The CHAIRMAN: The legal point is a difficult one. I have no doubt there is some justification, but I am not prepared to say now what it is.

It was agreed to postpone the report and to hold a special meeting to consider the matter.

Medical Service under the Act.

The Medical Service and Medical Benefit Subcommittees reported with reference to the instruction of the Committee on April 3rd to consider whether the present system of medical benefit in London could be improved (SUPPLEMENT, April 12th, p. 317). The Medical Benefit Subcommittee recommended that all questions relating to the technical, scientific, or medical details of treatment should be remitted to a special committee consisting of the medical practitioners who were members of the Insurance Committee. These matters would then not be dealt with directly by the Medical Service Subcommittee, which contained only three medical practitioners out of its seven members.

The Medical Service Subcommittee, however, thought this suggestion open to serious objection. It pointed out that the majority of complaints were not of a purely medical or scientific character, but were, in effect, complaints that a practitioner had not given adequate attention to a patient; questions partly of a medical character were sometimes inextricably intermingled with questions of fulfilment of contract. A special committee, such as the one suggested, would have no power to take evidence—a power which the Medical Service Subcommittee possessed—and its advice would have to be given on a general statement without first hand contact with the parties. The Medical Service Subcommittee thought the proper body to perform the functions suggested would be a subcommittee of the statutory Local Medical Committee, when recognized by the Commissioners. The subcommittee, however, did not wish to stand in the way of removing some of the uneasiness members of the medical profession felt at the possibility of lay interference in professional matters, and therefore recommended:

(a) That as a purely temporary measure, and until the new Medical Service Subcommittee shall have been appointed by the new Insurance Committee and the Local Medical Committee, when recognized by the Commissioners, the Medical Service Subcommittee be empowered to consult the Special Medical Subcommittee with regard to any questions involving purely technical, scientific, or medical details of the treatment provided by a practitioner.

(b) That the Chairman of the Medical Service Subcommittee be authorized to determine which cases should be dealt with in the manner suggested in the foregoing resolution.

(c) That the Special Medical Subcommittee do consist of the medical members of the Insurance Committee and the medical members of the Medical Service Subcommittee.

Mr. O. E. WARBURG, the Chairman of the Medical Service Subcommittee, in moving these recommendations, said he hoped they would meet the objections of the medical profession. The legitimate grievance would have to be met later on by an alteration of the Regulations, but if the Committee was to keep within the Act and Regulations as at present framed, it could not go further than the Subcommittee proposed. In reply to a question, Mr. Warburg said the proposed special committee would be consultative only; generally speaking, the subcommittee would always take its advice in medical matters, but it reserved its right to make its own decisions.

Mr. E. B. TURNER remarked that unless the interests of the insured persons were to suffer it was imperative to get more practitioners on the panel. It would be possible for the Insurance Committee, by a self-denying ordinance, to remedy a grievance that was militating against acceptance of service by doctors who ought to be on the panel if the Act was to be a success. One of the principal reasons why medical men had shown reluctance to accept service was the objection to any body on which they were in a minority determining questions of purely

technical, medical, scientific interest. He was prepared, on behalf of the practitioners of London, to accept the report as an indication that the Committee was disposed to meet the objections of the profession. If the Committee took this action he believed there would be a large influx of capable men, and that the medical service in London would be proportionately improved. Medical men did not wish a professional reputation to be at the mercy of a passing wave of prejudice: the proposed Special Medical Committee would afford the Insurance Committee authentic advice, and there was no doubt that doctors who were in the wrong would be much more severely dealt with by members of their own profession than by any lay body.

Mr. F. BRIANT expressed the opinion that the Committee, by passing this proposal, would do much to lessen the difficulty with regard to the allocation of the £34,000 in respect of persons who had not chosen doctors. A considerable influx to the panel might be expected to result in a reduction of the number of these persons. Medical men were justified in objecting to giving their medical opinions in a committee with laymen, and the Insurance Committee should meet this legitimate grievance.

Other members of the Committee spoke in sympathy with the proposal, and Mr. F. COYSE, Chairman of the General Purposes Subcommittee, said he hoped the discussion would assure members of the medical profession that there was no fear of lay control of their scientific work, and that there would in consequence be a large addition to the panel.

The recommendations set out above were then unanimously agreed to, and the words "as a purely temporary measure" were by consent deleted from Recommendation (a).

Proposed Extension of Contracting Out.

Another recommendation, directed to securing the wider co-operation of the medical profession, was also reported to the Committee, but as the papers had only been in the hands of members a few hours, its consideration was adjourned until the special meeting already mentioned. The recommendation suggested the extension of "contracting out" amongst the following classes of insured persons:

1. Sons and daughters of well-to-do parents who, through being on a rising salary, would go out of insurance in a short period.

2. Bank clerks and others similarly engaged who, being in a position to make extra payment, desired to continue treatment received from the family doctor who was not on the London panel.

3. Other cases of an exceptional nature, i.e., cases where a person specially desired to make additional payments to his doctor, whether on the panel or not, or where the medical practitioner, through age or the extent of his practice, was unable to join the panel, even for a limited number.

At the same time the Medical Benefit Subcommittee which made these proposals expressed the opinion that anything like wholesale contracting-out could not be allowed in the interests of insured persons, and that all applications should be considered on their merits.

Appointment of a Medical Referee Approved.

Discussion then took place at some length on a motion by Mr. KINGSLEY WOOD in favour of the appointment of a medical referee. Mr. Wood urged that such an appointment would assist medical men on the panel who could not be expected to include in their duties the task of detecting the astute malingeringer. It would save them from the disagreeable duty of reporting their own patients for malingering. The existence of a medical referee would make unnecessary the appointment of medical inspectors. He observed in the BRITISH MEDICAL JOURNAL that medical men in Gateshead and in Lancashire and Cheshire had put forward the same suggestion. The appointment of a medical referee would also help the approved societies which in some cases found themselves faced with claims by women to the extent of 50 per cent. beyond anticipations, and in the case of men 25 per cent. Malingering to the extent of 1 per cent. meant a very large sum weekly to the approved societies of the country.

The motion in favour of the appointment was carried by a large majority.

The Number of Patients on Lists.

Mr. P. ROCKLIFF then moved:

That it is undesirable that any medical man on the London panel should undertake to treat a larger number of insured persons than 2,000; and that the clerk of the committee do inform the doctors on the panel accordingly.

Mr. Rockliff urged that it was no use trying to induce more medical practitioners to join the panel if there were not sufficient patients available. Arguing from the fact that 30,000 prescriptions were received every day at the offices of the Committee, Mr. Rockliff made an elaborate calculation as to the number of minutes given to each patient by a doctor, and urged that 2,000 was the maximum number that should be allotted to each doctor. A large number of people who selected from the first 760 doctors to join the London panel would probably like to have a second choice now that the number was larger.

Dr. LAURISTON SHAW mentioned that the Medical Benefit Subcommittee had decided to indicate to all doctors with more than 2,000 on their lists that it viewed with some apprehension the effect upon the insurance scheme, and reminding the doctors that the Committee's duty was to see that proper attendance was given. Such a warning would doubtless prevent medical men from accepting an unduly large number of persons. He believed it was premature for the Committee to fix a limit; it had not yet sufficient knowledge of the conditions. Even if the Committee could decide what was the proper number of persons, it would be going against the whole spirit of the Act by interfering with the free choice of doctor. If the matter were left to work itself out, insured persons would be able to get the attendance they wished by exercising their right to free choice of doctor.

Dr. EVAN JONES supported the motion. He thought the evidence showed that 2,000 was a sufficient number of patients for each doctor.

Sir SHIRLEY MURPHY thought it was premature to limit the number of persons on each list. The present difficulty would be solved by the addition of a large number of men to the panel.

Dr. H. H. MILLS hoped the motion would not be pressed, and remarked that it would be an advantage in this matter if a new choice of doctor could be exercised at the end of six months, instead of twelve.

The CHAIRMAN: We have no power to deal with that.

Dr. MILLS: Have we power to limit the list?

The CHAIRMAN: It will only be an opinion on the part of the Committee, if carried.

The resolution was approved by 13 votes to 7.

A Complaint and a Warning.

It was resolved to inform a doctor as to whom a complaint had been received, and who had accepted about 3,650 persons up to April 5th and a further 150 up to April 14th, that if the list was materially increased after May 22nd it might be necessary for the Insurance Committee to consider whether such a number on his panel would not be prejudicial to the efficiency of the medical service of insured persons.

INSURANCE NOTES.

THE DIFFICULTY IN WALES.

No date has been fixed at present for the reception of the deputation of Welsh medical men which, we understand, is to be introduced by Dr. Addison. There appears, however, to be a sincere desire on the part of the Commissioners and other parties interested to arrive at an amicable settlement, and we are encouraged to hope that a method of adjustment will be found which will be acceptable to both parties.

THE POSITION IN GILLINGHAM.

The position here is still full of interest. The refusal to accept certificates from practitioners not on the panel was very persistently maintained by some members of the committee, but within a day or two of the decision in *Heard v. Pickthorne* the town was red with large posters announcing the verdict, and every possible means was taken to disseminate the information. The thanks of all are undoubtedly due to the National Medical Guild for so pluckily seeing this matter through. Interest is chiefly

centred in the attempt of the committee, backed by the Commissioners, to coerce the panel doctors into treating dependants at fees considerably lower than those usually charged in the town. This at present is a local matter, but it will be well for those who are disposed to think that Gillingham is making a fuss about nothing to remember that if it succeeds there the system will spread very rapidly to the whole of the county. This is in reality a *ballon d'essai*, and members of the profession who trust the Commissioners' statement that it is not going to become general will probably find that they are leaning on a bruised reed. It is to be hoped that the doctors who have joined the panel will refuse to be used as tools to help the lay committee to crush out of existence those who do not feel disposed to do so. The long-talked-of allotment of insured persons has not yet taken place; some members of the committee recognize that it is a dangerous game, even in England, to coerce thousands of people to go to doctors to whom they will not go voluntarily.

DISTRIBUTION OF ACCUMULATED FUNDS.

In response to a proposal by the Northampton Insurance Committee to distribute the money accumulated in respect of insured persons who have not chosen a doctor in equal shares amongst the doctors on the panel, the Insurance Commissioners have stated that this suggestion could not be carried out and that advances should be made to doctors only on the basis of the number of insured persons accepted for treatment.

REPORTS OF LOCAL ACTION.

CROYDON.

A MEETING of doctors upon the panel for the County Borough of Croydon was held at the Croydon Hospital on May 23rd, Dr. WILLOCK being in the chair and twenty members present.

Temporary Residents.—The following resolution was adopted and a copy directed to be sent to the National Health Insurance Commission (England):

That this meeting of doctors upon the panel for the Borough of Croydon strongly protests against any deduction as foreshadowed in Memorandum 159/L.C., and suggests:

(a) That concerning that class of insured persons temporarily changing their residence for holiday or health purposes the regulations be so amended as to provide that medical benefit shall not be understood to include medical attendance and treatment in such class while so temporarily resident; and

(b) That insured persons temporarily resident by reason of the nature of their occupation should be required to make their own arrangements.

Representatives on the Insurance Committee.—Drs. Willock and Wayte were appointed by the panel, Dr. Redfern by the Commissioners, and Dr. F. Nicholls by the Corporation of Croydon.

Vouchers for Medical Attendance.—It was reported that so far the Commissioners had refused to supply a voucher for each insured person to send to his doctor when requesting medical attendance, but the matter was still under the consideration of the Croydon Insurance Committee, and Dr. Nicholls had pointed out to the Commissioners that the regulations (Section 17, subsection 3) entitled the doctors to demand one.

Payments to Medical Practitioners.—The monthly amounts paid to the medical practitioners on the panel were printed in the reports of the Insurance Committee, but not published in the press.

Copies of Prescriptions.—Instead of allowing the proposed fee of 1d. to chemists for copying each prescription, the book has been so modified that a duplicate prescription can be given by the doctor.

Transfer of Patients.—It was reported that in the form for the transfer of insured persons from one doctor to another the Croydon Insurance Committee did not ask the reason for the desired change.

Certificate for Sickness Benefit in Maternity Cases attended by Midwives.—Attention was drawn to the fact that, to give a certificate for sickness benefit in respect of cases attended by a midwife, a doctor would have to attend an insured person at least once, while Section 8 (6) of the Insurance Act provided that medical benefit shall

not include any right to medical treatment or attendance in respect of a confinement.

Allocation of Insured Persons.—It was stated that the Local Medical Committee had arranged a method for the assignment of all insured persons who had not chosen their doctor, but the necessary tickets, which should be supplied by the Croydon Insurance Committee, were still in "the dim and distant future."

SCOTLAND.

Edinburgh Royal Maternity Hospital and Maternity Benefit.

From the minutes of the Administration Subcommittee of the Burgh of Edinburgh Insurance Committee it appears that on April 30th a deputation from the directors of the hospital was received. The deputation included Mr. J. R. Middleton (Chairman of the Maternity Hospital Board), Mr. McLeod Gardiner, Dr. T. G. Nasmyth, and Councillor Buchan. It was emphasized by the deputies that the hospital should receive all possible support from the approved societies and the Insurance Committee, and it was stated that the hospital authorities, for their part, were prepared to give treatment to women entitled to maternity benefit in respect of their own or their husband's insurance, on such terms as might be arranged between each approved society and Insurance Committee and the directors. The draft proposed agreement was then considered and a clause was adjusted providing for the payment to the hospital out of the maternity benefit due to any member of an approved society or deposit contributor to whom or to whose wife or widow the hospital has given its services at her confinement of the sum of 15s., or such other less sum as represents 50 per cent. of the maternity benefit available in the particular case.

Mr. Leishman's Presence at Meetings of the Medical Benefit Subcommittee.

At the meeting of the Burgh of Edinburgh Insurance Committee on May 22nd some discussion arose as to the presence of Mr. Leishman, the Chairman of the Scottish Commissioners, at meetings of the Medical Benefit Subcommittee. The minutes of the subcommittee showed that Mr. Leishman had been present and had spoken in support of a letter from the Commissioners asking the Committee to reconsider their decision regarding the Post Office system. Mr. Andrew Eunson moved disapproval of the recommendation from the subcommittee that the Insurance Committee approve the Post Office medical system under Section 15 (4) of the Act, and complained of Mr. Leishman's attendance at the subcommittee, regarding it as an infringement of the position of the Insurance Committee. The subcommittee, he thought, should be censured for allowing Mr. Leishman to be present. Baillie Rusk said that he did not wish to overturn the minute, but he would support the objection to Mr. Leishman's presence without invitation. He suggested that a rule should be made providing that neither Mr. Leishman nor any other official be allowed to attend the meetings without request. He did not agree that Mr. Leishman's presence would influence the voting, but he thought it detracted from the dignity and responsibility which the Committee should possess. This position was generally agreed to. After further discussion, the Subcommittee's recommendation to approve the Post Office system was rejected by 25 votes to 16. Since the meeting a letter has been received from the Commissioners explaining the Chairman's action and throwing light upon the proceedings.

Medical Certificates.

Several letters have been appearing in the *Scotsman* lately regarding the violation of professional secrecy in the statement of the nature of a patient's illness in the medical certificate required for the approved societies under the Insurance Act. "M.D.," for instance, calls upon medical men to stand firm in their refusal to give such information until, at any rate, the matter has been brought before the Branch meetings of the British Medical Association.

Edinburgh Students and Vacation Employment.

Recently a representation was made to the Scottish Insurance Commissioners on behalf of large numbers of students at the training colleges, and also at Edinburgh

University, who accept employment in the Post Office during the summer and other vacations. It was pointed out that the students during the time they were employed, often one or two months, had to pay the weekly contributions under the Act. These were deducted from the wage, which was usually £1 weekly to such workers. The students considered it a hardship to have to pay the contributions when it was certain that they would not at any time later come within the scope of the Insurance Act, especially as the vacation employment was undertaken to assist the payment of class fees, or the cost of their maintenance during the periods of study. On these grounds, and also on the ground that they were being employed in a civil service department, they considered they had made a case for exemption.

The Scottish Insurance Commissioners have replied that the students will be compulsorily insurable while and so long as they are employed in this capacity. Exemption can only be claimed if they prove that they are in receipt of any pension or income of the annual value of £25 or upwards not dependent upon their personal exertions, or that they are ordinarily and mainly dependent for their livelihood upon some other person.

IRELAND.

Medical Certificates.

A conference of representatives of the friendly societies and the County Insurance Committee for North Tipperary, to which delegates from the County Medical Committee were invited, was held recently in Nenagh to discuss the question of medical certification. The doctors laid their views before the meeting, and after full discussion a resolution was passed unanimously to the effect that the sum of £50,000 for certification in Ireland was altogether inadequate, and impressing on the National Health Commission that this sum should be largely increased.

The difficulty of obtaining the consent of the medical profession to form panels for purposes of certification for the various counties in Ireland continues to be a problem which the Irish Commissioners have so far failed to solve. As was mentioned last week, they are trying an experiment in the city of Limerick by advertising for salaried medical officers to carry on the work of certification. The rate of remuneration offered is £130 per annum, with permission to engage in private practice. This is done with the object of forcing the medical profession to submit rather than suffer imported doctors to rob them of their practice. However, it is highly improbable Limerick will give in, seeing that the profession in the city is well organized and thoroughly determined. It is extremely unlikely that any Irish medical men will be found willing to take the positions, for they know the position in which medical men who set themselves in opposition to the wishes of the profession in other cities in the South of Ireland have found themselves.

Objection to Extension of Medical Benefit.

At the last meeting of the Athlone Board of Guardians the proposed extension of medical benefits was unanimously objected to on the ground that it would mean double expense while the Poor Law medical dispensary service continued, without any corresponding advantage to the insured persons or ratepayers. A vigorous protest was entered against the reception of insured persons for hospital treatment, for whom the societies would not pay.

Tuberculosis.

The Clare County Council last week elected Dr. Michael Garry, well known as an Irish international footballer, to be tuberculosis officer. The salary was fixed at £350 with travelling allowances.

The Mayo County Council has elected Dr. P. F. Murphy, Kiltinagh, as tuberculosis officer for the county.

The Meath County Council has decided to adopt the recommendation of the Finance Committee on the tuberculosis scheme. The Committee in view of the indisposition of several Government departments and public bodies concerned to meet its views, and having regard to the uncertainty of the income and expenditure under any scheme proposed, recommended the council to postpone indefinitely the framing of a scheme dealing with tuberculosis treatment.

A curious situation has arisen in connexion with the working of Peamount Sanatorium. Less than a fortnight ago Dr. J. J. McGrath, of Limerick, was elected resident medical superintendent, and immediately afterwards a letter was received from the Local Government Board expressing surprise at the action of the committee, and refusing its sanction to the appointment. In consequence the committee met again and set aside its previous decision, and an order was made to readvertise the position. It is said that representatives of the contributing county councils supported the candidature of Dr. McGrath. The objection of the Local Government Board to Dr. McGrath's appointment is said to be based on the certificate he holds from the Allan Ryan Home and Collier Dispensary, which, however, was recognized by the Board last winter.

THE INSURANCE SCHEME.

STATE SICKNESS INSURANCE COMMITTEE.

A MEETING of the State Sickness Insurance Committee appointed by the Special Representative Meeting in November, 1912, was held at the house of the Association, 429, Strand, W.C., on Thursday, May 22nd. Dr. J. A. MACDONALD (Chairman) was in the chair, and the members present were:—*England and Wales:* Dr. R. M. Beaton (London), Mr. C. E. S. Flemming (Bradford-on-Avon), Dr. E. R. Fothergill (Brighton), Miss M. Frances Ivens, M.S. (Liverpool), Dr. Constance E. Long (London), Dr. E. O. Price (Bangor), Dr. D. G. Thomson (Norwich), Mr. E. B. Turner (London). *Scotland:* Dr. John Adams (Glasgow), Dr. R. McKenzie Johnston (Edinburgh). *Ex officio:* Mr. T. Jenner Verrall, Chairman of Representative Meetings.

AGED AND INFIRM MEMBERS OF FRIENDLY SOCIETIES.

The action of approved societies, in contravention of the agreement come to between the Association and the societies at the conference in October, 1911, with regard to the provision of medical attendance for aged and infirm members, was further considered, and the Committee decided that the Association should adhere to the opinion already expressed in respect to this matter,¹ and to continue its present policy of urging Divisions and Local Medical Committees to insist upon the carrying out of the provisions of Section 15 (2) (e) of the Act, which is as follows:

(e) The provision of medical attendance and treatment on the same terms as to remuneration as those arranged with respect to insured persons, to members of any friendly society which, or a separate section of which, becomes an approved society who were such members at the date of the passing of this Act, and who are not entitled to medical benefit under this part of this Act by reason either that they are of the age of 65 or upwards at the date of the commencement of this Act, or that being subject to permanent disablement at that date, they are not qualified to become insured persons.

AMENDMENTS OF THE ACT.

A report, with recommendations from the Amendments Subcommittee, was considered in detail. The State Sickness Insurance Committee, in accordance with the duty imposed upon it by the Council, decided to press for amendments of the Act or Regulations in the following respects:

Anaesthetics.

That a practitioner who finds it necessary in connexion with the medical attendance and treatment of any of the insured persons on his list, to obtain the services of another medical practitioner, should not be compelled himself to provide such services.

Income Limit.

1. That all persons whose income from all sources exceeds the sum of £160 per annum shall be required to "make their own arrangements," and that the amendment be so worded as to make it clear the words "income from all sources" includes any income received as a gift or allowance, and independent of the personal exertions of the recipient.

¹ The correspondence between the Association and Mr. Masterman, M.P., Chairman of the National Insurance Joint Committee, will be found in the issues of the SUPPLEMENT for March 6th (p. 236), March 22nd (p. 266), March 29th (p. 285).

2. That it shall be incumbent upon the Insurance Commissioners to require Insurance Committees to adopt a local income limit.

3. To ensure that any local income limit adopted by an Insurance Committee shall be submitted for the approval of the Commissioners in the same manner as various other arrangements of committees in respect of medical benefit are submitted.

Deputies.

Attention was called to the paragraph (91k) of the annual report of the Council, in which it was stated that the Council intended to recommend the Annual Representative Meeting to request the Insurance Commissioners to advise Insurance Committees that their work would be greatly facilitated by the appointment of deputies for the directly elected medical practitioners on Insurance Committees. It was reported that the Scottish Insurance Commissioners had issued a considered opinion to the effect that it would not be competent for a deputy to attend meetings of Insurance Committees on behalf of any member thereon, inasmuch as appointment to the Committee was personal. The Committee, after consideration, advised the Council to recommend the Representative Body not at the present time to seek an amendment of the Act or Regulations allowing the appointment of deputies for the directly elected practitioners on Insurance Committees.

Practitioners' Contracts with Insurance Committees.

In paragraph 92 of the annual report of the Council, which dealt with the question as to improvements of local administration of the Act, it was recommended that the form of contract between medical practitioners and Insurance Committees should be referred to the Local Medical Committees for consideration before being sent for signature to the practitioners concerned. The object of this recommendation was that the Local Medical Committees concerned should be afforded an opportunity of perusing the draft agreements with practitioners framed by the Insurance Committees after consultation with the Local Medical Committee as provided in Regulation 7 (1). The State Sickness Insurance Committee has decided to press for the addition to Regulation 7 (1) of the following or some similar form of words to secure the above object:

and shall before submitting such draft agreements for the approval of the Insurance Commissioners forward copies thereof to the Local Medical Committee and allow that body reasonable time for consideration.

The same subparagraph in the report of the Council recommended that the contracts after signature should be returned to the Local Medical Committee. On consideration of this suggestion it was decided that amendment of the Act or Regulations in this connexion was not required, and that the object could best be secured by local arrangements between Insurance Committees and Local Medical Committees.

Medical Representation on Insurance Committee.

The State Sickness Insurance Committee expressed the opinion that the Act should be so amended as to secure that no one section of the members of an Insurance Committee shall constitute more than two-fifths of the total number of the Committee, and instructed the Amendments Subcommittee to draft the necessary amendments.

With regard to the constitution of District Committees, it was resolved that the Association should press for the addition to Regulation 59, which authorizes Insurance Committees to delegate powers or duties to District Committees, of a proviso to provide for the due representation of the medical profession in the following or similar words:

Provided that as regards such District Insurance Committees the medical representation thereon shall be the same proportion as is accorded the medical profession on the Insurance Committees.

Night Calls.

The Committee resolved to press for an amendment of the Act enabling practitioners to make a small charge to insured persons in respect of night calls, such a charge being preferable, as a deterrent, to any system of fines.

Diseases due to Misconduct.

The Committee also resolved to press for the deletion of the word "not" in the Section 15 (4) of the Act, as follows:

(4) Where, under any such rules as aforesaid, payment of sickness or disablement benefit is suspended on the ground that the disease or disablement has been caused by the misconduct of the person claiming the benefit, such person shall *not* thereby become disentitled to medical benefit.

Miscarriages and Abortions.

The Committee resolved to press for the amendment of the Act by the addition to Section 8 (6) of the words printed in italics below:

Section 8 (6). Medical benefit shall not include any right to medical treatment or attendance in respect of a confinement, *miscarriage, or abortion, or any condition arising therefrom within twenty-eight days.*

Medical Referees.

The Committee expressed the opinion that under the terms of Section 57 (3) of the Act regulating the appointment of officers, inspectors, referees, and servants by the Insurance Commissioners the Commissioners had power to appoint medical referees should they decide so to do. The Committee therefore resolved to press for the embodiment of the following paragraphs in the regulations to be made by the Insurance Commissioners governing Local Medical Committees:

(a) Provisions whereby Local Medical Committees shall be consulted in those instances where the Commissioners decide to appoint medical referees, as to whether such officers shall be whole or part-time officers.

(b) Power to such Committees to make nominations for such appointments.

(c) Provision whereby, in those instances where the Commissioners decide to appoint a medical referee for a district containing more than one insurance area the various Local Medical Committees concerned shall combine and submit their joint nominations.

It was further resolved that the Association should seek for the inclusion in any regulation or order of the Commissioners concerning the appointment of medical referees of words to secure that such officer shall (a) be removable by the authority by which he was appointed with the consent of the Insurance Joint Committee and not otherwise, and (b) shall not be appointed for a limited period only.

Seamen's National Insurance Society.

The administration of the Seamen's National Insurance Society, which had on several previous occasions been discussed by the Committee, was further considered, and it was decided that it was desirable that Section 48 (5) of the Act should be amended by the insertion of the words printed in italics:

(5) The affairs of the Seamen's National Insurance Society shall be managed by a committee constituted in accordance with a scheme to be prepared by the Board of Trade with the approval of the Insurance Commissioners, comprising representatives of the Board of Trade, of shipowners, and of members of the Society in equal proportion, *and of representatives of the medical profession of the United Kingdom in the same proportion as is accorded the medical profession on Insurance Committees,* and the Society shall, notwithstanding anything in this part of this Act, become an approved society.

Maternity Fees.

The matter of fees to medical practitioners for attendance upon confinements in respect of which maternity benefit is received—a subject to which paragraph 127 of the annual report of Council was directed—was further considered in connexion with the report of the Midwives Subcommittee. It was resolved to transmit the opinion of the Council to the Insurance Commissioners.

Temporary Residents.

Upon this subject the Committee adopted the following resolution:

That the Association press for the amendment of the Act so as to provide—

1. That "medical benefit" shall not be understood to include medical attendance and treatment on insured

persons temporarily changing their residence for holiday or health purposes while so temporarily resident.

2. For the formation of a special fund entirely apart from any moneys already allocated for medical benefit to provide for the medical attendance and treatment of insured persons temporarily resident on account of ill-health.

Dispensing.

With reference to Regulation 30 (1), dealing with the arrangement for the supply by practitioners of drugs and appliances, and limiting its application to insured persons resident in a rural area at a distance of more than one mile from the place of business of a chemist on the list, the Committee, in view of the difficulties which have arisen as to the definition of the term "rural area," resolved to press for the deletion of the words "in a rural area," or for such other amendment of that regulation as would secure to medical practitioners the right, if they so elect, to dispense medicine for insured persons on their list in all cases in which the patient is more than a mile from a chemist on the list.

TERMINATION OF AGREEMENTS.

It was resolved to recommend that Regulation 21 should be amended by the inclusion of words to secure to a medical practitioner the right to terminate his agreement with an Insurance Committee by giving three months' notice at any time.

CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL COMMITTEES.

The Committee received with thanks the offer of the Executive Committee of the annual meeting at Brighton to arrange a conference of representatives of Local Medical Committees and to meet incidental expenses. The State Sickness Insurance Committee undertook to prepare a suitable agenda for such a conference, which it is provisionally proposed should take place at 3 p.m. on Tuesday, July 22nd.

INSURANCE JOINT ADVISORY COMMITTEE.

A letter was read from the Insurance Joint Committee acknowledging the Association's nomination of Dr. Cox for the vacancy on the Joint Advisory Committee, and stating that Dr. Cox had been appointed.

COMPENSATION CASES.

Three applications for compensation were considered; in one instance a grant was made, and in two others it was resolved to obtain further information. A letter of thanks from a recipient of a grant from the fund was read.

Drafting and Presentation of Amendments.

The Amendments Subcommittee was instructed to draft, with legal assistance, amendments to the Act and Regulations to carry out the above recommendations after taking into consideration the terms of the amending Act which the Government had undertaken shortly to introduce.

The Committee also resolved to forward to the Insurance Commissioners a memorandum on the amendments desired, together with an intimation that the Committee was prepared to appoint a deputation to discuss such amendments with the Commissioners prior to the introduction into Parliament of the proposed amending bill. The Chairman of the Committee, Dr. J. A. Macdonald, the Chairman of Representative Meetings, Mr. T. Jenner Verrall, Mr. E. B. Turner, Deputy Chairman of Representative Meetings, and Mr. C. E. S. Flemming, were nominated as members of any such deputation.

THE DRUG TARIFF.

The following communication has been addressed to the London Insurance Committee:

Gentlemen,

The duty of investigating the proposed charges of the Pharmaceutical Committee's new tariff of drugs, etc., has been delegated to us by the executive of the London Medical Panel Committee. In an interview with the Pharmacists' Committee we were informed that, taking an average wholesale drug house price list, 25 per cent. (twenty-five per cent.) was added to the charges on that list in arriving at the charges made in the official tariff. (Wholesale houses, it may be mentioned, are in the habit of allowing a considerable discount off their list prices.)

Practically in every instance the full 25 per cent. has been added for the tariff charges, but in a large number of instances this is greatly exceeded—a list of some of these excessive charges we append.

We note that the charge of 6s. 9d. is still adhered to as the price of an icebag for the head, whereas we have before pointed out that the article supplied is not the helmet-shaped ice cap which would allow of that price being charged, but the ordinary round icebag costing from 1s. 8d. to 3s. 9d.

The bandages are inferior, with frayed edges, and are of the cheapest possible quality.

All antiseptic dressings should be supplied in 1 oz., 2 oz., and 4 oz. sealed packages, as otherwise the word antiseptic is a misnomer, and a possible danger. Instances have come to our notice where antiseptic dressings have been cut off with shop scissors and wrapped up in ordinary paper.

We think that a charge of 4d. for dispensing a blister is exorbitant.

No charge for copying prescriptions should be allowed.

Many instances have come to our notice of discontent with the Act caused by chemists declining to dispense after 9 or 10 at night for patients who have just received their prescriptions. We think all chemists should dispense prescriptions if received by them up to 10 p.m., and should not tell patients they must wait until the next day.

Many medical men are in doubt as to whether they can order such necessary appliances as glass ear-syringes, camel-hair brushes, and eye-droppers. Some definite information as to the ordering of "extras" would be welcome.

Yours faithfully,

C. W. HOGARTH.
C. H. PRING.
M. BERNSTEIN.

As regards the prices given by us, we have taken for comparison the lists of Messrs. Evans, Lescher, and Webb, Limited, and the Hospital General Contracts Company as representative of the wholesale trades concerned.

| | Price. | Price Should Be. | Tariff. |
|----------------------------------|-----------------------------|------------------|------------------|
| Liq. gutta percha | s. d. 0 4 + 25% | s. d. 0 5 | s. d. 0 7 |

PAYMENT FOR MEDICAL BENEFIT.

RESULTS IN THE FIRST QUARTER.

We have been afforded an opportunity of inspecting the results of an investigation into the amount of medical work under the Insurance Act during the first quarter in an English district, partly rural and partly urban. The number of practitioners applied to were 100, of whom 40 replied, but the answers of only 32 were available for statistical purposes. The result of the analysis of the replies showed that the number of insured persons in the district was 20,161, and that the percentage of such persons under treatment each month varied from 5 to 15 per cent. Two practitioners reported under 5 per cent., five practitioners reported under 10 per cent., eighteen reported under 15 per cent., and five reported over 15 per cent. The total number of visits was 8,466, and the total number of consultations 15,677. The cases included 5 fractures, 76 operations, 26 cases in which a general anaesthetic was administered, 76 special visits, and 13 night visits. Sixteen practitioners stated that their private practice was diminished, eight that it was not affected, ten that the rate of remuneration would balance the loss, and three that it would not; the others were uncertain.

It appears, therefore, that as a rule from 10 to 15 per cent. of the insured persons were under treatment every month. This statement may be compared with those which have appeared in the daily press to the effect that the percentage was under 2. Taking the remuneration to be at the rate of 7s. a person per annum—namely, 6s. 6d. for medical attendance and 6d. for domiciliary treatment of tuberculosis—and comparing it with the ascertained number of visits and consultations, the rate of remuneration works out at 1s. 5d. an attendance. As in this district each medical man on the panel will have added to the capitation amount to which he is entitled, an amount for unallotted persons estimated at about 20 per cent., the rate for each attendance works out at 1s. 8d. This of course takes no account of medicine, nor is any allowance made for mileage, operations, etc.

The following comparison has been made with private practice at low fees:

| | | | |
|--------------------------------------|-----|-----|--------|
| INSURANCE WORK: | | | |
| 20,160 persons at 1s. 9d. each... | ... | ... | £1,764 |
| Add one-fifth for unallotted persons | ... | ... | 353 |
| | | | £2,117 |
| PRIVATE PRACTICE: | | | |
| 8,466 visits at 2s. 6d. ... | ... | ... | £1,058 |
| 15,677 consultations at 1s. 6d. ... | ... | ... | 1,175 |
| | | | £2,233 |

CORRESPONDENCE.

MEDICAL CERTIFICATES FOR SICKNESS BENEFIT.

DR. EDWARD A. CLARKE (Secretary, Dukinfield Local Medical Committee) writes: The following dictum is laid down in the annual report of the London and Counties Medical Protection Society for 1912:

"Medical certificates are so frequently required for one purpose or another that there is a danger of their being too readily given by medical men. Too great care cannot be exercised in giving medical certificates if they are to retain the consideration which is usually accorded to them. In no circumstances should a doctor sign a certificate containing any important statement which he knows merely from hearsay. In giving certificates of sickness medical men should not state the nature of the disease without the express permission of the patient or his legal representative. Accurate counterfoils or other records of all certificates should be kept. In the body of the certificate the use to which it is intended to be put should be stated, and so misuse of it may be prevented."

To-day under the Insurance Act medical men from north to south, from east to west, are expected to fill in and distribute broadcast these certificates, stating the nature of the illness from which the patient is suffering; and to stand up against this as futile as trying to knock down a stone wall by kicking.

Dr. Shaw's statement published in the SUPPLEMENT of May 24th, page 458, is a most excellent exposition of the whole matter.

The Cheshire County Medical Committee has fought the matter until the last moment, and the only reply we have is that under paragraph 7 of our agreements we are bound to give any certificate required by the rules of the society to which the patient belongs. At a meeting of the Cheshire Insurance Committee it was stated that the certificates were for statistical purposes, and also that the society officials were going to judge by the nature of the illness how long the patients were likely to be off sick, and, again, they were to be used for the purpose of preventing malingering.

How these purposes are going to be served I am unable to see, unless the societies at the same time insist that upon the certificates an accurate diagnosis is to be placed, and such general terms as "debility," "anaemia," "influenza," etc., are to be banned. Then, again, are the societies going to stand in judgement over the doctor's certificates, and say who is or who is not to have sick pay? A married woman suffering from endometritis may be greatly benefited by a week or two's rest from the factory and able to do a little housework in the afternoon. The collector calls in the afternoon and finds her blackleading the grate, and before sick pay can be obtained a long discussion into her ailments will have to follow.

There is no doubt that endless friction is going to arise from this question of medical certification. The whole question of malingering hangs upon it. The matter is of such grave import to my mind that I think the Council of the British Medical Association should give the matter careful study, and, if such a thing were possible, give the medical profession a lead as to what they should do in the matter of certificates.

In this town we have not stated the nature of illness upon our certificates since January 15th last, but owing to the pressure brought to bear upon the patients by the friendly societies withholding sick pay, and so punishing the patients, it behoves us in the cause of humanity to comply for the present with these demands. We do so under protest, and at the same time asking the British Medical Association to consider the matter carefully, and if possible to give a lead.

TEMPORARY RESIDENTS.

DR. T. CUMING ASKIN (Woodbridge, Suffolk) writes: The State Sickness Insurance Committee have given a lead—a belated one, I admit—in the case of temporary residents (vide SUPPLEMENT, May 17th, page 452). Are we going to follow their advice and refuse to attend these persons except as private patients—that is, refuse to sign the green vouchers? I hope so, because then the Government will be compelled to provide a special fund. If we do not we shall richly deserve all that is in store for us, and shall have nobody to blame but ourselves. Let us try to turn over a new leaf before it is too late. A wave of pessimism seems to be passing over the profession, and it is not to be wondered at, but I believe that even now we can do much if we only take heart and assert ourselves. One thing, however, is quite certain: the Local Medical Committees will soon become a laughing-stock and will lose all their power for good unless backed up by the profession generally.

As far as Memorandums 159 and 161 are concerned, we have a strong and unanswerable case. The fee of 8s. 6d. paid to the medical officers of the Post Office for "picked lives" and for a limited period is not tampered with, special provision being made for dealing with itinerants. Let us see to it that our capitation payment for all sorts and conditions of men is treated with equal respect.

In the Seamen's National Insurance Society the doctors are to be paid *in full* for work done and some provision is made for mileage, but none in the scale attached to Memorandum 161. Let us refuse to have anything to do with a credit scale of fees. It is not business.

"A FREE CHOICE!"

DR. J. J. GORHAM (London, S.W.) writes: I have been unable to read your leader (p. 1126) until to-night (Monday), and it almost takes my breath away. Who told you that insured persons are "placed on the level of a duker" in having a "free choice of doctor"? What a comforting placebo we get from our journal after the scandalous treatment that thousands of us have received at the hands of Insurance Committees!

Take my own case: For many years I have acted, and am acting still, as honorary medical attendant to a home for boys. There happen to be six people on the premises who come under the Insurance Act, and they naturally chose me as their doctor, on the grounds that I have always attended them, and that as I am frequently on the spot several times a week they would have ample facilities for consulting me. A long correspondence ensued between the home and the Committee, and the upshot was that as I refused to go on the panel, and my patients would have no other doctor, the Insurance Committee graciously consented that I should attend the six insured persons at the home and my certificates would be recognized, but that I must not look to them (the Committee) for any claims for attendance. And now the weekly contributions of my patients, which have been regularly paid hitherto, are being graciously handed over to some panel doctor whom they have never even seen. And really, Sir, when you tell us you have "convinced the Chancellor of the Exchequer" on a previous occasion, you might try to convince him again that it is discreditable for a statesman to break a promise which he made deliberately on this very question of a "free choice of doctor."

ATTENDANCES OF COUNCIL, COMMITTEES, AND SUBCOMMITTEES FOR 1912-13.

The President, Chairman of Representative Meetings, Chairman of Council, and Treasurer are *ex officio* members of all Committees.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A list of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian, at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

Meetings of Branches and Divisions.

DORSET AND WEST HANTS BRANCH.

THE annual meeting of this Branch was held at Bournemouth on May 21st. The President, Mr. F. WINSON RAMSAY, was in the chair, and thirty-six members were present.

Annual Report and Financial Statement.—The TREASURER presented the financial statement for 1912, showing a balance in hand of £10 2s. 6d. The annual reports of the Branch and Divisions were read and received.

Congratulations to Dr. J. Roberts Thomson.—The PRESIDENT proposed that the congratulations of the Branch be sent to Dr. J. Roberts Thomson, who had that day received the honorary freedom of the Borough of Bournemouth. The vote was carried with acclamation.

Induction of the President.—The PRESIDENT introduced his successor, Dr. H. G. LYS, who took the chair and thanked Mr. Ramsay and the Branch.

Summer Meeting.—It was decided to hold the summer meeting at Wareham or Swanage.

Presidential Address.—The President, Dr. LYS, then gave the presidential address. Mr. CHARLES J. MARSH proposed and Mr. RAMSAY seconded a hearty vote of thanks to the President for his address, and for his kindness in entertaining members to luncheon at his house before the meeting and inviting them to tea at its close.

New Members.—The PRESIDENT announced that Dr. T. Martland and Dr. H. H. Woods had been elected members of the Association.

GLASGOW AND WEST OF SCOTLAND BRANCH.

THE annual general meeting of this Branch took place in Glasgow on May 13th. Dr. W. SEMPLE YOUNG, the retiring President, being in the chair.

Adoption of Reports.—The reports of the Honorary Secretary and the Honorary Treasurer were adopted on the proposal of Dr. W. G. MACPIERSON (Bothwell). That of the Honorary Secretary stated that 139 new members had been added to the membership roll during the year, and that the net membership on December 31st, 1912, was 864, as compared with 781 on the same date in the preceding year. At meetings of the Branch and its Council the time had been occupied almost solely by consideration of the Insurance Act as it affected members of the Association and the profession in general. Much serious work remained to be done, and the profession would still best be served by the united action of the Association.

Dr. JOHN ADAMS, Representative of the Branch on the Central Council of the Association, reported in regard to various subjects under consideration of the Council at the present time.

Election of Officers.—The following officers were elected:

President.—Dr. A. T. Campbell.

President-elect.—Dr. John Goff.

Vice-Presidents.—Dr. W. L. Muir and Dr. William Semple Young.

Honorary Secretary.—Dr. William Bryce.

Honorary Treasurer.—Dr. William Caskie.

Before vacating the chair the retiring president, Dr. W. S. YOUNG, thanked the Branch for the confidence placed in him during a trying and arduous year.

Vote of Thanks.—On the motion of Dr. JOHN ADAMS a resolution conveying the thanks of the Branch to the outgoing office-bearers was adopted. It was acknowledged by Dr. W. D. MACFARLANE, who has been honorary secretary for several years.

On the completion of business a smoking concert was held.

LANCASHIRE AND CHESHIRE BRANCH:

PRESTON DIVISION.

THE annual general meeting of this Division was held on May 7th, when Dr. R. C. BROWN presided over twenty-six members.

Annual Report for the Year 1912.—The annual report showed that eleven general meetings had been held with an average attendance of 47. The Provisional Medical Committee had met thirteen times, with an average

attendance of 15.7. Reference was made to the loss the Division has sustained by the death of their Representative, Dr. J. E. Garner. The accounts of the Division and the Provisional Medical Committee were read and passed.

Election of Officers.—The following officers were appointed for the ensuing year:

President.—Dr. R. C. Brown.

Vice-Presidents.—Drs. A. C. Rayner and J. A. Harris.

Representative.—Dr. W. H. Irvin Sellers.

Deputy Representative.—Dr. J. E. Healey.

Representatives on Branch Council.—Drs. J. A. Harris and W. Sykes.

Honorary Secretary and Treasurer.—Dr. W. Sykes.

Committee.—Drs. J. E. Dunn, A. P. Mooney, W. J. Leighton, J. E. Healey, Turnbull Smith, A. I. Petyt, J. Lea.

Votes of Thanks.—On the motion of Dr. SHARPLES, seconded by Dr. DERHAM, a hearty vote of thanks was accorded to the officers for the very efficient way in which they had carried out their duties in this most trying year. Dr. BROWN and Dr. SYKES acknowledged the compliment.

Insurance Act.—A discussion was raised on maternity benefit, and the question of the appointment of whole-time consultants. These matters were referred to the Local Medical Committee. Dr. Petyt was elected for No. 5 Area, and Dr. W. J. Leighton for No. 11 Area, of the Lancashire County Medical Committee. It was decided to take no steps with regard to boundaries of Divisions unless requested by members.

Expenses of Representatives.—A communication having been read from the Branch Secretary with reference to the share of the Preston Division in the cost of paying the expenses of members attending meetings of the Representative Body, Council, and Committees, Dr. RIGG proposed, and Dr. SELLERS seconded, that a levy be made, and £5 5s. was collected from the members present. The Secretary was instructed to circularize the members not present at the meeting.

Temporary Residents.—Dr. RIGG opened a discussion on the method of payment by the Commissioners for the treatment of visitors and migratory persons. After considerable discussion, in which Drs. MOONEY, SELLERS, DERHAM, LEIGHTON, and PIMBLETT took part, Dr. DERHAM moved, and Dr. RIGG seconded, the following resolution, which was adopted:

That this meeting strongly protests against any deduction made from the capitation fees of persons making visits to other areas, except genuine removals in pursuit of their occupation. And is of opinion that such deduction would be a breach of their agreement with practitioners on the panel, on the part of the Commissioners.

WARRINGTON DIVISION.

At the annual meeting of this Division on May 26th, when Dr. BURROWS was in the chair, ten other members were present.

Vote of Condolence.—A vote of condolence with the family of the late Dr. Willett of Stockton Heath was passed.

Vote of Thanks.—A hearty vote of thanks was given to Dr. Burrows for his services as Chairman during the past twelve months.

Election of Officers.—The following officers were elected:

Chairman.—Dr. Langdale.

Vice-Chairman.—Dr. Bennett.

Honorary Secretary and Treasurer.—Dr. T. A. Murray.

Representative on Branch Council.—Dr. Bowden, vice Dr. Burrows, whose term has expired under the rules of the Division.

Members of the Executive.—Drs. Burrows, Naden, and Binns.

Election to Central Council.—It was resolved to support Dr. Garstang and Mr. Larkin as candidates for the Central Council.

Alteration of By-law.—The by-law relating to the election of the Executive was altered in accordance with the recommendation of the Council.

Expenses of Representatives.—It was decided to make a voluntary levy of 6s. a member towards the expenses of Representatives, etc.

METROPOLITAN COUNTIES BRANCH:

LEWISHAM DIVISION.

The annual general meeting of the Lewisham Division was held at Catford on May 19th.

Annual Report.—The annual report was adopted.

Election of Officers.—The following office-bearers were elected for the ensuing year:

Chairman.—Dr. T. Comber.

Vice-Chairman.—Dr. L. F. Hemmans.

Honorary Secretary and Treasurer.—Dr. H. M. Bunday.

Representative to Representative Meetings.—Dr. J. T. Macnamara.

Representative on Branch Council.—Dr. F. Hudson Evans.

Executive Committee.—Dr. T. W. Atkinson, Dr. F. S. Barnett, Dr. Charles Blue, Dr. A. Grayling, Dr. Wheeler O'Brien, Dr. W. Wilson.

Vote of Thanks.—A very hearty vote of thanks was accorded Dr. Toogood, the retiring Chairman, for his zeal and assistance during the past year.

LAMBETH DIVISION.

The annual meeting of the Lambeth Division was held at Bethlem Hospital on May 23rd.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. W. H. B. Stoddart.

Vice-Chairman.—Dr. R. J. Farman.

Representatives on Branch Council.—Dr. H. Taylor and Dr. J. V. C. Denning.

Representatives at Representative Meetings.—Dr. T. H. Parkes Peers and Dr. M. Moran.

Honorary Secretary and Treasurer.—Dr. T. H. Parkes Peers.

Executive Committee.—Drs. Harvey Norton, F. O. Stoker, J. Morris Stoker, D. Hammond Fraser, A. J. McNickle, D. McCarthy, A. G. Everard, Stanley Brook, A. R. Moore, W. A. Atkinson, A. R. French, and G. R. Elwin.

TOWER HAMLETS DIVISION.

The annual meeting of the Tower Hamlets Division was held on May 20th at the Public Health Offices, Stepney. Dr. GOODMAN was in the chair, and eleven other members were present.

Election of Officers.—The officers and committee were elected as follows:

Chairman.—Dr. Goodman.

Vice-Chairman.—Dr. Byrne.

Secretary.—Dr. Oxley.

Representative at Representative Meeting.—Dr. Oxley.

Representative to Branch Council.—Dr. Michael.

Committee.—Drs. Grant, Thomas, Cardale, Black, Hume, Williams, Toland, and Villacott.

Annual Report.—The report of the Executive Committee, which was adopted, stated that since the inauguration of this Division in July, 1912, nine general meetings, five Executive Committee meetings, and thirteen meetings of the Provisional Medical Committee had been held. The principal work of the Division had been in connexion with the Insurance Act. Four scientific meetings had been held and been addressed by Drs. Dundas Grant, Hadley, Russell Andrewes, and McAdam Eccles. The committee had considered the arrangements made for sanatorium benefit within the two boroughs concerned, and had made every effort to secure that this should be carried out on lines satisfactory to the local profession and in accordance with the policy of the British Medical Association. Negotiations were proceeding with the Seamen's National Insurance Society with the object of securing greater freedom of choice of doctor than at present exists for persons insured under that society, and especially to secure that the old patients of any particular doctor should have a right to continue to be treated by him. The committee was pleased to note the good work done by the Poplar and Stepney Medical Unions, and considered that some means of co-ordinating the work of these bodies and the Division would be of great advantage to the profession. The committee was pleased to report that in accordance with the by-laws of the Association the Division had now become a constituency for the purposes of the Representative Meeting, and was entitled to appoint a member to represent it at the forthcoming Annual Representative Meeting. The expenses of the Division had been heavy, owing partly to the committee's decision to invite all practitioners resident within the area to many of their meetings, in particular to those called to discuss matters in connexion with the National Insurance Act. The committee acknowledged the kindness of the chairman, who had allowed the use of his room for committee meetings. The number of members within the Division, which at the beginning of the year was seventy-eight, was now seventy-nine. The report concluded by expressing its indebtedness to Dr. Black, the late secretary,

for his arduous labours on behalf of the profession at a time of the greatest stress and difficulty.

Expenses of Representatives.—It was decided to raise a special fund by means of a subscription of 5s. from each member for the purpose of paying the expenses of the representative in so far as not met out of the central funds.

Medical Trade Union.—On the invitation of the CHAIRMAN, Dr. GORDON WARD, Secretary of the National Medical Medical Guild, addressed the meeting as to the advisability of joining a medical trade union.

Vote of Thanks.—The meeting terminated with a vote of thanks to the Chairman and Secretary.

MIDLAND BRANCH: CHESTERFIELD DIVISION.

The annual meeting of the Chesterfield Division was held at Chesterfield on May 20th.

Presentation to Honorary Secretary.

Before proceeding to the business of the meeting, Dr. J. G. SHEA stated that, as a mark of appreciation of the valuable services rendered by Dr. W. Duncan, the Honorary Secretary of the Division, the members had resolved to make a presentation to him, which, after consultation with Dr. Duncan, they had decided should be a useful article, that selected being a case of cutlery. Dr. R. A. McCREA then read an address, signed by the subscribers to the presentation. Dr. A. GREEN, the Chairman, added his personal testimony to the able manner in which Dr. Duncan had carried out the onerous duties of his office as Honorary Secretary during the past year, and handed the presentation to him. Dr. DUNCAN, in thanking his colleagues for their appreciation of his efforts, referred to the important and difficult part in the work which had been performed by Dr. R. Godwin Chase as organizer and Secretary of the Public Medical Service, and by the Subdivisional Honorary Secretaries, Drs. McCREA, A. M. PILCHER, A. COURT, and T. CORKERY; also to the work done by Dr. COURT as Honorary Secretary of the Provisional Medical Committee, who had devoted much time and energy to the getting in, classification and dispatching of the numerous resignations of contract appointments; that without such assistance the work would have been impossible. He joined with his colleagues in thanking them for their untiring attention to matters so important to the interests of the profession. He referred with regret to the fact that, whilst locally a strong and gallant fight had been waged against such of the statutory conditions as were unjust, many practitioners had in respect of the uninsured accepted in many instances fees lower than the statutory fees for insured persons; and he warned them that this fact would be surely raised against them when in the future efforts were made to obtain improved remuneration. He urged that they should revise these lower terms, and should continue the fight, that they should keep themselves banded together and support the central organization, seeing that in such a course lay their only prospect of protecting the interests of the profession.

Annual Meeting.

Financial Statement.—Mr. A. CHAWNER, the Honorary Treasurer, presented the accounts and balance-sheet, which were approved.

Report of Executive Committee.—Dr. W. DUNCAN, the Honorary Secretary, presented the report of the Executive Committee, from which it appeared that the membership had increased from 47 to 66; there were only 23 practitioners in the area of the Division who were not members of the Association. Of these non-members 14 were principals and 9 assistants. The report was adopted.

Election of Officers.—The following officers of the Division were appointed:

Chairman.—Dr. J. G. Shea, J.P.

Vice-Chairman.—Mr. H. B. Fletcher, J.P.

Honorary Secretary.—Dr. W. Duncan.

Representative to the Representative Meeting.—Dr. W. Duncan.

Honorary Treasurer.—Mr. A. Chawner.

Representatives on Branch Council.—Drs. A. COURT and A. GREEN.

Executive Committee.—Mr. C. THORNE, Dr. A. M. PILCHER, Mr. P. MARRIOTT, Dr. G. BOOTH, J.P., Mr. J. A. MAGEE, Dr. T. CORKERY, Dr. R. A. McCREA, and Mr. G. H. NEAD, with the following *ex officio* members: The Chairman, the Vice-Chair-

man, the Honorary Secretary and Representative to Representative Meeting, the Honorary Treasurer, and the Representatives to the Branch Council.

Vote of Thanks.—A hearty vote of thanks was passed to Dr. Green, the retiring Chairman.

Clinical Meeting.—It was resolved that an evening clinical meeting should be held at a date to be fixed.

Local Medical Committee (Derbyshire).—A letter from the Honorary Secretary was read, in which two resolutions passed by that Committee were set out, namely:

1. That there be a fee of not less than 6d. charged for each certificate or club note issued by any medical practitioner (except the official certificate required by the Insurance Act), and, further, that the fee for certificates in compensation cases be arranged locally.
2. That a charge of not less than 1s. be made for examination of any candidate for any society or club.

After discussion it was resolved that a return be obtained from each practitioner within the area of the Division, setting out fully the terms of each contract held, and that each be asked to state whether he would agree to comply with the above-mentioned resolutions, and that if prevented from compliance by current contracts whether compliance would be given on the expiration of such contracts.

NORTHERN COUNTIES OF SCOTLAND BRANCH: ROSS AND CROMARTY DIVISION.

The annual meeting of the Division was held in Dingwall on May 20th. Dr. McLEAN, Chairman, presided, seven other members being present.

Election of Officers.—The following office-bearers were appointed:

Chairman.—Dr. Kaye.

Vice-Chairman.—Dr. Adam.

Secretary and Treasurer.—Dr. Duncan.

Representatives on Branch Council.—Drs. Cameron and Knox.

Members of Executive Committee.—Drs. F. McRAE, SMITH, McLEAN, MIDDLETON, BRODIE, and SOMERVILLE.

Representation of the Division.—The question of a Representative for the constituency (Inverness, Ross, and Cromarty, Caithness and Sutherland) was discussed, and the Secretary was instructed to write the Secretaries of the other Divisions as to the mode of election. The meeting favoured a card vote owing to the difficulty in holding a joint meeting. The Secretary was also instructed to write the Council of the British Medical Association as to the special difficulties of holding joint meetings, and to ask for separate representation (By-law 30 (3)).

Model Ethical Rules.—The model rules for ethical procedure which were discussed at a previous meeting were approved and adopted.

Insurance Act.—Dr. MACKENZIE brought up the question of certificates for insured persons, and it was unanimously agreed that the nature of illness should not be stated on the certificate, and the Secretary was instructed to write to this effect to the Insurance Committee.

Vote of Thanks.—Dr. McLEAN (Seaforth Sanatorium), the retiring Chairman, was heartily thanked for his able and untiring services as Chairman during the past strenuous year.

SOUTH-EASTERN BRANCH:

GUILDFORD DIVISION.

The annual meeting of the Guildford Division was held at the Royal Surrey County Hospital on May 16th. Dr. KINGSFORD, Chairman, took the chair, and there were nineteen members present.

Annual Report and Financial Statement.—The SECRETARY read the report of the Division's work during the past year, which, with the statement of accounts, was formally adopted.

Presentation to Officers.—The thanks of the meeting were given to the retiring Chairman (Dr. Kingsford) and the Secretary (Mr. Lankester), and Dr. MITCHELL, President-elect of the Branch, made a presentation to each in the name of the Division. Dr. Mitchell referred to the services rendered by the gentlemen, especially in connexion with the fight against the National Insurance Act, recalling the fact that Dr. Kingsford had, at the special request of the Division, remained a second year in office. The testimonial took the form of a very handsome cheque, which Dr. Mitchell handed to the Chairman and

Secretary as an expression of the Division's gratitude and appreciation.

Election of Officers.—The following officers were elected for the ensuing years:

Chairman.—Mr. H. Branson Butler, F.R.C.S. Edin., Guildford.

Vice-Chairman.—Dr. Arnold Lyndon, Grayshott.

Honorary Secretary and Treasurer and Representative at Representative Meeting.—Dr. Cecil P. Lankester, Guildford.

Representative on Branch Council.—Dr. G. F. Bird, Godalming.

Executive Committee.—Dr. B. W. Bond, Mr. N. F. Kendall, Dr. B. H. Kingsford, Dr. A. M. Mitchell, Dr. B. H. Pain, Dr. H. F. Parker, Mr. F. E. Pearse, Dr. E. W. Sheaf, Dr. E. J. Smyth, Dr. A. Hope Walker, Dr. F. K. Weaver, Mr. R. W. Winstanley.

Reorganization of Branch.—A resolution of the South-Eastern Branch Council in favour of the division of the South-Eastern Branch into three Branches corresponding with the three counties of Kent, Sussex, and Surrey was then discussed and unanimously passed.

Subscription to Association.—Instructions were given to the Representative to the Annual Representative Meeting authorizing him (*inter alia*) to support an increase up to 10s. in the annual subscription for the general purposes of the Association; to oppose the suggestion of the Association becoming a trade union, but to support the motion by Leicester and Rutland in favour of the formation of a union registered under the Trade Union Acts.

Local Defence Fund.

A meeting was subsequently held of the guarantors to the Local Defence Fund, and it was resolved to make a levy of 5s. per guarantor (in addition to the one already paid of 15s.) as a grant to Central Office expenses.

Association Notices.

SPECIAL MEETING OF COUNCIL.

A SPECIAL Meeting of the Council will be held at Eleven o'clock in the forenoon of Friday, June 13th, in the Council Room at 429, Strand, London, W.C., to consider a Report of the Organization Committee on the Reform of the Present Constitution of the Association.

By Order,

GUY ELLISTON,

May 22nd, 1913. *Financial Secretary and Business Manager.*

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH.—Mr. J. Furneaux Jordan (9, Newhall Street, Birmingham) and Dr. J. G. Emanuel, Honorary Secretaries, give notice that the annual meeting of the Birmingham Branch will be held in the Medical Institute on Thursday, June 19th, at 3 p.m. Business: Election of officers. Annual report and financial statement. Inaugural address by the incoming President, Mr. W. F. Haslam.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—Drs. Laurence E. Price and Duncan Davidson (15, Priory Row, Coventry), Honorary Secretaries, give notice that the annual meeting of the constituency of the Nuncaton and Tamworth and Coventry Divisions will be held at 3.30 p.m. on Thursday, June 5th, at the Coventry Hospital, to elect a Representative for the Brighton Meeting, and any other business. At the conclusion of this meeting the annual meeting of the Coventry Division will be held for the election of officers, to consider a proposed alteration of date of meetings, and to receive the report of the Executive Committee.

BORDER COUNTIES BRANCH.—Dr. Livingston, Secretary, gives notice that the annual meeting of the Branch will be held in the Town and County Hotel, Carlisle, on Friday, June 27th.

METROPOLITAN COUNTIES BRANCH.—Drs. W. Griffith and R. E. Crosse (Honorary Secretaries) give notice that the annual general meeting of the Branch will be held at 429, Strand, W.C., on Tuesday, July 1st, at 4 p.m. The business will include a report as to the election of new officers, and the annual reports of Council and of representatives of the Branch on the Central Council. On the motion to adopt Model Ethical Rules for Branches, Dr. F. J. Smith gives notice that he will propose an alteration to the Model Ethical Rules by substituting the words "British Medical Association" for the words "Medical Profession" in Rule 1. President's address: The Profession and the Public. [The Model Ethical Rules are printed in the SUPPLEMENTS of September 21st and 28th, 1912, pages 325 and 350.]

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—Dr. A. G. Southcombe, Honorary Secretary (83, Sidney Road, Homerton, N.E.), gives notice that the eleventh annual general meeting of the Division will be held in Balfour Hall, Dunstan Street, Kingsland Road, on Friday, May 30th, at 3.30 p.m.

METROPOLITAN COUNTIES BRANCH: EAST HERTFORDSHIRE DIVISION.—Dr. H. D. Ledward, Honorary Secretary (123, Nerton Way, Letchworth) gives notice that the first annual meeting of the Division will be held at 2.30 p.m., on Friday, June 20th, at the Town Hall, Ware, to elect officers, the representative of the Division on the Branch Council, the ordinary members of the Executive Committee, and the Representative of the Division in Representative Meetings. To receive the Honorary Secretary's Annual Report. To alter Rule 1 defining the area of the Division in accordance with the decision of the Organization Committee of the Association. To consider the business of the Annual Representative Meeting and instruct the Representative thereon.

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—Drs. Walter E. Fry and P. C. Raiment, Honorary Secretaries, give notice that the annual meeting will take place at Kensington Town Hall on Thursday, June 12th, at 5 p.m., for the transaction of the following business: Annual report. Elect officers and Representatives for 1913-14, and elect Executive Committee.

MIDLAND BRANCH.—Dr. F. L. A. Greaves, Honorary Secretary and Treasurer (83, Friar Gate, Derby), announces that the annual meeting of the Midland Branch will be held on June 13th, at 3 p.m., at Central Buildings, Leicester Public Medical Service, Bond Street, Leicester.

SOUTH MIDLAND BRANCH.—Dr. E. Harries-Jones, Honorary Secretary (16, Castilian Street, Northampton), announces that the annual meeting of the Branch will be held at Bedford on June 12th, under the presidency of Dr. Canning Hartley.

SOUTH-EASTERN BRANCH.—Dr. E. A. Starling, Honorary Secretary (Chillingworth House, Tunbridge Wells), gives notice that the sixty-ninth annual meeting of the Branch will be held on Wednesday, June 11th, at 1.30 p.m., at the Lion Hotel, High Street, Guildford. Dr. Arthur M. Mitchell (President-elect) invites members to lunch at the Lion Hotel, High Street, at 12.45 p.m. sharp. Agenda: In addition to the business of an ordinary meeting, (1) to receive the report of the election of officers for 1913-14; (2) to receive the annual report of the Council and financial statement, and (3) the ethical rules presented by the Council; (4) to consider the following resolution: "The South-Eastern Branch Council advise the Branch to request the Council of the Association to consent to the division of the unwieldy South-Eastern Branch into three Branches, corresponding with the three counties of Kent, Sussex, and Surrey." An excursion is arranged for the afternoon, to view the Lord Mayor Treloar's Cripples' Home at Alton, where Dr. and Mrs. Gauvain kindly invite the members to tea. The special train leaves Guildford Station at 2.40 p.m., returning about 5.30 p.m. Tickets for the return journey, 3s. 6d. each. The annual dinner will be held at the Lion Hotel, at 6.30 p.m. Members intending to be present at the lunch, excursion, or dinner wishing hospitality for the night are requested to signify their intention to Cecil P. Lankester, Esq., 1, Rectory Place, Guildford, not later than Saturday, June 7th.

SOUTH-WESTERN BRANCH.—Mr. Russell Coombe, Honorary Secretary, gives notice that the seventy-fourth annual meeting will be held on Wednesday, June 11th, at the Museum, Babbacombe Road, Torquay, at 3 p.m., when Dr. Hardwick will resign the chair to Mr. Eales, who will deliver his inaugural address. The report of the Branch Council for the year 1912-13 and the annual financial statement for the year 1912 will be presented, and the officers of the Branch will be elected for the year 1913-14. Luncheon, by the kind invitation of the President-elect and Torquay members, will take place from 1 p.m. to 2.30 p.m., at the Museum, Babbacombe Road. The annual dinner of the Branch will be held at the Torbay Hotel at 7.45 for 8 p.m. Tickets 7s. 6d. (exclusive of wine) can be had from Dr. Lacey, Melita, Torquay; application should be made not later than the first post on Monday, June 9th. Several Torquay members of the Branch have offered to put up visiting members for the night, and gentlemen desiring to avail themselves of this hospitality are requested to inform Dr. Lacey when making application for their dinner ticket. By the courtesy of the Torquay and South Devon Golf Club, members of the Branch and their wives will be made honorary members for Wednesday and Thursday; those wishing games arranged should communicate with Dr. Dalby, The Rosary, St. Marychurch, Torquay.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

SUMMER SESSION, 1913.

Tuesday, May 27th, 1913.

Sir DONALD MACALISTER, K.C.B., President, in the
Chair.

THE ninety-seventh session of the General Council of Medical Education and Registration began at the offices of the Council, 299, Oxford Street, on Tuesday, May 27th.

NEW MEMBER.

Dr. William Russell, as representative of the Royal College of Physicians of Edinburgh for five years, from May 6th, 1913, in the place of Dr. George A. Gibson, deceased, was introduced by Mr. Hodsdon.

PRESIDENT'S ADDRESS.

The PRESIDENT then delivered his address:

Changes in the Council.

A year ago we welcomed Dr. George A. Gibson as a new member of the Council. At that time his great professional reputation encouraged us to look to him for long and valuable service as a colleague. Our hopes have now been frustrated by his untimely death. The expressions of regret which have come from those who best know what he was and what he had achieved serve to measure the greatness of our loss. We can but offer our sympathy to his bereaved family and friends, and record our own sorrow for the too-early close of his career of high purpose and endeavour. In his place the Royal College of Physicians of Edinburgh has appointed Dr. William Russell, a Fellow of the College, whose varied activities have won for him a prominent position among our Scottish brethren.

Irish Home Rule.

