resisting glazing and with fire-resisting party-wall doors. There was a large attendance of representatives of the various public authorities concerned in fire protection, such as the Home Office, H.M. Office of Works, the Admiralty, of the Post Office, Woolwich Arsenal, of municipal bodies, and of Colonial and foreign Governments.

AT a meeting of the Medico-Psychological Association of Great Britain and Ireland to be held at the house of the Medical Society of London at 3.15 p.m. on Tuesday, May 27th, Drs. R. G. Rows and David Orr will read a paper, illustrated by lantern slides, on the spread of infection by the ascending lymph stream of nerves (ascending neuritis) from the peripheral inflammatory foci to the central nervous system.

IN the announcement of the approaching twelfth International Congress of Ophthalmology published last week (p. 983) it should have been stated that it will take place in the month of August next year, and not August next. It will be opened in St. Petersburg on August 10th, 1914, under the presidency of Professor Arnaldo Angelucci of Naples, the city in which the last congress was held. The subjects selected by the Congress in Naples for special discussion at St. Petersburg were the etiology of trachoma and the nutrition of the eye. The general secretary in St. Petersburg is Dr. Th. Germana, the Ophthalmic Hospital, Mochowaja 38, St. Petersburg.

A FRENCH philanthropist who wishes to remain anonymous has offered a prize of £200 for the best memoir relating to the etiology, prophylaxis, or treatment of such forms of iritis, irido-cyclitis, or cyclitis as are not dependent on syphilis. Only such papers as have been communicated to one of the ophthalmological societies of France or some other country will be admitted to competition. The jury, three in number, will be chosen from the ophthalmologists of the principal institutions for eye diseases of Paris. Memoirs, which may be written or printed, may be in French, English, or German. They must be sent by August 15th, 1914, to the Bureau des Annales d'oculistique, 26, Boulevard Raspail, Paris.

THE Cremation Society of Geneva, which celebrated the twentieth anniversary of its foundation in November, 1912, has decided to present M. Burkhard Reber, its President, with a gold medal in commemoration of his strenuous labours for the advance of cremation during the last quarter of a century. M. Reber was the first to propose the establishment of a cremation society with its headquarters at Geneva. He met with much opposition from different quarters, and many difficulties had to be overcome. His persistence, however, overcame all obstacles, and cremation has now conquered its rightful place in Geneva. M. Reber has taken an active part in the propaganda in other parts of Switzerland and foreign countries. M. Reber, who is a pharmacist by profession, has a fine collection of antiquities relating to the history of medicine, pharmacy, and the natural sciences.

IT appears from an address recently published by Dr. Louis Stricker that an "Optometry Bill" was passed by the Ohio Legislature but vetoed by the Governor. A large fund had been collected by the opticians in the United States, and Dr. Stricker says that "it was not all used to engage learned counsel," and expresses regret that some medical men refer patients to these unqualified practitioners for refraction, and that some oculists accept commissions from opticians for the patients they send to them to have glasses fitted. It is necessary that the public shall be educated in the difference between the qualified medical men who are ophthalmic experts and the advertising spectacle vendors, but Dr. Stricker went on to say that some doctors who had had no special ophthalmic training posed as experts, and brought the whole profession into disrepute. Sooner or later he hoped that legislation would be introduced compelling all men calling themselves specialists in ophthalmology to pass an examination such as has been inaugurated by the Universities of Oxford, Liverpool, and Colorado.

THE Head Master of Eton lectured on Eugenics, Ethics, and Religion before a large audience at the May afternoon meeting of the Eugenics Education Society, which was held at the Grafton Galleries on May 8th. Canon Lyttelton said that the science of eugenics was concerned with racial development, and dealt with the past in a scientific way, hoping to extract from it lessons for the future, and emphasized the sense of the preciousness of human life, which was the direct outcome of Christianity. The eugenist should be welcomed in the religious training of the young, since he could show how vigorously science corroborated the true principles of child training; but the Christian could hardly be expected to welcome biology unless it came as an addendum to something deeper and more personal. The eugenist and the Christian were so near together, however, that there should be no difficulty about co-operation between them. The Christian could not say that his religion was not concerned with the bodily health of the present and future generations; and the Divine example warranted us in believing that we were intended to beautify, refresh, and cheer the lives of others in this world, and not only to prepare them for the next. In so far as we believed the eugenic principle to be true, we should plant it in young minds for its own sake, and not primarily because its outcome would be beneficial to humanity. If disloyalty to a common faith had been the real cause of the social disorders around us, then a return to our faith must be fraught with almost infinite hope. If what he conceived to be possible came to pass, there would be a saving revival of home life and training in England; but in the meantime we had to deal with innumerable young lives which had been in those respects stunted and starved. It could not be wrong to try to apply the principle of foster-parents, and huge though the sum total of failures might be, it must not be doubted that every worker who tried to quicken the lives of young people by inspiring them with the touch of love was doing his utmost to spread a great truth. It might be the truest eugenics to revive in every class of society the meaning of home as a place where the seeds of physical, moral, and

spiritual life were sown. Unless ideas of home were spread and deepened in the next hundred years the outcome must be the decay of the people.

At a well-attended dinner of the medical profession of Wigan and district held on May 8th. Dr. Monks, J.P., in the chair, a cheque for £50 was presented to Dr. Campbell, who has acted as secretary of the Local Medical Committee since the passing of the Insurance Act, and has expended much time and energy in securing equitable treatment for the medical profession in the area. As the chairman pointed out, the cheque would but barely recompense Dr. Campbell for the out-of-pocket expenses which he has incurred on behalf of his colleagues. Amongst those present were the Chairman and ex-Chairman of the Division (Wigan) of the British Medical Association, the Chairman and Honorary Secretary of the Wigan Medical Society, and Dr. John Campbell, Assistant Lecturer on Anatomy at the University of Liverpool, and brother of the guest of the evening.

THE members of the Dover Division of the British Medical Association entertained Dr. F. B. Hulke at a complimentary dinner on May 8th. when the Chairman, Dr. Charles Wood, presented to him a silver rose bowl, subscribed for by members of the Division as well as other members of the profession in the district, as a recognition of their gratitude to him for the ungrudging manner in which he had given his time and services, on their behalf, as a member of the Kent County Medical Committee since its formation. The toast having been duly honoured, Dr. Hulke thanked the subscribers and said he would always most highly value the gift and the feeling which had prompted it. After referring to the struggle through which the profession had passed during the last two years, a struggle which he believed was still in its infancy and likely to become more strenuous, Dr. Hulke urged on those present the necessity for perfecting their organization and binding themselves together, each individually supporting his neighbours. In the meantime they must remember that, though they were few in numbers, and their votes were not likely to turn any election, and that, for this reason, they were liable to be overlooked by both sides in party politics, still the profession possessed immense influence, if it only took the trouble to use it. The great mass of the people, the insured and their families, and the employers as well as the employed, must be won over.

DR. NEVILLE CROWE, Honorary Secretary of the Worcester Division, was entertained at a complimentary dinner on Friday evening, May 9th, and presented with a purse of gold and a silver salver bearing the inscription, "Presented to H. Neville Crowe by members of the Worcester Division of the British Medical Association in recognition of his services as their Representative, May 9, 1913." Dr. Stretton (Kidderminster), who presided, in making the presentation said that Dr. Crowe, who had carried on the duties of secretary in troublous times with such remarkable success, must have inherited his capacity from his father, who for twenty-six years had been honorary secretary of the Worcestershire and Herefordshire Branch. The improvements effected in the conditions of medical benefit as compared with those laid down in the bill as introduced, and the increased remuneration, were due to the action of the various Divisions and their secretaries throughout the country, and among those officers no one had worked harder than Dr. Crowe. Seventy-seven members of the Division had subscribed in order that Dr. Neville Crowe should have some tangible reminder of the work he had done. Dr. Crowe, in acknowledging the compliment and the gift, said that members of the Association had reason to congratulate themselves upon having been able to convince Mr. Lloyd George that he had underestimated the amount which should be paid to the medical profession for the work it was required to do. Even now, however, although the profession had undertaken to carry out the work at a certain price until January, 1914, the Government, as represented by the Insurance Commissioners, was trying to make certain deductions from the amount agreed to be paid. There were, however, two sides to every contract. Dr. Crowe also said that certain Insurance Committees seemed to consider that they had no responsibility to pay the doctor for those persons who had not yet exercised their right of choice, but the profession was responsible for the treatment of any person who presented the insurance card, and would therefore expect to be paid for every insured person from January 15th, 1913. It was essential that every doctor should keep the records required by the Government, for there might be an attempt to cut down the contract price in the future.

Letters, Notes, and Answers.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Articlegg, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National):—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

OMEGA asks for suggestions as to the etiology and treatment of pain in the back experienced by a patient on rising and throughout the day. Its locality can be covered by placing the hands over and on either side of the spine about the level of the waist belt. The kidneys are not movable, and all organs, as well as the spine, are apparently healthy. The patient, a domestic servant aged 35, presents no evidence of hysteria or of rheumatism of the joints, and though spare and of poor muscular development seems otherwise healthy.

LETTERS, NOTES, ETC.

A MEMBER of the British Medical Association, who died not long ago, left behind him a complete series of all the issues of the BRITISH MEDICAL JOURNAL from 1874 to 1910. They are well bound in half-yearly volumes, and the administrator of the deceased member's estate is willing to present them to any medical man or institution desirous to possess them. His name and address can be obtained on application at the office of the Association.

THE WATERS TESTIMONIAL FUND.

THE Honorary Secretary of the Bootle Ward of the Liverpool Division of the British Medical Association (Dr. J. Walker) forwards the following letter of thanks for publication:

On behalf of Mrs. Waters and the trustees of this fund, we beg to acknowledge with grateful thanks the liberal response of the members of the Liverpool Division to the appeal which we circulated last month. Subscriptions amounting to £63 6s. have been received since the issue of the circular, which, added to the amount previously subscribed, makes a total of £243 7s. 6d. It is proposed to use the fund for the education of the children of the late Dr. Waters, both girls, aged 11 and 6 years respectively.

E. J. CLAXTON.
J. DUNN.
J. WALKER.

MEDICAL EVIDENCE.

LAWYERS are in the habit of scoffing at medical evidence, unless it happens to be on their side. It cannot be denied that doctors sometimes cut a sorry figure under the ordeal of cross-examination by a keen-witted counsel. Sometimes the tables are turned, as when a much-badgered physician said, in reply to a suggestion that the mistakes of doctors are often buried underground, that the mistakes of lawyers were sometimes hung above it. We have come across another instance of a doctor scoring off counsel in the *South African Medical Record*. A medical witness in a Western State of America was giving evidence in a case of murder. One of the jurymen asked him whether the accused "had anything wrong with his head." "Yes," said the doctor, "he was the subject of old-standing and severe alopecia praesentilis." Counsel did not press the examination on this point further, and although the case for the prosecution was conclusive the accused was acquitted by the jury, who were under the impression that the man was not responsible for his actions.

CORRECTION.

IN the report of a case of abdominal aneurysm by Dr. J. Rupert Collins and Mr. C. Braine-Hartnell, published last week, it was stated, under the heading "Post-mortem Examination" (p. 983), that "The lower end of the wire was tucked away inside the aneurysm immediately outside the end of the liver." For "end of the liver" read "endothelium."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restante* letters addressed either in initials or numbers.

A Clinical Lecture

ON

THE TREATMENT OF PERNICIOUS ANAEMIA.

DELIVERED AT THE ROYAL INFIRMARY, EDINBURGH.

BY

BYROM BRAMWELL, M.D., F.R.C.P.E., LL.D.,
F.R.S.E.,

PHYSICIAN TO THE CHALMERS HOSPITAL, EDINBURGH; CONSULTING
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH.

I BEGAN the study of pernicious anaemia now almost forty years ago, when I was physician to the Newcastle-on-Tyne Infirmary. In the year 1874 two cases of profound anaemia were admitted to the Newcastle Infirmary under my care; both died, as these cases so often do. The disease was then very little known in this country, though it had been described by the celebrated Dr. Addison. He met with a number of cases of fatal and apparently causeless anaemia; he termed it "idiopathic anaemia," and it was while hunting about in the bodies of patients after death to try and find the cause of this peculiar form of anaemia that he discovered the remarkable lesion of the suprarenal capsules which is the pathological substratum of the disease, which we now, of course, all know as Addison's disease.

The terms "pernicious anaemia" and "progressive pernicious anaemia" were subsequently given to the idiopathic anaemia described by Addison, for it was found—as, indeed, he had found—that the patients suffering from this form of anaemia always, or almost always, died, whatever the form of treatment employed. Addison failed to discover any cause for this profound and fatal anaemia, and we are still ignorant of its exact cause.

Now, profound anaemia arising without any loss of blood or other apparent cause may, theoretically at least, be due to one or other of two great causes—namely, either a defective production or an excessive destruction of the red blood corpuscles. Either of these two conditions may, when acting in a marked degree, produce a very profound form of anaemia.

About the time that I commenced the study of pernicious anaemia a celebrated American physician, Dr. Pepper, Professor of Medicine, and afterwards Principal or Provost of the University of Pennsylvania, described the lesion in the marrow of the bones found in the bodies of patients who have died of pernicious anaemia. He termed the disease "myelogenous anaemia," for he thought it was due to defective production of red blood cells in the bone marrow. The bone marrow is, I need not say, the most important red-blood-producing structure. Pepper thought that this lesion in the bone marrow was the fundamental lesion of the disease.

Some years later, when I was assistant physician to this infirmary, I had as one of my assistants Dr. William Hunter, who has identified himself with the subject of pernicious anaemia. While he was my assistant in the out-patient department he made a series of very important observations with regard to the *post-mortem* findings in pernicious anaemia and with regard to the artificial production of anaemia in animals. He came to the conclusion that pernicious anaemia is not due to defective formation of red blood corpuscles in bone marrow, as Pepper had supposed, but to excessive destruction of the red blood cells in the portal circulation. In proof of this he advanced the fact that the liver in pernicious anaemia shows a large excess of iron.

In my early studies of pernicious anaemia I paid particular attention to the condition of the blood. I found that the red blood corpuscles, instead of being biconcave, circular discs, all about the same size, varied greatly in size and shape, some being larger, some smaller than the normal, and many of them misshaped in various ways—poikilocytosis, as it is now termed—some of them apparently nucleated. I described and figured this condition in the *Edinburgh Medical Journal*. The nucleated condition of the red corpuscles, as I took it to be—in unstained films parts of some of the corpuscles are more

deeply pigmented than normal—was subsequently shown to be merely an apparent, not a true nucleation, due to a concentration of the haemoglobin in a particular part of the corpuscles. But we now know that in many cases of pernicious anaemia some of the red blood corpuscles, stained by methylene blue and eosin, are actually nucleated; indeed, this nucleated condition of the red corpuscles is a characteristic feature of the blood in many cases of pernicious anaemia; but it is not the condition I described.

When Dr. Hunter told me of his researches and of his view that pernicious anaemia is due to an excessive destruction of red blood corpuscles in the portal circulation, I asked him how he accounted for the enormous number of small, immature, imperfectly-formed red blood corpuscles which is such a striking feature of the blood in pernicious anaemia—the presence in the blood of so many immature red blood corpuscles seems to show that there is a defective formation of red cells. He met that argument in, I think, a perfectly legitimate and satisfactory way. He said if you destroy at one end of the circulation, say in the portal circulation, an enormous number of red blood cells, you call upon the bone marrow—the red-blood-forming tissue—for an excess effort, with the result that a great number of immature and imperfectly-formed red blood corpuscles are thrown into the circulation. That certainly seems a plausible explanation, but it is not, perhaps, the whole truth.

We may take it, then, that there is excessive destruction of red blood corpuscles in the portal circulation, together with an excessive production of immature and imperfectly-formed red corpuscles in the bone marrow. Free iron is liberated and is stored up in the liver—this is seen *post mortem*. The bone marrow is called upon to produce an excessive quantity of red blood cells, and it is, as we know, found on *post-mortem* examination to be in an abnormal condition. The destruction of the red corpuscles in the portal circulation is probably due to the presence of some toxin, which is probably absorbed from the gastro-intestinal tract. But, if this is so, we do not know what the toxin is.

Now it is possible that the toxin which destroys the red blood corpuscles in the portal circulation also stimulates the bone marrow to excessive formation of red blood corpuscles, or perhaps acts injuriously upon the bone marrow; and, if this be so, the lesion in the bone marrow is not merely a compensatory effort to meet the excessive destruction of red blood cells which is undoubtedly present; it is not merely a secondary lesion, but is, in part at least, a primary lesion.

The bodies of persons who have died from pernicious anaemia are extremely bloodless; the tissues are very often stained yellow—canary or primrose yellow; the most characteristic naked-eye lesion is the fatty condition of the organs, particularly of the heart; the thrush-breasted or faded-leaf appearance of the muscle of the left ventricle is highly characteristic. In many cases small petechial haemorrhages are scattered throughout the body—in the retina, on the surface of the heart, lungs, brain, for example. Professor Stockman of Glasgow suggested some years ago that these haemorrhages are the cause of pernicious anaemia. But that is not so; they are merely secondary—a consequence not a cause of the condition. In some typical cases of pernicious anaemia no petechial or other haemorrhages are found on *post-mortem* examination.

In the fatal cases of pernicious anaemia which I examined *post mortem* in 1874, I was struck by the fatty condition of the heart. I knew that arsenic is a remedy which is often very beneficial in cases of fatty heart, and I said to myself, Why should one not try arsenic in cases of pernicious anaemia? I tried it, with very marked success.

During 1875 six cases of pernicious anaemia were admitted under my care in the Newcastle-on-Tyne Infirmary; all of them were treated with arsenic. One of these early cases lived for thirteen and a half years, and ultimately died of the disease, having had several relapses. That patient lived, I think, longer than any other case which has come under my notice.

It is a very remarkable fact that the first cases which one treats with any new remedy are often singularly successful. My experience of the thyroid treatment of

psoriasis shows this. In the first case of myxoedema which I treated by thyroid I gave too large doses, and produced acute thyroidism; it was attended with profuse desquamation of the skin. I argued that if thyroid tissue—I was then using the raw gland—could produce this extraordinary desquamation in myxoedema, it would probably be of use in psoriasis and other skin diseases. In the first three cases of psoriasis in which I tried it the result was remarkable. The extraordinary success in these first cases led me to think that I had made a remarkable discovery. There is no doubt that it was a discovery and advance, for many cases of psoriasis and certain other skin diseases are very greatly benefited by thyroid treatment, but the remedy is an uncertain one. Some cases of psoriasis are cured by it, or temporarily cured by it; others are not. I have had many successful and many unsuccessful results. I mention this for the purpose of showing how careful one should be in drawing therapeutic or indeed any other conclusions from a limited number of cases. I will give you another example—a remarkable coincidence which shows how fallacious it is to reason from a limited number of cases. Of the first 7 cases of pernicious anaemia which I treated by salvarsan three were women and four were men. The names of all the women began with P, and the names of all the men with S. Now if one limited oneself to these facts, and if one were dealing with a new disease one might perhaps argue that the names of all women affected with pernicious anaemia begin with P, and the names of all men affected with pernicious anaemia begin with S. This, of course, is a bizarre illustration, but it shows what I mean.

Since I began to treat pernicious anaemia with arsenic in 1875 I have had a long and continuous experience of this and other methods in the treatment of this very grave and fatal disease. The result has been to show that cases of pernicious anaemia, if they are first attacks, usually do exceedingly well under arsenical treatment; that many of them get apparently quite well, but that, with very few exceptions, they relapse and ultimately die of the disease. The remedy seems to lose its effect and to be much less efficacious in the relapses than in the primary attacks. Consequently, we want some better remedy than arsenic for pernicious anaemia.

Dr. William Hunter has directed attention to the condition of the mouth and tongue, and emphasized the importance of oral sepsis. I think he has attached far too much importance to this point. I have seen and published several cases of pernicious anaemia in which there were no decayed teeth, and in which for years before the onset of the disease the patient had had no teeth. I have seen several cases in which there had never been any ulcers on the tongue or any inflamed or irritative condition of the buccal mucous membrane; I look upon the ulcers in the mouth merely as part and parcel of the disease, perhaps due to the same toxin which destroys the red blood cells, but not the primary, or even a predisposing, cause of the disease.

In addition to arsenic, a great number of other remedies have, of course, been employed in the treatment of pernicious anaemia. Iron has been given, but in the great majority of cases it does harm rather than good. One would expect this from the condition of the blood in pernicious anaemia.

In the normal male the red blood corpuscles number 5,000,000 per cubic millimetre, the haemoglobin equals 100 per cent. (with Gowers's instrument, which we use, we rarely get 100 per cent.), and the colour index, which represents the percentage of haemoglobin divided by the percentage of red corpuscles, equals 1 ($\frac{C.I. 100}{R.C. 100} = 1$). In pernicious anaemia there is an enormous diminution of the red blood cells; in an average well-marked case the red blood corpuscles number 1,000,000 instead of 5,000,000; the haemoglobin equals 30 per cent. or more; and the colour index is consequently above the normal 1.5 or more ($\frac{C.I. 30}{R.C. 20} = 1.5$). The haemoglobin is in many cases much higher than this; in some cases the colour index is 2 or even more.

In chlorosis, another form of idiopathic anaemia, the red blood corpuscles usually number about 3,500,000 per cubic millimetre (the average normal number of red corpuscles in the female is 4,500,000); the haemoglobin is

about 50 per cent., and the colour index is often about 0.5 or less.

There is, then, this striking difference between chlorosis and pernicious anaemia, that in chlorosis each red cell contains on an average about half the normal amount of haemoglobin, whereas in pernicious anaemia it contains more than the normal amount of haemoglobin. Consequently, the indication is to give iron in chlorosis; and we find, as a matter of fact, that iron is a specific in that disease. But if you give iron in pernicious anaemia, if you stuff the red cells, which already contain too much iron, with more iron, you do harm rather than good. There are, however, some cases of pernicious anaemia in which iron seems to do good, but they are quite exceptional. I have published some cases of this kind.

Intestinal antiseptics, such as beta-naphthol and bismuth, also have been tried, and in some cases the result has been satisfactory. Treating the mouth, removing bad and decayed teeth and stumps, keeping the mouth so far as possible in an aseptic condition, has been insisted upon by Dr. Hunter. It should certainly be done, for a bad condition of the mouth may do harm and cannot do good.

None of the remedies which have been used, with the exception of arsenic, have stood the test of a prolonged trial. Experience has, I think, shown that arsenic is the only remedy which up to the present time has afforded any real benefit in the treatment of pernicious anaemia, but its beneficial effects are in the great majority of cases only temporary.

Two or three years ago salvarsan was introduced by Ehrlich for the treatment of syphilis; it contains arsenic and mercury. After seeing the remarkable effects of this remedy in some cases of syphilis, I thought that possibly it might give as good or better results in pernicious anaemia than the ordinary arsenical treatment—Fowler's solution by the mouth. In giving arsenic by the mouth, I begin with small doses—2 minims of Fowler's solution, three times a day after food—and gradually increase the dose by an extra drop every fourth or fifth day until the maximum which the patient can take is reached. This dose varies greatly in different cases; it is 10 or 12 drops in most cases, and 16 or 20 drops in some cases, three times a day. I push the remedy until I find the maximum dose which the individual patient can take; I then go on with that dose for several weeks. In some cases intestinal disturbance, particularly diarrhoea, is produced even by small doses; I have found in these cases that by combining a small dose of morphine—an eighth of a grain or less—with each dose of the arsenic, the arsenic is usually quite well borne.

Further, one must remember that if one gives arsenic in large doses for a long period of time one runs the risk of producing arsenical neuritis—a very serious condition; I have seen it produced in several of my cases of pernicious anaemia. But some risks must be run. Pernicious anaemia, if allowed to go on, will certainly kill the patient.

I commenced the salvarsan treatment of pernicious anaemia in October, 1910—two and a half years ago—and have treated eleven cases with salvarsan, with, on the whole, most remarkably beneficial effects. I will show four of the patients and briefly describe the results in all of the cases.

CASE I.

A man, J. S., aged 49, married, an electric hoist man, formerly a soldier, was admitted to the infirmary in October, 1910; I had seen him in October, 1909, and had then prescribed arsenic by the mouth. He presented all the characteristic features of pernicious anaemia. The red blood corpuscles numbered 1,035,000 per cubic millimetre, the haemoglobin equalled 30 per cent., the colour index was 1.5. He had four injections of salvarsan (December 21st, 0.2 gram; January 5th, 1911, 0.3 gram; January 19th, 0.3 gram; February 9th, 0.3 gram.) I may say that I have in all cases injected the remedy into the gluteal muscles; in none of my cases has the intravenous method been employed. He was discharged from the infirmary on February 22nd, 1911, looking and feeling perfectly well; all the anaemic symptoms had disappeared. The red blood corpuscles were then 3,580,000 per cubic millimetre, the haemoglobin equalled 78 per cent., and the colour index was 1.1. He has remained quite well and has been working regularly ever since. I saw him last, on March 7th, 1912; the red blood corpuscles then numbered 4,580,000 per cubic millimetre, the haemoglobin equalled 94 per cent., and the colour index was 1. When I saw him last, on March 7th, 1912, he had, in consequence of the railway strike, to walk ten miles to get here in time for the clinic. He was perfectly fit and fresh after the ten-mile walk.

You will see that he looks quite well. He tells me that he has been quite well and working regularly every day since March, 1912.*

CASE II.

A woman, Mrs. P., aged 40, was admitted to the infirmary on November 15th, 1910, suffering from all the characteristic symptoms of pernicious anaemia. On November 15th, 1910, the red blood corpuscles numbered 990,000 per cubic millimetre, the haemoglobin equalled 30 per cent., and the colour index was 1.6. She had four injections of salvarsan (December 24th, 1910, 0.3 gram; January 7th, 1911, 0.3 gram; January 24th, 1911, 0.3 gram; February 9th, 0.3 gram). She made an uninterrupted recovery and was discharged from hospital on March 16th, 1911, looking and feeling well. Her red corpuscles then numbered 4,420,000, the haemoglobin equalled 94 per cent., and the colour index was 1.1. When her blood was counted last, on March 7th, 1912, the red corpuscles numbered 6,210,000 per cubic millimetre, the haemoglobin equalled 120 per cent., and the colour index was 0.97. Now this is the only case of pernicious anaemia I have seen in which the red corpuscles have gone above the normal as the result of treatment. I will now show you this patient, whom I have not seen for a year. She looks, you will see, the picture of health. She states that during the past year she has been perfectly well, with the exception of several attacks of biliary colic.

CASE III.

This case was a very severe one. A woman, Mrs. P., aged 56, was admitted to the infirmary on March 30th, 1911, apparently in a dying condition; the red blood corpuscles numbered 680,000 per cubic millimetre, the haemoglobin equalled 18 per cent., and the colour index was 1.3. She had two injections of salvarsan (April 6th, 0.3 gram; May 4th, 0.3 gram). All of us who watched the case were profoundly impressed with the remarkable improvement in her appearance and symptoms which followed the treatment; the red corpuscles went up to 1,020,000, the haemoglobin to 28 per cent., and the colour index was 1.4. She discharged herself on July 25th; she relapsed and died on September 5th, 1911.

CASE IV.

This was a remarkable case. A woman, Mrs. P., aged 41, was admitted to the infirmary on March 28th, 1911. The red blood corpuscles numbered 695,000, the haemoglobin equalled 16 per cent., and the colour index was 1.15. She had two injections of salvarsan (April 6th, 0.3 gram; April 21st, 0.3 gram). On May 5th she had to go home to look after her house and children, one of whom was ill. She was in poor circumstances, she had to nurse her sick child and do all her housework, washing, etc. On her discharge from hospital the red corpuscles numbered 1,495,000 per cubic millimetre, the haemoglobin equalled 34 per cent., and the colour index 1.2. Well, she went home; I never expected that she would improve, and did not hear of her again till May, 1912. She was unable to leave her children and come into hospital for further salvarsan treatment, and on May 23rd, 1912, I sent her a prescription for arsenic—2 minims of Fowler's solution three times daily. She only took two bottles of the medicine, and has had no treatment since. I have seen her from time to time. I was able, through the kindness of some friends, to get up a small fund in order to enable her to live more comfortably. She has made a splendid recovery. On January 18th, 1913, the red corpuscles numbered 4,060,000 per cubic millimetre, the haemoglobin equalled 74 per cent., and the colour index was 0.91. You will see that she looks remarkably well. She tells me that she feels perfectly well, and has since her discharge from hospital done all her housework without any assistance.

On March 1st, 1913, the patient wrote to me as follows: "In reply to your letter of the 28th February, I hope you will not be displeased when I tell you that I have only taken two bottles of the medicine, and just started to take the third one now. I have not been taking it constantly. Doctor, I thought I would just tell you that I have never had to call in the doctor for myself since I left the Royal Infirmary, and this is the first two years in my life, as far back as I can remember. It is out of a full heart of gratitude I thank you again for your great skill and kindness shown towards me and my humble home."

This is a very remarkable case, because when the patient was discharged from hospital she was very ill—profoundly anaemic, feet swollen, etc.—and she had to struggle on under great disadvantages.

CASE V.

A man, W. S., aged 50, was admitted to the infirmary on May 12th, 1911, suffering from profound pernicious anaemia. He had two injections of salvarsan (May 15th, 0.3 gram; June 19th, 0.3 gram). Slight improvement followed the first injection, but the improvement was only temporary; he died on June 24th, 1911. In this case the treatment produced no benefit.

CASE VI.

A man, P. S., aged 31, was admitted to the infirmary on May 17th, 1911, with very marked pernicious anaemia. The red blood corpuscles numbered 955,000 per cubic millimetre, the haemoglobin equalled 26 per cent., the colour index was 1.4. He had three injections of salvarsan (May 29th, 0.3 gram; June

12th, 0.3 gram; July 12th, 0.3 gram), but he did not improve, and went home, we thought to die, with his red cells numbering 600,000 per cubic millimetre, haemoglobin 19 per cent., and the colour index 1.6. In this case salvarsan seemed to do no good whatever while the patient was under treatment in the hospital. After going home, he remained semicomatose for ten days. He then began to improve and ultimately got apparently perfectly well. When I saw him on November 11th, 1911, he looked quite well; his red blood corpuscles numbered 3,100,000 per cubic millimetre, the haemoglobin equalled 66 per cent., and the colour index was 1.1. He had no treatment for the anaemia after leaving the hospital.

He remained in good health, without any return of the anaemia, until February, 1912, when he died from acute croupous pneumonia.

I am not going to affirm that this extraordinary improvement was the result of the salvarsan treatment, for we occasionally see cases of pernicious anaemia which show those very remarkable alterations and improvements. At the same time I cannot altogether rid my mind of the idea that the salvarsan was, perhaps, the cause of the improvement, for in two cases which have proved fatal, and have been examined *post mortem*, the salvarsan was found to be encapsuled in the buttock, and much of it unabsorbed, even after a very considerable time. I think it is quite possible that the long-continued improvement which has resulted in many of the cases which I have treated with salvarsan is probably due to the slow and gradual absorption of the remedy. If that is so, the extraordinary improvement in this case may perhaps have been the result of the salvarsan treatment.

CASE VII.

T. S., aged 55, was admitted to the hospital on October 24th, 1911, suffering from profound pernicious anaemia. His red blood corpuscles numbered 790,000 per cubic millimetre, the haemoglobin equalled 27 per cent., and the colour index was 1.7. It was a very bad case indeed. He had one injection of salvarsan (October 27th, 0.3 gram), and a fortnight afterwards his red blood corpuscles had doubled—1,460,000 per cubic millimetre, the haemoglobin equalled 25 per cent., and the colour index was 0.8. He then unfortunately took an attack of bronchopneumonia and died.

Since I left this infirmary I have had some further experience in the salvarsan treatment of pernicious anaemia.

CASE VIII.

This was an extremely severe case of pernicious anaemia in a young man of 25; it was of three years' duration (it is very unusual for pernicious anaemia to develop at such an early age—22). It was one of the most severe cases I have ever seen. The patient was admitted to Chalmers Hospital on October 3rd, 1912; he had two injections of salvarsan (October 6th, 0.3 gram; October 12th, 0.3 gram); there was no improvement. He died on October 14th, 1912.

Now, in a severe case of pernicious anaemia—and the same statement applies to every grave organic disease—one must expect to find many failures from any plan of treatment, however successful it is in the great majority of cases. I do not claim that salvarsan will produce improvement in every case of pernicious anaemia, but I do say that it does produce remarkable improvement in a very considerable proportion of cases.

CASE IX.

A man, J. C., aged 72, was admitted to Chalmers Hospital on August 30th, 1912, suffering from very severe pernicious anaemia. His red blood corpuscles numbered 1,055,000 per cubic millimetre, the haemoglobin was 26 per cent., and the colour index 1.3. Although 72 years of age, he improved remarkably under this treatment. He had three injections of salvarsan (August 31st, 0.3 gram; September 14th, 0.3 gram; September 28th, 0.6 gram). He was discharged on November 27th, 1912; his red blood corpuscles then numbered 3,450,000 per cubic millimetre, the haemoglobin equalled 75 per cent., and the colour index was 1.

I intended to have brought this patient before you today, but I hear he is not well enough to come; whether it is simply a relapse of his old trouble or something else I do not know; but, be that as it may, the beneficial effects of the treatment in that case were very striking.

CASE X.

A man, J. T., aged 59, was admitted to Chalmers Hospital on December 12th, 1912, suffering from very profound pernicious anaemia with oedema of the feet, etc. His red corpuscles numbered 1,045,000 per cubic millimetre, the haemoglobin equalled 24 per cent., and the colour index was 1.14. He had two injections (0.3 gram of salvarsan on December 13th, 1912, and 0.3 gram of neo-salvarsan on January 9th, 1913.) He is now quite well. He looks the picture of health. On February 14th,

* Cases I to VII are fully reported in the BRITISH MEDICAL JOURNAL, June 22nd, 1912.

1913, his red corpuscles numbered 3,900,000 per cubic millimetre, the haemoglobin equalled 86 per cent., and the colour index was 1.1. This is one of the most successful cases I have had.

CASE XI.

A man, J. R., aged 53, was admitted to Chalmers Hospital on January 11th, 1913, suffering from moderately severe pernicious anaemia. His red corpuscles numbered 1,690,000 per cubic millimetre, the haemoglobin equalled 43 per cent., and the colour index was 1.4. He has had two injections of neo-salvarsan (January 14th, 1913, 0.5 gram; February 14th, 0.5 gram). Up to the present time the improvement in this case has only been slight, but sufficient time has not yet elapsed to allow of a definite statement regarding the result. On February 6th his red corpuscles numbered 2,490,000, the haemoglobin equalled 67 per cent., and the colour index was 1.2.

CASE XII.

Another case, which is perhaps a case of pernicious anaemia, though the diagnosis is somewhat uncertain, is that of a man aged 42. He was admitted to Chalmers Hospital on December 16th, 1912, suffering from subacute combined paralysis and a moderate amount of anaemia (the red corpuscles numbered 2,750,000 per cubic millimetre, the haemoglobin equalled 80 per cent., and the colour index was 1.4). The high colour index is very suggestive that the anaemia is of the pernicious type. He has had two injections of neo-salvarsan (December 23rd, 1912, 0.4 gram; January 24th, 1913, 0.4 gram). There has been a slight improvement in the condition of the blood, but no improvement in the nervous symptoms.

I mention this last case as I am anxious to give my full experience—every case in which I have employed this treatment—whether the result has been satisfactory or not.

I have now given the results of eleven cases of undoubted pernicious anaemia, and of one doubtful case treated by salvarsan; of the eleven undoubted cases, four have been apparently completely cured—whether in these cases a relapse will occur or not I am, of course, quite unable to say; in two cases there was very striking improvement; in one case there was very considerable improvement, but ultimately a relapse and death; in one case there was slight improvement and death from bronchopneumonia while under treatment; in two cases there was no improvement; and in one case slight improvement, the patient being still under treatment. In the case of subacute combined paralysis associated with anaemia (perhaps pernicious anaemia), I tried the remedy as a last resource, though I did not expect it to beneficially affect the spinal lesion.

These results are very striking and very encouraging. I have had nearly forty years' experience of the ordinary arsenical plan of treatment of pernicious anaemia, and I have the greatest confidence in saying that the salvarsan treatment, so far as my present experience enables me to judge, is superior to the ordinary arsenical treatment. Further experience is, however, required before one can say whether the beneficial effects, which it undoubtedly produces in many cases, will be lasting or merely temporary.

In giving salvarsan I have always given it intramuscularly. In syphilis the usual way is to give it intravenously. In syphilis we know there is a definite organism, and we want to kill that organism as rapidly and as effectually as possible. In the treatment of syphilis the usual plan is to inject 0.6 gram of salvarsan into a vein. In primary and secondary syphilis the results are quite remarkable; relapses occur, however. The results in some of the tertiary cases are not so satisfactory as was at one time supposed. The results of salvarsan treatment in such conditions as tabes and general paralysis of the insane—parasyphilitic lesions—are practically *nil*. There have been different opinions expressed on this point, but I think the experience of the great majority of reliable physicians is that in tabes and general paralysis of the insane salvarsan is of little or no use.

In pernicious anaemia I have employed the intramuscular method of administration, for, in this disease, we want, I think, a remedy which will produce sustained and continued effects. We do not know what the toxin is which appears to be the cause of pernicious anaemia—whether a germ toxin or a chemical toxin. The dose I have always employed has been 0.3 gram, half the dose which is usually given in syphilis. In severe and advanced cases of pernicious anaemia, in which the patient's hold of life is very precarious indeed—and this was the condition in many of the cases I have brought before you—a very

little thing will turn the scale. I have therefore hesitated in these cases to give the remedy by the intravenous method.

In some cases the salvarsan, when given intramuscularly, produces very considerable inflammation, pain, and swelling; but the neo-salvarsan seems to be much more satisfactory in this respect—it does not produce such marked local results. In the cases in which I have used neo-salvarsan I have found that there is little or no local pain or hardness, and little or no rise in temperature. In the meantime I shall continue to give the remedy intramuscularly.

ADDENDUM (May 7th, 1913).

CASE IX.

This patient was readmitted to Chalmers Hospital on March 3rd, 1913, suffering from a severe relapse. The red blood corpuscles numbered 1,010,000 per cubic millimetre; haemoglobin 36 per cent.; colour index 1.7. As the result of two injections of salvarsan he has improved very rapidly; I fear, however, that as soon as he is again discharged another relapse will in all probability occur, and that the effects of the treatment will be merely temporary.

CASE VII.

During February, 1913, this patient rapidly got worse, the paralysis passing into the flaccid stage. He died on March 22nd. *Post-mortem* examination showed all the typical appearances of pernicious anaemia.

ACUTE PERFORATION OF THE GALL
BLADDER:

WITH AN ACCOUNT OF SIX CASES.

BY

L. R. BRAITHWAITE, M.B., CH.B. VICT., F.R.C.S. ENG.
HONORARY ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY, ETC.

In these days, when the early and exact diagnosis of acute abdominal conditions is a matter of extreme importance, it is essential to form a clear conception of the characteristic signs and of the methods of treatment of even the rarest forms of abdominal catastrophe.

Although McWilliams¹ and Cotte and Arnaud² have given such excellent descriptions of perforation of the gall bladder, in nearly all its varieties, there are perhaps some points of particular interest in the cases given below.

The effect of sterile bile in the general peritoneal cavity is to destroy the bactericidal quality of serum.

In rabbits Noetzel showed that whereas a certain amount of *Staphylococcus aureus* or *Bacillus coli* or streptococci placed in the normal healthy peritoneal cavity was innocuous, a similar amount was always fatal provided the bile from the healthy gall bladder was allowed to escape into the body cavity.

Normal bile is well tolerated for a considerable time, and becomes gradually shut off by inflammatory adhesions.

In a case recorded by Garré, operation undertaken two months after the injury which ruptured the gall bladder showed a localized and large collection of bile; the patient got well. In a case recorded by Hildebrandt operation was successful twenty-three days after a tear into the hepatic duct.

Bile which escapes from a rupture in a gall bladder containing stones is not an aseptic fluid, it teems with the *Bacillus coli* or other organisms.

It is in cases in which gangrene and rupture occur in an infected gall bladder that rapid and fatal peritonitis develops. Clearly the prognosis depends chiefly upon the number, character, and virulence of the organisms present in the bile.

McWilliams, omitting the purely traumatic variety, describes three kinds of rupture of the gall bladder:

1. Rupture from over-stretching; with or without stones.
2. Perforation from pressure of stone on the wall.
3. Perforation from gangrene due to:
 - (a) Thrombosis of vessels with or without stones.
 - (b) Cutting off of circulation from pressure of stone.
 - (c) Diphtheritic, ulcerative infection of the wall with or without stone.

To these there must probably be added :

4. Subperitoneal perforation of the gall bladder with subperitoneal extravasation of bile as illustrated in Case vi.

Signs and Symptoms.

As Sir Berkeley Moynihan has frequently pointed out, in every case of gall-bladder trouble, provided the history be carefully noted, there is a complaint of flatulent indigestion over a long period.

Attacks of severe pain in the region of the gall bladder, with shivering fits of great or small intensity, may be present in nearly all cases where there is an infection of any degree of severity.

It is of great interest to find that the sudden agonizing pain characteristic of the rupture of a hollow viscus, followed by a zealous rigidity of the neighbouring body wall, does not occur in all cases; probably both conditions depend to some extent upon the virulence of the invading bile.

At the moment of perforation there is always severe pain in the region of the gall bladder, followed in two or three hours by pain referred to the umbilicus. Moynihan showed how the fluid from a perforated duodenal ulcer gravitates over the bend of the hepatic flexure to the right iliac fossa; fluid escaping from the gall bladder follows the same course, and gives rise to swelling and pain in the region of the appendix.

It is a matter of much interest and of some importance to note that the effusion of a quantity of bile of a degree of virulence sufficient to cause a peritonitis will in course of a day or two give rise to a definite fluid swelling simulating in every way an appendix abscess (Case v).

The degree of rigidity is most variable and there is hardly ever the "marble" hardness found in other abdominal catastrophes. In none of the cases seen by the writer has there been that degree of involuntary stiffness and inability to move about seen in other grave abdominal conditions.

It would appear that the absorption of bile from the peritoneal cavity slows the pulse-rate, just as absorption of bile in cases of jaundice reduces the normal pulse-rate. The pulse-rate after twenty-four hours will depend upon the virulence of the infection and the kind of peritonitis. The temperature may remain subnormal until the formation of an abscess or the onset of acute peritonitis.

Treatment.

Early operation naturally gives the best results. If one can be certain that a catastrophe has occurred, as evidenced by a clear history and by the presence of extensive rigidity in the right hypochondrium, operation should be undertaken at once, before a rise in pulse-rate indicates a considerable extent of peritonitis. The presence of dullness in the right flank would necessitate immediate operation. To be able to say with certainty that there is a perforation of the gall bladder in the early stage, and not a condition of cholecystitis, is probably impossible. So long as the rigidity does not extend beyond the neighbourhood of the gall bladder and so long as the pulse-rate keeps below 95 the case should be watched.

It is of great assistance in helping to come to this decision if the patient lies easily and placidly in his bed and moves about in comfort.

It may happen (Case v) that the condition rapidly settles down within a few hours, and in a few days there is left a localized, dull, tender swelling in the appendix region.

The incision must be vertical, splitting the rectus of the right side. It is an easy matter to extend the incision up or down as required.