In my address last November I mentioned the steps that were taken to give effect to your resolution regarding the Government of Ireland Bill. Amendments to the bill were duly proposed, for the purpose of ensuring that the control of legislation relating to the Medical and Dentists Acts should be reserved to the Imperial Parliament. At first it seemed likely that the amendments might be favourably regarded by the House of Commons; but in the end, for reasons that had no apparent relation to the merits of your proposal, the Government opposed its adoption, and it was rejected. The Minister in charge of the bill and other members of the House have expressed the opinion that, even in the absence of restrictive provisions, the Irish Government would not be likely to propose any local legislation which might have the effect of invalidating the general currency of professional qualifications granted in Ireland. Experience alone can show whether that opinion is well founded. Under the procedure laid down for the further progress of the bill, it is doubtful whether the Council will have any other effective opportunity of calling the attention of Parliament to its views on the subject. If such an opportunity should arise, it may, I think, be assumed that your instructions of last June are still operative.

Direct Representation.

The bill of the Lord President of the Privy Council, for amending those provisions respecting the election of direct representatives which experience has shown to cause inconvenience and waste of public money, passed the House of Lords, and was read a first time in the House of Commons. Before the second reading, however, notices of motion by private members were placed on the order paper, which had the effect of blocking the progress of the bill. The terms of these notices suggested that the members responsible for them had misapprehended both the functions of the Council and the scope of the bill itself. Efforts were made through the proper channels to remove these misapprehensions. Before they were successful the end of the session approached; and, as the Government was unable to find time for prolonged second reading debate, the bill was withdrawn. So far as I can ascertain, the circumstances of the present session of Parliament are not

favourable to its reintroduction. It is, however, satisfactory to know that the Government has recognized the imperfection of the statute under which our election regulations are made by the Privy Council, and that the Lord President has made a serious effort to procure its amendment in the interest of a more economical procedure.

Insurance Act.

In pursuance of your instructions respecting the National Insurance Act, the Special Committee has been active in considering the various professional questions to which its attention was directed, and in sending representations thereon to the Insurance Commissioners and other authorities concerned.

The Committee met in January, and had before it the revised Regulations for the Administration of Medical Benefit issued by the Commissioners. It was gratified to observe that practical effect had been given to its suggestions for the amendment of the draft Regulations, except in regard to the important question of "hospital or institutional treatment for insured persons requiring services beyond the competence of an ordinary medical practitioner." That question, it is now stated, cannot be dealt with by Regulations; it will require an amending or supplementary Act of Parliament.

Under one of the forms of agreement appended to the Regulations, it appeared that in cases requiring a surgical operation no special provision was made for the administration of anaesthetics by a qualified person other than the operator himself. The Committee has called the attention of the Commissioners to the resolution of the Council on this subject, dated November 27th, 1909, and has urged upon them the desirability of sanctioning arrangements whereby the safeguard contemplated in that resolution may be secured to insured persons under all forms of agreement with practitioners engaged in the National Insurance service. Communications on the subject are still taking place, but no formal deliverance has yet been issued by the Commissioners.

While the Departmental Committee on Tuberculosis was considering its report, certain questions connected with the administration of "sanatorium benefit" under Section 16 of the Act were confidentially submitted to your Committee for consideration, and its comments on the provisional resolutions of the Departmental Committee were requested. The request was complied with, and a carefully considered reply was forwarded to the Committee. The recommendations of the report, which has since been presented to Parliament, and transmitted to the office for information, made it clear that weight has been attached to the views expressed by the National Insurance Act Committee on the Council's behalf.

During the early months of the year, while committees, societies, and practitioners were actively engaged in discussing and elaborating the measures to be taken for setting up the National Insurance service, numerous communications were received by the Registrar suggesting that particular bodies or persons, some favouring the institution of the service and others opposing it, were resorting to methods of advertising or canvassing of a kind to which objection might justly be taken by the Council. As it seemed likely that the warning notices already issued by the Council in relation to such methods were imperfectly known or understood, copies of these were forwarded to the Insurance Commissioners for their information, and were also communicated to the press, and to the various bodies and persons who appeared to be concerned. Steps are now in progress for circulating the notices still more widely among societies, committees, and others engaged in the administration of medical benefit throughout the kingdom. It is to be expected that, when they are fully informed of the conditions proper to professional service, these bodies will realize that it is necessary, in the discharge of their important functions, to guard against the introduction of methods that are inconsistent with right standards of professional conduct. Up to the present no formal complaint which is in accordance with the Standing Orders relating to cases for inquiry by the Council has been received in respect of any practitioner. Personally I am not without hope that, when the uncertainty and unrest naturally accompanying the establishment of an unfamiliar system of medical practice shall have ceased to be felt, the cautionary measures

adopted by the Council will obviate all occasion for formal complaints and inquiries under this head.

Hong Kong.

A further advance has been made in the direction of medical reciprocity within the empire by the application to the colony of Hong Kong of Part II of the Medical Act, 1886. In the opinion of the Executive Committee, the legal conditions affecting the practice in that colony of practitioners registered in the United Kingdom were equitable, and afforded a just basis for establishing the reciprocal relations contemplated in the Act. This opinion was communicated to the Privy Council on February 24th, and on March 7th His Majesty in Council was pleased to issue the necessary order. The Executive Committee has considered the regulations regarding courses of study and examinations prescribed for degrees in Medicine and Surgery by the new University of Hong Kong, and finding these to be sufficient to guarantee the efficiency of its graduates, the Committee proposes to recognize such degrees as qualifying for registration in the Colonial List.

Canada.

The Medical Council of Canada assembles next month in Ottawa, and will proceed to formulate regulations governing the licensing and registration of practitioners throughout the Dominion. We must wait until we are informed of the precise conditions under which practitioners registered in this country will be admitted to the Register of Canada and to the privilege of practising within its territory, before we make a representation to the Lord President on the subject of reciprocity with the Dominion as a whole. We have every reason to expect that acceptable conditions will be proposed.

In the meantime the Province of New Brunswick proposes, by an amendment of its Medical Act of 1903, to admit to its own *Register* "Any person desirous of practising in New Brunswick who is duly registered by the General Medical Council."

The Legislature of Newfoundland has also, by a recent enactment, assimilated its local law to that of other parts of the empire, and now prescribes for practitioners a curriculum of five years, instead of the four years which have hitherto sufficed.

Finance.

Last year the Finance Committee reported with regret that in 1911 the income of the Council and its Branch Councils fell short of its expenditure by £1,370. This year it is able to show that in 1912 there was a surplus of income over expenditure amounting to £1,105. The receipts from registration fees are larger by some £500; and the outgoings, thanks mainly to shorter sessions of the Council, and to economies effected by the efforts of the Treasurers and the Registrar, are considerably smaller. It is satisfactory also to note that the number of students registered at the commencement of their curriculum has risen by 165, and now coincides with the figure representing the average for the preceding five years. It would appear that the misgivings regarding the future of our profession which were freely expressed during the unsettlement of last year have exercised no deterrent effect on the body of youthful recruits. Their faith may prove to be wiser than our forebodings.

During the five years 1907 to 1911 inclusive the accounts showed a net accumulated deficit of about £1,370. The surplus of 1912 reduces the accumulation to some £270. Should we this year be spared the necessity either for long sessions or for by-elections under the costly regulations now in force, we may count with some confidence on wiping out the unfavourable balance altogether. Every proper means to this desirable end will, I feel sure, continue to be taken by the officers of the Council.

Work of Committees.

I do not propose to anticipate the Reports of the Standing Committees, now in a forward state of preparation, by touching on their probable contents. But I do wish to assure the Council, on my own knowledge, that the Chairmen of these Committees and their colleagues have spent much thought and labour upon them, that much correspondence and consultation of authorities have been required, and that the conclusions reached deserve the Council's careful consideration. For those who are

charged with the guidance of these Committees, the period of recess is sometimes more laborious than the period of the Council's session.

After we have completed the formal business necessary at the opening of the session, it will be my duty to lay down the office which this day five years ago you were pleased to commit to my hands. I owe it to the devotion of the members and officers of the Council and to their ready response to every call made upon them if it should appear to you that my tenure of office has not greatly failed to meet your expectations. I cannot be ignorant of its shortcomings from my own hopes and desires, but I ask you to believe that these shortcomings are due to defect of power, not of will, to do better.

VOTE OF THANKS.

On the motion of Dr. LITTLE, seconded by Dr. NORMAN MOORE, a hearty vote of thanks was accorded to the President for his able address, and it was ordered to appear on the minutes.

SERVICE EXAMINATIONS.

The yearly tables relating to the examinations held by the different licensing bodies during 1912 were received and remitted to the Examination Committee for consideration, as were also tables showing the results of competitions for admission to the Navy, Army, and Indian Medical Services.

For the Indian Medical Service there were 22 entrants for 12 vacancies. In addition to the 12 who received commissions, 7 qualified but were not successful, and 3 were rejected. Two of the 12 successful candidates were graduates of the University of Aberdeen, 1 of these taking first place, 1 a graduate of the University of Glasgow, 1 a graduate of the National University of Ireland, and 7 were holders of the English Conjoint Diploma; 2 of the latter also held the licence in medicine and surgery of the University of Bombay.

For the Royal Army Medical Corps there were 44 entrants for 20 vacancies, but 9 did not compete. With one exception all were found qualified. Of the 20 successful candidates, 8 held the diploma of the English Conjoint Board, 1 of these taking the first place; 6 were graduates of the University of Edinburgh, 3 of the University of Dublin, 1 of the National University of Ireland, 1 of the University of London, and 1 was a holder of the Scottish Conjoint Licence.

At the Naval Medical Service examination 25 commissions were offered, but the number of candidates seems to have fallen below this number. Of the 14 commissions awarded, 7 went to holders of the English Conjoint Diploma, 1 being first on the list; 3 to graduates of the University of Edinburgh, 1 to a holder of the licence of the Society of Apothecaries of London, and 3 to holders of the Irish Conjoint Licence.

COMMITTEES.

The following Committees were appointed:

Pharmacopœia Committee.—The President (Chairman), Dr. Norman Moore, Sir George Philipson, Dr. Caton, Dr. Barrs, Sir Thomas Fraser, Dr. Cash, Sir John Moore, Sir William Whitla.

Finance Committee.—Mr. Tomes (Chairman), the President, Sir Henry Morris, Mr. Hodsdon, Dr. Little.

Dental Committee.—The President (Chairman), Sir Henry Morris, Mr. Tomes, Mr. Hodsdon, Sir Arthur Chance.

Dental Education and Examination Committee.—Mr. Tomes (Chairman), the President, Sir Henry Morris, Mr. Hodsdon, Dr. Knox, Sir Arthur Chance, Sir Charles Ball.

Students' Registration Committee.—Dr. Norman Moore (Chairman), the President, Dr. Langley Browne, Dr. Mackay, Dr. Norman Walker, Dr. Abye-Curran, Sir C. Nixon.

Business Committee.—Dr. Norman Moore (Chairman), the President, Sir Henry Morris, Sir Christopher Nixon.

Penal Cases Committee.—Dr. Saundby, Mr. Tomes, Dr. Norman Walker, and Sir Christopher Nixon.

Executive Committee.—Dr. Norman Moore, Sir Henry Morris, Mr. Tomes, Dr. Langley Browne, Mr. Hodsdon, Dr. Norman Walker, Sir John Moore, and Sir Charles Ball.

The President then vacated the chair, which was taken by Mr. TOMES.

Sir Donald MacAlister, whose term of office as President had expired, was unanimously re-elected.

Sir DONALD MACALISTER then took the chair, and briefly returned thanks for his re-election.

UNIVERSITIES OF CALCUTTA, BOMBAY, AND HONG KONG.

Reports from the Executive Committee were adopted, with the effect that the degrees of Master of Surgery and Master of Obstetrics of the University of Calcutta, the degrees of Medicine and Surgery of the University of Hong Kong, and the degree of Master of Surgery of the University of Bombay will in future be registrable on the *Medical Register*.

DENTAL REGISTRATION.

A report was received from the Executive Committee recommending that a person who is registered on the *Medical Register* should be permitted to register on the *Dentists Register* for a reduced fee of £2, and also that a duly qualified practitioner already registered on the *Dentists Register* desiring to be registered on the *Medical Register* should also pay a reduced fee of £2.

In moving the adoption of the report, Mr. TOMES said that it appeared only fair that if a man were on the *Medical Register* and wished to enter his name on the *Dentists Register*, he should pay a smaller fee than if he were not, and vice versa. The report was adopted, and the necessary alterations directed to be made in the Standing Orders.

FINANCE.

The Senior Treasurer, Mr. TOMES, in moving the adoption of the report of the Finance Committee, said that he had little to add to what the President had said in his address. The result for 1912 was very satisfactory in that there was a surplus instead of a deficit, although it did not wipe out the deficit of 1911. He paid a warm tribute to the efforts which the Registrar had made to reduce expenditure in a number of directions, in many instances with success.

Report.

The report showed that the income of the General and Branch Councils for the year ending December 31st, 1912, was £8,247, and that the expenditure was £7,142, so that there was a surplus of £1,105, and pointed out that the Council was especially fortunate in that an increase of income had coincided with a decrease of expenditure, so that a deficit of £1,370 in 1911 compared with a surplus in 1912. The committee saw no reason at present to anticipate that the accounts would be otherwise than satisfactory at the end of the present year. A new contract had been made for printing the *Register*, and in course of time this would, it was hoped, nearly wipe out the loss on the publication of the book, but the results would probably not be very apparent for two or three years. With regard to future receipts for the registration of practitioners, it was of interest to note that the number of students registered during the year was 1,397, which was 165 more than in 1911, and coincided almost exactly with the average of registrations for the previous five years. The investments of funds was being considered with a view of obtaining a better rate of interest, and the committee was sparing no efforts to place and keep the Council in a sound financial position.

The receipts by the Dental Fund for original registration fees showed an increase of £220, and as no further expenditure had been incurred on the inspection of examinations, a deficit of £153 in 1911 compared with the surplus of £466 in 1912.

Thanks to the contribution by the General Council to the funds of the Irish Branch, that Branch had started the year with a small surplus of £52. If circumstances were favourable, there might be no need to make a grant in 1913, but the Committee thought it best to ask permission to give £100 if required.

Mr. TOMES moved a resolution to give effect to the last recommendation, and this was seconded by Dr. LITTLE and carried.

RESTORATION TO THE "MEDICAL REGISTER."

The Council considered *in camera* a report by the Executive Committee in regard to application for restoration of names after erasure under Section xxix of the Medical Act, 1858.

The PRESIDENT subsequently announced that the names of Allan Douglas Cameron and of Robert Kirk had been restored to the *Medical Register*, and the Council adjourned.

Wednesday, May 25th, 1913.

SIR DONALD MACALISTER, K.C.B., President, in the Chair.

PENAL CASES.

The Council proceeded to the consideration of penal cases. Mr. Bodkin appeared as Legal Assessor and Mr. Harper as Solicitor.

Charge of Impersonation.

The first case for the consideration of the Council was that of Anthony Ciaramelli. The following notice of the inquiry had been sent:

May 2, 1913.

Sir,—On behalf of the General Medical Council I have to give you notice that on Wednesday, the 28th May, at 2 p.m., the Council will hold an inquiry at 299, Oxford Street, London, W., for the purpose of ascertaining the person at whose instance and the circumstances in which an entry was made in the *Medical Register* (Foreign List) as follows:

| Name. | Address. | Date of Registration. | Qualifications. |
|---------------------|---|-----------------------|--------------------------|
| Ciaramelli, Anthony | c/o Thomas Cook & Son, Ludgate Circus, E.C. | 1909, April 27 | M.D. Univ. Naples, 1903. |

and further entries of the following changes of address, namely:

148, Norfolk Street, Glasgow.

c/o Herr Löwy Jacob, 1, Tabor Utea, Maros Vasarely, Hungary.

Inhanguvo, Beira, E. Africa.

29, Langham Street, Portland Place, London, W.

c/o Löwy Lajos, Mav v. Lakatós, Verostoronny, Szebenmegyi, Hungary,

and whether the said entries have been incorrectly made or fraudulently caused to be made in the said *Register* and should be erased therefrom.

This notice is sent to you as the person now or lately carrying on practice as a legally qualified medical practitioner in the name of Anthony Ciaramelli.

I am instructed to add that you may attend the inquiry personally, or may be represented by a solicitor with or without counsel. Any communication or application which you may desire to make relating to the matter of inquiry should be addressed to the Registrar of the Council at 299, Oxford Street, London, W., without delay.

Yours obediently,

CHARLES J. S. HARPER,
Solicitor to the General Medical Council.

To Anthony Ciaramelli, Esq., M.D. (Naples),

c/o Löwy Lajos,

Mav v. Lakatós, Verostoronny, Szebenmegyi, Hungary.

The name of Anthony Ciaramelli was called, but no person attended in answer to the notice.

Dr. BATEMAN, Secretary of the Medical Defence Union, the informants, attended to assist the Council with regard to the facts of the case. He said the evidence which he would lay before the Council would prove that this was a case of the impersonation of a living practitioner who was entitled, under the Medical Act of 1836, to be registered on the Foreign List. In 1909 application was received by the Registrar for registration under the Medical Act by virtue of a number of qualifications which were duly set out and affirmed to, and the name was inserted in the *Register* and had remained there ever since. The actual name of the impersonator he was unable to give to the Council, but he had masqueraded the country under the name of Muscat, Muscot, and F. W. More. Under the latter alias he practised at Manchester, as appeared from the declaration of Isaac Ephraim, clerk to the Jewish Board of Guardians, and also in partnership in Glasgow. In the year 1910 he was elected a member of the British Medical Association, and was later transferred to the Metropolitan Counties Branch. Dr. Bateman stated that the person had joined the panel, and not content with joining one panel had joined six. He had joined Hampstead, Holborn, Paddington, Marylebone, St. Pancras, and Westminster. Dr. Bateman put in photographs of signatures by Dr. Antonio Ciaramelli, of New York, authenticated by a public notary, the supposed applicant for registration in the Foreign List (of the *Medical Register*), and of the person who, it was alleged, actually obtained registration. Dr. Bateman also read a letter from Dr. Antonio Ciaramelli, of New York, enclosing photographs of a F. W. More, who was his professional partner in New York, and who, it was alleged, was the person who actually obtained registration as Anthony Ciaramelli. Dr. Bateman also put in his own declaration and that of Mr. Jacob Herman, tailor, of 48, Huntley Street, Tottenham Court Road, W., and submitted that on the evidence the entry had been obtained by fraud, and that the name should be expunged from the *Register*.

Mr. COHEN, Secretary of the Jewish Association for the Protection of Women, of Upper Baker Street, having given evidence as to the so-called "Dr. C. Anthony," strangers

were directed to withdraw. On their readmission, the PRESIDENT said: Dr. Bateman, I have to inform you that the Council has come to the conclusion that the Registrar shall be directed to erase the entry from the *Medical Register* of the name of Dr. Anthony Ciaramelli as having been improperly and irregularly procured to be entered in the list. I have also, on behalf of the Council, to convey our thanks to the Medical Defence Union, and we also thank yourself for the assistance you have given the Council in arriving at a satisfactory conclusion. No doubt it will be your part to communicate to the genuine Dr. Antonio Ciaramelli the effect of the decision arrived at by the Council.

Misdemeanour.

At the meeting of the Council on November 27th, 1912, the case of H. A. De Pinna, registered as of 20, Grosvenor Street, W., M.R.C.S.Eng., L.R.C.P.Lond., was considered, and the President then announced to Mr. Robb, solicitor for the accused, that the Council had found the conviction for misdemeanour alleged in the notice of inquiry to have been proved, but had postponed judgement until the next session. The case was further considered on May 28th, when Mr. Harper, solicitor to the Council, said that the case had been postponed in order to enable Mr. Robb to produce evidence as to the mental condition of Mr. De Pinna both at the time of the offence and since, and on that occasion Mr. Robb had undertaken to have Mr. De Pinna in attendance. Mr. Robb said that Mr. De Pinna had been appointed medical officer of health and resident medical officer to the Malcolm District Hospital, Western Australia, and several testimonials had been received from responsible persons in Australia stating that since his arrival his conduct had been above reproach. Mr. Robb stated that he also had testimonials from officers of the ship in which Mr. De Pinna went to Australia, saying that he filled the position of surgeon during the voyage with satisfaction. After various troubles, and in particular money troubles, during the later part of 1911 and the early part of 1912, Mr. De Pinna had a nervous breakdown, and there was a short period of temporary derangement or temporary irresponsibility. Mr. Robb asked the Council to deal leniently with the matter, and hoped that it would agree that it was right in all the circumstances not to bring Mr. De Pinna back from Australia.

Strangers and parties were directed to withdraw, and on their readmission the PRESIDENT announced the judgement of the Council as follows:

Mr. Robb, I have to inform you that the Council does not see fit to direct the Registrar to erase from the *Medical Register* the name of Mr. Herbert De Pinna.

Passport Declarations.

Dr. Alfred Benson, registered as of 79, Maida Vale, W., M.R.C.S.Eng., M.B.Oxford, attended in answer to the following charge:

That, being a registered medical practitioner, you were on January 8th, 1913, convicted at the Central Criminal Court on your own confession of the following misdemeanour—namely, of having unlawfully, falsely, knowingly, and deceitfully put forward and represented that certain declarations made by you upon forms of application for passports for certain persons named Louis Kiseneyder and Lucas Kuschneyder respectively were true; for which offences you were fined £50.

The SOLICITOR for the Council said that the facts were admitted, but Dr. Benson stated that he had signed the papers without sufficient care and forethought. The Solicitor said that he did not believe that the declarations were signed fraudulently, but the practitioner had acted with great recklessness.

Dr. BENSON said that he had signed the forms by an error of judgement without giving close attention to the matter, and expressed his regret. In reply to the PRESIDENT, he said he took a fee for signing the documents—a consulting fee. The two men did not consult him medically. They gave him a name as that of a patient who knew them, and Dr. Benson, in the hurry of the moment, thought he recognized the name; he now knew that this was not so. The two men returned in August or September, requesting Dr. Benson to sign two more similar forms. He became suspicious and refused to do so. As far as he (Dr. Benson) recollected, they stated the certificates were for themselves.

Strangers were directed to withdraw, and on their readmission the PRESIDENT announced the judgement of the Council as follows:

Mr. Alfred Benson, I have to inform you that the Council has found your conviction proved, that the Council takes a very serious view indeed of the gravity of the offence of which you have been convicted, and that it has already marked its sense of the gravity of such offences by issuing, in the medical journals and elsewhere, in November, 1911, a warning notice to this effect: "Whereas registered medical practitioners are in certain cases bound by law to give, or may from time to time be called upon or requested to give, certificates signed by them in their professional capacity for subsequent use, either in courts of justice or for administrative purposes; and whereas such certificates include, amongst others"—I will read the one that refers to your offence—"certificates . . . for procuring the issue of Foreign Office passports . . . and whereas it has been made to appear to the General Council from time to time that some registered medical practitioners have given and signed untrue, misleading, or improper certificates of the above specified or other descriptions," and that is the offence of which you were convicted before the civil court, the Council, recognizing the serious nature of the responsibility thrown upon medical practitioners in relation to the giving of certificates, has gone further, and has given notice publicly—a notice of which you might have made yourself aware—"that any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate"—whether relating to the several matters I have specified or otherwise—"is liable to be adjudged by them to be guilty of infamous conduct in a professional respect, and to have his name erased from the *Medical Register*. In your case that is not the course adopted by the Council, because you were convicted in a civil court. In order to give you an opportunity to prove to the Council that you realize the gravity of the offence of which you were convicted, and of showing also to the Council that you are regarded by your professional brethren as one who in the future will conduct himself with scrupulous regard to the interests of the profession, the Council has postponed judgement until November next, and you will then be required to bring forward such evidence as it can accept on the points I have put before you—namely, your character generally, and your conduct as a medical man.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified by the Admiralty: Fleet Surgeon G. LEY to the *Duncan* on recommissioning, May 27th; Staff Surgeon P. D. RAMSAY to the *Ringdove* on recommissioning, May 27th; Staff Surgeon JOHN P. H. GREENHALGH to the *Portland Hospital*, June 2nd; Surgeon CECIL H. SYMONS to the *Duncan* on recommissioning, May 27th; Surgeon FRANCIS G. H. K. BLACK, M.B., to the *President*, additional, for survey of stores at Yarmouth Hospital, June 2nd, and Yarmouth Hospital, June 23rd, vice Hamilton; Surgeon ROBERT F. P. CORY to the *Hecla*, vice Black, June 2nd.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

COLONEL T. J. R. LUCAS, C.B., has been granted eighty-seven days' leave ex India.

Captain F. R. COPPINGER is appointed to the substantive medical charge of the 109th Infantry.

Captain G. F. GRAHAM is appointed to the substantive medical charge of the 20th Infantry.

Lieutenant H. S. CORMACK is appointed a Specialist in Ophthalmology, with effect from April 14th, 1913.

Vital Statistics.

HEALTH OF ENGLISH TOWNS.

IN ninety-six of the largest English towns 9,561 births and 4,573 deaths were registered during the week ending Saturday, May 24th. The annual rate of mortality in these towns, which had been 14.2, 13.9, and 12.8 per 1,000 in the three preceding weeks, rose to 13.4 per 1,000 in the week under notice. In London the death-rate was also equal to 13.4 per 1,000, against 14.2, 13.6, and 12.0 in the three preceding weeks. Among the ninety-five other large towns the death-rates ranged from 4.8 in Iford and in Eastbourne, 5.2 in Southend-on-Sea, 5.8 in Bootle, 5.9 in Acton and in East Ham, and 6.1 in Tottenham to 18.3 in Derby and in Middlesbrough, 19.2 in Dudley, 19.5 in West Hartlepool, 20.1 in Wigan, 22.6 in West Bromwich, and 22.9 in Walsall. Measles caused a death-rate of 1.6 in Salford, 2.0 in Stockton-on-Tees, 2.3 in West Bromwich, 3.0 in Dudley, and 7.3 in Walsall, and whooping-cough of 2.2 in Bootle. The mortality from the remaining infective diseases showed no marked excess in any of the large towns, and no fatal case of small-pox was registered during the week. The causes of 39, or 0.9 per cent. of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest; of this number 6 were registered in Birmingham, 4 in Liverpool, 3 in Manchester, and 2 each in London, Portsmouth, Bury, and South Shields. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1,375, 1,402, and 1,411 at the end of the three preceding weeks, had further risen to 1,441 on Saturday last; 193 new cases were admitted during the week, against 216, 206, and 171 in the three preceding weeks.

HEALTH OF SCOTTISH TOWNS.

IN the sixteen largest Scottish towns 1,172 births and 705 deaths were registered during the week ending Saturday, May 24th. The annual rate of mortality in these towns, which had been 17.2, 16.6, and 16.4 per 1,000 in the three preceding weeks, further fell to 16.3 in the week under notice, but was 2.9 per 1,000 above the rate in the ninety-six large English towns. Among the several towns the death-rates ranged from 8.5 in Clydebank, 9.6 in Coatbridge, and 10.4 in Kirkcaldy to 18.8 in Leith, 18.9 in Paisley, and 22.8 in Aberdeen. The mortality from the principal infective diseases averaged 2.1 per 1,000, and was highest in Motherwell and Aberdeen. The 312 deaths from all causes registered in Glasgow included 14 from measles, 14 from whooping-cough, 7 from infantile diarrhoeal diseases, 3 from diphtheria, and 1 from scarlet fever. Twenty-one deaths from measles were registered in Aberdeen, and 2 in Dundee; 2 deaths from diphtheria in Dundee, and 2 in Aberdeen; and 5 deaths from whooping-cough in Edinburgh, 3 in Motherwell, 2 in Aberdeen, and 2 in Greenock.

HEALTH OF IRISH TOWNS.

DURING the week ending Saturday, May 17th, 642 births and 416 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 629 births and 443 deaths in the preceding period. These deaths represent a mortality of 18.1 per 1,000 of the aggregate population in the districts in question, as against 19.3 per 1,000 in the previous period. The mortality in these Irish areas was, therefore, 5.3 per 1,000 higher than the corresponding rate in the ninety-six English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 27.9 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 17.9 (as against an average of 19.9 for the previous four weeks), in Dublin City 17.4 (as against 21.2), in Belfast 18.2 (as against 18.6), in Cork 21.1 (as against 23.8), in Londonderry 14.0 (as against 13.4), in Limerick 9.5 (as against 16.3), and in Waterford 20.9 (as against 19.0). The zymotic death-rate was 1.4, as against 1.2 in the previous week.

During the week ending Saturday, May 24th, 601 births and 442 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 642 births and 416 deaths in the preceding period. These deaths represent a mortality of 19.2 per 1,000 of the aggregate population in the districts in question, as against 18.1 per 1,000 in the previous period. The mortality in these Irish areas was, therefore, 5.3 per 1,000 higher than the corresponding rate in the ninety-six English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 26.1 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 21.5, as against an average of 19.2 for the previous four weeks,

in Dublin City 21.7 (as against 19.9), in Belfast 17.0 (as against 17.8), in Cork 27.2 (as against 24.6), in Londonderry 11.4 (as against 11.8), in Limerick 21.7 (as against 17.6), and in Waterford 22.8 (as against 20.4). The zymotic death-rate was 1.3, as against 1.4 in the previous week.

Hospitals and Asylums.

GUY'S HOSPITAL AND THE SOUTHWARK GUARDIANS.

BY the courtesy of the honorary secretaries of King Edward's Hospital Fund for London we have been furnished with a copy of the report of an inquiry by the Distribution Committee into complaints made by the Southwark Guardians in regard to Guy's Hospital. When considering the matter the committee had before it a summary of other cases which had been brought before it by the same guardians in 1903 and 1905, and two cases in 1911 to which its attention was drawn by press reports of inquests held on patients originally sent to Guy's Hospital. The differences of view in which all these matters originate is now quite an old story. The claim of the Southwark Guardians is to the effect that Guy's Hospital fails in its duty because when it states that it has no beds available, or considers a patient already in the hospital or seeking admission thereto, more suitable for treatment in a poor-law infirmary than in its own wards, the hospital declines any responsibility and sends the case to the guardians. This the guardians hold to be wrong, because they themselves fulfil their duty by making adequate provision for the necessitous poor, and it is the duty of Guy's to take in all cases above that class and particularly urgent cases. It would be foolish for them to establish a receiving house, because this would only encourage Guy's to send to them cases belonging to other unions. Guy's, on the other hand, claims that the fault lies with the guardians, who, having established their infirmary four miles away, ought to provide an emergency receiving house close at hand. The number of beds at Guy's is limited, and it cannot take in all kinds of cases, or even all urgent cases, and it is the duty of the guardians to provide for the sick poor for whom there is no accommodation in the hospitals. In regard to the question of establishing a receiving house, the Distribution Committee holds that in the circumstances the guardians ought to establish a receiving house, since they are legally entitled to do so. If the patients come from other parishes than those included in the Southwark unions this can be discovered and the expense made chargeable accordingly. Voluntary hospitals should not be expected to treat incurable cases, and it would be wrong for Guy's to overcrowd its surgical wards with emergency cases, the same observation applying, though not so strongly, to the medical wards. On the other hand, the Committee draws attention to one of the inquest cases mentioned and reaffirms the view which it expressed in the first instance. This was to the effect that additional provision ought to be made at Guy's for emergency cases, especially at night; two or more surgical beds should be kept free every night for emergencies. In regard to this the hospital has stated that when the scheme of extension on which it is engaged has been completed some years hence there will be space for a female accident ward if funds for its upkeep are then available. This, we confess, hardly seems to be enough, and we believe that the authorities of the hospital would be acting in the best interests of the institution if they made such provision for emergency cases as the Distribution Committee suggests, and, indeed, if they looked carefully into all the arrangements for dealing with such cases.

Vacancies and Appointments.

VACANCIES.

WARNING NOTICE.—Attention is called to a Notice (see Index to Advertisements—Warning Notice) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

ABERYSTWTH INFIRMARY AND CARDIGANSHIRE GENERAL HOSPITAL.—House-Surgeon and Secretary. Salary, £150 per annum.

MCCREA.—On May 23rd, at Ash Lodge, Chesterfield, the wife of R. A. McCrea, M.B., B.Ch., of a daughter.

DEATH.

ARCHER.—On Thursday, May 22nd, 1913, at 83, Vincent Square, Westminster, S.W., Thomas Launcelot Archer, M.R.C.S., Surgeon to the A Division, Metropolitan Police (Rochester Row), and Member of the British Medical Association, aged 52.

DIARY FOR THE WEEK.

TUESDAY.

ROENTGEN SOCIETY, King's College, Strand, W.C., 8.15 p.m.—Papers: (1) Professor C. G. Barkla, F.R.S.: Reflexion of X Rays. (2) Dr. R. W. A. Salmond: Experiments on the Reflexion of X Rays.

WEDNESDAY.

ROYAL SOCIETY OF MEDICINE:
SECTION OF OPHTHALMOLOGY, 8 p.m.—(1) Demonstration of Cases. (2) Annual Meeting. (3) Papers: Professor Worthington, F.R.S.: An Experimental Study of Normal Monocular Polyopia. Dr. Freeland Ferguson: (a) Glaucoma associated with Venous Congestion; (b) A Case of Corneal Ulceration associated with Organisms resembling those found in Vincent's Angina. Mr. N. Bishop Harman: The Education of High Myopes. Mr. G. H. Pooley: A Case of Cyst of the Iris

THURSDAY.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, 4.15 p.m.—Agenda: (1) Election of Officers. (2) Clinical meeting.

ROYAL SOCIETY OF MEDICINE:
SECTION OF OBSTETRICS AND GYNAECOLOGY, 8 p.m.—(1) Short Communications: Dr. Arnold Lea: A Case of Puerperal Venous Thrombosis. Mr. Corrie Keep: Two Cases of Solid Papilloma of Ovary. (2) Paper: Dr. R. H. Paramore: Intra-abdominal Pressure in Pregnancy.

FRIDAY.

ROYAL SOCIETY OF MEDICINE:
SECTION OF LARYNGOLOGY, 4.30 p.m.—Demonstration of Cases and Specimens.

POST-GRADUATE COURSES AND LECTURES.

BROMPTON HOSPITAL FOR CONSUMPTION, Wednesday, 4.30 p.m.—Demonstration of the Methods of Manufacturing and Testing Tuberculin.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.—Thursday, 2 p.m., Development of Mental Action.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.—General Medical and Surgical Clinics, daily. Throat, Nose, and Ear: Monday and Thursday. Skin: Tuesday and Friday. Eye: Wednesday and Saturday. Pathology: Wednesday. Radiography: Saturday. Special Lectures each week.

LONDON SCHOOL OF TROPICAL MEDICINE, Royal Albert Dock, E.—Lectures daily (Saturday excepted) at 12 and 4 p.m. Practical Laboratory Work daily (Saturday excepted), 10 to 12 a.m. Practical Entomology, 2 to 3.30 daily. Special Entomology, 10.30 to 1 p.m. daily. Medical Clinics, Tuesday and Thursday at 3 p.m. Operations, Friday, at 3 p.m.

MANCHESTER: ANCOATS HOSPITAL POST-GRADUATE CLINIC.—Thursday, 4.15 p.m.—Hydatids.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies Street, W.C.—The following Clinical Demonstrations have been arranged for next week at 4 p.m. each day: Monday, Skin. Tuesday, Medical. Wednesday, Surgical. Thursday, Medical. Friday, Ear, Nose, and Throat. Special Lectures at 5.15 p.m. daily except Friday and Saturday.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.—Tuesday and Friday, 3.30 p.m., Clinical Lecture.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.—Medical and Surgical Clinics and Operations at 2.30 p.m. daily. Also Monday, Throat; Tuesday, Gynaecology; Wednesday, Skin, Eye, Children, X Rays; Friday, Eye. Special Lectures and Demonstrations as announced.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.—Tuesday, 4 p.m., Diagnosis in respect of certain Symptoms and Signs in Children.

ROTUNDA HOSPITAL, DUBLIN.—Continuation of the Post-graduate Course on Obstetrics and Gynaecology daily throughout the week except Saturday.

THROAT HOSPITAL, Golden Square, W.—Monday, 5.15 p.m., Special Demonstration of Selected Cases. Thursday, 5.15 p.m., Clinical Lecture.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith Road, W.—Medical and Surgical Clinics, X Rays, and Operations, 2 p.m. daily. Gynaecology: Monday, Tuesday, Wednesday, and Friday. Eye: Monday, Wednesday, Thursday, and Saturday. Throat, Nose, and Ear: Tuesday, Wednesday, Friday, and Saturday. Skin: Tuesday and Friday. Pediatrics: Wednesday and Saturday. A Lecture at 5 p.m. every day except Saturday.

[For further particulars of Lectures consult the Index to Advertisements.]

National Insurance.

British Medical Association.

AMENDMENT OF THE INSURANCE ACT.
PROPOSALS BY THE BRITISH MEDICAL ASSOCIATION.

THE British Medical Association has forwarded to the National Insurance Joint Committee a memorandum upon the amendment of the Act and Regulations which it deems desirable. The memorandum was accompanied by the following covering letter:

Offices of the British Medical Association,
Medical Department, 429, Strand, London, W.C.,
May 30th, 1913.

Sir,

Amendments to the Act and Regulations Proposed by the British Medical Association.

In view of the approaching introduction into Parliament of a Bill to amend the National Insurance Act, the British Medical Association is anxious to take any opportunities that may be offered for bringing forward certain suggestions which, if adopted, would, it believes, have the effect of improving the efficiency of the Act. The Association realizes that it would facilitate the progress of its suggested amendments if it could secure for them the approval of the Commissioners. I am therefore instructed to forward a Memorandum which includes not only the amendments of the Act, but also points which could be met by amendment of the Regulations.

The Association would be glad to know how far it may expect the assistance of the Commissioners in pressing for any of the amendments suggested, and in order to assist the Commissioners in understanding its point of view the Association would be glad, if desired, to send a small deputation to meet the Commissioners.

It would be of material assistance to the Association if it were possible for it to be supplied with an early copy

of the amending Bill, and I am instructed to ask whether the Commissioners are in a position to comply with this request, or whether it should be made to the Chancellor of the Exchequer.

I am, Sir,

Your obedient Servant,

(Signed) ALFRED COX,
Medical Secretary.

The Secretary,
National Health Insurance Joint Committee.

MEMORANDUM

ON POINTS WHICH THE BRITISH MEDICAL ASSOCIATION DESIRES TO SUBMIT FOR THE CONSIDERATION OF THE INSURANCE COMMISSIONERS WITH A VIEW TO SECURING SUCH AMENDMENTS OF THE NATIONAL HEALTH INSURANCE ACT OR REGULATIONS AS MAY BE NECESSARY.

EXCLUSION OF CERTAIN SERVICES FROM MEDICAL BENEFIT.

1. Before the passing of the National Insurance Act, the British Medical Association lost no opportunity of impressing upon the Government the strong objection of the medical profession to providing certain services in respect of the remuneration payable to the medical profession for medical attendance and treatment. These services are (a) the provision of the services of a second practitioner; (b) attendance on insured persons for diseases caused by their own misconduct; and (c) attendance on miscarriages and abortions or any conditions arising therefrom within 28 days.

(a) *Provision of the Services of a Second Practitioner.*

2. The Association desires to press for the amendment of either the Act or Regulations, or both, as may be necessary, in order that it may be made clear that a practitioner who finds it necessary for any purpose in connection with the medical attendance on any of the insured persons on his list, to obtain the services of another practitioner, shall not be compelled as a part of his agreement to provide such services. In accordance with paragraph 2 of the First Schedule to the

Regulations, Part I., a practitioner is bound to give to his patients "such treatment as is of a kind which can consistently with the best interests of the patient be properly undertaken by a general practitioner of ordinary professional competence and skill." The Association would submit that no practitioner should be expected or encouraged to give an anæsthetic while at the same time rendering some other service to the patient; in fact, it is generally recognised that such a practice is dangerous and should be discouraged.

3. An insured person has no claim upon any doctor except that one in whose list his name is included. It is difficult, therefore, to see on what grounds, either legal or otherwise, an insured person can be expected to be provided with the services of a second doctor without extra payment. As a matter of fact contract practice patients at the present time do not expect anything of the kind, but in view of the inclusion of the administration of a general anæsthetic in Sections B, C, D, E, and F, of Part II. of the First Schedule to the Regulations, insured persons will undoubtedly begin to claim as a right the services of two doctors when such are needed. The encouragement of such an idea can only lead to disappointment and dissatisfaction when the claim is refused, or to the adoption of the dangerous practice of the simultaneous giving of an anæsthetic and the performance of some other service by one practitioner if it is insisted on. The Association would, therefore, press, quite as much in the public interest as in that of the medical profession, for such amendment of the Act or Regulations as is above specified.

(b) *Attendance on Insured Persons for Diseases caused by their own Misconduct.*

4. The Association desires again to press for the exclusion from the services included under medical benefit of the treatment of those cases of illness brought about by the misconduct of the person claiming benefit. The Association would propose the deletion of the word "not" in the following paragraph at the end of Section 14 (4) of the Act, or the embodiment of the principle in some other suitable way:—

"Where under any such rule as aforesaid payment of sickness or disablement benefit is discontinued on the ground that the disease or disablement has been caused by the misconduct of the person claiming benefit, such person shall not thereby become disentitled to medical benefit."

(c) *Attendance on Miscarriages and Abortions.*

5. The Association finds that the objection which was expressed by the profession generally to the inclusion, among the services expected as part of medical benefit, of the treatment of cases of miscarriage and abortion, or any condition arising therefrom within 28 days, is as strong as ever. The Association would urge that it would be quite in accordance with the custom of all contract medical practice systems that such attendance should be paid for separately. These cases are often of the most troublesome kind and it is felt that the present rate of payment for medical attendance and treatment does not fairly cover cases of this nature. The Association, therefore, proposes to press for the addition of the following words to the end of Section 8 (6) of the Act:—

"Miscarriage or abortion or any condition arising therefrom within 28 days."

EXTRA PAYMENT FOR NIGHT CALLS.

6. It has always been recognised that there is a great risk that persons whose medical attendance is provided for them at an inclusive rate, and especially when the payment they make is an indirect one, will be tempted to make undue calls upon medical practitioners. The first three months of the operations of the Act have confirmed the universal opinion of the profession on this point. The Commissioners have themselves recognised the risk indicated by framing, and urging Insurance Committees to circulate, certain Model Rules which impose a penalty on insured persons who make frivolous calls upon their doctors. It is felt that there are serious difficulties in the way of enforcing such Rules, and as regards night visits—the great hughbear of a medical man's life—it is believed that the knowledge that practitioners were entitled to make a small charge in respect of each night call would act as a far more efficient deterrent on unnecessary calls at these hours than the Model Rules. Moreover, the liability to pay a small charge would not act as a deterrent in really serious cases. The Association desires, therefore, to press for such an amendment to the Act or Regulations as would enable a small charge to be made in respect of night calls.

INCOME LIMIT.

7. The fear of the profession that Section 15 (3) of the Act, authorising Insurance Committees to fix an income limit, would be more honoured in the breach than in the observance has been entirely verified by the experience of the past few months. The adoption of the principle by a very few Insurance Committees encourages the Association, however, to hope that the justice of its contention that people who are relatively well-to-do should not be allowed to take advantage of the contract medical arrangements under the Act, will eventually gain general recognition. In order that the principle should have a fair chance, which, under the present constitution of the Insurance Committees it has not now, the Association would urge for the amendment of the Act and Regulations so as to make it incumbent upon the Insurance Commissioners to require Insurance Committees to adopt a local income limit which, like most of the other arrangements proposed to be made between Insurance Committees and the medical profession, must be submitted for the approval of the Commissioners.

8. The Association desires further to press for the amendment of the Act so as to ensure that when the income from all sources of an insured person exceeds the sum of £160 per annum he shall be required "to make his own arrangements." This request seems to the Association to be extremely reasonable, because that limit is already recognised in connection with the voluntary contributor and several Insurance Committees have already fixed an income limit of £160 per annum for their areas without serious objection being taken. As a person who is required to make his own arrangements does not lose the benefit of the money he has subscribed for the purposes of the Act, and, in fact, would receive towards the cost of his medical attendance the sum of 9s., towards which he will only have subscribed the sum of 2s. 8d., the Association fails to see that there could be any reasonable objection to the present proposal.

9. The Association further presses for such amendment of the Act as will clearly define that in this case, as also in Section 1 (3), the term "total income from all sources" shall include any income which is independent of the personal exertions of the recipient, whether received as an allowance or otherwise.

10. It is felt to be necessary to press for such a definition because at the present time there are a good many cases in which the sons of well-to-do fathers, whose earned income is a very small portion of their total income, are taking advantage of the medical attendance provided under the arrangements made by Insurance Committees. Such persons do not need, and were never intended to receive, the medical attendance so provided.

COMPOSITION OF INSURANCE COMMITTEES.

11. During the progress of the National Insurance Bill through the Houses of Parliament the Association repeatedly drew attention to the unfairness of the composition of the Insurance Committees, and experience has only strengthened the *a priori* opinion that a Committee in which one interest is given a permanent majority over all the other interests combined is unlikely by reason of the nature of its composition to give fair consideration to questions in which the interests of the dominant party are directly involved. The Association quite appreciates the argument that the insured persons, being subscribers to the Insurance Funds, are entitled to considerable representation on the Committees, but the recognition of the force of this argument makes it difficult to understand why the employers who are also subscribers, are not represented. The Association believes that the administration of the Insurance Act by the Insurance Committees would be more efficient, and that there would be less risk of friction among the different sections of the Committees, if no one interest formed more than two-fifths of the total membership of the Committees. The Association accordingly proposes to urge the modification of Section 59 of the Act to this effect.

MEDICAL REPRESENTATION ON DISTRICT COMMITTEES.

12. The absence of any Regulations providing for medical representation upon District Committees is giving rise to dissatisfaction in many areas. Although the Association understood that the profession would have similar representation on the District Committees to that afforded on the Insurance Committees, the understanding was not embodied definitely in the Act or Regulations. The Association can conceive of no valid objection to effective representation of the profession on the District Committees and is of opinion that the matter should now be dealt with definitely in the Regulations. The Association desires therefore to press for the addition to Regulation 59 of a proviso in the following or similar words:—

"As regards such District Insurance Committees the medical representation thereon shall be in the same pro-

portion as is accorded to the medical profession on Local Insurance Committees."

SEAMEN'S NATIONAL INSURANCE SOCIETY.

13. Attention has been drawn to the absence of any representation of medical practitioners on the Committee of the Seamen's National Insurance Society. The reasonableness of the claim of the medical profession to representation on the Insurance Committees, which fulfil, as regards the general body of insured persons, the same functions as are fulfilled by the Seamen's National Insurance Society in regard to seamen, was recognised by Parliament, and the Association respectfully submits that the reasons which were admitted to be valid in the one case apply with equal force to the other. Certain questions have arisen which have necessitated informal negotiations between the Association and the Seamen's National Insurance Society, and the Association is of opinion that it would conduce to the efficiency of the administration of medical benefit by the Seamen's Society if the medical profession were represented upon its Committee in the same proportion as the profession is represented on the Insurance Committees. It is therefore suggested that Section 48 (5) of the Act should be amended by the insertion, after the word "proportions" in the 7th line of that Section, of the following or such other words as will secure the object desired:

"and of representatives of the medical profession of the United Kingdom in the same proportion as is accorded to representatives of that profession on Insurance Committees."

MEDICAL TREATMENT OF TEMPORARY RESIDENTS.

14. The Association has given full consideration to the numerous difficulties connected with the provision of medical attendance and treatment to insured persons temporarily absent from their homes. No objection has been raised to the system laid down in Regulation 22, namely, that in the case of an insured person who changes his residence permanently, the remuneration due to the profession should be divided between the doctors concerned, in proportion to the time for which each of these doctors is respectively responsible for the treatment of the person concerned. Strong objection has been taken, however, as was mentioned in a communication forwarded by the Association on May 16th, 1913, to the proposed deduction from the moneys due under their agreements to the medical profession in order to pay for medical attendance on persons changing their residence temporarily either because they are on holiday, or for reasons of health. The Association has already proposed that persons who are on holiday should not be entitled to medical treatment under the Act, and would again press this upon the attention of the Commissioners. The Association proposes to move for the amendment of the Act so as to secure the provision by the Government of a special central fund, quite apart from the moneys already allocated for medical benefit, to provide for the medical attendance and treatment of insured persons temporarily resident on account of ill-health.

15. The Association desires also to press for the amendment of the Act or Regulations as may be necessary, so as to provide that insured persons temporarily resident by reason of the nature of their occupation should be *required* to make their own arrangements, as has already been done by the Insurance Committees, on the instruction of the Commissioners, as regards travellers, actors, etc.

TERMS OF PRACTITIONERS' CONTRACTS WITH INSURANCE COMMITTEES.

16. The Association has been informed that agreements between Insurance Committees and practitioners have in many cases been drawn up by the former bodies, issued, and often signed, before the local Medical Committees have had an opportunity of considering the terms of the agreement. The Association is aware that by the terms of Regulation 7 (1) the Insurance Committees must consult the Local Medical Committee before determining the conditions of service which it is proposed to invite practitioners to accept. It is evident, however, that this is not sufficient to secure that the terms of the agreement really get full consideration by both parties to the contract, and the Association would submit that the draft Agreement should be submitted to the local Medical Committees before individual medical practitioners are invited to sign it, and in addition, that the Insurance Committee, in forwarding the draft agreement to the Commissioners for approval, should forward with it (i.) a statement to the effect that it has been submitted to the Local Medical Committee, and (ii.) a statement of the view thereon of the Local Medical Committee.

17. The Association desires therefore to press for (i.) the addition to Regulation 7 (1) of the following, or such other words as will secure the above-named object:—

"and shall before submitting such draft agreements for the approval of the Insurance Commissioners forward copies thereof to the Local Medical Committee and allow that body a reasonable time for consideration,"

and (ii.) the addition to Regulation 8 (a) of words to the following effect:—

"together with a statement that such draft agreement has been submitted to the Local Medical Committee accompanied by a copy of the observations of the Local Medical Committee thereon."

FEES OF MEDICAL PRACTITIONERS FOR ATTENDANCE UPON CONFINEMENTS IN RESPECT OF WHICH MATERNITY BENEFIT IS RECEIVED.

18. The Association has given careful consideration to the Provisional Regulations of the Commissioners dealing with the fees payable to medical practitioners for attendance upon certain confinements in respect of which maternity benefit is received. So far as the Association has been able to ascertain the profession is absolutely unanimous that the maximum fee of 15s. allowed under these Regulations is entirely inadequate. It may be mentioned also, that very considerable objection is taken to the shortness of the time allowed to the medical practitioners in these Regulations in which they may claim the fees provided. The opinion of the profession is being asked for upon various questions arising under these Provisional Regulations, and it is hoped that in the meantime no steps will be taken by the Commissioners to make the Regulations permanent. After these opinions have been received and considered, the Association will approach the Commissioners again upon the whole subject.

TERMINATION OF AGREEMENTS BETWEEN INSURANCE COMMITTEES AND PRACTITIONERS.

19. The Association desires to suggest that arrangements should be made whereby a practitioner desiring to withdraw from the local list shall be allowed to do so by giving three months' notice at any time. At present, apparently by the terms of Regulation 21 (2), a practitioner can only withdraw by giving one month's notice terminable at the date of revision of the list.

DEFINITION OF RURAL AREA.

20. The Association has frequently been asked to secure a proper definition of the term "rural area" as used in Regulation 30 (1). At the present time there is no uniformity of action and a good deal of confusion is being caused by the indefiniteness of the present Regulation. The Association would therefore urge that the words "in a rural area" should be deleted from the aforesaid Regulation so as to enable medical practitioners, if they so elect, to dispense medicines for insured persons on their list in all cases where their patients are more than a mile from a chemist on the list.

MEDICAL REFEREES.

21. The Association is being made aware, as no doubt the Commissioners are, that there is a growing feeling in favour of the appointment of medical referees in connection with the National Insurance Act, to which officers cases of alleged malingerers could be referred either by the Insurance Commissioners, Insurance Committees, Approved Societies, or by medical practitioners. The Association is strongly in favour of the appointment of such officers and would urge that the appointments should be made, not by Insurance Committees or Approved Societies but by the Commissioners. This method of appointment the Association believes would give these officers a status superior to that of officers appointed locally, and would prevent that local wire-pulling which would almost certainly occur if the appointments were made either by the Insurance Committees or by the Approved Societies. The Association is aware that under the terms of the Act the Commissioners already have the power to appoint such officers. The Association would urge the great importance at the inception of any scheme of this kind of the adoption of the principle that an officer of this importance should have reasonable security of tenure of office so that he may be enabled to act without fear or favour. In the case of whole time officers being appointed they should, in the opinion of the Association, be entitled to superannuation. The Association would suggest that all such officers, when appointed, should be removable by the authority by whom they are appointed, that is to say by one of the bodies of National Commissioners, with the consent of the National

Insurance Joint Committee, and not otherwise, and should not be appointed for a limited time only. In making this suggestion the Association has in view the position of the Medical Officer of Health, who, it is common knowledge, is often prevented from acting as he would like to do in the interests of the community, because he knows that if he happens by his actions to offend some of the members of the local body which employs him, and who may be directly or indirectly affected by his actions, he may lose his position. The Association is anxious that a state of things which is a blot on one public service should not be allowed to obtain in connection with the proposed new service, and it trusts that the Commissioners will at the beginning lay down such terms of appointment as will attract the very best kind of officer.

22. In order that the persons appointed to these important posts shall be practitioners whose professional position and personality shall be such as will make them acceptable to the profession of the area in which they will have to act, the Association would suggest that in any Regulations to be made dealing with the method of appointment of medical referees the following points should be included:—

(a) Provision whereby the Local Medical Committee of an area or, if necessary, the combined Local Medical Committees, shall be consulted as to whether medical referees for that area should be whole or part time officers.

(b) Provision whereby the Local Medical Committees concerned may make nominations for such appointments.

LOCAL MEDICAL COMMITTEES.

LIVERPOOL.

THE sixteenth meeting of the Committee was held at the Liverpool Medical Institution on May 27th. In the absence of the Chairman (Dr. Larkin) Dr. T. CLARKE (the Vice-Chairman) presided, and fourteen other members were present.

Temporary Residents.—The discussion upon Memorandum 159 I.C. with reference to temporary residents was resumed. The HONORARY SECRETARY stated that, as requested at the last meeting, he had sent the following letter to the Insurance Commissioners:

May 15th, 1913.

Gentlemen,

The Liverpool Local Medical Committee has had before it Memorandum 159 I.C., and I am instructed to ask you if you would be good enough to make clear the following points:

Taking, as the Memorandum does, the "case-value" of an insured persons at 27s., and supposing a person removes temporarily to another district, say for one month, and during that time is seriously ill, and then returns to his proper area, how much of the 27s. is taken from the fund in his own area to the Central Fund for paying the fees of the doctor in the area in which he was temporarily resident?

Again, I am stating a case which I understand has actually occurred: an insured person was seriously ill for some weeks, and was attended by his doctor here in Liverpool for six weeks. He was then sent by his doctor to Buxton, and remained there for a fortnight under a doctor's care. His illness still continued, and he went to Blackpool where, under the care of another doctor, he made good progress, and returned home in another fortnight. What portion of this man's "case-value" would be apportioned to Liverpool, Buxton, and Blackpool respectively?

I am further instructed to inquire what steps the Commissioners propose to take to ensure that the procedure outlined in Section 10 will be the "normal."

It seems to this Committee that if the state of affairs mentioned in Section 2 as the result of experience is allowed, the procedure of Section 10 will become exceptional rather than "normal."

I am, Gentlemen,
Yours faithfully,
W. T. D. ALLEN,
Honorary Secretary, Local Medical
Committee.

No reply had been received from the Commissioners, and it was decided to adjourn the discussion of the arrangements for temporary residents until the next meeting.

Expenses of Committee. The Honorary Treasurer, Dr. HAMILTON SHAW, stated that the circular which had been issued to every member of the profession in the Liverpool area, asking for a contribution of 5s. to cover the expenses of the Committee during the first year, had so far been responded to by 54 non-panel and 61 panel practitioners.

LEWISHAM.

A GENERAL meeting of all the practitioners in the borough of Lewisham was held on May 29th, at Catford, for the purpose of electing a committee which shall seek recognition as the Local Medical Committee under the National Insurance Act. The meeting was representative of all the practitioners in the Division.

The following Committee was chosen:

Chairman: Dr. S. Barnett.

Honorary Secretary: Dr. H. M. Bunday, Endrick Bank, Honor Park Road, S.E.

Drs. T. Atkinson, Charles Blue, Hudson Evans, A. Grayling, T. Halliwell, L. Hemmans, F. Hogg, A. M. Moore, H. Munro, Wheeler O'Bryen, C. Peacock, W. Wilson.

The meeting terminated with a vote of thanks to the Chairman, Dr. Thornton Comber.

The Committee then met, and instructed the Honorary Secretary to apply for recognition.

ELGIN AND NAIRN.

MEETINGS of the Elgin and Nairn Local Medical Committee was held in Elgin on May 1st and 22nd, Dr. TAYLOR, Chairman, presiding.

Temporary Residents.—After considering Memorandum 159 I.C., it was unanimously agreed to inform the Commissioners that the Committee could sanction no scheme involving any deduction from the 7s. contracted for, but that a case-value contribution from the Insurance Committee was preferable to one on a capitation basis.

Charges by Chemists.—It was agreed to protest against the neglect to consult the Local Medical Committees as to charges of chemists.

Extra Certificates.—It was agreed that one certificate only be given for the purposes of the Insurance Act, and that for other certificates desired a fee of 1s. be charged, the fee to be paid by the individual requiring it or by his society.

Medical Members of Local Insurance Committees.—A letter was read from the Secretary of the Insurance Commissioners (Scotland) which stated they were now prepared to appoint two other medical men to the Local Insurance Committee, and asking the Local Medical Committee to suggest the names of medical men for the appointments. It was unanimously agreed to send up the names of Dr. Cruickshank (Nairn) and Dr. Campbell (Elgin), who had previously been offered these appointments but, at the request of the Association, had declined them.

Mileage.—The question of mileage was again discussed, and it was unanimously agreed to press for "one mile free" instead of "three miles free," as at present proposed.

Rules of Conduct, etc., for Insured Persons.—The SECRETARY reported that the additional rule suggested by the Local Medical Committee in regard to Sunday work had been passed by the Local Insurance Committee in the following terms:

Unless in cases of urgent necessity, an insured person shall not summon a practitioner to visit him or her on Sundays, nor attend at the practitioner's surgery on Sundays for advice.

Deputies.—The Secretary was instructed to bring before the notice of the Local Insurance Committee the desirability of allowing the medical members of the Committee to be represented by deputies.

Attendance at Contract Rates outside Scope of Insurance Act.—The question of medical men in the area having accepted appointments to attend the wives and children of insured persons at contract rates, without the consent of the Local Medical Committee, was considered by the Committee and referred to the Division.

SURREY

THE eleventh meeting of the Surrey Local Medical Committee was held at Surbiton on May 23rd, when Dr. LANKESTER was in the chair and seventeen other members were present.

Mileage.—The HONORARY SECRETARY read a letter received by the Surrey Insurance Committee from the Insurance Commissioners *re* mileage, asking for further details as to patients residing beyond three miles from their doctor. The Secretary was directed to see that this question was brought to the notice of the doctors on the panel who had patients residing in inaccessible places.

Finance.—A resolution was carried unanimously that all practitioners on the panel be asked to contribute a sum of 5s. each, and that other medical practitioners in the county not on the panel be asked to contribute 2s. 6d. to meet the expenses of the Local Medical Committee and of the nine District Medical Committees during the year 1913. Dr. A. K. Walter, of Reigate, was appointed Treasurer.

District Medical Committees.—A resolution was carried asking all District Medical Committees to deal as far as possible with the Insurance Commissioners and the Surrey Insurance Committee through the medium of the Local Medical Committee.

Prescription Book.—A new prescription book, containing a carbon fixed to the back of each prescription sheet, was agreed upon.

Temporary Residence.—A discussion on the Insurance Commissioners' Memorandum 159/I.C. took place, and it was unanimously agreed to forward to the Surrey Insurance Committee and the Insurance Commissioners the following resolutions:

1. The Central Fund suggested in the Memorandum 159/I.C. is to be made up of certain (variable) deductions from the capitation fee at present due to panel doctors.
2. The amount of this fee, after being promised in the circular from the Commissioners, was finally established by being embodied in the stamped and signed agreement entered into between the various Insurance Committees and the individual doctors.
3. Speaking for the doctors whom it represents, this Committee cannot possibly consent to any such breach of contract as would be caused by the reduction in the capitation fee proposed by this Memorandum.

Fees for Certificates.—The Local Medical Committee also discussed the fees for extra certificates and continuation certificates, and resolved that, "in the opinion of the Local Medical Committee, extra certificates and continuation certificates, whether weekly or otherwise, should be charged for at a minimum fee of 1s." The Secretary was directed to bring this statement to the notice of all the practitioners in the county.

Franking of Correspondence.—The Local Medical Committee was also unanimous in its opinion that all correspondence between practitioners and either the Insurance Commissioners or Insurance Committee should be franked.

Maternity Benefit.—A resolution was carried that it is desirable that practitioners when called in to assist a midwife shall not accept a lower fee than one guinea, and that all medical men practising in Surrey be informed of this resolution.

Medical Representatives on District Insurance Committees.—The following medical practitioners were unanimously elected to serve on the nine District Insurance Committees in Surrey:

Wimbledon: Dr. Purcell.
 Reigate: Drs. Spencer, Palmer, and Mackenzie.
 Sutton: Drs. Cazalet, Cressy, and Wilson.
 Richmond: Dr. S. S. Burn.
 Barnes: Dr. Wiggins.
 Guildford: Drs. Butler, Wilcockson, Kendall, and Hussey.
 Woking: Drs. Brewer, Woolridge, Pearse, and Gardiner.
 South-Eastern: Drs. Jackson and Ellis.
 Kingston: Drs. Sully, Cran, Carver, and F. G. Owen.

The Surrey Local Medical Committee consists of:

Chairman: Dr. Lankester, Guildford.
Vice-Chairman: Dr. A. E. Evans, Kingston Hill.
Honorary Secretary: Dr. Fain, Leatherhead.
Treasurer: Dr. A. R. Walters, Reigate.
 Dr. Harold Bently, Mitcham; Dr. J. S. Burn, Richmond; Dr. Norman Carver, Surbiton; Dr. Cowie, Wimbledon; Dr. S. A. Clarke, Horley; Dr. H. R. Cran, Malden; Dr. Daniel, Epsom; Dr. Deas, Merton; Dr. Wm. McD. Ellis, Woldingham; Dr. Floyer, Egham; Dr. Gaynor, Redhill; Dr. Gripper, Wallington; Dr. Hodgson, Chertsey; Dr. H. N. Holberton, East Molesey; Dr. J. R. Johnson, Richmond; Dr. Kingsford, Woking; Dr. Lyndon, Haslemere; Dr. Maguire, Kew Gardens; Dr. L. C. Newton, Richmond; Dr. Partridge, Sutton; Dr. Martin Randle, Wimbledon; Dr. F. W. Robertson, Bletchingly.

SOUTHPORT.

The Southport Local Committee, which has been recognized by the Commissioners, is composed as follows:

Chairman: Dr. Brown.
Secretary: Dr. Penrose, 43, Houghton Street, Southport.
 Drs. Baildon, Bentall, Lawson Cairns, de Courcy, Dall, Edmiston, Harker, Henderson, Limont, Littler, MacKay, Mulholland, Murison, Pridie, Reid, Harris, Lewis.

SUPP. 2

Representatives on Insurance Committee.—Elected by profession: Drs. Littler and Penrose. Elected by Borough Council: Dr. Mulholland. Elected by Commissioners: Dr. Lawson Cairns.

Members of the Insurance Committee being Elected as Town Councillors.—Drs. Limont and Pridie.

Medical Members of the Medical Service Subcommittee.—Drs. Brown, Dall, and Harris.

Medical Benefit Subcommittee.—Dr. Penrose.

Finance Subcommittee.—Dr. Pridie.

A number of meetings of the Local Medical Committee have been held, and delegates had been to London on two occasions to consult with the Commissioners regarding the day-book and prescription forms and arrangements for attending temporary residents. The question as to whether contracting-out should still be urged was fully discussed, and it was finally resolved:

That in view of the fact that contracting-out has hitherto been practically refused by the Insurance Committee, the members of the panel recommend that it shall not be allowed now.

Payment for Sanatorium Benefit.—It was resolved that payment be by capitation.

Distribution of Residue of Patients.—The Committee has decided that the residue of patients should be distributed *pro rata* to the number of patients already on the lists.

Expenses of Local Medical Committee.—An appeal for 2s. 6d. each is made to the local profession to meet the expenses of the year.

Schedule of Operations.—The question of preparing a schedule of operations which should not be performed under the insurance contract was raised. The general feeling was that it would be better not to have a schedule, but that each case should be dealt with as it arose.

Arrangements with Chemists.—A deputation from the chemists was received to discuss their claim for extra fees in certain cases. After negotiations the following arrangements were ratified by both parties.

- (a) The chemists to be given a duplicate prescription in each case, but, in the event of a duplicate not being supplied, a penny fee to be allowed for copying.
- (b) Chemists agree to accept "Rpt. Mist." when date of previous prescription is mentioned; in the event of the date not being supplied, a penny fee to be charged.
- (c) Special dispensing fee for night and Sunday work not allowed.

Temporary Residents.—A special meeting of the Committee to which all the members of the panel were invited was held on May 28th, to discuss the question of attendance on temporary residents and Memorandum 161/I.C. There was a large attendance, and after full discussion the following resolutions were carried *nemine contradicente*:

That the members of the panel protest against any deduction being made from moneys due to them under the Insurance Act for the purposes of the scheme outlined in Memorandum 161.

That members of the panel refuse to accept the "green vouchers" after June 1st, and will only treat temporary residents as private patients until such time as suitable arrangements are provided by the Commissioners, unless holders of the vouchers be allocated by the Insurance Committee.

MEETINGS OF INSURANCE COMMITTEES.

MIDDLESEX.

Discretion of a Practitioner giving Domiciliary Treatment.

At the meeting of the Middlesex Insurance Committee on June 2nd the Sanatorium Benefit Subcommittee recommended:

That no insured person receiving domiciliary treatment be given tuberculin or other similar substance without the consent of the tuberculosis officer.

Dr. BRACKENBURY said that if the tuberculosis officer had advised that a particular case was one for domiciliary treatment, it seemed to him as a practitioner a monstrous thing to say to that practitioner, "Yours is the responsibility for treating this patient, but you shall not use this or that drug in giving the treatment." He imagined the object of the proposal was that doctors on the panel should not administer large quantities of an expensive drug, but at the same time, if a patient were receiving treatment from a doctor in his own house, that doctor must be

allowed to say what drugs he would use in the best interests of the patient. No doubt, from the nature of the case, tuberculin would not usually enter into the treatment of domiciliary cases, and doubtless the doctor would avail himself of the services of a tuberculosis officer, but the proposal of the Subcommittee placed medical practitioners in a position no self-respecting medical man should be expected to acquiesce in. Dr. Brackenbury moved that the recommendation should be referred back.

Mr. W. REGISTER seconded it, and suggested that the insertion of the words "without consultation with the tuberculosis officer" would meet the views of Dr. Brackenbury.

Dr. BRACKENBURY was afraid he could not accept that.

Mr. REGISTER and the CHAIRMAN (Mr. W. S. Glyn-Jones, M.P.) appealed to the Chairman of the Subcommittee to withdraw the recommendation, and the report was then by leave withdrawn.

INSURANCE NOTES.

LONDON.

Distribution of Unallotted Funds.

WITH reference to the point raised at the last meeting of the London Insurance Committee as to the legality of allocating funds accumulated in respect of insured persons who have not chosen a doctor (SUPPLEMENT, May 31st, p. 475), the Medical Benefit Subcommittee has prepared a case for the opinion of the law officers of the Crown. Notice of an amendment to make no distribution from the accumulated funds until after the complete assignment of insured persons amongst the doctors on the panel has been given.

REPORTS OF LOCAL ACTION.

LONDON.

PROPOSED TRANSFORMATION OF THE MEDICAL COMMITTEE FOR THE COUNTY OF LONDON.

SIR,—Last November, at open meetings of practitioners throughout the Divisions of the British Medical Association in London, representatives, of whom I am one, were elected to serve on a Medical Committee for the County of London. The stated purpose of this Committee was to supervise and protect the interest of medical practitioners in relation to the National Insurance Act, and it might become constituted a statutory Medical Committee if and when the terms of the Act in respect of medical benefit were approved by the profession. I need not remind your readers that medical opinion throughout almost the whole of London was, at the time, most hostile to the Act, and that the terms of the latter have not been approved by the profession. On the afternoon of Saturday, May 31st, I received the following telegram: "Urgent meeting, 429, Strand, Monday next (June 2nd), four. Raiment." Mr. Raiment could give me no information as to the object of this meeting. I ascertained, however, from another source that some project was afoot for the creation of a committee which should act as a statutory committee, and should be composed partly of members of the National Insurance Practitioners' Association and partly of others, but whether I was summoned to a meeting of some subcommittee or other body I did not know. Official information or official notice I had none. Not until Monday did I come to realize, and then not clearly, but by conjecture, that the meeting in question must be that of the Medical Committee for the County of London. I was unable to attend it owing to a pressing and prearranged engagement, but I subsequently learnt what occurred. At this conference, summoned so irregularly in such haste—almost indecent haste—with no published title or agenda, no indication of its purpose, there jumped, as it were, a proposal that the committee which I have shown to have been established under conditions absolutely prohibitive, should be utilized in the formation of a so-called statutory committee.

Stranger still is the fact that the proposal was carried, though not by an overwhelming majority, but in the teeth of vigorous dissent. Let it be noted that by this decision practitioners in the metropolitan Divisions unconsulted have been committed by certain of their representatives to a policy which they have never as a body approved, and which is now throughout a great part of the metropolitan

area unreservedly condemned. It must be obvious that the whole method of these proceedings is unconstitutional and as contrary to established rule. It must be equally manifest that it is impossible to found on such a basis the authority of a committee which can be statutory under the terms of the Act.

In the circumstances recorded recrimination would be both natural and easy. It would not be quite unjustified. I shall not resort to it, but I shall express my deep regret, which without doubt has existence elsewhere also, that men of fundamentally honourable character should in this case have been misled into courses which cannot be regarded as either straight or fair. There is not the professional way. Some alien influence has come in. Our hive has been invaded by the wax-moth, and these are its issues. It must be purged and a stronger, simpler plan of action prevail, or farewell to mutual confidence, the basis not only of medical but of all truly ordered life.—I am, etc.,

Islington, N., June 3rd.

B. G. MORISON.

** We have referred the above letter to Dr. Haslip, who was in the chair at the meeting. Dr. Haslip writes as follows:

I thank you for the opportunity to give at once the true facts of the meeting of the Provisional Medical Committee elected for the County of London on Monday last. The meeting was held at the urgent request of one of the representatives of the medical profession on the Insurance Committee for the County of London. The meeting followed upon a previous meeting, at which the two medical representatives were instructed to find out in what position our Committee stood in the question of applying for statutory recognition. The report of their interview with Sir Robert Morant and Dr. Smith Whitaker was given by Dr. Evan Jones and Mr. E. B. Turner, and I also gave the result of my interviews with Sir Robert Morant. After a long discussion, the suggestion that there should be a round table conference of seven members of this Committee with seven members of a committee elected last January by the medical men who were on the panel was agreed to by the meeting, which consisted of 33 members out of a possible 52. The proposal was carried by a proportion of over three-sixths to two-sixths. The seven representatives nominated will have to report again to a meeting of my Committee before any final decision is arrived at. I have no desire to answer the personal side of Dr. Morison's letter. As Chairman of the Committee I have endeavoured to have no personal opinion, and the charge of dishonourable conduct I pass in silence, but I really think that any one who knew the work of Mr. Turner and Dr. Evan Jones should have hesitated before writing a letter casting on them the slightest suspicion of being concerned in any action which was not straightforward and fair.

LEICESTERSHIRE AND RUTLAND PUBLIC MEDICAL SERVICE.

THE first annual meeting of this Public Medical Service was held at the Central Buildings of the Service, Bond Street, Leicester, on May 23rd. The chair was taken by Dr. R. WALLACE HENRY, and the officers for the year were elected as follows:

Chairman.—Dr. R. Wallace Henry.

Vice-Chairman.—Dr. J. B. Pike.

Treasurer.—Dr. Astley V. Clarke.

Secretary.—Dr. T. Arnold Johnston.

THE TREASURER presented a report of the legal and other expenses associated with starting the Service, and explained how they had been met from a guarantee fund.

Reports were received from the eleven subdivisions of the Service, showing that the numbers who had become subscribers by March 31st were as follows:

| | | | |
|----------------------|-----|-----|--------|
| Leicester Borough | ... | ... | 47,800 |
| Ashby and Bosworth | ... | ... | 6,500 |
| Barrow-on-Soar | ... | ... | 1,800 |
| Blaby | ... | ... | 5,000 |
| Coalville | ... | ... | 10,000 |
| Hinckley | ... | ... | 2,384 |
| Loughborough (urban) | ... | ... | 5,137 |
| Loughborough (rural) | ... | ... | 1,750 |
| Market Harborough | ... | ... | 1,000 |
| Malton | ... | ... | 5,250 |
| Rutland | ... | ... | 2,500 |

Total uninsured persons 89,321

The Secretaries stated that in some of the districts in which collectors had been unknown formerly, members were slow in joining during the first few months, but as the Service became more widely known the numbers were increasing rapidly. All the speakers expressed the satisfaction of the medical practitioners with the altered conditions.

SCOTLAND.

CONFERENCE WITH LOCAL MEDICAL COMMITTEES.

ARRANGEMENTS have been made for a conference between the Scottish Committee of the British Medical Association and the Local Medical Committees in Scotland to be held at the invitation of the Dundee Branch in the University College, Dundee, on July 4th, at 10.30 a.m. Notices of appointment of representatives and notices for the agenda must be sent to the Honorary Secretary of the Scottish Committee, Dr. George R. Livingston, 47, Castle Street, Dumfries, by June 20th.

IRELAND.

Medical Advisers.

THE latest device of the Irish Insurance Commissioners in order to overcome the failure of the panel system for medical certification in Ireland is to advertise for "medical advisers," at a salary of £130 a year; they will almost certainly be required to sign the medical certificates of those patients whose doctor is not on the panel. This action of the Insurance Commissioners will be much resented and strenuously opposed by the whole profession. The Dublin County Borough Local Medical Committee held a meeting last week to consider the matter, and passed a resolution that, in their opinion, no practitioner should apply for the post of medical adviser as at present advertised by the Insurance Commissioners; a copy of this resolution has been sent to all doctors in Dublin. The terms offered to the profession in Ireland by the Insurance Committee of the Irish parliamentary party prior to the passing of the Insurance Act have never been withdrawn, and they were a minimum capitation fee of 2s. 6d. and a maximum capitation fee of 3s. for each insured.

Limerick.

The Insurance Commissioners have decided to send two medical officers to Limerick for the purpose of furnishing certificates in the case of insured persons under the Act, of whom there are over 10,000 in the city; the local doctors refused to go on the panel at a capitation rate of 9d. for each insured person. At this rate there would be about £400 to provide the salary for these two medical men, but the salary offered is £130 a year with permission to engage in private practice.

Tuberculosis Administration.

Dr. Thompson of Omagh, who is acting as tuberculosis officer for co. Tyrone during the absence in London of Dr. O'Keefe, who was recently appointed by the county council to this post, points out the following absurdity incidental to the working of the Insurance Act by the Commissioners. He has had occasion to visit cases of pulmonary consumption scattered over the county, some on the borders of Derry, others near Cookstown, and one forty miles from Omagh on the shores of Lough Neagh. All these cases had been treated carefully and generously by the dispensary doctors without special fee. Dr. Thompson had to examine those cases recommended for sanatorium treatment, and report on them to the County Insurance Committee. Some he recommended, but others he had to advise against as their condition was too advanced. The county committee increased the grant to these latter cases by a few shillings each week. When this action came to the notice of the Insurance Commissioners they objected to the extra payment to the advanced cases (so ill and helpless that they cannot either support themselves or their families, or encourage in many little ways an effort to limit the spread of the disease within the limits of their own families) unless they are under the direct care of a doctor, who must not be a dispensary doctor. To get over this difficulty the Insurance Commissioners suggest that these cases should be attended by the tuberculosis medical officer located at Omagh, whose chief business should be and is of course largely administrative, consultative, and for inspection purposes. Could any suggestion be more

absurd than that this officer should have to undertake to treat a number of cases of advanced phthisis, for which very little can be done by any medical treatment, at distances varying from the centre to over forty miles? The Commissioners must know that in numberless country districts there is no other doctor than the dispensary doctor available, and that therefore these patients who are too advanced to be recommended for sanatorium treatment can be treated by nobody except the Poor Law medical officer.

INSURANCE ACT IN PARLIAMENT.

AMENDING BILL.

IN reply to Mr. G. Locker-Lampson, the Prime Minister said that he was not prepared to anticipate the terms of the measure, and in a later reply to Mr. John Ward, Mr. Masterman said that he hoped the measure would be introduced shortly.

REPORT ON WORKING OF THE ACT.

IN reply to Mr. James Hogge, Mr. Masterman said that he hoped to present to Parliament the reports of the Insurance Commissioners on the administration of the Act within a few days. The report would be a single volume covering the operations of the Joint Committee and the several Commissioners; but he was arranging for the reports of each of the National Commissions to be available in separate volumes.

MEDICAL BENEFIT.

Fishermen.

Mr. Fell, in a question, called attention to the conditions under which medical benefit is available for fishermen.—In reply, Mr. Masterman said that benefits under the Act were not withheld from fishermen except where they were not entitled to medical attendance and maintenance during sickness from their employer. Arrangements had been made whereby any insured persons, including fishermen, could when absent from their usual place of residence, obtain medical attendance and treatment from doctors on the panel in the area in which they were temporarily resident. A society which admitted fishermen or seamen could make special arrangements for enabling its members to obtain medical attendance at any ports in the United Kingdom on the production of their cards from panel doctors without payment. There was no necessity, therefore, for them to pay doctors' fees themselves, and consequently there was no provision for repayment.

ELIGIBILITY FOR DISABLEMENT BENEFIT.

Mr. MacCallum Scott asked whether an insured person now ill and in receipt of sickness benefit was entitled to keep on stamping his card himself, even though his illness lasted for more than twelve months, in order to complete 104 contributions, and so to qualify for disablement benefit.—Mr. Masterman said that such a person might if he chose pay the full weekly contribution, that is, his own and his employer's, even though his illness lasted for more than twelve months, in order to qualify for disablement benefit.

Doctors' Remuneration for Persons moving about.

Colonel Weston asked the Financial Secretary to the Treasury whether the regulations contained in Memorandum 159/I.C. involved deductions from the amount guaranteed to medical practitioners for each insured person; and, if so, whether the consent of the doctors had been obtained to such deductions; and, if not, what steps he proposed to take for the purpose of providing the minimum capitation fee guaranteed to the doctors by paragraph 22 of the explanatory statement issued by the Commissioners in December, 1912.—Mr. Masterman said: As I stated in reply to the hon. member for Nottingham on May 8th, a doctor is entitled under his contract with the Insurance Committee to be credited with a sum of 7s. in respect of each insured person for whose treatment he is responsible during the whole year. It follows that a deduction must be made from this sum in respect of every insured person for whom he ceases to be responsible during any portion of that year in order to pay the doctor who is in fact responsible for his treatment during that period.

Funds on account of Unallotted Persons.

Mr. Hall called attention to the money at the disposal of the London Insurance Committee in respect of those insured persons who had made no choice of medical men, and inquired as to its distribution, speaking of it as a "surplus" medical fund.—In reply Mr. Masterman said: The hon. gentleman is under a misapprehension. There is no surplus in the fund for medical benefit. The agreements entered into by the doctors on the panel of every Insurance Committee provide that the whole of the funds available for the medical treatment of insured persons under the arrangements made by the Insurance Committee shall be divided among the doctors who have entered into such agreements.

Mr. Worthington-Evans: Is the right hon. gentleman aware that there is said to be a sum of £30,000 or over unclaimed to the credit of the London Insurance Committee? What is going to be done with it?—Mr. Masterman: If it is stated, it must be a considerable misstatement. No money can be unclaimed, because all the money has to go to the doctors on the panel.

Medical Institutes.

Mr. Werthington-Evans asked whether payments had been withheld from medical institutes for medical benefit till recently; whether only 1s. 3d. a head was being paid for the quarter as against 1s. 9d. to the committees for the panel doctors; whether many unnecessary forms had had to be signed by the patients at the institutes; and for what reason these difficulties were put in the way of the institutes.—Mr. Masterman: Payments have been made in all cases in which the institute has been able to give the Insurance Committee and the Commissioners a reasonable assurance that it will be able to fulfil the conditions of medical benefit. The amount payable per member is not necessarily 1s. 9d. per quarter, but such sum, not exceeding 1s. 9d. per quarter, as is actually expended in providing medical attendance and treatment, and the amount of the advance payments must be limited accordingly pending evidence as to the expenses actually incurred. Where there is satisfactory evidence that more than 1s. 3d. has been expended, more than 1s. 3d. has been paid. The answer to the third part of the question is in the negative, and the fourth part does not arise.

Mr. Wing: Is the right hon. gentleman aware that these medical institutions are being bludgeoned out of existence by the regulations of the Insurance Commissions, and that when the Insurance Bill was passing through this House the Home Secretary promised equal treatment for medical institutions as for doctors on the panel which is not given at present?—Mr. Masterman: I think if the hon. gentleman looks into the matter he will see that that pledge has been fully carried out and that medical institutes are receiving for medical attention and treatment to insured persons exactly the same amount as doctors on the panels.

Mr. Worthington-Evans asked whether Insurance Committees had power to allocate members who had not selected a doctor to medical institutes, and whether such allocation was being made by the Wolverhampton Insurance Committee with the consent of the Insurance Commissioners.—Mr. Masterman said that the answer to the first part of the question was in the negative, and no such proposals had been submitted to the Commissioners by the Wolverhampton Insurance Committee.

Allotment Extraordinary.

In reply to Mr. Hunt, Mr. Masterman said that, under a scheme drawn up by the Medical Committee for adoption by the Insurance Committee, it was suggested that 600 insured persons living at Woodbridge should be allotted to three doctors living at Wickham Market. He added that the insured persons living at Woodbridge could have chosen a Woodbridge doctor, but that the Insurance Committee was now considering an arrangement which will make the proposed allocation unnecessary.

MATERNITY BENEFIT.

Mr. MacCallum Scott asked whether an unmarried mother who went to a hospital for her confinement and who had to pay a fee for admission to the hospital could have the amount of that fee refunded to her out of the maternity benefit.—Mr. Masterman said that if the sum that would have been due as maternity benefit had the

woman not entered a hospital was not applied for the relief or maintenance of the woman's dependants, or paid direct to the hospital under an agreement previously concluded to pay for her treatment, it was payable to the woman herself when she left the hospital, either in kind or in instalments, or in a lump sum as the society determined, and such money might be available for repayment of the fee for admission.

In reply to Mr. Gretton, who inquired as to the cases in which the maternity benefit had been abused and squandered for extraneous purposes while the woman was in want or neglected, Mr. Masterman said that very few cases of the kind referred to in the first part of the question had been brought to the notice of the Commissioners. Under Section 19 of the Act it was the duty of a husband who received maternity benefit to make adequate provision, to the best of his power, for the maintenance and care of his wife during her confinement, and for a period of four weeks after her delivery, and if he neglected or refused to do so he was liable, upon summary conviction, to imprisonment, with or without hard labour, for any term not exceeding one month.

*SICKNESS BENEFIT.**During Pregnancy.*

Mr. G. Locker-Lampson asked at what time sickness benefit terminated in favour of maternity benefit; whether, when an employed woman was approaching her confinement and was certified a month before confinement to be incapable of work, she was entitled to sickness benefit, and up to how long before confinement; and whether such a woman ceasing work one week only before her confinement would receive sickness benefit.—Mr. Masterman said that an employed married woman was entitled to sickness benefit under the ordinary conditions while she was incapable of work through illness resulting from pregnancy, in addition to the maternity benefit payable in respect of her own or her husband's insurance, and without regard to the date at which that benefit is due. Sickness benefit was payable from the fourth day of her being rendered incapable of work by illness, and was payable while she so remained incapable both before and after confinement.

Persons in Hospitals.

In reply to Mr. James Mason, Mr. Masterman said that a circular was being prepared for issue to all societies, explaining that they could make payments in respect of sickness benefit to hospitals in respect of the treatment of their members if agreements had been concluded for the purpose.

REMUNERATION TO MEDICAL OFFICERS OF HEALTH.

Mr. Hunt raised a question as to the power of Insurance Committees to vote payments to medical officers of health as had been done by the County Committee, which had voted 200 guineas to Dr. Howarth for his services to the Committee.—Mr. Masterman, in reply, said: "I am informed by the Insurance Committee that the sum mentioned was voted by them in consideration of the services rendered by Dr. Howarth as medical adviser of the Committee from the time when it was constituted in June, 1912, until March 25th last. The work performed by Dr. Howarth during this time obviated the necessity of the Committee obtaining alternative expert professional assistance, which would otherwise have been necessary or the administration of sanatorium benefit, and which would probably have cost much more than the sum paid to Dr. Howarth. Similar payments to medical officers of health for services of a like character have been voted by many other Insurance Committees, and have been approved by the Commission."

Sick Pay for the First Day.

In reply to Mr. Godfrey Locker-Lampson, Mr. Masterman said that to give full sick pay from the first day of certified illness instead of from the fourth day as at present arranged, and to give full sick pay—that is, 10s. for males and 7s. 6d. for females—to insured persons under 21 years of age, would involve an additional charge on the Exchequer of £1,200,000.

NUMBER OF VOLUNTARY CONTRIBUTORS.

In reply to Sir A. Griffith-Boscawen, Mr. Masterman said that the number of voluntary contributors according

to the latest returns was 20,500. In further reply to Sir A. Griffith-Boscawen, who inquired the reasons for the smallness of the number, in view of the fact that there were over two million persons qualified and that the number estimated by the actuary was 829,000, Mr. Masterman said that he had no doubt the chief reason why the number was so much below the estimate of the actuary was the campaign carried on against the Insurance Act.

INSURANCE COMMITTEES (ADMISSION OF PRESS).

Mr. MacCallum Scott called attention to the decision of the Berwickshire Insurance Committee to exclude the press from its meetings and inquired as to the arrangements which were proposed to be made to afford publicity to the doings of Insurance Committees.—Mr. Masterman said: I am informed that the Committee have made arrangements to supply an official report of their proceedings to the press. The Scottish Commissioners have not issued any regulations on this subject. I may say, however, that the English Commissioners, in reply to questions on this subject, have suggested that the provisions of the Local Authorities (Admission of the Press to Meetings) Act, 1908, should be treated as applicable to meetings of Insurance Committees.

GRANT TO THE HIGHLANDS AND ISLANDS OF SCOTLAND.

In reply to Major Hope, Mr. Masterman said that the whole of the special grant of £10,000 for medical benefit and service in the Highlands and Islands of Scotland would be expended for the benefit of insured persons only.

CORRESPONDENCE.

TEMPORARY ABSENTEES.

Dr. H. W. JACKSON (Middlesbrough) writes: I have read your leader on temporary absentees with great interest, and every panel practitioner will agree with you on the main question, that the Commissioners are not justified in making deductions from the local funds.

When, however, you appear to favour the methods suggested in the Memorandums, it will, I think, fill many of your readers with astonishment, as the panel funds in industrial areas would suffer a reduction far greater than the attendance received out of the area warrants. The Commissioners' calculations will not give a "case-value," but only a "record card value," and as a record card may contain particulars of many separate illnesses or "cases," the importance of this distinction is very marked.

The injustice of the scheme is in making a voucher card have the same value as a record card. The former has a very short currency, perhaps a week or two, and in no circumstances longer than three months; it will usually relate to one illness and have marked upon it a much smaller number of attendances than the average record card, which has a currency for a whole year.

In an industrial area the voucher cards will be issued chiefly to holiday makers and convalescent patients on a visit to the country or seaside for a week or two, and it is absurd to consider the attendance received at the same value as all the attendances obtained during the rest of the year whilst at home. The Commissioners would be much nearer realizing their ideals if they had suggested calculating the "attendance value" for each Committee's area, and making deductions from the total number of attendances on the voucher cards on this basis.

Dr. R. H. DRX (Sunderland) writes: I see in your article "Temporary Absentees" you say: "We are disposed to agree with those members of the Association who have expressed the opinion that if the justice of making any deduction be acknowledged, the method for forming and distributing the central fund is worthy of trial upon the understanding that should experience show it to operate inequitably it will be amended." I beg to disagree with you, and submit that the scheme bears on its face the stamp of inequity and injustice, both in the method for forming and for distributing the Central Fund.

First, with regard to the method for forming of the Central Fund. The so-called "case-value" is not a true case-value; it is the "annual patient value," the amount

received for treating a patient for a *whole year*. A true "case-value" should be estimated from the number of illnesses and not from the number of patients. The true "case value" is less than the "annual patient value" and the method for calculating the value as set out in the circular will inflate the Central Fund at the expense of the Local Fund. An important point to note is the fact that, however slight the ailment of a temporary absentee, the total annual value of that patient is debited against the Local Panel Fund and credited to the Central Fund. This would be unjust, as I will presently show, even if a true case-value, for the whole of the illness is not paid out of the Central Fund in all cases.

Now with regard to the distribution of the Central Fund. Having got the Central Fund, who should be paid out of it? The answer should be, the man who does the work. A consideration of a few cases will show that this will not be so under the scheme, but that the strange doctor alone will receive anything for the treatment of these cases, and the panel doctor will get nothing.

1. A man is attended by a Central Fund doctor during the whole of his only illness during the medical year. This man's case-value goes to the Central Fund, and the Panel Fund doctor gets nothing. This is somewhere near justice, as the Panel Fund doctor does no work; but it is open to the objection that the remuneration for the slight cases is taken away when all cases are treated on a flat rate. It is only in slight cases where the whole of the attendance will be given by the Central Fund doctor.

2. A man is attended by a Central Fund doctor for a very slight ailment. This case value for the year is credited to the Central Fund. On returning home the same man has a serious illness requiring attendance by the Panel Fund doctor for three months. The Central Fund doctor is paid for his work out of the Central Fund. The Panel Fund doctor gets nothing because the case-value has been debited against the Local Panel Fund and the Panel Fund doctor cannot claim against the Central Fund for attendance given to any patient on his list.

3. A man goes through a serious illness for which he is attended by his Panel Fund doctor. During convalescence the doctor orders a change of air, and while away the patient sees a Central Fund doctor once or twice. Again the Central Fund doctor is paid for his work, while the Panel Fund doctor gets nothing and has no remedy.

Further instances are not required to prove that the Central Fund is not equitably distributed.

The Central Fund, if not subject to charges for administration, will provide a rate of remuneration greater than the area from which the patient comes, for two reasons, both of which act unfairly on the Local Panel Fund doctor.

1. The method of calculating the "case-value" is wrong and gives too high a value; it is the "annual patient value."

2. It is not intended to pay out of the Central Fund, formed by pooling the "annual patient values of these cases, the whole of the treatment required by the patient for the whole year, but only that part of the treatment which is given by the Central Fund doctor. For the rest of the treatment given by the Local Panel Fund doctor no one is paid.

And this is a scheme which, in the words of its framers, "will secure strict equity in the necessary apportionment of funds between Committees, and consequently in the amount of remuneration available for doctors undertaking the medical treatment of such persons." This is the scheme which you think might be tried by the profession to see how it will work. I submit that it would be utter folly for the profession to work the scheme, which bears its bad qualities on its face for anyone who has eyes to see, and I hope neither the Editorial department nor the Medical department of the British Medical Association will do anything but oppose it.

SURPLUS PANEL FUNDS.

Dr. W. ROBERTS HARRIS (Stamford Hill) writes: Surely under the following sections of the Insurance Act and the National Health Insurance (Administration of Medical Benefit) Regulations the medical profession are entitled to the surplus money in the panel fund:

1. Section 65 of Insurance Act gives power to make Regulations which have the same force as the Act itself.
2. The National Health Insurance (Administration of Medical Benefit) Regulations, Part IV, Section 40, par. 3, provides for the division of the money in the panel fund amongst the practitioners in the ratio of their accounts.

British Medical Association.

EIGHTY-FIRST ANNUAL MEETING,
BRIGHTON, JULY, 1913.

PROGRAMME OF BUSINESS.

President: Sir JAMES BARR, M.D., LL.D., F.R.S.E.,
Consulting Physician, Royal Infirmary, Liverpool.

President-elect: WILLIAM AINSLIE HOLLIS, M.A., M.D.,
F.R.C.P., Consulting Physician, Sussex County Hospital,
Brighton.

Chairman of Representative Meetings: THOMAS JENNER
VERRALL, M.R.C.S., L.R.C.P., Consulting Surgeon, Sussex
County Hospital, Brighton.

Chairman of Council: JAMES ALEXANDER MACDONALD,
M.D., LL.D., M.Ch., R.U.I., Honorary Physician, Taunton
and Somerset Hospital, Taunton.

Treasurer: EDWIN RAYNER, M.D.Lond., B.A., F.R.C.S.
Eng., Consulting Surgeon, Stockport Infirmary, Stockport.

The Eighty-first Annual Meeting of the British Medical Association will be held in Brighton in July, 1913. The President's Address will be delivered on Tuesday, July 22nd, and the Sections will meet on the three following days. The Annual Representative Meeting will begin on Friday, July 18th, at 10 a.m.

The Address in Medicine will be delivered by Professor GEORGE R. MURRAY, M.D., F.R.C.P., Physician, Royal Infirmary, Manchester, on Wednesday, July 23rd.

The Address in Surgery will be delivered by Sir BERKELEY MOYNIHAN, M.S., F.R.C.S., Surgeon, Leeds General Infirmary; Professor, Clinical Surgery, University, Leeds, on Thursday, July 24th.

The Popular Lecture will be delivered by EDMUND JOHNSON SPITTA, L.R.C.P.Lond., M.R.C.S.Eug., Hove, Brighton, on the evening of Friday, July 25th.

THE SECTIONS.

The scientific business of the meeting will be conducted in sixteen Sections, which will meet on Wednesday, July 23rd, Thursday, July 24th, and Friday, July 25th.

The President, Vice-Presidents, and Honorary Secretaries of each Section constitute a Committee of Reference for that Section, and exercise the power of inviting, accepting, or declining any paper, and of arranging the order in which accepted papers shall be read. Communications with respect to papers should be addressed to one of the Honorary Secretaries.

A paper read in the Section must not exceed fifteen minutes, and no subsequent speech must exceed ten minutes.

Papers read are the property of the British Medical Association, and cannot be published elsewhere than in the BRITISH MEDICAL JOURNAL without special permission.

BACTERIOLOGY AND PATHOLOGY.

*Municipal Training College, Class Rooms 4 and 5,
Second Floor.*

President: J. W. H. EYRE, M.D., M.S., London. *Vice-Presidents:* G. MORGAN, F.R.C.S.Edin., Brighton; MYER COPLANS, M.D., Leeds; Professor E. J. McWEENEY, M.D., F.R.C.P.I., Dublin. *Honorary Secretaries:* H. MILLER GALT, M.B., F.R.F.P.S., Sussex County Hospital, Brighton; J. A. BRAXTON HICKS, M.D., Westminster Hospital, London, S.W.; C. H. BENJAM, M.D., M.R.C.P., 27, Sackville Road, Hove.

The following is the provisional programme:

Wednesday.—Papers:

FARRANT, Mr. R. (London). Hyperthyroidism.
MCWEENEY, E. J., OROFTON, W. M., and MOORE, H. F. On Paratyphoid Infection.
GALT, Mr. Miller. On the Value of the Blood Count in Obscure Bacterial Infections.

Thursday.—Joint discussion with the Section of Pharmacology, Therapeutics, and Dietetics on Anaphylaxis: To be opened by Professor W. E. DIXON; followed by Professor G. Sims Woodhead (General Pathological Aspects), Drs. Thiele and Embleton (Special Bacteriological Aspects), E. W. Goodall (Clinical Aspects), H. H. Dale (General Experimental Point of View).

Papers:

COPLANS, Myer (Leeds). On the Action of Asbestos and other Finely Divided Substances on certain Toxins, Ferments, Protein, and other Materials.

COPLANS, Myer, and LLOYD, Mr. W. Gibbs. On the Action of Asbestos on Certain Physiological Substances.

Friday.—Papers:

The Staff of the John Howard McFadden Research Fund. Some Researches on the Jelly Method of Staining Cells Alive.
BUCHANAN, Dr. R. M. (Glasgow). On *Empusa Muscae* as a Trajector of Bacterial Infection.

LYONS, Mr. W. C. On the Specific Diagnostic and Therapeutic Value of Protease-free Tuberculin.

GALT, Mr. Miller. Microscopical Demonstrations on Haematology.

SECTION OF CLIMATOLOGY AND BALNEOLOGY.

Municipal Technical School, Room 13, Ground Floor.

President: F. J. PALEY, M.D., Hove. *Vice-Presidents:* R. WHITTINGTON, M.D., B.Ch., Brighton; W. GORDON, M.D., F.R.C.P., Exeter; R. ACKERLEY, M.B., B.Ch., Llandrindod Wells. *Honorary Secretaries:* A. H. COPEMAN, M.D., Pavilion Parade, Brighton; D. DURWARD BROWN, M.D., Norfolk Lodge, Leeds Road, Harrogate.

The following programme has been adopted:

Wednesday.—Discussion on Sea Bathing: To be opened by Dr. W. J. TYSON.

Thursday.—Discussion on International Aspects of British Health Resorts: To be opened by Dr. NEVILLE WOOD.

Friday.—Papers.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Sea Bathing.—(Dr. W. J. TYSON.) The literature of the subject in this country is scanty, but a good deal of work has been done by French and German writers. The subject naturally divides itself in the first place: (1) Sea water (composition, temperature, physical characteristics, and the immediate action of it on the skin and body generally). (2) Sea air (its composition, temperature, humidity, and their effects on the body). (3) The character and situation of the seaside resort—(a) aspect; (b) amount of verdure, (c) protection by cliffs and hills, (d) prevailing winds, and (e) bathing facilities). (4) Treatment by sea bathing. This will be under following heads: (a) Condition of the bather, (b) season or time of year, (c) time of day for bathing, (d) duration of stay in the sea, (e) mode of bathing, (f) frequency of bathing, (g) after the bath. Finally will be discussed the diseases that are benefited by sea bathing, some of the ills and minor ailments caused by it, and the diseases that are not improved by bathing.

Discussion on International Aspects of British Health Resorts.—(Dr. NEVILLE WOOD.) The term "health resort" will be used as implying a place to which patients are usually sent for a comparatively limited time and for a definite course of treatment, and as the equivalent of the German word *Kurort*. Hitherto the policy of British municipalities has been to beg the leaders of opinion to set their faces against the exodus to foreign resorts. Abroad the countries which make the least effort to keep their nationals at home reap the richest harvest from the health resort industry. Yet, notwithstanding their success in attracting foreigners, the natives are not outnumbered, for prestige achieved abroad enhances that enjoyed at home. It is this lack of international prestige which makes it difficult to convince many British invalids that British health resorts do not occupy a lower plane than those of the Continent. The remedial use of climates and baths is so well understood in the great medical centres abroad that there should be little difficulty in getting a hearing and securing a favourable

verdict when the value of British resorts for certain categories of foreign invalids has been sufficiently explained. It can be shown that Great Britain possesses spas of the highest rank, with a great variety of mineral waters from the weakest to the most concentrated in Europe, and well equipped for physiotherapy. Inland there are towns and villages now almost stationary in population which are awaiting a new stimulus for further development. Information as to such places is invited. In regard to Britain it is asked to what extent does it desire to be regarded as a resort? Is there any month in which it should be excluded from that category? It has been asked whether there is room at British resorts for any considerable number of visitors from abroad. The answer seems to be that the gain to those places whose chief season is in summer would arise from the fact that visitors from the Continent usually arrive in May or June, when they are not by any means overcrowded; while Americans come in the greatest numbers during the autumn months.

DERMATOLOGY.

Municipal Training College, Men's Common Room.

President: J. H. SEQUEIRA, M.D., F.R.C.P., London.
Vice-Presidents: A. W. WILLIAMS, M.B., Brighton; F. H. BARENDT, M.D., F.R.C.S., Liverpool; W. GRIFFITH, M.B., M.R.C.P., London. *Honorary Secretaries:* A. M. DALDY, M.D., F.R.C.S., 17, Palmeira Square, Hove; F. GARDINER, M.D., F.R.C.S. Edin., 60, George Square, Edinburgh.

The following subjects have been chosen for discussion on two of the days of the meeting:

(1) The Fungous Affections of the Glabrous Skin: To be opened by Dr. H. G. ADAMSON. (2) The Nature, Varieties, Causes, and Treatment of Lupus Erythematosus: To be opened by Dr. J. M. H. MACLEOD, followed by Dr. ALFRED EDDOWES, and others.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Fungous Affections.—(Dr. H. G. ADAMSON.) Recent observations and research have revealed the wide extension and the importance of diseases due to infection by mould fungi. The part of the subject to be dealt with here—Fungous Affections of the Glabrous Skin—may be conveniently considered under the following headings: (1) Ringworms of the Body (*Tinea Circinata*) and Pityriasis Versicolor. (2) Ringworm of the Groin (*Eczema Marginatum* or *Tinea Cruris*) and Erythrasma. (3) Ringworms of the extremities simulating Eczema. (4) Favus of animal origin. (5) Actinomycosis and Sporotrichosis and allied infections. Among other points which demand attention on account of their interest and of their practical utility are: The establishment of the plurality of these pathogenic fungi—of Ringworm, of Favus, of *Tinea Versicolor*, of Actinomyces, and of the more lately studied *Sporotrichum*; the importance of the comparatively recently acquired knowledge of the animal origin of many of these affections; the contrast between the superficial infections of Ringworm, *Tinea Versicolor*, Favus, etc., and those, such as Actinomycosis and Sporotrichosis, which may invade also the lymphatics, the bones, and the viscera; the question of the degree of immunity against further attacks produced by these various diseases; the method of contagion in epidemics of *Tinea Cruris*, a disease the causative fungus of which is distinct from those of all the animal ringworms and from other kinds of human ringworm; whether the rarity of Sporotrichosis in this country is real or merely apparent, and due to its confusion with cases of tertiary syphilis and of tuberculosis.

Discussion on Lupus Erythematosus.—(Dr. J. M. H. MACLEOD.) A description of the clinical varieties, namely, three—circumscribed or discoid types, lupus pernio, and the acute disseminated type. The histological characteristics: The primary and essential changes occur in the corium, those in the epidermis being secondary. Its nature and causation: (a) The arguments in favour of a tuberculous theory, namely: (1) In a certain number of cases of lupus erythematosus there is a personal evidence of tuberculosis, or a family history of the disease. (2) The clinical appearances of the lesions of lupus erythematosus may so closely resemble those of lupus vulgaris as to render the

differential diagnosis difficult or almost impossible. (3) Lupus erythematosus may occur in association with lesions of the so-called toxi-tuberculide type, and according to certain writers belongs to the same category. (b) The arguments against this theory, namely: (1) Tubercle bacilli have never been found in the lesions of lupus erythematosus. (2) Inoculation experiments with excised tissue in susceptible animals have given negative results. (3) The histological architecture is totally unlike that produced by the reaction of the tissue to the presence of the tubercle bacillus and its toxins in the skin. (4) There is no record of a tuberculin injection having been followed by an outbreak of lupus erythematosus. (c) The arguments in favour of its toxic origin, namely: (1) Tendency to a symmetrical distribution of the lesions. (2) Close resemblance of certain cases, especially of the acute disseminated type to the toxic erythematata (*E. multiforme*). (3) The association of cases of the acute disseminated type with general toxæmia and visceral disease. (d) The relation of lupus erythematosus to circulatory disturbances. Conclusions. Lupus erythematosus is not a morbid entity due to one specific cause, but may be called forth by a number of different causes in predisposed individuals. The chief predisposing causes are age, sex, type of skin, and a defective peripheral circulation the result of general or local causes. The direct causes consist of: (a) Toxin circulating in the cutaneous blood vessels and acting on the vessel walls. (b) Local causes, such as extremes of temperature, traumatism, bites from insects, etc. It is dependent on a delicacy of the affected part in which the circulation is so depressed and feeble that local injury or the presence of toxins in the blood of the cutaneous capillaries cause so profound and lasting a disturbance that recovery from it without loss of tissue is impossible. Methods of treatment: General and local.

The exhibition and demonstration of cases will be an important feature of the Section, and arrangements will be made for the demonstration of cases on the Thursday and Friday.

DISEASES OF CHILDREN, INCLUDING ORTHOPAEDICS.

*Municipal Training College, Class Room 2,
First Floor.*

President: G. F. STILL, M.D., F.R.C.P., London.
Vice-Presidents: W. C. CHAFFET, M.D., Hove; L. A. PARRY, M.D., F.R.C.S., Hove; A. F. VOELCKER, M.D., F.R.C.P., London; P. N. BLAKE ODGERS, F.R.C.S., Northampton. *Honorary Secretaries:* A. G. BATE, M.B., F.R.C.S. Ed., 8, Palmeira Avenue Mansions, Hove; A. E. NAITSH, M.B., M.R.C.P., 5, Clarkehouse Road, Sheffield.

The following discussions have been arranged:

Wednesday.—Affections of the Heart in Childhood: To be opened by Dr. F. J. POYNTON and Dr. CAREY COOMBS.

Thursday.—The Choice of Methods in dealing with Paralytic Deformities in Children: To be opened by Mr. T. H. OPENSHAW, C.M.G.

Friday.—The Diagnosis and Treatment of Acute Inflammatory Conditions of the Abdomen in Children: To be opened by Mr. C. B. LOCKWOOD.

Thursday.—Paper:

Professor FOERSTER (Breslau). Posterior Root Section in the Treatment of Spastic Paralysis.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Affections of the Heart.—(1) (Dr. POYNTON.) This will deal with the subject chiefly from the point of view of prevention. Allusion will be made to the importance of infection as a cause of heart disease, and opinions invited upon the relative importance of non-infective causes, such as overstrain, anaemia, etc. The bearing of these various causes upon prevention will be touched upon. The value of a study of the morbid anatomy of cardiac infections will be emphasized, as also the assistance afforded by the study of experimental carditis. The bearing of these studies upon the prevention of heart disease will also be considered. The symptomatology will be approached from the same aspect, and particular attention drawn to the rôle of the tonsils, and to a group of cases in which

tonsillitis and *morbus cordis* occur without other definite manifestations of illness. The symptoms of myocardial weakness will be considered and the assistance that new methods of investigation may afford in this direction referred to and the experiences of others cited. While admitting the great importance of myocardial lesions, Dr. Poynton will also direct attention to certain valvular lesions which take the prominent part in the course of *morbus cordis* in these particular cases. The difficulties that surround the symptomatology of heart disease in the young will be considered from the standpoint of prevention. The great need for preventive measures will be exemplified by the unsatisfactory position of the treatment of rheumatic heart disease at the present time, and the position of the salicylates and the value or otherwise of vaccine (specific immunity) methods put before the Section. Brief allusion will be made to some of the other cardiac infections, with the intention of obtaining from the various speakers their views as to their relative frequency as compared with the rheumatic. Some personal observations will be made upon the use of theolin-sodium acetate, anasarcin, and campher in heart affections. Lastly, the various indications for prevention will be put forward as his particular contribution to the discussion.

(2) Dr. CAREY COOMBS will deal, first, with the necessity of recognizing the nimportant nature of certain cardiac disturbances in childhood, and secondly, with the factors determining prognosis in the acquired heart disease in childhood, with special reference to cardiac rheumatism.

ELECTRO-THERAPEUTICS.

Municipal Training College, Library.

President: W. DEANE BUTCHER, M.R.C.S., London. *Vice-Presidents:* C. F. BAILEY, M.D., M.R.C.P., Brighton; A. F. HERTZ, M.D., F.R.C.P., London; W. IRONSIDE BRUCE, M.D., London. *Honorary Secretaries:* W. B. PROWSE, M.R.C.S., 31, Vernon Terrace, Brighton; L. E. CREASY, M.R.C.S., L.R.C.P., 36, Weymouth Street, London, W.

The following is the preliminary programme:

Wednesday.—Papers and discussions on Roentgen Diagnosis.

Thursday.—Papers and discussions on Electro-diagnosis and Electro-therapeutics.

Friday.—Papers and Discussions on Roentgen Therapy and Radium.

There will be an exhibition of radiographs (negatives, prints, and lantern slides), and of photographs of cases treated by electro-therapeutic methods, α rays, and radium. Members desirous of exhibiting are requested to communicate with Dr. Prowse.

GYNAECOLOGY AND OBSTETRICS.

Municipal Training College, Women's Common Room, Ground Floor.

President: R. SANDERSON, M.B., Hove. *Vice-Presidents:* CONSTANCE E. LONG, M.D., London; T. H. IGNIDES, M.B., F.R.C.S., Hove; R. J. JOHNSTONE, M.B., F.R.C.S., Belfast; Professor BENJAMIN P. WATSON, Toronto. *Honorary Secretaries:* LOUISA MARTINDALE, M.B., B.S., 10, Marlborough Place, Brighton; W. RITCHIE, M.B., 10, St. James Terrace, Glasgow.

The following is the preliminary programme:

Wednesday.—Discussion on the Best Methods of dealing with Malpositions of the Uterus, especially with reference to Retredisplacements and Prolapse.

Thursday.—Discussion on Affections of the Urinary Tract complicating Pregnancy.

Friday.—Short Papers and Pathological Demonstrations.

LARYNGOLOGY, RHINOLOGY, AND OTOTOLOGY.

Municipal Technical School, Room 45, Second Floor.

President: A. J. HUTCHISON, M.B., Brighton. *Vice-Presidents:* H. S. BARWELL, F.R.C.S., London; O. E. WOAKES, London. *Honorary Secretaries:* A. J. MARTINEAU, F.R.C.S. Edin., 22, Cambridge Road, Hove; W. S. SYME,

M.D., 10, India Street, Glasgow; E. D. DARELAN DAVIS, F.R.C.S., 81, Harley Street, London, W.

The following programme has been arranged:

Wednesday.—Discussion: The Technique and After-Treatment of the Radical Mastoid Operation.

Thursday.—Discussion: The Care of Patients after Operations on the Nose and Naso-Pharynx. To be opened by Mr. HERBERT TILLEY.

Friday.—Papers.

The following paragraph indicates the line that will be taken by the opener of the second discussion:

Discussion on Operations on the Nose and Naso-pharynx.—(Mr. TILLEY.) The introducer will refer only to operations frequently performed and speak solely from his own experience. (1) *Galvano-cautery:* Necessity for cleansing nasal passages previous to operation. Application of antiseptic to eschar. Danger of septic infection by way of eschar—a personal experience. (2) *Anterior Turbinatectomy:* Two complications to be guarded against: (a) Post-operative haemorrhage; (b) septic infection, which may lead to inflammation of tonsil or middle ear. (3) *Removal of Posterior End of Inferior Turbinal:* Chief complication is post-operative bleeding, often as late as the seventh or eighth day. Means of minimizing this risk by slowly removing enlargement by wire snare without previous application of cocaine or adrenalin, rest in bed, and avoidance of any straining movements. (4) *Sub-mucous Resection of Septum:* (a) Post-operative bleeding. Its chances minimized by careful packing of nasal cavities after operation by means of suitable plugs which can be easily removed. (b) Septic infection. The value of tr. iodine as a means of sterilizing the "vestibule," and the area of operation. (c) Laxity of mucous membrane septum after operation in cases of morbid deviation and the justifiability of making a large perforation. A warning on the use of nasal donches as a means of cleansing the nasal cavities and the little risk of using a coarse nasal spray. *Nasal Polypi:* The necessity for allowing a due interval of time between successive operations when the cold snare is used. The avoidance of the galvano-cautery following removal by the snare. Curettement of the ethmoid for polypi a more serious operation. Need for rest in bed for two or three days, and then careful cleansing and avoidance of septic infection. *Operations on Maxillary Antrum:* (a) Alveolar perforation only advisable in acute cases of dental origin. Irrigation until purulent discharge ceases. A plug preferable to a tube. (b) Caldwell Luc method. Little after-care required beyond rest in bed for three days, followed by careful intranasal irrigation of antrum through suitable cannula. (c) Simple intranasal operation to establish a free antral opening. In both operations the healing is favoured and absence of after-complications minimized by washing the pus out of the antrum immediately before the operation. *Frontal Sinus Operation:* (A) Acute inflammation. (a) Intranasal method. Irrigation only necessary together with measures directed to improve general resistance of patient. (b) External operation. Maintenance of free drainage until inflammation of mucous membrane has ceased, when external wound may be allowed to close. (B) Chronic empyema. (a) Intranasal method. Irrigation after removal of middle turbinal and any obstructing anterior ethmoidal cells. Daily irrigation to be followed by injection of milder or stronger antiseptics. (b) External operation. Necessity of very gently removing mucous membrane and establishment of free intranasal and external drainage. *Sphenoidal Sinus Operation:* After-treatment almost entirely limited to keeping opening patent; methods of attaining this end. *The Operation for Adenoids:* Need of rest in bed for three or four days. Value of breathing exercises after the operation in certain cases of defective chest development. Summary. Operations within the nasal cavities or in the naso-pharynx are little liable to complications, and demand little in the way of after-treatment if (a) the parts are rendered as aseptic as possible previous to operation, (b) the surgeon's instruments are aseptic, (c) free drainage be provided for.

Arrangements have been made to exhibit preparations, specimens, drawings, or any instruments or apparatus appertaining to the work of the Section in the Annual Pathological Museum. Such exhibits should be sent to Mr. A. J. Martineau, 22, Cambridge Road, Brighton.

MEDICAL SOCIOLOGY.

Municipal Technical School, Room 21, Ground Floor.

President: R. J. RYLE, M.D., M.A., J.P., Brighton.
Vice-Presidents: G. E. HASLIP, M.D., London; H. GERVIS, M.B., J.P., Brighton. *Honorary Secretaries:* E. R. FETHERGILL, M.B., B.S., 38, Dyke Road, Brighton; H. D. LEDWARD, M.A., M.B., 123, Norton Way, Letchworth, Herts.

The following subjects have been chosen for discussion:

1. Crime and Punishment. Dr. CHARLES MERCIER, Sir BRYAN DONKIN, M.D., and Dr. JAMES SCOTT will read papers on different aspects of this subject as an introduction to a general discussion.

2. Hospitals in Relation to the Stage, the Public, and the Medical Profession. Sir HENRY BURDETT, K.C.B., and Mr. I. G. GIBBONS, D.Sc., will read papers on this subject, and their discussion will, it is hoped, prove valuable in helping to elucidate the problems involved in providing hospital accommodation for insured persons under the National Insurance Act.

3. Eugenics. It is expected that the discussion on this subject will be introduced by Professor BATESON, and that he will be followed by Dr. Stewart Mackintosh (Hampstead) and Mr. Benedict Davenport (New York).

MEDICINE.

Municipal Technical School, Room 30, First Floor.

President: E. HEBHOUSE, M.D., F.R.C.P., Hove. *Vice-Presidents:* J. F. GORDON DILL, M.D., M.R.C.P., Hove; R. HUTCHISON, M.D., F.R.C.P., London; W. BROADBENT, M.D., M.R.C.P., Hove; A. P. BEDDARD, M.D., F.R.C.P., London. *Honorary Secretaries:* DONALD HALL, M.D., M.R.C.P., 29, Brunswick Square, Hove; T. FRASER, M.B., 45, Elmbank Terrace, Aberdeen; W. LANGDON BROWN, M.D., F.R.C.P., 60, Welbeck Street, London, W.

The following programme has been adopted:

Wednesday.—Discussion on Non-diabetic Glycosuria. To be opened by Dr. A. E. GARROD, F.R.S.

Thursday.—Discussion on Fibrositis and Muscular Rheumatism. To be opened by Dr. A. P. LUFF.

Friday.—Papers.

The following paragraphs indicate the line that will be taken by the openers of the two following discussions:

Discussion on Non-diabetic Glycosuria.—(Dr. A. E. GARROD.) Diabetes is not a single disease, but a symptom-complex. The pathological and clinical classification of glycosurias. From a pathological standpoint most glycosuria is diabetic. Clinical classification: False glycosuria. Lactosuria, laevulosuria, pentosuria. The so-called renal diabetes: Its characteristic features and uncertain prognosis; it is probably less rare than has been supposed; a truly non-diabetic glycosuria. Temporary glycosuria, true and apparent: The glucose test and its clinical importance; alimentary glycosuria *ex amylo*. The question of recovery from diabetes; difficulty of being sure that recovery is permanent. Symptomatic glycosuria; glycosuria in infective maladies. Glycosuria with diseases of the ductless glands: Thyroid, pituitary, adrenalin glycosuria. Glycosuria with intestinal disorders: The rôle of the pancreas. Glycosuria with cerebral lesions: Puncture diabetes and its allies. Toxic glycosuria. Conclusions: Importance of glycosuria as a symptom. Need of further investigations, especially of cases of temporary glycosuria. Difficulties of such investigations.

Discussion on Fibrositis and Muscular Rheumatism.—(Dr. A. P. LUFF.) *Pathology:* Essentially an inflammatory hyperplasia of the white fibrous tissue, associated with exudation and proliferation of the connective tissue elements. Structures affected. Indurations. Toxic causation. Microbic causation probably a rare occurrence. Reference to work of Geadby and Ware. *Etiology:* Cold, damp, and wet. Extremes of heat and cold. Local injuries. Absorption of irritating toxins from the alimentary tract. Toxic or microbic infection from oral sepsis, tonsillitis, pharyngitis, influenza, febricula, etc. *Various Forms of Fibrositis:* Muscular rheumatism. Rheumatism of abdominal muscles simulating the pain of appendicitis, renal colic, biliary colic, etc. Fibrositis of the retrocolic and temporal muscles a

common form of headache. Lumbago. Dupuytren's contraction. Fibrositis of the plantar fascia and painful sole and heel. Fibrositis of bursae. Fibrositis of joints. Fibrositis of the subcutaneous tissue. Chronic villous synovitis. *Treatment:* Rest. Limited use of the salicylates. Potassium iodide the most valuable drug. Fibrolysin. External applications. Leeching. Heat and ionization. Heat and the static wave current. Massage and exercises. Spa treatment. Diet. Underclothing.

NAVY AND ARMY, AND AMBULANCE.

Municipal Training College, Class Room 3, First Floor.

President: Colonel J. TURTON, V.D., F.R.C.S., late Assistant Director of Medical Service, T.F., Brighton.
Vice-Presidents: Lieutenant-Colonel C. J. JACOMB-HEED, R.A.M.C.T.F., Brighton; Deputy Surgeon-General P. B. HANDSIDE, R.N., Plymouth; Major E. T. BIRRELL, R.A.M.C., Queen Alexandra Military Hospital, Grosvenor Road, S.W.; Colonel C. H. MILBURN, V.D., Hull. *Honorary Secretaries:* Lieutenant J. R. STEINHAUSER, M.D., T.F., St. Andrew's Place, Lewes; Captain J. A. ROOTH, R.A.M.C.T.F., 1, Goldsmid Road, Brighton.

The arrangements so far made are as follows:

Wednesday.—Papers:

BIRRELL, Major, R.A.M.C. Notes on the Work of a British Red Cross Unit with the Bulgarians.
DONEGAL, Lieutenant-Colonel, R.A.M.C. The Relation of and Utility of Aeroplanes in connexion with Medical Services in the Field.

Thursday.—Papers:

DUREY, Dr. Louis, French Army Service. Study of the Use of Kinesitherapy in the After-treatment of Injuries received in the War.
KENNARD, Lieutenant D. G., R.A.M.C.(T.F.) A Proposed Light Ambulance for Yeomanry Regiments.
HOUGHTON, Major J. W., R.A.M.C. Spinal Analgesia in Military Service.

The following subjects are also suggested for discussion; The Medical Service in the Tropics.

Hospital Ships.

Disinfection and its Application in Ships.

Diet of the Soldier.

Sanitation on the Line of March.

Water Supply on Field Service.

NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Municipal Training College, Dining Room.

President: J. TAYLOR, M.D., F.R.C.P., London. *Vice-Presidents:* A. W. MACKINTOSH, M.D., Aberdeen; W. H. B. STODDART, M.D., F.R.C.P., London; HELEN BOYLE, M.D., Hove. *Honorary Secretaries:* J. L. BASKIN, M.D., New Church Road, Hove; T. G. STEWART, M.B., 54, Queen Anne Street, London, W.

The following is the preliminary programme:

Wednesday.—Discussion on Sleep and the Treatment of Sleeplessness: To be opened by Sir GEORGE H. SAVAGE, followed by Dr. W. H. BUTTER STODDART, and others.

Thursday.—Discussion on Vertigo: its Significance and Treatment. To be opened by Dr. RISLEN RUSSELL.

Friday.—Papers.

Members are invited to contribute any preparations, specimens or drawings, or any instruments or apparatus pertaining to the work of the Section, which have been designed by themselves, in order that arrangements may be made to form a special exhibit of such objects.

OPHTHALMOLOGY.

Municipal Technical School, Room 47, Second Floor.

President. T. H. BICKERTON, M.R.C.S., Liverpool.
Vice-Presidents: H. H. TAYLOR, F.R.C.S., Hove; W. H. GRIFFIN, F.R.C.S., Hove; A. NICHOLSON, M.B., Hove; J. H. PARSONS, F.R.C.S., London. *Honorary Secretaries:* W. B. INGLIS POLLOCK, M.D., F.R.C.P.S., 276, Bath Street, Charing Cross, Glasgow; W. H. BRAILEY, M.D., 21, Lansdown Place, Hove.

The following subjects have been suggested for discussion, and it is hoped that all members will express their views on the practical treatment of these conditions:

The Question of Excision in cases of Injury of the Eye—School Clinics and the Prevention of Myopia.

The Treatment of Chronic Dacryocystitis.

PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

Municipal Training College, Class Room 1, First Floor.

President: W. HALE WHITE, M.D., F.R.C.P., London. *Vice-Presidents:* J. C. UHTHOFF, M.D., Hove; H. BATTY SHAW, M.D., F.R.C.P., London; H. C. CAMERON, M.D., M.R.C.P., London. *Honorary Secretaries:* V. COW, M.D., The Bridge House, Great Shelford, Cambridge; E. R. HUNT, M.D., 3, Goldsmid Road, Brighton.

The following subjects have been selected for discussion:

Wednesday.—Urinary Antiseptics: To be opened by Mr. J. W. THOMSON WALKER.

Thursday.—Anaphylaxis: (Joint Discussion with Section of Bacteriology and Pathology. For a list of those taking part in the discussion see p. 506.)

Friday.—The Use and Abuse of Hypnotics: To be opened by Dr. W. H. WILLCOX.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Urinary Antiseptics.—(Mr. J. W. THOMSON WALKER.) Urinary antiseptics may be taken to include (1) drugs administered with the object of excretion in the urine, (2) serum and vaccine treatment, and (3) local applications to the different parts of the urinary tract. But in order to concentrate discussion the introducer suggests that only those falling into the first division should be considered. The following appear to be the lines along which discussion may most usefully be directed: (1) The varieties of urinary antiseptics and the method by which the antiseptic power of each is exercised. (2) The formaldehyde group is the most important, and should form the centre of discussion. (3) The effect of variation in the reaction of the urine upon bacterial growth in the urinary tract or upon the action of urinary antiseptics. (4) The causes, apart from changes in the reaction of the urine, of variation in the efficacy of urinary antiseptics in different cases. (5) Are urinary antiseptics selective in their action?

Discussion on the Use and Abuse of Hypnotics.—(Dr. W. H. WILLCOX.) By the term "hypnotic" is meant a drug, or a combination of drugs, which produces sleep resembling natural sleep. The dangers attaching to the use of hypnotics may be summarized as follows: (1) The unnecessary use of hypnotics. (2) The danger of the formation of a drug habit. (3) The danger of toxic symptoms resulting from the habitual use of hypnotics. (4) The danger of fatal poisoning. (5) Special dangers due to existing disease. (6) Idiosyncrasy. (7) The use of hypnotics when other measures of treatment should be employed; for example, the use of hypnotics when work should be given up and special treatment adopted. The pathological conditions in which the use of hypnotics is necessary may be summarized as follows: (1) The relief of pain. (2) Nervous causes of insomnia—for example, (a) psychical causes, (b) cerebro-spinal causes, and (c) the insomnia of insanity. (3) Toxic causes—for example, (a) microbic and parasitic infections, (b) chemical poisons, and (c) autointoxications. (4) Gastro-intestinal diseases. (5) Cardio-vascular diseases. (6) Respiratory diseases. (7) Genito-urinary diseases. (8) The insomnia of physiological epochs—for example, menopause, old age. The object of the discussion will be best attained by considering hypnotics individually and discussing the special uses and abuses attaching to them. They will be classified as follows, and the uses and abuses attaching to the respective members of each class discussed seriatim. (1) Derivatives of methane, namely, (a) the chloral-alcohol group, (b) the sulphone group, and (c) the uricide group. (2) Opium and its preparations and alkaloids and their derivatives. (3) The atropine group of hypnotics. (4) Cannabis indica and its preparations. (5) The inorganic bromides. (6) Vegetable hypnotics other than those mentioned above—for example, preparations of hops, etc. (7) Other hypnotics.

STATE MEDICINE.

Municipal Technical School, Room 16, Ground Floor.

President: E. W. HOPE, M.D., D.Sc., Liverpool. *Vice-Presidents:* A. GRIFFITH, M.D., Hove; G. V. BENSON, M.R.C.S., Lewes; W. A. BOND, M.D., M.O.H., London. *Honorary Secretaries:* G. W. STONE, M.R.C.S., L.R.C.P., Cumnor, Dyke Road, Brighton; T. B. HEGOS, M.D., Town Hall, Sittingbourne.

The following subjects have been selected for discussion:

(1) Port Sanitary Administration and the Importation of Disease: To be opened by Dr. HERBERT WILLIAMS, M.O.H. Port of London. (2) The Need for Popular Education in matters affecting the Public Health: To be opened by Professor H. R. KENWOOD.

Other subjects suggested are: (a) Maternity Benefit under the Insurance Act and its Connexion with the Midwives Act. (b) Treatment of School Children; Arrangements recently adopted for. (c) Prevention and Treatment of Tuberculosis; the Need for an Exact Comparison of the Methods at present used in. (d) Measles and Whooping-cough; the Need of Laboratory Investigation into the Means of Prevention.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Port Sanitary Administration.—(Dr. HERBERT WILLIAMS.) Conditions on shipboard predisposing to the conveyance and spread of infectious disease. Legal powers for dealing with ships at ports of arrival: (a) Public Health Acts and by-laws made thereunder; (b) regulations issued by the Local Government Board. Port sanitary administration: (a) Medical inspection and supervision; (b) "quarantine"; (c) disinfection and fumigation of vessels. International Sanitary Convention held at Paris, 1911-12. Suggestions for improving the regulations, etc., for preventing the introduction of infectious disease by persons arriving on vessels.

Discussion on the Need for Popular Education in Matters affecting the Public Health.—(Professor H. R. KENWOOD.) The large amount of ignorance and apathy in respect to matters affecting the public health can only be effectually counteracted by such education as will enlighten and impress without exaggerating or alarming. Without a public demand the necessary stimulus and support both to legislators and administrators is lacking; and when trade conditions are not meeting public health requirements (as, for instance, the public milk supply) an educated public demand is almost essential to reforms. Without this education, Acts of Parliament and the supervision by sanitary authorities have but a limited value in raising the standard of public health. It is the duty of (a) the education authority and (b) the sanitary authority to promote this education. Education authorities are but slowly preparing the way for the discharge of this duty. Growing opportunities are leading to an increase in the efforts of sanitary authorities; but further measures are necessary. Some other agencies can also assist in this education, and should do so.

SURGERY.

Municipal Technical School, Room 35, First Floor.

President: W. THELWALL THOMAS, F.R.C.S., Liverpool. *Vice-Presidents:* R. F. JOWERS, F.R.C.S., Hove; W. TAYLOR, F.R.C.S.I., Dublin; STANLEY BOYD, F.R.C.S., London; J. W. BATTERHAM, F.R.C.S., St. Leonard's-on-Sea; W. FURNER, F.R.C.S., Hove. *Honorary Secretaries:* H. J. WALKER, F.R.C.S., The Priory, Springfield Road, Brighton; C. A. R. NITCH, F.R.C.S., 69, Harley Street, W.; F. K. SMITH, M.B., 207, Great Western Road, Aberdeen.

The following programme has been arranged:

Wednesday.—Discussion on the Diagnosis and Treatment of Primary Carcinoma of the Stomach. To be opened by Mr. G. H. MAKINS, C.B., followed by Messrs. Hey Groves, J. K. DALZIEL, Paterson, R. F. Jowers, and Buck.

Papers:

WILKIE, D. P. D. Experimental Observation on the Cause of Death in Acute Intestinal Obstruction.
WARDEN, A. A. Radium and Inoperable Cancer.

Thursday.—Discussion on the Diagnosis and Treatment of Injuries of the Knee-joint other than Fractures and Dislocations. To be opened by Mr. A. M. MARTIN (Newcastle-on-Tyne), followed by Messrs. Openshaw, Walters, Deausly, Whitlocke, Hey Groves, Dalziel, and Pinch.

Papers:

GROVES, E. W. Hey. The Operative Treatment of Fractures.
DALZIEL, J. K. Chronic Intestinal Arteritis.

Friday.—Papers:

WADE, H. Prostatism.
DALZIEL, J. K. Neuralgia of the Fifth Nerve Simulating Visceral Lesions.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Primary Carcinoma of the Stomach.—(Mr. G. H. MAKINS.) Can a diagnosis of the disease at an early stage be obtained at present? *Methods of Diagnosis:* (a) In the early stages. Symptoms of indigestion accompanied by anaemia and progressive loss of strength, a possible history pointing to the earlier presence of a simple ulcer; the test meal; examination of the faeces; skiagraphy; direct examination by the gastro-scope; mechanical distension by air or carbonic acid gas; examination of the blood; examination of the urine; exploratory incision. (b) In the later stages. Symptoms such as pain, vomiting, haematemesis, or melaena. Dilatation is not always present; obvious peristalsis; the presence of a palpable tumour. Exploratory incision. (c) Differential diagnosis. *Methods of Treatment:* These depend on the position and extent of the growth; relative frequency of different locations; cardiac growths are unsuitable for any but palliative treatment; growths situated in the body of the stomach may be treated by gastrectomy, anastomosis, or rarely by jejunostomy; pyloric growths, which form from 50 to 60 per cent. of the series, the most generally satisfactory for operation. What are the limits within which radical operations may be undertaken? These are determined by: (1) The extent of the primary growth, the degree of lymphatic enlargement or infiltration, the extent of invasion of neighbouring organs—for example, transverse colon, pancreas, liver, and gall bladder. (2) The general condition of the patient. Operations are not justifiable in the presence of visceral metastases, distant lymphatic enlargements, as in the posterior triangle or groin, when the growth has extended to the abdominal wall at the umbilicus, or when malignant ascites is present. What are the respective fields of gastrectomy and gastro-enterostomy? Gastro-enterostomy is almost as severe an operation as partial gastrectomy, while the relief given extends over an average of only five months. Its adoption should be restricted to cases in which the extent of the growth renders a partial gastrectomy impracticable. Should this rule be adhered to when enlarged lymphatic glands alone form the practical difficulty? The objection to gastro-enterostomy as a preliminary procedure to gastrectomy is a real one. The technical conditions may be influenced for the worse when the second operation is undertaken, and the patient often puts off consent for the second operation too late as the result of the temporary relief afforded by the first. Gastrectomy is not a much more serious operation, and affords better results to the patient both immediate and remote. What is the best method of partial gastrectomy? An operation on the lines of Billroth No. 2 is the most generally useful. When the remnant of the cardiac end of the stomach is too small to allow of a successful lateral anastomosis, the loop of jejunum may be applied directly to the opening of the divided stomach by the methods of Polya, Reichel, Wilms, etc. Difficulties with the duodenal stump. Various methods of suture. Lewitt's method. Methods of dealing with partially resected organs. Results of partial, subtotal, and complete gastrectomy.

Discussion on Injuries of the Knee-joint other than Fractures and Dislocations.—(Mr. A. M. MARTIN.) (1) Points in anatomy of knee-joint bearing on injuries to be considered. (2) Diagnosis and treatment of simple traumatic synovitis; haemophilia; loose bodies. (3) Injuries to joints affected with other disease, such as osteo-arthritis, ruptured or torn semilunar cartilage.