In Case iv there was well-marked oedema of the subcutaneous tissues and staining by bile. To quote McWilliams:

He who is the keenest observer of the conditions found in the abdomen, who can best estimate the virulence of the infection present, the degree of adhesions, and the pathological conditions present in the gall-bladder system, who can make a good mental estimate of how much or how little the patient can stand, who can get in the quickest, inflicting the least possible trauma, will have the greatest successes in these trying cases.

If the gall bladder can be easily and quickly removed, this should be done in every case where there is gangrene present. A large maroon gall bladder with a perforation

and containing stones may be emptied and drained after widening the perforation. If there be a stone in the cystic duct, the gall bladder should be removed if circumstances permit (Case iv).

A small contracted gall bladder is difficult to remove at any time, and it would be well in most cases to open, empty, and drain rather than make any attempt to remove. In many cases it is quicker to remove the gall bladder than to drain it. Mere suture of the perforation should never be attempted.

Cholecystotomy gives the best immediate results, 60 per cent. recovering; probably in expert hands cholecystectomy will give the best permanent results.

In all cases the right kidney pouch and the area of the cystic duct must be drained, either by stab puncture through the right loin or from the anterior wound.

If the whole abdomen is flooded with bile, as much of it as can be mopped up by hot swabs should be removed and a suprapubic tube (inserted through a separate puncture) should be pushed to the bottom of the pelvis. In every case Murphy's rectal infusion in the Fowler position must be the after-treatment.

Where the bile has collected in the right iliac fossa, in the form of an appendix abscess (Case v), the incision should be lengthened downwards, the bile and pus mopped out, and the area drained by tube through a puncture over the right anterior superior spine or through the anterior wound.

Whatever the procedure adopted it must be gently and quickly carried out. Washing out the peritoneal cavity cannot be done effectually at any time or under any conditions, and should never be attempted. The condition of the patient may be so grave (Case iv) that very rapid drainage must be obtained and removal of stones from the gall bladder left for a subsequent operation.

Statistics.

In 3,180 cases operated upon for gall stones (McWilliams) there were 29 cases of acute perforation. In 1,000 cases operated upon for gall stones at the Leeds Infirmary there were 10 acute perforations, 1 being a perforation of the hepatic duct. McWilliams records 108 cases of perforation, and to these the cases in the writer's list must be added, and 2 cases published in Sir Berkeley Moynihan's book, *Gallstones*.

CASE I.

Seen by Sir Berkeley Moynihan in consultation with Dr. Hind of Harrogate. The writer assisted at the operation.

Mr. J., aged 60, had resided in Ceylon for thirty years. Enjoyed good health until three years ago, when he became dyspeptic, constipated and depressed. Two and a half years ago he developed diverticulitis of the sigmoid with obstruction and abscess, and underwent an operation.

During the time of this illness he complained of intense pain in the right hypochondrium, and it was feared there might be some further suppuration of the nature of that dealt with at the operation for diverticulitis. He was treated with *B. coli* vaccines, and was much relieved.

In April, 1912, he had a return of his old trouble, dyspepsia and constipation, and was treated by a pill of aloes and nuxvomica.

Suddenly on April 30th he was seized with great colicky pain and sickness, and for twelve hours could not locate the trouble. The abdomen was much distended, but there was no marked resistance. He then had rigors, the temperature reaching 105° F. Distinct tenderness over the gall bladder developed, and on May 1st Sir Berkeley Moynihan saw him and decided to wait.

On May 4th Sir Berkeley operated. An incision was made vertically over the upper part of the right rectus, the muscle being split longitudinally. Much free golden yellow bile escaped. The area of the gall bladder was shut off by huge masses of intensely engorged omentum which were adherent by lymph to each other and to the liver and gall bladder.

After separating the adhesions a small circular perforation was seen, about 2 mm. in diameter, on the inferior surface of the fundus of the gall bladder. The walls of the gall bladder were thinned away at this part so that the edges of the perforation were thin as tissue paper, and were stained a brilliant orange red. Yellow bile leaked in a slow stream from the opening. The aperture was enlarged, many small stones were removed, and a tube fixed into the gall bladder. There was no marked enlargement of the gall bladder, and removal would have been difficult. The area of the right kidney was drained and the abdomen closed.

The patient made an uninterrupted recovery.

CASE II.

Operation at Leeds General Infirmary by Mr. Collinson. Mr. E. O., aged 54. At 4 a.m. on October 24th he was seized with a sudden umbilical pain. He could not rest, got up,

partially dressed, and went downstairs. He had bad pain all day long, and vomited once. Next night he had very little sleep, and several attacks of colicky pain in the body; opium was given. Next morning (October 25th) the pain was no better, abdomen getting swollen, bowels not open. At 3.30 p.m. ill, pinched, abdomen distended and tender all over, especially in the upper zone. Liver dullness present.

The history, as far as he was able to give it, was that he had been for some years subject to attacks of pain in the upper abdomen, not related to food, and associated with vomiting. He was a painter by trade, but there was no blue line and the knee-jerks were present.

The diagnosis of perforation into the peritoneum (? nature) was made.

Operation.

Incision vertically over the right rectus, about opposite the umbilicus. Appendix area explored and found normal; marked spasm of the small intestines; some free bile seen at the root of the mesentery. Incision lengthened upwards, and much bile found free in the peritoneal cavity; only one flake of mucus noted. The gall bladder was small and very adherent to the omentum; there was a small perforation of the under part at the fundus, at a spot where there were no omental adhesions. The opening was enlarged and many stones removed, and the gall bladder was drained. Large tube drain through a separate opening in the right kidney pouch.

The patient recovered and went home on November 16th.

CASE III.

Operation at Leeds General Infirmary by Mr. Collinson.

G. H. C., a man aged 62, was in a most wretched condition on admission, and was incapable of giving any history whatever.

In addition to the abdominal condition he had marked aortic stenosis, and operation was undertaken under intraspinal injection of stovaine.

Temperature on admission was 99°, pulse 110, and respirations 33. Abdomen very distended, and moved very slightly on respiration.

Operation was performed at once (May 1st). A long incision was made over the right rectus; there escaped a quantity of yellow fluid, which was part of a collection around the gall bladder. This collection was shut off by adhesions of small intestines. A few small gall stones were found loose in the peritoneal cavity. There was a small perforation on the under surface of the gall bladder. The gall bladder was drained by tube, and the area of peritoneum invaded by bile was drained by another tube. The patient lived until May 9th.

Post-mortem, marked aortic stenosis, coronary atheroma, fat necrosis, and general peritonitis were found.

The three following cases were operated upon by the writer.

CASE IV.

Seen in consultation with Dr. Hall of Dewsbury.

Mr. M., aged 64, had some history of indigestion, but none of severe abdominal pain at any time. On April 25th, 1912, he was feeling a bit "run down," with vague abdominal discomfort. During that night he woke with severe pain in the body, and on the morning of April 26th Dr. Hall saw him. At that time he had very severe pain all over the body and was rolling about the bed in agony, the abdomen was markedly distended and very tender all over, the pulse was 120 per minute, and the bowels were open. On April 27th there was definite localized tenderness over the appendix and less pain and tenderness elsewhere.

I saw him on April 28th. He was a very stout, plethoric man, and he lay in bed on his back with his knees drawn up and apparently in comfort. His face and lips were livid and he had just a suggestion of jaundice. His abdomen was enormously distended and respiratory movements were only slight. There was general tenderness, but definite, localized, exquisite tenderness over McBurney's point. There was dullness in the right flank and a fluid thrill over the right half of the abdomen. The pulse was small and 130 per minute. Rectal examination revealed some fullness high up on the right side. Liver dullness was normal and he had not had a rigor. "Appendicitis with peritonitis" was diagnosed and possibly a large abscess.

Operation.

Immediate operation was decided upon. He was far too ill to be removed, and only very limited accommodation was available and very poor light. Under ether anaesthesia a vertical incision was made over the lower part of the right rectus and the muscle split. In cutting through the fat and deep fascia it was noticed, and remarked upon, that there was oedema of the tissues and obvious staining by bile pigments.

On opening the peritoneum a very large quantity of yellow bile mixed with mucus and purulent exudate escaped, the mixture looking like yellow pea-soup. In it were many small, faceted black gall stones. The incision was rapidly lengthened up to the costal margin, and large quantities of thick yellow fluid escaped, with dozens of gall stones. Innumerable small stones lay on the neighbouring intestines. There were no adhesions, but much flaky lymph and stringy mucus.

The gall bladder was one and a half times the natural size, and was intensely red. On its lower surface, near the fundus, was a small circular perforation about 3 mm. in diameter; its edges were a brilliant golden yellow. Large numbers of stones

lay in the gall bladder and others in the cystic duct. The perforation was enlarged by cutting with scissors up to the fundus and as many loose stones as could be got quickly out were removed. A tube about $\frac{3}{4}$ in. in diameter was stitched into the gall bladder. Some stones were picked off the intestines, but many were left, and much fluid was mopped away. From the lowest part of the wound a long, wide tube was placed as a drain to the bottom of the pelvis, and the wound closed in layers.

He was given continuous rectal infusion and fixed in the Fowler position. He made an uninterrupted recovery. The whole operation occupied thirty-five minutes. Large numbers of stones came through the tube, and for many months he had a mucous fistula from the gall bladder, but this is now healed.

It is nearly certain that had I attempted to remove the gall bladder in this case or to remove the stones in the cystic duct he would have died on the table. It was of great interest to note that some weeks after the operation the patient explained that the very first onset of his pain had been over the region of the gall bladder.

CASE V.

Seen in consultation with Dr. Orford, Pontefract.

Mr. W., aged 60, for many years had had indigestion, characterized by distension and frequently relieved by vomiting. On several occasions he had severe pains under the right ribs and occasionally some shivering. He had been jaundiced on one occasion.

Dr. Orford saw him on October 16th, 1912, and found him suffering from bad pain over the gall bladder and occasional vomiting. There was marked localized tenderness and some rigidity. Pulse was 80 per minute, temperature was 100° F., and respirations 30.

On October 17th he was worse, the pulse had gone up to 85, and the temperature had fallen to normal, but he looked ill. He complained of a catchy pain in the right ribs when he breathed deeply, but he easily rolled about in bed and sat up to have the back of his chest examined. There was definite rigidity over the upper half of the right side of the abdomen and exquisite tenderness. The right flank was resonant. The diagnosis of acute cholecystitis was made.

On October 18th he was removed to a nursing home in Leeds in much the same condition. Perforation of the gall bladder was now definitely suspected.

On October 19th he was better, the pulse falling to 80 and the temperature being normal. The rigidity and tenderness were restricted to the gall bladder region.

On October 20th there was some bile in the urine and he was slightly jaundiced. The bowels were opened and the tenderness over the gall bladder was less marked. There was tenderness and some rigidity over the appendix area.

From October 21st to 23rd he improved daily and a definite lump gradually made itself apparent in the appendix region, the size of an orange. Temperature rose gradually to 100° F. Tenderness over the gall bladder less marked.

Operation.

On October 24th an incision was made vertically over the middle half of the right rectus, splitting the muscle. There were recent plastic adhesions and intense engorgement of the intestines. On separating the adhesions clear bile escaped from the region of the gall bladder. The incision was lengthened up to the costal margin.

The gall bladder was of normal size, but thick and deep red in colour. On the under surface near the fundus was a clean-cut circular perforation 3 mm. in diameter, its edges pigmented a golden yellow. From it exuded clear yellow bile and some stringy mucus. Cholecystectomy was easily performed; the gall bladder contained many small faceted stones. Three or four spots of fat necrosis were noticed in the omentum. A large drain, reaching the stump of the cystic duct and the right kidney pouch, was introduced. Examination nearer the appendix region revealed a large collection of bile and pus, not unlike pea-soup, shut off on the lower, inner, and outer sides by recent adhesions, but open to the upper side by a channel leading up on the outer side and in front of the ascending colon to the gall bladder. Along the channel was yellow bile. The cavity was mopped out and drained by a tube through the lowest point of the wound.

He made an uninterrupted recovery.

CASE VI.

When admitted to the Leeds General Infirmary the patient was most gravely ill, pulse 160 per minute, respirations 36, temperature 101.5° F. He was a very big, stout man, aged 49, and was unable to give much history. He said he had pain all over the body and was vomiting frequently. For many years he had suffered from pain under the front of the ribs on the right side and constant indigestion. Fourteen days before admission he had a rigor, but no very bad pain; seven days later he began to have bad pain over the gall bladder which spread all over his body.

The abdomen enormously distended, moving well except over the right hypochondrium. There was exquisite tenderness over the gall bladder where there was some resistance suggesting a solid mass. Diagnosis of acute cholecystitis with possibly perforation was made.

Operation.

An incision was made vertically over the upper part of the right rectus splitting the muscle. A little clear free fluid escaped from the peritoneal cavity, but no bile. Plastic adhesions between coils of congested and distended intestine, confined to the right hypochondrium. Stomach, duodenum, hepatic flexure of colon adherent to the gall bladder by plastic lymph.

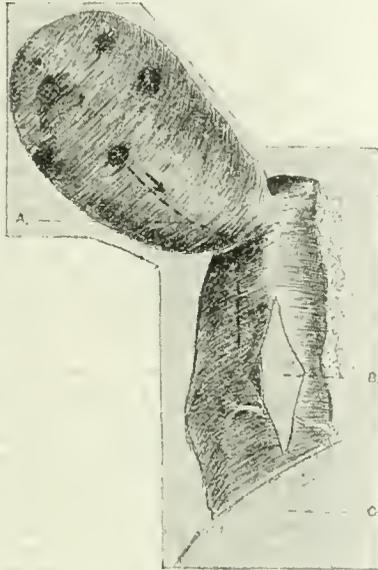

On separating the adhesions, the gall bladder was seen to be twice its usual size, deep maroon in colour, and presented five or six patches of black gangrene over which the peritoneal coat was intact and shiny. The patches of gangrene were each about the area of a sixpence.

The most remarkable appearance was over the region of the common duct, where there was a large swelling the size and shape of a banana looking like a full leech or a coil of gangrenous intestine; behind it the finger could be easily passed into the foramen of Winslow. There was no perforation into the general peritoneal cavity and no free bile.

The gall bladder was quickly and easily removed, and an incision made into the peritoneum over the position of the common duct. Free black bile escaped, probably about an ounce. The common duct lay in its usual position and was pale red in colour. No perforation of it could be found, and it was its usual size and lay free, stripped of its peritoneal coat by the layer of bile. (See diagram.)

The region of the cystic duct was drained, and the right kidney pouch was drained separately by a large tube through the right loin. The wound was closed.

The whole operation occupied thirty-five minutes. He was most gravely ill throughout, and he died some little time after the abdomen was closed.

A, Retroperitoneal track of bile. b, Common duct. c, Duodenum.

Post-mortem Examination.

There was very rapid decomposition; the common duct was reduced to a black-green pulpy mass, but there was no break in its continuity and no sign of a perforation. No stones were found.

There was a small recent abscess in the upper pole of the right kidney. The pancreas was soft and almost diffluent.

The gall bladder contained twenty-two stones. The wall was thick and intensely red. There were ten definite areas where the mucous membrane was black and thinned away until in some parts the peritoneum only remained.

In all the part covered by peritoneum there was no perforation, and none could be found in the portion devoid of peritoneal covering; curiously enough there was not a single patch of gangrene on this portion of the organ.

From one of the patches of gangrene on the under surface near the fundus, starting from the mucous surface, a probe could be passed under the peritoneal coat towards the cystic duct and along it.

It is a most unfortunate fact that the specimen was misplaced by the Pathological Department and cannot be found.

It is difficult to account for the presence of bile under the peritoneal covering of the common duct except on the grounds of a perforation. Whilst it was unfortunate the common duct underwent such rapid decomposition, it was not so bad but that one could come to a definite decision that no leakage had occurred from it. Gangrene of the duct was not present at the time of operation, because the duct could be seen looking pale red when the black bile had drained away.

Is it possible that bile had passed down from the gall bladder, through the breach in the mucous membrane at the gangrenous spot, along the track where the probe passed, and so to the cystic and common ducts?

It would appear no explanation other than a subperitoneal perforation of the gall bladder can be offered.

My thanks are due to Sir Berkeley Moynihan and to Mr. Collinson for giving me permission to use their cases.

THE INCIDENCE OF OPHTHALMIA NEONATORUM IN LONDON.

By N. BISHOP HARMAN, M.A., M.B.CANTAB., F.R.C.S. ENG.,

LECTURER IN OPHTHALMOLOGY TO THE WEST LONDON POST-GRADUATE COLLEGE; ASSISTANT OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL; OPHTHALMIC SURGEON TO THE BELGRAVE HOSPITAL FOR CHILDREN.

The first official statement on the incidence of purulent conjunctivitis in the newborn in London appears in the recently issued report of the Medical Officer of Health of the London County Council. The report is for the year 1911, and it bears the printed date of February 18th, 1913.

The information published in the report is the outcome of the order which made this disease notifiable within the London County area. This was done in March, 1911, by an order extending the provisions of Section 55 of the Public Health (London) Act, 1891, to ophthalmia neonatorum. Prior to this date there was no authoritative knowledge of the incidence of the disease in the population at large, and it was spoken of as "rare" or "common," just as cases bulked largely or otherwise in the minds of medical men and social workers who came in contact with them in maternity hospitals and in private practice. It was obviously impossible to obtain general information for a whole community without official action. Indeed, no attempt seems to have been made to obtain such information except on one occasion, when by the courtesy of several doctors in private practice in one quarter of London I was able to gather and publish statistics concerning some 12,000 births.¹ It will be of interest to put these private returns made in 1906 alongside the official returns for 1911.

The Council's notification order came into force on March 13th, and from that date until the end of the year 673 cases were notified (p. 82). The births in London for 1911—less stillbirths (corrected)—are given (p. 6) as 100,830. To obtain the percentage incidence of the disease it will be necessary to compute the probable figures of the disease for the whole year, instead of as is given, for nine and a half months. There is no reason to suspect any material variation in the incidence of the disease in different seasons of the year. The corrected figures for the year would be 850 cases. Compared with the number of births given, that means an incidence of 0.843 per cent. This figure is very nearly the same as that obtained in my private census for 1906; in 12,680 live births there were 110 cases of purulent conjunctivitis, or an incidence of 0.867 per cent.

The point of greatest importance is the number of cases in which the disease is productive of injury to or loss of sight. The Council's report states that the condition of 278 cases occurring in the practice of midwives was followed out so that in most the ultimate issue was known. There was a wastage, however; 17 children died whilst suffering from the disease, and in 30 instances the parents removed, and could not be traced. There are left 231 cases; of these, 218 were reported to be completely cured; in 13 cases there was impairment of vision.

The rate of injury is, therefore, 13 in 231, or 5.6 per cent. It is interesting to compare this with the private return. In that I found 6 children with permanently damaged eyes out of 110 affected, or an injury-rate of 5.4 per cent.

Details of the 13 cases in which the sight was affected are given:

| | |
|---|---|
| Blind in both eyes | 3 |
| Blind in one eye, other damaged | 1 |
| Blind in one eye, other unimpaired | 4 |
| Both eyes damaged | 2 |
| One eye damaged | 3 |

There was a history of vaginal discharge in the mother in 7 of these cases. In every case except one the eyes were cleansed with some antiseptic immediately or soon after birth; where there was delay it was due to the birth of the child before the arrival of the midwife. In the single case in which cleansing is not noted the disease did not appear until the eleventh day after birth, so that it is almost certainly a secondary infection. Efficient medical help was obtained with promptitude in most cases. There was delay of three, five, and, in one case, ten days, owing

to the opposition of parents or neglect of midwives in giving warning.

Of the 278 cases occurring in the practice of midwives a number of details of interest are given.

Mortality.

Whilst the disease was in progress 17 infants died. It is not possible to tell from the infant mortality statistics given in the earlier pages of the volume whether or no this death-rate is like or in excess of that found in healthy children, for the death-rates or infant mortality given are for infants under 1 year old. The mortality recorded is 12.9 per cent.; the death-rate among these new-born diseased children was 6.9 per cent., but the two figures are not comparable. It would be of interest if the death-rate of infants, say, of less than 1 month of age could be obtained for comparison. Lobenstine and Harrar² showed that infants born of gonorrhoeal mothers were less viable than those born of healthy mothers.

Date of Onset.

The Council's report gives the day of the puerperium on which the signs of inflammation were first noticed:

| Day ... | 1 | 2 | 3 | 4 | 5 | 6 | 6 | 7 | 8 | 10 | Later. | Not Ascer- tained. |
|---------|----|----|----|----|----|----|----|----|----|----|--------|-----------------------|
| Cases. | 18 | 23 | 38 | 33 | 28 | 29 | 18 | 23 | 19 | 11 | 26 | 4 |

Condition of the Mother.

A history of vaginal discharge was obtained in 111 instances—that is, in 40 per cent. of the cases.

Prophylaxis.

The antiseptics used for the child's eyes at birth or as soon afterwards as possible were: Boracic lotion in 125 instances, mercury perchloride (1 in 4,000) in 102, silver nitrate (a 1 or 2 per cent. solution) in 27, protargol in 1, and mercury bimiodide in 1 instance; in the remaining 22 cases sterile water was used. An interval between the birth and the use of an antiseptic occurred in 50 cases owing to the fact that the infant was born before the arrival of the midwife.

The report gives details of the methods adopted to warn midwives of their duties in regard to this disease, and the opportunities provided for them in the matter of further education and training.

Nursing and Treatment.

The difficulty of nursing the affected children early became manifest. The midwives could not be in attendance all day, and in any case their attendance ceased before the child was relieved. "The Council felt therefore that risk was being incurred by allowing cases of inflammation of the eyes to receive no more attention than was bestowed on them by the people living in the house." Four nursing societies were approached, and agreed to undertake the duties of attending to the infants under the direction of the medical practitioner called in. During the year their services were made use of in 68 cases.

The Council had under consideration the question of hospital treatment for severe cases, and an endeavour was made to secure accommodation for mother and child (infant), so that while the child was being treated it would not be deprived of the advantage of being breast-fed. The ophthalmic hospitals and the general hospitals had difficulty in providing such accommodation, but in some instances both mother and child were admitted to the Poor Law infirmaries. Of the cases occurring in the practices of midwives during the year, in 12 instances mother and child were admitted to hospitals or infirmaries, and in 20 the child alone was admitted; 101 other cases were treated by the ophthalmic and general hospitals as out-patients.

This report and the official figures given therein may be taken to settle once and for all the question whether or no it is advisable to promote the compulsory use of prophylactic measures; and by that is meant the use of a silver salt or other efficient preparation immediately after birth. The proposition has been frequently mooted. Strong opposition has been raised against the proposals both in this country and in America. After a discussion on the subject at the Obstetrical Society in London (1903), a strenuous protest appeared in the BRITISH MEDICAL JOURNAL by Sinclair. The objection to the proposal was

based on two grounds—(1) that the risk of the procedure outweighed its prospective advantages, seeing the incidence of such blindness was small; (2) that it was an unwarrantable stigma on the parents and an interference with the liberty of the subject.

In 1892 a special committee of the American Ophthalmological Society presented a report calling for legislation for the compulsory use of prophylaxis in almshouses and State institutions, and recommended the routine use of silver nitrate, in 2 per cent. solution, for all newly-born children. But there was also presented a strong minority report in which disapproval of compulsory legislation was expressed. It asserted that there was not sufficient data of the frequency of such blindness in the United States; that the statistics of other countries, especially Germany, are of doubtful value or positively misleading.

This was the position that I adopted in my little book published in 1907, and therein were given the figures which supported that contention and which are quoted above. The Council's figures are in entire agreement with that position. It is quite certain that no Legislature in the world would entertain for a moment an agitation for the compulsory use of a measure for the prevention of a disease to which no child need be liable, for it is not a disease that every and any one may contract; and which even in a huge conglomeration of human beings like London is found to affect less than 1 per cent. of the newborn. It is quite true that the effect of the disease is lamentable; it does not kill, but it blinds, and that in my experience is the worst of the possibilities. It does this in whole or in part in about 1 child in every 2,000 born. But the knowledge of the condition and the light that is thrown on the work of the obstetrician, by notification and the publication of returns such as these, is as likely, probably more likely, to ensure a minimum incidence of the disease or of damage arising therefrom than is the universal use of potent antiseptics, with the possibility that they may be carelessly used or used to cover dirty practice.

There is one other point in the report deserving of special mention. In 1807, at the time when microbes were unknown, and when the cause of the disease was so obscure that most of our profession thought that all would be well if the baby's eyes were protected from draughts or bright light, Dr. Benjamin Gibson,³ of Manchester, gave the earliest recommendations for the prevention of the disease; they are such that they cannot be bettered now. In fact, this report is a complete vindication of the measures he proposed. His rules were:

1. The leucorrhoea of the mother ought, if possible, to be cured during pregnancy.
2. When this has not been done, the noxious secretion ought to be removed from the vagina during delivery.
3. The infant's eyes ought, immediately after birth, to be cleansed with a fluid which either removes the noxious matter or is able to prevent its injurious effects.

I quote Gibson's recommendation because of the emphasis he lays on the necessity of curing the mother. His implication is that the disease ought, if possible, to be made impossible by proper attention to the maternal passages. The Council's report shows that in 40 per cent. of the mothers whose babies contracted the disease there was a history of vaginal discharge.

OFFICIAL statistics show that in 1911 there were in France 20,809 doctors, 2,848 dentists, 11,589 pharmacists, and 13,066 midwives.

A BILL regulating the importation and sale of foreign pharmaceutical products is now before the Cuban Parliament. It provides that foreign specialities are not to be allowed to circulate in Cuba unless the agent entrusted with the sale of them is a Cuban pharmacist. Further, the specialities must conform to the following conditions: (1) The label must indicate the components to which the product owes its therapeutic activity, and the quantity of these components; (2) the Cuban Academy of Science must satisfy itself that the preparation really possesses the properties claimed for it; (3) a certificate will be required showing that the product has been made in laboratories which work according to the law of the country from which it comes.

A PRELIMINARY NOTE UPON AN EXPERIMENTAL INVESTIGATION OF CONCUSSION OF THE SPINAL CORD AND ALLIED CONDITIONS.

By ALAN NEWTON, M.S.MELB.

(From Sir Victor Horsley's Laboratory of Experimental Neurology, University College, London.)

SIR VICTOR HORSLEY, in whose laboratory it has been my privilege to work, suggested the subject of this research, devised the methods and himself performed some of the experiments. For these and many other kindnesses I feel that I cannot adequately express my gratitude.

INTRODUCTION.

The term "concussion of the spinal cord" requires definition, for at least two separate meanings have been attached to it.

In the first place it has been used to denote a clinical condition comparable with cerebral concussion in which no structural lesion has taken place and from which the subject quickly recovers. Clinical and anatomical evidence has been adduced to disprove the existence of such a state in the spinal cord, and to show that the symptoms are due to organic change. Thus the expression has been more frequently employed in connexion with sudden injury to the spinal cord, and such is its use in the present instance, in which attention is mainly directed to the results of slight concussion.

The medico-legal importance of injuries resulting from railway accidents first directed general attention to this subject, and soon the symptoms were grouped together as of a definite clinical entity, "Railway spine," although it was realized that less sensational and remunerative accidents in everyday life often occasioned a similar condition. In addition to signs indicating involvement of the spinal cord, the cases often presented various psychical phenomena, and difficulty was experienced in differentiating them from those of pure malingering, so much so that Erichsen¹ wrote: "An extensive experience in railway accidents will probably impress the observer more with the ingenuity than the honesty of mankind."

The subject has since been extensively investigated from the clinical standpoint, but it is impracticable here to give a complete review of the literature, though mention must be made of the work of Charcot and Oppenheim. Oppenheim² says that though it cannot be denied that railway accidents, for instance, may give rise to organic changes in the cord without causing severe external injury, such a result is exceedingly rare, and that the affections of the nervous system occurring after them should, for the most part, be regarded as functional neuroses.

In his opinion traumatic neuroses are the effect of mental and physical shock, giving rise to molecular changes in the nervous system. He points out that this view does not exclude the possibility that minute organic changes (in the vessel walls—disintegration of myelin in single fibres, etc.) may exist and form the basis of individual symptoms.

Charcot,³ however, held that the condition is produced by auto-suggestion, while Strumpell⁴ affirms that the idea of making money out of the accident is the chief cause of the neurosis.

Unfortunately opportunities for pathological examination are few, but upon such observations as have been made many neurologists have based the opinion that actual organic changes are present more frequently than was supposed, and that the spinal cord is very susceptible to slight injury, although in some cases the results of such injury may not be obvious until time has elapsed (Warrington).⁴

The experimental literature on this subject is scanty. Schmaus,⁵ however, has conducted examinations upon kittens, and found that blows upon the spinal column produced sensory and motor interference in the spinal cord. Subsequent examination revealed no lesion of the bone and no meningeal haemorrhage. Capillary haemorrhage in the cord was rare, but swelling of axis cylinders and other slight changes were seen. He believes that as a result of external violence forceful movement in the

cerebro-spinal fluid occurs, producing slight injury to the spinal cord. These results have been confirmed by other workers.

Intimately connected with the question of changes in the cord following concussion are those dealing with spinal compression and anaemia. These factors are of importance in connexion with spinal tumours and vertebral caries, as, for instance, the reason for the persistence in caries of movements of the toes, after the disappearance of all other lower limb movements, is still doubtful.

In this investigation, therefore, an attempt has been made to determine the effect upon the exposed cord of varying degrees of concussion and compression, and also the effect upon cord function of obstruction of the aorta.

METHODS.

Experiments were performed upon fifty animals—three monkeys, eight dogs, and thirty-nine cats. Cats and monkeys were employed for the concussion and compression experiments, but dogs were used, because of the larger size of their vessels, in the aortic obstruction experiments. All the animals were kept free from operative sepsis. The anaesthetics used were mixtures of chloroform and ether.

The spinal cord was exposed by a laminectomy between the fourth and eighth dorsal vertebrae, but the dura was not opened except in two cases of slight compression, for two and five minutes respectively.

Concussion.

The momentum of a glass rod 8 mm. in diameter, weighing 50 grams, falling upon the cord, caused the concussion. The rod was removed immediately after the impact, accuracy of direction being obtained by means of a glass tube 1 cm. in diameter, through which the weight fell. This tube was maintained in a vertical position above the exposed cord by means of clamps. Variations could be introduced by altering the height from which the weight fell or the time during which the animals were allowed to recover from the concussion.

Table Indicating the Nature of the Experiments.

| Number of Animals. | Height of Concussion, in cm. | Time before Cortical Excitation, in Days. |
|--------------------|------------------------------|---|
| 2 | 1 | 3, 5. |
| 6 | 2 | 2, 2, 3, 4, 4, 4. |
| 1 | 5 | 1. |
| 7 | 10 | 0, 0, 1, 1, 4, 5, 10. |
| 5 | 20 | 1, 3, 3, 11, 12. |
| 2 | 30 | 9, 11. |
| 7 | 40 | 0, 1, 1, 4, 5, 6, 14. |

Twelve animals died after blows from heights of 10 to 40 cm., the number of deaths increasing in direct ratio to the height. Four of the deaths occurred in the first twenty-four hours, marked distension of the urinary bladder, producing respiratory interference, being constantly present. Owing, no doubt, to paralysis of the sphincters and infection from the faeces, a condition of purulent cystitis, with numerous semi-confluent submucous haemorrhages in the bladder wall, was present in the remaining eight animals, death occurring between the third and eighth days.

Compression.

In compression experiments the same glass rod, weighing 50 grams, was gently placed upon the exposed cord and allowed to remain thereon for varying times. It was maintained in position by the glass tube already mentioned.

Interference with the Circulation of the Cord.

At first the aorta was obstructed by means of a clamp applied through an incision in the thoracic wall, but this method was abandoned for one in which a distensible rubber tampon was passed down the lumen of the aorta from an opening in the right carotid artery.

The instrument consists of a graduated metal tube (No. 1 catheter size) with a slight terminal curve. Surrounding this tube at this curve for 2 cm. of its length and

extending almost to the distal extremity of the instrument is a rubber tampon, which could be inflated by an air pump attached to the proximal end of the tube. The mere presence of the instrument in the vessel caused no perceptible change in femoral pulsation, which, however, at once disappeared upon inflation, returning immediately at the conclusion of the experiment.

In this method the desired end is attained with a minimum of operative interference, a small incision in the neck being all that is necessary; no question of the influence of defective aëration can arise, and artificial respiration, which has been used to counteract the possible influence of the latter complication in the trans-thoracic method, can be dispensed with.

It was found that, though obstruction for fifteen minutes at the level of the twelfth dorsal vertebra produced no fatal effects, after obstruction for thirty minutes in this region four dogs died in the first twenty-four hours. Recovery, however, followed when the aorta was obstructed for this time immediately distal to the renal vessels.

Method of Testing the Effects.

Motor conduction was tested by faradic excitation of the hind limb area of the motor cortex. In many experiments the skin was removed from the limb in order to differentiate contraction in the different muscle groups.

A Kronecker coil, with 6 S.R.M. cells in the primary circuit, was employed in all cases. The excitation was bipolar, the electrodes being 1 to 2 mm. apart.

Sensory conduction was tested by the reflex effect upon respiration, and, in some cases, upon the blood pressure of stimulation of the sciatic nerve.

RESULTS.

The Effect of Concussion upon the Conduction of Motor Efferent Impulses.

At the outset it was necessary to determine what degree of violence inflicted upon the exposed spinal cord could be described as "slight concussion." To this end experiments were performed in which the weight of 50 grams was dropped upon the cord from heights of 40, 30, and 20 cm. It was soon seen, however, that such concussion was too severe in that it abolished motor conduction immediately, and, further, that no return thereof could be demonstrated by cortical excitation after periods varying from eleven to fourteen days. The animals exhibited paraplegia with increased knee-jerks and double extensor contracture. Yet, despite this marked disturbance of function, the surface of the cord upon inspection immediately after the impact did not appear to be greatly injured. It is true that slight subdural hæmorrhage was usually present, but this was not due to rupture of the larger superficial vessels.

However, it was obviously necessary to lessen the degree of the concussion, which was then inflicted from heights of 10 and 5 cm. Here again the disturbance of conduction was considerable, for cortical excitation produced no response distal to the injury after four to five days had elapsed, although in one cat, of 10 cm. concussion, conduction was demonstrated after ten days.

Further reduction in the degree of concussion was decided upon, so that the height was diminished first to 2 cm. and then to 1 cm. This extremely feeble blow produced no visible effect upon the surface of the cord, but nevertheless the disturbance of efferent conduction was pronounced.

After 2 cm. concussion no conduction could be demonstrated after the lapse of two days. After three and four days, however, a very interesting condition was apparent, in that cortical excitation was followed, not by the usual movement of flexion, but by extension of the hind limb. Increased stimulus naturally produced epileptic clonus in the fore limb and trunk anterior to the mid-dorsal region, but distally the sole effect was to increase the movement of extension, clonus being completely absent. In this instance a dissociation was clearly effected, the cortical character of the response was lost, and only spinal phenomena resulted.

Three to five days after 1 cm. concussion a similar result was produced by excitation, but in this case a further important difference was present, as increase of the excitation stimulus produced, not increased extension, but

flexion of the hind limb. If, however, the cortical excitability was lowered by deep anaesthetization, the increased stimulus again produced extension. In short, extension occurred during deep anaesthesia or as the result of a weak stimulus, but flexion followed reversal of either of these conditions. This interesting reciprocal demonstration is worthy of further investigation.

Experiments on the Cord in the Monkey.

Forty cm. concussion abolished motor conduction in *Macacus rhesus* as completely as in the cat, so that concussion from 2 cm. was performed in two monkeys. After four days cortical excitation of the hind-limb area was followed, not only by the usual movement of flexion of the opposite limb, but by a movement of progression—that is, central lateral flexion, with marked ipsilateral extension of the hind limbs.

Summary.

Slight concussion, producing no macroscopic and very little microscopic changes in the spinal cord, nevertheless produces marked alteration in motor conductivity. This is at first completely abolished, and later is so changed that, in the cat, excitation is not followed by the flexion movement which is predominantly represented in the cortex, but by the "lower centre" movement of extension, and, in the monkey, by the spinal movement of progression.

An attempt was made in these experiments to discover if, in the cat, conduction remained to one muscle group after it had been abolished to all others—that is, if a condition could be produced comparable with that already mentioned in connexion with vertebral caries, where slight toe movements often remain after all others have disappeared. Though such a condition has not yet been produced in these experiments, flexion of the ankle was in all cases more marked than similar movement at the knee and hip, and the march of flexion was in the order of ankle and toes, knee, hip.

The Effect of Compression upon Motor Efferent Conduction.

It was found that the compression caused by gently placing a weight of 50 grams upon the cord of a cat was sufficient to arrest conduction immediately. Here the question of the part played by vascular obstruction is important—that is, Was the arrest of conduction due to anaemia of the motor fibres?

Ehrlich⁶ and others have shown, however, that degeneration after arrest of circulation in the cord is limited to those fibres which arise from cells situated in the anaemic area, and that fibres of the long tracts escape degeneration even if deprived of blood for one hour. It would appear, therefore, that the motor fibres are very sensitive to compression, irrespective of changes produced in blood supply.

After removal of the compression conduction in the cord returns, after an interval varying directly with the duration thereof, and the degree of interference remaining after eleven to fourteen days depends upon the same factor. This will be seen from the following table:

| Time of Compression. | Lapse of Time before Excitation. | Effective Stimulus (Kronecker's Scale). |
|----------------------|----------------------------------|---|
| 2 minutes | 11 days | 1,000 |
| 5 " | 11 " | 2,000 |
| 30 " | 12 " | 3,000 |
| 45 " | 14 " | 6,000 |

The Effect of Concussion upon Sensory Afferent Conduction.

Although after concussion of the spinal cord of the cat by 50 grams falling from heights of 30 and 40 cm. no motor or efferent conduction could be demonstrated, yet it was found that changes in respiratory rhythm could still be induced by faradic stimulation of the sciatic nerve.

It would appear, therefore, that sensory conduction remains after concussion that has quite abolished motor conduction—a result which is in accordance with clinical evidence.

Experiments employing variations in blood pressure as a guide to sensory conduction have as yet proved less definite, but point to the same conclusion.

*Anatomical Changes in the Cord produced by
Concussion and Compression.*

After concussion by 50 grams falling 1 and 2 cm. the changes in the cord at the point struck were trivial. They consisted of small haemorrhages in the grey matter, usually in the basal region of the posterior cornua or in the posterior grey commissure, scattered swellings of axis cylinders and disintegration of myelin sheaths. Compression for short periods produced similar changes. After more severe injuries there were more marked anatomical changes, particularly in the grey matter. These consisted, as before, in haemorrhages, with swelling of axis cylinders and disintegration of fibre sheaths.

The vessels of the cord were not occluded by thrombosis, therefore the disturbance in structure could not be attributed to thrombotic softening by secondary degeneration. Sections stained by Marchi's method displayed both ascending and descending degeneration. The number of degenerated fibres varied with the severity of concussion, but even where this had been inflicted from a height of 10 cm., the resulting degeneration was less pronounced than might have been expected from the disturbance in conduction. After concussion from 30 and 40 cm., however, the degeneration was very extensive.

Ascending degeneration particularly affected Goll's column and the direct cerebellar tracts, but after the more severe injuries the area showing degeneration extended round the margin of the cord as far as the anterior fissure. Below the lesion degeneration was seen in the pyramidal and anterior tecto-spinal tracts.

*The Part played by Interference with the
Circulation.*

1. *State of Circulation at the Site of Injury.*—Though haemorrhages of varying extent were caused by concussion and compression, these were due to rupture of small vessels, for no thrombotic processes could be detected in the larger vessels. Apparently, therefore, there was no gross circulatory obstruction at the site of injury.

2. *The Effect of Obstruction of the Aorta upon the Conductivity of the Cord.*—The conductivity of the spinal cord rendered anaemic by aortic compression has been studied by Loewenthal,⁷ in whose paper a bibliography of this subject will be found. His experiments were performed upon cats, the aorta being digitally compressed in the thorax after resection of the sixth or seventh rib on the left side. To counteract the possible effect of deficient aëration artificial respiration was maintained. He found, in the first place, that after one or two minutes stimuli reaching the anterior cornual cells produced no motor response, but that the first effect of arrest of circulation upon the functions of the spinal cord was an increase in the readiness and strength of intraneural transmission of nerve energy lasting for thirty seconds.

In certain of the animals he observed convulsive phenomena in the posterior half of the body at the commencement of ischaemic paralysis, which, in his opinion, deserved the name of "spinal fits." Also, he considered that probably every single neuron as a functional unit retains its vitality for a period exceeding fifteen minutes, but that the mechanism linking them is rapidly destroyed.

In the present experiments motor conduction in the cord could not be demonstrated by cortical excitation fifteen to thirty seconds after the arrest of circulation, which is a much shorter interval than that described by Loewenthal.

No conclusions have as yet been arrived at regarding the initial increased response to excitation, nor did any of the animals exhibit convulsive phenomena. It must, however, be remembered that in the present research a smaller portion of the cord was rendered anaemic than in Loewenthal's experiments.

The arrest of circulation for fifteen minutes at the level of the twelfth dorsal vertebra was followed in the dog by considerable paraparesis, which was obvious after twelve days had elapsed, and was most noticeable in the anterior tibial muscles. Unfortunately no dogs survived arrest of

circulation for thirty minutes at this level. On the other hand, little paresis was produced by obstruction half an inch distal to the renal vessels.

It may also be mentioned that ligation of the aorta in the cat just distal to the inferior mesenteric artery produced no degeneration in the spinal cord.

It follows, therefore, that arrest of its blood supply rapidly causes a loss of conduction in the spinal cord, a result which may be reasonably ascribed to its action upon the interneuronic mechanism.

CONCLUSIONS.

The provisional conclusions to be drawn from these experiments are as follows:

1. The spinal cord is extremely sensitive to slight degrees of concussion and compression.

2. Despite the slight anatomical changes demonstrable after lesser degrees of injury, the resulting disturbance of function is considerable.

3. After concussion which has quite abolished motor efferent conduction, sensory conduction can still be demonstrated.

4. Arrest of the spinal cord circulation by aortic compression abolishes spinal cord function in from fifteen to thirty seconds.

5. These experiments support the view that there is an organic basis for the signs and symptoms of "railway spine" and allied conditions of traumatic neurasthenia.

PSEUDO-FRACTURES OF TRANSVERSE
PROCESSES.

By OWEN L. RHYS, M.D.,

MEDICAL OFFICER, ELECTRICAL DEPARTMENT, CARDIFF INFIRMARY.

ABOUT three years ago I published in the BRITISH MEDICAL JOURNAL the radiograph of a man whose lumbar spino showed an apparent separation of the left transverse process of the first vertebra. In that case there was no history of injury. Since that time I have met with five other cases of a similar kind showing the same abnormality of one or more processes.

The condition seen in most of the spines referred to was a distinct gap between the outer end of the process and the base. In three of them there was also displacement of the outer end upwards or downwards, so that it was not difficult to imagine that muscular strain had fractured the process and torn away the tip. In two of the cases the bony edges of the gap were thickened and curled as though callus had been formed.

In one man the tips of the third and fourth left transverse processes were displaced downwards for quite half an inch, and in a radiograph which I published in the JOURNAL in October, 1910, the second, third, fourth, and fifth left processes were much displaced. In this last case there was a definite history of muscular strain, the man being a collier. He complained of pain on the opposite side of the spine, but, finding the condition described, he was assumed to have fractured the processes.