TROPICAL MEDICINE.

Municipal Technical School, Room 17, Ground Floor.

President: Lieutenant-Colonel Sir WILLIAM LEISHMAN, M.B., F.R.S., R.A.M.C., London. *Vice-Presidents:* E. IRWIN SCOTT, M.D., Hove; Professor W. J. R. SIMPSON, O.M.G., M.D., F.R.C.P., London; Major W. S. HARRISON, R.A.M.C., Royal Army Medical College, Grosvenor Road, S.W. *Honorary Secretaries:* E. CURWEN, M.A., M.B., B.C., 1, St. Aubyn's, Hove; F. W. O'CONNOR, M.R.C.S., London School of Tropical Medicine, Royal Albert Dock, E.

The following is the preliminary programme:

Wednesday.—Discussion on the Causes of Invaliding in the Tropics. To be opened by Dr. CURWEN, followed by Drs. Basil Price (the Missionary Standpoint), Colonel

R. Simpson, R.A.M.C. (the Army Standpoint), and Dr. Law.

Thursday.—Discussion on Dysentery. To be opened by Captain S. R. DOUGLAS, I.M.S., followed by Drs. C. M. Wenyon (Morphology of the Intestinal Amoebae), Savage (Serum Treatment), and Willmore (Treatment).

Friday.—Discussion on Filariasis. To be opened by Dr. Low.

Paper:

BIRT, Colonel C. Dengue and Phlebotomus Fever.

The following paragraph indicates the line that will be taken by the opener of the third discussion:

Discussion on Filariasis.—(Dr. Low.) It is proposed, first, to review the literature of human filariasis from June, 1911, to the end of May, 1913. A considerable amount of work, some of it of a very interesting nature, has been accomplished in that time. Papers dealing with the geographical distribution of the filariae have been numerous, as have also others on the morphology and points of distinction between the different species of embryos. Little, however, has been accomplished as regards the further elucidation of the pathology of the disease, with the exception of an interesting paper on chyluria and another upon various obscure suppurative conditions probably originated by the parasites. Elephantiasis has been more fully dealt with, several new operations having been proposed for its treatment. As regards *Filaria loa* Leiper has discovered the intermediate host. He states that the embryos undergo their metamorphosis in the salivary glands of biting fleas of the genus *Chrysops*, *C. dimidiata*, and *C. silacea*. The steps in the development are very similar to those which take place in the embryos of *F. bancrofti* in the mosquito. No further advances have been made as to respective intermediate hosts of *Filaria perstans* and *F. demarquayi*. Different lines of investigation are suggested for future work on *F. bancrofti*. One of the most promising of these is the epidemiology of the disease, but questions such as hyperfilariation, the duration of the life of the embryos in the blood, the pathology and pathological anatomy of the diseased conditions produced, and many others are also of equal interest. Many points also require solution as regards *F. loa* infections. One of the most peculiar features in these cases is the prolonged absence of embryonic or larval forms from the peripheral blood even though there is evidence of a fair infection of adults. To solve these and other points the author is following up a series of cases in detail. Attention is also drawn to a case described by Meinoff illustrating the same point. Pathologically also it is not known how the adult worms produce the peculiar swellings to which the name "Calabar swellings" has been given. Though several theories have been brought forward to explain the origin of these lesions, none of them is probably correct. The general question of filarial eosinophilia is also suggested as a promising piece of work for future investigations. The author continues with a reference to *Onchocerca volvulus* (*Filaria volvulus*), and finally states that there is a fruitful source of investigation awaiting any one who wishes to take up the subject of "human filariasis."

PROVISIONAL PROGRAMME.

The following is the provisional time table for the Brighton meeting:

FRIDAY, JULY 18TH.
10 A.M.—Annual Representative Meeting.

SATURDAY, JULY 19TH.
9.30 A.M.—Representative Meeting.

MONDAY, JULY 21ST.
9.30 A.M.—Council Meeting.
10 A.M.—Representative Meeting.

TUESDAY, JULY 22ND.
9.30 A.M.—Representative Meeting.
2 P.M.—Annual General Meeting.
8.30 P.M.—Adjourned General Meeting, President's Address.

WEDNESDAY, JULY 23RD.
9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Medicine.
3 P.M.—Religious Services.
4 P.M.—Secretaries' Conference.
7 P.M.—Secretaries' Dinner.

THURSDAY, JULY 24TH.

- 8 P.M.—National Temperance League Breakfast.
 10 A.M. to 1 P.M.—Sectional Meetings.
 12.30 P.M.—Address in Surgery.
 7.30 P.M.—Annual Dinner.

FRIDAY, JULY 25TH.

- 9 A.M.—Council Meeting.
 10 A.M. to 1 P.M.—Sectional Meetings.
 8 P.M.—Popular Lecture.

SATURDAY, JULY 26TH.
Excursions.

Honorary Local Treasurer—

H. H. TAYLOR, F.R.C.S.,
 36, Brunswick Square, Hove.

Honorary Local Secretary—

LEONARD ARTHUR PARRY, M.D., F.R.C.S.,
 83, Church Road, Hove.

THE PATHOLOGICAL MUSEUM.

THE Pathological Museum Committee, whose constitution was set forth in our issue for May 17th, proposes to arrange the material it receives under the following heads:

- (i) Exhibits bearing on discussions and papers in the various Sections.
- (ii) Specimens and illustrations relating to any recent research work.
- (iii) Instruments relating to clinical diagnosis and pathological investigation.
- (iv) Individual specimens of special interest, or a series illustrating some special subject.

The Committee wishes it to be understood that the above are only suggestions, and that specimens illustrating any subject of special interest will be welcomed.

The Committee desires to enlist the hearty co-operation of members, and the Honorary Secretary will be glad to hear from those who are able to make an exhibit. Every care will be taken of specimens, and the contents of the Museum will be insured.

It is hoped that it will be possible for arrangements to be made whereby exhibitors may have an opportunity of demonstrating their specimens.

The Museum will occupy a central position in the same building as that in which the sectional work is carried on, and will be easy of access.

The Chairman of the Committee is Dr. E. Hobhouse (Hove), but all communications concerning it should be addressed to Dr. W. Broadbent or Dr. H. M. Galt, Honorary Secretaries, Pathological Museum Committee, 14, North Street, Brighton.

Association Notices.

SPECIAL MEETING OF COUNCIL.

A SPECIAL Meeting of the Council will be held at Eleven o'clock in the forenoon of Friday, June 13th, in the Council Room at 429, Strand, London, W.C., to consider a Report of the Organization Committee on the Reform of the Present Constitution of the Association.

By Order,

GUY ELLISTON,

May 22nd, 1913. *Financial Secretary and Business Manager.*

DISCONTINUANCE OF AN EXISTING BRANCH:
FORMATION OF TWO NEW BRANCHES.

THE following changes have been made in accordance with the regulations of the Association, and take effect from the date of publication of this notice (June 7th):

Discontinuance of Natal Branch: Formation, in Substitution therefor, of Two New Branches.

That the existing Natal Branch of the Association be discontinued, and that, in substitution therefor, the existing Divisions of the Branch—namely, the Durban and Pietermaritzburg Divisions—be constituted as two independent

Branches, having the following respective names and areas:

1. *Natal Coastal Branch.*—All the counties of Natal bordering on the sea coast, that is, the following counties: Alfred, Alexandra, Durban, Victoria, and the Province of Zululand (excepting the Nqutu District).

2. *Natal Inland Branch.*—All the inland counties of Natal—namely, Pietermaritzburg, Umvoti, Wenen, Klip River, Newcastle, Vryheid and Utrecht, and the Nqutu District of Zululand.

Representation in Representative Body.—Under the general principle adopted by the Council with regard to the representation in the Representative Body of Branches outside the United Kingdom (if adopted by the Council, 1913-14, when the representation of Divisions in the Representative Body for 1914-15 is being determined), each of the new Branches will be entitled to separate representation in the Representative Body, 1914-15, to return one Representative.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH.—Mr. J. Furneaux Jordan (9, Newhall Street, Birmingham) and Dr. J. G. Emanuel, Honorary Secretaries, give notice that the annual meeting of the Birmingham Branch will be held in the Medical Institute on Thursday, June 19th, at 3 p.m. Business: Election of officers. Annual report and financial statement. Inaugural address by the incoming President, Mr. W. F. Haslam.

BORDER COUNTIES BRANCH.—Dr. Livingston, Secretary, gives notice that the annual meeting of the Branch will be held in the Town and County Hotel, Carlisle, on Friday, June 27th.

EAST YORK AND NORTH LINCOLN BRANCH.—Dr. Edward Turton, Honorary Secretary (1, Albion Street, Hull), gives notice that the annual meeting of the East York and North Lincoln Branch will be held at Beverley on Friday, June 27th, at 4 p.m. Business: (1) Report of Branch Council. (2) Treasurer's Financial Statement. (3) Election of President-elect, Vice-President, and Honorary Secretary and Treasurer. (4) Address by the new President, Dr. J. Mitchell Wilson. (5) Any other business proper to annual meetings of the Branch.

EDINBURGH BRANCH.—Dr. Michael Dewar and Mr. E. Scott Carmichael, Honorary Secretaries (24, Lauriston Place), give notice that the annual meeting of the Edinburgh Branch will be held in the Royal College of Physicians' Hall, Queen Street, on Thursday, June 26th, at 4 p.m.

EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION.—Dr. M. J. Oliver (Honorary Secretary, St. Boswells), gives notice that the annual meeting of the Division will be held in the Railway Hotel, Newtown St. Boswells, on Friday, June 27th, at 3 o'clock p.m., for the election of officers, the consideration of the annual report of the Executive Committee and financial statement; the discussion of various matters concerning the Insurance Act, including certificates, duties of Medical Service Subcommittee, expenses of Local Medical Committees, payment for services to temporary residents, and for instructing the Representative on the Representative Body.

FIFE BRANCH.—Dr. G. C. Anderson, Honorary Secretary (Denbeath House, Methil), gives notice that the annual meeting of the Fife Branch will be held in the Station Hotel, Kirkcaldy, on Thursday, June 19th, at 3 p.m.

METROPOLITAN COUNTIES BRANCH.—Drs. W. Griffith and R. E. Crosse (Honorary Secretaries) give notice that the annual general meeting of the Branch will be held at 429, Strand, W.C., on Tuesday, July 1st, at 4 p.m. The business will include a report as to the election of new officers, and the annual reports of Council and of representatives of the Branch on the Central Council. On the motion to adopt Model Ethical Rules for Branches, Dr. F. J. Smith gives notice that he will propose an alteration to the Model Ethical Rules by substituting the words "British Medical Association" for the words "Medical Profession" in Rule 1. President's address: The Profession and the Public. [The Model Ethical Rules are printed in the SUPPLEMENTS of September 21st and 28th, 1912, pages 325 and 350.]

METROPOLITAN COUNTIES BRANCH: EAST HERTFORDSHIRE DIVISION.—Dr. H. D. Ledward, Honorary Secretary (123, Norton Way, Letchworth) gives notice that the first annual meeting of the Division will be held at 2.30 p.m., on Friday, June 20th, at the Town Hall, Ware, to elect officers, the representative of the Division on the Branch Council, the ordinary members of the Executive Committee, and the Representative of the Division in Representative Meetings. To receive the Honorary Secretary's Annual Report. To alter Rule I defining the area of the Division in accordance with the decision of the Organization Committee of the Association. To consider the business of the Annual Representative Meeting and instruct the Representative thereon.

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—Dra. Walter E. Fry and P. C. Raiment, Honorary Secretaries, give notice that the annual meeting will take place at Kensington Town Hall on Thursday, June 12th, at 5 p.m., for the transaction of the following business: Annual report. Elect officers and Representatives for 1913-14, and elect Executive Committee.

MIDLAND BRANCH.—Dr. Francis L. A. Greaves, Honorary Secretary and Treasurer (83, Friar Gate, Derby), gives notice that the annual meeting of the Branch will be held on Friday, June 13th, at 3 p.m., at Central Buildings, Leicester Public Medical Service, Bond Street, Leicester, for the election of Branch officers, and to receive the report of Branch Council and financial statement. A discussion on Leicestershire's Medical Methods will be opened by the President, and continued by Drs. McAllister-Hewings, Moffat Holmes, Wallace Henry, B. Martin, and J. C. Burkitt. The President-elect invites members from a distance to luncheon at his house, 19, Victoria Road, Leicester, at 1 to 2 p.m.; members accepting this invitation are requested to notify Dr. Astley Clarke on or before June 9th.

SOUTH-EASTERN BRANCH.—Dr. E. A. Starling, Honorary Secretary (Chillingworth House, Tunbridge Wells), gives notice that the sixty-ninth annual meeting of the Branch will be held on Wednesday, June 11th, at 1.30 p.m., at the Lion Hotel, High Street, Guildford. Dr. Arthur M. Mitchell (President-elect) invites members to lunch at the Lion Hotel, High Street, at 12.45 p.m. sharp. Agenda: In addition to the business of an ordinary meeting, (1) to receive the report of the election of officers for 1913-14; (2) to receive the annual report of the Council and financial statement, and (3) the ethical rules presented by the Council; (4) to consider the following resolution: "The South-Eastern Branch Council advise the Branch to request the Council of the Association to consent to the division of the unwieldy South-Eastern Branch into three Branches, corresponding with the three counties of Kent, Sussex, and Surrey." An excursion is arranged for the afternoon, to view the Lord Mayor Treloar's Cripples' Home at Alton, where Dr. and Mrs. Gauvain kindly invite the members to tea. The special train leaves Guildford Station at 2.40 p.m., returning about 5.30 p.m. Tickets for the return journey, 3s. 6d. each. The annual dinner will be held at the Lion Hotel, at 6.30 p.m. Members intending to be present at the lunch, excursion, or dinner wishing hospitality for the night are requested to signify their intention to Cecil P. Lankester, Esq., 1, Rectory Place, Guildford, not later than Saturday, June 7th.

SOUTH-EASTERN BRANCH: DARTFORD DIVISION.—Dr. H. Chisholm Will, Honorary Secretary (Southbank, Sidcup), gives notice that the annual meeting of the Dartford Division will be held at the Bull Hotel, Dartford, on Thursday, June 12th, at 3 p.m., when it is hoped that all members of the Division and all medical men residing therein will make a special effort to attend. Agenda: Report of Executive Council; election of officers and executive; consider Agenda of Annual Representative Meetings (see BRITISH MEDICAL JOURNAL SUPPLEMENT, May 3rd and 10th; members are particularly requested to bring their copies to the meeting); address by Dr. Courtenay Lord, member of Council of the British Medical Association.

SOUTH MIDLAND BRANCH.—Dr. E. Harries-Jones, Honorary Secretary (16, Castilian Street, Northampton), announces that the annual meeting of the Branch will be held at Bedford on June 12th, under the presidency of Dr. Cuning Hartley.

SOUTH MIDLAND BRANCH: BUCKINGHAM DIVISION.—Dr. A. E. Larking, Honorary Secretary (Buckingham), gives notice that the annual meeting of the Division will be held on Wednesday, June 18th, at 3.30 p.m., at the Royal Bucks Hospital. The Committee will present its report for the past year, the officers for the ensuing year will be elected, and the Representative will be instructed how to vote at the Representative Meeting. The following resolution will be submitted: "That the Bucks Division do all in its power to discourage all contract practice outside the Insurance Act." A paper will be read by Dr. J. Horne Wilson (London) on The Active Treatment of Tuberculosis, and Dr. Burra will take part in the discussion.

SOUTH-WESTERN BRANCH.—Mr. Russell Coombe, Honorary Secretary, gives notice that the seventy-fourth annual meeting will be held on Wednesday, June 11th, at the Museum, Babbacombe Road, Torquay, at 3 p.m., when Dr. Hardwick will resign the chair to Mr. Eales, who will deliver his inaugural address. The report of the Branch Council for the year 1912-13 and the annual financial statement for the year 1912 will be presented, and the officers of the Branch will be elected for the year 1913-14. Luncheon, by the kind invitation of the President-elect and Torquay members, will take place from 1 p.m. to 2.30 p.m., at the Museum, Babbacombe Road. The annual dinner of the Branch will be held at the Torbay Hotel at 7.45 for 8 p.m. Tickets 7s. 6d. (exclusive of wine) can be had from Dr. Lacey, Melita, Torquay; application should be made not later than the first post on Monday, June 9th. Several Torquay members of the Branch have offered to put up visiting members for the night, and gentlemen desiring to avail themselves of this hospitality are requested to inform Dr. Lacey when making application for their dinner ticket. By the courtesy of the Torquay and South Devon Golf Club, members

of the Branch and their wives will be made honorary members for Wednesday and Thursday; those wishing games arranged should communicate with Dr. Dalby, The Rosary, St. Marychurch, Torquay.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.—Dr. S. Colen Legge, Honorary Secretary (24, Foregate Street, Worcester), gives notice that the annual meeting of the Worcestershire and Herefordshire Branch will be held at the Infirmary, Kidderminster, on Thursday, June 19th, at 4 p.m.

THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

SOUTH-EASTERN BRANCH.

Dr. C. COURTENAY LORD of Gillingham, who is a candidate for election to the Council of the British Medical Association as representative of the South-Eastern Branch, asks us to state that he is the Honorary Secretary of the Rochester, Chatham, and Gillingham Division, is at present a member of the Council of the Association, and is a member of the Kent County Medical Committee.

Dr. C. H. Benham of Brighton, who is also a candidate, asks us to state that he was a member of the Council of the South-Eastern Branch in 1908-13, Honorary Secretary of the Brighton Division 1911-13, and its Representative 1912-13. He is also Chairman of the East Sussex Medical Committee and representative of the profession on the East Sussex Insurance Committee.

Meetings of Branches and Divisions.

[The proceedings of the Divisions and Branches of the Association relating to Scientific and Clinical Medicine, when reported by the Honorary Secretaries, are published in the body of the JOURNAL.]

GLASGOW AND WEST OF SCOTLAND BRANCH:

GLASGOW EASTERN DIVISION.

The annual meeting of the Glasgow Eastern Division was held in Bellgrove Hall on May 28th, when Dr. H. A. McLEAN, Chairman of the Division, presided.

Election of Officers.—The office-bearers for 1913-14 were elected as follows:

Chairman.—Dr. Robert Davidson.

Vice-Chairman.—Dr. Alexander Johnston.

Honorary Secretary and Treasurer.—Dr. Hugh A. McLean.

Representative in Representative Meetings.—Dr. J. Wishart Kerr.

Deputy Representative.—Dr. Alexander Johnston.

Representatives on Branch Council.—Dr. Robert Davidson, Dr. J. Wishart Kerr, Dr. Hugh A. McLean.

Executive Committee.—Drs. P. S. Buchanan, J. B. Miller, A. P. Granger, James Dunlop (Dennistoun), William Bryce, Robert Scott, J. B. Stewart, James Battersby, and W. L. Muir.

Annual Report.—The SECRETARY submitted the annual report for 1912, which was cordially approved. It stated that at the beginning of the year membership was 113, that 14 new members had been elected, and that 5 had removed into the Division, making an aggregate of 132. During the year 9 had been removed, 1 by death, and 8 by change of address leaving the net membership at December 31st, 1912, 123, an increase of 10 for the year.

Election to Local Medical Committee.—Dr. J. F. Macgregor was elected to the vacancy on the Local Medical Committee caused by the resignation of Dr. J. P. Granger.

Votes of Thanks.—It was unanimously agreed to minute an expression of the appreciation of the services of Dr. McLean as chairman during the past year; and also a vote of thanks to the late secretary for his labours during the four years he had discharged the duties of that office.

Instruction of Representative.—The agenda for the Annual Representative Meeting was discussed very fully and the Representative instructed as to the various motions.

LANCASHIRE AND CHESHIRE BRANCH:

BLACKPOOL DIVISION.

The annual meeting and dinner of this Division, to which all members of the profession resident in the area of the Division were invited, was held at the Clifton Hotel, Blackpool, on May 28th, at 8 p.m., Dr. STEWART in the chair. There was an attendance of twenty-two.

Report of Executive Committee.—The HONORARY SECRETARY read the report, which stated that the past year had been one of exceptional activity owing to the consideration given to the medical provisions of the Insurance Act. Thirteen meetings were held, to six of which non-members of the Association were invited. The attendance at all the meetings was excellent, and at one meeting, in December, 1912, sixty-one practitioners were present. The membership during the past year had increased from 67 to 69.

Election of Officers.—The following officers were appointed for 1913-14:

Chairman.—Dr. Mitchell Penman.
Vice-Chairman.—Dr. T. Carr.
Honorary Secretary.—Dr. W. J. McL. Baird.
Representative for Representative Meetings.—Dr. H. T. Barton.
Representative on Branch Council.—Dr. W. J. McL. Baird.
Executive Committee.—Dr. L. M. McIntosh, Dr. R. H. W. Dunderdale, Dr. F. S. Rhodes, Dr. J. Stewart, Dr. T. Godley, Dr. T. Taylor, and Dr. C. Court.

Vote of Thanks.—A vote of thanks was passed to Dr. Stewart for his services as Chairman during the past year, and the same compliment was paid to Dr. Barton.

LEINSTER BRANCH: EAST LEINSTER DIVISION.

The annual general meeting of the East Leinster Division of the Leinster Branch of the British Medical Association was held in the Royal College of Physicians, Dublin, on May 28th.

Election of Officers.—The following officers were elected:

Chairman.—Dr. W. V. Furlong.
Vice-Chairman.—Dr. W. B. Mackay.
Honorary Secretary and Treasurer.—Dr. R. C. Peacocke, Blackrock, Dublin.
Representative for Representative Meetings.—Colonel W. T. Johnston, M.D., 8, Vesey Place, Kingstown.
Deputy Representative.—Dr. R. C. Peacocke.
Representatives on Branch Council.—Drs. Boyce, Dampier-Bennett, Good, Johnston, and Peacocke.
Executive Committee.—The above and Drs. Dawson, Goff, Heard, Hatch, Law, and Professor A. H. White (*ex officio*).

MIDLAND BRANCH:

LEICESTERSHIRE AND RUTLAND DIVISION.

The annual meeting of the Division was held at the Royal Infirmary, Leicester, on May 21st, Dr. W. E. GIBBONS in the chair.

Election of Officers.—The following were elected officers for the year 1913-14:

Chairman.—Dr. Sessions Barrett.
Vice-Chairman.—Dr. McAllister-Hewlings.
Honorary Secretary.—Dr. R. Wallace Henry.
Representatives on the Branch Council.—Drs. Cosens, Fagge, Stamford Gibbons, McAllister-Hewlings, Sevestre, and Waite.
Executive Committee.—Drs. C. H. Clarke, Holyoak, Johnston, Pike, Tibbles, Bonis, Logan, Clare, Holmes, Hicks, and Young.

Hearty votes of thanks were accorded Drs. Gibbons and Wallace Henry for their work as Chairman and Secretary during the year 1912-13.

Annual Report.—The annual report of the Council, which was approved, stated that the number of members in the Division was now 204, a decrease of fourteen during the year. Ten meetings of the Division had been held: The annual meeting dealing with the business of the Division, six with various aspects of the National Insurance Act, one with malingering, and two with scientific matters. The average attendance was sixty-eight. The Executive Committee had met on eight occasions, when the average attendance was thirteen. During the year the attention of the Committee has been chiefly directed to questions arising out of the administration of sanatorium and medical benefit. The Committee desired to place on record the great loss sustained by the Division in the death of Dr. F. M. Pope. The accounts of the Division for the year ending December 31st, 1912, had been duly audited, and showed a balance in hand of £1 5s. 9d.

SOUTH WALES AND MONMOUTHSHIRE BRANCH:

NORTH GLAMORGAN AND BRECKNOCK DIVISION.

The annual meeting of this Division was held at Pontypridd on May 29th at 3 p.m., when the chair was taken by Dr. T. FINNEY, Aberaman.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. T. R. Llewellyn, Penygraig.
Vice-Chairman.—Dr. H. Davies-Jones, Mountain Ash.
Secretary and Treasurer.—Mr. C. J. Weichert, Penygraig, re-elected.
Assistant Secretary.—Dr. A. T. Jones, Mountain Ash.
Representative for Representative Meetings.—Dr. W. E. Thomas, Ystrad, re-elected.
Deputy Representative.—Dr. T. R. Llewellyn.
Representatives on the Branch Council, in addition to the *ex officio* members.—Drs. T. R. Llewellyn, C. Biddle, D. N. Morgan, Howard Davies, and B. M. Lewis.
Representatives on the Contract Practice Committee.—Drs. T. R. Llewellyn, W. E. Thomas, and A. T. Jones.
Executive and Ethical Committees.—Drs. J. M. Rees, T. Finney, I. N. Morgan, C. Biddle, H. Davies-Jones, B. M. Lewis, Howard Davies, R. Ryce, J. R. Armstrong, A. J. Griffith, Trevor Cory, S. Glanville Morris, the Chairman, the Direct Representative, and the Secretaries.

Medical Aid Association.—The meeting considered a resolution, submitted to the Divisions by the South Wales and Monmouthshire Branch, dealing with Medical Aid Associations and similar schemes that are being started under the Insurance Act in various places in Wales, and, on the motion of Dr. C. BIDDLE, it was resolved that:

This Division views with apprehension the formation of Medical Aid Associations in Wales, and calls upon the staffs of the various hospitals in Wales and Bristol to refuse professional recognition to those who accept such appointments, and to decline to attend, in any general or cottage hospitals, members of such associations or schemes, except under circumstances of grave emergency.

SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH. SCHOLARSHIPS.

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows:

1. AN ERNEST HART MEMORIAL SCHOLARSHIP, of the value of £200 per annum, for the study of some subject in the department of State Medicine.
3. THREE RESEARCH SCHOLARSHIPS, each of the value of £150 per annum, for research into some subject relating to the causation, prevention, or treatment of disease.

Each Scholarship is tenable for one year, commencing on October 1st, 1913. A Scholar may be reappointed for not more than two additional terms.

The conditions of the award of Scholarships are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C.

GRANTS.

The Council of the British Medical Association is also prepared to receive applications for Grants for the assistance of Research into the Causation, Treatment, or Prevention of Disease. Preference will be given, other things being equal, to members of the medical profession and to applicants who propose as subjects of investigation problems directly related to practical medicine.

The conditions of the award of Grants are stated in the Regulations, a copy of which will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C.

Applications.

Applications for Scholarships and Grants for the year 1913-14 must be made not later than Tuesday, June 10th, 1913, in the prescribed form, a copy of which will be supplied by the Medical Secretary on application.

Each application should be accompanied by testimonials, including a recommendation from the head of the laboratory, if any, in which the applicant proposes to work, setting out the fitness of the candidate to conduct such work, and the probable value of the work to be undertaken. This is not intended, however, to prevent applications for Grants in aid of work which need not be performed in a recognized laboratory.

ALFRED COX, *Medical Secretary*,
429, Strand, London, W.C.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

SUMMER SESSION, 1913.

Sir DONALD MACALISTER, K.C.B., President, in the Chair.

EXEMPTIONS FROM EXAMINATION.

THE Examination Committee, as instructed, presented a report on exemptions from examination granted by British licensing bodies in respect of portions of examinations conducted by bodies whose degrees and diplomas are not recognized for registration.

The Committee reported that tables prepared by the Registrar showed that during the five years 1907-1911 nine universities and licensing corporations had granted exemptions from some part of their professional examinations other than the final examinations on the ground that the candidates had passed equivalent examinations held by universities or bodies which did not grant qualifications recognized by the Council as entitling the holders to registration in the home, colonial, or foreign lists. The bodies granting such exemptions were the Universities of London, Edinburgh, Bristol, and Manchester; the English, Scottish, and Irish Conjoint Boards, the Apothecaries' Society of London, and the Apothecaries' Hall, Dublin. In 180 instances exemptions were granted from all the professional examinations except the final examinations in medicine, surgery, and midwifery. The report gave detailed tables of the exemptions granted by each of the nine bodies, and summarized the results in the following table:

Table showing the proportion between the number of qualifications granted and the number of candidates exempted from some portion of the earlier Professional Examinations during the five years 1907-1911 on the ground that they had passed equivalent examinations held by Universities or bodies whose qualifications are not recognized as admitting their holders to Registration in the United Kingdom Section of the "Medical Register" or the Colonial or Foreign Lists thereof.

| | Number Qualified. | Exemptions. | Percentage (About). |
|-----------------------------------|-------------------|-------------|---------------------|
| University of London... .. | 583 | 6 | 1.0 |
| University of Edinburgh | 949 | 10 | 1.0 |
| University of Manchester | — | 1 | — |
| University of Bristol | — | 1 | — |
| English Conjoint Board | 1,787 | 124 | 6.9 |
| Scottish Conjoint Board | 544 | 36 | 6.6 |
| Irish Conjoint Board | 301 | 5 | 1.6 |
| Apothecaries' Society, London ... | 302 | 18 | 5.9 |
| Apothecaries' Hall, Dublin... .. | 37 | 22 | 59.4 |

The Committee pointed out that this table showed that the Apothecaries' Hall of Dublin granted exemptions to a much larger extent in proportion to the number of qualifications granted than any of the other qualifying bodies, its percentage being more than six times that of the second on the list—the Apothecaries' Society of London. The Examination Committee expressed the opinion that the continued granting to candidates of exemptions in professional examinations on the ground that equivalent examinations had been passed before universities or bodies whose degrees and diplomas were not recognized by the General Medical Council for registration should be carefully supervised, and called attention to the fact that during the five years under review the majority of the universities and licensing bodies have stated that no such exemptions had been granted by them. The Committee did not recommend that the practice should be altogether discontinued, as many of the university examinations so recognized were undoubtedly of such high standard that it would be impossible to suggest that they were inadequate, or that they could be dealt with under Section XX of the Medical Act, 1858. The Committee, however, recalled the fact that last year the General Medical Council resolved:

That, in the absence of any sufficient evidence of the standard required, the Council advise the licensing bodies to refuse recognition of the First, Second, and Third Professional Examinations of Indian diplomates belonging to the "Subordinate Medical Department."

The Conjoint Boards in England, Scotland, and Ireland publish full lists of the universities and other licensing corporations whose examinations they accept as equivalent to their own for the purpose of exempting candidates; the Apothecaries' Society in London grant examination exemptions to candidates from all examinations except the final group, "on producing evidence that they have passed equivalent examinations before an examining board recognized by the Society." The Apothecaries' Hall, Dublin, states in its regulations that

A candidate is allowed for each professional examination which he has completed at any other licensing body, except the final.

Assuming that the words "licensing body" in this regulation mean a corporation granting qualifications accepted by this Council for registration, there is nothing to which the Council could object; but it appears to the Committee that the Apothecaries' Hall express their willingness to accept examinations held by any body, without any conditions whatsoever as to the approval or recognition of the said body by the Apothecaries' Hall or by any other authority.

The report was presented by the CHAIRMAN (Sir Charles Ball), who moved the following recommendation, which was seconded by Sir JOHN MOORE:

That a copy of this report be sent to the universities and other licensing bodies in the United Kingdom, and that they be requested to inform the Medical Council under what conditions (if any) they are prepared to recognize (as equivalent to their own) the professional examinations held by universities and licensing bodies whose degrees or diplomas are not registrable in the United Kingdom; and in the event of their proposing hereafter to grant such recognition, that they be further requested to supply the Medical Council with (1) a copy of their regulations on the subject, with (2) a list of the examining bodies whose examinations they are prepared to accept, for the purpose of exempting candidates from any of their own professional examinations, other than their final examinations in medicine, surgery, and midwifery, and with (3) a statement of the grounds on which they base their recognition of the examinations as being of adequate standard.

Dr. ADYE-CURRAN said that the regulation quoted should not be read in the sense the Committee had attributed to it. It was, he said, no doubt true that the Apothecaries' Hall, Ireland, granted more exemptions than other bodies, but that was because it had been deprived of its preliminary examination. The Hall had been starved by the authorities, but it did not intend to die without a severe struggle. It seemed to be subject to an organized persecution which he contended it did not deserve. It had done its best to fall into line with the views of the Council, and he objected to its actions being continually reviewed before the Council.

The recommendation was put and carried.

APOTHECARIES' HALL, IRELAND.

The Examination Committee presented a report upon the proposal made by its representatives in November last that the reports upon the Apothecaries' Hall of Ireland be discontinued until such time as the Council may direct, a motion which had been referred to the Committee for report. The first part of the report consisted of a brief summary of the origin of the special reports upon the Apothecaries' Hall, the effect of which was in part summarized in the statement that after the appointment of assistant examiners to the Apothecaries' Hall by the Medical Council the examinations held by that body were frequently inspected and reported upon, though there had been no regular inspection since 1902. In 1908 the assistant examiners had been instructed to conduct the surgical portion of the final examination and to supervise the medical and obstetrical portions, with the object of securing that at each qualifying examination the required standard of proficiency was maintained, and to report fully for the information of the Council as to the methods and standards that should be adopted at each qualifying examination. The Examination Committee recommended that these reports be discontinued, but in consequence of information before it was unable to advise the Council to dispense with all special supervision of the

examinations conducted by the Apothecaries' Hall. In view of the fact that, as appeared from the report on exemptions, those granted by the Apothecaries' Hall, Dublin, enormously exceeded the proportion granted by any other licensing corporations, the Examination Committee had made further inquiries as follows:

"The Examination Committee therefore have also had abstracted from the minutes for the same period of five years, the number of exemptions granted by the Apothecaries' Hall on account of similar examinations held by universities and other licensing corporations whose qualifications do admit to registration. The number is stated to be twenty-nine; this added to twenty-two, the number recorded in the above report on Resolution I, gives a total of fifty-one candidates who obtained exemption from some part of their professional examinations during the period of five years, 1907-11. During the same time only thirty-seven candidates passed the full examination in Medicine, Surgery, and Midwifery, and received the L.A.H., which admits the holder to registration, so that the number of candidates exempted from some portion of the necessary examinations exceeded the number of those who obtained the qualification by fourteen. This is equivalent in itself to a considerable rejection-rate, without counting candidates who presented themselves more than once for examination, or those, if any, who went up for all their examinations at the Apothecaries' Hall without obtaining any exemption.

"The returns as hitherto furnished by the Apothecaries' Hall to the Council do not show whether there were any candidates qualified who completed all their professional examinations at the Apothecaries' Hall, but in view of the above figures, if there were any, the number must have been extremely small.

"It is obvious that the candidates who seek this diploma are almost, if not entirely, those who have commenced their series of professional examinations elsewhere."

The report gave an analysis of the career of three gentlemen who during the last year had been registered on the qualification L.A.H. alone. From the full statement set out in the report it would appear that all three gentlemen had encountered considerable difficulty in satisfying the requirements of the examiners of other licensing bodies. The Committee concluded its report as follows:

The Examination Committee takes a very serious view of the statements contained in this report, especially in relation to the wholesale granting of exemptions from portions of the necessary examinations for obtaining the L.A.H., and also of the notice contained in the regulations published by the Apothecaries' Hall that without any reservation whatever "a candidate is allowed for each professional examination which he has completed at any other licensing body, except the Final."

The Examination Committee is of opinion that the Apothecaries' Hall should be afforded an opportunity of replying to this report before the Medical Council decides what, if any, action it desires to take in reference to it under Section 20 of the Medical Act, 1858.

The following recommendations appended to the report were then submitted seriatim by the Chairman of the Committee, Sir CHARLES BALL:

1. That a copy of this report be forwarded to the Apothecaries' Hall, and that they be requested to furnish the Medical Council with a detailed reply to the statements therein contained.
2. That the Apothecaries' Hall be requested for the future to send in their returns (required by the Medical Council under Section XVIII of the Medical Act, 1858) of exemptions from parts of examinations, and the results of examinations, in such a way that they can be presented to the Medical Council in the tabular form above indicated.
3. That, in accordance with the resolution of Council (Minutes, 1897, 41) assistant examiners for the Apothecaries' Hall be nominated by a committee elected for this purpose by the Medical Council and appointed by the President.
4. That an inspector be appointed under Section XVIII of the Medical Act, 1858, to visit the professional examinations held by the Apothecaries' Hall (other than the portions conducted by the assistant examiners) as often as he considers it necessary, to enable him to prepare an annual report to be submitted to the Medical Council dealing with the standard maintained, and the general character of such examinations.
5. That the inspector be appointed by the President, on the recommendation of the Committee referred to in No. 3. That the appointment be made in the first instance for one year, and that the remuneration of the inspector be 50 guineas for the year.
6. That for the future the Assistant Examiners in Surgery be required to report to the Medical Council only on the portion of the Final Examination which they conduct,

describing the general standard of knowledge displayed by the candidates, and the facilities afforded to them for conducting the examination.

7. That for the future no payment be made out of the funds of the Medical Council to Assistant Examiners for duties required of them under Section 5 of the Medical Act, 1858.

Upon Recommendation 3 Dr. ADYE-CURRAN said that the report was a cruel indictment of the body he represented. He had put down last session the motion that these reports should be discontinued, having regard to the many excellent reports received from the examiners, and why that motion was referred to the Examination Committee he did not know, unless it were to give an opportunity of reviving the fight with the Hall of years gone by by bringing up before the Council a rehash out of its musty volumes, in order to further malign and cripple its exertions in the Irish metropolis. Some twenty years ago the examination of the Apothecaries' Hall, Dublin, was reported upon as not being up to date, in common with many other bodies, and every half-year the fact was thrown in his face, and it was said, "This must be done," or something serious would happen, and an attempt was made to annihilate them, Apothecaries' Hall, Dublin. But it would fight to the last before submitting to being crushed out of existence by the Council. Many doctors under the Poor Law in Ireland could not hold their position unless they were compounders of some sort, and many of those who were otherwise qualified came up for the qualification of the Apothecaries' Hall, Dublin, in order to qualify themselves for holding appointments in Ireland, where they had to compound medicine. He protested that to adopt the recommendation that examiners should be appointed by the Committee would be taking a grave step without any just reason.

Dr. MACDONALD inquired if it were a fact that previously the Council selected the examiners, and that the method was deliberately changed some years ago, and power given to the Apothecaries Hall, Dublin, to nominate.

The President replied that no power was given to the Hall to nominate. Any member could nominate, and sometimes it happened that the Apothecaries' Hall submitted a name; it was thought that nomination by the Council was the preferable method.

In reply to Mr. VERRALL, the President said he had in emergency, such as the illness of an examiner, to appoint a substitute, but he felt the responsibility so great that he would be glad if the Council would undertake it.

Dr. LITTLE said the argument Dr. Adye-Curran had advanced as to the necessity for men who were dispensary doctors in Ireland being able to compound was as old as the hills. The Poor Law Board, Ireland, fifty years ago first passed a resolution that medical men seeking appointments as dispensary doctors or Poor Law medical officers should have the double qualification.

On Recommendation 6 Dr. ADYE-CURRAN said he understood that under the Act the assistant examiners could only report on the final examination. Now it appeared they were to report on a portion only of that examination.

After some further discussion, the recommendations of the Committee were adopted by the Council, together with the following resolution:

That the members of the Irish Branch Council be appointed a committee to nominate names to the President for assistant examiners in surgery to the Apothecaries' Hall of Ireland as vacancies arise.

Sir CHARLES BALL, Chairman of the Examination Committee, also presented the report of the Committee, accompanied by the reports of the assistant examiners, Sir Thomas Myles and Professor Conway Dwyer, on the final examinations of the Apothecaries' Hall, Dublin, held in January and April, 1913. Sir Charles Ball said it had been reported to the Examination Committee that at the surgical examinations at the Apothecaries' Hall, the examination on all subjects took place on one day. The candidates seemed to have been exhausted by the time the examination concluded.

The Examination Committee recommended:

That the examinations at the Apothecaries' Hall in clinical surgical paper, oral surgery (including surgical pathology), and surgical operations should occupy a period at each examination of at least two days.

Sir WILLIAM WHITLA seconded.

Dr. ADYE-CURRAN said the reason the candidates were

exhausted was owing to one of the examiners coming late and so keeping the examination on to a late hour.

The recommendation was put and adopted.

STANDARD OF PRELIMINARY EDUCATION.

The report of the Education Committee upon the standard of the preliminary examination in general knowledge and upon the revision of the list of examinations to be recognized after the close of the year 1913 was presented by the Chairman (Dr. MACKAY), who called attention to the improvement that the report marked. The attention of the Council was frequently drawn to the insufficiency of the general education of practitioners, and in 1900 three educational experts were called in. They were concerned with the minimum general education to be recognized by the General Medical Council. The examinations were graded, and the term "junior examination" introduced. The Committee found year by year that the ages of those entering was increasing, and in 1910 the Council decided that certain junior examinations should cease to be recognized at the end of 1913. Certain bodies were anxious to meet the wishes of the Council as regards the standard to be observed in future, and Indian and Colonial bodies had been examining up to the standard required. It became necessary for the Education Committee to define once more the standard of examination which might be called the minimum test, and the idea of the Committee was that the standard should be of the nature of an intermediate examination. The Committee suggested that the whole examination should be passed in not more than two sittings. With regard to Indian and Colonial examinations the Committee recommended a revised list for approval by the Council. In conclusion he moved that the Council adopt the following recommendations of the Committee:

Recommendations [proposed to be] adopted by the Council to indicate the standard to be maintained in any Preliminary Examination in General Education:

I. THE CHARACTER OF THE EXAMINATION.

(a) In languages, each examination should be of not less than two hours' duration; and, if it includes questions on prescribed books, of not less than three hours' duration.

In mathematics (which should include arithmetic, algebra, and geometry) the examination should be of not less than three hours' duration.

(b) In each examination the questions should be such as to test, not merely memory, but a power of intelligent application of knowledge.

In English the paper should include an essay, and should test the candidate's power to apprehend the meaning of an unprepared passage. History and geography should form part of the examination.

In classics and modern language each paper should include a sufficient passage from an unprepared book for translation into English; and questions on grammar. There should also be an adequate test of translation from English into the classical or modern language.

In arithmetic and algebra the questions and problems should involve intelligent knowledge of the principles underlying the rules. In geometry most of the questions should include a simple rider.

II. THE DISTRIBUTION OF MARKS.

In English not less than a third of the marks should be allotted to the essay and the unprepared passage taken together.

In classics and modern languages not more than a third of the marks should be allotted to translation from prescribed books.

In arithmetic and algebra the allotment of the marks among the questions should be, as far as possible, proportional to their difficulty, and the marks allotted to each question should be indicated upon the paper. In geometry simple riders to book questions should receive an adequate share of the marks.

III. The minimum percentage of pass in each subject should be:

- (a) Latin, 50 per cent.; Greek, 45 per cent.
- (b) Modern languages, 50 per cent.
- (c) English, 50 per cent.
- (d) Mathematics, 45 per cent.

[Section III was not adopted.]

IV. The whole examination should be passed at not more than two sittings; but candidates should be allowed to present themselves for re-examination as often as may be necessary to enable them to comply with this condition.

All the examining bodies should furnish yearly to the Council copies of the papers set at their examinations during the year for which the return is made.

The Committee also presented a list of examinations of Indian and Colonial bodies for recognition, in some instances only for the year 1914, pending the receipt of further information.

Dr. KNOX seconded.

Dr. THOMSON moved that instead of the words

"Recommendations adopted by the Council to indicate the standard to be maintained in any preliminary examination in general education," the following should be substituted: "The Council herewith indicates the scope of the preliminary examination in general education necessary for recognition as qualifying for admission to the *Students' Register*."

Sir HENRY MORRIS seconded.

Mr. VERRALL, as a new member, desired to know the exact position with regard to the *Students' Register*.

The PRESIDENT said the Council established the *Students' Register* under no statutory authority, but for its own convenience, and in order that students might get on to it, it had said it would recognize all examinations that came up to a certain standard.

Dr. NORMAN MOORE observed that a man might become qualified without his name ever having been on the *Students' Register*, although it was a matter of great convenience that he should go on. His own feeling with regard to the report was that it was not a series of hard-and-fast regulations, but a general indication of the amount of general education the Council thought desirable for a man commencing his medical studies.

Sir CHRISTOPHER NIXON thought the Council should try and secure the concerted action of all educational bodies in the endeavour to obtain a school-leaving certificate which would show the character of the education, leaving a certain latitude as to the number of subjects.

Sir HENRY MORRIS agreed, and said that it would be useful if it were known that the Council was desirous of having such a certificate established.

The PRESIDENT observed that the opinion was expressed by it as long ago as 1904.

Some discussion then ensued as to the phraseology both of the amendment and the recommendation.

Dr. THOMSON, with the consent of the Council, recast his amendment to read:

The Council herewith indicate the scope of the preliminary examination in general education recognized as qualifying for admission to the *Students' Register*.

The amendment was put and lost; thereupon

Dr. MACKAY withdrew the paragraph and substituted the following, which was agreed to:

Recommendations adopted by the Council to indicate the scope and character of the preliminary examination in general education recognized as qualifying for admission to the *Students' Register*.

Dr. SAUNDBY moved that Recommendations Nos. I, II, III, and IV be referred back for further consideration.

Dr. NORMAN MOORE seconded.

Sir JOHN MOORE opposed, as it would be unfortunate to postpone communications with the Indian and Colonial bodies.

Sir HENRY MORRIS was of opinion that it would be a farce to adopt the proposals of the Committee omitting these recommendations.

Dr. MACDENALD did not see the use of the reference back, as it would only hang matters up for another eighteen months or so. No suggestion had been made, as far as he could see, as to how the means suggested by Dr. Mackay could otherwise be obtained.

Mr. TOMES thought provisional recognition might be given, as recommended in the report.

Sir F. CHAMPNEYS considered the Council was in a dilemma. In the circumstances the best thing to do would be to pass the Regulations in some such form as the Education Committee suggested, and then express a pious hope for an early introduction of the system of a school-leaving examination.

Dr. MACKAY, in reply, said the recommendations were just the answers the educational bodies wanted from the

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant. Honorarium at the rate of 52 guineas per annum.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £200 per annum.

National Insurance.

NATIONAL INSURANCE ACT.

MEDICAL AID INSTITUTES.

A DEPUTATION was received by the Chancellor of the Exchequer on Wednesday, June 4th, consisting of officers and supporters of various medical aid institutes and similar associations. The deputation was accompanied by Mr. Worthington-Evans and Mr. Leif Jones.

We understand that the general purpose which the members of the deputation had in view was to make representations against the effect of the present Regulations relating to medical aid associations and existing institutions. These Regulations provide, in effect, that the grants to be made to such institutions shall only cover the cost incurred in providing medical treatment and attendance for insured persons, which must be of an adequate character whilst allowing a proper margin for maintenance and expenses, and do not permit of a profit being made out of the medical service. The provisions of the Regulations are designed to carry out the undertakings given by the Chancellor of the Exchequer in November, 1911, that the contributions from the funds out of which medical benefit is payable are towards the cost of medical attendance and treatment, and will not be allowed to be devoted to other objects. It is to be hoped that the medical profession will be keenly alive to the principles which are involved in this agitation, and which also are presented in another form in the movement towards collective contracting out which has arisen in Wales.

It is quite evident that contracting out on a large scale is a procedure which may cut both ways, and if collective contracting out were once permitted to large groups of insured persons, and they were able to obtain the full money contribution allotted for medical benefit, and to make a profit out of its administration at the expense of the medical services, there would be nothing to prevent the money voted by Parliament for providing medical attendance and treatment for insured persons being applied to other objects. This is a side of contracting out which should be clearly borne in mind, and is a danger which may be attendant upon any ill-considered movement in this direction.

SICKNESS CLAIMS AND MEDICAL CERTIFICATES.

It would appear that statements and representations are being freely made by officers of approved societies to the effect that the demands upon the sick funds of the societies are greater than was anticipated, and that certificates of inability to work are being signed, it is said, by some medical men with too much readiness. Arising out of this the demand for the appointment of medical referees is attracting increased attention; and, apart from the circular issued by the General Medical Council, it is clearly to the interest of members of the medical profession that they should unite to prevent any abuses in this direction. A ground for this warning is found in the fact that there are signs of renewed agitation on the part of the older societies to be allowed to appoint their own medical

officers to attend upon their members. This, of course, would mean an amendment of the Insurance Act in a direction which, it is true, is not to be anticipated, but at the same time it is a movement which has strong support, and, if allowed to develop, would be very harmful to the best interests of medical practitioners. It is quite clear that the most effectual way of preventing it is to exercise constant care in the granting of certificates, and to see that no encouragement is given by any laxity to trivial or frivolous claims.

WARNING RESOLUTIONS OF THE GENERAL MEDICAL COUNCIL.

It may be convenient here to reproduce the warning notice issued by the General Medical Council in November, 1911:

Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes. And whereas such certificates include, *amongst others*:

CERTIFICATES:

- (a) Under any statute relating to births, deaths or disposal of the dead.
- (b) Under the Lunacy Acts.
- (c) Under the Vaccination Acts.
- (d) Under the Factory Acts.
- (e) In relation to children or to excusing school attendance.
- (f) In connexion with sick benefit, insurance and friendly societies.
- (g) In connexion with workmen's compensation.
- (h) In connexion with naval or merchant shipping.
- (i) For procuring the issue of Foreign Office passports.
- (j) For excusing attendance in courts of justice, in the public services, in public offices, or at ordinary employments.

And whereas it has been made to appear to the General Council from time to time that some registered medical practitioners have given and signed untrue, misleading, or improper certificates of the above specified or other descriptions.

Now, therefore, the General Medical Council hereby give notice that any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate, *whether relating to the several matters above specified or otherwise*, is liable to be adjudged by them to be guilty of "infamous conduct in a professional respect" and to have his name erased from the *Medical Register* under Section 29 of the Medical Act, 1858.

CANVASSING AND TOUTING.

In March last the President of the General Medical Council, as noted in the SUPPLEMENT to the JOURNAL of March 22nd, p. 265, wrote to the National Insurance Commission stating that the attention of the Council had been called to allegations that objectionable methods of advertising and canvassing had been employed in various parts of the country with the object of procuring the enrolment of insured persons and their dependants as the patients of particular medical practitioners. In some instances it was stated that the advertisements were so framed as to suggest that they were issued with the cognizance of the Insurance Commission or of local insurance authorities; in other instances touting or canvassing was said to have been practised in the supposed interest of approved societies and institutions, and of medical practitioners associated with the National Insurance service. The President went on to state that the Council had repeatedly taken steps to inform practitioners themselves of the grave liability they incurred by resorting to practices of this kind, and had more than once exercised its disciplinary functions in the restraint of wilful offenders. It appeared, however, that some of the local authorities, institutions, and societies concerned in the administration of medical benefit under the National Insurance Act might have acted in ignorance of the principle which guides professional conduct in relation to advertising and canvassing, and had thereby seriously endangered the position of practitioners professionally

associated with them. The President therefore invited the Insurance Commissioners to call the attention of all Insurance Committees, Local Medical Committees, and approved societies and institutions to the following notices published by the General Medical Council on June 6th, 1889, and December 1st, 1905, and still operative:

Notices.

The General Medical Council considers that, in the interests of the medical profession, it is advisable to bring to the notice of its members certain resolutions which have from time to time been adopted as expressing the views of the Council upon certain forms of professional misconduct which have been or may be dealt with as amounting to "infamous conduct in a professional respect" within the meaning of Section 29 of the Medical Act, 1858. The Council, however, wishes it to be distinctly understood that these resolutions are not exhaustive of the forms of professional misconduct which may be dealt with by the General Medical Council under its disciplinary powers, and that the Council is not in any way precluded from considering and dealing with any form of professional misconduct outside the scope or precise language of the following resolutions:

(1) "That the Council strongly disapproves of medical practitioners associating themselves with medical aid associations which systematically practise canvassing and advertising for the purpose of procuring patients." (June 6th, 1899.)

(2) "Whereas it has from time to time been made to appear to the General Medical Council that some registered medical practitioners have, with a view to their own gain and to the detriment of other practitioners, been in the habit of issuing or sanctioning the issue of advertisements of an objectionable character, or of employing or sanctioning the employment of agents or canvassers, for the purpose of procuring persons to become their patients: And whereas in the opinion of the Council such practices are contrary to the public interest and discredit to the profession of medicine: The Council hereby gives notice that any registered medical practitioner resorting to such practices thereby renders himself liable to be charged under the 29th Section of the Medical Act, 1858, with 'infamous conduct in a professional respect,' and if after due inquiry he is judged by the Council to have been guilty of such conduct the Council may, if it sees fit, direct his name to be erased from the *Medical Register*." (December 1st, 1905.)

Copies of the letter addressed to the Insurance Commissioners, together with the resolutions quoted above, have recently been issued by the General Medical Council to secretaries of approved societies and institutions. (See also p. 527.)

THE POSITION IN SOUTH WALES.

TERMS ARRANGED AT SWANSEA.

At a meeting in Swansea, on June 6th, attended by the Mayor and by representatives of the labour organizations, the friendly societies, and of medical practitioners (Drs. Nelson Jones, F. Knight, L. Freeman Marks, and Edgar Reid), a settlement was come to between the trade unions and the friendly societies and the medical practitioners in the Swansea district. The following terms of settlement were agreed to and signed by those present:

1. Rates of attendance to be 10s. 6d. for wife and children under 16 years per annum; 8s. 8d. for any one uninsured person per annum.

2. The fees to be collected by the friendly societies and labour organizations, and handed over quarterly to the medical men.

3. Each patient to have free choice of doctor from a panel of those willing to serve, and each doctor to have free choice of patients desiring his services.

4. No doctor whose conduct has received the ban of the British Medical Association shall be eligible for this panel.

5. The services to be rendered by the doctors shall conform to the regulations laid down in the Insurance Act.

6. Officials of the friendly societies and trade unions shall have free access to the doctors for consultation in regard to any number on the sick funds.

7. All ordinary certificates such as "going on" and "going off" notifications shall be granted free of cost.

8. The friendly societies and labour organizations pledge themselves to the following undertakings:

- (a) That they oppose the formation of any medical aid society in Swansea.
- (b) That they will use all the influence they possess to prevent the formation of any medical aid society in the districts served by the Swansea Hospital.
- (c) That they will use all the influence they possess to get the kindred organizations in the district brought into line with the pledges given under (a) and (b).

9. The above undertakings are made in consideration of the recent resolution of the staff of the hospital—that is, refusing to treat patients from any medical aid society—being held in abeyance for a reasonable period, say till the end of the present year.

On the motion of Dr. KNIGHT, seconded by Mr. WILSON, one of the representatives of the labour organizations, a vote of thanks was carried to the Mayor for the leading part he had taken in bringing about the settlement.

The concessions made by the medical men are regarded as very generous. A Public Medical Service had already been started in Swansea to provide medical attendance and medicine for persons unable to pay the ordinary charges. All medical practitioners in the town and district became either honorary or active members of the service, which was open to all persons with incomes not exceeding £3 a week, who were given free choice of doctor from a list of fifteen names, subject to the consent of the doctor to act. The subscription for the service was 13s. per annum for the wife and (or) family under 16 years of age of an insured person, and for any one uninsured person 8s. 8d. per annum. It was arranged to charge the wives of permanently sick and aged members of friendly societies, 4s. 4d. per annum. The scheme provided that the subscriber was entitled to ordinary medical attendance and medicine, but not to attendance in respect of confinements, miscarriages, operations, or illnesses the result of personal misconduct. The friendly societies and labour organizations objected to these terms, and prepared the organization for a medical aid association to be put into force if the medical profession did not make concessions. The subscription to the association was to be 9s. 6d. per annum, and it was proposed to appoint two or three whole-time medical officers. At this stage the resolution of the staff of the Swansea Hospital, already published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of May 3rd, p. 398, was passed. This was followed by the announcement that the working classes proposed to stop their subscriptions to the hospital and so hamper the good work done in that institution.

The state of things which had come about in Swansea affected the whole of South Wales, as it was understood that in many places the lead of the friendly societies and labour organizations in Swansea would have been followed. It will be seen that in coming to the agreement last week in Swansea the medical practitioners have made the following concessions: They have accepted the rate of 10s. 6d. a year instead of 13s., but the lower rate will be the net payment to the practitioners, while from the higher rate proposed for the Public Medical Service, management expenses would have to be deducted; they have agreed to grant all ordinary certificates free of charge, and, according to Clause 5, to make no extra charge for operations, anaesthetics, etc. The terms now agreed establish free choice of doctor in place of the scheme for one or two doctors to be appointed by each society or club.

The settlement has been reached on the strict understanding that the labour organizations and friendly societies have pledged themselves to oppose the formation of any medical aid association in Swansea and the district, and to use their influence to disband those already formed. It is anticipated that the agreement will be loyally carried out on the side of the working man, and it is hoped that a friendly spirit will in future prevail between all the parties concerned. It will conduce to a satisfactory working of the agreement.

THE WELSH COAL FIELDS.

The position in the coal fields of Monmouth and Glamorgan still continues to be difficult and serious. We understand that, in response to the invitation that he should introduce the deputation to the Chancellor, Dr. Addison has visited South Wales, and that informal conferences have been held with a view to endeavouring to

arrange a basis for negotiations. The Welsh Commissioners, as well as the Glamorgan and Monmouth Insurance Committees, must necessarily be parties to any settlement apart from the colliery surgeons and the workers' organizations, so that an adjustment of the differences presents peculiar difficulties. It is hoped, however, that a conference of a more definite character may be arranged at an early date.

LOCAL MEDICAL COMMITTEES.

BARROW-IN-FURNESS.

This Committee was recognized on March 4th for the current year. As originally constituted, it was composed of all the doctors on the panel, but it has since been enlarged to include all other qualified men in the town. The membership is 33—24 on the panel, 3 in general practice not on the panel, 1 retired, 1 in practice as a dentist only, and 4 holding whole-time appointments.

The following officers were elected for the year:

Chairman.—Dr. Daniel.

Honorary Secretary.—Dr. Lorton Wilson, Norwood, Barrow-in-Furness.

Executive Subcommittee.—Drs. Callaghan, Livingston, J. A. Reed and Thompson, with Chairman and Honorary Secretary *ex officio* members.

Representatives on Insurance Committee.—Drs. Livingston and J. A. Reed.

Representatives on Medical Service Subcommittee.—Drs. Alexander, Harper, and Livingston.

Constitution of New Committee.—A new constitution has been adopted and sent to the Commissioners for approval after this year. By this the Committee will consist of all qualified men in the town, and those district men on the panel for the borough; an executive subcommittee of 4, 3 elected from the panel, and 1 from the non-panel men, with the Chairman and Honorary Secretary as *ex officio* members. Nominations for the Chairman, Secretary, Committee, and Medical Representatives on Insurance Committee and on Medical Service Subcommittee are to be sent to the Secretary not later than three days before the annual meeting; if a contest is necessary, a postal vote is to be taken. All officers to hold office for a year, and to be eligible for re-election. The annual meeting is to be held in the first fortnight of January. A special meeting may be called at any time on a requisition from 20 per cent. of the members. The quorum for meetings of the Committee is to be 5, and for Subcommittee 3.

Certificates.—It was decided to charge 6d. for all extra certificates, and 2s. for examining new members for clubs.

Conferences with Chemists.—Two conferences have been held with the chemists, and a small pharmacopoeia of thirty-five prescriptions has been drawn up. The new drug tariff was agreed to, including the clerical fee of 1d. on the understanding that the chemists continued to accept "Rep. mist." without any objection. Doctors were asked to supply duplicates of all original prescriptions; where this was not done the clerical fee would be charged; for repeat mixtures no duplicate would be necessary, and no clerical fee would be allowed.

Surgery Hours.—At the end of the first quarter it was unanimously agreed to have no surgery hours on Sundays or public holidays, but to attend urgent cases only.

Expenses of Committee.—The annual subscription is still unsettled, and a levy of 1s. a member has been collected to defray current expenses.

Malingering.—It was decided that this was a matter for the society complaining; the society should obtain the consent of the doctor in charge of the case to an independent examination, and should choose the consultant, preferably a man outside the town, and pay 11s. fee, minimum one guinea.

Payment for First Quarter.—Payment was made for all names on each practitioner's list at the end of the quarter, the remaining money to be carried to a suspense account to be dealt with when the residue of patients are allotted. Many of the names on the lists are incorrectly placed there, as a good many medical cards were issued to insured persons over 65 not entitled to medical benefit.

Allocation.—A conference was held with the Medical Benefit Subcommittee, and the Local Medical Committee's scheme for allotment was agreed to. This was a division in equal shares, as far as possible by districts, but no practitioner is to be allowed more than 2,000 (fixed locally as a limit). Any practitioner who wishes to limit his list to a smaller number is to be allowed to do so.

Medical Benefit Subcommittee.—The question of placing a medical man on the Medical Benefit Subcommittee was brought up at this meeting, and Dr. Livingston was appointed as a result.

Temporary Residents.—The following resolution was unanimously approved and sent to the Commissioners:

That inasmuch as the medical profession has been guaranteed a minimum capitation fee of 7s. per head per annum, we decline to accept Memorandums 159 and 161/I.C. as a fair solution of the question of payment for medical attendance on temporary residents, as it must involve the reduction of the amount of the capitation fee.

It was agreed to refuse to attend temporary residents except as private patients.

Income Limit.—The question of an income limit has been postponed till the election of the new Insurance Committee has taken place.

Committee Deputies.—The medical men on the Insurance Committee have been asked to urge on the Committee that deputies should be allowed to act for the medical men on the Committee, and that a doctor should be placed on all Subcommittees.

Persons over 65.—It was decided that no attendance be given to persons over 65 below the insurance rates—namely, 8s. 6d. including medicine, or 7s. without medicine.

Certificates for Sickness Benefit after Confinement.—It was decided that certificates for sickness benefit after confinement—as distinct from maternity benefit—in cases attended by a midwife only be a matter for private arrangement between doctor and patient, this being no part of a doctor's duty under the Insurance Act.

WEST RIDING OF YORKSHIRE.

The ninth meeting of the Local Medical Committee of the county of the West Riding of Yorkshire was held on May 30th. Dr. R. MAY was in the chair, and twenty-seven members were present.

District Insurance Committees.—A letter was read from the Clerk of the Insurance Committee acknowledging receipt of the resolution passed at the previous meeting, in which increased medical representation was demanded, and promising that the resolution should be submitted to the next meeting of the Medical Benefit Subcommittee.

Rules for Administration of Medical Benefit.—A letter was read from the Clerk stating that the applications of the Local Medical Committee for prints of these rules to be supplied to practitioners and insured persons had been considered by the Medical Benefit Subcommittee, which could not see its way to accede to the request. It was decided to renew the application.

Income Limit.—A letter from the Clerk was read stating that the resolutions which were carried unanimously by the Local Medical Committee at a meeting on April 11th had been considered by the Medical Benefit Subcommittee, which decided that no action be taken for the present, but that the matter should be reconsidered when the Insurance Committee was reconstituted in July.

New Representatives on the Local Medical Committee.—The HONORARY SECRETARY read a letter from the Commissioners recognizing the recent changes in the constitution of the Committee, whereupon the three new members were welcomed by the CHAIRMAN, and took their seats—namely, Dr. Orford (Pontefract), Dr. Craik (Swinton), and Dr. Ross (Selby).

Excessive Ordering of Drugs.—With reference to the case of excessive ordering of drugs, noticed in the SUPPLEMENT of May 24th, p. 459, it was reported that, after investigating the circumstances and hearing the practitioner concerned, the Committee reluctantly came to the conclusion that, under Regulation 46, the Insurance Committee might fairly surcharge him, should it think fit, for certain of the articles prescribed. The Secretary was directed to communicate this decision to the Clerk.

Pharmacopœia: Tariff of Drugs.—A further report of the Pharmacopœia Subcommittee was received, and, after

discussion, the report, together with the draft pharmacopœia, was referred back to the Subcommittee for further consideration and amendment. The report of the Subcommittee on the revised tariff of drugs, etc., declining to approve the tariff, as being premature and uncalled for, was adopted. The Subcommittee was directed to prepare a list of articles deemed to be foods or proprietary articles which should not be prescribed as medicines, to be printed and circulated for the consideration of the Local Medical Committee.

KINGSTON-UPON-HULL.

Temporary Residents.—At a meeting of the Kingston-upon-Hull Local Medical Committee, held on June 3rd, the following resolution was passed:

With regard to insured persons temporarily absent from home, the members of the Local Medical Committee are not willing to consent to, and protest against, any deduction from the remuneration of practitioners greater than the proportion of the capitation fees which covers the periods for which the practitioners cease to be responsible for the treatment of such insured persons.

EAST SUFFOLK.

MEETINGS of the East Suffolk Medical Committee have been held on April 24th, May 25th, and June 3rd.

Temporary Residents.—The Committee has recommended that temporary residents should be treated as private patients only, and should therefore not be accepted on lists as insured persons, and that the green vouchers should be ignored.

Tuberculosis Cases.—A suggested scale of fees for domiciliary attendance on these cases was considered and agreed to, with the exception of the item that 5s. could not be accepted as the limit allowed for attendance on any one case a week.

Payment of Accounts.—The action of the Insurance Committee in refusing to pay accounts of doctors (who had not signed the new agreement) for dispensing during the previous quarter was criticized, and the HONORARY SECRETARY reported that as the result of further correspondence the Insurance Committee had admitted its liability, and orders had been given for the accounts to be paid.

CARDIFF.

The following is a list of the members of the Local Medical Committee:

Chairman.—Dr. Thos. Wallace.

Vice-Chairman.—Dr. Jas. Robinson.

Secretaries.—Drs. W. B. Crawford Treasure and E. E. Brierley.

Committee.

|-----------------------|-------------------------|
| Dr. H. Campbell | Dr. H. Samuel |
| Dr. T. A. Chave | Dr. A. W. Sheen |
| Dr. H. G. G. Cook | Dr. H. E. Skyrme |
| Dr. E. T. Collins | Dr. R. J. Smith |
| Dr. D. Cargill Martin | Dr. W. Mitchell Stevens |
| Dr. Wm. Martin | Dr. C. T. Vachell |
| Dr. W. A. Neish | Dr. W. J. Corrigan |
| Dr. H. Paterson | Dr. A. L. Thornley |
| Dr. A. S. J. Pearse | |

The Committee has been recognized by the Welsh Insurance Commissioners and six meetings have been held. Among the matters dealt with have been the rules for insured persons and the provision of a pharmacopœia which has been issued to the local practitioners. The Committee has undertaken the allocation of insured persons who had been refused by the medical men of their choice, and has arranged for their attendance in several cases by the nearest medical man available.

CORNWALL.

The following resolutions were adopted at a meeting of the Cornwall Medical Committee held at St. Austell on May 27th:

Distribution of Mileage Grant.—That meetings be called by the conveners in each district.