In the light of subsequent cases I very much doubt if this was a case of muscular strain causing fracture. In only one of the other cases I have mentioned was there any history of injury, and that was a fall on the buttocks, which could not, I think, in any way have accounted for the abnormality seen, namely, an apparent separation of the first left transverse process. In this case also the pain was referred to the opposite side.

The psoas magnus, quadratus lumborum, and erector spinae are all attached to the transverse processes, and any violent lifting strain might, of course, snap the processes at their weakest point; but one would expect, first, displacement in each case, and secondly, union of the fractured bone where there was no great displacement, and not a permanent gap.

I think that the cause of these conditions is developmental, and in support of this view there is, first of all,

the absence of any injury in almost all the cases, and secondly, the fact that the first lumbar is the most frequently affected vertebra. In one case both transverse processes of this vertebra showed a distinct gap. The

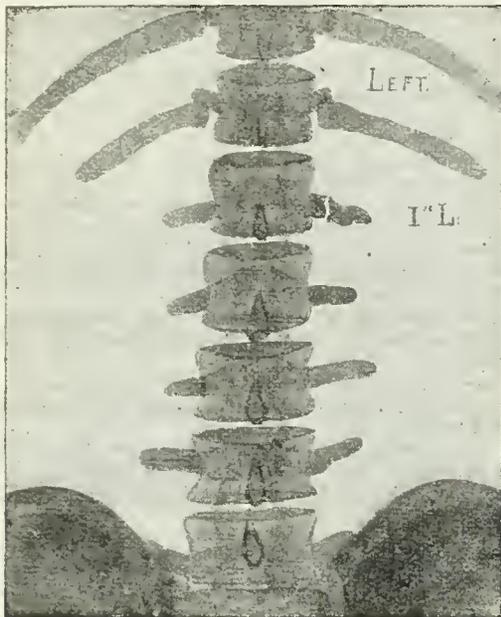

Fig. 1.—Showing a typical pseudo-fracture of the first lumbar transverse process.

epiphyses of the transverse processes are not united until the twenty-fifth year, and in the embryo there is a costal element in connexion with the transverse process of the first lumbar. Occasionally this develops into a rudimentary

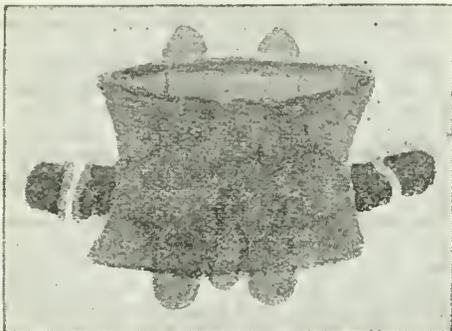

Fig. 2.—First lumbar, showing gaps in both transverse processes.

supernumerary rib, in fact the transverse processes are homologous with the first part of the ribs, and the appearance of such rudimentary ribs would correspond with the condition seen in some of these cases. Incomplete ossifica-

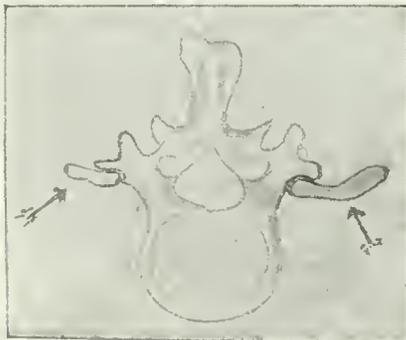

Fig. 3.—Rudimentary ribs attached to first lumbar vertebra. (After Allen Thomson.)

tion of the processes would also, of course, account for the transparent gap seen in some of the processes. All the six cases I have mentioned were those of adults, the youngest being about 20, the oldest nearly 60 years old.

The importance of such abnormalities in claims under the Workmen's Compensation Act was, of course, obvious from the first, but another aspect lately came to my notice in a case where a surgeon proposed to cut down upon and remove what had been diagnosed as an ununited fracture of a transverse process.

The accompanying diagrams show the appearance seen in most of the cases referred to.

A CASE OF TETANUS TREATED WITH INTRASPINAL INJECTIONS OF MAGNESIUM SULPHATE.

By H. LETHEBY TIDY, M.D. OXON., M.R.C.P. LOND.,
PHYSICIAN, GREAT NORTHERN HOSPITAL; DEMONSTRATOR OF
CLINICAL PATHOLOGY, LONDON HOSPITAL.

THE following is the record of a case of tetanus treated with intraspinal injections of magnesium sulphate:

A boy, aged 8 years, was admitted into the Great Northern Hospital on the morning of September 3rd, 1912.

History of Illness.

Quite well previous to August 30th. On that day did not seem well, and noticed some difficulty in opening the mouth.

On August 31st had "some kind of fit" and fell down. On September 1st and 2nd had attacks of pain, becoming rigid, but with no loss of consciousness. The jaw remained stiff after the attacks.

Previous History.

No fits previously and no illnesses. One month ago fell and cut right side of head, and three weeks ago fell and cut chin. Both cuts slight.

Condition on Admission.

Well developed boy. Conscious and understands perfectly. Mouth tightly shut. Slight "risus sardonicus." Neck rigid. No squint. Ocular movements perfect. Pupils equal and react to light and accommodation. No head retraction. Body rigid. Arms and legs stiff but easily moved and flexed. Knee-jerks present on both sides. No cuts or septic foci. The temperature was 98° F. and the pulse 112 and regular.

During the afternoon of September 3rd he had several slight spasms, during which he cried out, and became rigid, with slight opisthotonos. In the early part of the night the spasms became very frequent. In these the mouth was tightly shut, there was marked risus sardonicus and opisthotonos, and apparently great pain.

Treatment.

Lumbar puncture was then performed, and 10 c.cm. of cerebro-spinal fluid, which was under considerable pressure, were withdrawn. Without removing the needle there was then injected into the subdural space 3 c.cm. of a sterilized 25 per cent. solution of magnesium sulphate. Following this the spasms ceased, and the patient had a quiet night.

On September 4th the temperature rose to 101.4°. The pulse remained between 100 and 120. There were no spasms during the day, and the mouth could be slightly opened. There was still general rigidity. On the 5th the temperature fell from 101° to 99°. There were no spasms, and the mouth could be opened a little further. Towards evening pain in the neck returned. On the 6th the general rigidity became more marked, and the teeth could scarcely be parted. The temperature was normal, and the pulse 100. A patch of herpes developed on the lower lip. The injection of magnesium sulphate was repeated.

On the following day the temperature rose to 100°, and fell again. During this and the next few days the rigidity became gradually less, and the spasm of the jaw diminished. The patient became able to say a few words consecutively, and was able to swallow custard on the 9th. On the 10th he complained again of pain in the neck, the jaw became stiffer, and there was one slight spasm. A third injection of magnesium sulphate was given. This was followed the next day by a rise of temperature to 101°, but the spasm and rigidity gradually diminished from this date, and no more attacks of spasm occurred. The pulse fell gradually. On September 13th 10 c.cm. of antitetanic serum were injected subcutaneously.

For about ten days there was severe headache, but this passed off, and the patient was allowed to get up on September 26th, and was discharged on October 3rd.

He has since remained in good health.

Remarks.

No septic focus was found when the patient was admitted, but the diagnosis of tetanus appears undoubted. Many cases of treatment by injections of magnesium sulphate into the subdural space have been recorded. Series of cases have been published from Egypt where the organism is much more prevalent than here. The results

are claimed to be good, although it must be remembered that the percentage mortality from tetanus in Egypt is not so high as in the British Isles. The percentage mortality is less the longer the period of incubation, and where this is between three and four weeks the mortality in the British Isles is about 50 per cent. For an adult a dose of 6 c.cm. of a 25 per cent. solution in distilled water may be given. This contains $1\frac{1}{2}$ grains (about 22 grains) of magnesium sulphate.

As the injection of antitetanic serum has proved to be of very little curative value in tetanus, the injection of magnesium sulphate in this manner is certainly worth a good trial. The withdrawal of cerebro-spinal fluid is doubtless an additional advantage.

I have to thank Dr. Alexander Morison, into whose ward the patient was admitted, for his kind permission to publish this case.

CAESAREAN SECTION, WITH ESPECIAL REFERENCE TO THE RARER INDICATIONS FOR THE OPERATION.*

By W. H. MAXWELL, M.A., M.B.CAMB., F.R.C.S.ENG.

THE title of this paper was suggested to me by the circumstance that, while it has fallen to my lot to perform this operation four times during the last two years, in none of these four cases, curiously enough, has the indication for it been that for which I suppose something like 90 per cent. of Caesarean sections are performed—namely, pelvic contraction. The three cases upon which my remarks are based form an interesting series, in that each illustrates certain points of importance to the student of what one may perhaps be allowed to call the "higher obstetrics." My personal experience of Caesarean section is relatively small; I have done the operation myself five times, and have had the opportunity of assisting at it in seven other cases. My own five cases have been unattended by a fatality; of the other seven, two died, the cause of the fatal issue being, as I shall point out later, apparently identical in both. In the first case that came under my observation the operation was done by my old friend the late Mr. E. H. Douty, of King's College, Cambridge, in Addenbrooke's Hospital in 1896.

For some reason or other, in South Africa we meet with few examples of the higher degrees of pelvic contraction; hence Caesarean section and kindred operations are called for somewhat rarely. I must make it clear that in speaking of Caesarean section I refer entirely to the classical operation of Sanger and Porro—that is to say, what should be designated "anterior transperitoneal hysterotomy"—my experience of the various modifications suggested, of which "vaginal" Caesarean section seems the most extolled, being *nil*. With this premise I will proceed to a brief description of the three cases referred to.

CASE I.

Mrs. M., aged 40, married twelve years, had had four children, of whom three were living still, and two miscarriages. She was admitted into the Queen Victoria Hospital for Women early one morning in labour, and her arrival intimated to me by a telephone message from the matron to the effect that she had examined and "could not find the os." Not, perhaps, without an inward smile, I obeyed the summons, and on making a vaginal examination likewise was unable to find the os. Finally, on introducing my arm, under light anaesthesia, nearly to the elbow, the partially dilated os could be made out lying right up in the lumbar region, the impression being that a very large rounded tumour was obstructing the pelvis and pushing the cervix upwards and backwards. The patient said (in explanation of a median abdominal cicatrix) that an operation had been done a year before in the General Hospital, but she was ignorant of its nature. Telephone inquiries elicited the fact that the operation had consisted in a direct "ventral fixation," and the nature of the case was now evident, the "tumour" being merely the body of an extremely anteverted uterus, which, in fact, was almost in an inverted position. It was fairly obvious that extraction of the child *per vias naturales*, even dead, was wellnigh, if not altogether, impossible, and my colleague, Dr. Gordon Grant, who saw the case, confirmed this opinion. I therefore decided on Caesarean section. The patient was prepared as quickly as possible, the child, a

healthy full-term male, extracted without any difficulty, and the placenta and membranes removed; the womb was then drawn out through the abdominal incision and carefully sutured. Haemorrhage was negligible in quantity throughout and subsequent contraction was excellent. The mother made an uneventful recovery and was able to nurse the child as usual.

It was noteworthy in this case that, in spite of the almost incredibly anteverted position of the uterus, one was not troubled during the operation by any obvious adhesions or other sources of difficulty. Hitherto in performing the—often very useful—operation of ventral fixation or hysteropexy (in contradistinction to the "indirect" operation of Gilliam and its countless modifications) I have always had in my mind the fear lest it might—as it certainly does—interfere with subsequent pregnancy, unless great care be taken to pass all sutures well down on the anterior uterine wall; and not a few cases have been published in which recurring abortions seem to have followed the operation; but I had never realized before that such an extreme malposition of the uterus could result as to demand Caesarean section. About two years ago, however, there was published in the BRITISH MEDICAL JOURNAL¹ by Dr. Amand Routh a carefully collected series of eight cases similar to the one I have just described. I can only say that had I not seen the condition before delivery in this case I should have felt somewhat sceptical as to the validity of the indications for the operation. Possibly a similar suspicion might arise in the minds of many as regards the next case to which I have to refer.

CASE II.

Mrs. T., aged 34 years; married five years; one child living aged 4 years. Had had a "bad miscarriage" eight months previously. This patient was sent into the Queen Victoria Hospital one afternoon with a diagnosis of placenta praevia, by her medical attendant, Dr. Brebner. When I saw her soon after admission she appeared pale, but not markedly exsanguine; there were no pains and not the slightest sign of dilatation of the cervix; the general indications were those of about six and a half months pregnancy, the fetal heart being audible. She had bled a good deal, and I decided that something ought to be done on the following day.

During the night she had steady and almost continuous bleeding, and when I saw her at 6 a.m. she was in an extremely grave condition, partly, it appeared, owing to cardiac failure supervening on pretty severe haemorrhage. There was still not sufficient dilatation of the cervical canal to admit even the tip of a finger, and her condition was so bad that it seemed doubtful whether we could get her alive on to the operating table. Saline infusion (subcutaneous and rectal) improved the pulse a little, but it was tolerably obvious that any attempt at an *accouchement forcé* must result in death from the further haemorrhage inevitable during extraction of the uterine contents; I therefore decided upon Caesarean section as giving her a better chance. This was performed in the usual manner, saline infusion being kept up during the operation. The uterus was opened with the greatest possible rapidity after being drawn right out through the parietal incision; the child, followed by the placenta and membranes, was removed, with an astonishing absence of haemorrhage, in about three minutes from the start. The pulse practically disappeared, but was restored by filling the peritoneal cavity with warm normal saline solution while the stitching up of the uterine wound proceeded, another jugful being introduced just before closing the abdominal incision. The only loss of blood worth mentioning came from the placental site after removal of the uterine contents, but good contraction prevented any great loss.

For the first twenty-four hours it seemed very doubtful whether the patient would recover, as the cardiac condition gave rise to grave anxiety; but after this she improved so rapidly that she was able to sit up by the seventh day, and her recovery was not retarded by any complication. The child, of course, though delivered alive, was not viable. I should mention that the placenta, as far as a hurried examination allowed one to determine, was as nearly "central" in position as it could possibly be.

The great point of interest in this case lies in the consideration of *placenta praevia* as an indication for Caesarean section. The question has, of course, been raised often enough; and while it is usually admitted that on purely theoretical grounds Caesarean section should be the ideal treatment in certain cases, yet the general consensus of opinion appears to condemn this operation as a practicable line of treatment owing to the absence of any reliable method of gauging, in any given case of placenta praevia, how much or how little difficulty and danger the condition is going to cause. Any one who has had an even moderately extensive experience of this dangerous complication must have observed that many cases do extremely

* Read before the Witwatersrand Division of the Transvaal Branch of the British Medical Association.

well in spite of pretty severe bleeding, and that frequently the expected degree of trouble fails to materialize. The mortality *qua* the child is very high, no doubt because the very condition that plays so important a part in conserving the waste of maternal blood—namely, obliteration by thrombosis of the torn sinuses of the placenta *pari passu* with its detachment during delivery—is actually inimical to the child's chance of surviving; given, that is to say, a certain degree of placenta detachment the child, in spite of its being extracted with the utmost rapidity, is of necessity delivered in a too exsanguine condition to be capable of surviving; the drainage of blood from the placental sinuses during delivery means also, it must be remembered, drainage from the child's vascular system. It would appear from such considerations that those who have been foremost in urging the propriety of hysterectomy in cases of placenta praevia have for the most part had in mind rather the child's welfare, and if this be so the case I have recorded here is, I think, an interesting one in view of the fact that it illustrates the possibility of Caesarean section being desirable in the interest of the mother, though perhaps it must not be held to establish a precedent.

It is noteworthy that the late Mr. Lawson Tait strongly urged the adoption of Porro's operation in cases of placenta praevia, and recently I came across a remark of Professor Japp Sinclair's in 1901 to the effect that sooner or later placenta praevia would have to be considered as a possible indication for Caesarean section. Yet the statement was made only the other day, without qualification, "Placenta praevia is *not* an indication for Caesarean section"! Without wishing to emphasize unduly the value of my own judgement, I can affirm without any hesitation that in this particular case and at the particular stage at which the operation was performed no other kind of treatment would have availed to save this patient's life, though I am willing enough by all means to class such a case among those proverbial exceptions which are said to "prove the rule."

CASE III.

A woman, aged 42, was sent to see me when just five months pregnant for the first time, having been married two years. She complained chiefly of a good deal of pain about the rectum (though not markedly constipated) and some increased frequency of micturition. The first thing that struck one was that, while the menstrual history suggested five months' pregnancy, the uterus reached well above the umbilicus. Examination revealed a fibroid (evidently), about the size of a large orange, lying in the pelvis and pressing on the rectum, the cervix being pushed forward, considerably flattened, in front of the tumour against the pubes. It was quite impossible to push the tumour up, and at first, on account of the pain and pressure symptoms, I nearly decided on immediate operation, but was deterred from this course by the wellnigh certain prospect of having to do a hysterectomy; the position of the tumour gave very little hope of the possibility of a myomectomy with conservation of the uterine contents.

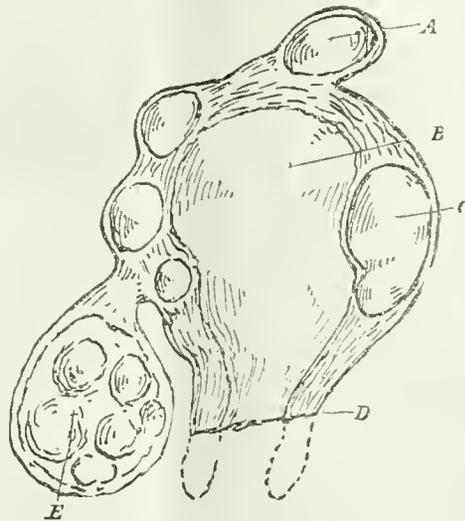

I put it, therefore, to the patient, who was extremely anxious to have a child, that it was worth while for her to try and hold on until full term, as she would then have a good prospect of a living child, and it was not likely that things would get very markedly worse during the next four months.

She followed this advice, and although at intervals of every few weeks she had rather severe attacks of pain and occasional slight bleedings, she managed to get along fairly comfortably up to within a week of the time reckoned upon for natural delivery—had that been possible—and two days before the time at which I had advised her to come into hospital I received a telephone message at 7 a.m. saying that she had arrived and was in labour.

Realizing the danger of delay, I operated at 9.30 a.m., the skin being prepared by the iodine method; no vaginal examination had been made for more than six weeks previously. The abdominal incision reached to about 2 in. above the navel, and swabs were then packed in between the abdominal wall and the uterus, the latter, which was studded with fibroids, being incised without evisceration. The organ was so much distorted

by these numerous tumours, more particularly by one rather large intramural fibroid in front, that it was unusually difficult to hit off the uterine cavity, especially as it was now obvious that the membranes had already ruptured, evidently before admission, labour being, in fact, well on in the first stage. I feared at first that the child was dead; but it speedily revived and did well (male, weighing 5 lb.). I removed placenta and membranes, all of which were somewhat adherent, and then drew out the uterus. It was obviously futile, in view of the large number of fibroids of all sizes studding the uterus, to attempt multiple myomectomies, and the tumour in particular which had obstructed the pelvis, as shown in the diagram, was situated so low down posteriorly that even after emptying the womb it would have been practically impossible to enucleate it. I proceeded, therefore, to remove the uterus by supravaginal amputation; both ovaries looked healthy and were not interfered with. The cervix had undergone such a degree of dilatation that it formed quite a broad stump, which, after approximating its cut surfaces with "mattress" sutures, was covered over in the usual manner with peritoneum. Haemorrhage gave no trouble—a somewhat unusual feature, to judge by my own experience, in amputation of the pregnant uterus, the cervical region often being the seat of a good deal of troublesome oozing.

The operation took over an hour and a half, but the patient's condition gave rise to no anxiety then or later, and she made an excellent recovery; plenty of milk appeared by the fifth day, and the child likewise did well. The obstructing myoma was subserous and almost pedunculated, but could not have been pushed up, being apparently incarcerated below the sacral promontory, on the one hand pressing upon the rectum and on the other pushing the cervix and bladder forwards against the pubes.

Diagrammatic representation of the condition of the uterus in Case III. A, Small fibroid, palpable before operation. B, Uterine cavity. C, Intramural fibroid. D, Line of section of cervix. E, Subserous fibroid obstructing pelvis.

In seeking to emphasize the points of chief importance which the cases I have referred to seem to illustrate, I venture to crave the indulgence of some of my colleagues whose experience of Caesarean section is possibly more extensive than my own, and I think sufficient justification for so doing can be found in the extreme importance to the obstetrician and his patients of a proper grasp of both the possibilities and the limitations of this time-honoured method of delivery; one would be tolerably correct in asserting that in no other department of surgery have such triumphant results attended the progress of aseptic technique. But it is of prime importance to understand that the modern diminution of the mortality of the operation is due, next to the development of a proper application of the principles of asepsis, to the fact that the operation is now performed, not as a last resort—a desperate measure to save the mother's life—but either before the onset of labour or, at all events, before labour has proceeded very far. Even now, it seems to me, the cardinal point to remember is to operate early; Caesarean section done before rupture of the membranes (or, at any rate, before the end of the first stage) is one thing, Caesarean section done after the end of the first stage is quite another. Probably the mortality proper to the former operation is between 2 and 5 per cent.; that of the latter even now must be something like 15 to 20 per cent. And I must point out here that, especially if the rule be adhered to that vaginal examination just before the operation should be avoided whenever possible, one is very apt to discover that labour has progressed much further than one had suspected. In the only two fatal cases that have come under my own observation labour was found to be well on in the second stage; that is to say, not only were the membranes ruptured, but the child's head was in the vagina, and so, in order to release the head, the operator had to prolong his uterine incision down through the cervix—a proceeding which not only involves an otherwise unnecessarily long incision, but is almost certain to result in trouble, owing to haemorrhage from the numerous veins surrounding the upper part of the vagina. Proper apposi-

* The specimen was shown at the October meeting of the Branch.

tion of the edges of the uterine wound is much more difficult in this region, owing to the thinning of the uterine walls produced by the phenomenon known as "retraction." The whole operation is easier if the uterine incision can be kept high up, where the uterine muscle is thicker, though I can see no definite advantage in the transverse incision known as the *Fundusschnitt nach Fritsch*. Any one, too, who has had some experience of these cases will have noticed that the opening of the uterus is an easier proceeding when the membranes are intact.

Providing that one be lucky in avoiding the placenta, the uterine incision may be made slowly and deliberately with an extremely small loss of blood until the membranes bulge into the wound, when the amniotic cavity can be opened at leisure. The only disadvantage in cutting through the placenta is that one is obliged, in order to arrest the haemorrhage as soon as possible, to hasten the process of extraction of child and secundines, but it is scarcely worth while, as some have suggested, to try and work round the edge of the placenta instead of cutting through it. I can see little, if any, advantage in "eventration" before delivery of the child; a much longer abdominal incision is required, whereas, if the womb be left *in situ*, it is easy enough, by arranging a couple of large gauze swabs on either side between the uterus and the abdominal wall, to prevent the escaping liquor amnii and blood from entering the peritoneal cavity.

As soon as the placenta and membranes have been removed the uterus should be drawn right out and suturing begun. The manner of closing the uterine incision is of considerable importance. I personally prefer a not very coarse "chronicized" (Red Cross No. 1) catgut, and for the first row I use "mattress" sutures, as they are less liable to cut out than single interrupted stitches, each stitch taking a wide grasp of muscle and just missing the uterine mucosa. The second layer is a continuous suture ensuring proper approximation of the serous coat. There should not be more than a quarter—or at the outside three-eighths—of an inch between any two sutures of the first row.

The history of the development of the modern conservative operation is of some interest, because for a very long time it was the universal custom not to stitch up the uterus at all, and the mortality arose principally from infection of the peritoneal cavity through the uterine wound, and without any understanding of sepsis it will easily be believed that any attempt to close the uterine wound probably made matters worse. Hence it is understandable what a different complexion was put upon the operation by Porro's suggestion (first carried out in 1876) of removing the uterus altogether. Now, it must be remembered that the modern operation of supravaginal amputation is *not* the original method of Porro. His operation consisted in drawing out the uterus, transfixing with the "pin," and applying the Koeberlé *serre-noeud*, after which the body of the uterus was cut off; the whole operation could, of course, be done very rapidly, and the mortality was enormously reduced by this method. I believe that even now there are not a few cases, especially among those operated upon late in labour, where the mother's life could be saved by Porro's method.

It is no doubt hard for us to realize what Porro did for Caesarean section. His operation at once precluded the possibility of subsequent peritoneal infection and of haemorrhage, besides possessing the advantage already mentioned of extreme rapidity. The objection has been raised that the operation is "unsurgical." This is nonsense; the most "surgical" procedure is that which, under any given circumstances, gives the best chance of saving the patient's life, and, as regards safety, Porro's original method is not easily beaten. At the time when, in 1777, young Sigault of Paris performed the first successful symphysiotomy, public opinion as regards Caesarean section was at so low an ebb that the operation almost fell into disuse, but it was Baudelocque chiefly who demonstrated the fallacy of supposing symphysiotomy to be so very much the safer operation. So things continued without much progress until relatively late on in the nineteenth century, when Porro (of Milan) introduced his operation; immediately prior to this the mortality was well over 50 per cent. It is difficult to get satisfactory statistics, but it is probable

that Porro's method further reduced the mortality by about another 20 per cent. What we may call the final stage was reached when Singer of Leipzig not very long afterwards proposed the adoption of proper suturing of the uterine wound, and Singer's *conservative Kaiserschnitt* remains, with various modifications and improvements, the operation of to-day. With the advent of Singer's operation conservatism justifiably reasserted its claims, and at present the universal practice is to trust to careful suture and leave the uterus intact; the question as to whether sterilization should be effected must of course be decided by a consideration of the merits of the individual case.

In only one of my own cases did union by primary intention fail, and this occurred in a patient from whom I removed an acutely inflamed appendix early in labour (primipara), Caesarean section being done simultaneously because it appeared the best course in the circumstances. The appendix infected the uterine wound and a large abscess had to be opened and drained; the patient ultimately made a good recovery though a slow one.

Since the above paper was written it has, by a curious coincidence, fallen to my lot to operate on a second case very similar to one of those already mentioned; it seems worth while, therefore, to place on record a brief note of the case.

CASE IV.

A woman, married twelve years. Had had eight children, the last two and a half years ago. Prior to her admission to hospital she had been in labour for twenty-four hours; the membranes had ruptured early and repeated vaginal examinations had been made by an unqualified midwife and subsequently by two medical men. On admission the head of the child could be made out lying high above the pelvic brim, the pelvic cavity being nearly filled by a large firm rounded mass, which the examining finger could not pass (a fortunate circumstance, in all probability, for the patient and myself); the pains were fairly strong.

It was obvious that in this case Caesarean section was the cause *et necessitate*; the usual preparations were therefore made, and the operation proceeded with. The only difficulty in the first stage of the operation arose from the scantiness of liquor amnii, but the child was extracted in a fairly healthy condition, only to succumb ten days later to the effects of a severe burn of its back produced by contact with a damp hot-water bottle. Haemorrhage was easily controlled after eventration, and it was then seen that the fibroid was a solitary subserous one, growing from a point about level with the os internum outwards and backwards under the right broad ligament; the shelling-out process occupied some considerable time, but it was possible to leave a good cervical stump with abundant peritoneal covering, the operation being completed in the usual way. The right ureter had a somewhat extraordinary course, and the right uterine vessels were difficult to secure.

The patient was eventually discharged practically well, but had to remain in hospital for nearly two months on account partly of a troublesome phlebitis arising in old varices of both legs and partly of grave failure of compensation in an old rheumatic heart with rather well-marked mitral disease, the existence of which was discovered subsequently to the operation. The wound healed *per primam*, and gave no trouble. The uterus with the tumour weighed, after removal, about 9 lb.

REFERENCE.

¹ BRITISH MEDICAL JOURNAL, 1911, i, p. 189.

THE eleventh international conference on tuberculosis will be held this year at Berlin in October (22nd to 25th). All communications relative to the congress should be addressed to the General Secretariat, Berlinerstrasse, 137, Charlottenburg.

A PAPER by Surgeon Grow, of the United States Navy, published recently in *Ophthalmology*, deals with a subject which has already received the close attention of the British Admiralty—the vision necessary for the men who train and point large naval guns. The United States naval authorities insist that gun-layers shall possess a vision of 6.45 in the sighting eye, and 6.6 in the other. In other words, a gun-sighter must have normal vision, for 6.6 is subnormal, although conventionally accepted as normal. The author concludes that all candidates for the original rating of gun pointer or trainer should have a minimum vision of 6.45 in the sighting eye, and of 6.6 in the other eye. Hypopia of over 3.00 dioptries should be a cause for rejection. The medical officers should carefully re-examine the eyes of these men once a year, and if any deterioration be present the man should be examined by an ophthalmic surgeon. A slight reduction may be accepted in the case of successful gun-layers who have served a considerable time. In all cases the navy "unlearnable vision test cards" should be used.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF ASPIRIN POISONING.

At the present time aspirin is probably more frequently employed than any other medicinal substance. The frequency with which it has been given in moderate and large doses in varying painful conditions resulting from widely divergent etiological factors without untoward results has earned for it a reputation not only as an efficacious but also as a safe remedy. Only a few cases have been published in which its administration has been followed by toxic symptoms, and the writers until the present case had never seen any untoward symptoms from its use, although they have administered this drug to many hundreds of patients.

The patient was a painter aged 29 who, when in the Royal Mineral Water Hospital one day, complained of a slight cold, and at 7 p.m. was given 10 grains of aspirin. Just previously he had taken a glass of milk. An hour and a half later he felt a burning pain in his epigastrium, and his right eyelids began to swell. The swelling then quickly spread over the left eyelids, the face, lips, tongue, and pharynx. The roof of his mouth "felt dry," his speech became thick, and urticarial blotches appeared over his chest and arms. At the end of three hours from the time of taking the aspirin he could see out of the right eye only with difficulty. There was no dyspnoea. He experienced some discomfort from the swelling of the face and presented a very bloated appearance. Next morning, that is, fifteen hours after the administration of the drug, the only sign remaining consisted of some puffiness of the eyelids, which did not entirely disappear until the fourth day.

This case shows that alarming symptoms may follow moderate or even small doses of aspirin, and corresponds with those described by Barnett, Abercromby, and Brown. More severe symptoms, however, such as violent palpitations, feeble rapid pulse, dark green urine, and gradually approaching unconsciousness, have also been described. The onset in one of such cases occurred in only from fifteen to twenty minutes after administration.

The fact that the patient in our case had had a glass of milk previous to taking the aspirin may possibly have had some bearing on the case, because alkaline substances decompose aspirin with liberation of salicylic acid, which produces the toxic phenomena. At the same time, idiosyncrasy doubtless plays an important rôle.

We are of opinion that aspirin should be taken on an empty stomach, and unaccompanied by anything except water. It is said that one grain of powdered ergot, owing to its antagonistic action, will prevent symptoms of poisoning.

A CASE OF FILARIASIS IN DEVONSHIRE.

In the middle of March a girl aged 19 years (a National Insurance patient) presented herself for treatment for a sore throat, and on recovery from this told me she had for six months or more suffered from a vaginal discharge, which had at one time nearly ceased, but had again become more profuse than ever. But for the sense of uncleanness, the discomfort, and deep yellow stains on her linen, she would not have mentioned it, as it was occasioning no other symptom whatever.

On examination she was found to be a virgin, and no inflammatory signs were present in or around the parts. The urine was normal. I took a swab and made several slides of the discharge for examination, and ordered her injections and cinchona.

Under the microscope there were found pus cells, but no Gram-positive cocci or gonococci or rod forms in any quantity, but almost every field contained embryonic filaria.

The discharge apparently ceased under or during treatment. I therefore directed that it should be omitted for several days and again made a film, and found only what were apparently broken parts of filaria. At the same time (2.30 p.m.) I made a blood film from the finger, and found

an increase of mononuclear and polynuclear leucocytes and eosinophiles, and also what was apparently an aggregation of several filaria, and also separate ones.

What, in my opinion, makes this case worth recording is the fact that the girl has never resided away from Devonshire or the adjoining southern counties, nor has she been in contact with any persons from countries where filariasis is common, and she is, moreover, seemingly in average health.

The microscopic examination of course removed a suspicion from the girl's mind and also from her parents' as to the nature of the "whites" as she called it, and at the same time revealed the unexpected to me and made me wish I had taken a swab of the throat.

It is also worth noting that a few days ago, in attending a recognized phthisical patient, struck by the little body-wasting in an otherwise typical and formerly haemorrhagic case, I made an examination of the sputum, and picking on a tiny nodule, found beside the acid-fast tubercle bacillus, the streptothrix or actinomycosis clump and very numerous loose mycelial spore-bearing tubes or threads.

This latter mixed infection is probably not rare, and I see has been reported in a paper by Dr. Frank Nicholson (BRITISH MEDICAL JOURNAL, February 12th, 1912) but regarding the filariasis I can find no mention of it as occurring in residents of this country.

Bow, North Devon.

THE PRESENCE OF INTRACELLULAR AND FREE AMOEBOID PARASITES IN NOGUCHI'S CULTURES OF *SP. PALLIDA*.

IN THE BRITISH MEDICAL JOURNAL of December 14th last we described certain intracellular parasites found commonly in syphilitic lesions. These parasites were demonstrated by the jelly method of *in vitro* staining; and their development into spirochaetes was also described. They have now been found by us, and their presence has been confirmed by others, in every case of syphilis examined—in the primary and secondary lesions, in the circulating blood of syphilitics, and in some tertiary manifestations. In addition to these intracellular parasites, free amoeboid developmental forms were mentioned as occurring in chancres, glands, and sores. Analogous parasites found in certain animals suffering from allied affections were also noted (in rabbits, hares, guinea-pigs, earthworms). Lastly, these parasites were given the generic name of Lymphocytozoa, all species of which possess a spirochaete-like phase, the spirochaetes being the gametes.

As soon as Noguchi's cultures of the *Spirochaeta pallida* could be obtained a search was made in them for the parasites described. The medium employed by Noguchi consists of a mixture of agar and ascitic fluid in which are suspended small masses of rabbit tissue cells, and the spirochaetes grow anaerobically. After the sixth day of incubation, in the tissue cells (in those cultures which show the spirochaetes) what appear to be intracellular parasites have been found, and these seem to be indistinguishable from those seen by us in chancres, glands, sores, and blood of syphilitics. Moreover, the same free amoeboid forms, as described by us in the paper mentioned, have been found in the cultures. The cultures under observation were subcultures taken from those obtained from the Rockefeller Institute, New York.

The method of demonstrating these intracellular and extracellular parasites in the cultures is as follows: A subculture is chosen which contains spirochaetes. A long sterile pipette, with its upper end sealed, is thrust down through the layer of paraffin used to keep the medium anaerobic, through the semi-solid mixture of agar and ascitic fluid, into the mass of tissue cells at the bottom of the tube. The sealed end of the tube is then cut off, and some of the cells, some parasites, and perhaps some spirochaetes, enter the lower end. The upper end of the pipette is then sealed again, and it is withdrawn. Finally, some of its contents are shaken out on to a cover-slip, and this is inverted on to a ready-prepared jelly when the cells and parasites are stained by the jelly method. In old cultures, where there is considerable destruction of tissue, the parasites appear to undergo development outside the cells. The parasites in the cultures seem to be morpho-

logically similar to those described in the BRITISH MEDICAL JOURNAL of December 14th, 1912, and pictured therein.

Howard McFadden Researches.)

Reports

ON MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

LEEDS GENERAL INFIRMARY.

A CASE OF PUERPERAL ECLAMPSIA TREATED BY CAESAREAN SECTION.

(By JOHN B. HELLIER, M.D., Honorary Obstetric Physician to the Infirmary; Professor of Obstetrics in the University of Leeds.)

THE patient in the following case, an unmarried girl aged 18, was admitted on February 24th, 1913, in the eighth month of pregnancy. She had had good health before pregnancy, but since conception had suffered from vomiting all the time, and in the later weeks from headache and from oedema of feet, and of the eyes and face in the mornings. On the day of her admission she had had convulsions, and had bitten her tongue.

State on Admission.—She was very ill indeed, with a temperature of 101°, pulse 156, respirations 48. She was profoundly comatose, and there was a very large amount of albumen in the urine. Labour had not begun. The prognosis was considered rather bad.

Treatment.—It was decided to evacuate the uterus by abdominal Caesarean section, and, chloroform having been administered, this simple and easy operation was performed without any difficulty or complication. The child could not be got to breathe, being poisoned by the toxæmia.

Progress.—The patient had seven fits after the operation, and received saline injection and hypodermics of morphia and atropine. At 2 a.m. of the night following the operation the temperature was 104.8°. The fits ceased at 4.30 a.m.

February 25th. She improved during the day, and showed some return of consciousness by evening, but passed no water.

February 26th. She was much better, and passing urine freely, with less albumen. The temperature was normal.

On February 27th she was quite conscious, and on February 28th passed 76 oz. of urine.

On March 2nd she was again very much better, and was reading a paper.

Result.—On April 9th she was sent to the Convalescent Home, and inspected again by me at the infirmary on April 16th. She was very much better; all oedema had gone, but some albuminuria remained.

REMARKS.—Eclampsia occurs only in connexion with pregnancy, and the emptying of the uterus stops the formation of the toxins, although time is needed to eliminate what is already in the system. Abdominal Caesarean section is the quickest way of emptying the uterus when labour has not begun and it causes wonderfully little shock, and all trauma of the cervix and vagina is avoided; this is no small matter in an eclamptic primipara.

I do not advocate this operation as a routine treatment, but it seemed quite a good plan to adopt in this case, for the patient was little more than a girl, the symptoms were urgent, labour had not begun, and was not due for a month, and the parturient canal was not infected; moreover, she was in a clinic with all appliances handy for the operation, and where much experience has been acquired in the rapid and successful performance of Caesarean section. Such an operation also offered the best chance for the child. I did not desire to try the vaginal section. I have recently seen it performed on the Continent in a very similar case, and was much struck with the serious amount of trauma involved. Owing to the great force required for delivery I am sure the trauma was many times more severe than if the abdominal route had been adopted.

THE next congress of French-speaking paediatrists will take place in Paris on October 3rd and 4th, under the presidency of M. Netter. The subjects proposed for discussion are obesity in children and cerebral tumours.

Reports of Societies.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

At the first meeting of this society under its revised constitution, which was held on April 24th and 25th, Mr. J. B. LAWFORD, President, in the chair, Mr. FRANK JULER described a case of *Acute purulent keratitis in exophthalmic goitre*, which he had treated by repeated tarsorrhaphy. Mr. ORMOND recorded two cases of permanent hemianopia following migraine, the patients being young and apparently healthy persons, and he referred to three similar cases recorded by Dr. Thomas of Boston. Both Mr. Ormond's cases had suffered from sick headaches for years, with very severe migraine, followed by hemianopia. Observations had been made in other patients temporarily blinded by attacks of migraine, in which a spasmodic condition of the retinal arteries had been seen with the ophthalmoscope. The probable cause of the blindness in these two cases was a spasm of that branch of the middle cerebral artery supplying the visual centre, resulting in a permanent interference with the visual function of that side, and so leading to blindness on the opposite side. Dr. JAMES TAYLOR and Dr. GORDON HOLMES described two families showing a similar defect in vision, and emphasized the following: (1) The coexistence of family optic atrophy with tabes, yet the absence of any apparent effect of the tabes on the optic nerve in the cases affected. (2) The transmission of the optic atrophy in the female line. (3) The occurrence of migraine in several of the patients affected, and its persistence even after practical blindness had been reached. (4) The occurrence of other eye defects in members of the family. Mr. ANGUS MACNAB read a paper on an operation for the *Excision of the conjunctival sac and lid margins*, which he described in detail. He had been impressed by the relief given to the patients who had discharging sockets by this operation, and had no hesitation in recommending it to those persons with an empty socket covered with a shade, especially as the appearance was greatly improved by the procedure. Mr. N. BISHOP HARMAN supplied an analysis of 300 cases of high myopia in children, with a scheme for the *Grading of fundus changes in myopia*. These cases were collected during educational work in London, and all belonged to the elementary schools, so were socially of the working classes. All had come under observation in connexion with the new schools for myopes; many had been watched for several years; out of the 300, boys were 46 per cent., girls 52 per cent., a difference of 8 per cent., which agreed with the difference in the sexes in ordinary vision tests. The bulk of the cases seen were aged 8 to 12 years. Dealing with fundus conditions, the speaker criticized adversely their present nomenclature for changes about the disc. He proposed that the fundus should be spoken of as first, second, or third degrees, according as the atrophy at the disc was as wide as one-half the disc diameter, the whole diameter, or greater than that. To this would be added other details about the macula, etc. He showed a chart giving the correlation of refraction and fundus change according to this plan; it bore out his contention. He maintained some definite notation was necessary when these cases came under observation for a definite object such as the regulation of education. The next communication, by Mr. TREACHER COLLINS and Mr. HUDSON, dealt with the pathological examination of an eye with *Congenital anterior staphylocoma*. Mr. TREACHER COLLINS followed with a paper dealing with *Fibrous tissue formation in connexion with the fibro-vascular sheath and visible vessels on the surface of the iris*. Mr. E. ARTHUR DORRELL, speaking of *Tobacco amblyopia*, said the dilatation of the pupil obtained when the skin of any part of the body was stimulated was either in abeyance or obtained only by increased stimuli in the condition. His 100 cases were divided into three classes: Class A, ordinary unselected cases, showing no signs of nervous disease and not suspected of tobacco poisoning; Class B, cases suspected of tobacco poisoning and showing no signs of nervous disease; Class C, cases showing signs

of nervous disease. In Class A 58 eyes were examined, with the result that in 89 per cent. only five to seven cells were required to produce the reflex. In Class B 121 eyes were examined and in only 20 per cent. was dilatation obtained with five to seven cells, and in over 50 per cent. of the remaining 80 per cent. no dilatation was obtained at all, with the strongest stimulus the patient could stand. In Class C 18 eyes were examined and in only 22 per cent. was the reflex obtained with five to seven cells, and over 75 per cent. of the remainder gave no dilatation. Owing to the similarity in the results in Classes B and C this test was not a positive sign in favour of tobacco poisoning alone, but should be included in the symptom complex of locomotor ataxia and allied affections of the spinal cord.

Retinal Changes Associated with Systemic Disease.