That the medical men in each district check the lists of insured persons, ruling out all persons who live within three miles by road of any doctor on the panel, and make a return to the County Medical Committee of:

(a) Number of patients in each practice living beyond a three-mile radius.

(b) All points in connexion with difficulty of access in any special cases.

Temporary Residents.—That we should urge on all practitioners in Cornwall:

(a) Not to agree to any deduction from moneys due to,

them under the Insurance Act for the purposes of the scheme outlined in Memorandum 161.

(From this Memorandum it appears that the attendance on visitors is to be paid for out of a central fund, which will be formed out of moneys deducted from that due to practitioners in the district from which the visitor comes. And then the Commissioners only promise to pay a dividend.)

- (b) Only to treat the above-mentioned classes of insured persons as private patients until such time as suitable arrangements are provided by the Commissioners.

Medical Certificates for Sickness Benefit in Respect to Cases Attended by Midwives.—That it is no part of the duties of insurance service practitioners, under their agreement, to visit maternity cases for the purpose of giving certificates, when such cases have been under the care of midwives, and it is hoped that imposition of this kind will be resisted by the individual practitioners and by the Local Medical Committees.

Fees for Non-Insured Members of Clubs.—That 8s. 6d. per head per annum be the charge for all non-insured members of clubs who were under the age of 65 years in July, 1911.

That the District Medical Committees be informed of this, and asked to see that this is carried out everywhere, and report to the County Medical Committee.

That non-insured persons (being members of clubs) over 65 years of age in July, 1911, be treated at the old rate, plus 2s. 6d. Government grant, where it was payable.

District Committees.—The Honorary Secretary to send to each district convenor a list of men in his district, and ask him, when he calls his meeting, to arrange for the election of four medical representatives to serve on the District Insurance Committees.

(The names of those elected as representatives ought to be sent in, immediately after the election takes place, to Dr. J. W. Haughton, "Tannachie," Wood Lane, Falmouth, Honorary Secretary, Cornwall Medical Committee.)

HAMPSTEAD.

A MEETING of the Hampstead Provisional Medical Committee was held on June 5th, when Dr. J. FORD ANDERSON was in the chair and nine members were present.

National Insurance Act.—A letter from the Medical Secretary of the British Medical Association with reference to charges by chemists for copying prescriptions was read, and the consideration of documents relating to the expenses and co-ordination of Local Medical Committees, and regarding temporary residents, received from the Medical Secretary through the Honorary Secretary of the Hampstead Division, were postponed until there was a properly constituted medical committee able to deal with them.

MEETINGS OF INSURANCE COMMITTEES.

LONDON.

Distribution of Unallotted Funds.

A SPECIAL meeting of the London Insurance Committee was held on June 5th to consider the allocation of the funds accumulated in respect of 400,000 persons who had not exercised their right to select a doctor.

It will be recalled that at the last meeting of the Committee (BRITISH MEDICAL JOURNAL SUPPLEMENT, May 31st, p. 475) a proposal to distribute the money (£34,000) in proportion to the number of insured persons up to 2,000 on the list of each practitioner on the panel was withdrawn in order that the legal aspects might be considered. The Medical Benefit Subcommittee now recommended that the Insurance Commissioners be asked to take the opinion of the Law Officers of the Crown on the following points:

1. Whether, in view of the fact that there has been no allocation either by number or by name to doctors of insured persons who have not been accepted by a doctor, the Committee is (i) compelled, or (ii) has the right, to distribute the amount appropriated for medical benefit and domiciliary treatment in connexion with sanatorium benefit in respect of such insured persons, and which is approximately £34,000, among the doctors who, on or before April 14th, 1913, had joined the London panel.

2. If the reply is in the affirmative to either of the alternatives above mentioned, whether the Committee is empowered to adopt all or any of the methods suggested in Circular 10, I.C., dated February 18th, 1913, and also to set aside a certain portion of the sum in hand for the purpose of refunding to insured persons who had not made use of their medical tickets sums paid by them to doctors on the panel for attendance upon them during the period January 13th to April 14th, 1913.

3. If the reply is in the negative to both the alternatives above mentioned the Committee will be (i) compelled, or (ii) has the right to distribute the amount after the allocation of the residue of insured persons to the doctors has been made, and, if

so, (iii) whether only to those doctors who were on the panel during the first quarter, or (iv) to all the doctors on the panel at the time of the allocation of the persons.

4. If the reply to the questions in the foregoing paragraphs 1 and 3 is in the negative, in what way the above-mentioned sum of £34,000 should be dealt with by the Committee.

5. Whether the Committee is justified in treating the amount to be distributed or otherwise dealt with as at the rate of 7s. per annum per insured person, notwithstanding that of this amount 2s. 6d. per insured person has not been authorized by Act of Parliament, but rests on a resolution of the House of Commons voting a supplemental amount to meet such 2s. 6d. per insured person.

6. Generally with regard to the matter.

Mr. O. E. WARBURG (Chairman of the Medical Service Subcommittee) moved an amendment:

That inasmuch as insured persons who have not selected a doctor are equitably entitled to the value of the treatment for which they have paid, it be referred to the Medical Benefit Subcommittee to consider and report as to the arrangements necessary to allow of the money due to those persons being carried to the Special Arrangements Fund.

Mr. Warburg said it was inequitable that money accrued in respect of persons who had not chosen a doctor should be allocated to practitioners on the panel who had performed no service to those persons nor had them allotted. He did not think medical men on the panel would desire to be paid for services they had not rendered or be given fees in respect of persons they had not undertaken to attend.

Dr. EVAN JONES seconded. He said that as these 400,000 people had not availed themselves yet of the services of any doctor and had paid their own medical bills, they were entitled to have the contributions they had paid held over for their own benefit. He was doubtful whether the accumulated funds would ever materialize; he thought that any money not spent out of the special 2s. 6d. provided by the Government would be retained by the Treasury.

Mr. MOFFREY suggested that Mr. Warburg's proposal should be submitted with the others for the opinion of the Law Officers of the Crown.

Dr. LAURISTON SHAW hoped this would be done. At the same time, he remarked that it would be ridiculous to suggest that the 400,000 people had received nothing during the last four months. They had received cover and the doctors had taken the insurance risk, for which they should receive payment.

Dr. H. H. MILLS opposed the amendment. He said that the reason the number 400,000 remained as high as it was was that the people had not become ill. Many of them were young adult persons who would probably not be ill in the first months or even years of the working of the Act. The amendment vitiated the principle of insurance, and in equity the money should be paid to the doctors who had undertaken the risk of sickness in the county during the time the money had accrued. Postponement of payment would be a great injustice to the medical profession. He hoped the Committee would proceed not to allot persons, because there were difficulties attached to that, but certainly to allot numbers of insured persons to individual doctors. He had the authority of the Chairman of the Joint Committee for stating that the money available for medical benefit would not be paid except to those doctors actually on the lists for the quarter.

Mr. KINGSLEY WOOD hoped that statement would not be taken as the last word on the subject.

The CHAIRMAN said he ought to have stepped Dr. Mills from making the statement.

Mr. F. BRIANT said that the persons who had not chosen a doctor were mainly of the indifferent and careless class. The amendment proposed to give them special consideration which other persons had not obtained. It placed a premium on the carelessness and indifference that had been one of the greatest difficulties in getting the Act into operation at all.

Mr. EDWARD SMITH thought the amendment ill-advised; the doctors on the panel might as well be asked to repay the moneys they had received in respect of persons who had been accepted but who had not received treatment. How would Dr. Evan Jones like his colleagues to be asked to do that? To submit this proposal to the Law Officers would be to make the Committee look ridiculous.

The CHAIRMAN remarked that he could not accept the amendment; and Mr. WARBURG said that as the feeling of

the Committee was obviously against him he would withdraw it.

Mr. KINGSLEY WOOD proposed that counsel's opinion, instead of that of the Law Officers, be taken, but after some debate this proposal was lost.

The recommendations of the Subcommittee as set out above were then carried.

The Medical Benefit Subcommittee also recommended:

That the further consideration of the question of the distribution of the amount available in the panel fund be postponed until the opinion of the Law Officers has been received.

Mr. KINGSLEY WOOD moved an amendment:

That no distribution shall be made of the amount in the panel fund until after the complete assignment of insured persons amongst the doctors on the panel.

He said there had been a great deal of heartburning amongst medical men in London as to the distribution of the amount accumulated, and he wanted the Committee to establish the principle that no allotment would be made until all the insured persons had been assigned. He felt that to be the intention of the Act and Regulations.

Mr. ROCKLIFF seconded.

Mr. COYSH hoped this proposal would not be carried. It was well known at the offices of the Committee that the assignment of insured persons could not be made for some months.

Dr. LAURISTON SHAW thought the doctors on the panel would hardly feel themselves to be properly treated if this proposal were carried.

Mr. BEN COOPER remarked that the amendment assumed a right on the part of the doctors to the money.

The CHAIRMAN asked Mr. Wood not to press the amendment, as it rather prejudged the questions to be submitted to the Law Officers.

The amendment was withdrawn and the recommendation carried.

Proposed Extension of Contracting-Out.

The Committee considered the adjourned recommendations of the Medical Benefit Subcommittee for the extension of contracting out under the conditions set out in the SUPPLEMENT of May 31st, p. 476.

Mr. COYSH moved an amendment to the effect that the Medical Benefit Subcommittee should consider each application on its merits. He said the General Purposes Subcommittee, on whose behalf he moved the amendment, felt there would be a risk in classifying definitely the classes of people who would be allowed to contract out. The Committee should have a perfectly free hand, but he hoped it would be understood that there would be no factious opposition, and that persons who made out a clear and reasonable case would have their applications granted.

The amendment was carried, with the proviso that the final decision should rest with the Insurance Committee. The report of the Subcommittee as amended was then approved.

ISLE OF WIGHT.

Medical Representation on Subcommittees.—At the last meeting of the Isle of Wight Insurance Committee a letter was read from Dr. J. W. Pridmore, Honorary Secretary of the Local Medical Committee, asking that one more medical representative might be placed on each Subcommittee of the Insurance Committee, and that a deputy might be allowed to attend if the member appointed was unable to be present. [At the last meeting it was decided, contrary to the wishes of the profession, to appoint only one of the three medical men on the Committee to each of the Subcommittees (SUPPLEMENT, April 19th, p. 338)].

Dr. G. BENINGTON WOOD urged that the acceptance of the proposal of the Local Medical Committee would promote goodwill and concord. The attitude the Committee had adopted up to the present suggested that it did not realize that the Local Medical Committee was a statutory body, and had a right of appeal to the Insurance Commissioners. The proposal was seconded by Dr. ROBERTSON, but opposed by several speakers, including Dr. WALKER.

The Committee decided not to accede to the request of the Local Medical Committee.

Other Medical Business.

A further letter was read from the Local Medical Committee asking that matters connected with the administration of medical benefit might be debated in private, and referred in the first place to the Medical Service Subcommittee; that the form of contract with medical men on the panel should be referred to the Local Medical Committee for consideration before being sent to the practitioners for signature; and that a common form of medical certificate should be adopted.

Some members expressed the wish that no notice should be taken of the letter, but by a majority it was decided that the letter be referred to a subcommittee.

Temporary Residents.

The following resolution, passed at a meeting of practitioners serving on the Isle of Wight panel, held at Newport on June 3rd, was afterwards adopted by the Local Medical Committee, and forwarded to the Insurance Committee and to the Insurance Commissioners (England):

That this meeting advises all practitioners on the panel to refuse to treat insured persons temporarily resident outside their own district, except as private or non-paying patients, until arrangements satisfactory to the profession have been formulated by the Commissioners, and also to decline to agree to any deduction from the amount which they should receive under their agreement for a capitation payment for the purpose of forming a fund for the provision of medical benefit for temporary residents.

OLDHAM.

Temporary Residents.

The Finance Subcommittee of the Oldham Insurance Committee on May 30th adopted the following resolution:

That no further green vouchers be issued until definite information is forthcoming as to the source of the income wherewith to meet the liability thus incurred.

This resolution was forwarded to the Commissioners, but we understand that no reply has been received. At an earlier date representations had been made to the Commissioners objecting to the proposal to arrive at the "case value" by taking the number of persons who had been sick during any year in the area as a basis of calculation, and it was argued that the basis that should be taken was the number of cases of sickness, since many insured people had many attacks of sickness in the year. When the Memorandums 159 and 161/I.C. were published, and it was seen that the case value was there calculated on the basis of sick persons, and not on cases of sickness, further representations were made to the Commissioners, who on May 31st replied that the question as to the precise method of reckoning cases for the calculation of the case value to be transferred to the Central Fund was under consideration.

INSURANCE NOTES.

EMPLOYERS' PARLIAMENTARY ASSOCIATION.

SIR CHARLES W. MACARA, Bart., President of the Employers' Parliamentary Association, has addressed a letter to the press, in which, on the part of his association, he expresses a strong opinion that a special Commission of a thoroughly representative character should at once be appointed to consider the insurance scheme with a view to such material amendment as may be found necessary, and that until this commission has reported no serious attempt should be made to amend the Act. He considers that in existing conditions of parliamentary business Parliament cannot give time to the consideration of the hundreds of amendments suggested, and that a repetition of the rushing tactics pursued in 1911 may result in making confusion worse confounded. He recalls the fact that during the passage of the bill through the House of Commons he took occasion to urge on the Chancellor of the Exchequer the necessity for due consideration of the measure, and that later on he and the association he represents strongly urged a postponement of the date of the coming into force until January, 1913, and proposed to the Prime Minister to receive a deputation of representatives of the great industrial employers in the kingdom, a request which Mr. Asquith refused. The case for postponement of the date of bringing the Act into

operation rested, Sir Charles Macara says, upon the view that the scheme was ridiculously complicated, needlessly cumbersome, grossly extravagant, and, moreover, that the incidence of taxation under it was evidently unequal and inequitable. He now contends that already, though sickness benefit has been payable for less than six months, the responsible leaders of approved societies are alarmed at the grave increase of malingering and in sickness claims, which threaten their institutions with insolvency, and are destroying the morale of a people hitherto noted for their self-reliance. While not opposed to a scheme of national sick insurance founded upon a knowledge of industrial conditions and upon experience, he considers that the Act operates most harshly upon those who need most consideration and help; that it is financially unsound; that it will issue in bitter disappointment to thousands; that its conditions and restrictions are arbitrary and offensive; that its incidence is invidious and unjust, and must ultimately result in increasing the cost of living and the burden of life; and that all these evils could have been avoided if reasonable time had been taken to enable those most interested to give the scheme due and proper consideration. He traverses the statement of the Chancellor of the Exchequer and his friends that the Act is working smoothly, and alleges that as regards vast numbers of people the scheme is as yet a dead letter, and that people are being compelled to pay but are not in many instances getting the benefits. Sir Charles Macara, as a member of the Liberal party, discusses the effect of the Act upon the prospect of that party, a matter into which we need not follow him.

STATEMENT OF NATURE OF DISEASE UPON CERTIFICATES.

At a meeting of the Lancashire and Cheshire Miners' Federation in Manchester, on June 7th, it was stated that the Insurance Commissioners were asking approved societies to require the nature of an illness to be stated on medical certificates for sickness benefit, and that certain societies were making this requirement. It was also stated that medical men were refusing to comply with this condition, and the delegates at the meeting passed a resolution "strongly supporting" the medical men in this action, and protesting against societies requiring the illness to be stated on medical certificates, as they believe it "to be fraught with the gravest danger to the interests of working people." It was also stated that Mr. Masterman's attention had been drawn to the matter.

MANCHESTER AND SALFORD.

A union of medical practitioners who are not working the Insurance Act has been formed under the title of the Northern Division of Non-panel Doctors (Manchester and Salford). The honorary secretary is Dr. Andrew C. Clarke, 402, Bury New Road, Higher Broughton, Manchester.

REPORTS OF LOCAL ACTION.

LONDON.

PROPOSED TRANSFORMATION OF THE MEDICAL COMMITTEE FOR THE COUNTY OF LONDON.

DR. B. G. MORISON (Islington, N.) writes: Dr. Haslip, in criticizing my letter in last week's issue (p. 502), refers to what he calls its personal side. I should like to state that I deliberately avoided personalities, which appear to me to be best left out of controversy. Moreover, I did not know of any particular person to whom the responsibility for the proceedings objected to should be attached. Dr. Haslip mentions the names of Mr. Evan Jones and Mr. E. B. Turner. I have always regarded both of these as honorable gentlemen who have done excellent work for their profession, and so I still regard them, even while differing from some of their opinions. Of Dr. Haslip himself I may say the same. I have no wish to discuss anew the procedure in connexion with the meeting of June 2nd; accusations would be odious and extenuations compromising.

SCOTLAND.

SCOTTISH MEDICAL INSURANCE COUNCIL.

The Chairman of the Scottish Medical Insurance Council, Dr. William Russell, has by a circular dated June 3rd

intimated its dissolution. The circular states that when the Council was formed it was determined that it should consist of representatives of the medical faculties of the four Scottish universities, of the three medical corporations, of the Scottish Committee of the British Medical Association, and of a representative elected by the practitioners in each Scottish insurance area. The circular goes on to state that a letter had been received from the Scottish Committee of the British Medical Association stating that it had unanimously decided to withdraw from the Scottish Medical Insurance Council. The Chairman of the Council took the view that having been constituted in the manner indicated above, the withdrawal of any one of the participating bodies led necessarily to the dissolution of the Council. His letter concluded with the following statement: "Whether the Council will be reconstituted at some future date will probably be determined by those who hold that the National Insurance Act requires drastic amendment in the interests of the public health as well as of the medical profession."

THE INSURANCE SCHEME.

STATE SICKNESS INSURANCE COMMITTEE.

A MEETING of the State Sickness Insurance Committee appointed by the Special Representative Meeting in November, 1912, was held at the house of the Association, 429, Strand, W.C., on Thursday, June 5th. Mr. T. JENNER VERRALL (Chairman of Representative Meetings) was in the chair, and the members present were:—*England and Wales*: Dr. R. M. Beaton (London), Mr. C. E. S. Flemming (Bradford-on-Avon), Dr. E. R. Fothergill (Brighton), Dr. Herbert Jones (Hereford), Dr. D. F. Todd (Sunderland), Mr. E. B. Turner (London). *Scotland*: Dr. John Adams (Glasgow), Dr. R. McKenzie Johnston (Edinburgh).

CERTIFICATES.

The Committee considered in connexion with communications it had received, the difficulties which have arisen in certain areas with respect to the number of separate certificates demanded by many approved societies. It was reported that the issue of a universal form of certificate promised by the Commissioners might be expected at an early date, and that at the last meeting of the Advisory Committee Sir Robert Morant had, in reply to a question, stated definitely that the only certificates which could, under the terms of the agreement, be required of medical practitioners were the initial certificate, the continuing certificate, and the final certificate.

CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL COMMITTEES.

A communication was received from the local Honorary Secretary of the Annual Meeting at Brighton, stating that Mr. E. B. Turner had consented to act as chairman of the conference of representatives of Local Medical Committees to be held in Brighton during the Annual Meeting of the Association in that town.

The Chairman of the Committee, Mr. E. B. Turner, and the Medical Secretary were appointed to act in co-operation with the Brighton executive in arranging the agenda for the conference.

CANVASSING AND ADVERTISING IN CONNEXION WITH THE INSURANCE ACT.

The Medical Secretary reported that he had received the following letter, dated June 3rd, from the Registrar of the General Medical Council:

Dear Dr. Cox,

With reference to your letters of the 15th and 22nd April, relating to canvassing and advertising on behalf of medical men, the matter was considered by the National Insurance Act Committee of the Council during the recent Session, and in a few days I shall be issuing to the Secretaries of all approved Societies and to Societies under Section 15 (4) a copy of the letter which was recently addressed to the National Health Insurance Commission.

I think I am interpreting correctly the feeling of the Committee when I say that practitioners have been so

overwhelmed with circulars lately, and pamphlets of all sorts from the Commissioners and others, that the chanees are that they would not read carefully a warning which was addressed to them, and consequently the very great expense involved would not be justified. The greatest offenders probably are the Societies, which frequently are ignorant of the subject of advertisements, and it is hoped therefore that one may to a large extent put a stop to the evil by means of circularizing them. I may mention that it will involve sending out something like 5,000 circulars as it is.

Yours faithfully,
(Signed) NORMAN C. KING,
Registrar.

The Committee adopted the following resolution:

That the Registrar of the General Medical Council be informed that the Committee regrets that the letter addressed by the Council to the Insurance Commissioners and subsequently published in the medical press, concerning the subject of advertising in connexion with the National Insurance Act, appears to have been insufficient to prevent such practices: that the Committee would suggest for the consideration of the General Medical Council that a fresh circular couched in much stronger terms be issued; that the Committee, while noting the proposal to issue a copy of the previous letter to all approved societies and to "institutes" recognized under the Act, is of opinion that members of the profession should have the views of the Council brought to their notice individually; that the Committee, while not pressing the latter suggestion for the present, hopes that in any individual case brought to the notice of the General Medical Council, a communication will be forwarded to that individual drawing attention to the views of the Council upon the subject.

PERSONS MAKING THEIR OWN ARRANGEMENTS.

The Committee considered a recommendation from the Amendments Subcommittee to the following effect:

That the Association press for the amendment of Section 15 (3) of the Act to provide that every insured person applying to be allowed to make his own arrangements for medical attendance and treatment with a private medical practitioner shall be allowed so to do.

The Committee had before it the opinion of counsel (Mr. Sankey, K.C.) on the interpretation and amendment of the section. The Committee, after considerable discussion, finally resolved to obtain further legal opinion as to the possibility of framing an amendment of the Act providing that every insured person applying to be allowed to make his own arrangements with a private medical practitioner shall be allowed so to do, if this can be done, without running the risk of encouraging similar action to that taken in South Wales—namely, the wholesale granting by Insurance Committees of permission to insured persons to "make their own arrangements," and the consequent formation of medical aid schemes under lay control providing medical attendance and treatment both to insured persons and their dependants.

TEMPORARY RESIDENTS.

On further consideration of this subject the Committee directed that a communication should be immediately addressed to Local Medical Committees, Branches, and Divisions to the following effect:

1. That the Committee, fortified by the expression of opinion by Scottish Commissioners and the similarity between the wording of the Scottish and English agreements, is of opinion that it is not legal for any deduction for the medical attendance and treatment of temporary residents, in the way suggested in Memorandums 159 and 161 of the English Commissioners, to be made from the capitation allowance without the consent of those affected.

2. That the Committee is of opinion that Regulation 22 does not refer to the question of provision of medical attendance and treatment to temporary residents, but only to those who really change their residence.

3. That the Committee suggests that practitioners should strongly oppose any deduction for the purpose suggested from moneys due to them, and repeats its former advice that temporary residents should only be treated as private patients pending the production of an equitable scheme.

4. That the Committee is of opinion that if the above advice is carried out the Government will have eventually to provide a special fund quite apart from money already allocated to medical benefit for the purpose.

5. That the Committee would advise those Local Medical Committees in whose area Insurance Committees are issuing the green ticket with respect to temporary residents to ask their Committees from what source they propose to obtain the funds to pay for the treatment of this class, and at the same time (if not already done) to intimate that the local practitioners object to any deduction of any part of the capitation allowance.

6. That Local Medical Committees be informed that the Memorandum upon Temporary Residents issued by Commissioners is a circular and not an order, and therefore does not carry any legal authority.

COMPENSATION CASES.

A communication was received from an applicant whose case had been dealt with at the previous meeting, expressing his thanks for the compensation granted to him. With regard to a fresh application received, the Medical Secretary was instructed to make the customary inquiries.

SCHEMES FOR THE TREATMENT OF INSURED PERSONS.

Various schemes for the treatment of insured persons were considered and generally approved, subject to the recommendation of the Council, to be considered at the forthcoming Annual Meeting, that in the matter of the treatment of uninsured persons no person earning more than £104 per annum should be treated under contract terms at all.

TREATMENT OF TUBERCULOSIS CASES.

The CHAIRMAN reported that at a conference between representatives of the Association and the Society of Medical Officers of Health, on May 28th, the question of the treatment of tuberculosis cases had been discussed, and that it was for the Committee to consider what suggestions it would, under the instructions contained in Minute 63 of the Special Representative Meeting of January, 1913, recommend the Council to place before the Representative Body. The relative minutes were as follows:

Annual Representative Meeting, 1912.

Minute 205.—That the payment to be made to medical practitioners for domiciliary attendance on patients certified to be suffering from tuberculosis shall be on a scale of fees, and not by capitation.

Special Representative Meeting, November, 1912.

Minute 92.—That if the form of payment for sanatorium benefit be the suggested capitation fee of 6d., it shall be for insured persons only, and shall not include dependants, and shall be for domiciliary treatment only.

Special Representative Meeting, January, 1913.

Minute 63.—That it be an instruction to the Council to consider the question of the attitude of the profession towards the tuberculosis treatment under the Act in view of the conditions as altered by this meeting.

The point was raised whether, in view of the decision of the Representative Meeting, the policy of the Association was that medical practitioners should be paid upon a scale of fees or upon a capitation fee. The CHAIRMAN expressed the opinion that in view of the minutes above quoted the policy of the Association was in favour of the payment of practitioners upon a scale of fees and not by capitation. Finally, the Committee decided to advise the Council to recommend the Representative Body that Minute 205 of the Annual Representative Meeting, 1912, should be reissued, in order to leave to the local profession of any insurance area the right of deciding whether the profession of that locality shall be paid for the treatment of tuberculosis under the Insurance Act upon a scale of fees or by a capitation fee.

MEMORANDUM TO INSURANCE COMMISSIONERS.

The memorandum addressed to the National Insurance Joint Committee, published in the SUPPLEMENT of June 7th, p. 797 et seq., was approved.

DEVELOPMENT OF POLICY REGARDING INSURANCE ACT.

The question of the development of the policy of the Association with regard to the Insurance Act and its possible extension in the future was considered and the following resolution was adopted:

That it be recommended to the Council:

(a) That it be reported to the Representative Body that, in view of the fact that it is exceedingly likely that the scope of the National Health Insurance Act will be so extended as to include in its operations various additional matters—for example, the treatment of children and dependants of insured, dental treatment, hospital treatment, alterations in the method of dealing with deposit contributors and casual labourers—it is desirable that the Association should be ready with its policy as to what a National Health Insurance Act should be, not merely from the point of view of the interests of the profession

but also from that of public health and the advancement of medical science. And

(b) That it be recommended to the Representative Body that the preparation of a full report upon the above lines be referred to a Committee; that such report be issued to the Divisions for their consideration and comment; that the report, together with a statement of the views of the Division thereon, be submitted if possible to the next Representative Meeting; and that the Council be given power to act for the Representative Body should an emergency arise in the meantime.

INSURANCE ACT IN PARLIAMENT.

INSURANCE ACT AMENDMENT BILL.

THERE is no further information available respecting the provisions of the proposed amending bill. According to the statement of the Prime Minister in the House of Commons on June 9th, we may expect the bill to be introduced shortly, and it is proposed after the second reading that it should be sent to a Grand Committee. On June 10th Mr. Masterman informed Lord Ninian Crichton-Stuart that the bill would not contain any proposals for death benefits.

COST OF PRINTING.

In reply to Mr. Cotton, Mr. Masterman furnished the following table showing the amounts received under the National Insurance Act up to May 1st, 1913, and the amounts spent on printing, etc., to that date:

| | England. | Scotland. | Ireland. |
|--|--------------|-------------|-----------|
| Total amount received to May 1st, 1913, National Health Insurance Fund | £ 14,291,826 | £ 1,965,353 | £ 677,611 |
| Unemployment Fund | 1,361,725 | 236,448 | 60,815 |
| | 15,656,552 | 2,201,801 | 738,426 |
| Estimated total expenditure on printing in connexion with Part I. (Health Insurance) and Part II. (Unemployment) to May 1st, 1913... | 114,000 | 12,000 | 8,000 |

ALLOTMENT OF MONEYS RELATING TO INSURED PERSONS.

In an answer to Sir William Bull, Mr. Masterman repeated, on behalf of the Government, the explicit statement that the moneys relating to those insured persons who had made no choice of a medical attendant would be allotted in full amongst the medical men who are enrolled on the list. He said: I have no reason to suppose that any appreciable number of domestic servants or other insured persons will in case of illness neglect to avail themselves of their right to medical attendance and treatment from the doctors on the panel who are collectively responsible for such attendance and treatment; and who, for this reason, are entitled under their agreements to have divided among them the whole of the funds available for the medical treatment of insured persons under the arrangements made by the Committee.

In reply to Mr. Hunt, who asked whether doctors got money for patients they had not attended, Mr. Masterman said that if the doctors only got money for the patients they attended the Act would break down at once. They undertook the treatment of a certain number of persons, a large number of whom did not require treatment at all.

MEDICAL BENEFIT.

Old and Disabled Members of Friendly Societies.

Mr. Masterman said, in reply to Sir Henry Havelock-Allan that he had nothing to add to previous answers to questions with regard to the provision of medical benefit for old and disabled members of friendly societies.

Size of Medical Lists.

Sir P. Magnus asked whether an Insurance Committee could place any limit on the number of insured persons to be allotted to a medical practitioner; and, if so, by what principle the Committee were guided in so doing.—Mr. Masterman said: It is the duty of the Insurance Committee in each area to see that the arrangements for medical benefit are such as to secure that the insured persons in

their area receive adequate medical attendance and treatment. Subject to this, it appears to be undesirable to fix in advance a maximum number of insured persons to be allotted to a doctor, as the number for whom a doctor can properly be responsible must necessarily vary according to the circumstances of each particular case.

Medical Representation on Insurance Committees.

In reply to Mr. C. Bathurst, Mr. Masterman said that the membership of the Gloucester Insurance Committee was being increased from fifty to sixty in order to give the medical profession a representation of one-tenth without altering the composition of the Committee as prescribed by Section 59 of the National Insurance Act.

Conscientious Objectors.

Mr. F. Hall asked whether the decision as to what insured persons were to be allowed to make their own arrangements for medical attendance and treatment was one for the sole discretion of the Insurance Committees; if so, why had the Government promised the People's League of Medical Freedom to make every endeavour to secure that permission was granted to those who did not believe in the orthodox system of medicine, and desired the services of herbalists and other unqualified persons; and whether the Government would use its authority to ensure that permission to make their own arrangements was granted to those who had been unable to obtain the doctor of their choice because he refused to go on the panel, a condition with which unqualified persons were not asked to comply.—Mr. Masterman said that he had distinctly informed the deputation of the People's League of Medical Freedom that Insurance Committees could not be deprived of the discretion which was given them by the Act in regard to the matter. He had, however, promised that the Government would endeavour to secure that insured persons who had conscientious objections to orthodox systems of medicine, and were willing to make an assertion that they wished for some other form of treatment, should be given the money which otherwise would have been available for their medical benefit.

In reply to a further question by Mr. Hall, Mr. Masterman said that any Insurance Committee should authorize an insured person to deal with a doctor who was not on the panel. To Mr. Hall's further observation that no Insurance Committee was doing this no reply was returned.

MATERNITY BENEFIT.

Mr. Butler Lloyd asked the Chancellor of the Exchequer if the agent of an approved society was within his rights in withholding maternity benefits under the National Insurance Act for two months when the application was in perfect order.—The Financial Secretary to the Treasury, who replied, stated that an insured person duly qualified for maternity benefit, and making proper application for it, should certainly receive it without delay. If he were informed of any particular case in which delay had occurred he would make inquiries as to its cause.

SANATORIUM BENEFIT.

Tuberculosis Dispensaries in London.

The President of the Local Government Board, in replying to a question by Mr. Astor, said he understood that up to the present eighteen whole-time tuberculosis officers had been appointed on the staff of tuberculosis dispensaries in London. The boroughs in which these officers had been appointed were Battersea, Bermondsey, Camberwell, Deptford, Fulham, Hampstead, Lambeth, Paddington, Poplar, Marylebone, Shoreditch, Stepney, Wandsworth, and Woolwich.

IRELAND.

Rosslare Sanatorium.

In reply to Mr. Fetherstonhaugh, the Chief Secretary for Ireland said that an application for the approval of Rosslare as a sanatorium under Section 161 (a) of the National Insurance Act was made by the Women's National Health Association to the Local Government Board. The place had previously been visited by Sir William Thompson, the treasurer of the association, and a favourable report had been obtained from an architect, whose suggestions as to improvements had been carried

out. By the direction of the Board one of its medical inspectors, Dr. Brendan McCarthy, visited Rossclare, and, after personal inspection, recommended the approval of the sanatorium temporarily for a specified number of patients. Dr. McCarthy was a medical inspector of great experience, and was fully qualified to report on the points referred to him. The application for the Board's sanction was made on the responsibility of the Women's National Health Association, which had satisfied itself that the site was suitable for a sanatorium from a medical point of view. He was aware that Dr. Thompson of Omagh was professionally consulted by the association, and, as he had not visited the place for years, saw no reason why he should have been consulted. The Board was aware that the place had not been a financial success when run as a private sanatorium, but had no knowledge of the reasons for this failure. He understood that the demands for admittance to the institution were now in excess of the accommodation, and that a number of the patients had greatly improved. The medical officer of the sanatorium resided at Enniskillen, about eight miles away, but he was in telephonic communication with Rossclare, and had a motor car.

CORRESPONDENCE.

[It is particularly requested that communications intended for publication should be written on one side of the paper only, and should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 429, Strand, London, W.C.]

SHIPS' SURGEONS AND SEAMEN'S BENEFIT.

DR. A. G. BATEMAN (General Secretary, Medical Defence Union, 4, Trafalgar Square, W.C.) writes: The question as to whether ships' surgeons acting as medical officers upon vessels sailing from British ports under the British flag are entitled to any remuneration under the Insurance Act for medical attendance upon seamen and others who are insured persons has been put to the Medical Defence Union and a decision sought from the National Insurance Commissioners. It may be mentioned that neither the shipping companies nor the Seamen's Approved Society were able to give any decided opinions, although their advice was sought by the medical officer concerned. A letter was sent by me to the Insurance Commissioners, asking for a decision, on May 20th, and a reply was received on June 6th, as follows, from the Secretary:

I am directed by the National Health Insurance Commission (England) to state that no insured person is entitled to medical benefit while resident temporarily or permanently outside the United Kingdom. In the circumstances indicated in your letter an insured person is therefore not entitled to medical attendance under the National Insurance Act, and a ship's surgeon who in such cases attends an insured person is not entitled to remuneration under the Act.

This decision, which excludes all seamen from medical benefits under the Act, although both employers and employed have to pay their share of the tax under the Act, would appear to clash with the enactment that members of the Seamen's National Insurance Society, which is the approved society for seamen, shall be "deemed to be resident in England"; but that I must leave to more legal minds than my own to determine. As the decision may be of interest to ships' surgeons generally, I venture to ask that you will kindly give this letter publicity in the JOURNAL.

THE AMENDMENT OF THE ACT.

DR. THEOBALD A. PALM (Aylesford, Kent) writes: While fully appreciating the efforts which have been made by the British Medical Association on behalf of the profession and in the interest of the public to minimize the evils of the Insurance Act, may I venture to criticize the memorandum with regard to amendment of the Act published in the SUPPLEMENT to the JOURNAL for June 7th?

However desirable or necessary the suggested amendments may be, the question arises whether in seeking to amend the Act we are not fostering the economic folly of tinkering machinery which is only fit for the scrap-heap, or committing the disastrous blunder of the practitioner who should ply with palliatives a patient suffering from a

morbid growth for which the only remedy is removal by the knife. The Act subjects the rank and file of the profession to the tyranny of a body of Commissioners who are themselves the nominated and paid agents of a despotic Chancellor of the Exchequer. Can any amendment abolish the Commissioners? Imagine the butchers, bakers, and grocers of the United Kingdom put under the thumb of a similar body of Commissioners, who issued despotic regulations as to the terms upon which they should supply their customers. Would they be content with making respectful representations to those very Commissioners to ameliorate the conditions imposed upon them? Rather they would raise such a storm of indignation in the country as would drive the Chancellor and his Commissioners into private life.

What is wrong in principle can never be right in the application of the principle, and this is the reason why the Insurance Act is a tissue of wrongs to employed and employers, to the medical profession, and to the general public. The fundamental principle of the Act is interference with the liberty of the subject in his private and personal concerns, and the inevitable consequence is that it galls every one whom it touches. Not only so, it is demoralizing to all concerned. Freedom is not only the birthright of every Briton, it is the essential condition for the development of character. With regard to a proposed Act of Parliament involving a similar interference with personal freedom, many years ago an English bishop said that he would rather see England free than England sober. So to-day we would rather see the working class of England free than thrifty by compulsion, and free rather than panel-doctored. For the medical profession the alternative is to be free, even though underpaid as before the Act, or to be State slaves still underpaid under the Act. My conviction is, that in seeking to amend the Act we are straining out gnats and swallowing a camel. To agitate for the repeal of the Act may be quixotic, but it seems to me that the least we can demand is that we should have no dealings with Commissioners, and that every insured person should be perfectly free to make his own arrangements with any medical man he pleases. If this means "breaking down the Act," that may be a matter of chagrin to its author and its administrators, but no loss to any one else.

LIVERPOOL MEDICAL COMMITTEE AND TEMPORARY RESIDENTS.

DR. HENRY THOMAS BARTON (Secretary, Blackpool Medical Committee) writes: Through the courtesy of Dr. W. T. D. Allen I am able to state that the case cited by him in correspondence with the Commissioners regarding treatment of temporary residents (SUPPLEMENT, June 7th, p. 500) was hypothetical, and was put forward to illustrate the carrying out of conditions laid down in Memo. 159/L.C. I wish this to be clearly understood, as here in Blackpool we are not accepting the green vouchers, and temporary residents are treated as private patients.

THE POSITION IN LONDON.

DR. E. H. WORTH (Streatham, S.W.) writes: There is no doubt that we London men are in a strong position. The Insurance Committee are in a hopeless muddle; they must have 3,000 men on the panel to work the Act, especially as they have limited the number of insured persons per doctor to 2,000. They have only got 1,244 up to recently, and a good number have only accepted service for another three months; these men are tired of it already, and therefore are unlikely to renew their agreements. We stated our terms last year to Mr. Lloyd George, and, thank heaven, we have been manly enough to stick to them. London has held up the dependent's scheme of the Chancellor. I have it on good authority that it would have been brought in this year but for us. I congratulate the men of the metropolis. There are non-panel societies in all the suburbs; we want also a strong central body as a rallying point, and we must have one; if it wants money, 2s. 6d. from 5,000 non-panel doctors will produce £600. Harley Street must come in as well. Such a central body would be a rallying point not only for London, but for the good men and true all over the country, and perhaps the Manchester Society might see its way to amalgamate with it, and make it stronger than ever.

Meetings of Branches and Divisions.

[The proceedings of the Divisions and Branches of the Association relating to Scientific and Clinical Medicine, when reported by the Honorary Secretaries, are published in the body of the JOURNAL.]

BIRMINGHAM BRANCH: COVENTRY DIVISION.

THE annual meeting of the Division was held on June 5th. Dr. HAWLEY was in the chair, and was supported by eighteen members.

Election of Officers.—The following officers were unanimously elected:

Chairman.—Dr. T. A. B. Soden.
Vice-Chairman.—Dr. W. Growse.
Honorary Secretary.—Dr. D. Davidson.
Representative on Branch Council.—Dr. Orton.
Members of the Ethical Committee.—Drs. Kendrick, Pickup, Hawley, Lowman, Snell, and Worsley.

Monthly Meetings.—It was resolved that the monthly meetings should be held on the first Thursday of the month.

Annual Report.—The annual report of the Executive Committee was read and approved.

Vote of Thanks.—The Honorary Secretary was requested to write to the Committee of the Hospital thanking it for the use of the Board Room for the meetings of the Division.

NUNEATON, TAMWORTH, AND COVENTRY DIVISIONS.

THE annual constituency meeting of the Nuneaton and Tamworth and Coventry Divisions was held at the Coventry Hospital on June 5th. Dr. NASON was appointed to the chair, and fifteen members were present.

Election of Representative.—Dr. Orton was elected to represent the constituency at Brighton, with Dr. Milner Moore as his deputy.

Insurance Act.—The following resolution was unanimously passed:

This constituency wishes most emphatically to reaffirm its opinion as to the nature and probable effects of the existing Regulations of the Insurance Act, and to protest with indignation against the methods of coercion applied by the Government to an honourable profession.

BORDER COUNTIES BRANCH: SCOTTISH DIVISION.

THE general meeting of this Division was held at Dumfries on May 30th.

Annual Report.—The SECRETARY'S annual report was received.

Election of Officer-bearers.—The following officers were elected:

Chairman.—Dr. E. Shaw, Wigtown.
Vice-Chairman.—Dr. G. R. Livingston, Dumfries.
Honorary Secretary.—Dr. J. Dewar Robson.
Representative.—Dr. J. Dewar Robson.
Executive Committee.—Drs. Easterbrook, Rodger, Sanders, and Mr. George Watt.

Instruction of Representative.—The report of the Council having been considered, the Representative was instructed to move or support the amendment to Recommendation 21:

That the time has arrived when the Representative Body should seriously consider the advisability of raising the annual subscription in order to meet *inter alia* the out-of-pocket expenses of Representatives at the Representative Meeting as well as their travelling expenses.

EAST ANGLIAN BRANCH: SOUTH SUFFOLK DIVISION.

THE annual meeting of the South Suffolk Division was held at Ipswich on June 5th.

Election of Officers.—The following were elected officers for the year:

Chairman.—Dr. J. Hossack.
Vice-Chairman.—Dr. T. C. Askin.
Secretary.—Dr. J. Gutch.
Representatives on Branch Council.—Drs. J. Hossack and T. C. Askin.
Representative at Representative Meetings.—Dr. T. C. Askin.
Executive Committee.—Six additional members of Executive: Drs. Brogden, Havell, Redpath, Francis Ward, Young, and Staddon.

Annual Representative Meeting.—The business of the annual meeting was considered, and instructions given to Representative.

GLASGOW AND WEST OF SCOTLAND BRANCH: GLASGOW NORTH-WESTERN DIVISION.

THE annual meeting was held in the Hillhead Burgh Hall on May 22nd. Dr. A. T. CAMPBELL presided, and five other members were present.

National Insurance Act.—Letters and various circulars forwarded by the Medical Secretary conveying information as to the action of the Council and various committees were read, and in accordance with the suggestion therein contained the Secretary was instructed to bring the matters to the notice of the Local Medical Committees.

Election of Officers.—The following office-bearers were appointed:

Chairman.—Dr. A. T. Campbell.
Vice-Chairman.—Dr. J. Lindsay.
Secretary.—Dr. E. J. Primrose.
Representatives to Branch Council.—Dr. Morton, Dr. Primrose.
Representative to Representative Meeting.—Dr. A. T. Campbell.
Members of Committee.—Drs. J. Baird, Mackintosh, Snodgrass, Todd, Graham, Caskie, A. G. Hay, Gray.

Election of Members.—It was proposed by Dr. MORTON, seconded by Dr. GRAY, and unanimously agreed:

That a Branch Council should have the power to elect applicants for admission as members of the Association if the nomination is duly made by two members of the Branch concerned.

GLOUCESTERSHIRE BRANCH.

THE annual meeting of this Branch was held at the Royal Infirmary, Gloucester, on May 15th, at 6 p.m. Dr. MACARTNEY was in the chair, and twenty-eight members were present.

Election of Officers.—The following officers were appointed for the year 1913-14:

President.—Dr. C. V. Knight (Gloucester).
Council.—Dr. Anerum, Mr. C. Braine-Hartnell, Mr. Buckell, Dr. Carter, Dr. Collins, Dr. A. B. Davies, Dr. Dent, Dr. Goss, Dr. Grosvenor, Dr. Johns, Dr. Mellish, Mr. G. A. Peake, with Dr. Macartney and Dr. Buchanan (from Forest of Dean section).

Scrutineers.—Dr. Ancrum and Mr. T. S. Ellis.
Auditors.—Mr. E. A. Dent and Mr. G. A. Peake.
Ethical Committee.—Mr. Buckill, Mr. T. S. Ellis, Mr. O. H. Fowler, Mr. Waddy, Dr. Mellish.
Secretary.—Dr. D. E. Finlay, Wells Dene, Gloucester.
Assistant Secretary.—Dr. Longridge, London Road, Cheltenham.

Nomination for Central Council.—Dr. G. Parker was nominated for election to the Central Council.

Annual Report and Financial Statement.—The annual report and financial statement, which had been circulated, was taken as read and passed.

Address.—Dr. H. MACNAUGHTON JONES (London) gave an address, entitled "*Bene diagnoscit, bene curat*," illustrated by lantern slides. A vote of thanks to Dr. Macnaughton Jones was proposed by Mr. WADDY, seconded by Mr. T. S. ELLIS, and carried.

LANCASHIRE AND CHESHIRE BRANCH: BURNLEY DIVISION.

THE annual meeting of this Division was held on May 29th, Dr. CRUMP in the chair, nearly forty members being present.

Election of Officers.—The following officers were elected for the ensuing year:

President.—Dr. T. M. Scott.
Vice-President.—Dr. T. G. Crump.
Honorary Secretary and Treasurer.—Dr. A. E. Bird (re-elected).
Representative for Representative Meetings.—Dr. H. J. Robinson (re-elected).
Representative on Branch Council.—Dr. Jas. M. Ferguson (re-elected).
Executive Committee.—Drs. Chas. A. Anderson, A. Callam, F. E. Crossley, J. W. Clegg, Jas. Gardner, A. C. Glashan, A. Heys, F. W. Marsden, J. A. Mackenzie, G. S. Pullon, W. J. Purves, R. C. Rogers, T. Snowball, R. Stewart, J. Hoyle.

Vote of Thanks.—Dr. Crump was unanimously accorded a most hearty vote of thanks for his able and untiring work as President during the last twelve months—a period of the greatest anxiety and activity the Division had known.

Report of Committee.

The report of the committee, which was adopted, stated that the Division now numbers 94. There had been eleven Division meetings with an average attendance of 44, and twenty-nine committee meetings, with an average attendance of about 11, and two deputations. The greater part of the work of the Division during the year had been in opposing the obnoxious features of the Insurance Act as applied to medical benefit, and in trying to get the Act and its regulations amended so as to make it possible for the medical profession to undertake willing service under the Act, and still maintain the freedom and dignity of the profession. Although these efforts were not successful, still the Division held out in its fight for right until the very last, and not until the profession in practically the whole of the country had been coerced into unwilling service did the Division yield by a slight majority in the last twenty-four hours to accept service under the Act. The whole of the Division was loyal, any small minorities always falling in readily with the majorities, and thus the Division was able to keep a level front.

The Education Committee had sent out a circular and book of certificates asking the profession to state thereon the exact disease from which the certified child was suffering. The Executive Committee opposed this, and asked the members not to use these certificates.

The Dispute with the Poor Law Guardians.

The dispute between the Division and the guardians remains unsettled. The Division has taken action on behalf of the union district medical officers on account of the inadequacy of the remuneration, which was still far below the average paid in similar and local unions, although last June the guardians slightly increased the salary of some of the district medical officers. The Division has tried on two occasions to induce the guardians to meet a deputation from the doctors, but failed; the Mayor of Burnley on one occasion was likewise unsuccessful in bringing about an interview after the Executive Committee had agreed to accept his kindly offices. Letters sent to the guardians had no effect, and the Division, after securing the signatures of loyalty from all local medical practitioners (except one), asked the nine district medical officers to terminate their appointments as on January 1st, 1913. This they did. The guardians then, instead of discussing the matter with the profession, or raising the salaries as desired, brought forward a new scheme making the nine districts into fifteen, at the same time dismissing their public vaccinators and giving their duties to the suggested fifteen district Poor Law medical officers.

The Burnley Division opposed this to the guardians, and memorialized the Local Government Board. The Poor Law Medical Officers' Association of England and Wales also took the matter up, and supported the Burnley Division in its action, and wrote to the Local Government Board fully stating the facts, and especially calling attention to the action of the guardians in offering public vaccinator appointments to assist in obtaining underpaid Poor Law medical officers.

The Burnley Division at its last meeting in March, when forty members were present, resolved:

That this Division regards the action of the guardians in giving a month's formal notice to the public vaccinators in the union who were in no way a party to the original dispute, as an arbitrary act, and requests that these notices should be withdrawn, and that the present holders be reinstated in office.

That no application for any medical posts that may be advertised under the guardians shall be made until the Committee is satisfied.

That this Division would welcome the interference of the Local Government Board in this dispute either in the direction of holding an inquiry into the whole subject or in any other way that may be deemed advisable.

These resolutions were sent to the guardians, but without the desired effect.

The Executive Committee again, on April 15th, asked the guardians to meet a deputation to lay the medical aspect of the dispute before them, but again the reply was, "the Guardians passed no resolution thereon."

On May 15th the Local Government Board guardedly gave its assent "generally" to the proposals of the guardians as to the rearrangement of the districts—in the first instance for twelve months only—but made no reference whatever to the salaries to be paid, which was the matter in dispute.

The guardians next day advertised the fifteen appointments. On the same day the Executive Committee of the Division circularized every medical man in the district. A Warning Notice has been in the *BRITISH MEDICAL JOURNAL* for months, and articles and editorials had also appeared from time to time in it, and the *Lancet* had been asked to support the Division by refusing advertisements.

The Committee trust and rely on the written pledge of the members of the profession, and loyalty to one another, to uphold the late district medical officers, and public vaccinators, and support them, and the profession as a whole, against underpayment and sweating of their services.

Letter to the Local Government Board.

We gave last week an account of the present position in the Burnley district and a summary of the way in which it had been brought about. We are informed that the three medical men who accepted appointments under the guardians of the Burnley Union are now doing all the Poor Law and public vaccination work in the whole union. The Burnley Division has addressed the following letter to the President of the Local Government Board:

The British Medical Association, Burnley Division.

To the Right Hon. John Burns, M.P.,

President of the Local Government Board.

Sir,—With further reference to my letters of December 9th, 1912, and March 8th, 1913, to your Honourable Board, I am directed by the Burnley Division of the British Medical Association to protest very strongly to your Honourable Board against the confirming of (a) the medical appointments and (b) the medical arrangements in the other twelve districts for attendance on sick poor made on Thursday last (May 29th) by the Burnley Board of Guardians.

The grounds of the protests are:

The Inconsistency of the Guardians.

1. The reasons the guardians gave for splitting the union into smaller districts was that the population of most of the districts exceeded the number allowed under Article 159 of the General Consolidated Order, July 24th, 1847, of the Poor Law Commissioners.

On Thursday last (May 29th) the guardians considered applications for the fifteen medical posts they had advertised. There were only three applicants, and these applicants were appointed to the three districts for which they made application.

A small subcommittee was appointed at the same guardians' meeting to consider the question of medical relief in those districts for which there was no application.

This subcommittee has decided that the whole of the union is to be worked by these three medical officers and have fixed salaries for this work.

The first contention of the guardians—namely, that the original districts were too large and contained too great a population for one man to look after—thus falls to the ground, in that they now appoint three men to do the work which they considered was too great to be done as formerly by *nine*, and which they contend can only be efficiently done by *fifteen*.

2. It is impossible that considerable hardship to the sick poor will not be the result of this arrangement, many of whom will be called upon to travel five or six miles to get medical attendance; and, further, I am to point out that these three officers, who are busy general practitioners, will not be able to attend these persons at their own homes with any degree of efficiency or regularity.

3. I would further point out that in none of the three districts to which medical officers were appointed is the salary a sufficient one for the work to be done.

The whole of the profession in the Burnley Union, with these three exceptions, is unanimous in the opinion that the conditions of service offered are not such as can be accepted.

4. We understand that the opinion of the Local Government Board is that vaccination is most efficiently performed when done by officers holding appointments for large areas; the present policy of the Burnley Guardians is to appoint public vaccination for very small areas.

Moreover, without there having been any application for an increase of fees for vaccination, the guardians, after dismissing their public vaccinators, have voluntarily increased the fees for vaccination when giving the post to that of district medical officers. The reason appears obvious.

The Burnley Division of the British Medical Association therefore prays that you will not confirm the appointments made by the Burnley Guardians, nor will you permit the arrangement made by the said guardians for medical relief in those districts for which there were no applicants for office.

As the new Board of Guardians refused at their first meeting to receive a deputation of medical men, I am now desired to ask your Honourable Board to receive a deputation of medical men practising in the union. If, therefore, you are willing to receive such a deputation, and will inform me which would be a convenient date for you, I will arrange the matter for that date.—I am, your obedient servant,

A. EDWARD BIRD, Hon. Secretary.

Trafalgar House, Burnley, Lancs., 4th June, 1913.

BURY DIVISION.

THE annual meeting of the Bury Division was held on June 5th in the Derby Hotel, Bury. Dr. BAIRD occupied the chair, and fifteen members were present.

Annual Report.—The annual report stated that there had been eight meetings of the Division and nine meetings of the Provisional Medical Committee. All the Division meetings were open to non-members, and the attendance, which averaged about thirty, showed that the interest in the British Medical Association was well sustained. The membership, which was sixty-one at the beginning of the year, was now fifty-nine. There had been three deaths among the members—Drs. Lees, Deans, and Luck—and one resignation. New members and additions through change of address had nearly compensated for the losses, and the present membership showed as good a proportion to the medical population as any other Division in the country. The Committee had done much work, and thanks were expressed to its members for so faithfully responding to calls at short notice, and for the support they had given the Secretary in carrying out the work of the Division. Special thanks were due to the Chairman, who had given up much of his time and sacrificed many evenings to attend meetings. Since January 15th most of the local work had been done by Local Medical Committees, and regret was expressed that committees outside the borough had not availed themselves of the information and authority of the Association. It was to be hoped, however, that in the future some scheme of organization might be drawn up whereby Local Medical Committees were co-ordinated through the British Medical Association. The Bury Division included three Insurance areas: (1) the County Borough of Bury, (2) Area 16, and (3) Area 17 of the County of Lancashire. If Prestwich and Bacup were added to the Division the boundaries would be exactly coterminous, and the mutual interests of all three would, it was thought, be served by the Division. The financial statement for 1912 showed a small deficit on the ordinary fund, since made up by a grant from the Branch, and a small balance on the extraordinary fund derived from a levy on the members. This balance had since been expended, and a small deficit produced. The Division had responded very well to the call for the Central Defence Fund, the guarantees amounting to nearly £1,000, which for the size of the Division was the best in Lancashire and very near the top for the whole country. During the year a dinner has for the first time been held, which was heartily enjoyed by those who found it convenient to attend.

Election of Officers.—The following were duly elected:

Chairman.—Dr. A. B. Vine, M.B.

Vice-Chairman.—Dr. R. Crompton.

Joint Honorary Secretaries and Treasurers.—Dr. J. C. Turnbull, 134, Walmersley Road, Bury; Dr. P. F. Braithwaite, 123, Tottington Road, Bury.

Representative for Representative Meetings.—Mr. I. W. Johnson, F.R.C.S.

Deputy Representative.—Dr. J. W. Smith, Radcliffe.

Representatives on Branch Council.—Mr. I. W. Johnson, F.R.C.S.; Dr. A. B. Vine.

Executive Committee.—Drs. W. J. Baird, G. R. Hitchen, A. P. Nuttall, and Mr. A. Lucas.

Local Secretaries.—Radcliffe: Dr. J. W. Smith. Ramsbottom: Dr. H. Lawrie. Haslingden: Dr. J. A. Harrison. Rawtenstall: Mr. W. MacLaren McIlraith.

Special Meeting.—It was unanimously resolved to call a special meeting to consider the report of Council, and especially the proposed amendments to the Insurance Act.

Ethical Rules.—The model ethical rules were adopted unanimously.

Central Council Election.—It was resolved to recommend the members to vote for Dr. Helme and Mr. Larkin.

Votes of Thanks.—Votes of thanks to the retiring Chairman and Representative were heartily accorded.

MANCHESTER CENTRAL DIVISION.

AT the annual meeting, held at the Onward Buildings, Deansgate, on May 29th, Dr. JUDSON BURY was in the chair, and five other members were present.

Annual Report.—The Honorary Secretary (Dr. TYLECOTE) presented the annual statement, which, on the proposition of the CHAIRMAN, seconded by Dr. DAHMS, was received and adopted.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. T. Arthur Helme.

Vice-Chairman.—Dr. Judson Bury.

Honorary Secretary and Treasurer.—Dr. Tylecote.

Representative to Representative Meetings.—Dr. Booth.

Deputy Representative.—Dr. T. Arthur Helme.

Representatives on the Branch Council.—Dr. Booth and Dr. Heywood.

Other Members of the Executive Committee.—Drs. John Ferguson, Annacker, Shaw, Douglas, and Ollershaw.

Representatives on the Joint Committee of Manchester and Salford.—Drs. Helme, Melland, Annacker, Cryer, and Tylecote.

Dr. HEYWOOD then took the chair, and on the motion of Dr. TYLECOTE, seconded by Mr. RAYNER, the best thanks of the Division were accorded to Dr. Judson Bury for his able and courteous conduct in the chair during the past year.

At the conclusion of the annual meeting an ordinary meeting of the Division was held, presided over by Dr. HEYWOOD.

Model Ethical Rules.—The Honorary Secretary (Dr. TYLECOTE) reported that the model ethical rules, which had been adopted by the Division, had now been sanctioned.

Expenses of Representatives, etc.—On the proposition of the CHAIRMAN, seconded by Mr. RAYNER, it was unanimously resolved:

That the Honorary Secretary be instructed to issue a circular calling on each member for a contribution of 5s. as his share of the voluntary levy agreed to by this Division on November 12th last as a contribution to the expenses of the Representatives, members of council, and committees from the Branch who are away in London or at the Annual Meeting on Association business.

Representative Meeting.—On the proposition of Mr. RAYNER, seconded by Dr. DAHMS, it was unanimously resolved to instruct the Representative to the forthcoming Representative Meeting that unless a special meeting be called in the meantime to give him other instructions he be instructed to use his own discretion when voting at the forthcoming Representative Meeting at Brighton.

ST. HELENS DIVISION.

THE annual meeting of the St. Helens Division was held at St. Helens on June 2nd, when there was an exceptionally good attendance of members.

Election of Officers.—The following were elected officers for the ensuing year:

Chairman.—Dr. Arthur Dowling, J.P. (Haydock).

Vice-Chairman.—Dr. Jos. Unsworth.

Representative for Representative Meetings and Representative on the Branch Council.—Dr. F. Pickering Bassett.

Secretary and Treasurer.—Dr. F. J. Knowles (re-elected).

Executive Committee.—The office-bearers, together with Drs. Kerr and G. H. Cooke (St. Helens), Dr. Harold Watkins (Newton-le-Willows and Earlestown), and Dr. Youatt (Prescot).

METROPOLITAN COUNTIES BRANCH:

GREENWICH AND DEPTFORD DIVISION.

AT the annual general meeting of this Division, held on June 6th, the following were elected officers and committee for the ensuing year:

Chairman: Dr. R. D. Mair.

Vice-Chairman: Dr. E. G. Annis.

Honorary Secretary and Treasurer: Dr. W. H. Payne.

Representative for Representative Meetings: Dr. H. W. Roberts.

Representative on the Branch Council: Dr. C. J. Parke.

Executive Committee: Drs. T. Berry, W. S. Carpenter, C. G. Gooding, C. W. Hogarth, J. H. Keay, H. S. Knight, J. P. Purvis, C. G. Wallis, J. P. Walsh.

Annual Report.—The annual report and balance sheet was adopted unanimously. The report stated that 12 meetings of the Division had been held—7 of the old Greenwich Division, with an average attendance of 47; and 5 of the new Greenwich and Deptford Division, when the average attendance had been 36. The number of members of the Division was 83. The financial statement showed a small balance in hand.

Instruction of Representative.—It was decided to instruct the Representative not to vote for any increase of subscription to the Association, and that motions 12, 21, 23, 25, 28, 36, 37, 38, 39, 40, 43, 45, as in the provisional agenda, be agreed to; that motion 42 be not agreed to; that rider 44, 1 be not agreed to, 3 be agreed to; that motions 14 and 15 be left to the discretion of the Representative.

NORTH MIDDLESEX DIVISION.

THE eleventh annual meeting of the Division was held on May 21st. Dr. RICHMOND BRYCE was in the chair, and twenty-five members were present.

Model Ethical Rules.—The Model Ethical Rules were adopted, and on the motion of Dr. ALICE WINTER, seconded by Dr. LAWRENCE, it was resolved that a copy of the rules be sent to every member of the Division before the next meeting.

Election of Officers.—The following office-bearers were elected for the coming year:

Chairman.—Dr. Leonard Grant.
Vice-Chairman.—Dr. Richmond Bryce.
Secretary and Treasurer.—Dr. Robert Bruce Marjoribanks.
Assistant Secretary.—Dr. Stewart Smith.
Representatives at Representative Meeting.—Dr. Fuller and Dr. Percival Barnes.
Deputy Representative.—Dr. R. T. Vivian.
Representatives on the Branch Council.—Dr. Brackenbury and Dr. Distin.
Other Members of the Executive Committee.—Dr. Burton, Dr. Cohen, Dr. R. T. Vivian, and Dr. F. C. Wood.

Dr. J. A. Percival Barnes, who had been nominated as one of the Secretaries of the Branch Council, withdrew in favour of Mr. Bishop Harman.

Secretary of Branch Council.—It was proposed by Dr. BRACKENBURY, seconded by Dr. VIVIAN, and resolved:

That in the opinion of this Division the Secretaryship of the Branch Council be divided between London and the extra-metropolitan area, and that this opinion be sent to the Secretary of the Branch Council to be placed on the agenda of the annual meeting.

Vote of Thanks.—A vote of thanks to Dr. Richmond Bryce for his services in the chair for the past year brought the business of the meeting to a close.

STRATFORD DIVISION.

THE annual meeting of the Stratford Division was held on June 5th at West Ham Hospital.

Election of Officers.—The following were elected office-bearers for the ensuing year:

Chairman: Dr. Percy Rose.
Vice-Chairman: Dr. C. Sanders.
Honorary Secretary: Dr. P. J. S. Nicoll.
Representative at Representative Meetings.—Dr. H. S. Beadles.
Representatives on Branch Council.—Dr. Percy Rose and Honorary Secretary.
Executive Committee.—Mr. A. J. Couzens, Drs. Dayus, Drake, Frederick, Grogono, Hay, Randall, Steen, Taylor, and Troup.

Annual Report.—The annual report was read and adopted.

WILLESDEN DIVISION.

THE annual meeting of the Willesden Division was held at St. Andrew's Schools on May 30th, when Dr. CONAM JAMES was in the chair, and twenty-two were present.

Election of Officers.—The following officers were elected:

Chairman.—Dr. Macevoy.
Vice-Chairman.—Dr. Armitage.
Honorary Secretary.—Dr. Skene.
Representative to Representative Body.—Dr. Macevoy.
Representative to Branch Council.—Dr. Traylen.
Committee.—Drs. Brindley, Cardinal, Clayton, James, Joy, Mehan, Moore, Rawes, Anderson Smith, Soden, Stocker, and Turner.

Annual Report.—The HONORARY SECRETARY reported that the first meeting of the Division, which was formed by splitting off from the Hampstead Division, was held on May 30th, 1912. There were then 66 members; of these, 6 had left the district, 3 had resigned, and 1 was in arrears with his subscription. To make up for the loss of these 10, there were 16 new members, 5 of whom came into the district as new members; 11 already in general practice in the district had joined. The number of members in the Division was now 72. The Division had held during the year 14 meetings, to most of which non-members had been invited. There had been an average attendance of 36, the largest being 70, and the lowest 18. The Executive Committee and the Local Medical Committee usually met together. Eleven meetings had been held, with an average attendance of the Division's Executive of 11 out of 16.

Instruction of Representative.—The Representative was instructed to support Motions 15, 21, 23, 25, and 38, and to oppose Rider 44, and on other points to use his own discretion in voting.

MUNSTER BRANCH.

THE annual general meeting of this Branch was held on May 29th, Dr. J. T. O'CONNOR, President, in the chair.

Elections to the Association.—The following were elected members of the British Medical Association:

Dr. Henry Barter (St. Anne's, Blarney), Dr. J. T. Bouchier Hayes (Rathkeale, co. Limerick), Dr. J. T. Devane, F.R.C.S.I. (Limerick), Dr. H. Greene Moloney (Ballingarry, co. Limerick).

Election of Officers.—The following officers were elected:

President.—Dr. J. Reid (Bandon).
Vice-President.—Dr. McCall (Crosshaven).
Honorary Secretary and Treasurer.—Dr. Philip G. Lee (Cork).
Representative to Representative Meeting.—Dr. John Reid (Bandon).
Deputy Representative.—Dr. W. MacFettridge.
Representative of the Branch on the Irish Committee, British Medical Association.—Dr. J. Giusani (Patrick's Hill, Cork).
Council.—Drs. H. R. Townsend, Lucy Smith, J. T. O'CONNOR, E. Murphy, J. Cotter, C. Yelverton Pearson, W. Ashley Cummins, W. Donovan (Queenstown), T. Gelston Atkins, R. Crosbie, J. Booth, R. E. Footit (Monkstown).

Adoption of Model Rules.—The rules, which had been modified and received the approval of the Central Ethical Committee, were read and unanimously adopted as the rules of the Munster Branch.

Life Assurance Fees.—A short discussion took place on the matter of fees paid for life assurance.

NORTHERN COUNTIES OF SCOTLAND BRANCH:
INVERNESS-SHIRE DIVISION.

THE first annual meeting of the Inverness-shire Division was held on May 28th at the Northern Infirmary, Inverness. *Present:* Dr. MACFADYEN, Chairman, and ten members.

Election of Officers.—The following officers were appointed for 1913-14:

Chairman.—Dr. John Munro Moir.
Vice-Chairman.—Dr. A. C. Miller (Fort William).
Honorary Secretary.—Dr. John W. MacKenzie (5, Castle Street, Inverness).
Representatives on Branch Council.—Dr. John MacDonald, M.O.H., and Dr. Thos. MacDonald (Beauly).
Executive Committee.—Dr. Balfour (Abermore), Dr. Gillies (Inverness), Dr. Johnstone (Fort Augustus), Dr. Lindsay (Ardersier), Dr. T. C. Mackenzie (Inverness), and Dr. MacFadyen (Inverness). It was resolved that the first two names on the above Executive Committee should retire annually.
Representative for Representative Meeting.—Dr. John Munro Moir.
Deputy Representative.—Dr. James Murray.

Report of the Executive Committee.—The report of the Executive Committee, which was approved, stated that the Inverness Division was inaugurated on May 4th, 1912, when Dr. MacFadyen, senior, was appointed Chairman. Six meetings were held during the year with an average attendance of twelve members. The principal work of the Division has been in connexion with the Insurance Act. The Provisional Local Medical Committee, which has been approved by the Insurance Commissioners, also held numerous meetings. While regretting that all the points urged by the British Medical Association had not been granted, the Executive Committee recognized that it was largely owing to the pressure brought to bear on the Government and the Insurance Commissioners that better terms were granted to the profession. The Executive Committee felt, therefore, that the British Medical Association through the State Sickness Insurance Committee should still endeavour to obtain by an amending Act further improvements in connexion with several points relating to the administration of medical benefit. The Executive Committee noted with satisfaction that the recommendations of the Dewar Committee on medical service in the Highlands and Islands would do much to improve the condition of medical practitioners practising in those areas, and it was gratifying to recall that the Vice-Chairman of the Division (Dr. Millar, Fort William) was one of the Dewar Committee, and had given it valuable assistance. An Ethical Committee of the Division was appointed, with Dr. J. MacDonald, M.O.H., as chairman; it had met once, and ethical rules had been adopted and approved by the Central Council and circulated to members of the Division. The Executive Committee recorded the interest with which it heard that an

invitation had been sent by the Aberdeen Branch asking that the annual meeting of the British Medical Association should be held in Aberdeen in 1914. It was of much interest to the profession in Scotland to learn that through representations made by the Scottish Committee to the Central Council the duties of organizing the Branches, Divisions, and Local Medical Committees in Scotland had been transferred to the Scottish Committee. Sanction had also been given by the Central Council of a grant of £200 being given to the Scottish Committee for the expenses of the Committee. It was proposed to hold a conference of representatives of the Scottish Local Medical Committees once a year, and that when necessary special conferences should be held. It was considered that the action of the Scottish Committee would do much to consolidate the interests of the profession in Scotland.

Instruction of Representative.—The business of the Annual Representative Meeting (SUPPLEMENTS, BRITISH MEDICAL JOURNAL, of April 19th, May 3rd and 10th) was considered, and the Representative was instructed accordingly. Among other items, to oppose any motion to turn the British Medical Association into a trade union.

Vote of Thanks.—Dr. MacFadyen, the retiring Chairman, was thanked for his services in the chair during the past year.

OXFORD AND READING BRANCH:

OXFORD DIVISION.

A SPECIAL general meeting of the Division was held on May 30th at the Radcliffe Infirmary, Oxford. Sir WILLIAM OSLER presided, and about thirty members were present.

Reorganization of City Medical Committee.—The SECRETARY read the report of the subcommittee on the constitution of the City Medical Committee, and the reorganization recommended was duly ratified by the meeting.

Tuberculosis Scheme.—Dr. TURRELL introduced the following scheme, which after some remarks by Dr. ORMEROD (M.O.H. for City), Dr. BROOKS, and Sir WILLIAM OSLER, was accepted *nomine contradicente*, on the proposition of Dr. COLLIER.

SUGGESTED TUBERCULOSIS SCHEME FOR THE COUNTY AND CITY OF OXFORD.

In discussing a tuberculosis scheme it should be borne in mind that the primary object of the tuberculosis campaign is the eradication, as far as possible, of tuberculosis rather than the treatment of the disease.

Officers to be Appointed under the Scheme.

Bearing in mind the object mentioned above it is evident that the officer responsible for the working of the scheme should be the M.O.H. for the district or area affected; it is therefore suggested that the M.O.H. for each area should be appointed under the title of Chief Administrative Tuberculosis Officer for the administration of the scheme in his area.

The duties of this officer would be to exercise a general supervision and control over the working of the Act, and to carry out the duties and exercise the powers set forth in the Public Health (Tuberculosis) Regulations, 1912, Articles xi, xii, and xiii.

This scheme, however, must provide not only for the prevention of tuberculosis, but also for the treatment of such cases of tuberculosis as may either exist or arise.

The detection, clinical observation, and treatment of cases of tuberculosis belong more to the province of the Physician than to that of the M.O.H. It is therefore recommended that an Assistant (Clinical) Tuberculosis Officer be appointed, who, though under the general direction of the M.O.H., shall be head of the dispensary and have control of diagnosis and treatment.

The following is suggested as an outline of the duties of the Clinical Tuberculosis Officer:

1. To keep himself informed of the distribution and home conditions, etc., of all notified cases. All information would be obtained by the ordinary sanitary staff, and there would be no need for him to visit private cases.
2. To confer with the M.O.H. as to preventive measures, etc.
3. To be available for consultation with medical men both for diagnosis and to suggest lines of treatment.
4. To be responsible for examination of sputum.

5. To examine and keep under observation contacts and suspicious cases at the request or with the consent of the medical attendant (if there is one).
6. To act as Tuberculosis Officer to the Insurance Committee and to advise the local authority for purposes of sanatorium benefit.
7. To take charge of such tuberculosis dispensaries as may be established in his area.

It is anticipated that the time of the clinical tuberculosis officer for the county would be fully occupied in attending the dispensaries throughout the county and in attending to his other duties. The work of the City Clinical Tuberculosis Officer will not be so scattered, and he will therefore have more time at his disposal; it is therefore suggested that he be in addition appointed Assistant School Medical Officer. This additional appointment would bring him into touch with the poorer school children and would give him a useful insight into some of the social conditions prevailing among the poor of Oxford. And this arrangement would have the great additional advantage of relieving the M.O.H. of a portion of his present work, thus enabling him to perform the suggested duties of Chief Administrative Tuberculosis Officer, which otherwise, owing to the pressure of his public health work, he would be unable to undertake.

It is strongly recommended that these officers shall not be permitted to engage in private practice.

Institutions required under the Scheme.

The following institutions will be required for the efficient working of the scheme:

A Sanatorium; Dispensaries; Institution for observation of hospital cases, and for education of patients in preventive measures; Institution for incurable and dying cases.

It is felt that it does not fall within the scope of this scheme to urge the immediate building of a sanatorium.

Dispensaries.

In order to minimize expense it is recommended that wherever possible existing buildings and institutions should be made use of, and it is especially recommended both on the ground of economy and efficiency that the existing facilities at the Radcliffe Infirmary be utilized to the fullest extent.

It is recommended that a tuberculosis dispensary be established at the Radcliffe Infirmary under the charge of the City Clinical Tuberculosis Officer for the attendance at such times as may be determined of tuberculosis patients within the area of the City of Oxford.

It is recommended that a Tuberculosis Dispensary be established at the Radcliffe Infirmary under the charge of the County Clinical Tuberculosis Officer for the attendance of such cases as may reside in the neighbouring parts of the county, and for the attendance of such cases as from the nature of their complaints may need such facilities for their treatment as cannot be supplied at the Branch Dispensary.

It is recommended that Branch Dispensaries already established in the County of Oxford should be maintained under the care of the County Clinical Tuberculosis Officer.

Hospital for Observation Beds.

It is recommended that beds be provided at the Radcliffe Infirmary for the observation and treatment of such cases as may be considered by the City or County Tuberculosis Officer to require hospital treatment.

It is recommended that such cases, while occupying beds in the Infirmary, should be under the care of the Physician or Surgeon of the Institution to whom they are assigned; also that the Clinical Tuberculosis Officer concerned shall have free access to such cases for the purpose of taking such notes or keeping such records as may be required by the Insurance Committee or Commissioners.

Institutions for Incurable and Dying Cases.

It is strongly felt that neither of the above described institutions is a suitable place for the hopelessly incurable or dying cases; it is recognized nevertheless that these cases, especially in the latter and helpless stages, when they are apt to be surrounded with sympathetic relatives and friends, present an extremely dangerous source of infection. It is recommended that accommodation be provided for such cases.

Insurance Act.—On the motion of Dr. DUGAN, Secretary, it was resolved that notice be sent to members and non-members in the Division area, and also to secretaries of clubs and friendly societies, to the effect that no persons

with an income above the insurance limit (£160 per annum) would be attended at contract rates.

Temporary Residents.—Dr. HIGGS (Secretary of City Medical Committee) raised the question of attendance on migratory insurance patients, and it was unanimously resolved to support the State Sickness Insurance Committee in its request to every Division

1. Not to agree to any deduction from moneys due to them under the Act for the purpose of the schemes outlined in Memorandum 161, and
2. Only to treat the above-mentioned classes of insured persons as private patients until such time as suitable arrangements are provided by the Commissioners.

Notice of this resolution was directed to be sent to members and non-members in the Division.

The proceedings then terminated.

PERTSHIRE BRANCH.

A MEETING of the Perthshire Branch was held in the Perth Infirmary on May 30th, to which every practitioner in Perthshire was invited. Twenty members were present, and a keen discussion took place in regard to difficult questions in the Insurance Act.

Temporary Residents.—After discussion, on the motion of Dr. TAIT (Alyth), seconded by Dr. ANDERSON (Pitlochry), the following resolution was carried unanimously:

That the decision come to by the Joint Local Medical Committee of Perth and Perthshire, at a meeting with Dr. McVail the Friday previous, be not approved of, either in regard to Schemes I or II, brought forward by the Scottish Insurance Commissioners, concerning the provision of medical benefit to temporary residents; and that we approve of the decision come to by the State Sickness Insurance Committee (see SUPPLEMENT, BRITISH MEDICAL JOURNAL, May 17th, p. 452), that no fraction should be deducted from the doctors' 7s. promised by the Act; and that meantime we adhere to the decision previously come to by the practitioners in Perth and Perthshire, that insured persons who are temporary residents or summer visitors must make their own arrangements for medical attendance if required.

Medical Certificates for Sickness Benefit.—On the motion of Dr. LYELL, it was unanimously agreed to send a protest to the Insurance Commissioners—

- (1) That medical men were compelled to put down the nature of diseases treated, thus giving private information which members of Local Insurance Committees may get access to; and (2) that it was high time some uniform certificate was agreed upon by the Commissioners.

Non-payment of Medical Men.—On the motion of Dr. PATON it was decided to protest strongly against the present holding up of moneys due to them by the Commissioners for insured persons, both allocated and unallocated. It was reported that great dissatisfaction prevailed on these and other points throughout the county of Perthshire, especially in view of the question of signing on for a further period of service on the panels at an early date.

SOUTH-EASTERN BRANCH:

DOVER DIVISION.

THE annual meeting of the Dover Division was held on June 3rd. Dr. C. WOOD, Chairman, took the chair, and there were eleven members present.

Annual Report.—The SECRETARY read the annual report of the Executive Committee and presented the statement of accounts, both of which were adopted.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. Ian D. C. Howden, Dover.

Vice-Chairman.—Dr. F. B. Hulke, Deal.

Honorary Secretary and Treasurer.—Dr. J. H. Acheson, R.N.

Representative on Branch Council.—Dr. J. H. Acheson, R.N.

Executive Committee.—Drs. C. Wood and J. J. Day, besides the following (*ex officio*): The Chairman, Vice-Chairman, Representative for Representative Meeting, and Honorary Secretary.

Instruction of Representative.—Resolutions were subsequently passed that the Division approved of an increase up to 5s. in the annual subscription of the Association, but was opposed to the suggestion of the Association being formed into a trade union.

Votes of Thanks.—The meeting terminated with a hearty vote of thanks to Dr. C. Wood, the retiring chair-

man, for his services as Chairman of the Division for the past two years, who, in responding, said that he felt confident that the loyal support which he had always received from the members would be extended to his successor.

EASTBOURNE DIVISION.

THE tenth annual general meeting of the Eastbourne Division was held on May 16th, when there were present Mr. A. C. ROBERTS, Chairman, and twenty other members.

Annual Report.—The report of the Executive was read and adopted. It stated that the year was one of continued activity owing to the Insurance Act, and that the brunt of the work in organizing the local profession had been borne by the Provisional Medical Committee formed on April 4th. The results of its efforts had been (a) to induce every practitioner engaged in contract friendly society practice to tender his resignation last September, and (b) to negotiate successfully the Association's scale of fees for the domiciliary treatment of tuberculous persons with the Local Insurance Committee. The amended scheme for the treatment of elementary school children had failed to receive the sanction of the Board of Education. The number of members of the Division at the end of the year was sixty-seven. Eleven meetings of the Division, including seven jointly with medical non-members, were held, with an average attendance of twenty-four members and five non-members. The Executive Committee had held two meetings, when the average attendance was eight. The Provisional Medical Committee held four meetings, and the average attendance was sixteen.

Election of Officers.—The following were unanimously chosen:

Chairman.—Dr. A. Harper.

Vice-Chairman.—Dr. J. H. Ewart.

Honorary Secretary and Treasurer.—Dr. Wm. Muir Smith.

Representative on Branch Council.—Dr. Wm. Muir Smith.

Representative for Representative Meeting.—Dr. J. H. Ewart.

Executive Committee.—Dr. C. O'Brien Harding, J.P., A. A. Martin, R. Howie, W. J. C. Merry, and M. Milner Moore.

Reorganization of Branch.—On the consideration of the proposal of the South-Eastern Branch Council it was resolved to support the resolution of the South-Eastern Branch Council to obtain the consent of the Council to dividing the present unwieldy Branch into three separate Branches, corresponding with the counties of Kent, Sussex, and Surrey.

Dinner.—After the meeting members dined together under the chairmanship of Dr. A. Harper.

SOUTH-EASTERN OF IRELAND BRANCH.

AN extraordinary meeting of the Branch was held in the Council Chamber, Town Hall, Clonmel, on June 4th. In the absence of the newly-elected President, Dr. P. O'GORMAN (Gowran), Dr. R. R. O'BRIEN (Clonmel) occupied the chair; seven other members were present.

Resolutions.

The following resolutions were passed unanimously:

1. That our Secretary be directed to write to the Chairman of the Representative Meeting asking that an end be put to the dilatory proceedings under which the Representative Meeting lasts for several days, when it ought to be finished in two days.
That our Representative be directed to move a resolution on the subject.
2. As it has come to our knowledge that blackleg certifiers are being sent to a neighbouring city, we wish to express our disapproval of that course, and, if persisted in, we call on all medical men within the area of the South-Eastern of Ireland Branch of the British Medical Association to discontinue all connexion with the working of the tuberculosis section of the Insurance Act.
3. We call the attention of the Representative Meeting of the British Medical Association to the fact that maternity benefit is being paid in Ireland to women attended by unqualified midwives, and urge that meeting to take such action as will prevent in the interest of the ignorant poor the continuance of such practice.
4. That all members of the Conjoint Committee who are on the panel or support those who are on the panel be called on to retire from that body before the Irish Medical Association co-operate with it.
5. That we, the South-Eastern of Ireland Branch of the British Medical Association, warmly protest against the

action of the BRITISH MEDICAL JOURNAL in refusing insertion to letter protesting against the dilatory proceedings of the Representative Body, whereby close on an entire week (a full week if time for travelling be taken into account) is consumed every year by the Representative Body instead of the couple of days which at most would suffice for the transaction of all useful business.

Election of New Member.—At a meeting of the Branch Council subsequently held Dr. Patrick Reid, Borris, co. Carlow, was elected a member of the Branch.

Dinner.—At the conclusion of the meeting the members dined together at the Ormonde Hotel.

SOUTHERN BRANCH:

CHANNEL ISLANDS DIVISION.

A MEETING of the Channel Islands constituency was held at the Royal Hotel, Guernsey, on May 22th. Dr. VOISIN (Jersey) presided, and seventeen others were present.

Statement of Representative.—The Representative, Dr. J. F. CARRUTHERS, suggested that as he had already fully reported to both Jersey and Guernsey the work of the Association for the last year and had nothing new to add, the meeting might dispense with a formal report from him. This was agreed to, and a unanimous vote of thanks was accorded to Dr. Carruthers for his services during the past year as Representative.

Election of Representative.—On the motion of Dr. BULTEEL, seconded by Dr. MAJOR, Dr. Carruthers was re-elected Representative for the coming year, with power to nominate a Deputy.

Vote of Thanks.—With a vote of thanks to the Chairman the meeting terminated.

GUERNSEY AND ALDERNEY DIVISION.

AT the annual meeting of this Division, held at Gardner's Royal Hotel, Guernsey, on May 29th, the Honorary Secretary, Dr. J. F. CARRUTHERS, made his annual report and financial statement, which were unanimously adopted; and a vote of thanks was accorded to him for his services in the past year.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. H. Draper Bishop, M.O.H.

Honorary Secretary and Treasurer.—Dr. J. F. Carruthers (re-elected).

Librarian.—Dr. M. H. Bulteel (re-elected), with Drs. Aikman and Carruthers on the Committee.

Representative on the Branch Council.—Major E. H. Myles (re-elected).

Executive Committee.—Drs. Aikman, C. Carey, and Bulteel, with the President, Honorary Secretaries, and Branch Council Representative members *ex officio*.

Annual Dinner.—The annual dinner followed, at which sixteen members sat down; Drs. H. C. Major and E. O. B. Voisin of Jersey attended as guests, and ten other visitors were present, including His Excellency the Lieutenant-Governor, Sir Edward Hamilton, Mr. E. C. Ozanne, Procureur du Roi, and Mr. V. G. Carey, King's Receiver-General.

SOUTH MIDLAND BRANCH:

NORTHAMPTONSHIRE DIVISION.

THE annual meeting of the Division was held in the Northampton General Hospital on May 29th. The chair was taken by Dr. BAXTER, and later by Dr. COOKE; seventeen other members were present.

Election of Officers.—The following officers for the ensuing year were elected:

Chairman.—Dr. Cooke.

Vice-Chairman.—Dr. Bull (Stony Stratford).

Honorary Secretary and Treasurer.—Dr. Hiehens.

Divisional Committee.—Drs. Cropley, Grindon, Linnell, Relton, and Tolpott.

Representatives on Branch Council.—Drs. Cooke, Greenfield, and Arthur.

Representative for Representative Meetings.—Dr. Dryland.

Deputy Representative.—Dr. Roughton.

Representatives on South Northants Nursing Committee.—Drs. Darley and Harrisson.

Vote of Thanks.—Dr. COOKE then took the chair and proposed a vote of thanks to Dr. Baxter, the retiring Chairman, which was carried with acclamation; and Dr. BAXTER replied.

Annual Report.—Dr. HICHENS then read the annual report, which showed that the membership, which on 1 December 31st, 1912, numbered 126, had increased by 4, after allowing for 1 death, 5 resignations, and the loss of 8 members from the Division through change of residence. The financial statement showed a balance in hand at the end of 1912 of £19 7s. 7d. Nine meetings of the Division had been held, chiefly for the consideration of the National Insurance Act, and the average attendance had been over 45; the Executive Committee had met seven times.

Instruction of Representative.—The agenda for the Annual Representative Meeting was then discussed, and the Representative was directed to support or reject certain resolutions.

Expenses of Representatives.—The Division passed the following resolution:

That Divisions be allowed to pay their Representatives' out-of-pocket expenses other than travelling expenses.

SOUTH-WESTERN BRANCH:

PLYMOUTH DIVISION.

THE annual meeting of the Plymouth Division was held in the Medical Societies' Rooms, Plymouth, on May 27th. Dr. E. L. FOX, in the unavoidable absence of Mr. R. JAKUES, presided. The attendance was smaller than usual.

Election of Officers.—The following were elected officers for the ensuing year:

Chairman: Mr. R. Jaques, F.R.C.S.

Honorary Secretary: E. J. Donbavand.

Branch Councillors: Drs. C. Cooke, Musgrave, McCulloch.

Executive Committee: Drs. Glinn, Lander, Pethybridge, and Style.

Vote of Thanks.—A cordial vote of thanks for past services was unanimously carried.

Instruction of Representative.—The meeting then considered the Council's report and recorded the opinions that it was desirable: (1) To increase the subscription to the Association. (2) To form a trades union for the whole rather than part of the members. (3) That the Representatives should receive out-of-pocket expenses, in addition to railway fare. (4) That postal votes are very necessary in obtaining a reliable estimate of the general opinion of the profession.

Contract Practice.—The HONORARY SECRETARY said that there was reason to believe that some medical men were underselling their colleagues in respect to certain clubs, and proposed that a circular should be sent to all practitioners in the Plymouth Divisional area to the effect that any practitioner in the Plymouth Divisional area of the British Medical Association who accepted friendly society and other appointments on contract terms less than those agreed to by the Division, would be considered as acting in a manner derogatory to the interests of the profession. This was carried, and the meeting terminated.

STIRLING BRANCH.

THE annual general meeting of the Stirling Branch was held at Alloa on May 23th.

Report of Branch Council.—The report of the Branch Council stated that eight meetings had been held during the year, with an average attendance of thirty-nine members.

Election of Office-bearers.—The following were elected for the ensuing year:

President.—Dr. Dyer (Alloa).

Vice-President.—Dr. Clarkson (Larbert).

Secretary.—Dr. Moorhouse (Stirling).

Branch Council.—Drs. Buist (Dunblane), Hunter (Falkirk), Joss (Denny), and McFarlan (Stirling).

Representatives of the Branch on the Colliery and Public Works Surgeons Committee for Scotland.—Drs. Joss and Robertson.

Annual Representative Meeting.—In connexion with the consideration of the business of the Annual Representative Meeting Dr. DYER read a paper on the Insurance Act in the light of experience. The address covered all the points which a four months' experience of the Act had brought to light, and was followed by an interesting discussion. The meeting passed a cordial vote of thanks to Dr. Dyer for his address, and directed that it should be printed and circulated to all practitioners within the Branch area.

NEW SOUTH WALES BRANCH.

ANNUAL MEETING.

The annual meeting of the New South Wales Branch of the British Medical Association was held on March 28th, Dr. CLARENCE READ, President, being in the chair.

Annual Report of Council.

The annual report of the Council showed that at the end of the year the Branch numbered 894 members and that during its course eighteen meetings were held, the discussion thereat auguring well, it is stated, for the future development of the scientific side of the Branch's work. The Council itself held thirty-one meetings, while those of its Organization, Ethical, Contract Practice, and Premises Subcommittees aggregated thirty-eight.

Organization of the Profession.

The report afforded evidence that a considerable amount of work had been accomplished in the direction of the organization of the profession and the progress of the Federal movement among the various State branches of Australia. Three new local associations have been formed during the year which are affiliated with this Branch. These were: The City Medical Association, which may be considered to be a revival of the old Sydney Metropolitan Association; the North-Eastern Medical Association, comprising the area of the northern rivers of the State; and the Illawarra Suburbs Medical Association. The Balmain District Medical Association, which was inaugurated in 1891 and reorganized in 1903, has now decided to become affiliated with the Branch. This raises the number of local medical associations affiliated with the New South Wales Branch of the British Medical Association to fifteen.

The Federal Committee.

The Federal Committee of the British Medical Association in Australasia, under the provisional constitution adopted for it by all the seven branches in Australasia, held its first session in Melbourne, May 27th to 29th, 1912, when several important subjects of general interest to the medical profession in Australasia were considered. This first meeting of the Federal Committee was duly recognized by the members of the Victorian Branch as an epoch-marking event in the organization of the profession in Australia. They took the opportunity of drawing public attention to it by entertaining the Committee at a dinner, at which His Excellency the Governor, Sir John Fuller, presided, and at which the Commonwealth Government was represented by the Hon. G. F. Pearce, Minister for Defence, and the State Government by the Premier, Mr. W. Watt. The second session of the Committee was held in Sydney at the British Medical Association Library, January 7th to 10th, 1913.

Conference with Friendly Societies.

The Council reported that during the year a conference was held between representatives of the friendly societies and the Council of the New South Wales Branch of the British Medical Association with a view to arriving at a better understanding between friendly societies and their medical officers. The result of this conference is briefly summarized as follows:

1. There are no real obstacles to the establishment of harmonious relations between the friendly societies and the members of the Association.

2. The medical institutes which support the practice of paying their medical officers by salary instead of on a per capita basis are discountenanced by the friendly societies.

3. The form of agreement approved by the Council and adopted by the North-Eastern Medical Association for use as a common form of agreement by its members was approved of by the conference as a suitable form of agreement for use by all lodges and their medical officers throughout the State.

It is interesting to know that the friendly societies' representatives at this conference admitted the justice of the principle of the wage limit in lodge contract practice.

The Hospital System.

Reference was made to the extension of the hospital system introduced during the year by the Government

by the equipment of three of the asylums for the destitute near Sydney as general hospitals with honorary visiting medical staffs. In recognition of their new function they are now called State hospitals and asylums, and the Coast Hospital at Little Bay is now referred to as the National Hospital. These changes may easily be regarded as an instalment of a State general hospital system as distinct from the system in vogue in New South Wales of general hospitals supported by the contributions of the charitable and endowment of the benevolent, and not under Government management. An effort was made during the year by the Government to introduce a further extension of the hospital system by the establishment of free State general dispensaries, independent of the out-patients' department of the general hospitals. The New South Wales Branch of the British Medical Association promptly took steps to counteract this move by passing the following resolutions, namely:

That in view of the fact that medical attendance can be made available for all classes of the community through the agencies of public hospitals, friendly societies, and medical practitioners in their private practice, it is unnecessary and inadvisable to establish free general dispensaries; and that no member shall accept a position as honorary medical officer to any free general dispensary under Government control.

The British Medical Association Building.

Reference is also made to the financial success of the British Medical Association building, which is largely owing to the energy and devotion of the manager, Dr. W. H. Crago. The net result of the British Medical Association building operations for the year shows a profit of £594 7s. 2d.

The Influence of the Association.

The *Australasian Medical Gazette* at the end of 1912 completed its first year as a weekly publication. As anticipated, its value to members as a newspaper has been immensely increased as a result of the change of the monthly to the weekly issue.

In conclusion, the Council notes with satisfaction the steady growth of the influence of the Association in public matters in which the medical profession is concerned and the recognition afforded to the Association by the Government and public bodies. During the year Departments, both of the State and Commonwealth Governments, have consulted the Council on medical matters requiring consideration.

Election of Officers and Council.

The following were elected officers for the year: President, Dr. Sydney Jamieson; Vice-President, Dr. David Thomas; Members of the Council, Drs. Abbott, Armstrong, Barrington, Blackburn, Brady, Crago, Craig, Dick, Gillies, Hinder, Lipscomb, Maitland, Millard, Morton, Read, Rennie, Sandes, Todd. Dr. R. H. Todd was elected Representative of the Branch at the Annual Representative Meeting of the British Medical Association at Brighton in July, 1913. Drs. R. H. Todd and Gillies were nominated as delegates, on the invitation of the President-elect, Dr. W. Ainslie Hollis, to attend the Annual General Meeting of the British Medical Association at Brighton.

At the first meeting of the new Council, held on April 1st, Dr. R. H. Todd was re-elected Honorary Secretary, Dr. Sandes, Assistant Honorary Secretary; Dr. W. H. Crago, Honorary Treasurer; Dr. J. A. Dick, Honorary Librarian; Dr. G. E. Rennie, Editor of the *Australasian Medical Gazette*; Dr. J. B. Cleland, Assistant Editor; Dr. W. H. Crago, Manager.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian, at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

British Medical Association.

EIGHTY-FIRST ANNUAL MEETING,
BRIGHTON, JULY, 1913.

THE SECTIONS.

THE scientific business of the meeting will be conducted in sixteen Sections, which will meet on Wednesday, July 23rd, Thursday, July 24th, and Friday, July 25th.

The President, Vice-Presidents, and Honorary Secretaries of each Section constitute a Committee of Reference for that Section, and exercise the power of inviting, accepting, or declining any paper, and of arranging the order in which accepted papers shall be read. Communications with respect to papers should be addressed to one of the Honorary Secretaries.

A paper read in the Section must not exceed fifteen minutes, and no subsequent speech must exceed ten minutes.

Papers read are the property of the British Medical Association, and cannot be published elsewhere than in the BRITISH MEDICAL JOURNAL without special permission.

The following additional information in regard to the work of certain Sections has been received since our last issue:

SECTION OF DERMATOLOGY.

Paper:

WALSH, D. Circulatory Disorders in relation to Alopecia Areata and other forms of Baldness.

SECTION OF GYNAECOLOGY AND OBSTETRICS.

Wednesday.—Discussion on the Best Methods of dealing with Malpositions of the Uterus, especially with reference to Retrodisplacements and Prolapse, to be opened by Dr. MARY SCHARLIEB, Dr. HANS SCHLIMPERT (Freiburg), Mr. CUTBERT LOCKYER, and Professor H. CORBY, followed by Messrs. A. E. Giles, Christopher Martin, N. T. Brewis, G. B. Marshall, W. Ritchie, F. Edge, and Drs. May Thorne and Mary Ivens.

Thursday.—Discussion on Affections of the Urinary Tract complicating Pregnancy, to be opened by Sir JOHN HALLIDAY CROOM, followed by Messrs. H. O. Nicholson, G. B. Marshall, W. H. P. Newham, H. Williamson, Bryden Glendinning, and F. Edge.

Friday.—Papers and pathological demonstrations:

GILES, A. E. Reasons for Early Operation on Uterine Fibroids.

MCLROY, A. Louise, WATSON, H. Ferguson and MCLROY, J. Hamilton. The Significance of the Wassermann Reaction in Gynaecological Diagnosis.

SCHLIMPERT, Dr. Hans. Abderhalden's Serum Reaction of Pregnancy.

The following paragraphs indicate the line that will be taken by the openers of the formal discussions:

Discussion on Methods of Dealing with Malpositions of the Uterus.—(Dr. SCHLIMPERT). Suture of the muscles of the pelvic floor as a remedy for the more severe cases of prolapse has been in use in the Frauenklinik at Freiburg since July, 1909. Two methods are in use:

(1) Suture of the deep transverse perineal muscles without isolation of the musculi levatores. The musculi levatores are included in the suture or only approached to one another by suture of the deep transverse perineal muscles. (2) Suture of the separated musculi levatores. First the deep transverse perineal muscles are isolated, then the centrum peritoneum is cut through until the sphincter is reached. Then the deep transverse perineal muscles are also cut through, and the final stage is the union by iodine catgut of the edges of the pubic portion of the levator ani. At the same time as this operation an anterior and posterior colporrhaphy are performed, the bladder wall being also folded in, and besides this ante-fixation of the uterus (Alexander, Adami or ventrifixation, or vaginal fixation) is performed. In the case of multiparæ, resection of the Fallopian tubes for the purpose of sterilization was usually performed in addition. Indications for this treatment; the operation, although the results are better than those formerly employed, must be acknowledged to be somewhat dangerous, and thus must be reserved for the severer forms of prolapse. For cases where the span

between the levatores ani is about two fingerbreadths, the method (1) of operating is employed; on the other hand, where the space between the levatores ani is three to four fingerbreadths in width, method (2) must be used. In cases where the levatores ani cannot be palpated, the space between them being even more than four fingerbreadths, then colpocleisis must be performed.

Discussion on Affections of the Urinary Tract complicating Pregnancy.—(Sir HALLIDAY CROOM). (1) Abnormal constituents of urine: (a) Albumen, and urinary products associated with toxæmia of pregnancy; reference to the kidney of pregnancy; pre-eclamptic and nephritic toxæmia, eclampsia, eclampsia without albuminuria, hyperemesis gravidarum, coefficient of ammonia, anuria in toxæmia. (b) Sugar; glycosuria, lactosuria, pregnancy in diabetes. (2) Infection of urinary tract: pyelitis, cystitis, path of infection—upwards or downwards? (3) Retention of urine; in pregnancy, in the puerperium. (4) Incidence of stone in pregnancy. (5) Bladder—its anatomy in labour. Distension—diagnosis from retraction ring. Fistula formation.

SECTION OF ELECTRO-THERAPEUTICS.

The following is the programme:

Wednesday.—Introductory address by Professor C. G. BARKLA, F.R.S., on Secondary X-ray Radiations in Medicine.

Papers on Roentgen Diagnosis.

HERTZ, A. F. Suggested Normal Standards of the X-ray Examination of the Alimentary Canal.

BRUCE, Ironside. Collargol Injections in the Diagnosis of Diseases of the Urinary Tract.

JORDAN, A. C. Cardiospasm.

BYTHELL, W. J. S. The Radiography of Tuberculous Sinuses injected with Bismuth.

Thursday.—Papers on Electro-diagnosis and Electro-therapeutics.

JONES, Lewis. On the Use of Condensers in Electrical Testing. NAGELSCHEIDT, Professor (Berlin). On Electrical Treatment of Nutritional Disorders.

BAILEY, C. F. Electro-therapeutics in Neuron Lesions.

CUMBERBATCH, E. P. Results of Muscle Testing by the Condenser Method.

LEWIS, T. The Electrocardiograph.

HARRIS, J. D. Secondary X Rays in connexion with Ionization.

HUMPHRIS, F. H. Electricity in the Reduction of High Arterial Tension.

Friday.—Discussion on the Use of the Gamma Radiations in Surgery, to be opened by Sir A. PEARCE GOULD and Dr. ROBERT ABBE (New York).

Papers on Roentgen-therapy and Radium.

HEERNAMAN-JOHNSON, F. Indication for X-ray Radiation before, during, and after Operation for Cancer.

FOWLER, F. The Technique of X-Ray Treatment of Cancer.

SAVILL, Agnes. Two Cases of Fibroma cured by X Rays (Bordier's Method).

BATTEN, G. B. X-Ray Treatment of Ringworm.

SECTION OF LARYNGOLOGY, RHINOLOGY, AND OTOTOLOGY.

Wednesday.—The discussion on The Technique and After-Treatment of the Radical Mastoid Operation will be opened by Dr. WILLIAM MILLIGAN.

Thursday.—In opening the discussion on this day Mr. H. TILLEY will be associated with Sir R. H. WOODS.

WILLIAMS, Watson. Exploration of the Accessory Sinuses of the Nose (Demonstration).

Friday.—Papers:

MAURICE, A. (Paris). The Re-education of the Powers of Hearing.

O'MALLEY, J. F. Suggestive Points of Analogy in Oto-sclerosis and Arthritis Deformans.

LETT, G. Seecombe. The Physiology, Anatomy, and Embryology of the Palatine Tonsils.

The following paragraph indicates the line that will be taken by the opener of the first discussion:

Discussion on The Technique and After-Treatment of the Radical Mastoid Operation.—(Dr. WILLIAM MILLIGAN). Importance of a detailed examination of the functional activity of the labyrinth prior to the performance of the radical mastoid operation; risks of a "radical" operation in cases of diffuse purulent (latent) labyrinthitis; possibility of converting a circumscribed into a diffuse serous

or purulent labyrinthitis; clinical symptoms in such an event. If latent labyrinthitis present, either no mastoid operation or a complete mastoidectomy and labyrinthectomy; danger of incomplete operations. *Method of Closing the Eustachian Tube*: Preparation of patient and operation area. Methods of opening mastoid antrum, hammer and gongue, gouge without hammer, burrs, advantages; objections; necessity of free removal of posterior meatal and outer attic walls. Flaps. Inner tympanic wall, how to deal with it. Disinfection of antromeatal cavity. *After-Treatment*: Packing; advantages, disadvantages; dry treatment; use of spirit drops. Skin grafting; cell proliferants; blood-clot treatment; combination of one or more methods. Various methods statistically compared.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Friday.—Paper:

BROWN, Professor. The Psycho-Analytical Method of Freud.

SECTION OF PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

Wednesday.—After the discussion on Urinary Antiseptics a paper will be read by Dr. H. GRAY BARBOUR (University of Yale) on the Pharmacology of Body Temperature.

Friday.—After the discussion on Hypnotics the following papers will be read:

PRICE, F. W. Some Further Investigations of the Action of Digitalis on the Blood Pressure in Man.

HAIG, A. The Acid Child in Relation to Dietetic Errors.

SECTION OF TROPICAL MEDICINE.

Wednesday.—Discussion on the Causes of Invaliding in the Tropics. To be opened by Dr. G. BASIL PRICE and Colonel R. J. S. SIMPSON, C.M.G., A.M.S. (ret.).

Thursday.—Discussion on Dysentery. To be opened by Captain S. R. DOUGLAS.

The following paragraphs indicate the line that will be taken by the openers:

Discussion on the Causes of Invaliding in the Tropics.—

(1) (Dr. PRICE). Some general considerations on climatic factors involved in tropical and subtropical residence. The report on an investigation into the causes of invaliding of missionary lives from 1890 to 1906 belonging to eighteen English missionary societies. The statistics available are in most cases very incomplete, since only the Church Missionary Society had medical records of its agents. This society deals, however, with a staff of about 1,200 missionaries, men and women; a careful analysis, therefore, is given of the returns afforded by this society, and compared with those obtained from other sources. The principal headings of the analysis are: (1) The country or region concerned; (2) number of lives involved, men or women; (3) average years abroad and on furlough; (4) percentage of invalided and healthy lives; (5) incidence of illness which did not necessitate invaliding; (6) causes of illness and invaliding from each country. *Conclusions.*—

(1) That the causes of illness and invaliding vary very widely according to the country concerned. As an example from the Church Missionary Society figures: *Japan*: 105 men and women; 16 invalided (or 15.2 per cent.), of which 13 (or 81.25 per cent.) are for neurasthenic conditions. *East Africa and Uganda*: 125 lives; 25 (or 20 per cent.) invalided, the more prominent causes of which are (a) malaria (20 per cent.), (b) blackwater fever (16 per cent.), (c) anaemia (16 per cent.). (2) The greater incidence of disease in certain countries, and the frequent susceptibility of the nervous and circulatory systems as the focus of disturbance. (3) The analysis brings into prominence the rôle that infective disease plays in invaliding and as a cause of illness; malaria, enteric fever, and bowel disorders are probably the most common. (4) The need for education of all going abroad as to the adoption and practice of safeguards to health is urgent, particularly as regards the use of quinine, vaccination against enteric, and small-pox. A further reference is made to cases of enteric fever and tuberculosis, stating the time of incidence and, in the latter case, to what extent family predisposition had been present. Tuberculosis occurring in a class of life which may be termed "selected" proves to be a very definite and repeated cause of invaliding and death amongst missionary lives.

(2) Colonel R. J. S. SIMPSON.—The questions to be answered are: (1) To what extent are tropical diseases effective in producing invaliding? (2) What are the diseases which most frequently result in invaliding? (3) Are the same causes effective in producing invaliding that were effective twenty years ago? The materials used in answering these questions are: The Army Medical Department Reports, taking the ratios of invaliding per 1,000 of strength for the periods 1886-95, 1896-1905, 1906-10 for India alone, and the period 1906-10 for all foreign stations. The term "invaliding" as applied in the Army Medical Service is defined, and the following conclusions are drawn: (a) Tropical diseases of themselves produce a relatively large temporary disability only. (b) The temporary invaliding from a station for causes other than tropical diseases is, over the whole of the foreign stations, closely related to the proportion of invalids from tropical diseases. (c) The important causes of invaliding, temporary and final, are in order of importance: Nervous and mental diseases, tuberculous diseases, diseases of the organs of special sense, including the eye; diseases of the heart, functional and organic. These are the same causes which are effective in Great Britain, and almost in the same order.

Discussion on Dysentery.—(Captain S. R. DOUGLAS).

(1) The life-history of amoeba causing dysentery. (2) Cultivation of pathogenic amoeba. (3) Experimental work on animals. (4) Occurrence of amoebic dysentery in Europe. (5) Some of the rarer complications of dysentery. (6) Treatment of dysentery.

Honorary Local Treasurer—

H. H. TAYLOR, F.R.C.S.,

36, Brunswick Square, Hove.

Honorary Local Secretary—

LEONARD ARTHUR PARRY, M.D., F.R.C.S.,

83, Church Road, Hove.

THE PATHOLOGICAL MUSEUM.

The Pathological Museum Committee, whose constitution was set forth in our issue for May 17th, proposes to arrange the material it receives under the following heads:

- (i) Exhibits bearing on discussions and papers in the various Sections.
- (ii) Specimens and illustrations relating to any recent research work.
- (iii) Instruments relating to clinical diagnosis and pathological investigation.
- (iv) Individual specimens of special interest, or a series illustrating some special subject.

The Committee wishes it to be understood that the above are only suggestions, and that specimens illustrating any subject of special interest will be welcomed.

The Committee desires to enlist the hearty co-operation of members, and the Honorary Secretary will be glad to hear from those who are able to make an exhibit. Every care will be taken of specimens, and the contents of the Museum will be insured.

It is hoped that it will be possible for arrangements to be made whereby exhibitors may have an opportunity of demonstrating their specimens.

The Museum will occupy a central position in the same building as that in which the sectional work is carried on, and will be easy of access.

The Chairman of the Committee is Dr. E. Hobbouse (Hove), but all communications concerning it should be addressed to Dr. W. Broadbent or Dr. H. M. Galt, Honorary Secretaries, Pathological Museum Committee, 14, North Street, Brighton.

In the article on the Annual Meeting which appeared in the JOURNAL of June 7th, there are three misprints at the top of the right hand column of p. 1227 which we wish to correct. The name of the divine who sang the fame of Richard Russell, the founder of the fame of Brighton as a health resort was not "Mannington," but Manningham; and he was parson not of "Levington," but of Jovington, a hamlet nestling in a hollow of the South Downs. In the second line of the Latin distich quoted, "selinet" should be "retinet."

PROVISIONAL PROGRAMME.

The following is the provisional time table for the Brighton meeting:

FRIDAY, JULY 18TH.

10 A.M.—Annual Representative Meeting.

SATURDAY, JULY 19TH.

9.30 A.M.—Representative Meeting.

MONDAY, JULY 21ST.

9.30 A.M.—Council Meeting.
10 A.M.—Representative Meeting.

TUESDAY, JULY 22ND.

9.30 A.M.—Representative Meeting.
2 P.M.—Annual General Meeting.
8.30 P.M.—Adjourned General Meeting, President's Address.

WEDNESDAY, JULY 23RD.

9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Medicine.
3 P.M.—Religious Services.
4 P.M.—Secretaries' Conference.
7 P.M.—Secretaries' Dinner.

THURSDAY, JULY 24TH.

8 A.M.—National Temperance League Breakfast.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Surgery.
7.30 P.M.—Annual Dinner.

FRIDAY, JULY 25TH.

9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
8 P.M.—Popular Lecture.

SATURDAY, JULY 26TH.

Excursions.

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

The following books were added to the Library between October and December, 1912:

Presented by the Author.
Stoddart, W. H. B.: The Mind and its Disorders, second edition. 1912

Presented by the General Medical Council.
Harper, C. J. S.: Legal Decisions upon the Medical and Dental Acts. 1912

Presented by the Faculté de Médecine et de Pharmacie de Lyon.
Thèses pour le Doctorat. 1910-11 and 1911-12

Presented by the Superintendent, Government Printing, Calcutta.
Scientific Memoirs by officers of the Medical and Sanitary Departments of the Government of India:

- No. 51. Listou and Williams: A Streptothrix isolated from the Spleen of a Leper 1912
- No. 52. Wells, R. T.: Dysentery in Hazaribagh Central Jail in January, 1910 to March, 1911 1912
- No. 53. Patton, W. S.: The Development of the Parasite of Indian Kala-Azar 1912
- No. 54. Cragg, F. W.: Studies on the Mouth Parts and Sucking Apparatus in the Blood-sucking Diptera 1912
- No. 55. Cragg, F. W.: The Structure of Haematopota Pluvialis 1912
- No. 56. Christophers, S. R.: Malaria in the Andamans. 1912

Added to the Library through the "British Medical Journal."
Aberhalden: Synthese der Zellbausteine in Pflanze und Tier 1912

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH.—Mr. J. Furneaux Jordan (9, Newhall Street, Birmingham) and Dr. J. G. Emanuel, Honorary Secretaries, give notice that the annual meeting of the Birmingham Branch will be held in the Medical Institute on Thursday, June 19th, at 3 p.m. Business: Election of officers. Annual report and financial statement. Inaugural address by the incoming President, Mr. W. F. Haslam.

BORDER COUNTIES BRANCH.—Dr. Livingston, Secretary, gives notice that the annual meeting of the Branch will be held in the Town and County Hotel, Carlisle, on Friday, June 27th.

EAST YORK AND NORTH LINCOLN BRANCH.—Dr. Edward Turton, Honorary Secretary (1, Albion Street, Hull), gives notice that the annual meeting of the East York and North Lincoln Branch will be held at Beverley on Friday, June 27th, at 4 p.m. Business: (1) Report of Branch Council. (2) Treasurer's Financial Statement. (3) Election of President-elect, Vice-President, and Honorary Secretary and Treasurer. (4) Address by the new President, Dr. J. Mitchell Wilson. (5) Any other business proper to annual meetings of the Branch.

EDINBURGH BRANCH.—Dr. Michael Dewar and Mr. E. Scott Carmichael, Honorary Secretaries (24, Lauriston Place), give notice that the annual meeting of the Edinburgh Branch will be held in the Royal College of Physicians' Hall, Queen Street, on Thursday, June 26th, at 4 p.m.

EDINBURGH BRANCH: LOTHIAN DIVISION.—Dr. Alex. M. Easterbrook, Honorary Secretary (Arnprior, Gorebridge, Midlothian), gives notice that the annual meeting of the Lothians Division will be held on Thursday, June 19th, at Bangour Village, where Dr. Keay has kindly invited all medical men resident in the Lothians to lunch at 1.30 p.m. The business of the meeting will be: Consideration of ethical rules; Insurance Act—organization of profession, etc.; election of office-bearers. Dr. Keay will afterwards be glad to show members features of interest of Bangour Village. Tea. Members who propose attending the meeting are requested to inform Dr. Keay not later than June 16th.

EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION.—Dr. M. J. Oliver, Honorary Secretary (St. Boswells), gives notice that the annual meeting of the Division will be held in the Railway Hotel, Newtown St. Boswells, on Friday, June 27th, at 3 o'clock p.m., for the election of officers, the consideration of the annual report of the Executive Committee and financial statement; the discussion of various matters concerning the Insurance Act, including certificates, duties of Medical Service Subcommittee, expenses of Local Medical Committees, payment for services to temporary residents, and for instructing the Representative on the Representative Body.

FIFE BRANCH.—Dr. G. C. Anderson, Honorary Secretary (Denbeath House, Methil), gives notice that the annual meeting of the Fife Branch will be held in the Station Hotel, Kirkcaldy, on Thursday, June 19th, at 3 p.m.

GLASGOW AND WEST OF SCOTLAND BRANCH: LANARKSHIRE DIVISION.—Dr. J. Livingstone London, Honorary Secretary (Hamilton), gives notice that the annual meeting of the Division will be held in St. Enoch Station Hotel, Glasgow, on Wednesday, June 18th, at 3.15 p.m. The business will include the reception of the Secretary and Treasurer's annual report; election of officers; matters referred to Divisions (see particularly SUPPLEMENT TO BRITISH MEDICAL JOURNAL, April 19th and May 3rd and 10th); consideration of "Model Rules for Ethical Procedure" (see SUPPLEMENT TO BRITISH MEDICAL JOURNAL, September 21st and 28th, 1912); domiciliary treatment of phthisis cases in dependants of insured persons.

LANCASHIRE AND CHESHIRE BRANCH: ST. HELENS AND WARRINGTON DIVISIONS.—Drs. T. A. Murray and F. J. Knowles, Honorary Secretaries, give notice that a meeting of these Divisions will be held at the Town Hall, Earlestown, at 4 p.m., on Tuesday, June 17th. Agenda: Election of Representative; agenda of Representative Meeting.

METROPOLITAN COUNTIES BRANCH.—Drs. W. Griffith and R. E. Crosse (Honorary Secretaries) give notice that the annual general meeting of the Branch will be held at 429, Strand, W.C., on Tuesday, July 1st, at 4 p.m. The business will include a report as to the election of new officers, and the annual reports of Council and of representatives of the Branch on the Central Council. On the motion to adopt Model Ethical Rules for Branches, Dr. F. J. Smith gives notice that he will propose an alteration to the Model Ethical Rules by substituting the words "British Medical Association" for the words "Medical Profession" in Rule 1. President's address: The Profession and the Public. [The Model Ethical Rules are printed in the SUPPLEMENTS of September 21st and 28th, 1912, pages 325 and 350.]

METROPOLITAN COUNTIES BRANCH: EAST HERTFORDSHIRE DIVISION.—Dr. H. D. Ledward, Honorary Secretary (123, Norton Way, Letchworth), gives notice that the first annual meeting of the Division will be held at 2.30 p.m., on Friday, June 20th, at the Town Hall, Ware, to elect officers, the repre-

sentative of the Division on the Branch Council, the ordinary members of the Executive Committee, and the Representative of the Division in Representative Meetings. To receive the Honorary Secretary's Annual Report. To alter Rule I defining the area of the Division in accordance with the decision of the Organization Committee of the Association. To consider the business of the Annual Representative Meeting and instruct the Representative thereon.

METROPOLITAN COUNTIES BRANCH: WANDSWORTH DIVISION.—Dr. Hugh McD. Parrott, Honorary Secretary, gives notice that the annual meeting of the Wandsworth Division will take place on Thursday, July 10th, at 3.15, at Stanley's Restaurant, 235, Lavender Hill, Clapham Junction. Members of the Wimbledon Division are invited to attend at 4 p.m.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—Dr. J. Munro Moir, Honorary Secretary (4, Ardross Terrace, Inverness), gives notice that the annual meeting of this Branch will be held at the Highland Hotel, Strathpeffer Spa, on Friday, June 27th, at 11.30 a.m.

SOUTH-EASTERN BRANCH: ISLE OF THANET DIVISION.—Dr. Hugh M. Raven, Honorary Secretary (Barfield House, Broadstairs), gives notice that the annual meeting of the Isle of Thanet Division will be held at the Carlton Hotel, the Parade, Broadstairs, on Tuesday, June 17th, at 4 p.m., when Dr. F. Brightman will take the chair. The business of the meeting will be: (1) Election of officers for the year; (2) to receive the annual report of the Executive Committee and the accounts for the year; (3) alteration of Divisional rules; (4) to consider the business of the Annual Representative Meeting; (5) Correspondence, etc.

SOUTHERN BRANCH.—Dr. James Green, Honorary Secretary (Brandon House, Mile End, Portsmouth), gives notice that the fortieth annual meeting will be held at the Institute, Shanklin, Isle of Wight, on Thursday, July 3rd, at 1.30 p.m., Dr. F. W. Jollye, President, in the chair. Agenda: Election of officers for 1913-14, annual report of Council, balance sheet, general business. An address will be delivered by Dr. J. Cowper, of Shanklin, the President for the ensuing year. Dr. Cowper invites members of the Branch to luncheon at Daishe's Hotel at 2.15 p.m., and to a garden and tennis party, to which ladies are also invited, at 4 o'clock. The Arthur Webster Memorial Hospital and the Scio Hospital can be visited during the afternoon. Those members who wish to play golf are invited to do so by the Shanklin and Sandown Golf Club, and, if possible, a match will be arranged between the club and the medical visitors. Intending players will please communicate with Dr. Cowper not later than June 27th. Those gentlemen who intend to accept the President's hospitality will oblige by sending word to that effect to Dr. G. Benington Wood, Newlands, Sandown, Isle of Wight, not later than June 28th.

SOUTH MIDLAND BRANCH: BUCKINGHAM DIVISION.—Dr. A. E. Larking, Honorary Secretary (Buckingham), gives notice that the annual meeting of the Division will be held on Wednesday, June 18th, at 3.30 p.m., at the Royal Bucks Hospital. The Committee will present its report for the past year, the officers for the ensuing year will be elected, and the Representative will be instructed how to vote at the Representative Meeting. The following resolution will be submitted: "That the Bucks Division do all in its power to discourage all contract practice outside the Insurance Act." A paper will be read by Dr. J. Horne Wilson (London) on The Active Treatment of Tuberculosis, and Dr. Burra will take part in the discussion.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SOUTH-WEST WALES DIVISION.—Dr. D. R. Price, Honorary Secretary (Ammanford, Carmarthen), gives notice that the annual meeting will be held at the Infirmary, Carmarthen, on Wednesday, June 18th. The out-going chairman (Dr. Edgar Davies) invites all the members to lunch at the Ivy Bush Hotel at 1 p.m.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.—Dr. S. Colen Legge, Honorary Secretary (24, Foregate Street, Worcester), gives notice that the annual meeting of the Worcestershire and Herefordshire Branch will be held at the Infirmary, Kidderminster, on Thursday, June 19th, at 4 p.m.

YORKSHIRE BRANCH.—Dr. Adolph Bronner, Honorary Secretary (33, Manor Row, Bradford), gives notice that the annual meeting of the Yorkshire Branch will be held at the Clayton Hospital, Wakefield, on June 25th, for the election of Vice-President, Secretary, and Treasurer. Members intending to read papers, make any communications, propose new members, or show cases or specimens are requested to notify the Honorary Secretary at once. The annual dinner will take place at the Bull Hotel, at 6.30 p.m.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

SUMMER SESSION, 1913.

Sir DONALD MACALISTER, K.C.B., President, in the Chair.

(Continued from p. 518.)

PUBLIC HEALTH COMMITTEE.

A REPORT from the Public Health Committee was presented by the Chairman, Sir JOHN W. MOORE, and approved. One of the matters dealt with in the report had reference to Section 18, subsection 2, of the Local Government Act, 1888, which made it essential for any person appointed after January 1st, 1892, to be medical officer of health to a county district or combination of districts containing a population of 50,000 or more inhabitants to be registered as the holder of a diploma in public health. It appeared that certain medical officers of health of such districts had failed to register their diplomas, but, in consequence of representations made by the Registrar, seven out of fourteen medical officers of health who had not previously registered their diplomas in public health had done so.

STUDENTS REGISTRATION COMMITTEE.

The report of this committee, presented by the Chairman, Dr. NORMAN MOORE, contained particulars with regard to certain exceptional cases and recommended that the City of London School, Giggleswick School, and the West Bromwich Municipal Secondary School, should be added to the list of institutions approved by the Council. The report was adopted.

BRITISH PHARMACOPOEIA.

The report of the Pharmacopoeia Committee was adopted. It stated that the annual average sale of the *British Pharmacopoeia*, 1898, was maintained, and that up to the present time 45,029 copies of the *Pharmacopoeia* and 4,522 of the *Indian and Colonial Addendum* had been sold. A further impression of the *Pharmacopoeia* had been printed and had been placed for distribution in the hands of Messrs. Constable and Co., who had been appointed publishers to the Council. Six sections of the draft text of the new edition of the *Pharmacopoeia* had been prepared by the editors, and were undergoing revision by the Committee with the help of several committees of reference, and the greater part of the work was ready to go to press.

The Committee recommended that in response to an invitation received through the Privy Council Office the President should be authorized to appoint a delegate to represent the Council at the conference summoned by the Belgian Government to discuss the proposed establish-

ment of an international bureau of information relating to pharmacopoeial unification.

RESULTS OF EXAMINATIONS.

The Examination Committee presented a report which was received and entered on the minutes. It embodied the accompanying table, showing the results of professional medical examinations during 1912.

In the subject of Operative Surgery :

- 5 Examining Boards give the passes and rejections.
- 5 Examining Boards state that it is included in Surgery.
- 12 Examining Boards do not allude to it.

In the subject of Ophthalmic Surgery or Ophthalmology :

- 6 Examining Boards give the passes and rejections.
- 6 Examining Boards state that it is included in Surgery.
- 9 Examining Boards do not allude to it, while the University of Oxford grants a special diploma in Ophthalmology.

In the subject of Mental Diseases :

- 14 Examining Boards give the passes and rejections.
- 2 Examining Boards say it is included in Medicine.
- 1 Examining Board says it has no special examination in it.
- 5 Examining Boards do not allude to it.

The Committee also presented a report on the returns as to examinations for the Medical Department for the Royal Navy, Royal Army Medical Corps, and the Indian Medical Service. (See SUPPLEMENT, May 31st, p. 491.)

PENAL CASES.

The Effect of a Divorce Court Decree.

The Council was occupied during a part of its sittings on May 28th and 29th in the consideration of the case of Dr. Arthur Richard Hopper, against whom it was alleged that he had abused his position as a medical man by committing adultery with a Mrs. Waite, whom he was attending professionally. It appeared that the events upon which the charge was founded took place in 1901-2, and that when an action brought by Mr. Waite was heard last year in the Divorce Court Mrs. Waite did not give evidence and was not in court, but Dr. Hopper went into the box and denied adultery. The jury found that adultery had been committed, and a decree dated March 7th was made absolute on September 18th, 1912. Mr. HARPER, Solicitor to the Council, said that Dr. Hopper had put in a letter in which he again denied that he ever committed adultery, but Mr. Harper submitted that the Council had to start from the point that a verdict had been given by a special jury of the High Court, and it was not competent for the Council to go behind that. All Dr. Hopper could do was to bring before the Council such circumstances in extenuation of his conduct as might reduce the gravity of the offence, and enable him to avoid being struck off the roll.

Mr. HARPER read the summing-up in the divorce proceedings, which he put in, and also the decree nisi, decree absolute, and the copy of the *Times* containing a report of the trial.

* At these Examinations Medicine, Surgery, and Midwifery must be passed at one time.

Mr. TOBIN, on behalf of Dr. Hopper, submitted that it was an erroneous view of the law to start with that the mere fact that a jury had found a verdict was conclusive upon the Council. It was no proof that Dr. Hopper was guilty of the charge made against him that a jury had found him guilty of adultery. He submitted that an erroneous verdict in this case was brought about because Mrs. Waite, for reasons of her own, was absent from the Divorce Court at the time the case was tried. She was now present to-day, and he should ask the Council to hear from her the reasons why she did so. Replying to the LEGAL ASSESSOR, he admitted the Council could take into account the verdict of the jury in judging the circumstances of the case, but it was not binding upon it. As he understood the law a verdict when proved simply showed that such and such a verdict had been found in the case. If the Council ruled that he was precluded from laying evidence before it to show that that verdict was erroneous it might be committing a terrible wrong so far as his client was concerned.

When the Council resumed the consideration of the case on May 29th, Mr. HARPER asked that the Council should give a definite ruling on the question whether the decree nisi was conclusive evidence of the fact of adultery having occurred between Dr. Hopper and Mrs. Waite.

Mr. TOBIN said that the decree nisi was evidence only of the fact that the jury had found adultery proved. If the Council were to hold that that verdict was binding on it and that it was thereby precluded altogether from judging of the facts, it would not be doing justice. Such a procedure, to say that a man might be struck off the *Register* without any inquiry by the Council as to whether the verdict was right or not, would lead in some cases to a great miscarriage of justice. No evidence had been laid before the Council proving that there had been misconduct.

Mr. HARPER reminded the Council that it was not a court of law, armed with the power of putting witnesses on oath. The contention of Mr. Tobin was that, according to the rules of evidence as laid down by the courts, the Council had to receive fresh evidence of the fact of adultery, and ought not to take notice of the finding of the jury. He submitted that that was not a right conclusion. Dr. Hopper now denied adultery, but he had taken no steps to have the decree pronounced against him revised. Mr. Harper submitted it would be unwise for the Council not to accept the decrees which had been proved as conclusive evidence of the adultery.

Mr. TOBIN, in answer, submitted that he had a right to go into the true merits of the case. He contended that the Council, being the judges, had to ascertain the facts, and the decree nisi was only a factor in ascertaining the true facts; he submitted that the Council was bound in law to inquire into the case and come to an honest conclusion.

Strangers and parties were directed to withdraw. On readmission the PRESIDENT, addressing Mr. Tobin, said: With regard to the points raised by you, I have to inform you that the verdict and decree of the Divorce Court will be regarded as evidence in this inquiry of the facts involved in the verdict then delivered, but the Council will hear you in answer to the charge as formulated against Dr. Hopper and any evidence you may wish to submit to the Council.

Dr. HOPPER was called. He said that it was wholly untrue that any impropriety had taken place between himself and Mrs. Waite on any occasion.

Mrs. WAITE was called, and, in reply to Mr. TOBIN, denied that she had ever misconducted herself with Dr. Hopper.

Cross-examined by Mr. HARPER: She was in an out-of-the-way place in Herefordshire at the time of the trial, and only heard of it the night before it came on for hearing. She took no steps to have the decision reviewed, as she had lived a miserable life with her husband. Since the trial she never communicated with Dr. Hopper till May 21st this year.

In answer to the LEGAL ASSESSOR, she said she had had a child and registered it as her own and husband's child. Her husband had no knowledge of it until she told him some time before the divorce proceedings. He left her and she commenced proceedings for restitution of con-

jugal rights, to which he replied by instituting proceedings for a divorce, as he alleged the child was the result of adulterous intercourse with Dr. Hopper.

Strangers and parties were directed to withdraw. On readmission,

The PRESIDENT announced the judgement of the Council as follows:

Dr. Hopper, I have to inform you that the facts alleged against you in the Notice of Inquiry have not been proved to the satisfaction of the Council, and the complaint is accordingly dismissed.

DENTAL DISCIPLINARY CASE.

A report from the Dental Committee on complaints received against Joseph John Macaulay and Francis Clement Chandler, registered as in practice before July 22nd, 1878, was presented on May 30th. The Dental Committee reported that a company called Cole and Co. (Ireland), Ltd., was registered on July 29th, 1911, with a nominal capital of £2,000 in £1 shares, of which 1,802 had been issued—namely, 1,800 to Thomas Loftus Cole, who is not a registered dentist, and one each to J. J. Macaulay and F. C. Chandler. The report stated that the principal objects of the company shewn in its memorandum were to acquire the various businesses carried on by Thomas Loftus Cole under the style or firm of Cole and Co. in Ireland, and to carry on the business of surgeon dentists, dentists' manufacturers of and dealers in artificial teeth and apparatus, preparations and appliances of all kinds for preserving or improving teeth or for providing artificial substitutes therefor, and any other business incidental thereto. From the annual returns registered February 11th, 1913, it appeared that each of the three shareholders was also a director. During the trial at the Cork assizes in March, 1913, of an action for negligence brought against the company, one John O'Dwyer gave evidence that he was employed by the firm, and performed dental operations in that capacity. The company had advertised extensively in the Irish press as surgeon dentists. Mr. J. J. Macaulay had written in answer to the notice of inquiry under date May 6th, 1913, stating that he had no alternative but to sever his connexion with the company, and that he had done so. Mr. F. C. Chandler had written that the notice of inquiry was the first intimation to him that he was a director, and that he would leave the employ of the company. No evidence was produced before the Committee by or on behalf of either practitioner in verification of these statements.

Mr. R. W. TURNER, counsel, who appeared for the British Dental Association, said that as the two practitioners were described as directors the company was rendered immune from prosecution for using the title of surgeon-dentists. As the company could not be penalized, the practitioners were charged with entering into contracts contrary to law, and covering unqualified men; he submitted that this was proved by the report of the Committee.

The matter having been considered by the Council *in camera*, the PRESIDENT announced the decision of the Council as follows:

Mr. Turner, I have to announce to you and to the public that, on the facts found in the report of the Dental Committee, it has been proved that Joseph John Macaulay and Francis Clement Chandler have been guilty of infamous or disgraceful conduct in a professional respect, and that the Registrar has been directed to erase from the *Dentists Register* the names of Joseph John Macaulay and Francis Clement Chandler.

VOTE OF THANKS.

On the motion of Dr. NERMAN MOORE a hearty vote of thanks was accorded to the President for his able services in the chair during the session, and the proceedings terminated.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on May 22nd, with Sir FRANCIS H. CHAMPNEYS in the chair.

Proposed Amendment of Rules.

A letter was considered from the Clerk of the Bedfordshire County Council, suggesting that the Rules should be amended so as to entail an obligation on the midwife to advise medical assistance in any case in which the

patient's temperature rises to above 100° F. in the morning on two successive days.

The Board resolved to reply that its suggestion would be noted for consideration at the next revision of the Rules.

Uncertified Persons.

A letter was considered from the medical officer of health for the County of Durham asking the opinion of the Board as to whether an uncertified person attending a woman in her confinement in company with a registered medical practitioner, and afterwards alone attending the mother for ten days without supervision from the medical practitioner, was guilty of an offence under Section 1 (2) of the Midwives Act, 1902. The Board resolved to reply that in the circumstances described the uncertified woman appeared to have acted as a monthly nurse, and not as a midwife.

Midwife and Pupil.

A letter was considered from the Clerk of the Hants County Council calling the attention of the Board to the system adopted by a midwife approved by the Board for training pupils in sending a pupil to act as her substitute in nursing a patient after her confinement.

The Board directed that the Clerk of the Hants County Council be informed that the Board had carefully considered the facts as stated in his letter, but did not think they proved that the midwife did not exercise adequate supervision, nor that the pupil was acting as an uncertified midwife.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty: Surgeon-General HOWARD TODD, C.B., K.H.S., has been placed on the retired list at his own request, June 5th; Staff Surgeon GEORGE E. MACLEOD to the *Ermouth* on recommissioning, July 1st; Surgeon GEORGE A. S. HAMILTON to the *Lancaster* on completing, July 7th; Surgeon H. M. WHELAN to the *Hearty*, June 6th; Surgeon J. T. D. S. HIGGINS to the *Triton*, June 6th.

ROYAL NAVAL VOLUNTEER RESERVE.

ROBERT H. H. JOLLY, M.B., has been appointed Surgeon (unattached), June 4th.

ARMY MEDICAL SERVICE.

COLONEL R. J. GEDDES, D.S.O., appointed Assistant Director of Medical Services, South-Western Coast Defences.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel THOMAS E. NODING is placed on retired pay, May 25th.

Major CHARLES DALTON to be Lieutenant-Colonel, vice J. J. C. Donnet, retired May 7th.

Major W. R. P. GOODWIN has been appointed to the command of the Station Hospital, Cawnpore.

Major H. O. B. BROWNE-MASON has been appointed to officiate as Deputy Assistant Director of Medical Services, Poona Division.

Major W. A. WARD has joined the London District for duty.

Major OLIVER L. ROBINSON to be Lieutenant-Colonel, vice T. E. Noding, retired, May 25th.

Captain ERNEST G. FRENCH, M.D., to be Major, May 28th.

Captain A. C. A. AMY has been granted leave for seven months and eighteen days on private affairs.

Captain A. HENDRY has been granted six months' leave out of India.

Captain T. McM. PHILLIPS has been transferred to the Station Hospital, Cawnpore.

Lieutenant E. G. S. CANE has been appointed to the charge of the Brigade Laboratory, Colaba, with effect from May 1st.

SPECIAL RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS.

The following Lieutenants to be Captains: WILLIAM H. L. MCCARTHY, M.D., May 17th; JOHN INESTER, M.B., May 24th; RONALD MACKINNON, M.B., June 7th.