Dr. JAMES TAYLOR, in opening a discussion on vascular and other retinal changes in association with general disease, said he proposed to direct particular attention to thrombosis or embolism of retinal vessels, and to raise some points in reference to other conditions embraced in the title of the discussion. He asked first as to the prognosis in albuminuric cases, and referred to the short duration of certain cases and the length of life in others. He referred also to diabetic cases, and mentioned a case in which the condition had existed during eight years, the patient being still alive. The condition of "silver wire" arteries, described by Marcus Gunn, was also alluded to, and a case, seen by Gunn and diagnosed by him, was mentioned as being still alive after nine years. Dr. Taylor then referred to 4 cases with the ophthalmoscopic appearance of embolism of the central artery of the retina. In 2 of these heart changes were present; in 2 no such changes existed, and there was no albuminuria. Reference was made to the frequent occurrence of the characteristic ophthalmoscopic appearance of embolism of the central artery in which no heart disease could be discovered. Such were probably thrombotic. Eight cases of venous thrombosis were then described. In 7 albuminuria with a hypertrophied heart was present; in several both conditions. One was alive and in fair health after two years. A brief reference was made to retinal hæmorrhage resulting from syphilitic disease—not a very common condition. He concluded by expressing the opinion, gained from the experience which his colleagues at Moorfields had afforded him, that in most cases of venous thrombosis cardiac hypertrophy and vascular disease with or without albuminuria might be present. In his experience, venous thrombosis was not very common in glycosuric cases. The prognosis in such cases was bad, yet exceptionally the duration of life after venous thrombosis was much longer than one would naturally expect. Mr. L. WERNER (Dublin) dealt with the subject of angio-sclerosis chiefly from the chemical and ophthalmoscopic points of view. The ophthalmoscopic evidences of the disease were first considered and discussed. The necessity of an ophthalmoscopic examination in cases of suspected angio-sclerosis in general practice was emphasized, and some cases were related illustrating several points of interest. Obstruction of the retinal circulation was next treated of in connexion with two cases, illustrative of different types of disease. In conclusion, the interesting subject of sudden temporary obscurations of sight was referred to, the ophthalmoscopic appearances observed during the attacks were summed up, and the cause discussed, including the theory of arterial spasm. Mr. GEORGE COATS described first the normal structure of the central artery and vein, and pointed out the changes which took place in disease. In the retinal vessels the commonest form of disease, at least in cases of obstruction of the central vein, was a thickening of the fibrous tissue of the wall fibrosis. It was not improbable that endothelial proliferation occurred in response to the stimulus of a circulating toxin. Mr. Coats also demonstrated the pathological features of some cases of obstruction of the central vein, and showed that in early stages a homogeneous thrombus might be found, which subsequently underwent invasion and organization from the surrounding connective tissues, or sometimes from the endothelium. Two cases were also demonstrated which proved that some cases of arterial obstruction were not due to endarteritis and thrombosis, but that the condition might be caused by embolism.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

At a meeting on May 7th, Sir ANDERSON CRITCHETT, President, in the chair, the following were among the exhibits:—Mr. N. BISHOP HARMAN: (1) A case of *Ectentration of the orbit*, with partial excision of the maxilla and ethmoid for rodent ulcer. The woman had first seen the rodent seventeen years ago, and she treated it herself with caustics. It frequently recurred, and nine years later was as large as a farthing. She then had x rays at every recurrence for four years. Next, zinc ions were used, followed by radium for nine months. When sent to Mr. Bishop Harman for operation the ulcer was as large as a penny, and was fixed to the bone. Ultimately an extensive operation had to be performed, for the growth was found to have extended into the orbit and the bony walls. In reference to the case the exhibitor said that none of the newer measures for the treatment of rodent ulcer could compare with the knife for certainty and security, and the knife was infinitely less costly than any other method. Had this growth been excised in the first instance, the woman would have escaped the necessity for this severe operation, and would have preserved to herself two sound eyes. (2) Drawings of a case of extreme *Hyperphoria*, for which he had operated by his new method of subconjunctival reefing. The patient, a woman aged 28, had been a martyr to severe headaches since school days, and could obtain no relief from them. Examination of the eyes revealed hyperphoria, or latent vertical squint, requiring a 15° prism to correct. It was impracticable to wear such a high degree prism. Concluding from other signs in the case that the left superior rectus was at fault he operated, shortening that tendon by his new method. She had now orthophoria to every test, and the headaches had completely ceased. Seven months had elapsed since the operation, and the result was perfect in every way. Mr. EDGAR CHATTERTON: A case of *Tuberculous iritis* in both eyes. The boy noticed that his sight was bad when at school thirteen months ago. He had never had pain, and there was no history of tubercle or syphilis. Two months ago he had yellow vascular nodules in both irides at the angle of the anterior chamber, posterior synechia, keratitis punctata, and vitreous opacities. He was now having tuberculin injections, $\frac{1}{1000}$ mg. once a week, and frequent tappings of the aqueous. The condition had improved on that treatment. Mr. SYDNEY STEPHENSON: A case of *Ocular torticollis* in a boy aged 13½. At 3 months of age, when recovering from whooping-cough, he held his head towards the left shoulder, and that habit had persisted. While he was in the wry-neck posture there was no squint nor diplopia. But when he straightened his head the right eye turned upwards and outwards, and vertical and contortional diplopia developed. Mr. G. H. POOLEY and Mr. HAROLD GRIMSDALE: Some cases of *Angioma of retina*. Mr. POOLEY: A case of *Giant-celled sarcoma* in which there had been several operations for recurrences, the last in November, 1911, since which there had been no further appearance of the disease. The PRESIDENT commented on the present procedures as a great advance on the days of removal followed by the application of caustic zinc paste to the remaining surface of the wound. Mr. H. HERBERT: A case of *Third nerve paralysis* with rhythmic clonic spasm. No divergence was to be seen, but there was the same absence of strabismus as in congenital paralysis of the sixth nerve. The synchronous raising of the lid to the normal extent was due to spasm of the unstriped levator muscle, which was innervated by the sympathetic. Mr. H. J. FISHER: A case showing arterio-venous communication in the cavernous sinus successfully treated by *Ligature of the common carotid*. Mr. ELMORE BREWERTON, discussing the case, pointed out the reason why the internal carotid should be tied in preference to the common carotid, and said he thought that measure would be followed by more cures and less cerebral complications. Mr. ERNEST CLARKE: A case showing an unusual arrangement of *Opaque nerve fibres*. The patient was a myopic youth aged 20. There was a peculiar ring round the disc, bulging forward, giving to the disc a crater-like appearance. Opaque nerve fibres spread from all parts and partly involved the macula. Mr. R. CRUISE: Three instances of *Sclerotic trephining*, combined with insertion

of thread in glaucoma, the object being to increase the area after trephining. The aqueous filtered along the course of the thread and did not cause inconvenience. He explained that the procedure was on its trial. The PRESIDENT said one of the cases shown he sent to Mr. Cruise for treatment, expecting that cneclation would have to be performed, but from a tension of T - 3 the tension was now found to be normal or even subnormal, and the pain had gone. Mr. RICHARDSON CROSS (Bristol): *A Pigmented growth of the conjunctiva.* The general impression was that free excision followed by the galvano-cautery to the residue should be done.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

At a meeting on May 1st, Dr. AMAND ROUTE, President, in the chair, Dr. NAPIER BURNETT (Newcastle-on-Tyne) recorded a case of *Bacterial infection of the fetal membranes* in a primigravida, aged 28, who had an abortion in the twenty-third week. Pregnancy had run a normal course until sixteen days previously, when a discharge of watery fluid occurred, which was followed in two days by a more copious discharge; this continued intermittently, and the fetal movements were still felt by the patient. During the miscarriage there was practically no liquor amnii, and the afterbirth was discharged spontaneously. On examination of the membranes a thickened yellowish patch about the size of the palm of the hand was noticed, situated upon the pole opposite to the placenta. The puerperium was complicated by an attack of appendicitis, but in other respects was normal; the appendix was removed four weeks later and found to contain about 2 drachms of purulent fluid. The thickened patch of fetal membrane was examined by Professor Stuart Macdonald. He found the thickening affected chiefly the chorion, which presented nodular bulgings on its decidua aspect; the amnion was only slightly affected. The thickened parts showed leucocytic infiltration and extensive areas of necrosis; in the latter were found isolated areas closely resembling miliary abscesses in appearance. These parts also showed extensive bacterial invasion, but, as the membranes had been hardened in preservative fluid, no cultures of these organisms could be made, and consequently their identification was impracticable. The author believed that the fluid discharged was liquor amnii, and further expressed the opinion that the bacteria had probably been lying dormant in the vagina during pregnancy; no vaginal examination had been made previous to the miscarriage. Dr. RUSSELL ANDREWES described a case of *Rupture of the uterus* in a multipara admitted to the London Hospital twenty-four hours after labour. She had been attended by a doctor who reported that he had had great difficulty in delivering with forceps, and then directly after delivery a pendulous mass came down through the vulva. The patient was extremely ill; the swollen, torn cervix protruded through the vulva, and examination under anaesthesia showed the following lesions: (1) Incomplete rupture of the perineum with much bruising; (2) vagina completely separated from cervix except for about three inches in front and to the right side; (3) lower uterine segment and cervix separated from the upper uterine segment except on the right side and in front; (4) lower segment and cervix torn through from top to bottom on the left side. There was a large quantity of blood in the peritoneal cavity. Vaginal hysterectomy was at once performed. There was some pyrexia for four and a half weeks after the operation, but ultimately the patient made a good recovery. The author believed the injury had been caused by one blade of the forceps having been applied outside the uterus, and that the cervix and lower uterine segments had been pulled away with the head by main force.

SECTION OF LARYNGOLOGY.

At a meeting on May 2nd, Mr. HERBERT TILLEY, President, in the Chair, Dr. DE HAVILLAND HALL, in introducing a discussion on the etiology of unilateral *Paralysis of the recurrent laryngeal nerve*, drew the following conclusions: (1) Aneurysm of the aortic arch is the most common cause of recurrent paralysis, and may be the only symptom for a year. (2) The left recurrent nerve is almost exclusively affected in aortic aneurysm; the transverse and descending arch constitute the particular site.

(3) The occurrence of valvular disease is a cause of recurrent paralysis. (4) When the paralysis is due to pressure it is almost always left-sided, which is four times more frequent than right unilateral paralysis. (5) In malignant disease of the oesophagus the recurrent nerves are almost equally affected. (6) Right recurrent paralysis and dysphagia are almost always due to malignant disease of the oesophagus; left recurrent paralysis and dysphagia are usually due to this disease. (7) If recurrent paralysis be due to central causes the nerves are affected nearly equally. Sir DAVID FERRIER contended that the Semon-Rosenbach law should be regarded as an illustration of his view that in all motor nerve trunks the nerve fibres of extensive muscles were more vulnerable. Paralysis of the recurrent laryngeal nerve was either (1) complete, in which case the cord was relaxed and assumed a cadaveric position, or (2) incomplete (more common), when the posterior crico-arytenoid muscle was more affected than the adductors. The toxins of beri-beri and lead picked out the extensors, as did also the pressure of the fetal head in the case of the anterior crural nerve. Injections into the sciatic nerve had a selective effect, and after death the extensor nerves lost their power first. In tabes there was probably a neuritis of the vagus trunk, and the recurrent was affected in this selective fashion and led to abductor paralysis. The nucleus ambiguus, or motor nucleus of the tenth nerve, was closely related to other nuclei. In only two tabetic cases had central changes been proved, and in one of these other nuclei were involved with no resulting symptoms. The nucleus ambiguus supplies three nerve branches: (a) Upper, supplying the crico-thyroid and oesophagus; (b) middle, distributed to the palate; (c) lower, which supplies the recurrent laryngeal and inhibitory fibres to the heart. In bulbar disease and muscular atrophy no selective abductor action could be recognized. Dr. PERMEWAN stated that cases due to aneurysm were not so frequently published as those due to the rarer causes, hence the preponderance of these cases in the records. Of Avellis's cases, published in 1891, in nearly one-half the cause was not ascertained. Taking the record of the last ten years, and classifying according to Sir StClair Thomson's scheme, he had collected 360 cases. The greater accuracy had resulted from (1) the use of x rays, (2) the recognition of paralysis of the cord in chronic bulbar lesions, (3) the assignment of toxic causation, (4) the discovery of the association of paralysis with forms of cardiac enlargement. In the aneurysm cases two-thirds were confirmed by an x-ray examination. Mitral stenosis resulted in an expanded left auricle stretched rather than pressed on the recurrent laryngeal. From the point of view of prognosis, the frequency of recovery in the neuritic group was of great importance. Sir FELIX SEMON considered that his law held good both for nuclear as well as nerve affections. The abductor action of the cords could not be described as analogous to extension of the limbs. The respiratory movement of the cords was bulbar in origin, while phonation was voluntary and cortical. There was no antagonistic action between the abduction of respiration and the adduction of phonation. Organic disease affected the abductors and functional disease disordered adduction; to this there was no analogue in limb paralysis. Probably the nucleus ambiguus and the recurrent nerve were affected on different occasions in a manner analogous to oculo-motor paralysis, which might be either cortical, nuclear, or peripheral. Possibly bulbar paralysees as described were really due to pseudo-bulbar paralysis; it was essential to rely only on clinical cases where a *post-mortem* examination was recorded. Dr. P. WATSON-WILLIAMS supported the view that the nucleus was affected in tabes, and instanced the association of palatal paralysis with abductor paralysis. In tabes interference with the inhibitory fibres of the vagus was the explanation of the high pulse frequency so often observed. Mr. E. D. DAVIS alluded to the rarity of abductor paralysis in tuberculous disease of the right pleura. Dr. DUNDAS GRANT mentioned the difficulties of mediastinal skiagraphy. Mr. T. GUTHRIE described certain definite cases of abductor paralysis where the patient recovered. The PRESIDENT described 3 cases of unilateral abductor paralysis in whom he had observed complete recovery; influenza played an important part in the causation of the neuritis. The prognosis was very different in the aneurysmal cases.

SECTION OF OTOLOGY.

At a meeting on May 16th, Dr. DUNDAS GRANT, President, in the chair, the following were among the exhibits:—
Dr. DONELAN: A case of persistent paroxysmal cough, apparently due to *Irritation of the chorda tympani nerve*. The patient, a man aged 45, was seized, a few days after visiting some engineering works, with a violent fit of coughing. Coughing fits persisted for the ensuing two years without ascertainable cause. Except for general laryngeal hyperæmia, probably due to the coughing, the larynx appeared normal, and various medical examinations failed to assign a cause. On examining the ears, there was found on the left tympanum a tiny black spot surrounded by a reddish areola, just behind the malleus where the chorda tympani nerve crossed it. Under cocaine a small spicule of steel 3 mm. long was extracted; this was followed by violent coughing, but there had been no further trouble. **Mr. JOHN F. O'MALLEY:** A girl, aged 10, a congenital syphilitic, whose *Bilateral deafness* of one year's duration was cured by neo-salvarsan, three doses of 0.3 gram intravenously having been administered over a period of three months. **The President:** (1) A case of *Chronic attic suppuration* treated by an operation, which enabled the ossicles and the remains of the membrane to be retained. The patient, aged 23, had had discharge from the left ear about ten years, and it was found to issue from the attic. Hearing was very good. The operation shut off the diseased cavity from the Eustachian tube and naso-pharynx, and healing ensued quickly. Removal of ossicles and membrane would have left the cavity of disease in communication with the pharynx, and rendered it liable to continuous reinfection. (2) A case of *Chronic Suppuration of the middle ear* which had proved rebellious to transmeatal treatment until that was supplemented by tubal injections of chloride of zinc. The patient, a girl aged 20, had had discharge from the right ear since childhood. The lower part of the tympanic membrane was absent. The injection of a few drops of a 1 per cent. solution of chloride of zinc up the Eustachian tube through the Eustachian catheter, followed by a few drops of paroline to drive the chloride of zinc into the tympanum, led to speedy improvement, and there was now no sign of pus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

At a meeting on April 4th, Dr. J. O'CARROLL, President, in the chair, Dr. J. B. COLEMAN, in a paper criticizing the *Iodoform and benzoyl chloride treatment of pulmonary tuberculosis*, said that in the year 1911 the advocate of this treatment practised intramuscular injection of iodoform and benzoyl chloride dissolved in ether and liquid paraffin, the use of benzoyl chloride being suggested on the assumption of its proved efficacy in leprosy—an assumption which more recent investigation at the Mahaica Leper Asylum in British Guiana proved to be erroneous. In the same year the treatment was carried out in Steevens's Hospital, Dublin, and abandoned after 4 out of 7 cases so treated had died. Later on the exploiter of the treatment, in a paper read before the Academy (see *BRITISH MEDICAL JOURNAL*, vol. i, 1913, page 21), reverted to the method, introduced by Dewar in 1903, of intravenous injections of half-grain doses of iodoform dissolved in ether and liquid paraffin (followed by tuberculin and vaccines). He contented himself with accepting Dewar's conclusions, and he made no attempt to justify the administration of iodoform on scientific grounds. His narration of 6 cases of pulmonary tuberculosis, in which successful results were claimed for the treatment, was of no scientific value as it was not a complete enumeration of all the cases in which the treatment was tried by him. Amongst the objections to iodoform was the fact that the drug was weak, not fatal to bacteria, and not monotropic for the tubercle bacillus, in the sense in which this term was used in connexion with the specific chemotherapy of Ehrlich. On the other hand, it was toxic to human beings. In pulmonary tuberculosis the intravenous injection of iodoform was attended with special dangers, as the injection was liable to be followed by severe attacks of coughing, and thereby entailed the risk of hæmoptysis or of pneumothorax. Sir Almoth Wright, in a report dated October, 1912, in reference to an inquiry

into the treatment of pneumonia by ethylhydrocupreinhydrochlorate, considered the conditions which ought to be satisfied before any drug treatment could be applied with a view to killing the causal agents of disease in the infected body. He discussed the relation in which the specific pharmacotherapy of Ehrlich stands to the prescribing of antiseptics, and pointed out that "it never entered into the conception of the physician who prescribed antiseptics to require of these that they should be monotropic for the causal agents of disease, nor did he appreciate that the effective dose of a therapeutic agent was capable of being determined by blood tests." He pointed out that the medical profession regarded it as "an indefensible proceeding to administer a drug concerning which we have neither *a priori* grounds for believing that it will, nor evidence to show that it does, do what is intended. And we condemn not only treatment which is based upon notoriously erroneous assumptions, but also treatment which is simple random experimentation." *Mutatis mutandis*, the rules laid down by Sir Almoth Wright, in investigating the effect of ethylhydrocupreinhydrochlorate in pneumonia, applied to an inquiry on similar lines in reference to the use of iodoform in pulmonary tuberculosis. Dr. WALTER SMITH said that when called upon to judge of the success or otherwise of any method of treating disease there were two postulates—(1) an adequate knowledge of the drugs or methods used; (2) sufficient clinical and scientific evidence of their fitness. There might be a third, but doubtful, method—namely, the method of analogy. In regard to the second postulate, the paper in which the treatment now criticized was advocated had not produced satisfactory evidence. Enough was known about iodoform to justify scepticism as to a half-grain dose introduced into the body of a man exercising any influence. Even *in vitro* it was harmless to the *B. tuberculosis*. As for benzoyl chloride, he could not understand how so irritating a compound could be tolerated by the human organism. Dr. CROFTON, the reader of the paper criticized, said that, owing to the extraordinary *a priori* objections to the use of intravenous injections of iodoform in ether he had tried to get something as good to be given intramuscularly, and had, therefore, tried iodoform and benzoyl chloride, and if he had not succeeded in the advanced cases referred to, he considered that he had not hurried their end, and since some cases had much improved, he held that he was therefore justified in trying the treatment. As to the assumption that iodoform would do no good, he showed that rabbits had been injected with the bovine bacillus, and when the disease had developed had been completely cured with iodoform in ether given intravenously. This, he considered, gave good grounds for its use in human cases. Could it be shown that fresh air or sanatorium treatment had ever cured such infected rabbits? Iodoform with the molecule intact he admitted was a weak germicide, but in the presence of pus it was split up with the liberation of free iodine, and he suggested that it acted as an inactivator of the toxin of the tubercle bacilli. He had never met with pneumothorax in any of his cases, nor had he ever heard of such an accident. He concluded by giving a summary of 29 private cases in which the treatment had been carried out: 6 early cases, apparently cured; 8 second stage cases, apparently cured; 15 advanced cases, 6 apparently well, 2 very much improved, 7 died. Dr. PARSONS said that it did not take very long after the introduction of a treatment which was successful for that treatment to become general, and pointed to salvarsan as a notable instance of this recently; but this had not been the case in regard to the iodoform treatment suggested by Dewar. Sir JOHN MOORE discussed the dangers attending this form of treatment. Dr. T. GILMAN MOORHEAD said that he did not think that any member should be allowed to remain under the impression that the Academy disapproved of the trial of any method of treatment unless that method was dangerous; he did not consider this method dangerous, and he saw no objection to its trial. What should be deprecated was bringing a method of treatment before the public before the profession was satisfied that it should be brought forward. All desired to arrive at the truth of the matter, and he therefore suggested that it might be well if a certain number of cases could be submitted to independent examination, and then treated and compared with

some other cases which had not been treated, and that the results might then be reported to the Academy. Dr. KIRKPATRICK said that several of the cases in which the treatment was employed were under his care. The patients had been in hospital for some time under satisfactory conditions, the majority of them being treated in the open air on the balcony, where they were in as good circumstances as in a sanatorium. He could say that in no case did the treatment seem to do them any harm, nor did the patients object to the treatment. Dr. BEWLEY endorsed what Dr. Moorhead had said. He had tried the treatment, but had not yet arrived at any conclusions; he looked forward to bringing his results before the Academy. The President said he considered that Dr. Moorhead's suggestion would get over all the difficulties. He suggested that the profession should, as far as possible, keep clear of doing away with healthy scepticism.

ULSTER MEDICAL SOCIETY.

At a meeting on May 8th, Dr. R. W. LESLIE, President, in the chair, Mr. A. FULLERTON read a paper on 48 cases of *Nephrectomy*, with four deaths. He laid stress upon the necessity of using the ureteral catheter, and demonstrated the accuracy of diagnosis attainable by its use. Mr. HICKS, in a paper on *Cæsarean section for eclampsia*, enumerated three successive cases of eclampsia; in one no operation was allowed, and the patient died; in another operation was not performed till the second or third day, and the patient died; in a third, section was done twelve hours after the first symptom of the eclampsia, and the patient made an uninterrupted recovery.

HARVEIAN SOCIETY OF LONDON.

At a meeting on May 8th, Dr. LEONARD GUTHRIE in the chair, the following were among the exhibits:—Mr. LAMING EVANS: A case of *Congenital dislocation of the hip*, in which he had replaced the head of the bone two years previously, and complete functional use of the limb had been recovered. Dr. HAY: A case of *Friedreich's ataxia* in a boy; another member of the family had no knee-jerks. Dr. PATTERSON: A case of *Bronchiectasis* in a child aged 5, the symptoms having been present for at least two years. Dr. TORRENS: A boy suffering from *Splenomegalia*. Dr. WILCOX: (1) A woman who had had a temperature for about a year, with signs of endocarditis; no treatment proved of any avail until a virulent *Rheumatic vaccine* had been injected. (2) A man with *Fibrosis of the left lung*; some fluid had been found by means of the *x* ray, although the physical signs all pointed to the complete absence of fluid. Dr. TURTLE: A case in which there had been marked *Separation of the lower epiphysis of the humerus*, followed by complete recovery. Dr. FITZ-WILLIAMS: A case with a swelling at the root of the neck, the diagnosis lying between a hernia of the lung, a lymphangioma, and a blood cyst. Opinion was fairly evenly divided between the first two.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

At a meeting on May 6th, Dr. CONSTANCE LONG, President, in the chair, Dr. FLORENCE WILLEY, in a paper on *Menstruation*, raised the following questions: (1) What is normal menstruation? (2) In women whose type of menstruation has undergone any change, what conditions are found of an abnormal character which may reasonably be supposed to account for that change? If physiological menstruation rendered the majority of women invalids for a day or two each month, then all women workers, she said, ought to have the necessary leave of absence. But if menstruation were normally a physiological function, performed without pain or distress in healthy women, it were well that this should be generally recognized. The speaker had investigated 500 consecutive cases. Among the conditions found in hospital patients attending the gynaecological out-patient department were the following: Age of onset between 12 and 17 years in

86 per cent., at 14 or 15 years in 44 per cent.; menstruation regular in 84.7 per cent.; recurring every twenty-eight days in 80.9 per cent.; loss moderate in 72.5 per cent., scanty in 15.1 per cent., profuse in 12.4 per cent.; in 73.7 per cent. menstruation was painless, in 5.6 per cent. it caused slight pain, and in 20.7 per cent. it was definitely painful. In 68 per cent. the period lasted four to seven days, in 18 per cent. less than four days, in 14 per cent. more than seven days. These cases, though representing a series of women complaining of some gynaecological ailment, showed that in over 75 per cent. the women had begun to menstruate at the age of 13 to 16, the period recurred regularly every twenty-eight days, the amount of blood lost was moderate, and the whole function was performed painlessly. Statistics obtained from a series of private patients agreed closely with those quoted, except that less than half (45 per cent.) menstruated painlessly, whereas more than three-quarters of the working women experienced no pain. With regard to pathological conditions found among those patients whose menstrual habit had undergone some change, the speaker, after stating that a very large proportion of gynaecological patients showed no menstrual change at all, claimed that the most important conditions influencing menstruation were marriage, reposition of the uterus, pelvic inflammation, and constipation. Metrorrhagia almost invariably indicated one of four conditions—malignant disease, polypi, haemorrhages associated with pregnancy, inflammation of the appendages. The influence of marriage on the menstrual periods generally appeared to be entirely beneficial. The conclusions she drew from her investigations were: (1) That normal menstruation was not an incapacitating experience either from the amount of blood lost or from the association of pain; (2) that it was an experience to which normal healthy women paid no more attention than they did to other physiological functions, such as defaecation or micturition, which also were normally performed painlessly, but might become acutely painful under pathological conditions; (3) irregularity, pain, excessive loss, and incapacitating malaise during menstruation were due to pathological conditions requiring treatment. Painful menstruation was due either to some abnormal condition of the muscle of the uterine wall or to some failure of that polarity of the uterus by which dilatation of the cervix tended to make contraction of the body less painful and more effective. Dysmenorrhoea was most commonly found in girls leading sedentary lives, who suffered from constipation and anaemia. Outdoor exercises or gymnastics were often effectual in curing dysmenorrhoea with excessive loss. She advocated much outdoor exercise for girls during school life, excluding, however, violent exercise at the time of the periods. In the discussion which followed, Dr. CONSTANCE LONG advocated the playing of games but not of matches during school life, and said that bicycling was specially useful in relieving the pelvic circulation. She attached no importance to the occurrence of amenorrhoea apart from a definite pathological condition, as it practically always righted itself. Dr. ALICE CORTHORS had conducted inquiries among 1,000 school girls and had found that only 5 per cent. suffered from dysmenorrhoea. Dr. EMILY FLEMING and Dr. DOROTHEA COLMAN disapproved of excessive exercise for school girls during the menstrual periods but considered moderate exercise to be permissible. Other members having joined in the discussion, Dr. WILLEY replied.

THE estate of the late Dr. George Bruce McDonald, of Shepperton, has been sworn at £17,021.

IN a paper in the *Quarterly Journal of Experimental Physiology* Lyda May Degener reports the results of experiments to test the statement of Simpson and Hunter that (in sheep) thyroidectomy was followed by some increase in the weight of the pituitary body; the increase was much less than had been recorded by other observers. Degener removed the thyroid glands completely from twelve adult rabbits which were killed at periods varying from ten to 179 days after the operation. The hypophyses were weighed after death, and found to be distinctly heavier than in control animals. The increase in weight appeared to run parallel with the time that intervened between thyroidectomy and the death of the animal. After an interval of 179 days (six months) the pituitary had increased to about three times the normal size.

Rebuclos.

THE ORIGIN OF LIFE.

THE veteran author of *The Origin of Life*¹ has for years maintained that the spontaneous development of lowly forms of life may occur in solutions of various composition which have previously been submitted to sterilization by heat. He has maintained the correctness of his observations in the face of the most strenuous, and sometimes unfair, criticism, and when possible fallacies in the methods have been suggested he has always been ready to meet them. The solution principally employed is composed of distilled water with ammonium phosphate, phosphoric acid, and sodium silicate; another contains a few drops of sodium silicate and liquor ferri pernitratii to the ounce of distilled water. Tubes of soft glass about 1 in. in diameter and 3 in. long, sealed at one end and drawn out to a tapering extremity at the other are half filled with the solution through the tapering end, which is then sealed in the flame. The tubes are afterwards sterilized by heat, either by boiling in a water-bath for twenty minutes on three successive days, or by heating in a calcium chloride bath to 115° to 130° C. for from ten to twenty minutes. These prepared tubes are then exposed to daylight in an east window, or are kept in an incubator at 30° to 33° C. for some six or eight months, after which the contents are examined microscopically with or without staining. In successful experiments, Dr. Bastian claims that bacteria and torulae, and occasionally thread and mould forms, are to be found entangled in the colloidal precipitate which forms in properly prepared tubes. They are never free in the liquid. By observing the organisms in ringed cells or by transferring some of the precipitate to tubes containing a sterilized solution of ammonium tartrate and sodium phosphate, the organisms are found to multiply, and are thus proved to be living.

The solutions named were employed because, admitting that life originated at an early period of the earth's history before organic compounds had yet been formed, they would presumably be more likely to favour the development of life *de novo* than the complex organic solutions commonly employed by the bacteriologist. The solutions are in an unstable condition, and very readily yield colloidal precipitates. Silicon is employed because of its chemical affinities with carbon. There would also be present a sufficiency of carbon dioxide to yield the necessary carbon if silicon does not replace it. Such solutions do, in fact, contain all the elements necessary for the constitution of ordinary protoplasm; it is true some might be present in the minutest traces, but still sufficient for the formation of all the organisms detected, for even good distilled water contains sufficient nutrient material to support the life of millions of bacteria in every cubic centimetre! The principal criticisms which have been made regarding Dr. Bastian's work and conclusions may be summarized as follows:

1. Organisms of the comparatively high development of bacteria and torulae could not be expected to be the primitive forms which would originate *de novo*. In reply to this it may be pointed out that these organisms are not found in the solutions until a lapse of some months after their preparation—a period presumed to be sufficient for development to proceed from molecular aggregates, through ultra-microscopic into visible forms.

2. The organisms presumed to have originated *de novo* have developed from organisms originally present in the solutions—that is, the solutions have not been sterilized by the process. As against this it may be stated that the methods employed are such as in the majority of instances do yield sterile solutions, though it must be admitted that occasionally resistant organisms occur (for example, in inulin) which are not destroyed by the processes ordinarily employed for sterilization. But if control experiments show, as they seem to do, that no growths can be obtained from the solutions immediately

after sterilization, this criticism to a large extent falls to the ground.

3. The organisms found are the dead bodies of organisms originally present in the solutions. Dr. Bastian admits that a few organisms, and therefore their dead bodies, are present in the solutions, but points out that the organisms found after incubation for a period of several months are far more numerous than are ever found at the commencement of the experiment.

4. The presumed organisms are "artefacts," or simulations of organisms, due to peculiar aggregates of the colloid. This is a more serious objection, because we know from the work of Ledue and others how extraordinarily colloidal and other aggregates may simulate organic forms. Moreover, such aggregates may stain and increase in numbers just as organic forms do. The crucial test is the cultivation and multiplication of the "organisms" in solutions free from the colloid, and this, too, Dr. Bastian claims to occur (in solutions of ammonium tartrate and sodium phosphate).

The work undertaken by Dr. Bastian is most laborious, and is surrounded by pitfalls, some of which are difficult to guard against. We congratulate him on the present presentation of his views. He has made out a *prima facie* case, and his work cannot be dismissed in the light-handed manner hitherto customary. Already interest has been excited in the work in several quarters, and we may expect that in the course of a year or two the correctness or otherwise of his conclusions will be established. In any case, no one can fail to admire the courage and tenacity with which Dr. Bastian has carried on the investigation of this subject, resuming, after a long interval filled by successful labours in another field, the study which had first engaged his attention at an early stage of his distinguished career.

THE SURGICAL WORK OF THE BROTHERS MAYO.

It is interesting to note the movements of the great centres of surgical influence. It may, perhaps, be said that half a century ago France—that is, Paris—dominated the surgical world; a quarter of a century later the great German schools were the most influential, while to-day the keen surgeon of our country recognizes the value of widening his outlook by a visit to the United States, or at least by cultivating a close acquaintance with the work of American surgeons. The advance in American surgery has been for the past decade or more extraordinarily rapid. It is to be accounted for by the influence of a few men. Two summers ago we had opportunities of making personal acquaintance with some of the best-known surgeons of the States when they visited this country; all were distinguished by strong energetic personality. Without disparagement of others, perhaps few features of American surgery attract British surgeons more than the Brothers Mayo and their work at St. Mary's Hospital, Rochester. In two volumes before us, entitled *A Collection of Papers Published Previous to 1909 by William J. Mayo and Charles H. Mayo*,² papers have been carefully collected and edited by Mrs. MELLISH with the object of preserving a complete file of the writings of these two surgeons from the time of their graduation up to February, 1909. Chronological order has been observed in the arrangement so that the development of the subject may be watched. All the original subject matter has been incorporated and careful search has been made to avoid omission.

The record of work thus presented is really enormous, not in quantity only, but in the extent of the field covered. It displays originality of conception, elaboration of detail, and careful regard for the writings and doings of others.

The subjects are too numerous and varied for us to notice all. The addresses to medical colleges and societies on the experience gained in visiting foreign clinics, and on subjects of general interest relating to the welfare of the profession, are bright and happy. The Mayos are strong advocates of indulgence in *Wanderlust*; other men and different methods must be studied, and so they tell of what they have seen in European and other American

¹ *The Origin of Life. Being an Account of Experiments with Certain Superheated Saline Solutions in Hermetically Sealed Vessels.* By H. Charlton Bastian, M.D., F.R.S., Emeritus Professor of the Principles and Practice of Medicine, University College, London. Second edition. London: Watts and Co. 1913. (Pp. 98. Price 3s. 6d. net.)

² *A Collection of Papers Published Previous to 1909 by William J. Mayo and Charles H. Mayo.* In two volumes. Philadelphia and London: W. B. Saunders Company, 1912. (Roy. 8vo, vol. i, pp. 506, figs. 46; vol. ii, pp. 538, figs. 71, 42s. net.)

medical centres. The address on the "medical profession and the issues which confront it" is particularly appropriate to our country and the status of our profession to-day. The doctor starting practice is strongly recommended to keep up the habit of daily study, and is advised to put in even one hour a day reading journals and books of reference, and to make frequent trips away for purposes of observation. Thus only will he avoid the rut of self-satisfied content which checks advancement and limits usefulness.

The surgery of the intestinal tract forms the major part of this collection, and of that region the stomach has the most prominent place, no fewer than 300 pages in the first volume being devoted to that organ. The surgery of the stomach is dealt with freely, untrammelled by tradition. The gradual development of the surgical treatment of ulcer in stomach and duodenum leading up to the no-loop posterior gastro-jejunostomy can be traced through these pages. We venture to think that some of these papers will rank with the classics, and we are particularly pleased to note that the pictures by Miss Dorothy Peters illustrating gastric operations so familiar to students of the subject are here preserved. The quantity of material at the disposal of the surgeons in St. Mary's Hospital is very great. Some idea of this may be formed when we find that in the more limited region of the gall bladder and bile ducts 1,500 operations have been performed in the fifteen years ending May 1st, 1906.

We feel certain that surgeons will be glad to possess and to read these volumes. They are a mine of surgical wealth. It is true that some of the papers might well have been excluded. Even poets do not always like to see their earliest effusions printed in later years. Many of these papers are simply records of cases of little value, others embody conclusions drawn from consideration of groups of cases which are served up again in later papers. But it is easy to find the wheat. These volumes show the workings of two brilliant minds; they bristle with evidences of originality and resource; they are an exposition of virile personalities which could well have made their mark in any sphere of human activity, but which, fortunately for surgery, had an hereditary bias towards the art of healing.

DISEASES OF THROAT, NOSE, AND EAR.

If the law of supply following demand holds good in the matter of elementary textbooks on diseases of the throat, nose, and ear, then the demand by practitioners and students of medicine for instruction in a subject which, not many years ago, was practically not taught is truly remarkable. To the large selection of textbooks on the subject Dr. W. G. PORTER has added another entitled *Diseases of the Throat, Nose, and Ear; for Practitioners and Students*.³ His main object has been to provide the practitioner and senior student with a single volume of moderate size, embracing sufficient information on the diseases of the throat, nose, and ear to be of value in practice. We may say at once that he has attained his object. This success is to be attributed to the special attention paid to diagnosis. In a region in which so much can be brought under ocular inspection by modern methods, accurate diagnosis is possible. It cannot be too strongly emphasized that a student must be trained to be a diagnostician of diseases of the throat, nose, and ear before he can be entrusted with their surgical treatment. Dr. Porter has wisely confined his remarks on treatment within the limit that the latter can be carried out by the non-specialist. Therefore the major operations have not been described; the indications for their performance and their general features alone are given. The book naturally falls into four sections dealing respectively with the pharynx, the larynx, the nose, and the ear. Each section is prefaced by a full account of the ordinary methods of examination, and this is followed by remarks on general semeiology and therapeutics. The diseases in each section are described with a due sense of proportion. The practitioner is put on his guard against performing operations

which even in the hands of experts do not always yield the gratifying results that textbooks and papers would lead him to expect. As an instance, we may take Dr. Porter's remarks, which we fully endorse, on the surgical treatment of suppurative disease of the ethmoidal labyrinth:

The employment of curettes, guided only by the sense of touch, is to be deprecated, as there is considerable danger of causing meningitis by fracturing the cribriform plate, or of endangering or even losing the eye by perforating the wall of the orbit.

The index unfortunately broke down under the first test. A reliable index is of all importance to the busy practitioner who has to refresh his knowledge at short notice. Accordingly we turned to a disease commonly diagnosed by the public—nasal polypus. We are referred to page 114. There is no account of the disease on that page or in that chapter or in the following chapter, but on page 128 we find the condition described and illustrated. This, however, is a defect to be remedied in the future editions which the book well deserves.

Amongst the volumes dealing with aural diseases we welcome that of LAKE,⁴ which has reached the fourth edition. It has been considerably enlarged, and will be found useful both by students and practitioners who desire to become generally acquainted with the causes of deafness and its treatment. This *Handbook of Diseases of the Ear* is well illustrated in coloured drawings of various pathological conditions of the membrana tympani, and some good prints of sections of the temporal bone, depicting the various important structures it contains seen from different points of view. The definitions given throughout the book are concise and to the point, and the explanations of somewhat abstruse points are generally excellent. There are few typographical or clerical errors. The work shows evidence of a careful weeding out of all unnecessary matter, and, if any fault is to be found with it, it is that in one or two instances questions which are still *sub judice* are dealt with as if settled—for example, that of increased labyrinthine pressure. The indications for intranasal treatment are dealt with, and the chapter on the estimation of acuteness of hearing is well written, though the value of "the proportional test" to one not thoroughly experienced in its use is doubtful. Chronic non-suppurative diseases are well dealt with and most useful information given. The treatment by inflation of the middle ear is thoroughly described and valuable hints given regarding those cases in which it is inadvisable. Bärányi's test is described, but more detailed instructions and advice would have been useful. Intracranial complications of middle-ear diseases are fully discussed, but the statement that "optic neuritis or papillitis is found during the whole of this"—the second—"stage" of cerebral abscess should have been prefixed by the proviso—when present. The paragraph on post-influenzal mastoiditis is excellent, and if the hints there given were always borne in mind, some lives would be saved; for the failure to recognize that grave danger may exist with a normal temperature has been responsible for more than one death. Various prescriptions are given in an appendix, and there is a very good index.

Our great debt to Professor ONODI is increased by the addition of his book entitled *The Accessory Sinuses of the Nose in Children*⁵ to the list of valuable works he has contributed towards the perfection of our knowledge of the normal anatomy of the nose and its accessory cavities. He has, in accordance with his custom, gone direct to Nature, and has elaborated his descriptions from the data afforded by 102 specimens derived from subjects varying in age from six and a half months of fetal life up to nineteen years of extruterine existence. At some of the most interesting ages he gives skiagrams of a very informing character. Curiously it happens that in more than one of them one of the frontal sinuses is undeveloped, but it is

⁴ *Handbook of Disease of the Ear*. By Richard Lake. Fourth edition. Four coloured plates and 77 original illustrations. (Demy 8vo; pp. 301 7s. 6d. net.)

⁵ *The Accessory Sinuses of the Nose in Children*. By Professor Dr. A. Onodi, Director of the University Clinic of Diseases of the Nose and Throat in Budapest; with a Preface by Professor Dr. W. Waldeyer. Translated by Carl Prausnitz, M.D., M.R.C.S., L.R.C.P., London. John Bale, Sons, and Danielsson, Limited; Würzburg: Curt Kabitzsch. 1911. (Imp. 8vo, pp. 23, photographs 102. 21s.)

³ *Diseases of the Throat, Nose, and Ear; for Practitioners and Students*. By W. G. Porter, M.B., B.Sc., F.R.C.S. 15d. With 77 illustrations, 44 of which are in colours. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1912. (Demy 8vo, pp. 287. 7s. 6d. net.)

not contended that this indicates the true average frequency of this condition. In a chapter devoted to a consideration of the application to surgery of the results of anatomical investigation, Professor Onodi draws attention to the fact that "we observe more often than in the fully developed cavity a certain amount of blurring and indistinctness of the outline, although the sinus may be perfectly healthy." Reference is also made to the tendency for infectious disease to attack the partially developed accessory sinuses. "In the first years of childhood the value of skiagraphy and the conclusions to be drawn from it, so far as the frontal sinus is concerned, are very limited; this is shown by our results and pictures where, with few exceptions, the sinus in the first years only reaches the lower limit of the basal portion of the squama or exists as a definite cavity only in the inferior basal portion of the squama" (pp. 17-18). In view of these observations it devolves upon us all the more to study the other clinical features in our diagnosis, and above all to familiarize ourselves with the anatomy of these cavities in their various stages of development. When dealing with them the surgeon could have no more valuable work of reference than the one now before us. The descriptions of the illustrations which form what is really an atlas, are given in English, French, and German; the text of the work in English.

EMERGENCIES AND MINOR MALADIES.

To use a single word where ten will do is repugnant to a true child of the Fatherland, and accordingly Dr. RICHARD LENZMANN has chosen a lengthy title for his excellent work⁶ on the pathology and treatment of emergencies. It has now reached its third edition, and has been translated into Spanish, Italian, and Russian, as we are told in the third of its three prefaces. A great deal of ground is covered by its contents, as the emergencies met with in medicine, surgery, and midwifery are most of them discussed from the point of view of a didactic and highly competent general practitioner. The first section of the book deals with emergencies arising in diseases of the brain and nerves, the second with those of the disorders of the respiratory tract. Then follow sections given to the diseases of the circulatory and digestive systems and the kidneys, emergencies that may occur during pregnancy and the puerperium, and finally come seventy pages devoted to cases of all sorts of poisonings and to the dangers occasioned by anaphylaxis. The book ends with an indifferent index. Dr. Lenzmann writes clearly and at full length, and his book is intended for the general practitioner. One cannot, perhaps, agree with all the statements it contains; Dr. Lenzmann, for example, would diagnose nephritis whenever the arterial blood pressure is found as high as 190 to 220 mm. Hg (p. 475), and he would treat acute oedema of the lungs with cardiac excitants only, and without the use of morphine. But there are singularly few omissions in this carefully written volume, and few directions as to treatment that are not well within the scope of the general practitioner's means. The book may be recommended with confidence to those for whom it is designed.