The following have been appointed Lieutenants on probation: Cadet Lance-Corporal H. W. MALTYE, from the Liverpool University Contingent, Officers' Training Corps, May 6th; Cadet Lance-Corporal MAURICE P. INGLIS, from the Edinburgh University Contingent, Officers' Training Corps, May 12th; Cadet ALLAN D. FRASER, from the Glasgow University Contingent, Officers' Training Corps, May 14th; BASIL W. BROWN, M.B., May 17th.

INDIAN MEDICAL SERVICE.

SURGEON-GENERAL SIR CHARLES F. LUKES, K.C.S.I., M.D., has been appointed Honorary Surgeon to the King, vice G. Bidio, C.I.E., M.B. (deceased), February 20th; Surgeon-General ALEXANDER M. CROFTS, C.I.E., has been appointed Honorary Surgeon to the King, vice Sir C. COLVIN-SMITH, K.C.B., M.B. (deceased), March 2nd; Major T. O. HOLDING LEICESTER, M.D., M.R.C.P., F.R.C.S., has been appointed to officiate as Professor of Midwifery and Gynaecology at the Medical College, Calcutta, and Surgeon to the Eden Hospital for Women, during the absence on leave of Lieutenant-Colonel C. R. M. GREEN, M.D., F.R.C.S., I.M.S.

Major S. HOWE has been appointed to officiate as Residency Surgeon, Bushire, with effect from April 15th, 1913, during the absence on leave of Captain C. B. McConaghy,

Captain C. B. McCONAGHY has been granted combined leave for two years, with effect from April 2nd, 1913.

Captain A. J. LEE, I.M.S., is appointed a Specialist in Electrical Science with effect from April 30th, 1913.

Captain T. C. BOYD, I.M.S., is appointed to the substantive medical charge of the 42nd Deoli Regiment.

Lieutenant R. W. G. HINGSTON has been placed temporarily on deputation with No. 15 (Survey) Party, with effect from April 11th, 1913.

Lieutenant T. A. HUGHES, I.M.S., is appointed a Specialist in Prevention of Disease, with effect from May 5th, 1913.

INDIAN SUBORDINATE MEDICAL DEPARTMENT.

Senior Assistant Surgeon and Honorary Captain FREDERICK F. BEDELL has retired, February 3rd.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Third Home Counties Field Ambulance.—Lieutenant HECTOR G. G. MACENZIE, M.B., to be Captain, April 20th.

Highland Mounted Brigade Field Ambulance.—GEORGE G. MIDDLETON, M.B., to be Lieutenant, April 1st.

South-Eastern Mounted Brigade Field Ambulance.—Lieutenant FREDERICK B. TREVES, M.B., to be Captain, December 8th, 1911.

First East Anglian Field Ambulance.—Captain ERNEST V. GOSTLING to be Major, March 15th.

Second East Anglian Field Ambulance.—THOMAS A. FLYNN to be Lieutenant, May 5th.

Third Home Counties Field Ambulance.—ALEXANDER H. BREWER to be Lieutenant, May 2nd.

First East Lancashire Field Ambulance.—JOHN C. BRAMWELL (late Cadet Staff Sergeant, Cambridge University Contingent, Senior Division, Officers' Training Corps), to be Quartermaster with the honorary rank of Lieutenant, April 10th.

First Wessex Field Ambulance.—FRANK A. ROPER, M.B., to be Lieutenant, April 22nd.

First Southern General Hospital.—Captain WALTER J. CLAREB resigns his commission, June 4th.

Attached to Units other than Medical Units.—Lieutenant CECIL JOHNSON, M.B., to be Captain, December 4th, 1912.

For Attachment to Units other than Medical Units.—JAMES HENRY CRANE, M.D., to be Lieutenant, January 22nd. ERNEST S. STOKK, M.D., to be Lieutenant, April 23rd. Major JAMES S. WARRACK, M.D., from the First Home Counties Field Ambulance, to be Major, June 4th.

COLONIAL MEDICAL SERVICES.

The following changes have been notified by the Colonial Office:

WEST AFRICAN MEDICAL STAFF.

New Appointments.—The following gentlemen have been selected for appointment to the Staff: T. A. Dewse, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Cantab., Gold Coast; J. M. Benson, M.B., Ch.B. Edin., Northern Nigeria; E. H. Mayhew, M.D., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Sierra Leone; E. M. Condy, M.B., B.Ch., B.A.O. Dubl., D.P.H. Belfast, Gold Coast; F. M. P. Rice, M.R.C.S. Eng., L.R.C.P. Lond., Southern Nigeria; F. E. Whitehead, M.R.C.S. Eng., L.R.C.P. Lond., Sierra Leone; G. G. P. Beckett, M.D., B.Ch., B.A.O., L.M. Dubl., Gold Coast; W. A. Young, M.B., Ch.B. St. Andrews, Sierra Leone.

Retirements.—E. E. Maples, M.D., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., Medical Officer, Southern Nigeria, retires on pension; C. W. S. Roggs, L.S.A. Lond., Medical Officer, Gold Coast; H. Fleming, M.B., Ch.B., B.A.O. Dubl., Medical Officer, Sierra Leone.

Resignation.—G. M. Gray, M.D. Glasg., F.R.C.S. Eng., Medical Officer, Southern Nigeria.

OTHER COLONIES AND PROTECTORATES.

W. M. Chambers, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glas., has been selected for appointment as a Medical Officer in the Federated Malay States. L. H. Taylor, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been selected for appointment as a Medical Officer in the Federated Malay States. V. T. W. Eagles, L.R.C.P. and S. Edin., L.R.F.P. and S. Glas., has been selected for appointment as a Medical Officer in the Federated Malay States. Miss E. M. Layman, M.B., B.S. Lond., has been selected for appointment as a Lady Medical Officer in the Federated Malay States. Miss L. S. McLean, M.B., Ch.B. St. Andrews, has been selected for appointment as a Lady Medical Officer in the Federated Malay States. V. Blacher Kyle, M.D., B.Ch., B.A.O. Dubl., L.M. Rotmda, has been selected for appointment as a Medical Officer in the Straits Settlements. G. S. Richardson, L.M.S.S.A. Lond., has been selected for appointment as a supernumerary Medical Officer in Jamaica. T. R. Boyd, M.B., Ch.B. Edin., has been selected for appointment as a Medical Officer in Fiji. C. R. Maitland Pattison, L.R.C.P. and S. Irel., L.M. Irel., has been selected for appointment as an Assistant Medical Officer at the Lepor Asylum, Makogai Island, Fiji.

Vital Statistics.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

[SPECIALLY REPORTED FOR THE "BRITISH MEDICAL JOURNAL."]

THE Registrar-General has just issued his return relating to the births and deaths in the first quarter of the year, and to the marriages during the three months ending December last. The marriage-rate during that period was equal to 17.5 per 1,000, or 0.8 per 1,000 more than the mean rate in the ten preceding fourth quarters.

The 216,330 births registered in England and Wales during the first three months of the year were equal to an annual rate of 23.8 per 1,000 of the population, estimated at 36,919,339 persons in the middle of the year; this rate is 3.1 per 1,000 below the mean rate in the ten preceding first quarters, and is the lowest rate recorded in the corresponding period of any year since civil registration was established. The birth-rates in the several counties ranged from 16.2 in Cardiganshire, 17.2 in Sussex, 17.8 in Dorsetshire, and 17.9 in Somersetshire and in Carnarvonshire to 27.4 in Carmarthenshire, 27.5 in Staffordshire, 28.3 in Monmouthshire, 29.4 in Glamorganshire, and 30.0 in Durham. In ninety-six of the largest towns the birth-rate averaged 25.4 per 1,000; in London it was 25.7 per 1,000, and in the other towns it ranged from 13.1 in Hastings, 14.3 in Southport, 15.2 in Bournemouth, 15.3 in Bath,

and 15.4 in Hornsey to 31.7 in St. Helens and in Stockton-on-Tees, 32.0 in West Ham, 32.1 in Middlesbrough, 32.5 in Rhondda, and 32.9 in Warrington.

The excesses of births over deaths during the quarter was 69,774, against 85,284, 80,455, and 77,947 respectively in the corresponding quarters of the three preceding years. From a return issued by the Board of Trade, it appears that the passenger movement between the United Kingdom and places outside Europe resulted in a net balance outward of 66,620 persons of British nationality and of 19,901 aliens. Between the United Kingdom and the Continent of Europe there was a balance outward of 2,361 British and a balance inward of 26,114 aliens; thus the total passenger movement resulted in a net balance outward of 62,768 persons.

The deaths registered last quarter in England and Wales numbered 146,556, and were equal to an annual rate of 16.1 per 1,000, or 1.1 per 1,000 less than the mean rate in the corresponding period of the ten preceding years. The lowest county death-rates last quarter were 12.3 in Middlesex, 13.3 in Buckinghamshire and in Dorsetshire, 13.4 in Surrey, 13.6 in Essex, 13.7 in Hampshire, and 13.8 in Sussex; the highest rates were 17.6 in Cumberland and in Cardiganshire, 17.7 in Pembrokehire, 17.9 in Anglesey, 18.0 in Northumberland, 18.3 in Lancashire, and 18.7 in Durham and in Merionethshire. In ninety-six of the largest towns the rate averaged 16.3 per 1,000; in London the rate was 17.5 per 1,000, and in the other towns it ranged from 10.9 in Hornsey, 11.0 in Ilford, 11.2 in Ealing, 11.3 in Gillingham, 11.4 in Enfield, and 11.6 in Eastbourne to 20.5 in Liverpool, 20.7 in Bootle and in South Shields, 21.7 in Preston, 22.1 in West Bromwich, 23.8 in Wigan, 24.7 in Stockton-on-Tees, and 25.7 in St. Helens.

The 146,556 deaths from all causes last quarter included 4,865 that were attributed to measles, 1,693 to whooping-cough, 1,551 to diarrhoea and enteritis (among children under 2 years of age), 1,196 to diphtheria, 542 to scarlet fever, 320 to enteric fever, and 5 to small-pox. The mortality from measles was 43 per cent. above the average, that from enteric fever, scarlet fever, and whooping-cough was little more than half the average, and that from diphtheria about two-thirds of the average.

The rate of infant mortality, measured by the proportion of deaths among children under 1 year of age to registered births was equal to 122 per 1,000, or 4 per 1,000 less than the average in the ten preceding first quarters. Among the several counties the rates of infant mortality last quarter ranged from 79 in Hertfordshire, 81 in Herefordshire, 84 in Montgomeryshire and in Flintshire, 88 in Essex, and 89 in Hampshire to 146 in Staffordshire and in Cumberland, 149 in Monmouthshire, 155 in Durham, 157 in Pembrokehire, and 158 in Westmorland. In ninety-six of the largest towns the rate averaged 125 per 1,000; in London it was 116, while among the other towns it ranged from 65 in Hornsey, 68 in Gillingham, 69 in Eastbourne, 70 in Devonport, and 73 in East Ham to 183 in Rotherham and in Carlisle, 185 in St. Helens, 187 in Stoke-on-Trent, 202 in Preston, and 230 in Wigan.

The deaths among persons aged 1 to 65 years were at the annual rate of 8.6 per 1,000 of the population estimated to be living at this group of ages; and among persons aged 65 years and upwards the mortality was at the rate of 109.9 per 1,000 of the estimated population at those ages.

The mean temperature of the air last quarter was above the normal, and the rainfall during the quarter was everywhere in excess both as regards frequency and amount. The duration of bright sunshine was below the average in all parts of the country, the deficiency amounting in many districts to at least half an hour a day.

EPIDEMIC MORTALITY IN LONDON.

[SPECIALLY REPORTED FOR THE "BRITISH MEDICAL JOURNAL."]

THE accompanying diagram shows the prevalence of the principal epidemic diseases during the first quarter of the year. The fluctuations of each disease, and its relative fatality compared with the average in the corresponding periods of recent years, can thus be readily seen, except in the case of diarrhoea and enteritis among children under 2 years of age, for which the average mortality is not available.

Enteric Fever.—The fatal cases of enteric fever, which had been 28, 23, and 30 in the three preceding quarters, were 29 last quarter, and were 8 below the corrected average in the corresponding period of the five preceding years. This disease showed the highest proportional mortality in St. Marylebone, St. Pancras, Islington, Bethnal Green, and Lewisham. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 32, 49, and 37 at the end of the three preceding quarters, had risen again to 42 at the end of last quarter; 86 new cases were admitted during the quarter, against 93, 93, and 85 in the three preceding quarters.

Small-pox.—No death from small-pox was registered last quarter, and no case of this disease was under treatment in the Metropolitan Asylums Hospitals during the quarter.

Measles.—The deaths from measles, which had been 433, 376, and 783 in the three preceding quarters, numbered 845 last quarter, and were 138 in excess of the corrected average. This disease was proportionally most fatal in Kensington, Hammersmith, Finsbury, Shore-ditch, Bethnal Green, and Battersea.

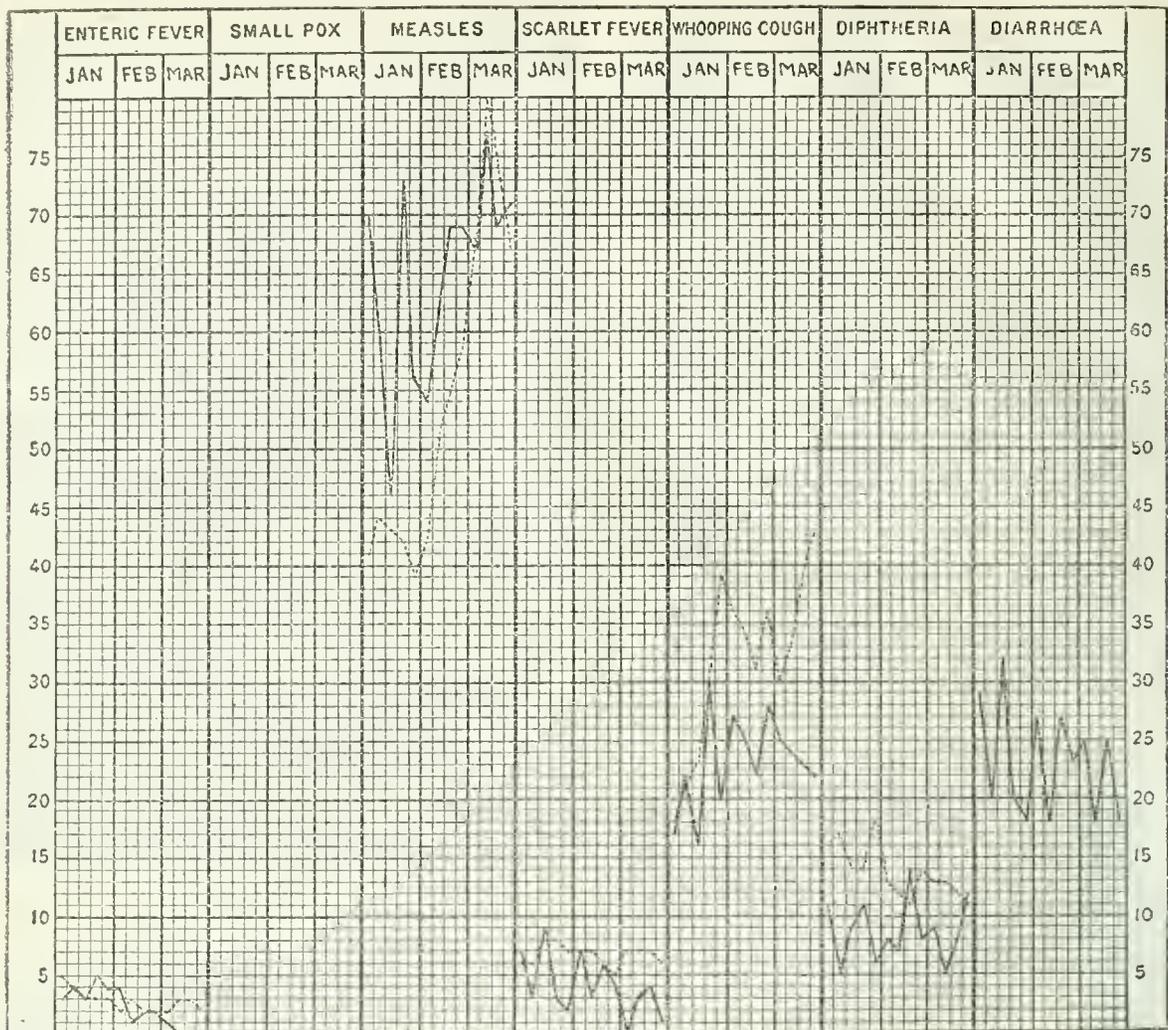

Scarlet Fever.—The fatal cases of scarlet fever, which had been 42, 44, and 50 in the three preceding quarters, were 52 last quarter, and were 35 below the corrected average number. Among the several boroughs this disease was most fatal in St. Marylebone, Islington, Hackney, Poplar, Lambeth, and Wandsworth. The Metropolitan Asylums Hospitals contained 1,436 scarlet fever patients at the end of last quarter, against 1,380, 1,845, and 2,068 at the end of the three preceding quarters; 2,365 new cases were admitted during the quarter, against 2,039, 2,856, and 3,542 in the three preceding quarters.

Whooping-cough.—The deaths from whooping-cough, which had been 354, 182, and 152 in the three preceding quarters, were 300 last quarter, and were 113 below the corrected average number in the corresponding periods of the five preceding years. The highest death-rates from this disease last quarter were recorded in Paddington, Hammersmith, Kensington, Brompton, Camberwell, Deptford, and Greenwich.

Diphtheria.—The fatal cases of diphtheria, which had been 99, 108, and 113 in the three preceding quarters, were 113 last quarter, and were 65 below the corrected average number. The greatest proportional mortality from this disease last quarter was recorded in Brompton, Deptford, Greenwich, and Lewisham. The number of diphtheria patients in the Metropolitan Asylums Hospitals, which had been 877, 941, and 959 at the end of the three preceding quarters, had declined again to 901 at the end of last quarter; 1,568 new cases were admitted during the quarter, against 1,440, 1,513, and 1,525 in the three preceding quarters.

Diarrhoea.—The 298 deaths under this heading are those attributed to diarrhoea and enteritis among children under 2 years of age; measured in proportion to the births registered in the several

DEATHS FROM EPIDEMIC DISEASES IN LONDON DURING THE FIRST QUARTER OF 1913.

NOTE.—The black lines show the recorded number of deaths from each disease during each week of the quarter. The dotted lines show the average number of deaths in the corresponding weeks of the five preceding years, 1908-12. Under the heading "Diarrhoea" are given the deaths from diarrhoea and enteritis among children under 2 years of age; the corrected average number of these deaths is not available.

boroughs during the quarter the mortality from this cause was greatest in Hammersmith, the City of Westminster, Islington, Shore-ditch, Bethnal Green, and Stepney.

In conclusion, it may be stated that the aggregate mortality last quarter from these epidemic diseases (excluding diarrhoea) was 5.8 per cent. below the average.

HEALTH OF ENGLISH TOWNS.

In ninety-six of the largest English towns 8,845 births and 4,129 deaths were registered during the week ending Saturday, June 7th. The annual rate of mortality in these towns, which had been 12.8, 13.4, and 13.5 per 1,000 in the three preceding weeks, fell to 12.1 per 1,000 in the week under notice. In London last week the death-rate was equal to 11.6, against 12.0, 13.4, and 12.9 per 1,000 in the three preceding weeks. Among the ninety-five other large towns the death-rates ranged from 4.3 in Hastings, 4.4 in Walthamstow, 5.0 in Swindon, 5.4 in Hornsey, 5.9 in East Ham, and 6.4 in Tottenham to 17.4 in Dewsbury, 17.5 in Smethwick, 18.2 in Dudley, 19.3 in South Shields, 19.5 in Walsall, and 19.9 in Stockton-on-Tees. Measles caused a death-rate of 1.6 in Wolverhampton and in Salford, 1.8 in Bury, 2.0 in Dudley, 4.0 in Aberdeen, and 5.0 in Walsall; scarlet fever of 1.8 in Newport (Mon.); and whooping-cough of 1.2 in Newcastle-on-Tyne and 1.6 in Brighton. The mortality from diphtheria and enteric fever showed no marked excess in any of the large towns, and no fatal case of small pox was registered during the week. The causes of 28, or 0.7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; of this number 6 were registered in Birmingham, 3 in Liverpool, 3 in St. Helens, and 2 in Sunderland. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1,411, 1,441, and 1,430 at the end of the three preceding weeks, were 1,427 on Saturday last; 202 new cases were admitted during the week, against 171, 193, and 177 in the three preceding weeks.

HEALTH OF SCOTTISH TOWNS.

In the sixteen largest Scottish towns 1,187 births and 687 deaths were registered during the week ending Saturday, June 7th. The annual rate of mortality in these towns, which had been 16.4, 16.3, and 16.7 per 1,000 in the three preceding weeks, declined to 15.9 in the week under notice, but was 3.8 per 1,000 above the rate recorded in the ninety-six large English towns. Among the several towns the death-rates ranged from 5.4 in Hamilton, 6.1 in Clydebank and in Ayr, and 9.7 in

Leith to 18.9 in Dundee, 19.5 in Kilmarnock, and 25.5 in Greenock. The mortality from the principal infective diseases averaged 2.2 per 1,000, and was highest in Dundee and Aberdeen. The 313 deaths from all causes registered in Glasgow included 19 from whooping-cough, 18 from measles, 5 from infantile diarrhoeal diseases, 4 from scarlet fever, 2 from diphtheria, and 1 from enteric fever. Eleven deaths from measles and 3 from whooping-cough were recorded in Aberdeen; 5 from measles and 3 from diphtheria in Dundee; and 5 from whooping-cough and 4 from infantile diarrhoea and enteritis in Edinburgh.

HEALTH OF IRISH TOWNS.

During the week ending Saturday, May 31st, 699 births and 392 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 601 births and 442 deaths in the preceding period. These deaths represent a mortality of 16.5 per 1,000 of the aggregate population in the districts in question, as against 19.2 per 1,000 in the previous period. The mortality in these Irish areas was, therefore, 3.1 per 1,000 higher than the corresponding rate in the ninety-six English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 30.4 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 16.0, as against an average of 18.9 for the previous four weeks, in Dublin City 16.1 (as against 19.8), in Belfast 16.7 (as against 17.3), in Cork 17.0 (as against 22.3), in Londonderry 11.4 (as against 10.5), in Limerick 20.3 (as against 13.0), and in Waterford 15.2 (as against 19.9). The zymotic death-rate was 0.6, as against 1.3 in the previous week. During the week ending Saturday, June 7th, 667 births and 393 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 699 births and 392 deaths in the preceding period. These deaths represent a mortality of 17.1 per 1,000 of the aggregate population in the districts in question, as against 16.5 per 1,000 in the previous period. The mortality in these Irish areas was, therefore, 5.0 per 1,000 higher than the corresponding rate in the ninety-six English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 29.0 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 15.9, as against an average of 17.8 for the previous four weeks, in Dublin City 16.9 (as against 18.0), in Belfast 17.1 (as against 17.3), in Cork 15.0 (as against 20.1), in Londonderry 22.9 (as against 14.9), in Limerick 16.2 (as against 16.9), and in Waterford 28.5 (as against 21.8). The zymotic death-rate was 1.3, as against 0.6 in the previous week.

Hospitals and Asylums.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

The report presented by the Executive Committee of King Edward's Hospital Fund for London at the annual meeting of its governors and general council on April 23rd was devoted mainly to a summary of the events of 1912, and of all these some account has already appeared in our columns. It brought into relief, however, a fact which is of somewhat lamentable kind if it is to be regarded as a presage of future years. Though the distribution last year was maintained at the maximum, this was thanks only to the existence of reserves. The true income for the year showed a material decrease in respect alike of legacies, donations, and subscriptions. The report made reference to the special inquiry held by the Fund in regard to the abuse of out-patient departments, the full text of which was published in the SUPPLEMENT to our issue for February 22nd, 1913. The council also received a report from the Distribution Committee relating to a controversy between it and St. George's Hospital in regard to the amount allocated to the medical school for pathological work done by the latter on behalf of the hospital. It has been suggested that if the sum paid to the school is in fact relatively large, this is due to the circumstance that as the school is small the expense involved by the maintenance of a pathological department for the joint benefit of itself and of the hospital is great in proportion to its means, and hence the hospital cannot be expected to get the services in question performed on the same terms as like institutions more happily situated. The Executive Committee of the Fund suggests that the hospital should pay the disputed amount, but should charge it against the discretionary fund and not against the general fund of the hospital, with the effect of avoiding any imputation that it is contributing towards medical education. A report of the Executive Committee recommended that a request by the hospital that the dispute between it and the Distribution Committee should be referred to an independent body should not be granted. Neither decision seems to us particularly happy. The proposed compromise would seem to involve a practical admission that the original allocation was right. As to the second point, it is not to be forgotten that an independent authority has in fact already investigated the facts of dispute, the late Lord Mayor having held an inquiry on behalf of the Hospital Sunday Fund, and found reason for holding that the allocation made by the hospital was just. But in any case it is to be hoped that in some way or other this unhappy controversy between St. George's Hospital and the King's Fund will now be brought rapidly to an end. It is most unfortunate that it should ever have occurred, for it is not inconceivable that, when taken in conjunction with the fact that two other great hospitals have given up applying to the King's Fund for assistance, it might help to raise a doubt as to whether the skill exercised by the Fund in the management of its affairs is as great as might be expected of so important a body.

ROYAL CANCER HOSPITAL, GLASGOW.

The report presented to the annual general meeting of the Glasgow Royal Cancer Hospital, when Dr. Robert Gourlay, president, was in the chair, showed that during the year 162 in-patients and 34 out-patients had been treated, while the district nurse had made 1,562 visits. The average daily number of patients in the hospital throughout the year was 34.7. The financial statement for the year ending December 31st, 1912, showed a serious deficit, notwithstanding an exceptionally large amount received from legacies during the year. In the report by Mr. Walker, director of the research department, it was stated that a considerable amount of work had been done with colloidal selenium. Claims had been made that cases of cancer had been cured by the intravenous injection of this substance, and a preparation was now upon the market. Colloidal selenium was made and used in that hospital before the claims just mentioned were published or its employment in the case of cancer had been suggested, but though it had been used both experimentally and upon patients, there did not appear to be any ground for supposing that any specific curative effect was produced upon malignant growths. On the other hand, there was reason to believe that colloidal selenium, when injected intravenously, did mitigate the effects of infection by micro-organisms. It had been found that these injections partially if not completely destroyed micro-organisms in the system of such widely different kinds as pneumococci and trypanosomes. Sir George T. Beatson, senior surgeon, in his report on the indoor department, stated that, unfortunately, no special advance in the medical treatment of cancer could be claimed for the year just passed away, but during that period the hospital had been able to furnish to a certain proportion of its cases that relief by surgical measures and by the light treatment which were at present the only real satisfactory means for the permanent cure of cancer. Dean of Guild Roxburgh, in proposing the adoption of the report and financial statement, congratulated the directors on having completed their new buildings at a cost of £26,900, and on having opened them free of debt. He also congratulated them on the change of name by the addition of the word "Royal," which showed the interest taken in the hospital by King George and also by Princess Louise, who opened it. Bailie J. W. Stewart, in seconding, referred to the decreased subscriptions, and said there had been a good deal of disturbance to the stream of

benevolence through the Insurance Act. He thought that would right itself as people came to realize that institutional treatment such as was provided in that and kindred institutions could not be had under any of the provisions of the Insurance Act.

AYR DISTRICT ASYLUM.

In his report on Ayr District Asylum for 1912, Dr. G. Douglas MacRae, the Medical Superintendent, states that in the beginning of the year the number of patients on the asylum register was 549 (294 men and 255 women). On December 31st there were 292 men and 257 women, giving a total of 549. The number of private cases was 30, one more than in the previous year. The admissions numbered 138 (71 men and 67 women). The total number of cases under treatment during the year was 687 (365 men and 322 women), or 17 below last year's number, which was the highest recorded. The men numbered 16 less than last year, but still 5 above the previous record in 1909, but the women numbered one less than last year. The number discharged was 82 (42 men and 40 women). The number of patients who died was 56 (31 men and 25 women). Hereditary predisposition to insanity was ascertained in only 22 per cent. of the cases, and alcoholic excess in 22 per cent. either as cause or symptom of the mental malady.

EDINBURGH ROYAL VICTORIA HOSPITAL.

The annual meeting of this hospital was held on February 18th, the president, Sir Alexander Christison, being in the chair. Reference was made to the opening of the new tuberculosis dispensary in the past autumn, and to the knighthood which had been conferred upon Sir Robert Philip. The dispensary had several objects in view. It was intended to create a centre where the manifold aspects of tuberculosis could be comprehensively handled; it was to be a collecting centre for patients among the poorer classes where advice and treatment on modern lines would be available; and it was to be a centre from which a practical knowledge of the great principles of prevention would pass to the homes of the people. "The breeding-grounds of tuberculosis must be raided."

WESTERN DISPENSARY, EDINBURGH.

At the annual meeting of the Western Dispensary, Riego Street, held on March 14th, Dr. John Orr presiding, it was reported that there was a regrettable decrease of 10 per cent. in the amount received from ordinary subscriptions. The Chairman commented on the alterations which had been carried out in the dispensary, which constituted a great improvement. He regretted the resignation of Dr. Murdoch Brown, who had given eight years' service as one of the medical staff. The appointment of Dr. Robert Cumming as one of the physicians was confirmed.

BIRMINGHAM GENERAL DISPENSARY.

The number of patients admitted during 1912 by tickets was 62,520, showing a decrease of 448; but 4,527 dental patients were treated, showing an increase of 364. Emergency cases treated without tickets numbered 1,791, bringing up the entire number of patients to 68,838. The special expenditure of the year, amounting to £450, included an outlay of £400 on the furnishing and equipment of the tuberculosis department in Great Charles Street. The receipts totalled £12,556. The tuberculosis department was opened on the first Monday in November, 1912, and from this date up to February, 1913, the total number of new patients examined was 420. The subsequent attendances of those patients who were instructed to continue treatment averaged 64 a day during the past month. Those who were prevented by their occupations from attending during the day were seen from 5.30 to 9 p.m. on Monday and Thursday.

DUBLIN HOSPITAL SUNDAY FUND.

The thirty-ninth annual report of the Dublin Hospital Sunday Fund states that the amount contributed in 1912 was £3,448 18s. 1d., being a decrease of £105 8s. 8d. as compared with 1911. The expenses of the year amounted to 7.13 per cent. of the total sum collected. The sum of £3,180 had been divided among the following sixteen institutions: Sir Patrick Dun's, Royal City of Dublin, Steevens's, Meath, Mercer, Drumcondra, Coombe, Rotunda, Royal Victoria Eye and Ear, Stillorgan Convalescent Home, Cork Street, Adelaide, Monkstown, Orthopaedic, National Children's, and the Rest for the Dying. A speaker said that he hoped that the public would continue to support the fund, notwithstanding the Insurance Act, which he thought would not in any way benefit the hospitals.

WEST END HOSPITAL FOR NERVOUS DISEASES, LONDON.

The report submitted at the annual meeting of this hospital in March stated that, though subscriptions had fallen off, the deficit had been balanced by an increase in the receipts from patients' payments and legacies. The average weekly cost, both of in-patients and out-patients, had been reduced. The in-patients treated numbered 319, and there was a long waiting list, amounting, in the case of women, to four or five for each bed. The number of out-patients had risen from 2,528 in 1911 to 2,774 in the recently completed year.

THE CHILDREN'S HOSPITAL, BIRMINGHAM.

THE annual report for 1912 of the Birmingham and Midland Hospital for Sick Children showed that the in-patients numbered 845, against 1,023 in 1911; out-patients 12,295, against 13,542; and casualties 686, against 1,247; giving a total of 13,826 compared with 15,612. The average detention-rate of in-patients was 24.7 days in 1912, and 20.43 days in 1911. The contract for the erection of the new hospital had been made with Messrs. Barnsley and Sons, and the building operations were now in progress. A sum of about £13,000 was still required to complete the new hospital. The accounts for the year showed a deficiency of £88, but the income was larger by £315. The After-care Committee reported that 83 cases had been sent to them, which meant no less than 300 visits paid.

BRISTOL GENERAL HOSPITAL.

THE report presented to the annual meeting of the subscribers to the General Hospital showed that during the past year 2,340 in-patients, 15,199 casualties and emergencies, 13,493 out-patients, and 4,638 dental cases had been treated, an increase of 53 in-patients, and a decrease of 2,249 out-patients. This latter the committee thought satisfactory, and could not put it down to the Insurance Act, as it was not then working. There was a slight falling off of workmen's subscriptions, only £16, but on the whole the income was about the same. Expenditure showed an increase of £645, of which the Insurance Act accounted for £58. The extension of the hospital was progressing, and would cost when finished £36,676.

BRISTOL CHILDREN'S HOSPITAL.

THE Lord Mayor presided at the annual meeting of the Children's Hospital on March 5th. The report showed that during the year 1,450 women and 3,487 children were treated at the institution as out-patients, and 743 children and 73 women had been admitted as in-patients. Subscriptions from almost every source showed a falling off, which the honorary treasurer attributed to the Insurance Act. Several important changes had been made in the fabric of the hospital during the year, the operating theatre had been remodelled, electric light had been installed, and an efficient warming system had recently been completed. On the whole the financial state of the hospital was not much worse than a year ago, for the debt to the treasurer had only been increased by £20.

Vacancies and Appointments.

VACANCIES.

RECENT PUBLICATIONS.

First Aid to the Injured and Sick. By F. J. Warwick, B.A., M.B.Cantab., and A. C. Tunstall, M.D., C.M.Edin. Eighth edition. 1913. Bristol: John Wright and Sons. (Medium 16mo. pp. 260. Price 1s. net.)

A fresh and revised edition of a well-illustrated book containing a great amount of precise information on all aspects of its subject. A book only suited and intended for those prepared to study first aid very thoroughly. Despite a somewhat unattractive style of writing, necessitated by compression of matter, it has justly met with much success.

Consultations Médicales Françaises. Fasc. 37 to 51. By various authors. Paris: A. Poinat, 1912. (Double foolscap 16mo. 6d. post free.)

Further issues of a monthly publication to which we have frequently drawn attention. Each consists of a brief monograph on some subject in medicine, the authors, as a rule, being recognized teachers in French medical schools. They are usually of a very practical character and easily read in half an hour.

PUBLISHERS' ANNOUNCEMENTS.

AMONG the new books included in Mr. Murray's quarterly list are the following: A new edition of Sir Lander Brunton's *Therapeutics of the Circulation*, and volume iii of the John Howard McFadden *Researches into Induced Cell-Reproduction and Cancer*, and other papers by H. C. Ross, J. W. Cropper, H. Bayon, W. J. Atkinson Butterfield, M.A., F.I.C., Assoc. Inst. Civ. Eng., and S. R. Moolgaoker, F.R.C.S. A part of these researches has been reprinted separately as a pamphlet entitled *The Problem of the Gas Works: Pitch Industries and Cancer*, for the purposes of the special inquiry now being made into the question of cancer in the gas work industry. Another work published is *The Reduction of Domestic Flies*, by Mr. Edward Holford Ross.

An English translation by Dr. Léon Blanc and Dr. H. de Méric of Dr. Albert Robin's book, the third edition of which was reviewed in the JOURNAL last November, will be published shortly under the title "Treatment of Tuberculosis" by Messrs. J. and A. Churchill. The same publishers have nearly ready an English translation by Mr. T. H. Pope, of the University of Birmingham, of a treatise on general and industrial organic chemistry by Ettore Molinari. The text contains 500 illustrations. They will also publish a new and revised edition (sixth) of *Surgical Pathology*, by Sir Anthony A. Bowlby, C.M.G., and Dr. F. W. Andrewes.

Mr. Henry Kimpton will shortly publish *Tuberculin in Diagnosis and Treatment*, by Francis M. Pottinger, M.D. (illustrated); *Epidemic Cerebro-Spinal Meningitis*, by Abraham Sophian, M.D. (illustrated); *The Modern Treatment of Nervous and Mental Diseases*, by British and American authors, edited by William A. White, M.D., and Smith Ely Jelliffe, M.D., in two volumes (illustrated); *Asthma and its Radical Treatment*, by James Adam, M.D.; *Handbook of Diseases of the Rectum*, by Louis J. Hirschman, M.D., second edition, revised and enlarged (illustrated).

Messrs. Smith Elder and Co. will publish on June 26th a work by Dr. W. McC. Wanklyn, formerly Medical Superintendent of the Small-pox Receiving Stations and River Ambulance Service of the Metropolitan Asylums Board, and now an Assistant Medical Officer of the London County Council, entitled *How to Diagnose Small-pox*. The work is based on an experience of small-pox extending over twenty years, and including the revision of the diagnosis of upwards of 10,000 cases.

DIARY FOR THE WEEK.

TUESDAY.

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester Square, W.C.—4 p.m., Annual Meeting and Election of Officers. 5.15 p.m., Paper:—Dr. E. J. Reeve: The Treatment of Diseases of the Skin by Intensive Iodine Administration.

THURSDAY.

SPECIAL NOTICE TO MEMBERS.

Every member is requested to preserve this "Supplement," which contains matters specially referred to Divisions, until the subjects have been discussed by the Division to which he belongs. **BY ORDER.**

Association Intelligence.

PROCEEDINGS OF COUNCIL.

A SPECIAL meeting of the Council of the British Medical Association was held on June 13th, for the discussion of a report of the Organization Committee on matters arising out of its consideration of the scheme for the reorganization of the Association drawn up by the Council of the Metropolitan Counties Branch. This scheme, which was printed in the SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL of May 10th, p. 415, is quoted in the report now referred to by the Council of the Association to the Divisions and the Annual Representative Meeting.

Present:

Dr. J. A. MACDONALD, LL.D., Taunton, Chairman of Council, in the Chair.

Sir JAMES BARR, M.D., LL.D., Liverpool, President.

Dr. W. AINSLIE HOLLIS, Hove, President-Elect.

Dr. EDWIN RAYNER, Stockport, Treasurer.

- | | |
|---|--|
| Dr. R. M. BEATON, London | Mr. C. COURTENAY LORD, Gillingham |
| Dr. M. G. BIGGS, London | Dr. J. LIVINGSTONE LOUDON, Hamilton, N.B. |
| Dr. CHARLES BUTTAR, London | Mr. ALBERT LUCAS, Birmingham |
| Dr. Wm. CLOW, Paisley | Dr. H. C. MACTIER, Wolverhampton |
| Professor HENRY CORRY, Cork | Dr. JAMES METCALFE, Bradford |
| Dr. J. SINGLETON DARLING, Lurgan | Dr. C. H. MILBURN, Hull |
| Mr. E. J. DOMVILLE, Exeter | Dr. C. G. D. MOHIER, London (Victoria, South and West Australian Branches) |
| Dr. D. E. FINLAY, Gloucester | Dr. H. FALCONER OLPHAM, Morecambe |
| Dr. B. E. FORDYCE, Cambridge | Dr. GEORGE PARKER, Bristol |
| Mr. T. W. H. GARSTANG, Altricham | Dr. E. S. REYNOLDS, Manchester |
| Dr. JOHN GORDON, Aberdeen | Dr. F. J. SMITH, London |
| Surgeon-General J. P. GREANY, I.M.S., Ealing (Indian Medical Service) | Mr. E. B. TURNER, London |
| Dr. T. D. GREENLEES, London (South African Branches) | Mr. R. J. TURRELL, Oxford |
| Dr. MAJOR GREENWOOD, London | Professor A. H. WHITE, Dublin |
| Dr. G. E. HASLIP, London | Mr. D. J. WILLIAMS, Llanelli |
| Mr. R. J. JOHNSTONE, Belfast | Mr. E. H. WILLOCK, Croydon |
| Mr. EVAN JONES, London | |
| Mr. F. CHARLES LARKIN, Liverpool | |

The report of the Organization Committee was presented by its Chairman (Mr. LARKIN), and certain general principles were first considered. After a long and animated discussion, in which most of the members of Council present took part, a resolution that paragraphs 26, 27, and 28 stand part of the report was adopted *nemine contradicente*. These paragraphs embody the principle that the Representative Body should be a deliberative assembly instead of, as at present, a body of delegates who are bound by any resolution which may have been passed by their constituencies during the three months previous to the meeting. During the course of this discussion the CHAIRMAN

directed attention to a resolution adopted by the Council at its ordinary meeting on April 23rd last, and reported in paragraph 36 of the Annual Report of Council (BRITISH MEDICAL JOURNAL, SUPPLEMENT, May 3rd), expressing the opinion that a Representative of a constituency should be able to resign his position, or in the alternative that the constituency should be able, at a special meeting called for the purpose, and by a three-fourths majority of those present and voting, to call upon a Representative to resign. The Council further recommended that any vacancy so arising should be filled by the constituency in accordance with the rules of the Division or Divisions forming the constituency, and that if a Representative were permitted to resign the constituency should not be empowered to dismiss him. It was considered that it would be inadvisable to allow a deputy to act for a constituency during such portion only of a meeting of the Representative Body as the Representative might be unable to attend.

The sections of the report dealing with the proposal to reduce the size of the Representative Body were discussed at length, and eventually the following resolution was adopted:

That the Council considers that the Representative Meeting is too large and ought to be reduced, but regards the reduction of the number of constituencies as inadvisable and more or less impracticable.

The method of taking a vote in the Representative Meeting detailed in paragraphs 12 and 13 was approved as a suitable method should the principle be accepted. A resolution was adopted recommending the Annual Representative Meeting in that case to instruct the Council to frame rules so that the votes of members representing large constituencies shall have due weight on a vote by a show of hands or on a roll call.

In the discussion on the paragraphs dealing with the suggestion that the Council should be elected directly by the Representative Body, with the addition of *ex officio* members and Representatives of Colonial Branches, the Chairman of the Organization Committee, in reply to a question, said that it was intended that the persons proposed for election by the Representative Body should be members of that body. After some discussion, during which the importance of retaining the territorial system of election was insisted upon, the following resolution was carried:

That the Council recommend that no change should be made in the method of election for the Council.

The paragraphs of the report were gone through seriatim, and settled in the form in which they are printed in this issue.

The Council also adopted and referred to the Divisions a report on the referendum and postal vote embodying a history of the subject and concluding with six questions submitted for the consideration of Divisions upon which the Annual Representative Meeting will be invited to come to a decision.

MATTERS REFERRED TO DIVISIONS.

British Medical Association.

REPORT OF THE COUNCIL ON THE SCHEME OF REFORM OF THE PRESENT CONSTITUTION OF THE ASSOCIATION SUBMITTED BY THE METROPOLITAN COUNTIES BRANCH COUNCIL.

1. The Council has considered the Scheme of the Metropolitan Counties Branch Council, and submits its comments. Suggestions similar to many of those of the Metropolitan Counties Branch Council had already been before the Council and the conclusions of the Council on these are, for convenience, given as if they arose solely on this Scheme.

Report of the Metropolitan Counties Branch Council on the Reform of the Present Constitution of the Association.

DIVISIONS.

(i.) The Divisions would consider all matters of local interest and all matters referred to them by the Representative Body and Council. In matters of purely local interest the Divisions should report their decisions to the Branch Council and the Branch Council shall have power to forward reports received direct to the Central Authority, otherwise to consider them from the point of view of its Divisions collectively, and then report upon the whole question to the Central Authority.

(ii.) The powers of a Division in ethical matters brought before its notice be limited to the making of necessary preliminary inquiries, and to forwarding complaints to the Branch Council; the power to go direct to the Central Ethical Committee and the right of appeal being preserved as at present.

(iii.) Arrangements to be made for the enlargement of Scientific and Social Meetings, to which non-members resident in the Division would be, as far as possible, invited.

(iv.) The System of Wards to be encouraged in each Division.

Election to Branch Council.

(v.) That each Division be allowed to have one Representative up to 200 Members, and an extra Representative for every 200 Members in addition or to the nearest 100 over 150 Members.

Election to Representative Body.

(vi.) The Representative Body to be elected directly by the Divisions of group of Divisions in the proportion of one Representative for every complete 200 Members.

POWERS OF BRANCH COUNCILS.

(i.) To deal, as at present, with finance and boundaries of Divisions.

(ii.) To deal with all questions that concern their areas, and to co-ordinate their constituent Divisions, reporting upon the questions involved to the Representative Body or Council, when it is necessary or desirable or when so directed by either of these bodies.

(iii.) To deal with ethical matters arising in the Divisions; the power to go direct to the Central Ethical Committee, and the right to appeal, being preserved as at present.

Composition of Branch Council.

(iv.) (a) To be composed of one representative up to 200 members from each Division, and an extra representative for every 200 members in addition or to the nearest 100 over 150 members.

That the President, President-Elect, Treasurer and two Honorary Secretaries of the Branch be *ex-officio* Members of this Council.

THE REPRESENTATIVE BODY.

Composition.

(i.) To be composed of Representatives elected directly by the Divisions by postal vote or in Divisional meeting as determined by the Divisions.

Duties.

(ii.) (a) To meet at least once in every year, but the existing machinery to be altered to enable meetings to be called at shorter notice than is at present possible.

(b) To be an assembly with full deliberative powers, and to be responsible for formulating the policy of the Association.

(c) To appoint the Council.

(d) To be empowered to delegate specific powers to the Council to take action upon its behalf until the next meeting of the Representative Body.

(NOTE.—The calling together of the Representative Body in a crisis may be very disadvantageous to the Association owing to the impossibility of keeping the transactions in any way private, thus involving the disclosure of the opinions and future plans of the Association to those to whom for the time being it finds itself in opposition.)

THE COUNCIL.

Election.

The Council shall be composed of the President of the Association, the President-Elect, the Past-President, the Chairman of Representative Meetings, the Chairman of Council, the Past Chairman of Council, and Treasurer *ex officio*.

(i.) To be elected by the Representative Body, and at least five-sixths to be Members of the Representative Body. Special provision to be made for Colonial Representatives.

Duties.

(ii.) (a) To carry out the duties assigned to it by the Representative Body.

(b) To appoint Standing Committees as at present, such to be reduced in size as far as is compatible with efficiency, and to be composed in the proportion of two Members of the Council to three or four Members elected by the Representative Body.

(NOTE.—This course would tend to shift some of the burden of work from Members of the Council.)

The Scotch and Irish Committees.

(c) More use to be made of these Committees, which should, in fact, co-ordinate their respective Branches.

The Scotch and Irish Committees shall have power to co-opt Members for local purposes.

(NOTE.—Many questions could thus be speedily dealt with on the spot by those competent to do so, and loss of time and the expense of journeys to London avoided.)

The Institution of New Committees.

(iii.) (a) To appoint a Parliamentary Committee with power to co-opt additional Members, to maintain and increase the influence of the Association in the Houses of Parliament, to keep in touch with all legislation, existing or proposed, that affects the medical profession, and to perform all such duties as at present are entrusted to the Parliamentary Sub-Committee of the Medico-Political Committee.

(b) To appoint a new Committee to organise and control systematic endeavour to awaken and keep awake interest in the Association, and to devise means to make it more attractive.

(NOTE.—Such a Committee should always have ready to date, lists of speakers, on various subjects, whether Medico-Political or Scientific, who would be willing and able to address Meetings in all parts of the Country, and it would be part of the duties of this Committee to arrange for interesting and attractive meetings to which non-members would be largely invited. Under the auspices of this Committee a new and valuable special department might be established to deal with all such questions of development, and, in addition, to

undertake on behalf of Members of the Association only, the transference of practices, the supply of "Locum-tenentes," and all business of that kind. If this were done at a charge for out-of-pocket expenses only, as might have to be the case, it would be a great boon to many Members and might attract others to join an Association, which would be of practical use to them.)

(c) To appoint for the purposes of each lawsuit in which the Association may be engaged, a special small Committee to represent the Association in the matter of conferring with and instructing the Solicitor with regard to the preparation and presentation of the case.

Points to be considered with regard to General Re-organisation.

(a) The Committee draws attention to the supreme necessity of economy before any question of raising the subscription is entertained.

(b) To consider the appointment of a chief to the Central Office, to supervise and co-ordinate the work and to ensure that the services of each department shall be readily available for the other departments, and to place the whole office upon a business basis.

(NOTE.—The Committee recognises the difficulties of such a step at the present time, and offers the suggestion that such difficulties might be overcome, for the time being, by the establishment of a small House Committee to supervise generally.)

(c) The establishment of definite departments and the more definite allocation of duties in the Medical Department, thus abolishing the present system under which all business goes through the hands of one official, and which cramps the development of the department, and throws more work upon the shoulders of one man than is wise or desirable.

The Branch Council is of opinion that it is undesirable to alter the Articles of Association, and the above plan has been proposed in accordance with this view.

Report of Council on the Scheme.

A.—DIVISIONS.

2. On consideration of paragraphs (i) and (ii), viz. :—

Divisions.

(i.) *The Divisions would consider all matters of local interest and all matters referred to them by the Representative Body and Council. In matters of purely local interest the Divisions should report their decisions to the Branch Council and the Branch Council shall have power to forward reports received direct to the Central Authority, otherwise to consider them from the point of view of its Divisions collectively, and then report upon the whole question to the Central Authority.*

(ii.) *The powers of a Division in ethical matters brought before its notice be limited to the making of necessary preliminary inquiries, and to forwarding complaints to the Branch Council; the power to go direct to the Central Ethical Committee and the right of appeal being preserved as at present.*

the Council suggests that the following paragraph conveys more clearly and fully what the suggestions of the Metropolitan Counties Branch Council would involve :—

General Powers.

The Divisions shall consider all matters referred to them by the Representative Body and Council, and in the case of matters to be brought before the Representative Meeting shall convey their views to their Representatives.

Save as regards the above mentioned matters, Divisions shall report to the Branch Council all their decisions and all matters they may wish to bring forward. Decisions of Divisions shall not become effective until confirmed by the Branch Council, but in cases of special emergency the President and Secretary of the Branch shall be empowered to act for the Branch Council.

Ethical Machinery.

The Council is of opinion that in cases involving the insertion of a Warning Notice, Divisions must have the right to deal with the Central Office direct, and ethical matters should be dealt with in strict accordance with the Model Ethical Rules, after communication with the Central Office.

3. The Council disagrees with the Branch Council in its proposal to alter the present ethical procedure. The present procedure has been evolved through long experience, and the last stage of this evolution, viz., the uniform Ethical Rules of Procedure, is only now in process of adoption by Divisions and Branches. It would, therefore, in the opinion of the Council, be unfortunate if this were interfered with before it has had an adequate trial.

Proposed Limitations of Powers of Divisions.

4. It appears to the Council that, inasmuch as the proposal of the Metropolitan Counties Branch Council limits the freedom of the Division to govern itself as it thinks fit and compels it to act only with the sanction of the Branch Council, it is a contravention of Article 17, so that the desire of the Metropolitan Counties Branch Council to produce a scheme which would not require any alteration of the Articles has, unfortunately, not been realised.

5. It should be noted that all power to instruct a Representative as contained in By-laws 32 and 39 is removed, as is also the power to send resolutions, or amendments, from the Division direct to the Representative Meeting, that is to say, a Resolution will first have to pass through the Branch Council where it may possibly be vetoed.

Scientific and Social Functions.

6. With regard to paragraph (iii.) of the Metropolitan Counties Branch Council's Scheme, viz. :

(iii.) *Arrangements to be made for the enlargement of Scientific and Social Meetings, to which non-members resident in the Division would be as far as possible invited,*

the Council suggests the following paragraph as a clearer statement of the objects aimed at by the paragraph :

That the Council should increase its efforts to encourage the Divisions to hold more scientific and social meetings, and to use these meetings as a means of inducing non-members to join the Association.

Wards, or Sub-Divisions.

7. With regard to paragraph (iv.) of the Scheme, viz. :

(iv.) *The System of Wards to be encouraged in each Division,*

the Council prefers the title of Sub-division to that of Ward, because the term Ward suggests merely town areas, whereas the idea contemplated by the Branch Council is the subdivision of either town or country Division areas.

The Council is strongly of opinion that the system of Sub-divisions might be very useful in some areas, and suggests that the paragraph be amended to read as follows :—

The system of Sub-divisions should be encouraged in suitable Division areas; Sub-divisions to have such powers only as are conferred upon them by the Division.

B.—ELECTION OF BRANCH COUNCIL.

8. The Council has considered paragraph (v.) together with paragraph (iv.) (a) under the heading, "Composition of Branch Council," in the Metropolitan Branch Council's Scheme, viz. :—

Election to Branch Council.

(v.) *That each Division be allowed to have one Representative up to 200 Members, and an extra Representative for every 200 Members in addition or to the nearest 100 over 150 Members.*

Composition of Branch Council.

(iv.) (a) *To be composed of one Representative up to 200 Members from each Division, and an extra Representative for every 200 Members in addition or to the nearest 100 over 150 Members.*

That the President, President-Elect, Treasurer and two Honorary Secretaries of the Branch be ex-officio Members of this Council,

and is of opinion that the composition of the Branch Council should be left in great measure for local determination, as the circumstances in different areas vary so much.

9. The Council suggests that By-law 16 (c) at present gives effect to the desires of the Metropolitan Counties Branch Council as regards *ex officio* Members of a Branch Council, and that the number of other Members of the Branch Council would best be regulated by an amendment of By-law 16 (d), which at present reads as follows:—

(d) In the case of a Branch comprising more Divisions than one, Members elected by such Divisions in such manner that the number to be elected by each Division shall be as nearly as possible proportionate to the Membership of such Division.

The Council suggests that the By-law should be amended to read as follows:—

(d) Such other Members as the Branch may by its Rules decide.

10. In any case By-law 16 (d) should be altered at the first opportunity, because if it were strictly carried out as it stands the Council of a Branch of only one Division would consist only of *ex officio* Members. This is not desirable, nor was it contemplated when the By-law was drafted; moreover, the Branches have found this Rule to be most difficult to carry out, and much ingenuity has had to be exercised in drafting Branch Rules that should be useful while yet not conflicting with By-law 16 (d).

C.—ELECTION OF REPRESENTATIVE BODY.

Restriction of Size.

11. With reference to the question of the size of the Representative Body, raised in paragraph (vi.) of the Scheme of the Metropolitan Branch Council, viz. :—

Election to Representative Body.

(vi.) *The Representative Body to be elected directly by the Divisions or group of Divisions in the proportion of one Representative for every complete 200 Members.*

the Council has given a good deal of attention to the question of the diminution in size of the Representative Body, and is of opinion that the Representative Body is too large and should be reduced, but regards the reduction of the number of Constituencies as inadvisable and more or less impracticable.

The reduction of the number of Constituencies is surrounded with very great difficulties, as will be seen by reference to a hypothetical scheme for the election of the Representative Body having a maximum membership of 150 (exclusive of Members of Council), which has been drawn up for the information of the Divisions and Representative Body (see Appendix). Reference to this Appendix will show that any attempt to cut down the number of Constituencies must lead to the grouping of many Divisions which have very little in common, and in many cases to the swamping of the rural areas by towns. The Council is therefore of opinion that any attempt to reduce the size of the Representative Body should be directed to the cutting down of the number of Representatives coming from large Constituencies. This the Council considers can be done without any injustice to these Constituencies by arranging that on a vote by show of hands or by roll call the votes of Members representing large Constituencies shall have their due weight. If the Representative Body agrees that an attempt should be made to cut down the size of the Meeting in this way, the Council suggests that the Representative Body should refer to the Council the framing of By-laws and Standing Orders of the Representative Meeting which would secure that a Constituency which now sends, say four Representatives, and which under the new system might only send one, should be able to record, whenever desired, four votes.

Card Vote in Representative Meetings.

12. In considering the above matter it was realised that if the number of Representatives were reduced, thinly populated and rural areas would tend, if they are to be represented at all, to become, relatively to their numbers, more and more over-represented in comparison with densely populated districts. It is therefore probable that under such conditions, when important decisions were to be taken, the card vote would be more frequently resorted to.

13. Appreciating the great loss of time entailed by the present machinery of the card vote the Council has considered whether the matter might not be simplified, and recommends the following procedure to the Representative Body for adoption, whether the size of that Body is reduced or not:—

That the following be the Standing Order for the taking of a card vote.

A card vote shall be taken in the following manner:—

At the commencement of the Representative Meeting a list of those entitled to vote shall be prepared, with, in a column opposite the name of each, the number of votes to which the voter is entitled in accordance with By-law 39 (3).

The names of the Representatives shall be grouped together under their respective Branches in the alphabetical order of their Constituencies and the reply "Aye" or "No" entered opposite his name in another column. The necessary additions shall then be made.

Specimen List. In alphabetical order of Branches.

| Name and Constituency. | Vote. | | Card Vote Number. | Ayes. | Noes. |
|-----------------------------------|-------|-----|-------------------|-------|-------|
| | Aye. | No. | | | |
| <i>Bath & Bristol Branch.</i> | | | | | |
| Whitby, C. J. (Bath) .. | | X | 132 | | 132 |
| Carter, T. M. (Bristol) .. | X | | 292 | 292 | |
| Devis, H. F. (Bristol) .. | X | | | | |
| Parker, G. (Bristol) .. | X | | | | |
| Pearse, J. (Trowbridge) .. | | X | 43 | | 43 |

[NOTE.—By forming the list in alphabetical order of Branches, with orderly arrangement of Divisions inside the Branches, those possibilities of error in counting are avoided which might arise, in the case of Divisions with more than one Representative, if the arrangement were that of alphabetical order of names of Representatives. This sheet when once printed could be used for "roll-call vote" and probably for record in Minutes of attendance of Representatives. Or it might be simply written out by a clerk.]

POWERS OF BRANCH COUNCILS.

14. On consideration of paragraph (i.) of this section of the Scheme, viz. :—

Powers of Branch Councils.

(i.) *To deal, as at present, with finance and boundaries of Divisions,*

as the Branch Councils at present deal with the finances and boundaries of Divisions, there is no necessity to make further comment.

15. As regards paragraph (ii.) of this section of the Scheme, viz. :—

(ii.) *To deal with all questions that concern their areas, and to co-ordinate their constituent Divisions, reporting upon the questions involved to the Representative Body or Council, when it is necessary or desirable or when so directed by either of these bodies,*

the Council suggests the following paragraph as more fully elaborating the intention of the Metropolitan Counties Branch Council:—

(a) The Branch Council shall decide whether any matter reported to it by a Division is of purely local interest; and if in the opinion of the Branch Council such is the case, it shall have the power to (1) approve, (2) disapprove, or (3) refer the matter back. Should the Branch Council come to the conclusion that it is not a matter of purely local concern, the Branch Council shall have the power to (1) approve, (2) disapprove, (3) refer the matter back to the Division, (4) convene meetings of any or all of its Divisions for consideration of the matter, or (5) report the matter to the Representative Body or the Council of the Association with such comments as it thinks fit.

(b) The Branch Council shall report to the Representative Body or Council upon any matter when so directed by either of these Bodies, or when it deems such action desirable.

(c) The Branch Council shall have the power to take such steps as it may think desirable to co-ordinate the work of its constituent Divisions, or to initiate action amongst the whole or part of its Divisions.

16. The Council agrees with the Branch Council that it is desirable to enlarge the scope and increase the responsibilities of the Branch Councils, thereby making them more useful and important bodies than they are at present, giving them greater powers over the constituent Divisions of the Branch, and enabling Branch Councils to be used as a medium of communication between the Representative Body, or the Council, and the Divisions. It is believed that the adoption of such a principle would ensure greater local uniformity of action than at present, and that the Branch Councils would deal with many matters of minor or merely local importance which are now referred to the Representative Body.

Ethical Machinery.

17. The subject dealt with in paragraph (iii.) of this section of the Scheme, viz. :—

(iii.) *To deal with ethical matters arising in the Divisions; the power to go direct to the Central Ethical Committee, and the right of appeal being preserved as at present,*

has already been alluded to in paragraphs 3 and 4 of this Report.

Composition of Branch Council.

18. The subject dealt with in paragraph (iv.) of this section of the Scheme has already been considered in paragraphs 8 and 9 of this Report.

THE REPRESENTATIVE BODY.

Composition.

19. As Representatives may at present be elected either by postal vote or in Meetings of Constituencies, as determined by the Constituency, paragraph (i.) of this section of the Scheme, viz. :—

Composition.

(i.) *To be composed of Representatives elected directly by the Divisions by postal vote or in Divisional meeting as determined by the Divisions.*

does not seem to require discussion:

Duties. Report on the Possibility of Convening a Special Representative Meeting more quickly than at present.

20. As regards paragraph (ii.) (a) of this part of the Scheme, viz. :—

Duties.

(ii.) (a) *To meet at least once in every year, but the existing machinery to be altered to enable meetings to be called at shorter notice than is at present possible,*

the Council reports that this matter is one to which it has already given a good deal of attention. The Council thinks it advisable to deal with the matter very fully in connection with this paragraph of the Scheme as there is evidently considerable confusion as to the procedure at present in force as regards calling Special Representative Meetings.

21. The circumstances in which such a Meeting is required are, according to the experience of the Association, mainly of two kinds. First, when alterations are needed in the regulations of the Association, and have been drafted in accordance with the instructions of an Annual Representative Meeting. In this case there is no special hurry and the fourteen days' notice has not been felt to be too long. Secondly, when, as in January last, either the Council or some of the Divisions have come to the conclusion that circumstances demand that the policy of the Association, or some particular decision of the Representative Body needs at once to be reconsidered. In this case speed may be of the utmost importance.

22. According to By-law 36 a Special Representative Meeting shall be convened by the Chairman of Representative Meetings on a requisition of the Council or of 7 Constituencies.

23. It may be as well to state briefly the stages of the necessary procedure in each case.

A. *Special Representative Meeting called upon the requisition of the Council.*

(i.) The proposition originates—

(a) With the Chairman of Council, or (b) with 15 Members of Council.

(ii.) Chairman of Council orders notices to be issued for Special Meeting of Council.

(iii.) Preparation and issue of Council Meeting Notices.

(iv.) Period of Notice at discretion of Chairman of Council (By-law 56). It is, however, usual to give seven clear days' notice of the Agenda of each Meeting of Council (Standing Order 2 of Council).

(v.) Meeting of Council.

(vi.) Requisition of Council forwarded to Chairman of Representative Meetings. As the latter is generally present at a Council Meeting no interval would usually occur.

(vii.) Chairman of Representative Meetings orders insertion of notice in JOURNAL.

(viii.) Fourteen days' interval (By-law 36 (2)) occupied by :—

(1) Constituencies in

(a) Honorary Secretaries of Constituencies issuing notice of meeting of Constituencies.

(b) Period of Notice which, by Rules of some Divisions, must be several days.

(c) Meeting of Constituencies and instructions to Representatives.

(2) By Central Office in (a) engaging rooms, (b) printing of documents, (c) other general arrangements.

B. *Representative Meeting called on Requisition of Seven Divisions.*

(i.) Originates by intercommunication between the Divisions, and passage of identical resolutions demanding meeting and stating specific business.

(ii.) Requisition received at Central Office.

(iii.) Requisition forwarded to Chairman of Representative Meetings (interval of 1 day occupied in transmission by post. (By-law 73 (3)).

(iv.) The Chairman of Representative Meetings orders insertion of Notice in JOURNAL (interval of 1 day).

(v.) Same as A (viii.).

24. It will be clear from the above statement that except for other delays caused by unavoidable or avoidable causes the only stage that could be shortened is A (viii.) or B (v.). By giving only 10 days' notice in the JOURNAL, the Meeting could be held in the middle of the second week after the notice was published, that is to say if the notice appeared in the JOURNAL published on Friday, January 1st, for example, the Meeting could be held on Tuesday the 12th. But it is very doubtful whether such a short notice would allow of the proper discussion of a matter which would necessarily be of vital importance. In the first place the JOURNAL does not reach all parts of the United Kingdom before Saturday night. Secondly, the pressure put upon the Secretaries of Constituencies in making their arrangements, getting out notices, etc., especially in scattered Constituencies where arrangements have to be made between two or more Secretaries of Divisions, would be extreme. Thirdly, it would often be difficult for Representatives to make their arrangements for getting away from their practices at any shorter notice than at present, and it must be remembered that it takes some Representatives nearly two days to reach London. It should be borne in mind that the minimum time of 14 days now allowed for the arrangements to be made centrally, is felt to be quite short enough, and it is doubtful whether they could be carried through efficiently in less time. Above everything the Council feels that for an Association of the magnitude of the British Medical Association, whose Members are so widely scattered and whose difficulties of meeting are so great, it is important that the time allowed for the formation of a decision which may be crucial should not be too drastically curtailed.

25. As regards the special point raised by the Notice of Motion given by the Maidstone Division for the Annual Representative Meeting, namely :—

That the following words be added to the end of paragraph (2) of By-law 36 :—

“In case of urgency the period of notice may be shortened at the discretion of the Council,”

it is to be noted that if the 14 days' notice is to be curtailed at all it would need to be curtailed in every case, that is to say that it should be reduced to a definite lesser period by the By-laws. The idea of the Maidstone Division of giving discretion to the Council to shorten the period is

in the opinion of the Council impracticable, at any rate in procedure B. In procedure A, it might be possible to allow the Council, at the Special Meeting at which it passed the requisition to the Chairman of Representative Meetings, to call a Meeting, to ask him also to shorten the period of notice if the Council and the Chairman of Representative Meetings were satisfied that the matter was of special importance and could be dealt with in the shortened time. But, in procedure B, the Meeting is called on the requisition of the seven Divisions. To give the Council power to shorten the period of notice in that case would be useless, as the Council to act would have to meet, and this would probably mean lengthening the time required to call a Special Representative Meeting instead of shortening it.

Proposed change in nature of Representative Body.

26. As regards sub-paragraph (b) of this section of the Scheme, viz. :—

(b) *To be an assembly with full deliberative powers, and to be responsible for formulating the policy of the Association,*

the Council reports that it is in full agreement with the suggestion that the Representative Body should in future be an assembly with full deliberate powers. It is important that the Divisions should thoroughly realise the full force of the proposed change. If the suggestion were carried out the Members of the Representative Body would no longer be fettered as they are at present by the restriction contained in By-law 39 (4) which reads as follows :

39 (4) In voting upon any matter upon which a constituency has passed a resolution within the three months immediately preceding such Meeting, the Representative or Representatives of that Constituency shall be under obligation to vote in accordance with such resolution :

27. The Council is of opinion that the events of the past few months have shown that an assembly of delegates, who, whatever the evidence placed before them at the Representative Meeting may be, are unable to vote except in a way which has already been fixed for them, perhaps three months previously, is unfitted for the needs of the Association. The function of the Representative Body is to arrive at decisions which will represent the desires of the average member of the Association, and to formulate a policy which will be acceptable to as large a number as possible under the conditions existing at the time the policy is adopted. When the constituencies meet, those members present are aware of what they wish, on the evidence placed before them; but they are not aware of the feelings of other constituencies. To instruct a Representative, therefore, that he must not vote except in a manner laid down by his own particular constituency is to deprive him of the opportunity of profiting by the opinions of others, and of voting in the way which, after mature consideration and full debate, he thinks will most conduce to the welfare of the Association. In addition to this, as recent events have well proved, the political situation may change almost from day to day, and the instructions conveyed to a Representative at a meeting on one day may well turn out to be totally unsuitable to the needs of the situation existing on the day of the Representative Meeting. It appears to the Council therefore, that the object to be aimed at is to secure an assembly of men of judgment and honesty of purpose, trusted by those who elect them, and believed by their constituents to understand and represent the feelings and the opinions of the constituency, rather than one of men who are bound to vote in a given way irrespective of the evidence placed before them.