The third edition of Dr. LEONARD WILLIAMS'S *Minor Maladies and their Treatment*⁷ is no less welcome than its predecessors. It contains much, we venture to believe, that the average practitioner has never really learnt or, if so, has forgotten, and in this lies its chief value. Of the vast amount of knowledge that the student of modern medicine is supposed to assimilate, a certain quantity—if we may so put it—is necessarily "bolted," resulting in a not inconsiderable residue of otherwise quite valuable mental pabulum. It is this fact that Dr. Williams has seized upon and turned to such admirable account. He has a knack of picking up these apparently uncared-for trifles and appraising them at their true value. We note, for example, his remarks on the diagnosis of diphtheria. While not disparaging in any way the value of bacterio-

logy in this connexion, he quite properly reminds the general practitioner that, in the absence of knee-jerks and in the presence of albumen in the urine, which are to be noted quite early in the disease, he possesses a corroborative diagnosis too often ignored. He rightly lays great stress upon the far-reaching effects of eye-strain on the nervous system, apart from the occurrence of headache. The chapter on indigestion follows more or less closely modern views on this difficult subject. Quite naturally, but not obtrusively, the author indicates his preference for certain drugs or combinations of drugs in this malady, and although he banishes to the rubbish heap one or two cherished formulae, he provides some excellent substitutes. Without wishing to be accused of preciosity, however, we view the combination of potassium iodide and bismuth with a certain measure of distrust. The wine merchant, who has suffered much at the hands of the profession of late years, will be cheered to read Dr. Williams's strictures on the "whisky and soda school," and will feel grateful for his temperate appreciation of the juice of the grape. The book concludes with a very clear and instructive chapter on insanity, not omitting to mention the procedure necessary in the notification of insane persons, a matter with which the average medical man is not, as a rule, too familiar.

INTERNAL SECRETIONS.

PROFESSOR BIEDL'S book on the *Internal Secretory Organs*⁸ has been translated from the German by Miss LINDA FORSTER, and issued with an introductory preface by Dr. Leonard Williams. The exact physiological study of the internal secretions has illuminated the pathology of myxoedema, cretinism, and goitre, of acromegaly, of Addison's disease, of diabetes, and of the sexual life. Professor Biedl has analysed all the experimental work which has been done up to a recent date, and gives the reader what appears to be a complete list of references to the literature in each department of the subject. Professor Swale Vincent's book on the *Internal Secretions*, published by Arnold, and recently noticed in these columns,⁹ resembles in its general scope and contents Professor Biedl's work, and the English reader is now supplied with two admirable summaries of the present knowledge of the internal secretions. Each author has enriched his work with the fruits of his own research. The conceptions which result from the study of the organs of internal secretions must, when generally realized, have a profound effect on the ethical opinions of mankind. The atrophy of a small gland such as the thyroid changes a normal child into a stunted and frightful cretinous idiot; the hypertrophy and hyper-secretion of the thyroid produces the over-emotional, restless, and unstable nature of the subject of exophthalmic goitre; an adenoma of the cortex of the suprarenal gland may induce precocious development of the sexual organs in a child of 4, and lead to his expulsion from the kindergarten school for offences against little girls; castration of the child entirely changes the development of the sexual secondary characteristics and the mental and moral nature; the transplantation and successful grafting of an ovary, in place of the complete removal of both, ensures the continuance of menstruation and sexual appetite; the sexual organs of each sex contain developmental traces of the opposite sex organs, and each of us is to a greater or less extent a hermaphrodite in mental nature. A greater tendency towards the characteristics of the opposite sex may lead to non-sexuality, or to sexual perversion, change the life not only of the subject, but of his or her mate, and help to swell the sum of human misery and the work of the Divorce Court. These are the facts which the philosopher, the priest, the politician, and the judge have to grasp. The efficacy of prayer and moral training are powerless to help the cretin, while thyroid tablets will convert him into a normal and useful being. No man by taking thought can add a cubit to his own stature, but he can add many inches to a boy, who is too short to enter the navy, by feeding him with thyroid if the cause of the arrested growth is deficiency of this gland.

NOTES ON BOOKS.

IN the preface to his book on *Geometrical Optics*¹ Mr. A. S. PERCIVAL states that it is primarily intended for medical students preparing for the preliminary scientific examinations, but that it also contains most of the optics necessary for the ophthalmic surgeon. The work treats of the nature of illumination, pinholes and shadows; reflection at plane surfaces; reflection at a spherical surface; refraction at plane surfaces; refraction at spherical surfaces; and finally of lenses. At the end of each chapter a few examination questions are given for the student to work out, and the answers are contained in an appendix. It will be seen that the theory of the ophthalmoscope and of retinoscopy are not included, and so the book would not be sufficient for a candidate for a diploma in ophthalmology. It is really a mathematical treatise upon optics, and as such is eminently useful to a student who is reading for an examination in pure optics. The subject is treated as simply as possible, and a knowledge of algebra and trigonometry will allow the reader to follow the demonstrations. The author insists that the use of cardinal points—a valuable procedure—has been much neglected, and he treats the solution of the problem in a simpler manner than is customary.

Practitioners of all classes will be interested in the publication of Dr. JOHN B. MURPHY'S *Surgical Clinics*.² A number is issued bimonthly and contains the clinical account of various representative cases. The story of each appears to have been taken down in shorthand and published very much in the same language as was used at the clinical demonstration. This method, when carried out in describing the steps of an operation as the various structures are dealt with, is apt to lead to confusion; indeed, the description of many of the operative procedures is ragged. We find, further, that even very simple questions put to the intern—that is, the house-surgeon—and equally simple answers on matters of fact are inserted verbatim. The Socratic method is most excellent in clinical education, but Socratic questions should lead up to something, should conduct the learner gently and by the use of his own reasoning powers along the path of knowledge. Simple facts, such as dates of previous operations, and the temperature of the patient, would better be given in preliminary statements.

"But to return to static treatment," writes Dr. HOWARD HUMPHRIS, when discussing neurasthenia in his *Electro-therapeutics for Practitioners*.³ And that is what Dr. Humphris is often doing; very frequently does he return to the static treatment. Seven chapters at the beginning of this volume are devoted wholly to static electricity, and elsewhere we find it referred to in connexion with the treatment of many ills, from eczema, herpes, and pruritus, to sciatica, and synovitis, and rheumatoid arthritis, and constipation, and dysmenorrhoea. Some emphasis is placed upon its value in enlarged prostate, and in the form of the static bath it is recommended as an adjunct in the treatment of inebriety. The only considerable section in which there is no reference to this agency seems to be that dealing with malignant disease. Here, apparently, the static machine is impotent, except, of course, as a means of exciting the x-ray tube. Dr. Humphris would probably plead guilty to being an enthusiast for the static modalities, and the consequence is that, in spite of the catholic title of the book, the other forms of medical electricity get rather short shrift. But his enthusiasm has, at any rate, given to his essays—for that is how he describes these sharply cut chapters—a refreshingly personal and original outlook. The pages in which he advances his electrical theory of pain, for instance, whether convincing or not, are an oasis in the dry desert of electrical literature, and so is his frank discussion of the failures encountered in this branch of medical healing, with its recognition that there is such a thing as idiosyncrasy to electricity, apart from electro-phobia. The incandescent light treatment also occupies a good deal of space, and the author foreshadows, not in so many words, the prospect of a light bath in every home, in which the overworked and sedentary slaves of

our latter-day civilization may recoup their energies and regain their tone. The work may not be as comprehensive as a textbook—Dr. Humphris disclaims that description for his modest volume—but it is decidedly more interesting than many.

The *British Guiana Medical Annual* for 1911,⁴ though somewhat late in putting in an appearance, is nevertheless welcome. It contains the following papers: (1) The narcotics and stimulants of the Guianese Indians, by Walter E. Roth (Commissioner of the Pomeroon District); (2) Trichosporosis nodosa, by J. W. H. Macleod, M.D. (reprinted from the *British Journal of Dermatology*, April, 1912); (3) A case of tinea cruris in British Guiana, by J. H. Conyers, M.B., C.M.; (4) Causes of cough, by Mrs. E. M. Minett, M.B., B.S.; (5) The treatment of leprosy by nastin and benzoyl chloride, by E. P. Minett, M.D., D.P.H.; (6) Studies in enteric fever, by K. S. Wise, M.B., B.Sc., D.P.H.; (7) The frequency of *Bacillus violaceus* in the water and milk supplies of British Guiana, by E. P. Minett, M.D., D.P.H., D.T.M. and H.; (8) Reviews of the milk question in British Guiana, by K. S. Wise, M.B., B.S., B.Sc., D.P.H., and E. P. Minett, M.D., D.P.H.; and (9) Myiasis, by F. E. Field, M.D., D.P.H. Part II is devoted to clinical notes. Part III contains the *Transactions* of the British Guiana Branch of the British Medical Association for 1911 and 1912; while Part IV deals with the public health, statistics, and medical institutions of the Colony. Many of the papers are of interest and importance, and are worthy of careful perusal.

The fifth edition of *Physical Diagnosis*,⁵ by Dr. R. C. CABOT, is as attractively illustrated as its predecessors. The pictures, indeed, have been considerably increased, and the book as a whole is likely to be regarded in every wise as satisfactory a guide as the earlier editions. It is clear and practical throughout, both qualities being partly due, no doubt, to the principle on which it is written. The author, who is the Assistant Professor of Medicine at Harvard University, does not attempt to describe every method of physical diagnosis ever suggested by any one. In respect of technique he details solely those with which he himself is familiar and has found useful, but sometimes records the information stated to be obtained by other methods. A case in point is the use of electro-cardiograms.

MEDICINAL AND DIETETIC ARTICLES.

An Acetone Soap.

WE have received from Mr. W. Martindale (10, New Cavendish Street, London, W.) a sample of acetone solution of soap. This is a clear stable liquid containing about 25 per cent. of soft soap. The solvent and penetrating properties of the acetone are added to the cleansing properties of the soap, and we have not observed any unpleasant effect on the skin as a result of using it. It will doubtless prove a useful preparation.

Salts of Emetine for Hypodermic Injection.

The observations of Professor Leonard Rogers, recorded in our columns, on the great value of hypodermic injections of salts of emetine in amoebic hepatitis and amoebic dysentery have led to a considerable demand for the pure salts of this alkaloid. We have received from Messrs. Whiffen and Sons, Limited (Lombard Road, Battersea, S.W.) samples of emetine hydrochloride and emetine hydrobromide prepared by them; they are white minutely crystalline salts, readily soluble in water. For hypodermic use the salt employed should be dissolved in sterile normal saline solution. It was for a long time supposed that the value of ipecacuanha in dysentery was due to some constituent other than the alkaloids, and to obviate the vomiting caused by the drug "de-emeticized" ipecacuanha, or ipecacuanha from which most of the alkaloid had been removed, was largely employed, but failed to give the desired results. Professor Rogers's recent observations have shown not only that emetine is the important constituent of the drug in the treatment of dysentery, but also that when given hypodermically it does not usually cause vomiting.

TREATMENT OF FRACTURES.

PRELIMINARY REPORT OF THE AMERICAN COMMITTEE.

THE American Surgical Association at its meeting in Montreal in 1912 appointed a committee, consisting of Dr. John B. Roberts (chairman), Dr. Edward Martin, Dr. W. L. Estes, Dr. Thomas W. Huntington, and Dr. John B. Walker, to report on the relative value of the operative and non-operative treatment of fractures of the long bones, and on the value of radiography in the choice of the method of treatment.

This committee presented a preliminary report to the meeting of the American Surgical Association held in Washington on May 6th, 1913.

The committee expresses its high appreciation of the value of the report issued by the Fractures Committee of the British Medical Association (published in the *BRITISH MEDICAL JOURNAL* of November 30th, 1912), and in a preliminary discussion of that report points out that in it all recent closed fractures not treated by incision and fixation of the fragments were included in the non-operative category, which, therefore, must have included some cases that not even the ardent advocates of operation would consider proper for operative treatment. The statistics in the operative class of cases referred almost entirely to selected cases under the care of surgical experts, though among the fractures in the non-operative class were some presenting serious general and local lesions, and many treated by practitioners of no special skill in fractures. The members of the American Committee think it possible that the non-operative results would have been better had all the cases been in the hands of experienced surgeons, and had the complicated fractures been eliminated. To obtain a true estimate of the value of the best non-operative means of treating those fractures, they contend that only the best non-operative method should be compared with an operative method used in selected cases by experts.

The American Committee proceeds to point out that the general methods for the non-operative treatment of fractures are immobilization, early gentle massage or friction, and an intermediate method, now largely used in the United States, by which a considerable amount of passive and active mobility with friction is allowed early in the treatment of fractures. This method is probably more frequently adopted in the treatment of fractures of the upper than of the lower extremity, because in American hospitals patients with fractures of the upper limb are largely treated as ambulant cases.

In order to afford data for forming an estimate of the relative value of the two methods—the non-operative and the operative—of closed fractures of the long bones of the limb, the circumstances should be the same, and the Committee observes:

The surgical attendant in each case should be equally skilled, the fracture identical in character and situation, and the patients similar in temperament, in environment, and in social and financial standing. Diagnosis in both forms of treatment should be made with the aid of the *x* ray and immediate reduction attempted under anaesthesia and the method of treatment then selected. After a few days the correctness of the reduction should be confirmed by *x* rays, and attention given to active and passive motion of the joints to prevent stiffness occurring as the result of traumatic arthritis, which often happens in fractures, as it does in sprains. Prolonged abstinence from weight-bearing must be insisted upon in fractures of the bone of the lower limb.

The three questions the American Committee set itself to answer were:

I. What should be the routine method for the average general practitioner and those unskilled in surgery as a speciality?

II. What should be the routine treatment for trained surgeons with the usual facilities afforded by small or cottage hospitals?

III. What should be the routine treatment for skilled surgical experts with adequate hospital facilities?

It answers these questions as follows:

For all three classes of medical attendants the Committee believes that *prolonged* immobilization with *continuous* fixation by means of external splints or apparatus should be abandoned. This ancient method frequently leads to bad anatomical and bad functional results. The

evil sequels may be caused by concealment of imperfect reduction or by overlooked later deformity from imperfect maintenance of coaptation of fragments. Ankylosis of joints may arise from unrecognized coincident traumatic arthritis or from prolonged immobility of proximal joints. Pressure sores, ischaemic palsy, and gangrene may follow the omission of frequent examination of an exposed limb. This method, fortunately, has long been abandoned by the surgical expert. Some surgeons and medical attendants mentioned in the first class may not yet have replaced the immobilization method by more modern procedures.

I.

For the first class, which includes all those not trained in surgery as a speciality, the Committee suggests the study and adoption of a routine method midway between that of immobilization on the one hand and the mobilization of Lucas-Championnière or the traction method of Bardenheuer on the other. It is believed that either the method of the French surgeon mentioned or that of Bardenheuer, the German expert, probably will be found to require too much skill, experience, and attention to be safe in the hands of those who only occasionally have need to treat the more troublesome fractures. For these general anaesthesia should nearly always be employed for the diagnosis and reduction of the fracture, unless *x* rays are used during the manipulations preceding the application of the fracture dressing. General anaesthesia should always be used by such practitioners in the diagnosis and reduction of fractures involving joints. It alone will solve many difficulties of diagnosis and often simplify the subsequent treatment of the injury.

If reliance is placed upon *x*-ray readings, the study of the skiagraphic plate must be under the direct supervision of a medical man accustomed to both clinical and radiographic examination of bone lesions. The radiographic reports of even expert radiographers alone are not always reliable guides to surgical practice. They must, as other pathological reports, be studied in association with expert surgical experience and clinical observation.

The maintenance of reduction of the fragments should be assured by position, traction, splints, or other easily removable and adjustable apparatus. Splints should be so arranged as to allow easy and frequent inspection of the condition of the fragments and soft parts, and to permit early passive and slight active movements. Moulded splints of gauze and gypsum or other plastic materials fit well, and best fulfil the above requirements. The watchwords for this first class of practitioners are general anaesthesia, plastic splints or traction, frictions, and frequent inspection, early mobility, delay in weight-bearing.

II.

By most trained surgeons in America, restricted by the moderate facilities of small or cottage hospitals, prolonged immobilization has probably been largely discarded already, when they take personal care of the entire treatment of a fracture. This is especially true of patients in private practice. Mobilization, less than that advised by Lucas-Championnière, or traction apparatus, to a less extent than that used by Bardenheuer, varying with the locality of the injury, has been adopted by many, and probably should be adopted by all such surgeons for the usual run of fractures. One or the other method will probably continue to be the routine at the hands of the class of surgeons mentioned in private practice and in small hospitals with moderate facilities.

This opinion suggests, it will be observed, that the operative treatment be restricted to especially rebellious fractures known to be such or found to be such after a very few days' study. This judgement is recorded because of the difficulty under such circumstances of insuring perfect asepsis and sufficient trained assistance.

The troublesome fractures that may with propriety be mentioned as probable candidates for operative treatment are:

Fractures of the surgical neck of the humerus, T-fractures at the lower end of the humerus, fractures of the upper third of the radius, fractures of the upper third of the radius with dislocation of the radial head, fracture of the radius and ulna in the shafts, especially in adults; fractures of the upper third of the femur, supra-condyloid fractures of the femur, fractures of the tibia and fibula near the ankle occasionally. In a general way it may be said that operative treatment suggests itself as the preferable method in any fracture which cannot be properly reduced or retained after reduction.

If operative treatment be selected, the metal plate under absolute asepsis is the final resource, unless open reduction alone, or sutures, nails, or screws be effective.

When reduction of fragments is not easily gained or its maintenance is doubtful, plating will be usually found better than wiring. A few cases will not need direct fixation after the reduction has been accomplished through the incision. The operation should be immediate—that is, within a week or ten days after the receipt of injury. It is, in fact, better to operate within a few hours than to delay even a few days, unless shock or other contraindication requires delay. The method selected by the surgeon within the first week should, as a rule, be continued, if the surgeon be familiar with both operative and non-operative procedures.

III.

As to the routine treatment for skilled surgical experts with adequate hospital facilities, the Committee considers that if prolonged immobilization has not been discarded, the surgeon can hardly be termed a skilled surgical expert in fracture treatment. He is behind the times in the surgery of fractures, though he be a recognized expert in abdominal, cerebral, thoracic, or pelvic surgery or other branches of the medical art. To a fracture specialist with the facilities, a sufficient number of trained assistants, and the other essentials of a well-organized modern hospital, it makes little real difference in morbidity or mortality whether he select the non-operative or the operative plan. The latter, like all aseptic surgical procedures, requires more time, more care, and more conscientious service at the beginning, but makes the after-days easier for the surgeon, less painful for the patient, and less troublesome for the nurses. These surgeons may at times gain great advantages from the use of the fluoroscope while adjustment is in progress.

The time must soon come when metropolitan hospitals will not be considered satisfactorily organized unless fractures are assigned for treatment to specially equipped wards under the care of surgeons particularly interested in the pathology and treatment of these injuries. Gun-stock deformities of the elbow, forearms incapable of full pronation and supination, deformed wrists, valgus ankles, coxae varae, and shortened and crooked femurs all too frequently prove the need for increased surgical skill, perhaps specialism, in the treatment of fractures of the tubular bones of the extremities.

It is probable, though not certain, that consolidation of a fracture takes place a little more slowly after direct fixation of fragments with a metal plate than in a well-reduced fracture under non-operative treatment. The statement that the surgical expert will be able to conduct in safety the patient to the point of recovery with good result in most fractures by either the operative or the non-operative route is only true provided he personally dominates the situation as to reduction, fixation, and after-treatment, and sets the time at which the patient shall be allowed to resume his original occupation. Such a surgeon, if of a mechanical turn of mind, will obtain good anatomical and good functional results in many fractures without blood-letting measures. In others he will not fail to recognize early the need for open reduction and direct fixation, nor will he fear sepsis, haemorrhage, or shock. Similarly he will seldom fail to recognize those cases in which these risks of operation outweigh the benefits likely to be obtained through it. Then some of his patients will be treated by non-operative methods, and may, perhaps, show poor anatomical restoration of the skeleton, as well as bad functional use of the injured limb. They will, however, live.

If, on the other hand, this expert have more liking for operative surgery and a mind less mechanical in its attitude toward fracture repair, he will apply operative procedure to a greater number of fractures than will his colleagues above mentioned. He will, however, equally recognize those cases in which operative surgery of the blood-letting kind has no place.

The report of the American Committee concludes by suggesting to Fellows of the Surgical Association a series of questions to which they might give attention, with the object of presenting succinct reports of the result of their inquiries two months before the next annual meeting of the American Surgical Association.

THE Royal Dental Hospital, Leicester Square, has received a donation of £400 from the trustees of Smith's (Kensington Estate) Charity.

THE Board of Management of the Metropolitan Convalescent Institution announces that at the Home for Adults at Walton, near Weybridge, 24 beds are now provided for patients requiring surgical treatment after operation.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, 1913.

SECTION OF STOMATOLOGY.

THE Stomatological Section will hold its meetings in the lecture theatre of the Royal Dental Hospital, Leicester Square.

The following discussions have been arranged:

The pathology and treatment of periodontal disease. To be opened by Dr. N. N. Znamensky and Mr. E. B. Dowsett as reporters.

The relation of nasal obstruction to dental disease. To be opened by Dr. Jules Ferrier and Mr. J. G. Turner.

Dental disease in relation to public health, which will be introduced by Dr. Harold Williams and Dr. J. Sim Wallace.

A discussion on the supervision of the health of children between infancy and school age will be held conjointly with the Section of Hygiene and Preventive Medicine. Mr. W. W. James will report on behalf of the former Section, and Dr. Leslie Mackenzie on behalf of the latter.

The final discussion of the meeting will be on reflex and functional disturbances in connexion with teeth. Drs. Rousseau-Decelle and A. W. W. Baker being the reporters.

The papers to be read include the following:

The enamel organ and its products, by A. S. Underwood and A. W. Wellings, assisted by T. G. Brodie and Lovatt Evans.

The relation of mouth conditions to cancer of the alimentary canal, by Mr. F. St. J. Steadman, founded on an extended clinical investigation of cases in various London hospitals.

Dr. J. Zilz, of Hungary, will read a paper on general infection via the tooth pulp, and Dr. Besson will discuss suppuration in the temporal fossa of mouth origin.

Mr. K. Goadby will contribute a paper on arthritis deformans of mouth origin.

There will be a clinical demonstration at the Royal Dental Hospital on Monday, August 11th, at 5 p.m., of cases of interest collected from the various dental hospitals in London. It is anticipated that between seventy and eighty patients will be shown. In addition there will be an exhibition of pathological specimens and stereoscopic skiagrams. To this gathering the Stomatological Section will welcome any members of the congress.

Some special entertainments have been arranged. A dinner will be held at the Hotel Metropole on Friday, August 8th, and on Saturday the President of the Section will give a garden party at Phyllis Court, Henley.

The President of the Section is Mr. Morton Sinalo and the Secretary is Mr. J. F. Colyer, 11, Queen Anne Street, W.

A SCHEME FOR MEDICAL ATTENDANCE ON WORKMEN.

WITH the concurrence of its workmen the Metropolitan Water Board applied for exemption from the Insurance Act, and submitted to the Commissioners a scheme which was accepted by them. While giving the men better terms than they would have received under the Act, it does not provide for medical attendance. Most of the 3,000 workmen were in clubs, into which they paid 1d. a week for medical attendance, and it was found that they were willing if they had free choice of doctor to continue paying this 4s. 4d. per annum if the Board would pay the difference between that sum and the amount agreed to by the Board's district medical officers. After conferences with the doctors and the men a subcommittee of the Board recommended the following terms, which have been provisionally accepted by all concerned:

1. An inclusive payment to the doctor of 10s. per annum for each man on his list, this sum to include attendance, medicine, and all certificates required by the Board.

2. A payment of 3s. 6d. for first aid and a special fee for serious surgical cases.

3. Every medical practitioner who, on April 1st, 1913, was attending not less than twenty-five of the Board's permanent employees to be included among the medical officers.

The total estimated cost of the scheme is £1,500 a year, and of this sum the men will contribute about £625.

This scheme was entered into with good will by the Board, the doctors, and the workmen, was carried out in a spirit of give and take, and ultimately accepted by the representatives of all concerned as a good working compromise. It is in pleasing contrast to the bungling and irritating schemes of the Insurance Commissioners in too many instances.

Nova et Vetera.

PROVERBIAL MEDICINE.

PROVERBS ON ARTICLES OF FOOD—BREAD AND CHEESE.

Most of the ordinary articles of food make their appearance in one or more of the proverbs which are in common use; in this way their chief characters, or their supposed characters, are emphasized, and some at least of these are medical in their nature. A beginning may be made with bread and cheese, although "some folk by nature do abhor cheese," and others hate cats, perhaps for no better reason.

Swift, in *A Tale of a Tub*, makes Peter say, "Bread, dear Brothers, is the staff of life"; and this saying must be a very old one. Homer, in the *Odyssey*, speaks of bread as the "marrow of men" (*μελὸς ἀνδρῶν*); and Matthew Henry, in his *Commentary* on the Psalms (Ps. civ), says: "Here is bread which strengtheneth man's heart and therefore is called the staff of life." Lean¹ also has found "staff of life" in Howell's *Parley of Beasts*, published in 1660. Well, too, does the writer remember a reproof he received when a child for passing a piece of bread to a guest on the sharp end of a knife: would you offer the staff of life on the point of death? The paramount position in nutritional values which is occupied by bread is recognized by its name being sometimes used as synonymous with subsistence or means of livelihood: and "to take the bread out of one's mouth" or "to know on which side one's bread is buttered" have another meaning than the strictly literal one. Lean² quotes from Havergal's *Herefordshire Words and Phrases* this distich:

Bread when you're hungry, drink when you're dry,
Rest when you're weary, and Heaven when you die;

and it is true that most of life's pressing needs are thus supplied.

But one can have too much even of a good thing, although Rosalind asked, "Why, then, can one desire too much of a good thing?" and Herrick sings:

Bad are all surfeits, but physicians call
That surfeit took by bread the worst of all.

Perhaps the reason is to be found in the biuding tendency of bread—at any rate, of white bread—for does not brown bread help to check constipation? There is a proverb which gives no uncertain sound on this matter—namely, "Bread's a binder, wealth's a miser; drink down care and thou art wiser"; Lean quotes it from Brathwaite's *Barnaby's Journeys*.³

New bread is difficult of digestion and does harm, and yet all over this country the bakeries are at work at two o'clock in the morning to supply freshly-baked bread! There is a French proverb⁴ which warns against too new bread: it runs thus: *Le pain de nuit Grandement nuit*—that is to say, last night's bread greatly hurts; or, to make a rhyme for the nonce, Last night's baking sets you aching. In another language there is a similar saying: *Nacht broot is een letsel groot*; and an Italian proverb⁵ seems to refer to the pain in the back due to indigestion, for it reads: *Quando se taia pan fresco, se fa doler la schena a quei che l'ha fatto*. Peter Lowe,⁶ writing more than 300 years ago, gives counsel on the kind of bread which should be preferred: "Good breade of wheate, that is neither over new, nor too stale, as counsaileth Avicen; for over new and hote bread doth digest evil, altereth the body, and ingendereth obstructions, sending vapours and fumes to the head." Again, W. Ellis, in *The Modern Husbandman*, ascribes great force to new bread, and quotes the saying, "New beer, new bread, and green wood will make a man's hair grow through his hood," whatever that terrible result may be.

There are proverbs which define exactly the best age of bread for eating. Bohn (in his reprint of Ray) gives "Bread of a day, ale of a month, and wine of a year"; and two French proverbs (both from Joubert's collection)

read, *Pain d'un jour, vin d'un an, farine d'un mois*, and *Oeuf une heure, pain d'un jour, chair d'un an, poisson de dix*. Lowe, again, gives the reason why too old bread is not good: "It drieth too much and remaineth long in the stomacke." To digest bread of a fortnight old calls for an insatiable hunger; at least, that is what Meurier's proverb of the sixteenth century seems to mean, *A pain de quinsaines, faim canine de trois semaines*. Proverbs, however, are not at one on this question of stale bread. In a play of Ben Jonson,⁷ Peter Onion says to Antonio, "My mind to me a kingdom is"; Antonio answers, "Truly a very good saying." Onion then says, "'Tis somewhat stale, but that's no matter," and Antonio goes further: "O, 'tis the better, such things ever are like bread, which the staler it is the more wholesome." Bullein⁸ says both are to be avoided: "And also bread muste neither be eaten new baken, nor very stale or old, for thone causeth drynesse, thirst and smoking into the hed, troubling the brains and cics, through the heat thereof. The other drieth the body and bringeth melancholy humours, hurting memori. The best bread is that which is of a day old, and the loaves or manchets may neither be greate nor little, but mean." We may leave the virtue of stale bread undecided; probably there are two opinions about it to-day even.

There are differences of opinion, too, regarding the grain which makes the best bread. To quote Robert Burton, "By profession a divine, by inclination a physician," we find the following:⁹ "Bread that is made of baser grain—as pease, beans, oats, rye, or over-hard baked, crusty, and black—is often spoken against, as causing melancholy juice and wind. Joh. Mayor, in the first book of his *History of Scotland*, contends much for the wholesomeness of oaten bread. It was objected to him, then living at Paris in France, that his countrymen fed on oats, and base grain, as a disgrace; but he doth ingenuously confess, Scotland, Wales, and a third part of England, did most part use that kind of bread, that it was as wholesome as any grain, and yielded as good nourishment. And yet Wecker (out of Galen) calls it horsemeat, and fitter for juments than men to feed on." This quotation, by the way, seems to cast some light on Johnson's famous definition (now proverbial in force) of oats: "A grain which in England is generally given to horses, but in Scotland supports the people," and on Lord Elibank's repartee which it provoked, "Very true, and where will you find such men and such horses?"¹⁰ Dr. Johnson, it is well known, was an enthusiastic student of Burton, and the latter's *Anatomy* was the only book that ever took him out of bed two hours sooner than he wished to rise. It is more than likely that the sentences quoted above were in his mind when he defined oats. Burton,¹¹ in another place, names the Chinese as "scuffling at our Europeans for eating bread, which they call tops of weeds, and horse-meat, not fit for men." Well, well, every one to his taste; but it is to be remembered that "all breads are to be eaten, and all maids to be wed."

"Bread with eyes and cheese without eyes" is a Spanish proverb, given by Ray; and Bullein¹² says, "The lighter the bread is, and the more full of holes: it is the holisomer, as Averrois and Rasis saye"; this we take to mean that light bread and solid cheese are best. But what, we wonder, is the origin of the superstition, "A hollow loaf is a sign of death?" Is it because it is hollow like the tomb, or because it betokens a scarcity of grain? In this connexion it may also be asked why it is a bad omen if bread-and-butter fall on the buttered side; and why it is unlucky to take the first slice or outside of a loaf—the so-called "loaf's picce." Perhaps the buttered side is more likely to have the dirt of the floor adhere to it, perhaps it is impolite or selfish to take the first slice; but these are hardly convincing explanations. Ramsay's proverb, "Broken bread makes hale bairns" is a puzzling one, too. Why should the fragments left from a meal make healthy (whole) children? Of course the verbal point of the proverb lies in the contrast between broken

and whole; but the saying may perhaps have been meant for the pampered child, who turned away his head from plain bread and demanded cake. There is another Scots proverb, "A bread house skailed never," meaning that a house with bread in it is never empty; it is used, says Wright,¹³ "when we have bread and perhaps want something finer."

After all has been said, we shall come back to this, that bread is of the first importance. In *Don Quixote* is the old Spanish saying, *Todos los duelos con pan son menes* (All sorrows are less with bread). Burton¹⁴ says, "S. Hieromo esteems him rich that bath bread to eat" (*Satis est dives qui pane non indiget*); and in Juvenal¹⁵ we read: "Two things only the people anxiously desire, bread and the circus games" (*Duas tantum res anxius optat, panem et circenses*). The Herefordshire distich (quoted above) has its counterpart in the Italian proverb,¹⁶ *À fame pane, a sete aqua, a sonno panca* (For hunger bread, for thirst water, and for sleep a plank or bench); and there is a French saying,¹⁷ *Pain le meilleur metz à qui a faim* (Bread is the best dish to him who is hungry). "Bread at pleasure, drink by measure" is a good motto; and "Better halfe a lofe than no bread" is a piece of worldly wisdom.

That "ever famous Thomas Moffet,¹⁸ Doctor in Physic," has preserved for us two proverbs of the Elizabethan age both touching upon bread, and both with a medical flavour in them. Dr. Moffet, for so his name is to be spelt, and not Muffet or Mouffet, was very high in his praise of bread; he never saw, read, or heard of any man that naturally hated it; it is, he thought, the staff of life, without which all other meats would either quickly putrefy in our stomachs, or sooner pass through them than they should, whereupon crudities, belly worms, and fluxes do arise to such children or persons, as either eat none or too little bread; it is never out of season, disagreeing with no sickness, age, or complexion, and therefore truly called the companion of life; it neither inflameth the choleric, nor cooleth the phlegmatic, nor overmoisteneth the sanguine, nor drieth the melancholic; it also best nourishes both man and beast; is mentioned in Genesis and in the Lord's Prayer; and indeed, "all troubles are easie with bread, and no pleasure pleasant without bread." Here are his two proverbs: "Money and bread never brought plague," and "Bread and cheese be the two targets against death." Of course it is possible that the plague of the first of these sayings simply means any trouble or annoyance not necessarily of the nature of a disease, and it is hardly likely that it signifies the great plague; but yet it may indicate a malady of some kind. The second proverb is very interesting, for it gives us the verbal picture of a man defending himself against his Apollyon with a shield or buckler in each hand, one of bread and the other of cheese! Whether he is thus "lock'd up in steel" against all death's darts may be doubted; but there is no denying that much may be done on bread and cheese, and in the case of bachelors, with kisses added, so goes the adage.

Cheese has been mentioned in alliance with bread, and the alliance is a good one; but the proverbs on cheese are important enough to be considered separately. There is one at least which comes into conversations pretty often and has quite an up-to-date peptonizing sound about it, although exactly what it means would form a hard question in a physiology examination paper. "Cheese is a peevish elf, It digests all things but itself." In this proverb the phrase "peevish elf" may be taken to mean a perverse, obstinate, contrary sort of little creature, freakish in his behaviour, doing for others in the matter of digestion what he will not or cannot do for himself. The writer, when a child, well remembers a story he was told to explain this mysterious statement about cheese; it was a story which fixed itself firmly in his mind, probably by reason of its gruesome ending, and possibly, who knows, turned his young thoughts to the art of healing. It was about a very clever but somewhat eccentric and rough spoken doctor; there seemed to be a fashion in that particular type of medical man in those days. A child was ill, and

the doctor was sent for; he was busy (confinement case it may be, such things being commoner then than now) and could not go, but inquired what the child had been eating. He was told it was cherries—a great many of them. "Then give him cheese," was the voice of the oracle. The child grew worse, and the anxious parents sent again; the doctor, still busy, asked if his orders had been carried out, found they had not been, and again repeated them, "Give him cheese." The child, however, was not given cheese, and died. The doctor then came along, but too late: "Why did you not give him cheese?" Then, to show that he had offered the best advice, so the story went (becoming a trifle blood-curdling to the lay mind), the doctor cut open the little one's stomach, revealed the cherries lying there in a heap, called for a piece of cheese, put it on them, and immediately they were seen to melt away.

There are two medical maxims¹⁹ of the School of Salerno, one at least of which has a bearing on the "peevish elf" proverb. The one is *Casus est nequam quia concoquit omnia secum*, or "Cheese is bad because it digests all other things with itself;" and the other is *Casus est sanus quem dat avara manus*, or "Cheese is wholesome when given with a sparing hand." The former is evidently another version of the saying about cheese digesting everything but itself; and the latter seems to refer to the fact that cheese is a highly nutritious form of food, to be taken, therefore, in moderation. Both ideas appear in the position commonly assigned to cheese in a meal, expressed in Ray's laconic proverb, "After cheese comes nothing." Lean²⁰ has found a sort of rhyming version of this in Franck's *Northern Memoirs*—namely, "Cheese after meat prohibits other dishes, and after shell-fish rarely other fishes."

There is a medical flavour in a number of other proverbs about cheese. Lean is our source for a saying found in the Harleian MSS. (6395), "Cheese is physic for gentlemen and meat for clowns"; the "fees" in the adage "Bread and cheese for the sound are good fees," are probably perquisites, wages, or rewards. Cheese is also conjoined with bread in the Latin proverb, *Casus et panis sunt optima ferula sanis*, and with an onion in the other Latin one, *Casus et carpe veniunt ad prandiu sæpe*; about butter and about fruit as well as about cheese it has been said "Gold in the morning, silver at noon, lead at night." Two French proverbs emphasize the wisdom of eating little cheese or none at all, namely, *Fourmage qui moins en mange est tenu le plus sage*, and *Jamais homme sage ne mangea fromage*; but if a man must have his cheese with his bread then another French proverb says, *Pain legier, pesant fourmage, devez toujours prendre si vous estes sage*; and Howell gives "White loaf and a hard cheese never shames the master."

For a proper appreciation of the meaning of some of these old sayings about bread and cheese, it is almost necessary to know the varieties of bread and the characters of the cheeses which were eaten in the days of the Tudors or even earlier. The white, brown, and black breads of the past; the white, wheaten, and household breads; the rye, oat, barley, maslin (mislun), and mongcorn breads; and cheeses innumerable have ceased to be found in the common language of a people who buy their bread from the baker and their cheese from the grocer, and have almost forgotten that their ancestors baked and worked in their cheeseries.

There is the old proverb, "To believe that the moon is made of green cheese," but although one has a general idea of its meaning it is unlikely that many know exactly what green cheese is. It is not called green, says Boorde,²¹ "by the reason of colour, but for the newnes of it, for the whey is not halfe pressed out of it." There were four cheeses in those days, green, soft, hard, and spermyse, whatever the last named may have been. Then, again, the well-known saying, "as like as chalk to cheese" (meaning, of course, that it is unlike) loses its point, if we think of some of the modern fancy cheeses. Still, we have a fair notion of what Tom Hood meant when he sang of Miss Kilmansegg's adulators, "Flatterers make cream cheese of chalk, they praised—how they praised—her very small talk, as if it fell from a Solon."

²¹ Boorde, *Dyetary*, xiii, 266, 1542.

Addison, in the *Spectator*,²² has some very interesting remarks upon antipathies, and cites cheese as one of the things which some people cannot abide. Some of these persons, he wrote, "offered to our consideration the miraculous Powers which the Effluvioms of Cheese have over Bodies whose Pores are disposed to receive them in a noxious Manner; others gave an account of such who could indeed bear the Sight of Cheese, but not the Taste; for which they brought a Reason from the Milk of their Nurses." In this connexion one wonders how much the threats launched against us in our childhood's days have to do with the antipathies of later years; many of us still remember the vague sense of something terrible happening if we ate too much cheese. There is an Italian proverb,²³ too, which carries a terrible warning to the child who eats cheese or too much of it: *Il caccio fa romperle scarpette e ingrossar la lingua*. Certainly it is very alarming to think of any foodstuff bursting our shoes and making the tongue swell up! Perhaps this is the origin of the saying which the writer remembers being discharged at him when he was a boy and a lover of cheese, "You may eat cheese and choke."

We must bring these rambling remarks on bread and cheese proverbs to an end with two adages which illustrate once more the two views of cheese—that it is good, and that it is bad unless taken in great moderation; the one is, "You may eat bread and cheese till you become hungry again," and the other is, "A pennyworth of cheese is enough."

Before, however, we leave the subject altogether, let us hear Dr. Thomas Moffet;²⁴ we have taken his views upon bread; what has he to say about cheese?

Now if the Butter be at Market when the Curds or Cheese is prest at home, then are they both utterly unwholsom, clamming the stomach, stopping the veins and passages, speedily breeding the stone, and many mischiefs; but if they be equally mingled with the butterish part, then the Cheese made thereof is wholsom, unless age or ill-housewifery hath made it bad: For new, sweet, and fresh Cheese nourisheth plentifully; middle-aged Cheese nourisheth strongly, but old and dry Cheese hurteth dangerously: for it staveth siege, stoppeth the Liver, engendereth cholera, melancholy, and the stone, lieth long in the stomach undigested, procureth thirst, making a stinking breath, and a scurvy skin: . . . But was not that a great Cheese think you, wherewith Zoroaster lived in the Wilderness twenty years together, without any other meat? or rather was it not most enningly made or preserved, when at twenty years end it did eat as soft as at the first day? Which though some do think impossible, yet the Parmisan of Italy will prove it true, by age waxing mellow and softer, and more pleasant of taste, digesting whatsoever went before it, yet it self not heavy of digestion. Our Essex Cheese, being well handled, would in my judgement come next unto it. . . . The Irishmen, like to Plinies Barbarians, have not yet so much wit as to make Cheese of Milk; and our Welshmen want cunning to make it well. French Cheese in Plinies time tasted like a medicine; but now the Angelots of Normandy are counted restorative; which many of our Gentlewomen (and especially a Niece of mine own) have so well counterfeited, that they excell their first pattern. Spain hath forgotten the art of Cheese making; and Portugal makes them but indifferently well, though sometimes the best in the world were made at Cuna, near to Cape Vincent. . . . As for our Country Cheeses, Banbury and Cheshire yields the most, and are best; to which the Holland Cheeses might be justly compared, if their makers could but soberly put in salt.

There was published in 1599, by a certain Henry Buttes, a book called *Dyets Dry Dinner*, in which a good deal was put forward in praise of tobacco; but the author had something to say about cheese as well as the "weed nicotian." Here it is: "They that have best leisure, and love cheese best I would wish them to write an Apology in defence of the common dislike thereof why so many love it not." But these remarks are growing wearisome, and the writer must desist, lest the reader say to him, as Sir Hugh Evans²⁵ said to Simple: "I pray you, be gone: I will make an end of my dinner; there's pippins and cheese to come."

THE FUTILITY OF THE CORONER'S INQUEST.

THE discussion of Dr. Brend's paper, entitled "The Futility of the Coroner's Inquest" (*BRITISH MEDICAL JOURNAL*, May 3rd, p. 940), was resumed at the meeting of the Medico-Legal Society on May 20th.

Sir FREDERIC HEWITT said that he had intended to speak on the subject from the point of view of one who was interested in the use of anaesthetics, but he was so much impressed with Dr. Brend's paper that he desired to extend the scope of his remarks. He regarded that paper as a most valuable contribution to the subject, and there was no doubt it made out a strong case for reform. The verdict of the coroner's jury sometimes contained some valuable information, but generally it was quite useless. In most cases in which inquests were held there was much unnecessary mental suffering entailed, without any adequate return from the public point of view. After vacillating for some years, he had come to the conclusion that inquests were of no use in relation to deaths under anaesthetics. In collaboration with a London coroner who also took a particular interest in this subject, he had prepared a series of questions to be administered to medical practitioners at inquests of this character, but even the statistics so obtained were wholly useless. The time had in his (Sir Frederic's) judgement arrived when some action should be taken. He agreed with Dr. Brend's proposals. To have a medical inquiry in the first instance would enable most valuable statistics to be compiled.

Mr. G. C. GARDINER said that the chief charge Dr. Brend appeared to make against the present system was that deaths frequently formed the subject of a dual inquiry, but that was no real objection. Inquests were of more importance now than they were in days gone by. Many inquests had to do with death by accidents. Liability for the accident was not the question. Recently the Home Office had instructed its solicitors to appear and report at every inquest relating to a motor accident. The chief object, therefore, of these somewhat informal inquiries was not to settle who must pay damages but how could such accidents be prevented in future. It had been stated by Dr. Brend that coroners' verdicts were ignored by insurance companies, but many cases never reached the courts. The information elicited at inquests was frequently made use of by the insurance companies. As to medical evidence, he advocated an autopsy by an independent medical man, preferably a public official, and suggested that the medical evidence should be that of independent persons. As to the proposed reforms, it was already difficult to obtain medical certificates. How much more difficult would it be to get the practitioner in a poor district to give evidence which would have the effect of preventing a poor widow getting compensation! Personally he would be inclined to enlarge and not restrict the function of the coroner's jury.

Dr. J. SCOTT said that a strong case had been made out for altering the functions of the coroner. Speaking as one who had had considerable experience at the Old Bailey, he was far from saying that inquests were useless. In the Central Criminal Court he found the coroner's depositions very valuable, especially when he was inquiring into the state of mind of a prisoner. The coroner could call the prisoner's wife as a witness, while a court of law could not. On the whole he thought that the second of Dr. Brend's proposals was the better. He had not had much experience of Scottish inquiries, but agreed with Dr. Brend that there was very little disadvantage in having the private inquiry.

Mr. A. M. FROOKS said that public inquiries were essential. A large percentage of the inquests held concerned the poorer classes of the community. From their point of view publicity was of vital importance by discovery of suspicious circumstances and preventing abuses. The English system was preferable to the Scottish. It was only by accident that the Ardlamont mystery was revealed in Scotland. Had the case arisen in England it would have been discovered at once in the ordinary course. Although his experience as a coroner had not been very long, he had noticed an improvement in the treatment of children, and he believed it was largely due to the influence

UNDER the will of the late Miss Helen Margaret Grewell of Oxford, the Radcliffe Infirmary receives a bequest of £1,000.

of the coroner's inquest in giving publicity to dangerous methods of treating children. Dr. Brend had said that "criminal courts are nearly always guided by the magistrate's decision." Only a fortnight before he had a case in which the inquest showed conclusively that the shot which caused death was accidental. The person who had fired the gun was before the magistrate, and as a result of the inquest the prisoner was at once discharged. The question usually raised at an inquest was such as was best decided by a jury. He had often felt grateful to a member of the jury who evinced special knowledge of the building or some other trade.

Dr. MORGAN FINUCANE said he entirely disagreed with Dr. Brend. What was necessary was the attachment of a specialist to each court. In the early days the coroner was a high judicial officer. The coroner's function was performed untrammelled by the laws of evidence. He and his jury had to inquire "to the best of their skill and knowledge." In compensation cases he fully appreciated the enormous advantage of having an independent pathological examination. He regarded the coroner's court as a progressive institution, although he admitted that the procedure might be improved.

Mr. HERBERT SMITH, LL.D., said that his experience at the Bar led him to desire the abolition of coroners' courts. Only recently he had appeared at an inquest at which his client was found guilty of gross negligence without his advocate having had the right to address the court. Such a verdict might give rise to expensive litigation. In criminal courts, if the grand jury threw out the bill, and counsel attempted to proceed on the coroner's inquisition, what would the judge say to him? Coroners' courts did not attend to the rules of evidence, but if the verdicts returned were to be judicially recognized the inquiry should be conducted judicially.

Earl RUSSELL, whose remarks concluded the discussion, said that sufficient weight had not been attached to Dr. Brend's statistics, but he could not agree with Dr. Brend's conclusions. The object of the coroner's inquiry was to allay public apprehension. It also served to fix liability upon some one. If a mere legal inquiry was begun at once there would be no "fishing" inquiry, and that would be a disadvantage. The suggested scientific inquiry was a counsel of perfection from the point of view of the general public, which looked to the coroner to make sure that a number of undetected murders did not occur. Another advantage was that at an inquest a man was put on oath soon after the event. In his view Dr. Brend had been led astray by a desire to formulate a scientific system.

Dr. BREND, in reply, said that those who had criticized his observations had founded themselves upon experience of London coroners. It should not be forgotten that country coroners' inquests were often conducted in a slipshod manner. Only a medical man could properly understand medical terms. In translating his evidence into simple English, which was necessary if the coroner was a layman, the medical witness was bound to lose some of his accuracy. The complaint that no coroner appeared to have any principle on which to go in deciding whether to hold an inquest or not had not been met. He regarded the suggestion that an expert pathologist should be present as an admission that the present system was defective.

UNDER the will of the late Mr. Isaac Danson of Boston the General Hospital, Birmingham, receives a bequest of £1,250 for the endowment of a bed in memory of the testator and of his sister, Jane Danson.

AN attempt is to be made to determine the standard of physical development of the normal American child. It was announced on April 28th that the New York Milk Committee, with the help of a number of recognized experts from different States of the Union, have undertaken the task. For the purposes of the investigation a series of competitive examinations of normally healthy children will be held in county, city, and State contests. One hundred thousand children will be scientifically tested and measured, and the weight, height, physical measurements, condition, and mental development will be entered on cards furnished by the committee. Prizes will be given to encourage the mothers, who will also be afforded opportunities of instruction in the art of rearing children. It is hoped that by these investigations the standard of the normal healthy American child will be established beyond dispute.

LITERARY NOTES.

MESSRS. OLIPHANT, ANDERSON, AND FERRIER announce a volume on the late Dr. Joseph Bell. The identification in the public mind of the well-known Edinburgh surgeon with Sir Arthur Conan Doyle's "Sherlock Holmes" has, since Dr. Bell's death, given more and more weight to the mistaken presentation of a good man's personality. A volume of reminiscences written by an old friend of Dr. Joseph Bell will, it is stated, "show his absolute unlikeness, save in one respect, to Conan Doyle's masterpiece."

Advantage is to be taken of the occasion of the opening of a new hospital at Toronto to publish an account of the General Hospital of Toronto. That institution was, according to the *Canadian Practitioner*, established by means of funds supplied by the Loyal and Patriotic Society in 1812. The medals struck for the heroes of the war of 1812 were never issued, but were melted down, the bullion sold, and the proceeds handed to the hospital. A complete history of the hospital will be published for the first time, and it is expected that it will form an interesting contribution to Canadian history as well as to hospital literature.

The Cambridge University Press will shortly publish Mr. F. Kingdon Ward's record of his experiences and observations when engaged in plant collecting in Western China and South-Eastern Tibet during the year 1911. The book, which is entitled *The Land of the Blue Poppy*, is not one for botanists only; the author has many interesting tales to tell of the Tibetan people, amongst whom he often played the part of medicine-man, receiving presents of milk and eggs as his fee. A number of maps at the end of the book show the exact districts—some of them not visited before by white men—covered by Mr. Ward in his travels; the book will contain also forty photographs taken by the author. The book is dedicated to the memory of the author's father, Professor H. Marshall Ward.

The W. B. Saunders Company, of Philadelphia and London, has in active preparation a work on the *History of Medicine*, by Dr. Fielding H. Garrison, Principal Assistant Librarian, Surgeon-General's Office, and editor of the *Index Medicus*. The book, which will be in one volume, will give a concise account of the evolution of the healing art from primitive times, the story being carried on through Egyptian, Sumerian, and Oriental medicine, Greek medicine, the Byzantine period, the Mohammedan and Jewish periods, the mediæval period, the period of the Renaissance, the revival of learning and the Reformation. Then the history of modern medicine is related—the seventeenth century ("the age of individual scientific endeavour"), the eighteenth century ("the age of theories and systems"), the nineteenth century ("the beginning of the organized advancement of science"), and the twentieth century ("the beginning of organized preventive medicine") being successively passed in review. The account of each period will be followed by a brief survey of its social and cultural phases. There will also be appendices covering the medical chronology, the histories of important diseases, the histories of drugs and therapeutic procedures, and the histories of important surgical operations, with bibliographical notes for collateral reading. The book will be illustrated.

"Alba," writing in the *Aberdeen Weekly Journal* of May 9th, says that Dr. John Brown's *Horæ Subsecivæ* had been anticipated, so far as the title is concerned, by another Edinburgh physician, Dr. John Fletcher, lecturer in physiology and medical jurisprudence in the Argyle Square School of Medicine. The book was published in 1835 by John Carfrae and Son, 62, South Bridge, Edinburgh, and was entitled *Horæ Subsecivæ; or First Steps to Composing and Conversation on Medical Subjects in Latin Language*. Dr. Fletcher died in 1834, and there is a tablet to his memory in St. John's Episcopal graveyard, Edinburgh. After Dr. Fletcher's death a posthumous work of his entitled *Rudiments of Physiology, or a General Treatise on Organism and Life*, was published in 1835. In some of the reviews of the book Fletcher was

described as the most original thinker and writer on medical subjects of his day. John Brown was then a young medical student, and probably attended Fletcher's prelections, but beyond the title, there was no likeness whatever between the two books. Duport published *Musae Subsecivae* some 200 years before, and Paley his *Horae Paulinae* in 1790; but Latin titles to English books have deservedly fallen into disuse now. The Americans, in their reprint of Dr. Brown's book, translated the title and called the book *Leisure Hours*.

Dr. W. L. Storey (Belfast) writes: Dealing with Latin misquotations, you very pungently observed, in "Literary Notes" in the JOURNAL of April 26th:

That Latin as written by many journalists and authors is a dead language is sufficiently shown by the corrupt fragments so freely strewn about certain kinds of current literature.

But what about our own language? Specimens of the English tongue have been handed down to us in original bottles, but many of the present-day writers and speakers refuse to dispense them until they have altered them by additions of their own. The result is that the full effect of the original is lost, and a malodorous composition foisted on the public, "though every rare ofact it not." Shakespeare, perhaps, suffers more from sophistication than any other great original. Take a few samples: "The ills that flesh is heir to," "Screw your courage to the sticking point," "Make assurance doubly sure," "Such stuff as dreams are made of," "There is a Providence that shapes our ends," "The sere and yellow leaf." Milton, too, has been adulterated—for example, "Fresh fields and pastures new," "That last infirmity of noble minds." Cowper's generous hospitality has been reduced to "The cup that cheers," while Keble's duties have been altered to "The common round, the daily task." Possibly one of the most generally accepted substitutes is "A little knowledge is a dangerous thing." The Bible itself has not been left alone by our dispensers. We are assured that the British workman earns his bread by the sweat of his brow, as did Adam. But is this the exact wording of Adam's curse? "There is nothing new under the sun," except the surprise some people will experience if they refuse that imitation and insist on having Solomon in the original. Was it some facetious K.C. or Q.C. who first told us that "in the multitude of counsellors there is wisdom"? An unsuccessful litigant will not subscribe to this declaration. Indeed, he will find it difficult to accept the statement even in the original.

Readers of *Pickwick* will remember that Mr. Robert Sawyer refused the offer of a head for dissection on the ground that he could not afford expensive luxuries. In resurrection days prices of bodies ruled high, but we were told by a distinguished professor of anatomy who had been a student during that period that the cost to students was not appreciably higher than it is now, the school paying the difference. In an article in the February number of *Aesculape* Dr. Marcel Fosseyeux, of the Paris Assistance Publique, who has access to the archives of the Assistance Publique and the manuscripts in libraries relating to old Paris, gives a number of facts as to the price of bodies in the seventeenth and eighteenth centuries. In a memoir presented to the Académie des Sciences in 1785 by Tenon on the hindrances to the progress of anatomy one of the principal of these is said to be the difficulty of getting bodies for dissection. To remedy this drawback he proposed to establish dissecting rooms communicating with the mortuary of the Hôtel-Dieu, so as to avoid the exhumation and transport of bodies. He estimated at 500 the number of subjects necessary for the instruction of students at that day, and putting the price of each body at 6 francs he said a sum of 3,000 livres a year would have been available for the payment of the hospital attendants whose duty it was to take the remains to the cemetery after dissection, or in case of need for prayers for the repose of the souls of the original owners of these fragments of humanity. Two kinds of persons supplied bodies to anatomists for anatomical purposes—students who wanted them for their own use, and men who looked for profit from a dangerous trade. Often it was necessary that the students should co-operate with the resurrection men in order to direct them and prevent scandals which these men, almost always drunken, were only too apt to cause. Frequent complaints were addressed to the office of the Hôtel-Dieu

by people living in the neighbourhood of the Clamart Cemetery, whose rest was disturbed by the raising of bodies at night. This was not the only subject of complaint. It was not always easy to get rid of the remains. Some cremated the bones, then the neighbours complained of the foul-smelling smoke; the soft parts were thrown into privies, making these even more horribly insanitary than they always were; or into the Seine. Fragments stopped by rafts or boats caused terror among the people always ready to suspect crimes. In the archives of the Bastille are recorded the doings of a student of the Charité who, accompanied by a porter and six soldiers, used to break after midnight into the cemetery of Saint Sulpice, where he raised bodies and took them away in a coach. He gave 10 francs to each of his assistants, and the price at which he sold the bodies was on an average 150 francs. In the seventeenth century there is evidence that bodies cost 40, 80, and even 100 livres. Sometimes the price went up to 250 francs. For dissections students paid 40 sous the first year, 20 the second, 10 the third. After that no further payment was required. A Bachelor of Medicine, elected every year, and known as the "arch-deacon," was charged with the duty of getting hold of the bodies of people who had been executed and of having them buried after the demonstrations and dissections. There was often much unseemly haggling over these bodies, although the charges to be paid had been fixed by Parliament in 1632. The law was invoked, but the "arch-deacon" often paid what was demanded so as to fulfil his contract.

The fourth annual *Year Book of the Viking Society for Northern Research*, recently published, contains a full account of the proceedings of the society during the year 1911-1912. Many interesting discoveries that throw light upon domestic life and customs during the Viking period are here described; one of them reveals the ingredients used by the cooks of that period in the making of their household bread. Under the heading "Notes and Queries" we read that "Dr. Schmittger, professor at Stockholm University, has made an interesting find relating to the remote past of his country at Ljunga, in Eastern Gothland—namely, some bread dating from the time of the Vikings. Microscopical examination has shown this bread to be made from pine bark and pea meal, thus proving that peas were grown in Sweden as far back as a thousand years ago." It seems to prove also that their staple article of diet must have been a fruitful source of appendicitis to the hardy Norsemen, or else that they were blessed with better teeth and stronger digestions than their more weakly descendants. The Ljunga loaf is not the only specimen of ancient bread exhumed by Dr. Schmittger, who, in the course of the excavation of Boberg Castle five years ago, dug up a loaf dating from the fourth century of the Christian era. With these two exceptions, however, few finds of this kind have been made in Northern Europe, though several prehistoric loaves have been discovered from time to time in the Swiss lake dwellings and in Egypt. The contents of the *Year Book* also includes some excellent reviews of current literature, and a short account by Dr. Haakon Schetelig of Captain H. J. Negaard's recent discovery of a number of stone huts in the mountains of Western Norway. These huts, which belong to the Stone Age, are said to have been the dwelling-places of a prehistoric race of hunters, who inhabited the lonely plateau in the mountains between Hardanger and Hallingdal, and whose only means of supporting life must have been the reindeer still found in considerable numbers in certain parts of Norway.

Sir James Paget, in an introductory address delivered at St. Bartholomew's Hospital in October, 1863 (*Memoirs and Letters*, edited by Stephen Paget), warned his hearers that they must be prepared for the apparent success of dishonesty. He added:

In our department of social life, as in all others, the supply of rogues is duly proportioned to that of fools. For the most part medical dishonesty is but the complement of non-medical folly. Therefore until there is a widespread teaching of natural science there probably will always be much success in quackery.

We are glad to find so strong a confirmation of what we have always insisted upon—that the only cure for quackery is the education of the public. This will, as Lecky said, create an atmosphere in which superstition and credulity cannot live.

SATURDAY, MAY 24TH, 1913.

THE FRIENDLY SOCIETIES' CONFERENCES AND THE MEDICAL PROFESSION.

THE members of the medical profession are apparently not the only people concerned with the National Insurance Act who have a difficulty in acquiring a taste for its "rare and refreshing fruit." The friendly societies, judging from the reports of their Whitsuntide conferences, are succeeding in at least dissembling their enjoyment very creditably. We can quite understand their feelings of soreness. When the bill was first talked about, it was understood that the friendly societies were practically to have a monopoly. Their representatives went about with advance drafts of the bill in their pockets and a smile of great contentment on their faces, but during the progress of the bill a change came over the scene. The friendly societies found that the collecting and industrial societies, with no claim based on past history, but by superior commercial ability and influence, had managed to secure a very handsome share in the administration of the Act. Moreover, since the beginning of the operation of the Act duties have been imposed on the friendly society officials to which they were little accustomed, and which must have proved a source of much irritation. We can therefore quite understand that the societies met this Whitsuntide in a somewhat resentful spirit and prepared to vent their resentment on somebody. The Chancellor of the Exchequer, of course, was the subject of some bitter reflections, and the Commissioners were told, more in anger than sorrow, that they knew nothing about the business they are supposed to administer.

Mr. Lewis, of the Hearts of Oak, with the most engaging candour, indicated that the Commissioners required careful watching by a "lively, keen body of men," of which we presume Mr. Lewis might be induced to become one. He also gave hints, by no means obscure, to Sir Robert Morant that the eyes of the Hearts of Oak were upon him, and that unless that gentleman mended his ways he would soon get his marching orders. We trust that Sir Robert will give this warning such attention as it may deserve. Mr. Lewis wound up by expressing the opinion that the Government had made a mistake in not giving the administration of medical benefit to the approved societies, as they could have done it much better and more cheaply than the Insurance Committees. Mr. Lewis is, however, prepared to give the Government another chance of doing the proper thing in the forthcoming amending Act.

Probably it has not occurred to the gentlemen who made speeches of this kind at the various conferences, nor to those who applauded them, that any desire they may conceive the medical profession to have had to see medical benefit

administered by the friendly societies—and of any such desire we have found no evidence—is not likely to be increased by these petty exhibitions of meanness and wrath at the loss of opportunities of patronage which have escaped the friendly societies, for ever. How much cheaper would the societies like to make medical attendance for the insured person? He pays four-ninths of the original 6s. estimated for medical benefit, the rest of the 6s. being found by the employer and by the State, and an extra 2s. 6d. by a special State grant. That is to say, the insured person himself pays 2s. 8d. per annum for his medical attendance, medicines and appliances, as against an average cost to himself in days before the Act of 4s. per annum if he were a member of a friendly society, and probably more if he were a private patient. The less the representatives of the friendly societies say about the cost of medical attendance the better, considering their own record in the way of sweated rates against which the Association has so long and so successfully protested. But it is really not so much the cost of medical attendance which is worrying the friendly society official, though doubtless he thinks some of the money which now goes to the doctor might well have been spent in some other way—the encouragement of the hard-worked friendly society official, for example. The real thorn in the flesh is the fact that the friendly societies have lost their control over the profession. No longer is it possible for a doctor who does not "keep in with" the officials of a lodge to find that by means of the clumsy wire-pulling of a little coterie he is to lose at one swoop the whole body of club members. The contract practice doctor has regained his freedom to an extent which can never be understood by those members of the profession whose first experience of contract medical work has been gained in the insurance service. There are irksome restrictions inherent in all contract practice, but, thanks to the work of the Association, these have been greatly reduced under the Act compared with what they were in friendly society club work. If a medical man unwittingly offends a person on his insurance list, the trouble only entails the loss of that person, and perhaps a few of his immediate relatives, just as would happen in private practice, whereas in the old days it might have meant the loss of the whole membership of a club numbering hundreds. If a complaint were made against a friendly society doctor, he might or might not have an opportunity of meeting it; but the final decision on which his tenancy of the appointment rested lay with a body of laymen without any admixture of his professional peers. We say this, not as loving Insurance Committee control more but as loving friendly society control less—a lesson taught by long and bitter experience. It is not that the friendly societies did not know all this, but when they had it in their power to remove many of the grievances of those members of the medical profession who served them, they refused; yet they appeared to be surprised when the profession declared with one voice for Insurance Committee control, for any control in fact, rather than that of the friendly societies.

The efforts of Mr. A. H. Warren at the conference of the Manchester Unity of Oddfellows at Scarborough excite special admiration. He was in fine form, and made what is described in the *Yorkshire Post* as a "slashing onslaught on the medical profession." He complained bitterly of the House of Commons, who with only seventeen exceptions agreed to hand over the administration of medical

benefit to the Insurance Committees, and said this administration was now less satisfactory and less efficient than at any previous time. Warming to his subject, he said, "deliberately," that in the eyes of the friendly societies the doctors had played a most despicable part, and when the history of the British Medical Association on this question came to be written it would not be regarded as a credit to a great and honourable profession. The line taken by the profession was quite unaffected by any praise or blame it might receive from the friendly societies, and when Mr. Warren went on, as he did, to accuse the doctors of not playing the game fairly, of treating their insurance patients like paupers, of taking their money but not being willing to work for it, he overreached himself. Where is the evidence that the insured persons are not receiving proper treatment? If any such instances are produced we shall be the last to defend such lapses. If any one is in a position to hear of these abuses it should be the various bodies of Insurance Commissioners. We challenge Mr. Warren to apply to those bodies for the production of any cases justifying the statement he makes and to lay them before the public. The fact is Mr. Warren and his fellows cannot rid themselves of the obsession that insured persons are unable to look after their own interests but need the protection of the friendly societies. When will they learn that free choice of doctor gives the insured person all the protection he needs, and in fact places him on the level of the duke whose only protection is that if he is not satisfied with the attention he receives he can change his doctor? So can the insured person, and we venture to say that any abuses of the nature mentioned by Mr. Warren, if they exist at all, will be righted by the full play of the principle of free choice of doctor. That is the safeguard of the insured person, and not anything which the Manchester Unity can do for him. We would, however, remind Mr. Warren that accusations of not playing the game come with a singularly bad grace from one who was a party to the bargain made by the friendly societies with the Association that the aged and infirm members of those societies should be attended at the same rate as is charged for insured persons. Mr. Warren was present at the conferences, and there is no doubt that he was one of those who thought they had done a good stroke of business when they got the bargain embodied in the Act; yet he has been prominent amongst those who have tried ever since to evade the friendly societies' side of the bargain. The profession has not sunk so low that it needs to take its lessons on "playing the game" from persons who act in this way. Mr. Warren wound up by moving "that in the opinion of this Annual Conference the National Insurance Act should be so amended as to restore to approved societies the right to administer medical benefits under the Act." This resolution was, of course, carried unanimously. We know how the Association convinced the Chancellor of the Exchequer that friendly society control of medical benefit had been a bad thing in the past, and would damn his bill if persisted in. We know how the House of Commons almost unanimously endorsed that opinion, and we have little fear of the result if the question is again raised, but the transfer is in our opinion already outside the range of practical politics. As to the action of the medical profession we have no doubt. Whatever differences of opinion there may be in the profession in regard to other points in

connexion with the Act, there are absolutely none in regard to this, and we can confidently assert that there would be no difficulty in bringing about an almost complete breakdown of the medical benefits of the Act if the Government were so misguided as to trust their administration to the approved societies. The profession has had a long experience of that kind of refreshing fruit, and its motto is, "Never again."

THE PLACE OF HYGIENE IN TREATMENT.

THE old time apothecary, whose extinction has recently been deplored by Lord Rosebery, was an example of a system which tended to foster overconfidence in the efficacy of drugs. Medical counsel was an imponderable to which no value was attached unless it was expressed in the concrete form of pills and potions; charges for medicines were recoverable at law, but professional advice had no place in the apothecary's account. Sir William Gull considered it one of the best achievements of his life that he with Sir William Jenner disabused the public mind of the notion that drugs were the beginning and end of medical treatment. We remember his saying publicly that during the whole time of the severe attack of typhoid which nearly robbed the nation of the future Edward VII, not a single dose of any medicine whatever had been given. His prescriptions were habitually of extreme simplicity, and he once said that if every drug in the world were abolished a physician would still be a useful member of society.

How far the medical mind has travelled on this path is shown by an address recently delivered by Dr. C. Mongour, Professor of Therapeutics at Bordeaux.¹ He says that the importance of drugs has diminished as the applications of physiotherapy have developed. Our notions of therapeutics now depend on the nature and evolution of diseases, and on the natural means of defence which the organism possesses. Acute maladies which run a definite course—measles, scarlatina, typhoid fever, bronchitis, pneumonia, erysipelas, and so forth—have a natural tendency to spontaneous cure. Even tuberculosis, when it takes an acute pneumonic or bronchopneumonic form, tends, he maintains, to get well. He suggests that this may, perhaps, explain why specific drugs appear more efficacious in acute than in subacute or chronic forms of tuberculosis. He asks why we make war on the symptoms which constitute the normal manifestation of an infection. His answer is, Because we are still under the sway of the old notion that every morbid reaction is an evil which must be suppressed forthwith as an exciting cause of organic lesions. But, he points out, the symptoms may be factors in the curative process. For instance, in typhoid fever the pyrexia, he thinks, hastens the destruction of morbid germs; the temporary constipation, by immobilizing the intestines, lessens the risk of perforation; and the want of appetite prevents overloading with undigested material. He adds his testimony to that of those who insist on the harmful influences of antipyretics, purgatives, and aperients, used as matters of routine in the treatment of acute affections. In many cases even of such affections as acute diseases of the liver, of the biliary passages and the kidney, ulcer of the stomach, and

¹ *Province médicale*, 1912.

appendicitis, there is a natural tendency to cure. His doctrine is that the physician must respect the natural means of defence in the organism, and that, in short, the true scientific attitude is, to use a phrase erroneously attributed to the late Lord Salisbury, "animated expectancy." But to maintain this attitude judiciously one must know well the normal course of diseases, and how to distinguish a regular from an abnormal morbid reaction. Professor Mongour denies that he is a nihilist in therapeutics, and admits the difficulty of the position of the doctor, who is credited by patients and those about them with the power of curing disease by means of drugs. He is expected to "do something." This conviction, says Professor Mongour, must be respected, and he recognizes that at certain times and for special reasons antipyretics, analgesics, and hypnotics are often necessary.

He complains of the neglect of the expectant method. Whereas the hour for a draught or a cachet is not often forgotten, it is exceptional for friends to obey the directions as to feeding strictly, to attend rigidly to the hygiene of the sick chamber, to take the temperature regularly, and to collect the whole of the urine that is passed. In these things the doctor often meets with an indifference or a covert opposition which discourages him. His drug treatment may not be discussed, but the family will criticize his hygienic directions, and if anything goes wrong it is that part of the treatment which will be blamed. Chronic diseases have no tendency to spontaneous and definite cure, but they have periods of rest in their evolution, provisional cures which can be prolonged by opportune intervention, and this often, of course, consists in advising hygienic measures.

His address is not a depreciation of drugs, but a plea for still greater reliance on hygiene and physiotherapy. Diet, which is only one form of this, is, he says, neglected in the treatment of chronic disease, because we have not yet acquired the habit of methodically and regularly testing the functional capacity of the different organs by means of the procedures which the clinical laboratory places in our hands. But functional testing thoroughly carried out means an expenditure of time the patient is not disposed to compensate and the expenditure of efforts which he does not appreciate. It is extremely difficult, too, to get a regimen adhered to, and often, owing to social or personal conditions, it is practically impossible to expect it to be carried out; in such a case its severity must be mitigated.

We take it that professional opinion is largely agreed that over-drugging is a bad thing, but it is quite easy to go to the other extreme. Some of the distrust of drugs is to be traced to the employment of preparations of uncertain stability or inferior quality. At the same time, it will not be denied that what may be called the hygiene of disease is too much neglected by the public, owing to the persistence of prejudices which are not easy to overcome. Most patients of all classes are not quite satisfied unless they get a prescription. Man seems to have a craving for medicine. Sir William Osler says: "Heroic dosing for several generations has given his tissues a thirst for drugs. As I once before remarked, the desire to take medicine is one feature which distinguishes man the animal from his fellow-creatures. It is really one of the most serious difficulties with which we have to contend. Even in minor ailments which would yield to dieting or to simple home remedies, the doctor's visit is not thought to be complete without the prescription." Patients expect it, even those

among them who scoff most at physic and boast that they throw their medicine out of window. Why in such cases they should go to the expense of buying it is one of those contradictions in human nature which we must leave the psychologists to explain. But although that kind of polypharmacy which gave rise to the "small-shot prescription" is dying a natural death among doctors, there are still a good many who have a remedy for every symptom. Practitioners of this class are particularly ready to prescribe new remedies with names of "learned length and thundering sound." Hardly has a new synthetic product made its first bow to the public than they hasten to use it. They order it indiscriminately, till, more or less quickly, the truth is forced upon them—first, that there are disadvantages attending the use of the new elixir; next, that its benefit is doubtful; lastly, that it is useless. It is this eternal cycle that led Broussais to tell a patient to make haste to take a certain medicine while it was still in the curative stage, *Hâtez vous de prendre ce remède pendant qu'il guérit*.

Of course the opposite course is equally to be avoided; doing too little is, perhaps, worse than doing too much. Expectant treatment must not lend itself to the application of the line:

Rusticus expectat dum defluat annis.

Our aim must be to make diagnosis more and more accurate, and by experimental research to discover remedies and the means of applying them with accuracy so that they shall produce the exact effect that is wanted. In a word, our pharmacopoeia should be an armoury of weapons of precision, used with the knowledge gained by clinical observation made surer by the growth of physiology and pathology. In this way, and in this way alone, can therapeutics strengthen its position as a science.

AN ACTUARIAL STUDY OF SANATORIUM STATISTICS.

AT the present time work throwing light upon the value of the sanatorium method in the treatment of pulmonary tuberculosis is of peculiar importance, and a recent paper of Messrs. Elderton and Perry¹ is of interest in this connexion. The writers, who are professional actuaries, have been provided with data from several sanatoriums, the principal series being derived from the records of Dr. Lawrason Brown at Adirondack, and from material extracted from the case-books of the late Dr. Austin Flint relating to phthisical patients seen between 1845 and 1870. The authors analysed the records in the following way. A certain life table (The English Life Table, No. 6) was used as the standard, and the data were tabulated into a number of groups, regard being had to sex, age, and number of years under observation. A comparison was then instituted between the number of deaths observed and the number to be expected on the basis of the life table used. The subdivisions employed in the case of the Adirondack records were as follows: Three sets of one thousand each were taken; the first comprised patients admitted between 1885 and 1897; the second fell between 1897 and 1904; and the third comprised admissions from

¹ *Drapers' Company Research Memoirs: a Fourth Study of the Statistics of Pulmonary Tuberculosis; the Mortality of the Tuberculous; Sanatorium and Tuberculin Treatment.* Based on (1) Dr. Lawrason Brown's Adirondack Sanatorium Data; (2) Data from two Scottish Sanatoriums; (3) Dr. Austin Flint's Data from Prosa Sanatorium Days. By W. Palin Elderton, F.I.A., and Sidney S. Perry, A.I.A. London: Dulau and Co. 1913. (Med. 4to; pp. 55. 3s. net.)

1903 to 1909. Each thousand was then subdivided into (1) incipient, (2) advanced, (3) far advanced cases. These groups correspond roughly, but not exactly, to Turban's three stages.

The authors find that in almost every group the rate of mortality diminished on passing from the first to the third thousand; thus the ratio of actual to expected deaths for incipient cases (females) was 2.7 for the first thousand, 2.5 for the second, and 1.0 for the third, the number of years at risk being reckoned from the date of admission to the sanatorium. For advanced cases the corresponding figures were 11.4, 10.7, and 7.9. For far advanced cases the rates were 50.3, 48.3, and 8.0, but the last ratio was based on a very small number of patients. The authors believe that a different selection of cases has had a good deal to do with the improved experience, that the incipient cases in the later experience may have been less advanced than the same group in the first thousand. Taking the last 2,250 cases admitted, the ratios for incipient, advanced, and far advanced cases were 3.6, 10.0, 36.8 for males, 2.3, 10.4, and 45.4 for females. Flint's patients, allotted as far as possible to the same clinical groups, gave 13.9, 18.4, and 106.0 for males and 9.1, 37.2, and 90.0 for females. There were, however, very few incipient cases in the Flint series, and, as the authors point out, a comparison between this and more recent experience is fraught with difficulties. Thus, to mention but one drawback, a modern English life table is perhaps hardly an appropriate standard of mortality even in the case of contemporary American lives, it is certainly inappropriate in the case of persons living some half a century ago, because the mortality at the ages principally involved has markedly diminished.

The writers have also applied their method to those cases in the third thousand from Adirondack which had been treated with "TBF" or "TBF Co" ("Broth Filtrate" and a mixture of "Broth Filtrate" and "Bacillary Emulsion"). The incipient cases so treated showed a slightly lower and the advanced cases a slightly higher mortality than those of the third thousand as a whole.

A comparison is also instituted between the mortality experiences of patients classified in other ways. It is found, for instance, that the mortality of patients with tubercle bacilli in the sputum was more than twice as heavy as that of patients whose sputum did not contain the bacillus, and that the mortality of those suffering from the disease was not heavier if their parents also had the disease. As the authors are careful to point out, this last result has no bearing on the question whether the offspring of phthisical parents are or are not more likely to develop the disease than the children of healthy persons.

The main conclusion which emerges from this patient inquiry is that we can hardly base a decided judgement as to the real value of modern methods of treatment upon existing data. The impression any reader derives from a perusal of Messrs. Elderton and Perry's memoir can hardly fail to be coloured by his personal predilections. Professor Karl Pearson, who contributes an introductory note, pleads for the expenditure of a "few thousand pounds on a more thorough study of the origins of phthisis and of the relative value of existing and alternative treatments." Most medical readers will be in sympathy with this plea, even if they have some misgivings as to whether the difficulties in the way of a compilation of adequate statistical data may not be greater than can be overcome even by the expenditure of many thousand pounds.

That a task is difficult is not, however, any reason for declining to undertake it, and it is satisfactory to observe from its final report that the Departmental Committee on Tuberculosis was alive to the importance of statistical research; its recommendations are now, we understand, receiving the careful consideration of the Government, and it is probable that an announcement as to the steps proposed to be taken will be made before very long. The scientific study of medical statistics has advanced by leaps and bounds in the last few years, and it is not too much to expect that before long a more satisfactory statistical stock-taking of our tuberculosis results will be practicable. When that time arrives, Messrs. Elderton and Perry's pioneer work will not pass without recognition, and in the meantime their suggestive paper will be useful both to the student and the general reader.

THE HOSPITAL CLINICAL UNIT.

MR. GREY TURNER has printed in a pamphlet an interesting address he gave last October as President of the Newcastle-on-Tyne Clinical Society. It is the outcome of the visit made to certain surgical clinics abroad by an informal club of British provincial surgeons, who, beginning with various centres in this country, have extended their range to Berne, Vienna, Paris, and some other places. The pamphlet, which has the title, *What English Surgery Needs*,¹ may be read with particular interest at the present moment by London teachers and old London students, for what Mr. Turner considers we need in this country is the highly organized and amply staffed clinic hospital unit which the Royal Commission on University Education in London has recommended as the proper basis for the medical faculty of the reformed University. The system has advantages and disadvantages, and if its adoption meant the abandonment of the English system of progressive appointments for students the loss would be greater than the gain to the student if not to the progress of medicine and surgery. But it need not mean this, as the Commissioners take care to point out. Mr. Turner gives most of his space to the clinics of Koehler in Berne and von Eiselsberg in Vienna. Of the needs of British surgery the two chief are, in Mr. Turner's opinion, first "recognition by performance"—that the universities, to get the best teaching in the clinical subjects, should go into the open market of all the men who speak the language, as they have already learnt to do in regard to professors of anatomy, physiology, and pathology. The second great need is adequate assistance—a graded staff to work with the professor and more or less under his guidance and his inspiration. Already we have moved some way in this direction. A surgeon and assistant surgeon if they work together, with a surgical registrar, house-surgeon, assistant house-surgeon, dressers, and clinical clerks, would form such a unit easily capable of expansion. The greater part of the staff exists and some at least of the material, but expansion and better organization are needed so as, in particular, to afford more time and greater facilities for the study of the problems of disease with all the assistance modern laboratories can provide, and to permit the utilization of the whole system for the education of the students in principles. The chief danger of the system of university clinical hospital units is that, unless effectively controlled by the governing body of the university, it may throw far too much power and patronage into the hands of a single dominating personality. This is not an imaginary danger, as the history of some great European centres sufficiently proves. There is the risk of crushing independence, and producing conditions which favour the

¹ *What British Surgery Needs*. Newcastle-on-Tyne: Eassey and Best, 1913. Reprinted from the *North of England Clinical Journal*. (For private circulation.)

pliant rather than the original mind. We do not want to copy slavishly the German or Austrian, and still less perhaps the French system, but it seems clear that the growing complexity of medicine and surgery make it necessary that we should learn from them some of the lessons in organization they have to teach.

TUBERCULIN TESTS IN ANIMALS.

DURING the experimental work carried out by the Royal Commission on Tuberculosis many tuberculin tests were applied to a variety of animals, and the results systematically recorded. A carefully prepared summary of these has now been issued as a supplementary volume to the final report of the Commission.¹ It is believed that it will prove of value not only to the laboratory and farm investigator of tuberculosis, but, in view of the increasing employment therapeutically of tuberculin in the tuberculosis of human subjects, to the clinical physician also. The report has been written by Dr. L. Cobbett and Dr. Stanley Griffith, by whom, along with Dr. F. Griffith, the tests were made. In the preparation of the report Mr. Cyril Fox has given much assistance by making detailed analyses of the immense number of records. The first part of the report discusses the tests applied to the ox, pig, goat, horse, dog, cat, rabbit, fowl, and various species of apes and monkeys. In this, perhaps, the most interesting information given is as to the reliability of the tests as a proof of the presence or absence of tuberculosis. According to the standard of reaction adopted, 88.8 per cent. of the 250 tuberculous bovine animals tested reacted, while of 1,217 normal animals of the same species 0.4 per cent. only reacted. In the case of tuberculous pigs (53 animals) the percentage of reactions was the same as that obtained in the tuberculous ox, while among 136 tests on normal pigs no reactions occurred. Of the tuberculous goats (21 animals) no fewer than 95 per cent. reacted, while of 70 normal goats tested, 3 (4.3 per cent.) reacted, but 2 of the reactions occurred in kids, in which the temperature is notably unstable. Ten tuberculous horses only were tested and all reacted; 23 normal horses were tested and none reacted. These figures show that the tuberculin test, while not infallible, is nevertheless sufficiently constant in its action to afford a means of diagnosis of great practical value for the large domestic animals included in this first group. In tuberculous animals of the other species investigated the tuberculin test proved very inconstant in its action, especially in the case of the monkeys and apes. Of 32 tuberculous dogs 14 reacted, and of 11 tuberculous cats, 6. The results in rabbits and fowls were similar, and the general conclusion is that in this second group of animals the tuberculin test as employed is of little practical value. Stress is laid on the importance, when looking for a reaction, of taking the temperature sufficiently early and sufficiently often. In order not to miss in the ox and pig reactions which end unusually early, or begin unusually late, it is necessary to record temperatures every three hours from the sixth to the twenty-first hour after injection. In the goat it would seem to be permissible to begin at the ninth hour. The importance of taking the temperature often is due to the fact that the rise may be of very short duration, producing a "steep curve." Since such steeples may reach their highest point as early as the sixth hour and as late as the twenty-first hour, it would seem advisable to take temperatures even at the third and twenty-fourth hours, in order that when a curve of this kind occurs records of the temperature before and after the maximum may be at hand to support it. In this way fallacies due to an error in a single observation would be avoided. Some experiments on the results of successive injections of tuberculin in tuberculous animals, chiefly bovine, were also made. They showed that for the most

part tuberculous bovine animals might react more than once to tuberculin, even when the injections followed one another at intervals of a few days. Sometimes a second reaction might be even more marked than the first, though usually it was less prolonged. As a rule, the capacity to react showed a progressive diminution with successive injections, and in many it became completely exhausted. It persisted longest in animals with general tuberculosis—that is, in animals in which the disease was in all probability active. The experiments did not give any certain answer to the question whether capacity for reacting when once completely exhausted was later on regained.

ANTITYPHOID INOCULATION.

THE final report of the Antityphoid Committee, appointed by the Army Council in March, 1904, to investigate the practical prophylactic and therapeutic value of current methods of immunization against enteric fever, has been issued this week. An immense amount of research work has been quietly carried out by the committee, and valuable statistical data have been collected by officers of the Royal Army Medical Corps attached to units to make the inoculations and to observe the results. Much of the work has already been published, mainly in the *Journal of the Royal Army Medical Corps*, but this report gives a complete summary. We may direct attention to the following points: The first subject investigated was the development of immunity against the typhoid bacillus as shown by the quantitative estimation of the antibodies produced; the agglutinins, bacteriolysins, and bacteriocidal substances were all found to be much increased as a result of inoculation with a typhoid vaccine. The next subject to be investigated was the most efficient way of killing the bacteria. Chloroform, alcohol, toluol, and glycerine were tried, but were not found to be altogether satisfactory. Lysol 0.25 per cent. sterilized a culture in twenty-four hours without reducing its immunizing properties. Exposure to a temperature of 53° C. for one hour was found to be the most satisfactory procedure; after the culture has cooled to room temperature 0.25 per cent. of lysol is added, to minimize the risk of subsequent contamination. The relative efficacy of vaccines prepared in different ways was also thoroughly investigated, both by measuring the development of protective substances in the blood and by determining the degree of protection which the different vaccines conferred on animals against multiple lethal doses of virulent typhoid bacilli. The vaccine prepared according to Sir A. E. Wright's method was found to be the most satisfactory. Many attempts were made to devise a simple method of standardizing the vaccine; a modification of Sir A. E. Wright's method of counting the number of bacteria in a given volume has been finally adopted. An important point which has been cleared up is the effect of storing the vaccine and of exposure to heat on its keeping qualities; after six months considerable deterioration takes place in its immunizing properties. The effect of swallowing the vaccine was also investigated; unfortunately this simple plan has been found to be too uncertain in its results to warrant its general adoption. The reaction which follows inoculation is much increased in severity by fatigue, exposure to the sun, or by the ingestion of alcohol. For statistical purposes the histories of 19,314 soldiers, whose average period of service abroad was twenty months, were carefully followed, and in all cases of typhoid fever every care was taken to verify the diagnosis bacteriologically. Of this number 10,378 were inoculated, and 8,936 were not inoculated. The case incidence of typhoid fever among the inoculated was 5.39 per mille, and among the non-inoculated 30.4 per mille. A subcommittee composed of Dr. James Galloway, Dr. R. Feord Caiger, and Sir William Leishman, investigated the medical history sheets of 258 undoubted cases of

¹ H.M. Stationery Office (through any bookseller). (Cd. 6796. 5s. 7d.)

typhoid fever. Of this number 202 were not inoculated and 56 were inoculated. The cases were divided into two main groups, the mild and the severe, including fatal cases; among the inoculated men 66.1 per cent. of the cases belonged to the mild group, and only 33.9 per cent. to the severe group. Among the non-inoculated men only 29.3 per cent. of the cases could be placed in the mild group, while 70.7 per cent. were classed as severe. The committee recommends that the protective inoculation against typhoid fever should be extended as much as possible, or better, be made universal, and that research work on this subject should be continued. It may be noted that inoculation against typhoid fever is now compulsory for everyone under 45 years of age in the American Army.

THE SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH.