28. The checks upon the Representative must be those exercised on a Member of Parliament by his constituents, namely, first of all the pride which the average Representative takes in proving himself worthy of the trust reposed in him, and secondly the knowledge that if he misrepresents the feelings of his constituents he will not be elected at the next occasion, and may even be called upon to resign.

NOTE :—*The Council has already recommended an alteration of By-laws which would enable a Representative to resign his position and would also enable a constituency to call upon a Representative to resign (see paragraph 36, Annual Report of Council, Supplement to B. M. J., May 3rd, 1913, page 373).*

Method of appointing Council.

29. The subject of sub-paragraph (c) of this section of the Scheme is dealt with later in paragraphs 33-36 of this Report.

Delegation of duties to Council.

30. As regards sub-paragraph (d) of this part of the Scheme, viz. :—

(d) *To be empowered to delegate specific powers to the Council to take action upon its behalf until the next meeting of the Representative Body,*

it appears that those responsible for the Scheme have overlooked, as indeed has generally been done, the wide powers conferred upon the Council as set forth in Article 34. It is laid down in that Article that not only is it the duty of the Council to act as the Executive of a General Meeting or of the Representative Body, but that it "shall exercise such powers and do such acts and things as may be exercised or done by the Association, and are not by the provisions of any statute or of the regulations or the By-laws directed to be exercised or done by a General Meeting or by the Representative Body." That is to say that in the absence of a direct ruling of the Representative Body, the Council, in the interval between Representative Meetings, has imposed upon it the duty of acting in the fullest way for the Association.

31. It would, therefore, be well within the powers of the Representative Body definitely to delegate much of its power in the interval between the Representative Meetings to the Council, even in reference to matters as to which the Representative Body had passed definite resolutions, and if the suggestion made by the Metropolitan Counties Branch Council, under the heading "The Council" were adopted, namely, that the Council be elected mainly by the Representative Body, it is probable that there would be little hesitation in so delegating these powers. In order that there shall be no misunderstanding of the situation, however, it would be desirable that each Annual Representative Meeting should by specific Resolution delegate its powers to the Council in the interval. If this were done the undoubted dangers mentioned by the Branch Council in the note to sub-paragraph (d) of this section of the Scheme, namely the risks entailed by a public discussion of policy or tactics, could be obviated to a large extent; as the Council, being definitely instructed to carry on the policy of the Association and if necessary even to modify it, would be able to act on the information placed before it in an emergency, or in a situation in which discussion in open Representative Meeting might seriously prejudice the interests of the Association.

32. Any compunction felt by the Representative Body as to thus handing over its powers even to the Council of the Association, would be modified by the fact that these powers could be regained at any time by summoning a Special Representative Meeting.

D. THE COUNCIL.

Election and Composition.

33. The preliminary paragraph of this section of the Scheme, viz. :—

Election.

The Council shall be composed of the President of the Association, the President-Elect, the Past-President, the Chairman of Representative Meetings, the Chairman of Council, the Past Chairman of Council, and Treasurer ex officio,

being simply a statement of the present position as regards the *ex-officio* membership of the Council, the Council does not think it necessary to deal further with the subject.

34. Careful consideration has been given to the suggestion made in the Scheme as follows :—

To be elected by the Representative Body, and at least five-sixths to be Members of the Representative Body. Special provision to be made for Colonial Representatives.

namely, that the Council should in future be elected mainly by and from the Representative Body. The suggestion that the Council should be the Executive of the Representative Body and elected by it, was mooted by the Constitution Committee which re-organised the Association in 1902, but the proposal was felt at that time to be inopportune. Even then it was obvious that such a step was the logical consequence of the new constitution, but the old feeling in favour of Branch representation was very strong, the Representative Body was an untried body, and the result arrived at and embodied in the constitution was a compromise by which part of the Council is elected by grouped Branches and part by the Representative Body. The Council is of opinion that there is no reason to believe that the proposed change is desired by the Association as a whole, and considers that it would be inadvisable to adopt it.

35. The Council recognises that there is a good deal to be said in favour of the argument that the election of the Council by the Representative Body would go far to prevent distrust of the Council, the existence of which feeling has at times rendered the Council much less effective as the Executive of the Association than it would otherwise have been. The Council having stated its opinion on the proposed change leaves the matter to the judgment of the Association.

Duties.

36. The question, raised in sub-paragraph (a), of this part of the Scheme, viz. :—

Duties.

(ii.) (a) *To carry out the duties assigned to it by the Representative Body.*

has been fully dealt with in paragraphs 30 and 31 of this Report.

37. As regards sub-paragraph (b), viz. :—

(b) *To appoint Standing Committees as at present, such to be reduced in size as far as is compatible with efficiency, and to be composed in the proportion of two Members of the Council to three or four Members elected by the Representative Body,*

the Council is of opinion that the Committees are already as small as is compatible with efficiency, and therefore should not be reduced. The Council would draw attention to the fact that only at the last Annual Representative Meeting it was resolved to increase the size of the Public Health Committee because its membership had been found by experience to be too small for efficiency. As regards the respective proportions of Members of Council and Members elected by the Representative Body on each Committee, the Council believes that it is unnecessary at this stage to enter into details.

E. COMMITTEES.

Scottish Committee.

38. In view of the action of the Council at its meeting on April 23rd, 1913, as reported in paragraph 172 of the Annual Report of Council, page 388, of the Supplement, May 3rd, 1913, in taking steps to increase the powers of the Scottish Committee, the intention of paragraph (ii.), (c) of this section of the Branch Council's Scheme, viz. :—

The Scotch and Irish Committees.

(c) *More use to be made of these Committees which should, in fact, co-ordinate their respective Branches.*

The Scotch and Irish Committees shall have power to co-opt Members for local purposes,

seems to be met so far as Scotland is concerned.

Irish Committee.

39. The Irish Committee already possesses considerable powers for dealing with local affairs, but the situation in Ireland is complicated by the existence of the Conjoint Committee, of which all members of the Irish Committee are *ex-officio* members, but which also comprises an equal number of members selected from the Council of the Irish Medical Association, together with sixteen directly-elected representatives of the profession, two representatives of the medical women of Ireland, and representatives of the various teaching institutions and medical societies. This Committee has been recognised by the Association, and has been in part financed by it. The Irish Medical Association has however withdrawn its Representatives on this Committee by a Resolution passed at its Annual Meeting in June, 1913, and the effect of this step may be to put an end to the continued existence of the Conjoint Committee, at least for the present.

Parliamentary Committee.

40. The Council agrees with the suggestion of the establishment of a Parliamentary Committee as recommended by the Branch Council in sub-paragraph (a) of this section of the Scheme, viz. :—

The Institution of New Committees.

(iii.) (a) *To appoint a Parliamentary Committee with power to co-opt additional members, to maintain and increase the influence of the Association in the Houses of Parliament, to keep in touch with all legislation, existing or proposed, that affects the medical profession, and to perform all such duties as at present are entrusted to the Parliamentary Sub-Committee of the Medico-Political Committee.*

Propaganda Sub-Committee.

41. The Council agrees with the principle contained in sub-paragraph (b) of this part of the Scheme, viz. :—

(b) *To appoint a new Committee to organise and control systematic endeavour to awaken and keep awake interest in the Association, and to devise means to make it more attractive,*

(Note.—Such a Committee should always have ready to date, lists of speakers on various subjects, whether Medico-Political or Scientific, who would be willing and able to address Meetings in all parts of the Country, and it would be part of the duties of this Committee to arrange for interesting and attractive meetings to which non-members would be largely invited. Under the auspices of this Committee a new and valuable special department might be established to deal with all such questions of development, and, in addition, to undertake on behalf of Members of the Association only, the transference of practices, the supply of "Locum-tenentes," and all business of that kind. If this were done at a charge for out-of-pocket expenses only, as might have to be the case, it would be a great boon to many Members and might attract others to join an Association which would be of practical use to them.)

and is of opinion that the proposal could best be carried out by a special Standing Propaganda Sub-Committee of the Organisation Committee, which Sub-Committee could also consider the cognate subject of the Organisation of Medical Students. This Sub-Committee could also undertake the duties suggested in the first sentence in the note to sub-paragraph (b) of this section of the Branch Council's Scheme.

The Proposed Undertaking of Medical Agency Business.

42. As regards the suggestions contained in the remainder of the note to sub-paragraph (b) of this section of the Scheme the Council must point out that they are outside the powers obtainable by the Association, and it is therefore useless to consider them further.

Proposed Law Suits Committee.

43. As regards sub-paragraph (c) of this part of the Scheme, viz. :—

(c) *To appoint for the purposes of each lawsuit in which the Association may be engaged, a special small Committee to represent the Association in the matter of conferring with and instructing the Solicitor with regard to the preparation and presentation of the case,*

the Council has dealt with the subject herein mentioned by setting up a Standing Libel Actions Sub-Committee of the Journal Committee for dealing with any libel actions arising out of the publications of the Association, and has decided to leave any libel actions arising out of ethical procedure in the hands of the Central Ethical Committee.

F. GENERAL REORGANISATION.

Necessity for Economy.

44. As regards paragraph (a) of this section of the Scheme, viz. :—

Points to be considered with regard to General Reorganisation :—

(a) *The Committee draws attention to the supreme necessity of economy before any question of raising the subscription is entertained,*

the attention of the Representative Body is directed to recent decisions of the Council as reported in the Annual Report of Council, paragraphs 23 and 24, page 369, Supplement, May 3rd, 1913.

Direction of Central Office.

45. As regards paragraph (b) of this part of the Scheme, viz. :—

(b) *To consider the appointment of a chief to the Central Office, to supervise and co-ordinate the work and to ensure that the services of each department shall be readily available for the other departments, and to place the whole office upon a business basis,*

the Council is of opinion that the proposed appointment of a chief to supervise the work of the whole of the Central Office is impracticable. The Representative Meeting of 1908 on the recommendation of the Special Finance Inquiry Committee decided that the whole of the work of the Association

should be co-ordinated in three departments—Financial, Editorial, Medical and Professional respectively, under the following officers:—

- (a) Financial Secretary and Business Manager.
- (b) Editor.
- (c) Medical Secretary.

who shall hold equal official positions in the Association. As the Council is of opinion that the reasons which led to the adoption of this principle in 1908 apply with the same force now, it recommends that the suggestion of the Metropolitan Counties Branch Council be not entertained.

Medical Department.

46. As regards paragraph (c) of this part of the Scheme, viz. :—

(c) *The establishment of definite departments and the more definite allocation of duties in the Medical Department, thus abolishing the present system under which all business goes through the hands of one official, and which cramps the development of the department, and throws more work upon the shoulders of one man than is wise or desirable,*

the Council is giving attention to the question of the allocation of duties in the Medical Department and hopes to be able to report on the matter in its Supplementary Report to be issued early in July.

APPENDIX.

REPORT SHOWING THE CHANGES ENTAILLED BY AN ATTEMPT TO REDUCE THE REPRESENTATIVE BODY TO A MAXIMUM NUMBER OF 150 (EXCLUDING MEMBERS OF COUNCIL), WITH A TENTATIVE SCHEME OF GROUPING DIVISIONS INTO CONSTITUENCIES.

1. The following scheme is presented for the information of the Divisions and Representative Body to show how the reduction of the Representative Body might be brought about, and to illustrate the practical difficulties in any such attempt.

2. The Report shows (A) the general changes that would be entailed by the foregoing proposal, (B) a tentative Scheme of grouping for the election of Representatives not to exceed a maximum of 150 for the whole Association.

(A) *Changes involved in setting up a Representative Body composed of not more than 150 Representatives (in addition to the Council).*

3. These changes may be indicated under the following heads, though doubtless other aspects would also require consideration:—

- (a) Size of Constituency.
- (b) Mode of Election of Representatives and Deputy-Representatives.
- (c) Mode of Instruction of Representatives.
- (d) Composition of Division Executive Committee.
- (e) Election of Members of Council by grouped Representatives.
- (f) Expense of Representative Meetings.

(a) Size of Constituency.

4. As will be seen in detail on reference to Part (B) of this Report, a change from the present principle of "total number of Constituencies not to exceed 300," to a scheme where the maximum number of Representatives would be 150, would on an average slightly more than double the size of the Constituencies.

(b) Mode of Election of Representatives and Deputy-Representatives.

5. The proposal, if carried out, would probably tend to make a larger number of Constituencies than do so at present, elect their Representatives and Deputy-Representatives by voting paper instead of by the alternative method of a general meeting of the Constituency.

As Constituencies will under the suggested scheme, cover such wide areas, the difficulty of rapid calling together will be much increased, and therefore to elect a Deputy Representative in a hurry, would be probably found in many cases impossible. It might be well to recognise in the By-laws what is often done already, *i.e.* the election of a Deputy-Representative at the same time as the Representative.

(c) Mode of Instruction of Representatives.

6. It is, however, in connection with the question of the instruction of Representatives that the chief difficulty of a proposal of the kind would be found. At present, in whatever way Representatives are elected (general meeting or voting paper) a general meeting of the Constituency to instruct the Representative or Representatives must be held in order that the Representative shall be eligible to attend the meeting of the Representative Body. General meetings would continue to require to be held if the Representative is to continue to be specially instructed. Even if the proposal that a Representative should no longer be a delegate be adopted, the difficulty of his keeping in touch with the opinions of the larger constituencies will be considerable, as it would be difficult, if not impossible, for Divisions adequately to keep Representatives acquainted with their views through the post.

7. In connection with this and the foregoing item, it might be well in any event to arrange by By-law that the Honorary Secretary of the largest Division comprised in a Constituency should *ipso facto* act as Secretary of the Constituency, this provision to take the place of the present somewhat clumsy arrangement contemplated by By-law 32 (2).

(d) Composition of Division Executive Committee.

8. If the number of Representatives is decreased to the extent contemplated in the proposal under consideration, on the basis laid down in present By-law 18 the effective membership of the Executive Committee of a Division will be decreased, inasmuch as the Member (Members) representing in the Representative Body a Constituency of much wider area than the average present Constituency will, *ex-officio*, be a Member (Members) of the Executive of each Division comprised in the Constituency. It is probable in these circumstances that the Representative would not find it easily practicable to attend the meetings of the Executive Committees of all the Divisions comprised in his Constituency.

(e) Election of Members of Council by Grouped Representatives.

9. The principle of the election of Members of Council by grouped Representatives, if adhered to, would be vitally affected by any such reduction of the number of Representatives as is proposed. Whether only twelve members of Council, as at present, be elected by the grouped Representatives, or all the Members of Council be so elected, except the *Ex-officio*, Overseas, and Service Members, the group of electors would in many cases be reduced to a number so small that it would probably be considered inadvisable for the Council to be elected in this way.

(f) Expense of Representative Meetings.

10. The main expense of meetings of the Representative Body, namely, travelling expenses, would under this proposal be reduced by approximately one-half, and doubtless some of the other expenses would also be reduced, though not to the same extent.

(B) *Tentative Scheme of Grouping for the Election of a number of Representatives not to exceed a Maximum of 150 for the whole Association.*

11. If it were decided, under such a proposal as is contemplated, to retain the principle whereby as regards the United Kingdom additional Representatives are conceded in the case of large Constituencies, it is obvious that any suggested scheme of grouping must be framed with due recognition of the fact that substantial increases of membership must necessarily be accompanied by an increase in the number of Representatives. In addition, fresh formation from time to time of new Branches and Divisions in areas previously unorganised also at once necessitates an increase in the number of Representatives. If, therefore, the maximum possible number of Representatives for the whole Association is to be fixed at 150, any scheme of grouping on that basis must (unless it is to be liable to be materially altered upon every substantial influx of new or newly organised members) provide only, as at present, for a number of Representatives which is definitely short of the maximum possible.

12. At present the maximum possible number of Constituencies for the whole Association is fixed by the By-laws at 300. The actual number of Constituencies provided for by the Council is 213, namely, 170 inside and 43 outside the United Kingdom, carrying a total of 250 Representatives, namely, 207 for the United Kingdom and 43 for the Overseas.

constituencies. The total number of Representatives actually elected for 1912-13 was 224, made up of 204 for the United Kingdom and 20 for the Constituencies outside the United Kingdom.

13. The present membership of the Association organised into Branches and Divisions is : (a) United Kingdom, 19,174 ; (b) outside the United Kingdom, 5,136 ; total, 24,310.

14. Reserving, in accordance with precedent, as a provision for representation of new or newly organised members joining or becoming organised at later dates, 20 seats in that portion of the Representative Body other than the Council, 130 seats remain for distribution between the Divisions and Division-Branches at home and abroad.

15. In distributing these 130 seats between the home and overseas bodies, it would appear to be reasonable to take as a basis of apportionment the respective numbers of Representatives, home and overseas, who attended at the Annual Representative Meeting, Liverpool, 1912. The very fullest opportunities have for several years been given by the Association to the overseas Divisions and Division-Branches to return Representatives to the Representative Body, it having been the custom of the Council to accord independent representation in the Representative Body to every organised overseas Division and Division-Branch. The average number of Overseas Representatives who have attended the Annual Representative Meetings during the past five years is nine. The numbers of Representatives recorded as attending at Liverpool were :—

| | |
|--|-----------|
| Representatives of United Kingdom Constituencies | 202 |
| Representatives of Overseas Constituencies | 15 |
| | <hr/> 217 |

16. Distributing on these proportions the 130 available seats between the United Kingdom and Overseas bodies we arrive at the following numbers of Representatives :—

| | |
|--|-----------|
| Representatives of Divisions and Division-Branches in the United Kingdom | 121 |
| Do. do. outside do. | 9 |
| | <hr/> 130 |

SCHEME OF CONSTITUENCIES FOR ELECTION OF A REPRESENTATIVE BODY TO CONSIST OF NOT MORE THAN 150 REPRESENTATIVES (EXCLUSIVE OF MEMBERS OF COUNCIL).

17. Under the tentative scheme submitted below there are provided for—

- (1) 82 Constituencies in the United Kingdom, returning 107 Representatives.
- (2) 4 Constituencies outside the United Kingdom, returning 9 Representatives.

This apportionment would continue the principle embodied in the procedure laid down by the existing By-laws, whereby the Divisions and Division-Branches in the United Kingdom have a larger representation in proportion to their membership than the Divisions and Division-Branches outside the United Kingdom. On the other hand if it were so desired, it would be an easy matter to allot, from the margin of 35 seats still available (namely, the 35 seats which together with the 116 seats as referred to above, make up a total number of Representatives "not to exceed 150,") additional seats to the bodies outside the United Kingdom.

18. An allotment of 121 Representatives to the Association in the United Kingdom gives, on an average, 1 Representative to each 158 members in that area, while an allotment of 9 seats to the members of the Association outside the United Kingdom organised into Branches and Divisions, gives, on an average, 1 Representative to each 570 members.

19. Tentatively, 150 is taken as the minimum number of members necessary to form a 1-Representative Constituency in the United Kingdom, a Constituency being allotted an additional Representative for each complete number of 150 members after the first 150. In the case of the Divisions and Division-Branches outside the United Kingdom 4 Constituencies are formed, electing among them 9 Representatives.

20. In forming these Constituencies the integrity of Branch areas is as far as possible preserved. The Branches and Divisions concerned would doubtless be formally consulted on the subject before their grouping was actually decided upon by the Council.

21. The proposed Constituencies are stated, in geographical order of Branches, for each of the main sub-divisions of the United Kingdom, namely (A) England and Wales (B) Scotland (C) Ireland, commencing with the northern Branches in each case, and (D) for the bodies outside the United Kingdom.

Divisions bracketed are grouped.

(A) England and Wales.

| Halifax (N.S.) Branch | 51 | Tasmanian Branch | 70 |
| Jamaica Branch | 49 | Victorian Branch | 727 |
| Leeward Isles Branch | 20 | West Australian Branch | 122 |
| Montreal Branch | 53 | New South Wales Branch | 897 |
| St. John (N.B.) Branch | 25 | Egyptian Branch | 41 |
| Saskatchewan Branch | 35 | Gibraltar Branch | 17 |
| Toronto Branch | 276 | Malta Branch | 25 |
| Trinidad Branch | 22 | | 2,818 |
| | 612 | | |

22. It will be seen that the above tentative Scheme furnishes a total of 116 Representatives, namely:—

| | |
|---------------------------|------------|
| (a) For England and Wales | 89 |
| (b) For Scotland | 13 |
| (c) For Ireland | 5 |
| (d) For Overseas | 9 |
| Total | 116 |

The total number of Constituencies is 86.

23. Provision for this number of Representatives would leave a total margin of 35 seats, to be drawn upon gradually as the membership of the Association increased.

24. It is obvious from the Scheme that it would give practical effect to the proposal for a Representative Body not to exceed 150 (exclusive of Members of Council), if 150 were fixed by By-law as the minimum number of Members of the Association for a Constituency in the United Kingdom and at the same time about 9 or more seats were allotted to the overseas bodies, additional 150's to qualify a Constituency (in the United Kingdom) for additional representation, at the rate of one additional Representative for each such 150.

25. It would be more conducive to a satisfactory grouping of the Divisions and Division-Branches outside the United Kingdom if say 15 seats (Representatives) were allotted to those bodies, the question of the size of the Constituencies outside the United Kingdom being left by By-law to the Council to determine, and if necessary to vary, at its discretion.

26. As regards the steps necessary to be taken to modify the composition of the Representative Body in the manner proposed in the resolution of the Committee, this could apparently be effected by comparatively simple alterations of the By-laws. It might be well to fix by By-law the maximum number of Representatives as well as, as at present, the maximum number of Constituencies. To simplify matters further a provision might at the same time be introduced into the By-laws to the effect that no Division or Branch shall be entitled to take part in the election of a Representative to the Representative Body which had not, according to the Annual List in operation when the grouping is decided upon, a duly appointed Executive Committee or Branch Council and officers. This principle has practically already been adopted by the Council with regard to the overseas bodies. It might also be worth while considering whether possession of proper rules should not be a condition of representation in the Representative Body.

REPORT OF THE COUNCIL
ON THE QUESTION OF REFERENDUM AND
POSTAL VOTE.

1. Ever since the re-constitution of the Association, and especially while the attempt to obtain a Royal Charter was before the Association, there have been many active Members of the Association who were not satisfied that sufficient safeguards existed to ensure that as far as possible the decisions of the Representative Meeting represented accurately the opinion of the Association, and the taking of a Referendum by Postal Vote was strongly urged as a satisfactory means of ensuring this.

At the Annual Representative Meeting, 1910, the following resolution was passed:—

330. That while recognising the necessity of proceeding without delay with the formation of a new Company, the Representative Meeting considers it desirable that a full consideration should be given by the Association to the question of the Referendum by postal vote, and the arrangements generally for securing that the decision of the Representative Meeting shall, as far as possible represent accurately the opinion of the Association, and that it be an instruction to the Council to prepare a Report on these subjects for the consideration of the Divisions, and, after receiving and considering the replies of the Divisions, to submit a Report with recommendations to the next possible Representative Meeting, whether that takes place under the present Company or under the new Company which it is proposed to form.

2. This Minute received the careful consideration of the Council and a detailed report with recommendations was published and "referred to Divisions" in the BRITISH MEDICAL JOURNAL Supplement, April 29th, 1911. Only 5 Divisions replied to the questions referred and the Council reported the whole matter to the Representative Meeting of 1911.

3. The recommendations of this report provided for (1) alterations being made in the Regulations to provide *inter alia* that a referendum might be demanded by 1/5th of the constituencies (containing not less than 1/5th of the membership of the Association); (2) enabling members under certain conditions to record their votes by post; (3) giving the Council or 1/10th of the constituencies power to compel reference to the Divisions of any resolutions which had been passed by the Representative Body without having been previously referred to the Divisions.

4. The Report was approved and the Council proceeded in the usual constitutional manner to carry out the instructions contained in the above Recommendations, and Counsel was asked to make the alterations in the Regulations and By-laws necessary to carry out the wishes of the Representative Meeting. Counsel pointed out, however, that if constituencies were to have the power to initiate a referendum all resolutions of the Representative Body, even of trivial character, would have to be submitted *after they were passed and before they could be acted on* to all the Divisions of the Association, even the most distant Colonial ones, and time would have to be given them to consider and decide whether or not they should demand a Referendum.

5. It was pointed out that this would mean the hanging up of every resolution of the Representative Meeting for fully six months in every case before action could be taken, and if a Referendum were demanded another six months would elapse before the resolution could become effective.

6. This opinion of Counsel was reported to the Annual Representative Meeting of 1912, and the following Resolution was carried:—

40. That in view of Counsel's opinion on the question of giving effect, in the Regulations of the Association, to the report on the Referendum and Postal Vote, approved by the Annual Representative Meeting, 1911, Minute 330 of the Annual Representative Meeting, 1910, be referred to the Council for further consideration and report as soon as possible.

7. In accordance with this instruction the Council has further considered the matter and reports as follows:—

It agrees with Counsel,

(a) That as regards the present Referendum (as provided for in the Regulations and By-laws) it is impracticable to give the power to constituencies to demand it because such a provision would involve constant and useless delays.

(b) That there is no need to distinguish between matters which have or have not been before Divisions, as in any case the Council in taking a Referendum would only be justified in doing so if it were not satisfied that the decisions of the Representative Body or General Meeting truly reflected the opinion of the Association, and the Representative Body or General Meeting could not reasonably object to the Council conscientiously exercising its constitutional duties.

8. It is at present the duty of the Council to obtain the opinion of the Members,

(a) for information and instruction before action is taken by the Representative Meeting or General Meeting,

(b) on appeal (*i. e.*, the Referendum, vide Art. 32) against a decision of the Representative Meeting or General Meeting which the Council does not consider truly reflects the opinion of the Association.

9. In either case the vote might be taken,

(a) by Members assembled in meetings of Constituencies or Divisions, or

(b) by a postal vote.

10. The Council is convinced that the Imperial character of the Association with its members spread over the whole globe makes a real plebiscite of the members, if not quite impossible, certainly absolutely useless. Not only for the reason of delay above mentioned, but because questions of common interest to the whole Empire seldom arise and nearly all matters with which the Association has to deal affect only a limited portion of the King's dominions.

11. The Council is of opinion that the present machinery is adequate for dealing with matters affecting the whole Association, whether it be the obtaining of information or instruction to be submitted to a General or Representative Meeting in order that it may give a vote, or the taking of a Referendum in accordance with Article 32.

12. The difficulty is that matters of such wide interest seldom arise. The majority of the questions with which the Association has to deal affect portions of the Empire only, and usually only the United Kingdom or some part of it. If appeals to members are to be of any real use they must be capable of being made to those only who have some direct interest in the result.

13. The Council accordingly drew up the following questions

for consideration and submitted them to Counsel with a request for his opinion:—

* *Minute 570.*—(a) The possibility, under the Regulations of the Association as now in force or to be altered for the purpose, of empowering the Council to make an appeal by means of a postal vote to a portion only of the Members of the Association in cases where it is felt that the question or questions upon which the vote is to be given affect only that portion of the Members of the Association appealed to.

(b) Whether the decision obtained by means of a postal vote from a portion only of the Members of the Association in the manner above prescribed could be made binding on such portion of Members.

(c) If so, whether instead of a fixed majority being laid down the Council could be given a discretionary power to make the decision binding on such portion of Members if, in its opinion, the majority in support justified it in doing so.

To this the following reply was received:—

OPINION OF MR. T. R. COLQUHOUN DILL.

As to the matters mentioned in Resolution 88* of the Organisation Committee (8th April, 1913) I am of opinion as follows:—

(a) (b) The existing Regulations do not contemplate or authorise an appeal by the Council by means of a Postal Vote to a portion of the Members, and if such an appeal were actually made the decision obtained thereby would not be binding on the Members appealed to.

Leaving out of sight decisions of the Central Ethical Committee (or the Council) on matters of professional conduct, the only way in which under the existing Regulations the members generally can be bound is by Resolution of the Representative Body or of a General Meeting of the Association (approved by the Council or on a Referendum). And it is outside the intention of the present Regulations that even the Representative Body should legislate specially and differentially for certain Divisions or Branches or groups of Divisions or Branches or for separate areas.

The proposals before me are therefore a new departure.

I have no doubt that the Regulations could be altered so as to enable such appeals to be made and to declare that decisions so obtained should bind the members appealed to.

The intention would, I presume, be that as to the members affected; these decisions would override any decision of the Representative Body or even of a General Meeting on the same subject, and would be enforceable (in the last resort) by expulsion. I need hardly point out that the alterations in the existing Regulations which would be required for these purposes would be extensive and far reaching.

I presume that the questions as to which such appeals might be made would be questions of general policy; it might however be considered whether they should be limited to any defined classes of question. The important point of the areas which may be dealt with separately in this way appears to have been already decided, viz., England, Wales, Scotland and Ireland.

(c) In my opinion it would be possible to give to the Council the discretionary power suggested; or possibly the discretion might be made exercisable only if some specified majority were obtained.

T. R. COLQUHOUN DILL.

Lincoln's Inn.
8th May, 1913.

14. From this it appears that "decisions of the Association" at present apply to the whole Association, but Counsel thinks that the suggested alterations could be made.

15. In view of the history of this matter, and of the latest opinion of Counsel, the Council now places the whole subject before the Representative Body in order to ascertain in what way, if any, it desires the Regulations of the Association to be altered.

In the opinion of the Council the following are the questions on which the opinion of the Association should be

* *Minute 570* of the Council is the same as *Minute 88* of the Organisation Committee.

ascertained. When this has been done the desired alteration of the Regulations can be proceeded with immediately:—

(a) Whether the Council should be empowered to take a referendum on any decision of the Representative Body either in the way suggested in Article 32 (that is by Meetings of the Divisions) or by a postal vote, and should also be empowered to extend the referendum or postal vote if it thought fit to the whole profession.

(b) Whether the Council should have power to consider whether the question to be submitted was one which affected one or more parts of the Kingdom, namely, England, Scotland, Ireland, Wales, or some Dominion, and to take the vote in any one or more of these parts as it thought fit.

(c) Whether in taking a referendum or postal vote on any question the Council should have power to decide what majority of the votes received would justify it in making the result of the vote binding upon the Members of the Association in those parts of the country consulted.

(d) Whether the Representative Body should be empowered, when passing any Resolution, to say to what portion of the Kingdom the Resolution should apply. In this case, if the Council decided to take a referendum or postal vote it would consult only that portion of the country designated by the Representative Body.

(e) Whether it should be competent for the Representative Body to discuss and come to decisions upon matters of policy which are only to affect and to be made applicable to certain portions of the Association.

(f) Whether the Division shall be empowered to lay down in their Rules that the opinion of the Division may be ascertained either by a postal vote of its members or by a vote in meeting as the Division shall decide.

16. There are certain other points bearing on this question on which the Council thinks it advisable to obtain the opinion of the Representative Body. At present a resolution carried in accordance with Article 31 becomes a decision of the Association and it becomes the duty of the Council to carry such resolution into effect (Article 34) unless the matter is upset on a Referendum (Article 32). It is held that it would be advisable in many cases to take a vote before carrying out a policy of importance. Would it be possible for the Representative Body under the present regulations (or could they be altered to make it legal?) and if so, does the Representative Body deem it desirable after having decided that a certain procedure or policy was advisable, that it should be able to declare that its decision on the matter should not be considered "the policy of the Association", and should be ignored by the Council until the result of a postal vote of the Association or profession to be taken forthwith by the Council, either on the whole question or on some portion thereof, had been ascertained? Would it be possible and desirable for the Representative Body at the same time to lay down the majority, either of voters or of the whole members of the Association or profession, it considered necessary for the carrying of the question?

17. Further, would it be possible for the policy laid down in a specific resolution to be declared to be the policy of the Association in certain areas, and not in others, or in areas where a certain majority was reached—not in others, and if it were possible to have such local policy, would it be possible to have all matters connected with it kept local to the area affected? And if these questions are answered in the affirmative does the Representative Body deem it desirable to make provision for such a course of action.

NOTE.—The matter may be made clearer by consideration of the following example:—

England, Scotland and Wales objected to the medical arrangements of the National Insurance Act and it became the policy of the British Medical Association to oppose their introduction in these areas. But so bad were the conditions of practice in Ireland that the Irish profession preferred the Insurance Act to them, and it became the policy of the Association to advocate the extension of Medical Benefit to Ireland. Now, if the Representative Body had wanted to refer this matter to the Divisions for information and instruction, or if the Council had wanted to take a Referendum in accordance with Article 32 on the matter, the Irish question could not have been referred solely to Ireland, which alone was capable of judging, but India, Australia, Canada and New Zealand, etc., would equally have had their voice in the matter.

British Medical Association.

Annual Representative Meeting, Brighton, 1913.

NOTICES OF MOTION FORWARDED BY DIVISIONS

SINCE THE PUBLICATION OF THE PROVISIONAL AGENDA FOR THE ANNUAL REPRESENTATIVE MEETING AT BRIGHTON.*

Question of Advisability of Recognition by Association of some Existing Medical Trade Union.

1. **Amendment**, by CHELSEA, to Motion contained in Item 15 of Provisional Agenda, as to a union of medical practitioners:

That the question be considered by the Association as to the advisability or otherwise of recognizing some existing medical trade union as a necessary adjunct to the defence forces of the profession, and of handing over to it such work as it may be inexpedient for the Association to undertake; or, in the event of a federation of medical trade unions being in existence, of recognizing such federation for work of this class.

Question of Payment of Expenses of Representatives.

2. **Amendment**, by SCOTTISH DIVISION, to Recommendation of Council contained in Item 21 of Provisional Agenda:

That the time has arrived when the Representative Body should seriously consider the advisability of raising the annual subscription in order to meet *inter alia* the out-of-pocket expenses of Representatives at Representative Meetings as well as their travelling expenses.

3. **Amendment**, by NORTHAMPTONSHIRE, to Recommendation of Council contained in Item 21 of Provisional Agenda:

That Divisions be allowed to pay their Representatives out-of-pocket expenses other than travelling expenses.

Policy of Association in relation to National Insurance Act.

4. **Amendment**, by GLASGOW CENTRAL, to Motion contained in Item 41 of Provisional Agenda, as to approval of Remainder of Annual Report of Council under heading "(H) State Sickness Insurance":

That, in order to preserve union in the Association, to secure co-ordination of Local Medical Committees, and to promote harmonious working within the profession, Minute 45 of the Special Representative Meeting, January, 1913, be rescinded, and that the policy of the Association in relation to the National Insurance Act, 1911, be based on Minute 48 of the same Meeting.

[Minute 45 of S. R. M. of January, 1913, referred to.

Resolved (one dissentient):

That this Meeting records its emphatic protest against the discreditable methods adopted by the Government whereby a position of urgency was created under which many practitioners, finding themselves threatened with financial ruin, were compelled to give unwilling service under the National Insurance Act, on terms which this Meeting considers to be derogatory to the profession and against the public interest.

Minute 48 of S. R. M. of January, 1913, referred to:

Resolved: That the Council be instructed (a) to take all necessary steps to watch and protect the interests of the profession under the National Insurance Act; (b) to take any opportunity that may be afforded for placing the representatives of the Association on the Advisory and Insurance Committees; (c) to obtain statutory recognition of Local Medical Committees in every Insurance area;

* The Provisional Agenda of the Annual Representative Meeting, Brighton, will be found in the BRITISH MEDICAL JOURNAL SUPPLEMENT of May 10th, 1913.

(d) to collect information as to defects in the Act and Regulations and to take all possible opportunities of remedying them.]

Central Insurance Defence Fund.

5. **Amendment**, by CAMBRIDGE AND HUNTINGDON, to Motion contained in Item 41 of Provisional Agenda, as to approval of Remainder of Annual Report of Council under heading "(H) State Sickness Insurance":

That, in connexion with the question of the future of the Central Insurance Defence Fund, referred to in paragraph 141 of the Annual Report of Council, unless the Council is prepared to enforce payment of money guaranteed to the Fund, a complete statement of the receipts, expenditure, and outstanding liabilities of the Fund ought to be published immediately with a view to the early closure of that Fund, and that a Special National Fund should be instituted for the purposes outlined in paragraph 152 (a), (b), (c), and (d) of the Annual Report of Council.

6. **Amendment**, by WEST SUFFOLK, to Motion contained in Item 41 of Provisional Agenda, as to approval of Remainder of Annual Report of Council under heading "(H) State Sickness Insurance":

That, unless the Council is prepared to enforce payment of money guaranteed to the Central Insurance Defence Fund, a complete statement of the receipts, expenditure, and outstanding liabilities of the Fund should be published immediately with a view to the early closure of that Fund.

*Existing Regulations under National Insurance Act:
Methods of the Government.*

7. **Rider**, by COVENTRY, to Motion contained in Item 41 of Provisional Agenda, as to approval of Remainder of Annual Report of Council under heading "(H) State Sickness Insurance":

This Representative Meeting wishes most emphatically to reaffirm its opinion as to the nature and probable effects of the existing Regulations under the Insurance Act and to protest against the methods of coercion applied by the Government to an honourable profession.

*Question of Formation of a Welsh Committee of the
Association.*

8. **Rider**, by CARDIFF, to Motion contained in Item 61 of Provisional Agenda, as to Report of the Committee of the Metropolitan Counties Branch appointed to consider the reform of the present constitution of the Association, arising out of paragraph (c) of that Report, as to Scottish and Irish Committees:

That a Welsh Committee be established having similar powers and duties assigned to it as to the Scottish and Irish Committees.

ALFRED COX,
Medical Secretary.

June 18th, 1913.

Meetings of Branches and Divisions.

[The proceedings of the Divisions and Branches of the Association relating to Scientific and Clinical Medicine, when reported by the Honorary Secretaries, are published in the body of the JOURNAL.]

EAST ANGLIAN BRANCH:
WEST SUFFOLK DIVISION.

A MEETING of the West Suffolk Division was held at Bury St. Edmunds on June 12th. Dr. Wood presided, and seven other members were present. Dr. FORDYCE (Cambridge), who has recently been elected a member of Council, was also present by invitation.

Executive Committee.—The following with the office-bearers were elected to serve: Drs. Hinnell, Barwell, Bennett, Stiff, Leeming, Trotter, and Ritchie.

Election of Representative.—Dr. Wood was appointed to serve as Representative, vice Mr. Lucas, whose resignation

was accepted with regret; a cordial vote of thanks to him for his services was carried unanimously. The instruction of the Representative was postponed to the next meeting, to be held early in July, when the report of the Council on the reorganization of the Association will be considered.

Guarantee Fund.—After discussion the resolution numbered 6 in the first column of this page was passed for submission to the Representative Meeting.

Scale of Fees.—Dr. BARWELL raised the question of fees for certificates under the Workmen's Compensation Act, life insurance, and "extra" certificates under the Insurance Act. After discussion the Executive Committee was instructed to issue a leaflet to all practitioners in the Division stating the fees fixed by it or by previous meetings of the Division.

Insurance Act Certificates.—Dr. FORDYCE informed the meeting that a practitioner is obliged to give to an insured person or his accredited representative certificates in conformity with the rules of the society to which he belongs, and that the nature of the complaint must be stated if these rules so require. A hearty vote of thanks to Dr. Fordyce for his presence at the meeting was carried unanimously, and the meeting adjourned.

GLASGOW AND WEST OF SCOTLAND BRANCH:
GLASGOW CENTRAL DIVISION.

Presentation to Dr. John Adams.

ON Tuesday, June 10th, Dr. John Adams, the Representative of the Division, was entertained at dinner in the Grosvenor Restaurant, Glasgow, by a number of members of the Division. Dr. ROBERT JARDINE presided, and there were thirty-eight present. On behalf of those present and of thirty-three other members, the CHAIRMAN presented Dr. Adams with a fitted suit case, and expressed to him the appreciation by the members of the valuable services he had given, not only to the Division with which he is directly associated, but also to the larger body of medical men whom he represents on various committees connected with the Association and with the profession. All recognized the zeal, foresight, and consistency he had always displayed in regard to questions of interest to medical men, and even the minority in the Division could not but admire his consistent attitude towards the Insurance Act and the intimate knowledge which he had been at pains to acquire of its details, a knowledge which made his appointment to the Chairmanship of the Glasgow Burgh Medical Committee particularly appropriate. Dr. ADAMS thanked all those who had been associated with the presentation for the kindness shown to him and for the expression of esteem even from those who sometimes differed from him on matters of medical politics. After all, the British Medical Association was a democratic body, and he would urge all to take a keener interest in its affairs.

METROPOLITAN COUNTIES BRANCH:
HAMPSTEAD DIVISION.

THE annual meeting of the Hampstead Division was held on June 6th, when Mr. WARE was in the chair, and eleven members were present.

Election of Officers and Committee.—The following were elected:

Chairman.—Dr. A. W. K. Picard.

Vice-Chairman.—Dr. E. L. Pritchard.

Honorary Secretary.—Mr. Sidney Boyd.

Representative on Branch Council.—Dr. Oakley.

Members of Executive Committee.—Mr. C. W. Allen, Dr. J. Ford Anderson, Dr. E. Alice Brown, Dr. G. P. Coldstream, Dr. A. W. George, Mr. W. Howard, Mr. W. E. Hills, Dr. H. Oppenheimer, Dr. E. A. Seymour, Dr. G. E. Shuttleworth, Mr. E. E. Ware.

Annual Report of Council.

The annual report of the Council (SUPPLEMENT, May 3rd) was considered, and the following points were decided:

Organization.—Recommendations A, D, and E were approved. The Representative was given a free hand in respect of B, and it was decided to leave C to the Branches concerned. Recommendation F was approved after some discussion on the question of raising the annual

subscription; it was decided to give the Representative a free hand in this matter. Recommendation G was approved with the exception of paragraph (4), which it was agreed should be opposed, as also Recommendation H. With regard to Recommendation J it was agreed that paragraph (c), By-law 16, and paragraph (c), By-law 18, should be opposed. In connexion with paragraph (b), relating to the insertion of Warning Notices, it was agreed that the Division adhere to its former statement.

State Sickness Insurance.—Some discussion took place concerning medical representation on District Insurance Committees, and it was proposed by Dr. DOBBIE, seconded by Mr. WARE, and carried unanimously, that in Section (d) the words "the same as" be altered to "not less than." Paragraph 126 was discussed, and it was agreed that the principle of placing resident medical officers of hospitals and other institutions on the panel for the purpose of attending the hospital staffs was strongly to be condemned. Paragraph 129 was also discussed, and it was agreed that parturient women in receipt of maternity benefit should be regarded as eligible for treatment in voluntary hospitals, and that part of the benefit should be given to the hospital. With regard to the proposed special fund considered in paragraph 151, the Executive Committee suggested that the word "panel" be inserted before "member" in paragraph (c). This was carried unanimously.

Public Health and Poor Law.—The recommendations of the Council concerning appointments of M.O.H. and S.M.O. were approved.

KINGSTON-ON-THAMES DIVISION.

Election of Officers.—At a meeting of the Kingston-on-Thames Division, held at the Surbiton Cottage Hospital on June 13th, the following were elected as officers for the ensuing year:

Chairman.—Dr. H. COOPER.
Vice-Chairman.—Dr. A. E. EVANS.
Honorary Secretary and Treasurer.—Dr. N. C. CARVER.
Representative at Representative Meeting.—Dr. HOLBERTON.
Representatives on Branch Council.—Dr. A. E. EVANS, Dr. GOODMAN.
Other Members of Executive Committee.—Drs. COLEMAN, MOWLL, GALE, TAYLOR, CRAN, SULLY, MAXWELL, HYDE.

ST. PANCRAS AND ISLINGTON DIVISION.

The annual meeting of the St. Pancras and Islington Division was held on June 13th, the Chairman, Dr. R. M. BEATON, presiding.

Annual Report.

Dr. J. WILSON, the Honorary Secretary, presented the annual report, in which it was stated that the membership of the Division was 210 as compared with 233 last year. The 23 resignations included a number of migratory members—those attached to hospital staffs and others. Owing to the Insurance Act more meetings than usual were held during the year, and these were well attended. The report mentioned the self-sacrificing devotion to duty of the Chairman, Dr. Beaton, who, in addition to much other work on behalf of the Association, had attended every meeting of the Division and its committees except one.

The report was adopted, on the motion of Dr. B. G. MORISON, who heartily endorsed Dr. Wilson's reference to Dr. Beaton.

Election of Officers and Committee.

Dr. P. W. RATRAY was unanimously elected Chairman of the Division for the ensuing year, on the motion of Dr. BEATON, seconded by Dr. WILSON.

When the appointment of other officers was about to be considered, Dr. SHERRY raised the question that in the nominations of the Executive Committee doctors on the panel were inadequately represented.

The CHAIRMAN explained that the question of panel or non-panel doctor had never entered into the minds of the Executive Committee in drawing up the list of nominations. It was open for other names to be put forward by any one present.

Dr. SHERRY intimated that he was not prepared with any names at the moment, and the adjournment of the meeting was moved in order that other nominations might be made. This proposal, however, was negatived.

Several members spoke in favour of representation being afforded those members of the Division who are on the panel, and offered to resign in favour of other nominees. Ultimately the matter was adjusted in an amicable spirit.

The following elections were made:

Vice-Chairman.—Dr. ALEXANDER BROWN.
Honorary Secretary and Treasurer.—Dr. J. WILSON.
Representatives on Representative Body.—Dr. BEATON and Dr. MORISON.
Representatives on Branch Council.—Dr. G. F. GLINN and Dr. A. O. WICKHAM.
Executive Committee.—Drs. ALEXANDER ADAM, J. CRABB, J. N. GLAISTER, JOHN MATHESON, S. ROWNTREE, D. THURSTON, N. H. TURNER, and BRANSBY YULE.

DRS. BEATON and MORISON stated that they could accept the position of Representatives only if they were appointed as Representatives and not as delegates.

This was agreed to.

The Pledge.

The Executive Committee reported with reference to an instruction from the Division to take the necessary steps for the expulsion from membership of the Association of those members who, having signed the undertaking and pledge, joined the panel before January 18th. The Committee recommended that no further action be taken.

Dr. SHERRY supported the recommendation; to persist in a policy of expulsion, whether the Council endorsed it or not, would only engender ill feeling.

Dr. MORISON asked Dr. Sherry to include in his motion the words "in view of the fact that a vote of censure has been passed," in order that the action already taken by the Division might remain on record.

Dr. GORDON urged that the stigma on the twenty-six gentlemen referred to in the resolution should be removed by the rescission of the vote of censure.

Dr. FOURACRE hoped the advice of the executive would not be taken. Personally, he did not wish to remain in an Association with men who had been publicly declared guilty of conduct detrimental to the interests of the profession. The Association would be split if they were not removed.

Dr. GORDON said that in some cases it would have been suicide for the men to have kept off the panel until January 18th. He was one of the culprits, and he declared that if the resolution of condemnation were not rescinded he did not care to remain a member of the Association.

Ultimately the resolution that no action be taken was carried. The words suggested by Dr. Morison were also approved.

Finance.

It was stated that the Division had collected for administrative and defensive purposes £834, of which £437 remained in the bank. A meeting of the whole profession in the Division would be called to decide what to do with the money.

Valedictory Address by Retiring President.

Dr. BEATON, in acknowledging the various references to his services as Chairman and Representative, said that the Division had given him a splendid opportunity of helping the profession for which he thanked them, and that he was proud that the men of the Division had during the fight over the medical clauses of the Natural Insurance Act shown such a fine example and had stood together in a way that few constituencies had.

His year of office which closed that night was indeed a wonderful one in the history of the medical profession. They had entered upon it with high hopes, believing that a united profession would win reasonable conditions of service for itself, with freedom to act for the public weal. But they had failed. A little more determination, a little more readiness to suffer, and they would have won. Now the profession was diligently searching for a Jonah to throw overboard. Defective organization of the British Medical Association was very likely the Jonah it would send to the whales. Men were slow to accept blame. Yet slowly but surely this fact was being forced upon the mind of the profession, that the men, not the organization, were the cause of the failure. If they were to win in the fights of the future they must learn to suffer and be strong. One

of the results of the failure to get reasonable conditions of service was that in London and elsewhere many doctors on the panel had more patients than they could care for efficiently. This lack of efficient treatment had led to a loud outcry from the heads of the friendly societies, who accused the doctors of treating the insurance patients like paupers, of taking their money but not being willing to work for it. Moreover, these societies were not alone in complaining. The Rev. Silvester Horne, M.P. for Ipswich, who had been a staunch defender of the Insurance Act, allowed this criticism in the *London Signal*, which he controlled: "Those who come into contact very largely with insured persons are quite certain, notwithstanding all political assurances to the contrary, that medical benefit is neither satisfactory in character nor adequate in quantity. There are too few doctors by far, and many of those on the panel are such that if insured persons had really free choice they would never think of going to them." In corroboration of these complaints the following cases, supplied by a doctor in the Division who as examining doctor for a large commercial undertaking had special facilities for seeing how the insured persons were being treated by the panel doctors, were submitted for careful consideration: (1) A case of wound of the finger in December last. Treated at a London hospital with boric fomentations. In January a granulating wound of the subcutaneous tissues existed, and the panel doctor ordered bread poultices. The wound smelt of vinegar fermentation; necrosis of the phalanx supervened, notwithstanding which the bread poultices were continued. The man returned to the hospital, was still on the society's fund, and had lost a considerable part of the finger. (2) Bruised finger, effusion of blood under nail. Lead lotion ordered; finger became infected; lead lotion continued. (3) Inguinal hernia. Lead lotion ordered to be applied. Hernia not discovered. (4) A case of severe infected tonsillitis. Temperature 103°. Patient went to bed for eight days, and got up from bed three times to see the panel doctor, returning each time to bed. Full particulars of the above cases and others from the same source could be given if required. Surely it was not too much to say that conduct such as this was derogatory to the profession and against the best interest of the insured. The doctor was overworked, grew weary of his work and dissatisfied with himself. The patient distrusted the panel doctor, and suffered more than was necessary; many of them went to a non-panel doctor and so had to pay twice. An effective free choice of doctor would speedily put an end to this unfortunate state of things, and it was not beyond the bounds of possibility that a union of dissatisfied patients and dissatisfied doctors might force this important concession from the present Government.

A vote of thanks to the Chairman, proposed by Dr. ALEXANDER BROWN and seconded by Dr. MORISON, concluded the proceedings.

SOUTH MIDDLESEX DIVISION.

THE annual general meeting of this Division was held at Twickenham on June 4th, when Dr. C. C. SCOTT was in the chair.

Report by Honorary Secretary.—Dr. H. M. COOPER, the Honorary Secretary, reported that during the first year of the Division twelve meetings had been held with a good average attendance. The question of juvenile clubs, family clubs, uninsured adults, and temporary residents were discussed. The Honorary Secretary was directed to obtain the approval of the Association for the resolutions passed and then circularize all the practitioners in the Division.

Election of Officers.—The following officers were elected:

Chairman.—Dr. M. F. COCK (Asbford).
Vice-Chairman.—Dr. C. C. SCOTT (St. Margaret's).
Honorary Secretary and Treasurer.—Dr. H. M. COOPER (Hampton).
Representative for Representative Meetings.—Dr. R. LANGDON-DOWN (Hampton Wick).
Deputy Representative for Representative Meetings.—Dr. W. H. HASLETT, C.C. (Sunbury).
Representative on Branch Council.—Dr. W. H. HASLETT.
Executive Committee.—Drs. CAMPS, CHRISTIAN, DENDLE, GÜNTHER, P. LANGDON-DOWN, MARSHALL, MURPHY, STILL, BURSTAL, and VALÉRIE.

NORTHERN COUNTIES OF SCOTLAND BRANCH: BANFF, ELGIN, AND NAIRN DIVISION.

THE annual meeting of this Division was held at Gray's Hospital, Elgin, on June 7th, when a representative number of members were present.

Election of Officers.

The following office-bearers and committees were appointed:

Chairman.—Dr. BRODIE CRUIKSHANK, Nairn.
Vice-Chairman.—Dr. SELLAR, Aberlour.
Secretary and Treasurer.—Dr. J. A. STEPHEN, Elgin.
Representative in Representative Meeting.—Dr. B. CRUIKSHANK.
Substitute in Representative Meeting.—Dr. J. A. STEPHEN.
Representatives on Branch Council.—Drs. JOHNS and RENNIE.
Executive Committee; Ordinary Members.—Drs. ADAMS (Forres), ALEXANDER, CAMPBELL, FERGUSON, sen., TAYLOR (Keith), and WILSON.
Ethical Committee.—Chairman and Honorary Secretary, with Drs. FERGUSON, ALEXANDER, CAMPBELL, BRANDER, and TAYLOR (Elgin).

Annual Report.

The annual report submitted by the Executive Committee was adopted, as was also the financial statement showing a deficit of 4s. 6d.

Annual Representative Meeting.

The annual report of Council was considered, and the Division expressed its gratification at the decision of Council to make the changes in the detailed organization of the Association as affecting Scotland detailed in paragraph 172 of the annual report. The business for the Annual Representative Meeting was discussed, and the Representative instructed to support Motions 13, 21, 25, 27, 36, 38, and 43.

Seamen's National Insurance Society.

Considerable discussion took place with regard to this society, thereafter Dr. MURRAY moved:

That no medical man in this Division accept an appointment under the Seamen's National Insurance Society, and if any one has accepted, that he be requested to withdraw.

This was seconded by Dr. McHARDY and unanimously agreed to, and the Honorary Secretary was instructed to write to those who were known to have accepted such appointments requesting them to resign such. It was pointed out that under the scheme of this society there was not absolute free choice of doctor (in actual practice), and that the tariff was less than the minimum tariff proposed by the Association.

Dr. MURRAY then moved, and Dr. GALLOWAY seconded, that the following clause be included in any amending bill:

That the Seamen's National Insurance Society be put on the same basis as other approved societies as regards medical treatment, giving absolute free choice of doctor, and that no tariff be agreed to which is less than that accepted by the British Medical Association.

This was unanimously agreed to.

The Honorary Secretary was instructed to write to the members of Parliament for the Division asking their support, and the Representative was instructed to bring the matter up at the Annual Representative Meeting. During the discussion the opinion was expressed that the Association might have adopted a stronger attitude in regard to this society and should have done more by central action rather than have left it to individual Divisions to fight.

Dependants on Insured Persons.

An expression of opinion on attendance on wives and children of insured persons or club members having been asked for, it was after discussion agreed by a majority of 7 to 4 not to attend such on contract terms except under the Insurance Act, and the question of men having already accepted such was referred to the Ethical Committee.

SOUTH-EASTERN BRANCH: DARTFORD DIVISION.

THE annual meeting of the Dartford Division was held on June 12th, when Dr. R. H. STEEN, Vice-Chairman of the Division, presided.

Reorganization of Divisions.—It was resolved to agree to the proposed new Divisions.

Annual Report of Executive.—The HONORARY SECRETARY read the report, which showed an increase of three in the membership of the Division. The greater part of the meetings had been occupied with insurance work, but in spite of the efforts of the Division no material concessions had been obtained. District Insurance Committees had been formed for Gravesend, Erith, and Dartford, and two medical men appointed to each. A scientific paper had been read by Mr. J. F. O'Malley, of the Evelina Hospital (published in the BRITISH MEDICAL JOURNAL, April 26th, p. 699), and was much appreciated. Ethical and general rules had been adopted by the Division. The financial report showed that the Division had been threatened with a considerable deficit, owing to the inability of the Branch Council to give the usual grant, but, thanks to the decision of the Division to call for a levy of 5s. per member, the Divisional funds showed a slight balance.

Election of Officers.—The following were unanimously elected:

Chairman.—J. Crombie, M.B., Sidcup.
Vice-Chairman.—W. K. Glover, M.B., Dartford.
Honorary Secretary and Treasurer.—H. Chisholm Will, Sidcup.
Representative to Branch Council.—H. C. Will.
Representative to Annual Meeting.—H. C. Will.
Executive Council.—Drs. C. Firth, Greenway, Hartley, E. Knight, Murison, Pounds, Repton, Shute, H. Smith, Steen, and Walker.

Address.

A most interesting address was given by Dr. COURTENAY LORD, member of the Council, on the position of affairs. He dealt with the position in the country generally, then in the county of Kent, then that in Gillingham, and finally the position as regards the Association. Dr. Lord showed that the condition under all these heads was very unsatisfactory, and advocated many reforms which would place the Association in a stronger position, and enable it to do its work more efficiently. On the motion of Dr. STEEN, seconded by Dr. WILL, a hearty vote of thanks was accorded to Dr. Lord.

Agenda of Representative Meeting.—On the motion of Dr. SHUTE, seconded by Dr. HARTLEY, it was unanimously resolved to defer the consideration of the reports to the Annual Representative Meeting until the next meeting, to be held at Dartford on July 10th.

Votes of Thanks.—On the motion of Dr. HUGH SMITH a hearty vote of thanks was unanimously accorded to Dr. Chas. Firth (Gravesend) for the able manner in which he had acted as Chairman during the year. On the motion of Dr. SHUTE, a vote of thanks was accorded to Dr. H. Chisholm Will for his services as Honorary Secretary of the Division.

REIGATE DIVISION.

The annual meeting of this Division was held at Reigate on June 9th, at 4 p.m., when eleven members were present.

Election of Officers.—The officers for the ensuing year were elected as follows:

Chairman.—Dr. Alec Walters.
Vice-Chairman and Representative at Annual Meeting.—Dr. Spencer Palmer.
Representatives on Branch Council.—Dr. C. Caldecott.
Honorary Secretary and Treasurer.—Dr. Gayner.
Executive Committee.—Drs. Alec Walters, Spencer Palmer, Hewetson, Price, Clarke, Porter, Ogle, Gayner, Blackler, Prince, Mackenzie, Thornton, Caldecott, and Drake.

Annual Report.—The annual report by the SECRETARY was read.

Instructions to Representative.—The annual report of Council and the agenda of the Annual Representative Meeting to be held at Brighton were discussed, and Dr. Spencer Palmer was instructed to support any scheme that will tend to diminish the expenses of the JOURNAL. Mr. HENRY SEWILL spoke at some length on this subject, and said that the editorial matter and contributions might be very much cut down and condensed, thereby saving a considerable sum of money each year. Instructions were also given negating the raising of the subscription and the forming of a new company. By a small majority it was passed:

That it is desirable that the Association shall, if possible, be formed into a trade union.

The State registration of nurses also received the approval of those present.

Vote of Thanks.—A hearty vote of thanks to the Chairman for so kindly undertaking the duties for the second year in succession, and for his past devoted and invaluable work in the interests of the profession, closed the proceedings.

SOUTH-WESTERN BRANCH.

The seventy-fourth annual meeting of the South-Western Branch was held at Torquay on June 11th. Dr. HARDWICK (Newquay), the retiring President, took the chair, and forty-six members were present.

Annual Report.

The annual report presented to the meeting stated that the number of members of the Branch on April 30th, 1913, was 564, the same number as on April 30th, 1912. The matters that had chiefly occupied the attention of the Branch during the year related to the Insurance Act and contract practice, and the report enumerated various subjects which would call for serious attention in the immediate future. The first was the relation of Divisions and Branches to Local Medical Committees. As the latter did not and could not have ethical rules or disciplinary powers, it was desirable that points concerning uninsured persons should be referred to the Divisions of the Association, and one of the problems which confronted the Association was to provide machinery by which decisions of the majority of the practitioners on the panel, or of Local Medical Committees, could be brought into relation with the organization of the Association, so that its ethical rules and disciplinary powers could be utilized. The second point mentioned was the scheme of the Metropolitan Counties Branch for enlarging the powers of Branch councils, and enabling them to co-ordinate the work of the various Divisions in their areas. It was undesirable that three or four Divisions in a single insurance area should deal directly with an Insurance Committee notwithstanding the existence of a County Medical Committee. The necessary alterations in the areas of Divisions and Branches would in the case of the South-Western Branch be very slight. The third point was the regulation of contract midwifery attendance. The amount allowed for medical men in respect of maternity benefit under the Insurance Act was 15s., and arrangements would have to be made whereby the amount between this and the proper fee for a medical man was provided. This was a matter for Local Medical Committees. With regard to the considerable number of uninsured persons now getting midwives to attend ordinary confinements and sending for medical men only in cases of difficulty, it was incumbent on each Division to insist that nursing associations which employ midwives should make provision for the proper remuneration of medical men called in to assist midwives; co-ordination to provide for parallel fees was essential. The fourth point was the necessity for action on the part of the profession to combat the strenuous efforts of the friendly societies to depart from the agreement as to attendance on aged and infirm persons reached at the conference in 1911. The fifth point was as to the attendance on uninsured persons, women, and juveniles; as it was probable that before long the Act would be amended so that these persons also would become insured it would damage the profession in its future negotiations were the rates fixed below what had been agreed upon for insured persons. The financial statement showed a small balance in hand, which however might be absorbed in whole or in part by an outstanding account. The report went on to call attention to the great increase in the amount of secretarial work and the Branch Council asked the meeting to recognize the appointment of an assistant secretary. Further, it was becoming obvious that Local Medical Committees would in future need the services of a paid clerk, and it was pointed out that one county in England had, by arranging for the deduction of 1d. from every insured person's capitation fee, raised a sum of £500 a year to provide an office with a paid secretary and clerk for the Local Committee.

The report was approved.

Next Annual Meeting.—It was arranged that the annual meeting of the Branch for 1914 should be held in Plymouth, and Dr. W. L. Woolcombe of Plymouth was chosen President-elect. Dr. WOOLCOMBE returned thanks.

Re-election of Honorary Secretary and Treasurer.—On the motion of Dr. DONBIVAND, seconded by Dr. DEAS, Mr. Russell Coombe was re-elected Honorary Secretary and Treasurer. In returning thanks, he said that it would be a great advantage if the Branch Council had more power to co-ordinate the four Divisions in which the Medical Committees of the county of Devon worked.

President's Address.

Dr. Hardwick vacated the chair, which was taken by Dr. G. YOUNG EALES (Torquay), who moved a vote of thanks to Dr. Hardwick, which was seconded by Dr. DEAS and carried.

Dr. EALES then delivered his presidential address, in which he spoke of the great advances which had been made by Torquay during the last twenty-seven years. The corporation, which had done so much for the town, had now a scheme for establishing medicated baths and swimming baths. In the baths there would be a ladies' section containing seven baths and sixteen dressing-rooms, and a gentlemen's section containing six baths and thirteen dressing-rooms. It was estimated that it would be possible to treat over 100 cases a day without undue pressure. The system would supply a long-felt want, as patients who had visited the northern watering places during the summer months would be able to continue the treatment during the winter months in a mild and salubrious climate.

Vote of Thanks.—A vote of thanks was passed to Dr. Eales on the motion of Dr. DAVY, who expressed the hope that Torquay and its new baths undertaking would prosper.

Annual Dinner.—The annual dinner was held at the Torbay Hotel, where, among the invited guests, were the Mayor of Torquay, Colonel C. R. Burn, M.P., and the Archdeacon of Totnes.

YORKSHIRE BRANCH :

HALIFAX DIVISION.

At a meeting of the Division on June 11th Dr. CROSSLEY WRIGHT was in the chair, and twenty-six other members were present.

Presentation to the late Honorary Secretary.

The CHAIRMAN presented Dr. J. F. Hodgson, the late Honorary Secretary of the Division, with a silver teapot, on behalf of the members of the Division, and spoke in eulogistic terms of the capable manner in which Dr. Hodgson had conducted the arduous duties which had fallen to his lot.

Annual Report.

The annual report and balance sheet of the Division was read, and adopted, on the motion of Dr. PRIESTLEY LEECH, seconded by Dr. DORA MANN.

Election of Officers.

The following were elected officers of the Division for next year :

Chairman.—Dr. A. Drury.

Vice-Chairman.—Dr. P. V. Fry.

Representative for Representative Meeting.—Dr. A. Drury.

Representative on Branch Council.—Dr. A. Drury.

Honorary Secretary.—Dr. J. F. Gill.

Executive Committee.—Drs. T. W. Arnison, J. F. Hodgson, G. G. Lawson, Priestley Leech, J. Marshall, Armitage Morton, J. Sproull, and P. K. Steele.

Representative's Fund.

On the motion of Dr. MACAULAY, seconded by Dr. STEELE, it was decided to appoint a treasurer for the Representative's Fund, the method of collecting at meetings being unpleasant and unsatisfactory. On the motion of Dr. MACAULAY, seconded by Dr. PRIESTLEY LEECH, Dr. J. F. Hodgson was appointed Treasurer to the fund, and it was agreed, on the motion of Drs. HUNT and BRANSON, that there be an annual levy of 2s. 6d. a head on all members, to be increased if circumstances required.

Model Rules for Ethical Procedure.

At the last meeting of the Division these rules were adopted, with the exception of Rules 12 and 22. After letters from the Medical Secretary had been read, it was decided, on the motion of Dr. MACAULAY, seconded by Dr. PRIESTLEY LEECH, to adopt Rules 12 and 22 also.

Contract Practice Outside the Insurance Act.

The following motion, of which fourteen days' notice had been given in accordance with Rule 2 of the Rules for Ethical Procedure, was moved by Dr. MACAULAY, seconded by Dr. PRIESTLEY LEECH, and, after much discussion, was carried by 24 votes to 3 :

That this Division does not approve of contract practice outside the Insurance Act.

The case of a member then came up for consideration. The member in question had been allowed by the Executive Committee to resume a club appointment which he held previous to the passing of the Insurance Act. The meeting refused to ratify the action of the Executive Committee, and the member agreed to resign his appointment, although this will mean a considerable pecuniary loss to him, rather than oppose the wishes of the Division.

Medical Certificates for School Children.

It was announced that all the medical practitioners in the Calder Valley were refusing to give such certificates unless paid for by the Education Authority, as it is contended that they are given entirely for the benefit of that authority in order that it may not lose grants. A suggestion to make this action general throughout the Division was negatived.

Next Meeting of Division.

On the motion of