THE ceremony of initiating the building of the South African Institute for Medical Research, to which allusion was made in our issue for April 16th, was performed at Johannesburg on the last day of the following week on a site on Korte Street, not far from the General Hospital. The estimated outlay on building is £32,500, and towards this amount and the cost of its equipment the Witwatersrand Native Labour Association has furnished £40,000, while the Provincial Government gave the ground. The same two bodies will also for the time being provide between them a small annual sum by way of income for the institute. Two foundation stones—one inscribed in English, the other in Taal—were laid by Sir Kendal Franks, C.B., who subsequently delivered a short address. He had been invited, he said, to perform the ceremony because he was President of the South African Committee of the British Medical Association, a body which had members scattered all over South Africa and represented the medical profession as none other could. Hence it was the whole medical profession of South Africa which was honoured by the invitation accorded him to perform the ceremony, and it deeply appreciated the fact. Around the stones which he had laid would be raised a building dedicated to the good of mankind and the preservation of human life. The work done in it would, it was hoped, lead to the discovery, first, of the causes of the diseases chiefly affecting South Africa, and then of a means of freeing the land from these scourges. Such objects had been attained elsewhere, and could be attained in South Africa. What the revolution brought about in surgery by the discoveries of Pasteur and Lister had done for mankind was well known. When the same theories were applied to medical diseases the results were obtained more slowly, but they were none the less revolutionary. The problems to be solved were numerous, and bristled with difficulties, and had to be investigated separately. The prolonged, accurate, and patient investigation required could only be carried out in an institution such as was now to be erected. In regard to diseases of animals, a similar institution already existed at Pretoria, and was doing work which had in many instances spelt salvation for the farmer and his stock. An address was also delivered by Dr. Watkins-Pitchford, who is to be medical superintendent of the institution. The pessimistic outlook which in the past had called for the establishment of homes for the incurable had changed, he said, to an optimism which demanded the provision of institutions for medical research, and by the foundation of the future institution South Africa had placed itself in the front rank of civilized nations. Industrial diseases and those commonly associated with the aggregation of people in South African towns, compounds, and camps, would receive special attention, and inquiry would also be made into any subject pertaining to the domains of medicine and surgery and public health. The wards provided would give facilities for the systematic observation of the results of disease. Modern statistical methods would be employed,

and a library and museum relative to the special objects of the institution be acquired. Since the mining industry attracted natives from all parts of South Africa, advantage would also be taken of the opportunities for anthropological and ethnological research. Technical reports on the work done would be issued from time to time and facilities afforded to practitioners to acquire a knowledge of laboratory methods of investigation. There would also be provision for the holding of medical discussions, and popular lectures would occasionally be delivered. The institution, however, at present had nothing in the way of an assured income, and it was to be hoped that those who were amassing wealth in South Africa would provide an endowment fund. The plans of the institution show a handsome edifice surrounding three sides of a square; the transverse block has a cupola in the centre, but the general style of the architecture is classic.

THE SERUM TREATMENT OF EPIDEMIC MENINGITIS.

THE fourth and final report on the experience gained by the Rockefeller Institute during six years' treatment of epidemic meningitis with a specific serum has been published by Dr. Simon Flexner,¹ whose verdict is unequivocally in its favour. This system of treatment was started early in 1906, and the present report deals with an analysis of about 1,300 cases treated with serum distributed by the institute in the United States, Canada, Europe, and Asia. The mortality among 1,294 consecutive cases treated was 30.9 per cent., whereas that of the recent pandemic in the United States was approximately 70 per cent. The importance of giving the serum early is shown by a table in which the mortality among patients treated between the first and third days of the illness is seen to be 18.1 per cent., while it was 36.5 per cent. among patients treated later than the seventh day. It is a significant fact that this latter group includes 666 cases, while the group treated early includes only 199 cases. Less than one-sixth of all the cases were treated early, and one-half were treated after the first week of the illness. It is therefore probable that when the serum is more generally available and confidence in its value extends, it will be given earlier and the results will become better. The most favourable results were obtained at ages between 5 and 10 years, and the least favourable after 20. Spontaneous recovery from the disease is usually by lysis, and the number of recoveries by crisis is relatively small. Indeed, in some epidemics this class of case is unknown. After treatment with serum within the first three days of the illness, recovery by crisis was as common as by lysis. When the serum was given later in the illness recoveries by lysis became relatively more frequent. It was also noticed that the proportion of cases which recovered by crisis was highest at the age most favourable to recovery, and that it was lowest at the most unfavourable age. The incidence of complications and sequels to the illness was also reduced by the treatment, but affections of the middle ear were still frequent, and occurred in about 3.5 per cent. of all cases. Other complications which arose in spite of the treatment were impairment of vision and arthritis. The latter was invariably transitory, and its disappearance was hastened by the direct injection of the serum into the inflamed part. Although at first regarded as doubtful, it is now clear that cases of fulminant meningitis may also benefit by the treatment; for several recoveries followed it in such cases, and the lowering of the mortality in the first three days of the illness, which is the period in which the fulminant cases end in death, also supports this view. But it is undoubtedly the ordinary type of epidemic meningitis which responds most satisfactorily to the treatment, as shown by the general reduction in mortality and by the change of the termination of the

¹ *Journal of Experimental Medicine*, May 1st, 1913.

illness from lysis to crisis. It is this transformation, and the general shortening of the whole course of the illness, and the consequent suppression of the chronic form of infection, which justify the claims advanced by the advocates of the treatment. One of the most conclusive objective criteria of the action of the serum is its effect on the meningococci, whose multiplication is arrested and whose phagocytosis and intraleucocytic digestion are accelerated. The tendency to hydrocephalus in the young has been reduced, and the intraventricular injection of the serum has frequently abolished infection and inflammation of the cerebral ventricles, and has re-established communication between the ventricles and the subdural space of the spinal cord. The initial difficulties of administration by direct subdural injection have been largely overcome, and the serum is now being used in private as well as in hospital practice. Dr. Flexner discusses some of the latest epidemics in which the serum was extensively used. One of these is reported on by the Louisiana State Board of Health, and is known as the Shreveport epidemic of 1912. There were 250 cases, 176 of which were not treated with serum. The mortality among these was 85 per cent., whereas it was 30 per cent. among those treated with serum. Dr. Flexner's report concludes with a repetition of the claims made for the treatment in 1909, when an analysis of 400 serum-treated cases was made. "The antimeningitis serum, when used by the subdural method of injection, in suitable doses and at proper intervals, is capable of reducing the period of illness; of preventing in large measure the chronic lesions and types of the infection; of bringing about complete restoration of health in all but a very small number of the recovered, thus lessening the serious, deforming, and permanent consequences of meningitis; and of greatly diminishing the fatalities due to the disease." The Rockefeller Institute, it is stated, no longer prepares the serum, and will not continue to collect histories of cases treated with it.

THE SOFTENING, PURIFICATION, AND STERILIZATION OF WATER SUPPLIES.

MORE than a year ago the Director of Water Examinations for the Metropolitan Water Board presented an important and interesting report on the excess-lime method, primarily as a germicidal agent and secondarily for softening purposes. The germ of this report is to be found in the seventh report, which stated that "quicklime (about 75 per cent. CaO) added to raw Thames water in the proportion of 1 part of quicklime to 5,000 parts of water kills *B. coli* in five to twenty-four hours under laboratory conditions of experiment." During 1912 research work into the truth of this idea was pursued, and as a result of the year's work it is stated in the eighth report that if 15 lb. of quicklime is added to 7,500 gallons of raw un-stored Thames water it will kill within twenty-four hours the microbes of water-borne disease; then, if these 7,500 gallons were added to 2,500 adequately stored water, which would neutralize the excess lime, there would be 10,000 gallons of water which would have lost 15 parts of its total hardness, would contain no undesirable excess of lime, and would be innocuous. The process would quickly render an initially foul water absolutely safe bacteriologically, and would virtually increase the yield of the sources of supply by rendering the water always fit for abstraction. The complete fulfilment of these anticipations would raise the purity of the metropolitan water supply to a pitch of perfection never before attained, if ever seriously contemplated as possible, by any water works authority in the world dealing with sources of supply comparable to those of London. All this as the result of laboratory experiments is very satisfactory, but the practical question arose whether these conclusions would stand the test of a series of outdoor experiments on a large scale. To set

this question at rest the Water Board at a recent meeting decided to incur an expenditure not exceeding £600 to demonstrate the practical utility or otherwise of the "excess lime method." We look forward with interest to the result of these larger experiments. They should tell us what the lime method will cost per 1,000,000 gallons, including the capital cost of machinery and softening tanks, and the periodical removal and disposal of the sludge from the tanks. They should prove also whether the method will deal satisfactorily with the colour and contents of flood water, or whether it will result in browner water with more organic matter in it, and also whether the incidental softening of the water will be an unmixed good from the health point of view. These and many other questions are involved in the experiments about to be undertaken, which will, we hope, yield speedy and satisfactory answers. The question of the ultimate water supply, not only of London but of other places also dependent on contaminated rivers of limited flow to meet an increasing demand, will be less urgent if the water which now runs to waste can be made potable at a reasonable cost. Now that the Water Board has decided to incur the necessary expenditure for these experiments they should be pushed on with all reasonable speed. More than a year has passed since the "Excess lime" report was submitted to the Board, and it is seven months since the Committee specially interested in the quality of London's water first recommended that the laboratory experiments detailed in the report should be tested on a larger scale outside. So far there has been no evidence of hurry on the part of the Board. Further delay, however, would not only be highly undesirable in face of the heavy responsibility of the Board, but might also involve it in large expense, which may possibly prove to be unnecessary, in connexion with the new Thames reservoirs recently commenced.

THE LAW OF LEAST EFFORT IN SPEECH.

WE are hearing much at present of the "Board School Voice," and, of course, the accent of the cockney is distressing to a cultivated ear. But the voice and accent of a certain class of educated people make almost equal discord of our speech, which, when properly uttered, is far from deserving the reproach of harshness often brought against it by foreigners who cannot appreciate the richness of its melody. This reproach is doubtless founded on the wrong way in which it is often spoken. At present among all classes the law of least effort is coming more and more to govern our language. From the "arf a mo'" of the cockney to the clipping of words now so common at the universities, the tendency to spare the vocal organs any avoidable stress is everywhere in evidence; it is common among the class whom Bishop Warburton happily designated the "better vulgar." Young ladies speak of "undies" when they mean underclothing, and complain of "indies" when they suffer from indigestion. It used to be a mark of fashion to dock the "g" from the end of words, and to speak of "ridin'," "amusin'," and so on; and the fashion survives to-day, for any mutilation of speech which gives less trouble in utterance tends to persist. We may, however, comfort ourselves with the reflection that the tendency is not new, and that not all clipping habits become permanent. Nearly two hundred years ago Swift, in his *Introduction to Polite Conversation*, called the attention of the reader to the fact that he has been "diligent in refining the orthography by spelling the words in the very same manner as they are pronounced by the chief patterns of politeness at courts, at levees, at assemblies, at playhouses, at the prime visiting places by young templars and by gentlemen commoners of both universities who have lived at least a twelvemonth in town and kept the best company. For instance, *can't, han't, shan't, didn't, couldn't, wouldn't, isn't, en't*, with many more; besides

several words which scholars pretend are derived from Greek and Latin, but now pared into a polite sound by ladies, officers of the army, courtiers and templars, such as 'jommetry' for the geometry, 'vardi' for verdict, 'lard' for Lord, 'learnen' for learning, together with some abbreviations exquisitely refined as *poz* for positive, *mobb* for mobile, *phizz* for physiognomy, *rep* for reputation, *plenipo* for plenipotentiary, *incog* for incognito, *hypps* or *hippo* for hypochondriacs, *bam* for bamboozle . . . whereby much time is saved and the high road to conversation cut short by many a mile." "Mob" has been adopted into the dictionaries, and "plenipo," "phiz," and "incog" are still in use. "Rep," "hippo," and "bam" have become extinct. But, now that economy of effort has once more become fashionable, it may be expected that clipped forms will largely take the place of the full words in ordinary speech, and will in due course find their way into the select society of the dictionary. The movement is in accordance with the physiological principles which regulate pronunciation, and of these the chief is ease in articulation. We may hazard the conjecture that, in accordance with the law of least effort, the aspirate will in time fall into disuse, as has occurred in languages of Latin origin. The old Romans themselves had the same trouble with the letter *h* that vexes some Englishmen. Even 'Arry had his prototype among them, as we know from the *Arrius* ridiculed by *Catullus*, who

Chommoda dicebat, si quando commoda vellet
Dicere, et hinsidias Arrius insidias.

He was sent on a mission to Syria, and soon a dreadful report reached Rome that

Iónios fluctus, postquam illuc Arrius isset
Jam non Iónios esse, sed Híónios.

MICROMELIC DWARFS AT BERGAMO.

DURING a recent and somewhat hurried visit to Bergamo Professor Max Kassowitz of Vienna had his attention arrested by the extraordinary number of dwarfs whom he saw there.¹ They were all affected with micromelic microsomia, possessing large crania broad in the vault, with the root of the nose depressed and having short and twisted limbs. Professor Kassowitz was only about two hours in the Upper Town (*citta alta*), and yet he counted at least twenty of them there; he noted not more than one in the Lower Town (*citta bassa*). The subjects were both adults and children, and it seemed to him that there were more women than men. They all had intelligent faces. He calls upon the medical men of Italy, and especially of Bergamo, to investigate this curious instance of endemic micromelic dwarfism, and refers to a possible, although not a very probable, allusion to its occurrence in this same town in Northern Italy in Shakespeare's time. In *A Midsummer Night's Dream*² Bottom, the weaver, says: "Will it please you to see the epilogue, or to hear a Bergomask dance between two of our company?" "A dance of clowns" then takes place. A "Bergomask" is defined as a rude clownish dance, such as the people of the town of Bergamo were wont to practise, and there is evidence that the people of this town were spoken of commonly as clownish in manners and in speech. Leau, in his *Collectanea*,³ gives several sayings about Bergamo and its inhabitants, amongst which are two or three which refer to the thick speaking of the Bergamasks—for example, "Bergamasco ha 'l parlar grosso e ma 'l ingegno a far sottile." There is another saying in which the inhabitants of Bergamo are described as buffoons (*zanni*)—namely, "Sicilia da i Covelli, Francolini i Graziani, Bergamo gli Zanni." etc. There is also some evidence that in stage representations the clowns were made of a stunted and contorted, dwarfish appearance. It will be interesting if the Bergamask doctors are able to throw any light on this matter.

NOSTRUM LEGISLATION IN WESTERN AUSTRALIA.

For many years past the secret remedy proprietor has had a freer hand in the British Empire and America than in most Continental countries, both in regard to what he may put into his nostrum and to the claims he may make for it. Experience has shown, however, that the public interest requires this freedom to be severely curtailed. The American Pure Food law of a few years ago has had a good effect in preventing the sale of many fraudulent or dangerous medicines; the Australian States and New Zealand have for some time been engaged with proposals for legislation directed to the same end, and in this country the holding of the present Parliamentary inquiry is a step in the same direction. Western Australia, however, appears to be the first British state to have actually put into force a tolerably stringent law against the evils of this traffic, and it is of interest to note exactly what is the present position in that colony. By the Health Act of 1911, amended by subsequent Acts of 1911 and 1912, the general control and supervision of matters affecting the public health are put in the hands of a medical practitioner, who is styled the Commissioner for Public Health, while for matters relating to the sale of food and drugs an Advisory Committee, consisting of the Commissioner, the Government analyst, a bacteriologist, and two other persons conversant with trade requirements, is appointed by the Governor. The Act provides that the Commissioner may, on the advice of this Committee, prohibit the sale of any patent or proprietary medicine which in the opinion of the Committee is deleterious or dangerous to health, and any person selling or advertising such medicine shall be guilty of an offence; the general penalty for a breach of the Act is a fine not exceeding twenty pounds and a daily penalty not exceeding forty shillings. It is further made an offence to publish or cause to be published, whether in a newspaper or a publicly exhibited notice or by distribution through the post or otherwise, any statement intended to promote the sale of a medicine or appliance for the prevention, alleviation, or cure of disease, which is false in regard to the ingredients, composition, structure, nature, or operation of the article, or to the effects which have followed or may follow its use. An important section of the Act empowers the Governor, on the advice of the Advisory Committee, to make regulations on many matters arising out of the Act, and amongst other things such regulations may require any specified information to be given on the label of any food or drug. The regulations which have been made and are now in force require that the principal label attached to every package containing any patent or proprietary medicine shall bear a statement in English of the ingredients and the proportions of the same in such medicine. Exemption from this requirement as to labelling may, however, be obtained by the manufacturer or importer by depositing the same particulars with the Commissioner and signing an undertaking that all such medicine sold in the colony shall comply with the particulars so deposited. We are informed that considerable opposition has been shown by the owners of proprietary medicines and their agents, but that the Government has refused to withdraw or amend the regulations. It is not easy to see what objection can be taken to these enactments by persons desiring to sell harmless medicines and to make only true statements in regard to them, but it is evident that the sale of those which depend on false or exaggerated statements will become practically impossible. The manufacturer who deposits his formula with the Commissioner will avoid making it public, and will, therefore, not lose the commercial value of his trade secret—if he has one. But the maker's statement of formula—checked, of course, by the Government analyst—will enable the authorities to judge if the advertised statements in regard to the medicines are false, and, if they are, to take action against those responsible. It will be interesting and instructive

to watch the working of this law in Western Australia, which might well serve as a pattern for legislation in this country.

POOR LAW APPOINTMENTS AT BURNLEY.

WE have frequently had occasion to mention a dispute which has been going on for some time between the Burnley Division, acting on behalf of the Poor Law medical officers of the Burnley Union, and the local guardians. Some months ago all the district medical officers of that union resigned their posts on account of the inadequacy of the remuneration, but not until they had made attempts to get redress from the guardians. The Burnley Division has cordially supported the Poor Law medical officers in the attitude they have taken up, and, with one exception, every medical practitioner in the neighbourhood has, we believe, signed an undertaking not to apply for any post under the guardians to the detriment of the late holders until a settlement has been reached to the satisfaction of the Division. The guardians, instead of frankly meeting the difficulties, which are mainly those of underpayment, put forward a scheme of redistribution. The Division and the Poor Law Medical Officers' Association of England and Wales memorialized the Local Government Board, asking it to disapprove the scheme of the guardians, on the ground that though the new arrangement was an improvement on the old as regards the scale of payment, the remuneration of the doctors concerned would still remain far below the average of that paid in other unions. The Division and the Poor Law Medical Officers' Association took special objection to the proposal of the guardians to make each medical officer a public vaccinator in his own district, because it was obvious that this was a mere pretext for using the fees for public vaccination to make out the payment for the Poor Law work. It is to be regretted that the Local Government Board has sanctioned the rearrangement of the medical relief and public vaccination districts as proposed by the guardians, thus in effect washing its hands of the affair and throwing the responsibility upon the guardians. It is really unfair that the Local Government Board should shirk its responsibilities in this way. It is evident from the way in which that Board has dealt with the matter that it was, to say the least of it, doubtful of the wisdom of the proposed action of the Burnley Guardians. As one of the guardians said at the last meeting, the Local Government Board had played with the matter for five months. The Royal Commission on the Poor Law made severe comments on the extent to which sweating goes on in the Poor Law medical service; the Local Government Board itself has frequently protested against the small salaries offered, and particularly against that juggling with vaccination and parish appointments which is a striking feature of the present case. Yet it generally contents itself with mere protests, evasive answers, or futile delays, rarely taking decisive action. Those members of the medical profession and those public representatives who take action against the continuance of these grievances deserve more support from the Local Government Board. The guardians have now advertised for medical practitioners to fill the position of district medical officer and public vaccinator in fifteen districts. A Warning Notice regarding these appointments appears in our advertising columns, and it is earnestly to be hoped that no member of the profession will apply for one of them without making himself thoroughly conversant with the facts. We have little doubt that any one who makes such inquiries will decline to assist the guardians in attempting to defeat the local practitioners, who have so loyally bound themselves together for the ultimate good of the local profession and of the poor of the district. The paper who is unable, often through no fault of his own, to help himself, and who is under the protection of

the guardians, should have the best medical attendance that can be provided, not only for his own sake, but because it is more economical in the long run. Efficient medical attendance cannot be got at sweating rates, and it is this sweating which the Burnley Division has determined to destroy in that district. The action of the Division deserves the admiration and imitation of other districts. Do the Burnley public realize that their board of guardians, in refusing to meet a deputation of the local medical profession and in declining to raise the rate of remuneration, is perpetuating the worst abuses of Bumbledom?

CLINTON DENT.

THE Association of British Members of the Swiss Alpine Club recently presented to the Swiss Alpine Club a mountain hut, the Cabane Britannia on the Klein Allalinhorne, Saas Fee. It was opened with some ceremony on August 17th, 1912, and a letter dated August 13th from the President of the Association, Mr. Clinton Dent, was then read, in the course of which he expressed his profound regret that he was unable to take part in the festivities. In less than a fortnight after that letter was written Clinton Dent was dead. We gave in our obituary notice some account of his achievements as an alpine climber, and the association of which he was president has now issued a pamphlet containing an account of the ceremonies at the opening of the hut, commemorating Clinton Dent's influence in alpine affairs. It is well illustrated, among the photographs reproduced being a very characteristic photograph of Dent in mountain kit, and another of the Portjengret, one of the peaks which he was the first to ascend. The Committee of the Association of British Members of the Swiss Alpine Club, which has Mr. A. E. W. Mason as president, and among its vice-presidents Dr. O. K. Williamson and Dr. H. L. R. Dent, proposes to establish a Swiss memorial to Clinton Dent. A stone with an inscription will be erected outside the Cabane Britannia and a memorial tablet at Zermatt; further, if the sale of a certain number of copies can be guaranteed, Clinton Dent's book, *Above the Snow Line*, which is out of print, will be republished; this would be his best memorial as a climber. Subscriptions to the memorial should not exceed 10s. 6d., and may be sent to the Honorary Treasurer, Mr. J. A. B. Bruco, Selborne Lodge, Austen Road, Guildford, who will also, we presume, be glad to receive notifications of the desire to have a copy of the book if reprinted.

DR. WILLIAM H. WELCH, Professor of Pathology at Johns Hopkins Medical School, has been elected President of the American National Academy of Sciences for a term of six years.

THE annual dinner of the Indian Medical Service will be held at the Hotel Cecil, Strand, on Tuesday, June 10th, at 7.45 p.m., when the Director-General, Surgeon-General the Hon. Sir C. P. Lukis, K.C.S.I., will preside, and the Service will have the honour of entertaining the Marquis of Crewe, H.M. Principal Secretary of State for India. Officers intending to be present should communicate without delay with the Honorary Secretary, Lieutenant-Colonel P. J. Freyer, 27, Harley Street, W.

THERE will be four vacancies to be filled at the coming election of members of the Council of the Royal College of Surgeons of England on July 3rd. The President, Mr. Edmund Owen, and Mr. Golding-Bird have held their seats on the Council since 1905, but, being President, Sir Rickman Godlee does not vacate his seat, so that only two vacancies by rotation are to be contested this year, but there will be a third vacancy caused by the death of Mr. Clinton Dent, and a fourth made by Mr. Bruco Clarko's resignation. Mr. H. J. Waring, of St. Bartholomew's Hospital, has already expressed his intention to present himself for election on this occasion.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

JUBILEE OF DR. JAMES RITCHIE.

DR. JAMES RITCHIE, of Edinburgh, who has during the past few years occupied in turn the presidential chairs of the Obstetrical Society, the Edinburgh Medical Missionary Society, and the Medico-Chirurgical Society, and who has done much for the British Medical Association Branch in Edinburgh, was honoured on the evening of May 16th in connexion with another side of his activities. For fifty years Dr. Ritchie has been an office-bearer in Lady Glenorchy's United Free Church, and during that period he has acted for thirty-one years as Clerk of Deacon's Court and for fifteen years as Session Clerk, a post which he still holds. The congregation of Lady Glenorchy's church took the occasion of congratulating him and presenting him with a solid silver tray in commemoration of his jubilee. At the meeting at which the presentation was made by the Rev. Mr. James Harvey (the minister of Lady Glenorchy's), letters were read from several members of the medical profession (including Sir Alexander Simpson, Sir Halliday Croom, Sir James Affleck, and Sir Robert Philip) expressing the high esteem in which Dr. Ritchie was held by his brethren. Dr. J. W. Ballantyne and Dr. H. M. Church, who were present, also spoke, as personal friends, of Dr. Ritchie's manifold activities and constant attachment to all good causes. Dr. Ritchie, in acknowledging the presentation, gave interesting reminiscences of the Lady Glenorchy's Church of his boyhood, its ministers, elders, precentors, and its Mutual Improvement Society, which would nowadays be termed the Literary Society. He incidentally referred to the large number of persons pitted with small-pox then to be met with, and contrasted it with the freedom of the streets from such sights now, thanks to the protective effects of vaccination. There was a large gathering of friends and a pleasant evening was spent.

THE MIDLOTHIAN COUNTY COUNCIL AND SANATORIUMS.

At a meeting of the Midlothian County Council in Edinburgh on May 14th, presided over by Colonel Trotter, Convener of the County, a report was presented of the proceedings at the conference of county councils in the south-eastern district of Scotland regarding the provision of sanatoriums. The Chairman stated that the general opinion was that the councils should combine in the provision of sanatoriums under the Insurance Act rather than under the Public Health Act, one of the reasons being that they would under the former Act obtain large grants towards the original cost of erection of the sanatoriums. The opinion at the conference was that the counties concerned should combine for the purpose of providing a sanatorium, as being the most economical plan and the one likely to give the best results; it was also strongly favoured by the Local Government Board. They were not, however, in agreement as to the question of treating advanced cases of tuberculosis in the sanatorium. The report was approved. A letter was read from the Insurance Commissioners regarding the estimated expenditure on sanatorium benefit by the Midlothian Insurance Committee for the year commencing January 13th last. The Commissioners requested the county council to inform them whether it was prepared to sanction the expenditure, and pointed out that in that event the council would be liable to make good out of the general purposes rate half of any sum so sanctioned by it in excess of the amount available for defraying expenses. The Commissioners further stated that if the local authority agreed to pay half of any deficit incurred by the Insurance Committee the Treasury was prepared to find the remaining half. The Chairman pointed out that as the county was not in a position meantime to provide sanatorium benefit, it was hardly possible to rate the people for the present year. The amount required would probably mean $1\frac{1}{4}$ d. on the rates. He moved that the account should not be sanctioned at present, and this was agreed to.

EDINBURGH ROYAL MATERNITY HOSPITAL.

At the annual meeting of the subscribers of the Edinburgh Royal Maternity and Simpson Memorial Hospital

on May 19th, over which the Bishop of Edinburgh presided, a reference was made to the regrettable circumstance that the annual subscriptions showed a decrease of £121; this decrease, taken in conjunction with the fact that the ordinary income of the year (1912) had fallen short of the ordinary expenditure by the large sum of over £497, was causing the directors much anxiety. Part of the drop in annual subscriptions was probably due to the operation of the Insurance Act. The annual report which, along with the accounts was adopted unanimously, in referring to the effect of the Act, stated that it was too early to estimate its influence upon the numbers of patients taking advantage of the service offered by the hospital; but since the maternity benefit provided by the Act had become payable in January, 1913, the number of cases, both at the hospital and at the Leith branch, had diminished. The directors hoped that this was only a temporary condition, due to the unsettled state of affairs inevitably connected with the start of the operations of an Act of such magnitude. The Board had given earnest consideration to the new position created by the Act, and its delegates had been in consultation with the Commissioners, at whose suggestion communication had been opened up with the approved societies and the Insurance Committees of Edinburgh, Leith and district, with the view of coming to a satisfactory working agreement within the scope of the Act. After full consideration along with the Medical Board, the directors had suggested as a fair arrangement a flat rate of 15s. a case, payable by the societies on behalf of those who took advantage of the service of the hospital, either as intern or extern patients, and so far as the experience had gone, it was understood that the representatives of the societies considered the proposal reasonable and the rate moderate. It was reported that during the year (1912) the total number of patients attended through the hospital and its Leith branch was 1,915; 70 nurses had been trained in the institution, 78 undergraduates had attended the hospital and associated dispensaries, and some 50 medical men and women had received clinical instruction in August and September in connexion with the post-graduate classes then conducted. Professor Harvey Littlejohn, Dean of the Medical Faculty in the University of Edinburgh, spoke gratefully of the work which was being done in the hospital for the benefit of the students attending the university, but thought it was to be regretted that a larger proportion of the 200 undergraduates who annually passed away from Edinburgh as qualified medical men did not take advantage of the excellent teaching in the institution. The annual report also made reference to the improvements which had been made in the hospital during the year, more especially in connexion with the new operating theatre, the installation of the electric light, and the extended nurses' residence; of these changes some account was given in the JOURNAL for February 8th, p. 308.

BEQUESTS TO EDINBURGH ROYAL INFIRMARY.

Mr. William McEwan bequeathed £15,000 to the Royal Infirmary of Edinburgh and £1,000 to its Convalescent House at Corstorphine. A legacy of £1,800 by the late Sir James Pickering Gibson, Bart., some time Lord Provost of Edinburgh, and three other legacies amounting to £1,535 have also been received.

EDINBURGH SCHOOL BOARD AND MEDICAL MATTERS.

At a meeting of the Edinburgh School Board on May 12th, and on the motion of Mr. James Clark, K.C., C.B., who was in the chair, it was unanimously agreed to adopt the Committee's recommendation for the appointment of Miss Lisette A. M. Wilson, M.B., Ch.B., D.P.H., the City Poorhouse Hospital, to the position of Assistant Medical Officer under the board. Mrs. Leslie Mackenzie, the Convener of the Committee on Health, submitted the report of the medical officer for the session 1911-12, from which it appeared that the number of schools under the board's scheme of medical inspection was 70, compared with 62 in the previous year. There was marked improvement in the cleanliness of the children, of whom 27,000 had been examined in the year for their condition in this matter as well as for the state of their teeth, vision, and hearing. Mr. Ramsay, Convener of the Attendance Committee, stated that during the spring holidays 541 necessitous children had been provided with dinners. The proposal

to institute classes for defective children in the north side and in the west end of the city was agreed to, and the matter was remitted to the Health Committee. The Chairman then drew attention to the bill to enable the provision of medical treatment for children attending schools. Medical treatment followed as the inevitable corollary upon medical inspection, if the parents of the children were not in a position to provide it themselves. Whilst welcoming the principles of the bill, he pointed out that although the central authority undertook half of the cost of the medical inspection, there was no such provision made for the medical treatment. He proposed that the board should approve generally of the principle of the bill, but should express the opinion that the cost to the locality, like that of medical inspection, should not exceed half the total expenditure, the other half being met by Government grant. This was unanimously agreed to.

TREATMENT OF CONSUMPTION IN EDINBURGH.

Sir Robert W. Philip and several members of the Board of Directors of the Royal Victoria Hospital for Consumption met a subcommittee of the Public Health Committee of Edinburgh Town Council on May 19th in connexion with the arrangement proposed to be entered into between the Royal Victoria Hospital and the city for the treatment of tuberculosis, when various preliminary matters were discussed. Further meetings will be held with, among others, the Burgh Insurance Committee before the matter comes before the Town Council again in the form of a report.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

ROYAL MEDICAL BENEVOLENT SOCIETY OF IRELAND.

The annual meeting of the Belfast and District branch of this society was held in the Medical Institute, Belfast, on May 16th. Sir Otto Jaffé, LL.D., was in the chair, and Dr. Fielden (honorary secretary and treasurer) read the annual report. The total amount collected during the year was £157 19s. 2d., a slight increase over the previous year. The expenses were £6 3s. 2d., and the net contribution to the central fund was £151; 138 Belfast practitioners contributed £94, and 46 country practitioners, £28; this latter is a small proportion for country doctors; no doubt the difficulty lies in bringing the claims of the fund before them. The country practitioners form less than 25 per cent. of subscribers to the funds, yet over 60 per cent. of the money distributed in grants goes to widows of practitioners who live outside Belfast. Reference was again made in the report to the question of converting the institution into a medical insurance society, and one member withdrew his subscription as no attempt had been made to carry out such a project. Professor Symington was re-elected president, Sir William Whitla, Sir Alex. Dempsey, Sir Otto Jaffé, Dr. R. J. Purdon, Dr. M. F. Cahill, Dr. Gardner Robb (all of Belfast), Dr. J. B. Johnson (Gillford), Dr. J. J. Adams (Antrim), Dr. R. A. Shekleton (Holywood), Dr. James Wallace (Knockahollet) were elected members of committee, and Dr. Victor Fielden was elected honorary secretary and treasurer. A cordial vote of thanks was passed to Sir Otto Jaffé for taking the chair.

ROENTGEN RAYS AT SOUTH INFIRMARY, CORK.

At the monthly meeting of the South Infirmary, Cork, a letter was read from a firm of solicitors offering on behalf of a client £500 as a donation to the funds of the hospital, to be applied as may be arranged hereafter in connexion with the x-ray department of the hospital, so that its sphere of usefulness may be increased by the more extended employment of the Roentgen rays in the investigation and treatment of disease. The offer is made subject to the conditions that the committee of management appoints an honorary specialist to the department, who must be a duly qualified medical man who has devoted special attention to x-ray work, and that he shall be entitled to charge reasonable fees in cases of private patients applying to the department.

PRESENTATION TO DR. GEORGE ELLIOTT, BELFAST.

The medical profession was entertained by the council of the Belfast Medical Guild at a smoking concert in

the Medical Institute, Belfast, on the evening of May 13th. The more immediate object of the function was to make a presentation to Dr. George Elliott, who was leaving to take up practice in England. Dr. Elliott had been honorary secretary to the guild from its inception, and had worked strenuously and devotedly in the difficult and rough paths of medical politics and ethics during the past two years. He had also been secretary of the Belfast Division of the British Medical Association, and in that capacity had rendered valuable services. The president of the guild, Dr. T. C. D. Cathcart, made the presentation of a purse of sovereigns and an album on behalf of the profession. He extolled the services of Dr. Elliott, expressed regret at his departure, and wished him God-speed in his new sphere. Dr. Gardner Robb, chairman of the Belfast Division, supported the words of the president of the guild, and Dr. Elliott suitably replied. Mr. R. J. Johnstone said that in Mrs. Elliott the doctor had an indefatigable co-worker, and that their heartiest thanks and good wishes should be conveyed to her, and Dr. Elliott returned thanks on her behalf. An enjoyable evening, varied with songs and recitations, was passed.

PRESENTATION TO DR. LAVERTY OF RATHFRILAND.

On May 2nd, at a meeting of the medical men of South Down at Rostrevor, Dr. Laverty of Rathfriland was presented with a cheque as a mark of esteem and an expression of the sympathy of his colleagues in respect of charges of neglect of his professional duties, from which he was exonerated after a sworn inquiry held by the Local Government Board. Dr. McCartan, who occupied the chair, expressed the great pleasure it afforded him to be the spokesman of his colleagues in asking Dr. Laverty's acceptance of a cheque towards the expenses which he had incurred in meeting and successfully refuting the charges that had been brought against him. Dr. Laverty deserved the thanks of his brethren for the decisive steps he had taken, as in fighting his own battle he was also fighting for the rest of the profession. The cheque was the spontaneous outcome of his colleagues' confidence, sympathy, and respect. Dr. Laverty, in his reply, said that he was well rewarded for his fight by the kind sympathy and good fellowship of his brethren.

UNVACCINATED CONDITION OF IRELAND.

Of late years, chiefly owing to the energies of branches of the Antivaccination Society started throughout the country, the number of vaccination defaulters has risen so rapidly that to-day in many districts the majority of the children have never been vaccinated. The boards of guardians refuse to enforce the Vaccination Act, and pay no heed to the remonstrances of their medical officers or of the Local Government Board. However great the danger caused by this unvaccinated condition of the population may be in England, it is much greater in Ireland, owing to the less rigorous attention that is paid in this country to sanitation and inspection. The condition of the country may be gathered from the following figures which have been recently published: In Newry the guardians were notified by the dispensary medical officers that about 1,000 children in the union had not been vaccinated. In Gorey, co. Wexford, the dispensary doctor reported that there were 399 unvaccinated persons in his dispensary district alone; the board of guardians, however, made no order on the report. Reports to the same board of guardians, that the unvaccinated persons in Coolgreany numbered 140, and in Killenagh and Wells 283, were treated in the same way. At Fermoy a letter was read to the board of guardians from the Local Government Board stating that steps should be taken to ensure compliance with the law on the part of the defaulters under the Vaccination Acts in the union, whereupon a proposal that notices should be posted in the dispensary districts, warning people that they need not have their children vaccinated if they did not wish to do so, was carried unanimously.

OVERCROWDING IN ASYLUMS.

The resident medical superintendent reported at the last monthly meeting of the Clare Asylum Committee that there were in the house at the close of the year 488 inmates—273 males and 215 females, the largest number recorded. The asylum, he said, continued to be over-

crowded, specially on the female side. He hoped the new female observation dormitory would soon be ready for occupation.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

WALES.

THE UNIVERSITY OF WALES.

At the court of the University of Wales held on May 17th at Bangor, Mr. Lynn Thomas, C.B., Surgeon to the King Edward VII Hospital, Cardiff (the Cardiff Infirmary), was elected Junior Deputy Chancellor in succession to Colonel Sir Pryce Jones. The King is Chancellor of the university, and Lord Kenyon, who presided over the court, is Senior Deputy Chancellor. The other candidate for the post of junior deputy chancellor was Sir Marchant Williams, one of the Treasury representatives on the court of the university. We recently had occasion to refer to the steps which were in contemplation to complete the Medical Faculty of the University of Wales, and to establish a complete medical school in the University College for South Wales and Monmouthshire at Cardiff. In electing Mr. Lynn Thomas to the office of Junior Deputy Chancellor, the Court was no doubt actuated by the desire to place in high office one who is intimately identified with the scheme for the establishment of a complete Welsh medical school in Cardiff. His participation in the *Wanderlust*, to which, as noted elsewhere, British surgeons have wisely in recent years more and more given free rein, has afforded him opportunities of becoming acquainted with the system of medical teaching and research in the universities and university hospitals and institutes of other countries. This experience will stand the Welsh school in good stead during the deliberations on the many important questions which must shortly be decided.

GIFT TO THE NEWPORT HOSPITAL.

At the meeting of the directors of the Newport and Monmouthshire Hospital on May 30th, Sir A. Garrod Thomas, M.D., who was in the chair, announced that Lord Tredegar had presented, in memory of his uncle and predecessor in the title, the house and grounds of The Friars, a beautiful house of Gothic style, situated on an eminence above the hospital and quite close to it. The donor hoped that the house would be used as a convalescent home, and the gardens, which extend for some 14 acres, as pleasure grounds for the benefit of the hospital generally. Sir Garrod Thomas, in making the announcement, said that the gift would place the Newport Hospital in a most enviable position, and without encroaching upon the green fields, which extended right up to the present hospital grounds, it would be possible to make any necessary extension of the hospital buildings. The value of the gift is estimated at over £20,000. Lord Tredegar was unanimously elected president and trustee of the hospital in place of the late peer.

THE CARDIFF HOSPITAL.

The medical board reported to the governing body of the Cardiff Hospital on May 14th that a communication had been received from the Honorary Secretary of the Swansea Division of the British Medical Association with reference to the treatment of members of any society or association having for its object the employment of medical men under conditions not approved by the medical profession. After careful consideration the medical board had decided to reply that the medical staff was in full sympathy with the staff of the Swansea Hospital, but, as no communication had been received from the Cardiff Division of the Association, no action could be taken. After a member had urged the hospital board not to allow any local dispute to interfere with the work of the hospital, the discussion closed.

LIVERPOOL.

ROYAL INFIRMARY.

THROUGH the energy and enthusiasm of one of the Liverpool daily papers a fund of over £2,000 has been raised to provide the Royal Infirmary with a supply of radium sufficient for therapeutic purposes. It will be under the control of the radiographer of the institution, Dr. Thurstan Holland.

SWIMMING BATHS.

The City Council has decided to provide swimming baths at the Pier Head, the heart of the business portion of the city. This scheme will cost little short of £100,000, but the resulting building will be worthy of the city and in keeping with the important edifices in the same neighbourhood.

ABATTOIRS.

The question of the removal of the abattoir from the neighbourhood of the university and the Royal Infirmary is still undecided, but will shortly be brought to a definite issue. From a medical and an aesthetic point of view there can be little doubt as to the desirability of a removal.

GYNAECOLOGY AND OBSTETRICS.

Dr. Willett has been appointed to the staff of the Lying-in Hospital, and to the staff of the Hospital for Women. He thus fills the two vacancies caused by the death of the late Dr. Arthur Wallace.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

NEW COCAINE RULES.

REVISED rules regulating the import and possession of cocaine in the Punjab have recently been published. They cover, with certain exceptions, all cocaine preparations, and all drugs, synthetic or other, having a like physiological effect to that of cocaine. The quantities of such drugs allowed to be possessed by certain specified persons are as follows:—By officers of Government, such drugs as come into their possession in the course of their official duties; by medical practitioners (including medical and veterinary officers of Government when engaged in private practice) up to the limit of half an ounce; by a licensee, up to the limit of his licence; by any other person, up to the limit of such quantity as he may have purchased on the prescription of a qualified medical practitioner. The preparations of cocaine specially exempted from these rules are as follows:—Cocaine used in impure solutions in ointments for local application and made nauseous to the taste, or the following bona fide proprietary medicated articles:—(1) Toothache drops. (2) Ear drops. (3) Compound tablets of lozenges composed of—(a) cocaine, chlorate of potash, and borax; (b) krameria and cocaine; (c) menthol, cocaine, and red gum; (d) benzoin and cocaine, provided that they are stated by the makers to contain not more than $\frac{1}{16}$ grain of cocaine, novocain, eucaine, beta eucaine and beta eucaine lactate, or holocaine in each lozenge or tablet; and certain proprietary mixtures. There have recently been many cocaine raids, and the Report room at Sall Police Station has been overflowing every morning with persons arrested the previous night on charges of being in possession of the drug.

MOSQUITOS IN ASSAM.

An interesting experiment has been made by Captain T. C. McCombie Young, I.M.S., under the instructions of Government, which sanctioned an expenditure of Rs.900 in the new civil station of Dacca. The Ramna, as it is called, is a recently cleared area upon which the residences of civil officials and some of the new Government offices at Dacca were built. Numerous tanks and ruins of mosques give evidence of its former habitation. Captain Young started operations in November, 1911. The area under treatment comprised about two square miles, and the buildings on it were good class private houses with their compounds, a residential college, and

some Government offices. The operations consisted in cleaning such tanks as needed it, sweeping and flushing drains and watercourses, and the use of kerosene. Every breeding ground, actual or potential, within the area was marked down on a map and regularly treated, and Captain Young was satisfied that no breeding of mosquitos was taking place within the area. Nevertheless matters were not materially improved, for whenever there was even a gentle breeze from the south the cantonment was invaded by mosquitos transported from the breeding grounds in Dacca City a mile and a half away. Captain Young concluded therefore that it would be necessary to carry out larvicidal measures in Dacca City as well. To do this effectively it would first of all be necessary to provide an efficient surface drainage system at a cost of 50 lakhs of rupees.

Special Correspondence.

PARIS.

The Cause of Mercurial Tremor.—Transudates and Exudates.—Pericardotomy in Tuberculous Pericarditis.

DRS. GUILLAIN AND LAROCHE reported at a recent meeting of the medical society of the hospitals the results of a clinical study of the etiological factor of the tremor which occurs in chronic mercurial poisons. They pointed out the resemblance between mercurial tremor and the tremor of cerebellar disease, and the resemblance also of the symptoms of slurring of speech, nystagmus and ataxic movements frequently present. From these signs and from the fact that in many other drug toxæmias certain portions of the nervous system are selected for attack, they conclude that mercurial tremor is in reality caused by a toxic lesion of the nerve centres, and more especially of the cerebellum.

At a recent meeting of the Society of Biology, Dr. Villaret made some observations on the differentiation of a transudate from an exudate. A series of 200 effusions was examined by the Gaugi Rivalta collargol and violet reactions. The violet contact-reaction with hydrochloric acid pointed to the presence of blood corpuscles in the effusion. In the collargol reaction the silver salt was precipitated by the addition of a few drops of transudate, but was not precipitated by the addition of an exudate. The use of these reactions led to the conclusion that in ascites from cirrhosis of the liver the fluid was primarily a transudate, due to the hypertension existing in the portal system, and only became an exudate secondarily to an infection of the peritoneum.

The results of two operations of pericardotomy for pericarditis with effusion were recently communicated by Dr. Jacobs to the Surgical Society. In both pericardotomy without drainage was performed, and in both cure followed. The first patient was a soldier, aged 21. The temperature was 102.7° and the pulse 120, and cardiac dullness was markedly increased; the patient appeared very ill. Pericardotomy was performed, and 700 to 800 grams of fluid were evacuated. The pericardial incision was not closed, but the muscles and skin were sutured, and the wound healed satisfactorily, and complete cure resulted. Dr. Jacobs maintained that if tuberculous pericarditis were treated by leaving the pericardial incision open but without other drainage, recovery would be rapid and satisfactory. Aspiration of the pericardial sac was, he thought, always dangerous; adhesions might be present, so that no fluid was obtained; further, the heart muscle might be injured and death ensue.

How important a part in public life is played by doctors in South America may be inferred from the fact that in Paris alone the Minister Plenipotentiaries of Mexico, Chile, and of Ecuador are members of the medical profession. The representative of Mexico is Dr. Diego Suarez, while Chile and Ecuador are represented by Dr. Puga-Borne and Dr. Rendon respectively. Dr. Manrique was formerly Minister Plenipotentiary of Colombia. Drs. Olano, Santiago, Letond, Hernandez, Gana, Alberto Alvarez Canas, are Consuls-General of Salvador, Chile, Costa Rica, and other states.

Correspondence.

THE REORGANIZATION OF THE ASSOCIATION.

SIR,—It appears to me absolutely necessary that the Annual Representative Meeting in July should recognize that its primary duty and the one essential reform is the reorganization of the Association, beginning with a thorough overhaul and searching inquiry into the present organization from top to bottom. There will be few to deny this need and its vital importance. No time is more opportune than immediately after a severe test, while the details of cause and effect are fresh in mind. That the present organization is cumbersome, costly, dilatory, and withal ineffectual is admitted. As the medico-political machine for the protection of all the interests of the profession, the Association must have a strong, active, alive, and real organization.

There must be more active co-operation between its component parts, closer communication and touch with its extremities. In this way will confidence in the strength and power of the Association be inculcated in the individual members, and that mutual confidence obtained without which there can be no reliance.

I trust the Representative Body will take this matter in hand seriously as one of urgent necessity.—I am, etc.,

Sittingbourne, May 16th. T. BARRETT HEGGS, M.D.

* * * A reference to the paragraph headed "Reform of the Present Constitution" in the report of the Proceedings of Council, published on page 421 of the SUPPLEMENT of May 10th, will show that this subject is receiving the earnest attention of the Council, and that the matter is being expedited as much as possible. The Organization Committee has a report in preparation which will be presented to a special meeting of the Council on June 13th.

POST-GRADUATE STUDY IN PARIS.

SIR,—In starting next autumn a special course of post-graduate classes for the benefit of British medical men, Professor Widal's only aim is to offer, in Paris, the same opportunities as your fellow-countrymen are used to find in the German and Austrian schools.

If Sir William Osler's advice about studying in a foreign country is followed by any of your readers, here, then, is an opportunity of availing themselves of the very best resources of the modern Paris school, using school in the broad sense of the word, for this organization has nothing to do with the university: it is worked privately in Widal's private laboratories and wards.

A schedule will be published in due time. Our programme includes:

1. Clinical work and clinical teaching.
2. Practical bacteriology as regards diagnosis.
3. Practical teaching of biological methods applied to clinical researches, more especially the practical demonstration of Professor Widal's original methods.

Every opportunity will be given for those who want to study specialities, and hours will be arranged so that no time will be lost. But as we want more than anything else to be practical and useful, I would be glad to hear from those who may be interested in this new departure. Any advice, hint, or suggestion would be welcome.

For instance, we are not quite sure about the suitable time to start this course (we suggest October 15th); and we wonder if we might run it up to Christmas? It has also been suggested that the teaching should be done in English. Much may be said *pro et contra*. On this very important point I should like to hear from those who may be interested.—I am, etc.,

GUSTAVE MONOD, M.R.C.P.Lond., M.D.Paris.
Vichy, May 17th.

RHEUMATOID ARTHRITIS.

SIR,—Sir James Barr's article on rheumatoid arthritis was not very convincing. After an opening showing how impossible it was that the disease could be caused by any bacillus, he began his directions for treatment by advising that the mouth should be kept free from micro-organisms. This was not a piece of general advice, but part of the treatment of the disease known as rheumatoid arthritis.

As regards his argument as to a bacillary cause, it should seem that the absence of proof that a particular cause produces a particular effect is not a very strong proof that it may not do so. As a general rule a theory must have much added to it before it can become a theorem, but the fact of there being a transition stage cannot be held to be sufficient reason for rejecting the theory.

I have pointed out that there is no such thing as rheumatic fever in the Malay Peninsula, and Major Buchanan agrees with me that there is none in tropical India. I now add that in eighteen years' experience in the tropics I have never seen a case of rheumatoid arthritis, and think that the factor underlying this great difference between England and the Malay Peninsula should supply the knowledge of the cause of these diseases.

It seems to me more than possible that the absence of both these diseases in one place indicates a causal connexion, and that rheumatoid arthritis may be a sequel of the presence of the poison of rheumatic fever without the original disease necessarily ever having manifested itself, just as nephritis may manifest itself as a sequel of scarlet fever or of quartan malarial fever without any history of the occurrence of one of these diseases previously. I do not mean that rheumatic fever is the cause of rheumatoid arthritis, but suggest that the cause of rheumatic fever is a necessary constant in the production of rheumatoid arthritis. The fact that rheumatic fever does not occur in the Malay Peninsula may be due to the organism producing it being unable to exist extra-corporeally at a mean temperature of 80° F.—I am, etc.,

J. TERTIUS CLARKE,
Health Officer, Perak, South F.M.S.

Hinckley, May 14th.

SIR,—I have such a high opinion of the excellent work of Dr. Chalmers Watson on dietetics that I am quite prepared to receive any opinion of his with the greatest respect; but on the present occasion I am rather sorry to see him parting with the substance for the shadow. It will be time enough for Dr. Watson to clench his view "that the disease is a toxic arthritis of bacterial origin" when he has discovered either the bacterium or its toxin. I have shown that there are many cases of arthritis of microbic origin, but I think that such cases can be and should be differentiated from what I understand by rheumatoid arthritis. There is, in my opinion, no justification for allowing the numerous joint affections to remain in their present muddle in the medical mind.

The "curious inconsistency" which Dr. Chalmers Watson thinks he has discovered may turn out to be a mare's nest. I have no wish to shut my eyes to any inconsistency, if such can be shown to exist, as I always appreciate the saying of Burns:

O wad some pow'r the giftie gie us,
To see oursels as ithers see us!
It wad frae mony a blunder free us.

In this case, however, the blunder, according to Dr. Chalmers Watson, carries me in the right direction. Perhaps we will all get there in time.

I have always advocated, and I hope I shall always continue to advocate, the treatment of the patient rather than his disease. In any disease every morbid condition present or in any way associated with the disease should receive attention. If there be any interference with the digestion, either by pyorrhoea or anything else, it should be corrected. There are often acid-forming organisms in the mouth. The carbohydrate metabolism set up by acid-forming organisms cannot be cured by a vaccine, and organic acids introduced from without, though not so constant in their action, may prove almost as injurious. It is remarkable how scanty is the evidence of putrefaction in this disease considering the frequent constipation. We do now and again get a trace of indican in the urine, but not such as to justify any one in ascribing any rôle in this disease to putrefactive organisms. There is no vaccine which can harm any organism which has merely established a habitat on any unbroken surface of the body; the bacterium must get beyond the surface before the vaccine comes into play. I saw a lady the other day whom I had previously seen about six years

ago, when I found a luxuriant growth of the *Bacillus coli* in her stomach. My treatment with antiseptics and keeping the bacilli moving proved advantageous for a time, but on a relapse she got into the hands of a London physician, who gave her a long course of an autogenous vaccine. The last end of this woman is worse than the first, but I hope she has now had sufficient experience to make her give a rational treatment a fair trial. There has been plenty of evidence of putrefaction in her case but none of rheumatoid arthritis.

I am delighted to find Dr. Pagan Lowe among the converted; yesterday I came across a young woman (Mrs. E.) who about two years ago was a long time under his care with rheumatoid arthritis, and since then has seen many others, but has steadily got worse. She had sour milk, radiant heat, vaccines, and arsenic, all to no purpose so far as she is concerned. She is now on a Salisbury diet, and in a short time will be getting as much milk as would now please Dr. Pagan Lowe.

Dr. Thurstan Holland has pointed out to me that in my last letter I misunderstood Dr. Bailey's remarks about the skiagrams, and that Dr. Bailey did not mean, as I thought, absorption of lime salts at the seat of fracture, but absorption from some of the neighbouring bones—for example, in Colles's fracture of some weeks' standing there may be absorption of the lime salts from the carpal and metacarpal bones. I noticed in the skiagrams which Dr. Holland showed me that the finely stencilled lines of absorption occurred at the edges of the bones where the blood supply comes from the periosteum. So far there is no explanation forthcoming as to how this interesting fact takes place or why it should occur. The solution of this problem, which will repay the considerable amount of trouble necessarily involved, seems to me comparatively simple, or at least one which will offer no insuperable difficulties. It would appear as if the atrophic condition of bones and muscles did not entirely depend on the want of use, but had some underlying common cause. It is here not merely a question of dietetics but also of the oxidation of the sarcolactic acid generated in the muscles. It is well known that in tuberculous disease of the bones and in severe cases of phthisis there is a marked deficiency of lime.

It will take something more than Dr. Craig's recollection to make me believe that Sir Robert Christison ever uttered such a statement as that attributed to him by Dr. Craig. I look upon such a statement as a libel on the memory of a great man. In 1873 rheumatoid arthritis—a name which had been coined by Sir Alfred Garrod some years previously—was merely a generic term for a group of chronic joint affections which had not been differentiated, and the whole series were then as inextricably mixed as they are to-day by Dr. Craig.

Sir Robert Christison never wrote anything about rheumatoid arthritis; the principal physiological effects of calcium were not then known; his lectures on materia medica had no necessary connexion with therapeutics, and in his remarks on the actions and uses of the lime salts there is not one word about rheumatoid arthritis. I can find no reference to the use of the lime salts in this disease in any work which I have come across published about or before that time. The infusion of straw scarcely merits the contempt poured upon it by Dr. Craig, as it contains a large quantity of lime in solution, and might thus be of much more use in this disease than, say, barley-water or a "thermo-penetrating current."

Sir Robert Christison's admirable investigation on poisoning with oxalic acid was carried out in co-operation with Dr. Coindet of Geneva; they recognized that oxalic acid formed soluble salts with calcium and magnesium, and hence the alkaline salts of these metals were recommended as antidotes; after the absorption of the oxalic acid or of any of its soluble salts they ascribed its secondary poisonous effects to a sedative action on the nervous system, and did not recognize that it deprived the blood of its soluble calcium salts which are necessary for the maintenance of the heart's action. Dr. Coindet was the first to introduce iodine in the treatment of bronchocele, which sometimes had a good effect and at other times the result was rather disastrous. This no doubt arose from the fact that the endemic was not then differentiated from the exophthalmic variety.—I am, etc.,

Liverpool, May 17th.

JAMES BARR.

SYPHILIS AND CANCER OF THE TONGUE.

SIR,—As a letter by Dr. Renshaw in your issue of May 10th affects Mr. Ryall and myself, I may be allowed a reply for both. In endeavouring to establish the thesis that syphilis is an important factor in the production of cancer of the tongue, the limitations of inductive logic were quite well appreciated, but the argument is none the less cogent. The following facts were put forward by Mr. Ryall: (1) The history of syphilis in 80 per cent. of cases, (2) the accompanying evidences of lingual syphilis in most, (3) the observation of syphilitic tongues in which cancer afterwards supervened, (4) the marked local improvement that frequently results from the administration of antisyphilitic remedies in cases proved to be cancer of the tongue, and (5) the indication of a syphilitic taint given by the Wassermann reaction. There is probably not much weight in the contention that the oral administration of mercurial salts is a factor in the production of cancer of the tongue, nor are there any statistical data available to us which alone would enable it to be said whether the disease is more or less frequent in this country than on the Continent. The statement quoted in this respect is one of those unsupported assertions regarding cancer that are scarcely worth the trouble of refuting.

The main point with regard to the employment of the Wassermann reaction in cases of lingual lesions is that it is quite useless as a means of discriminating between cancer and syphilis. This is just what one would expect. In cases of cancer in other situations a positive Wassermann reaction, provided a reliable method is adopted, is very rare, and when it is found, as it has been by several other workers besides myself, a preceding syphilis is either known or cannot be excluded. Many of the reactions that pass under the name of "Wassermann reactions" are far from being reliable, and Dr. Renshaw was quite entitled to ask what technique was adopted and to reject the conclusions if the method used was, in his opinion, slipshod. A comprehensive reply to the request for precise information regarding percentages and methods could not be given, for the reason that the reports of others were not available for critical examination, but a definite statement could be made in respect of seven cases of lingual cancer investigated, amongst many other things, by a well-known quantitative method. This method and its rationale are, perhaps, unknown to Dr. Renshaw, for he would have spared me a little lecture on elementary principles, which I trust are as clearly understood as they were pontifically expressed by him. I would quite appreciate the criticism that my chance sample might be abnormal and capable of correction by more extended experience, but in view of the general strength of the case for syphilis as an etiological factor, in my opinion unassailable, such a research would be comparatively profitless endeavour.

I am sorry I have not the time, much as I have the desire, to be of service to Dr. Renshaw in controlling his results by the Browning-Mackenzie method, and I am regretfully precluded—for the present—from furnishing him with cancerous serum by the fact that my own serum investigations of another nature are only limited by the available supply of material, on which several friends have already a heavy mortgage.—I am, etc.,

Cancer Hospital, S.W., May 16th.

ARCHIBALD LEITCH.

WHOLE-MILK DIET FOR INFANTS.

SIR,—Dr. Cameron evidently believes¹ that the vast majority of digestive disturbances are due to excess of either sugar or fat in the diet. An excess of protein he believes will not cause dyspepsia, and in support of his hypothesis he refers to the great success of whole-milk feeding. The good results he attributes to the low percentage of sugar in cow's milk rather than to any means which may be employed to prevent the clotting of casein in the stomach. I have had considerable experience in giving undiluted cow's milk at my infant consultations during the last five years, and I can fully confirm Dr. Cameron's opinion as to the success of this method, but I fail to see why excess of protein should never cause dyspepsia, or that the clot which is formed in the stomach should have no effect on digestion. It is surely reasonable to assume that the gastric and intestinal juices find it

harder to battle with a solid substance than if the food is present in a fluid form. I have found the addition of sodium citrate of the greatest value in whole-milk feeding. I use 1 grain to each ounce of milk.

Later on in his article Dr. Cameron draws rather a gloomy picture of the child who is fed entirely on pure cow's milk. He says that "the want of sugar often leads to constipation, to want of growth, and to backward development generally." He writes of the pale, undersized pure-milk infants, and compares this with the larger and fatter infant who has some additional sugar in the diet. Now, I venture to say that this description gives an entirely false view of the pure-milk baby. No doubt at Guy's Hospital the infants are only brought when they are ill, so that Dr. Cameron would come in touch with the failures due to whole-milk feeding. On the other hand, at our infant consultations the object is to prevent illness, and so we are able to exercise some supervision every week with regard to the amount and quality of food. We certainly do not see these small, puny, backward children which we can definitely ascribe to whole-milk feeding and to no other cause. On the contrary, the vast majority are active and have hard muscles, and are better developed than those fed on milk mixtures. The growth of an infant is surely more dependent on the protein constituents of the food than on any other.

Dr. Cameron says, in referring to pure milk feeding, that he "has seen infants who for months showed no gain in weight, although they were daily taking enormous amount of milk of good quality." These cases, I should say, were suffering from dilated stomachs due to overfeeding. It is essential that the child should not be given more milk than it can digest; the small feeds which even breast-fed infants obtain, as shown by the "test feed,"² should put us on our guard in ordering cow's milk. I have repeatedly found the child puts on weight if the amount of milk is reduced. I cannot agree with Dr. Cameron that whole-milk feeding causes constipation. I find that the commonest cause of constipation is starvation, and that if the quantity of food is cautiously increased the bowels will act regularly. It stands to reason that if there is not sufficient residue in the bowel there can be no stimulation of the centre in the spinal cord. I have never found it necessary to give drugs or sugar to cure constipation.

I think proprietary foods should be prohibited amongst the poor because of their expense. Carbohydrate can be given in the form of bread jelly to infants of 6 months and over, and amongst the very young ones I order bread soaked in boiling water, and then squeezed through muslin; the portion which passes through the muslin can be added to the milk in the bottle.—I am, etc.,

RONALD CARTER, M.D., M.R.C.S., L.R.C.P.

Kensington, May 14th.

EXISTING UNSATISFACTORY CONDITION OF THE SCHOOL MEDICAL SERVICE.

SIR,—The success of any particular service—that is, its usefulness to the community—will be strictly in proportion to the talent and energy of those engaged in it. There are two ways of securing this talent and energy. You may arrange to have a good sprinkling of big plums in the way of remuneration and a host of comparatively inadequately paid minor positions. This is the traditional method of the church, the bar, the legal, and the medical professions, and it keeps up a steady stream of the most energetic and ambitious heads. Or you may offer a host of modestly satisfying positions, each sufficient to make a man able to maintain a status that the world will think dignified, with a slow but sure scale of increment. This is the method of the civil services; it is not perhaps so attractive as the other to our most enterprising youth, but it serves.

It must be admitted that the school medical service has neither big plums nor a steady if modest competency to offer. It is, indeed, fed at present by the enthusiasm which a new subject begets, the thrill and pride of pioneering. But this cannot, of course, last; and it is evident that, unless the school service can be put on the same footing of self-sufficiency as the public health and other services, it will be starved of its most energetic men and women.

¹ BRITISH MEDICAL JOURNAL, April 26th, 1913, p. 872.

² *Lancet*, September 2nd, 1911.

The general notion of linking up the school service with the public health service in each locality is thoroughly sound. We want for each county a chief medical officer, a great administrator, to co-ordinate all the medical interests—hospitals, asylums, river pollution, school inspection, and what not. But as a corollary each separate medical interest needs a seasoned and experienced chief who can feel that if he gets no further up the ladder, it will at least not mean disaster to his family.

It is evident that there will continue to be unrest in the school medical service until the conditions come more nearly to resemble those of the public health service.—I am, etc.,

Stafford, May 20th.

JOHN PRIESTLEY.

EVIDENCE FOR AND AGAINST TUBERCULIN.

SIR,—The question raised by Dr. Batty Shaw (May 3rd, p. 921) is one of primary importance, especially to the general practitioner. And it is time that an attempt were made to give a definite and authoritative answer to the question, Is there clear evidence that pulmonary tuberculosis can be cured by the use of tuberculin? Dr. Batty Shaw is specially qualified to deal with the question from his experience as a physician of the Brompton Hospital and the calm, judicial attitude of his mind.

One of the arguments which he brings forward on the negative side strikes me as having great significance:

"If it were proven," says Dr. Batty Shaw, "that tuberculous cattle could be cured by vaccination by means of tuberculin, we may be quite sure (1) that it would be widespread in veterinary practice; (2) that the whole medical profession would have adopted it with very little hesitation, and they would have been justified. But where are the reports on cattle which should make us at ease on this point? Frankly, they do not exist."

Surely that is a staggering blow to the tuberculin propaganda. If bovine tuberculosis has not been cured by bovine tuberculin, what reason is there to assume that human tuberculosis will be cured by human tuberculin?

In the BRITISH MEDICAL JOURNAL of May 10th I see a letter by Dr. J. Stavely Dick criticizing in a very temperate manner Dr. Shaw's address. But I cannot quite see the force of his remark that "the crucial experiment, however, of leaving Nature alone in one series of cases and introducing this or that factor in another series cannot, for obvious reasons, be made."

What are these obvious reasons, and what other method would Dr. Dick suggest to test the value of a doubtful remedy? Dr. Dick states that he is "convinced clinically (1) that in the doses suggested by Sir Almroth Wright it does no harm in afebrile cases; and (2) that in a very considerable percentage of such cases real good is effected"; but I should like to know whether the "real good" includes a decided and curative effect on the pulmonary lesion as revealed by physical examination of the chest.

My attitude is not one of hostility to tuberculin, but that of one who is desirous to have definite proof of its curative effects.—I am, etc.,

JAMES W. ALLAN,

Resident Physician, Bellefield Sanatorium, Lanark; late Physician, Glasgow Royal Infirmary.
May 12th.

VACCINATION INQUIRY IN THE ISLE OF MAN.

SIR,—Your condensed report of the above inquiry is quite fair, but your editorial remarks are not fair. They are contradictory. The reason of the difference is that the former is based upon the actual evidence supplied by an official verbatim report of the proceedings, whereas the latter consists of deductions drawn from the speeches of members of the Legislative Council, who were anything but correct in their statements and conclusions.

You quote the strong remarks of two members—the Attorney-General and the President (Lord Raglan). The former stating that my evidence "convinced him that there was absolutely nothing in the case against vaccination." But if you will look at his remarks uttered just before, you will see that he says:

I approached the subject strongly prepossessed in favour of the utility of vaccination, and the undesirability of in any way relaxing the law to enforce it,

This considerably discounts his estimate of my evidence. It was clear that every one of the ten members of the Council was in the same frame of mind, and the result, so far as they were concerned, was practically settled before the inquiry commenced.

You proceed to quote what the Attorney-General said of my remarks concerning the relationship between original cow-pox and syphilis. If you will compare his criticism with your own report of my evidence you will see that he never grasped my argument, and, if the full report of the examination and cross-examination is perused, it will be noticed that he quite failed to understand the subject at all.

It is to be regretted that you should quote the remarks made by Lord Raglan, and add that "what actually happened is reflected in the remarks of the Attorney-General and Lord Raglan" without first verifying the truth of the criticism. Both gentlemen have gravely misrepresented me. No such expression and no such "attack" as stated by Lord Raglan fell from my lips, and I indignantly repudiate his statements. Nothing of the kind professedly quoted by him can be found anywhere in my evidence.

I enclose a copy of my reply to Dr. Drury's evidence, together with my answer to the speeches of the members of the Legislative Council.—I am, etc.,

Gloucester, May 19th.

WALTER R. HADWEN, M.D., J.P.

Public Health

AND

POOR LAW MEDICAL SERVICES.

SCIENTIFIC RESEARCH FOR THE LOCAL GOVERNMENT BOARD.

THE President of the Local Government Board has authorized the following special researches to be paid for out of the annual grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease:

Continuation of the Board's inquiries into:

1. The cause of premature arterial degeneration, by Dr. F. W. Andrewes.
2. On insects in relation to disease: Professor Nuttall, F.R.S., on the life-cycle of the body-louse and bug; Dr. Bernstein and Mr. Hesse, on the *Empusa muscae* in flies.
3. As to infantile diarrhoea, by Mr. F. W. Twort and Dr. Edward Mellanby.
4. As to the virus of poliomyelitis, by Drs. Andrewes and M. H. Gordon.

And the following investigations:

5. By Mr. F. W. Twort, into the character and life-history of certain filter-passing micro-organisms.
6. By Professor Leonard Hill, F.R.S., on respiratory exchange in man under varying conditions.
7. By Mr. J. E. R. McDonagh, on the biochemistry of syphilis.
8. By Dr. L. Rajchman, into the possibilities of serological diagnosis of scarlet fever.
9. By Dr. D. M. Alexander, on the relation between the clinical symptoms and the bacteriology of the acute respiratory affections.

POOR LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

A COUNCIL meeting was held at 24, Copthall Avenue, London, E.C., on May 15th, Dr. Balding, J.P., being in the chair.

The Honorary Secretary reported the death of one of the members of the council (Dr. T. Carey Barlow); on the previous Friday he had gone to bed after his usual day's work, and passed away during the night. Much regret was expressed by the members present, and the Honorary Secretary was instructed to write to Mrs. Carey Barlow, conveying the sympathy of the council with her in her sad bereavement.

Dispute at Burnley.

The Honorary Secretary reported that there had been little change with regard to the Burnley dispute since the last council meeting. A copy of the last letter of the association dealing with the matter had been sent by the Local Government Board to the Burnley guardians, who had replied they had nothing further to add. The new board of guardians had endorsed the recommendations of the late board; but up to the present no further answer had come from the Local Government Board, but it was hoped that before coming to a decision it would hold a local inquiry.

Cost of Drugs.

A letter was read from one of the district medical officers of the East Ham Union, stating that the guardians were proposing

to supply at their own cost the medicines, etc., hitherto found by the medical officers, and that the clerk to the guardians had inquired what deduction from their salaries they were prepared to allow in consequence. The district medical officers strongly objected to any deduction. In addition to the pecuniary loss, it would further diminish the value of their superannuations in the future. The council was strongly of opinion that no deduction should be permitted. Drugs ought in all cases to be supplied at the expense of the guardians, and the present salaries of Poor Law medical officers were by no means exorbitant for the medical work alone. Dr. Holder (Hull) said that the Sculcoates Guardians not long ago decided to supply the drugs, and took that duty off the medical officers without diminishing their salaries. He believed the same had been done by other boards of guardians.

Emergency Attendances.

The responsibility of guardians to pay for services rendered to inmates of their workhouse by practitioners called in the absence of the workhouse medical officer was raised by a recent occurrence in a northern town. The council was of opinion that if outside medical assistance were called for on behalf of the guardians by an officer entitled to pledge the credit of the same a fee could be recovered. It was not clear why in this instance the deputy had not been sent for. It was decided that the annual meeting should take place in London on Thursday, July 3rd, at 3 p.m.

Insurance Act.

It was pointed out that complaints were arising in many places that the maternity benefit seriously interfered with the emoluments derived from the extra fees granted for attendance on midwifery cases. In one union a medical officer was petitioning his board for compensation on the ground that his quarterly account for extra fees, which had never been below £20 for many years, had dwindled down in the last quarter to £7. When the serious effect of such a reduction, if permanent, on the superannuation of the medical officer is considered, the reality of the grievance becomes obvious. It was thought by the council that Poor Law medical officers were quite as much entitled to compensation for losses of this nature as were vaccination officers for their loss of income through the "conscience clause" in the last Vaccination Act, and with regard to the latter compensation had been given in some instances.

Universities and Colleges.

UNIVERSITY OF OXFORD.

The following gentlemen have been appointed by the General Medical Electorate as members of the new Board of Faculty of Medicine:

Dr. A. E. Garrod, F.R.S., Dr. Cecil Wall, Mr. A. P. Dodds-Parker.

New regulations have been approved by the Board of Faculty of Medicine for the First B.M. Examination in Organic Chemistry, and will be published in the forthcoming issue of the *Examination Statutes*.

UNIVERSITY OF CAMBRIDGE.

New Psychological Laboratory.

The buildings of the new psychological laboratory at Cambridge, erected from the designs of Sir T. G. Jackson, R.A., in the English Renaissance style, were formally opened by the Vice-Chancellor on May 15th. The new laboratory is approached by the same entrance and staircase as the physiological laboratory now in course of construction. The psychological laboratory consists of three floors. On the ground floor are a lecture-room, a mechanic's workshop with a small organ bellows for blowing wind instruments needed for acoustic experiments, and a research room. On the first floor is a library, dark room, and two practical class-rooms. On the top floor are six research rooms, including a sound-proof room for auditory experiments and another which can be completely darkened. When the organization of a department of experimental psychology was begun by the appointment of Dr. Rivers, room was found for it in the physiological laboratory, but its growth compelled it to move in 1901 and again in 1903. In 1907 Dr. Rivers became lecturer in the physiology of the senses and Dr. Myers in experimental psychology, and the university thereafter offered a space on the Downing site for the construction of the new laboratory. Dr. Myers succeeded in collecting £4,000 for the building now completed, and grants have been made for its equipment and endowment from the Museum Fund and by the Cambridge University Association.

UNIVERSITY OF EDINBURGH.

UNIVERSITY COURT.

At the meeting of the University Court on May 13th, sympathetic reference was made to the death of the Right Hon. William McEwan, P.C., LL.D., which became known during the course of the sitting, and it was arranged that the chairman (Principal Sir William Turner) should represent the university at the funeral on May 15th at Bookham, in Surrey.

The Court had before it an Order of His Majesty in Council approving of the Court's Ordinance No. 14, which has to do

with the foundation of a Chair of Bacteriology (to which reference was made in this JOURNAL, vide p. 1076). Grants from the Earl of Moray Endowment for the promotion of original research, recommended by the Senatus, were approved.

Recognition, for a term of three years, was granted to Dr. John Orr, Edinburgh, as an extra-academical teacher, whose course of instruction in practical materia medica shall qualify for graduation in medicine.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The Council.

The constitution of the Council of the College is as follows:

President.

Sir Rickman J. Godlee, Bart.; C, (1) 1897, (2) 1905.

Vice-Presidents.

Mr. Clinton T. Dent (deceased); C, (1) 1903, (2) 1911.
Mr. G. H. Makins, C.B.; C, (1) 1903, (2) 1911.

Other Members of Council.

Sir Henry Morris, Bart.; C, (1) 1895 (substitute), (2) 1898, (3) 1905.
Mr. Edmund Owen; C, (1) 1897, (2) 1905.
Sir W. Watson Cheyne, Bart., C.B.; C, (1) 1897 (substitute), (2) 1901, (3) 1909.
Mr. F. Richardson Cross; C, (1) 1893, (2) 1906.
Sir A. Pearce Gould, K.C.V.O.; C, (1) 1900, (2) 1908.
Mr. R. Clement Lucas; C, (1) 1901, (2) 1909.
Mr. C. W. Mansell Moullin; C, (1) 1902 (substitute), (2) 1907.
Sir Frederic Eve; C, (1) 1904 (substitute), (2) 1907 (substitute), (3) 1912.
Sir Anthony A. Bowlby, C.M.G.; C, (1) 1904, (2) 1912.
Mr. C. H. Golding-Bird; C, 1905.
Mr. W. Harrison Cripps; C, (1) 1905 (substitute till 1908), (2) 1909.
Mr. W. Bruce Clarke (resigned); C, 1907.
Mr. Charters J. Symonds; C, 1907.
Mr. W. F. Haslam; C, 1908.
Mr. C. Barrett Lockwood; C, (1) 1908 (substitute), (2) 1910.
Mr. W. Arbutnot Lane; C, 1908.
Mr. Bilton Pollard; C, 1910.
Mr. C. A. Ballance, M.V.O.; C, 1910 (substitute for Mr. G. A. Wright till 1914).
Sir J. Bland-Sutton; C, 1910.
Mr. D'Arcy Power; C, 1912.
Sir Berkeley G. A. Moynihan; C, 1912 (substitute for Sir H. T. Butlin, 1919).

The medical schools are represented as follows:

| | | | |
|--|-----|-----|----|
| <i>London:</i> | | | |
| St. Bartholomew's ... | ... | ... | 5* |
| Guy's ... | ... | ... | 4 |
| King's College... .. | ... | ... | 1 |
| London | ... | ... | 2 |
| Middlesex | ... | ... | 3 |
| St. George's | ... | ... | 1† |
| St. Mary's | ... | ... | 1 |
| St. Thomas's | ... | ... | 2 |
| University College ... | ... | ... | 2 |
| Total, London Schools | ... | ... | 21 |
| <i>Provincial:</i> | | | |
| Birmingham | ... | ... | 1 |
| Bristol | ... | ... | 1 |
| Leeds | ... | ... | 1 |
| Making total of Council | ... | ... | 24 |
| * Including Mr. Bruce Clarke, resigned. † Mr. Clinton Dent, deceased. | | | |

On this occasion there will be four vacancies. Mr. Edmund Owen and Mr. C. H. Golding-Bird, who were elected in 1905, retire in rotation, having served the term of eight years. Sir Rickman Godlee, re-elected in the same year, does not retire, as he holds the office of President. The third vacancy is due to the death of Mr. Clinton Dent, re-elected in 1911, and the fourth to the resignation of Mr. W. Bruce Clarke, elected in 1907.

Owing to a misunderstanding it was stated last week that Surgeon-Major H. B. Hinton had been elected an Honorary Fellow. It should have been said that the Council had adopted a resolution congratulating him on attaining the hundredth anniversary of his birth.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Fellowship.

The following candidates have been admitted to the Fellowship:

F. Armstrong, C. B. Baxter, G. N. Braham, R. C. Brewster, H. A. Cookson, F. H. Diggle, K. R. MacGlashan, F. G. Raiphs, F. A. Scannell, R. L. Scott, A. D. Stewart, A. C. Thomson.

The Bathgate Prize in Materia Medica has been awarded to Mr. G. T. Mowat.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Appointments.

The following have been appointed to act on behalf of the College at examinations for the Conjoint Licence and the Diploma in Public Health: in *Anatomy*, A. C. Geddes and A. A. McConnell; in *Surgery*, C. A. Ball, G. J. Johnston, Seton Pringle, R. A. Atkinson; in *Physiology and Histology*, J. A. Scott; in *Pathology and Bacteriology*, A. H. White; in *Midwifery and Gynaecology*, F. W. Kidd; in *Biology*, J. Burgess; in *Ophthalmology*, H. Cunningham and R. D. Joyce; in *Chemistry*, S. Young; in *Sanitary Law and Vital Statistics*, M. Russell; in *Engineering and Architecture*, C. J. Powell.

The following have been appointed examiners for the Fellowship of the College and for its Licenses in Surgery and Midwifery: In *Anatomy*, A. C. Geddes and J. Keegan; in *Surgery*, O. A. Ball, L. G. Gunn, G. J. Johnston, and Seton Pringle; in *Physiology and Histology*, F. Purser and J. A. Scott; in *Pathology and Bacteriology*, R. J. Rowlette, A. H. White; in *Midwifery and Gynaecology*, F. W. Kidd; in *Chemistry and Physics*, E. Lapper and S. Young.

Mr. J. B. Story has been elected a member of the Council of the College.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—R. J. Bassett, E. J. Benson, T. F. Broderick, T. F. Corbett, E. M. T. Cymble, J. B. Cuihane, H. W. Hackett, H. I. Hawkes, D. Kelly, J. E. Lucas, J. A. McKinnon, *D. J. Steele.

SECOND COLLEGE.—H. M. Alexander, C. H. Brennan, M. Burke, W. R. Dimond, K. Elmes, B. Glasson, *H. Graham, F. Greene Kelly, M. J. Loftus, C. A. R. McCay, C. W. Robinson, J. Ryan, A. R. Soady, N. E. Stephens, P. J. Walshe.

THIRD COLLEGE.—T. M. Crouin, W. A. N. Fox, T. L. Enright, T. F. Higgins, J. D. Hamilton, W. J. A. Laird, J. S. McHugh, C. J. O'Carroll, D. V. O'Connor.

FINAL.—Miss M. J. Abern, B. N. Blood, J. Barrett, D. W. Beamish, H. J. Burke, P. D. Daly, A. J. Faulkner, F. E. Fitzmaurice, J. J. Glynn, T. J. Kelly, A. P. Kennedy, J. Kirker, V. J. Lawless, F. J. McCarthy, T. Mulcahy, C. Petit, C. L. Sproule, T. J. Sinnott, G. Wilson, W. Waugh.

D.P.H.—J. Hormasji Contractor, J. Daniel, *C. A. Farrell, M. Halpenny, Sheik G. Rasul, W. G. Ridgway, H. Roberts, *L. Robinson, *N. J. C. Rutherford, Major R.A.M.C., *P. Sampson, Captain R.A.M.C., *J. L. Thomas.

* Passed with honours.

Obituary.

COUNT RINALDO TAVERNA, Senator of the Kingdom of Italy, and President of the Italian Red Cross, who recently died, displayed great energy in organizing help for the sufferers from the earthquakes of Messina and Calabria, in the cholera epidemics of 1910, 1911, and for the wounded in the Tripoli campaign and in the war in the Balkans. His loss is greatly regretted by the medical profession.

MISS ARA GRAY MURCHISON, whose early death took place on May 10th, was a student of the Medical College for Women, Minto House, Edinburgh, during the years 1902-7; she graduated M.B., Ch.B. in Edinburgh University in 1907, and afterwards did work as an assistant in Lanarkshire; then for a time she was resident medical officer of Egilshay, Roushay, and Weir (or Viera), in the Orkney Islands; next she was assistant medical officer of health in Huddersfield and then resident medical officer to St. Luke's Hospital, Halifax. At this time, however, her health broke down and she underwent a serious operation. It was hoped that her health was restored and she returned to Edinburgh, where she was appointed clinical assistant in the Electrical Department of the Royal Infirmary, and busied herself also with research work; but her former trouble returned and after an illness of two months she passed away. She was buried in Rosebank Cemetery on May 13th.

In its May number our contemporary *Garden Cities and Town Planning* states that an International Garden Cities and Town Planning Association has been formed. For the present the offices will be at 3, Gray's Inn Place, London, W.C., and Mr. Ewart G. Culpin will act as honorary secretary. Already a number of organizations dealing with these matters have intimated their willingness to join such an international movement, and it is proposed to hold periodical conferences in the various countries represented. During the past two months over two hundred requests have been received from different parts of Europe, Asia, Africa, America, and Australasia for information on civic matters. These have in the past been dealt with by the Garden Cities and Town Planning Association, but the growth of the work both in Great Britain and abroad necessitates the promotion of the new association in order to link together the various bodies that are being formed in different parts of the world. Among the countries represented by these inquiries are the United States, France, Germany, Russia, Poland, Hungary, Austria, Roumania, Sweden, Belgium, Holland, and Spain, each of the States of Australasia and South Africa and the Canadian Provinces, India and Burma, and Trinidad.

Medical News.

THE late Mr. Jordan Lloyd, of Birmingham, left estate valued at £60,213 gross, with net personally £58,587.

PROFESSOR VON ROENTGEN, of Munich, has been elected an honorary member of the German Surgical Society.

SIR WILLIAM OSLER delivered the Silliman Lectures at Yale University recently, his subject being the Evolution of Modern Medicine.

THE Canadian Medical Association will hold its forty-sixth annual meeting in London, Ontario, on June 24th and 27th, under the presidency of Dr. H. A. McCallum.

THE sixth medical congress de la Langue Française de l'Amérique du Nord will be held at Quebec in 1914, not at Montreal this year as previously stated.

PROFESSOR BATESON's postponed lectures on the heredity of sex and some cognate problems will be delivered at the Royal Institution on Monday, June 2nd, and Wednesday, June 4th, at 3 o'clock.

AT the meeting of the Royal Society on Thursday next a paper on the action of radium rays upon the cells of Jensen's rat sarcoma by Drs. S. Russ and Helen Chambers will be read, and also a report from the Sleeping Sickness Commission on the morphology of the Mzimba strain of trypanosome.

MR. HENRY RUTHERFORD, of New York, who died in February, has bequeathed the sum of £40,000 to the Rockefeller Institute of Medical Research, the income to be applied to investigations into the causes and nature of the disease known as cancer and the methods of its prevention and treatment.

THE seventh annual meeting of the Women's Medical Society of New York State was held at Rochester on April 28th under the presidency of Dr. Helen J. C. Kuhlmann of Buffalo. About one hundred women physicians from various parts of the State attended the meeting. Dr. Marion Craig Potter of Rochester was elected president for the ensuing year.

THE Continental manager of the Great Eastern Railway will send to any one interested a copy of a little book well illustrated in colours and black and white describing the company's routes to Harwich and from it to the Hook of Holland, Antwerp, Hamburg, Esbjerg (Denmark), and Gothenburg. The route by the Hook of Holland is one of the best appointed to the Continent, and the traveller's only regret, on a fine night, must be that there is so little time to enjoy the comforts and convenience provided.

THE American Medical Association will hold its sixty-fourth annual session at Minneapolis from June 17th to 20th, under the presidency of Dr. John A. Witherspoon. The work of the meeting will be distributed among the following sections: The practice of medicine, surgery, obstetrics, gynaecology and abdominal surgery, ophthalmology, laryngology, otology and rhinology, diseases of children, pharmacology and therapeutics, pathology and physiology, stomatology, nervous and mental diseases, dermatology, preventive medicine and public health, genito-urinary diseases, hospitals and orthopaedic surgery.

AT a dinner attended by some fifty medical men of Burnley and the neighbourhood on May 10th, Dr. A. E. Bird, Honorary Secretary of the Burnley Division of the British Medical Association, was presented with a massive solid silver tea and coffee service and waiter. All the members of the Division had subscribed to the testimonial, which was presented in recognition of the arduous work of the honorary secretary during the past two years. The presentation was made by Dr. Cramp, chairman of the Division, and the service bore the following inscription:—"Presented to Dr. A. E. Bird by the members of the medical profession in the area of the Burnley Division of the British Medical Association as a mark of appreciation of his services as honorary secretary, May, 1913."

WE are asked to state that the National Medical Guild is a trade union for medical practitioners conducted on trade union lines—that is to say, its main policy is the defence of its members by all legal means. It has, as a trade union, immunity for many actions under the laws as to conspiracy and libel, and this is regarded as essential for the protection of its funds and for the success of any combined action on the part of the medical profession. The case *Heard v. Pickthorne*, which it successfully contested, has, it is held, established that it is not competent for an approved society to refuse non-panel doctors' certificates for the purpose of sickness benefit. This case was reported and commented on in the BRITISH MEDICAL

JOURNAL of May 10th, p. 1014 and p. 1033. Medical practitioners, whether on the panel or not, are eligible for election, and the subscription is one guinea per annum. Further particulars can be obtained from the Organizing Secretary, Dr. Gordon R. Ward, 34, Villiers Street, Strand, London, W.C.

IN connexion with the article on the carotid body published in the JOURNAL of May 17th, p. 1074, the following additional particulars will be of interest. In 1900 von Heinleth described the human carotid body as developing until puberty, and stated that it then either underwent atrophy or arrest of development. If it continued to grow after puberty it underwent tumour formation. In 1908 Gomez stated that it increased in size as the individual grew by increase of connective tissue, blood vessels, and parenchyma. Reaching a certain stage, between the age of 20 and 30 years, it remained stationary for a time, and then only the connective tissue increased, the interlobular blood vessels thickened, and sclerosis and atrophy of the gland resulted. Finally, in 1904 Mulon found that aqueous extracts of the carotid bodies of old horses, when injected intravenously into rabbits, gave invariably a rise of arterial pressure, and sometimes an acceleration of the heart and increased force of its beats.
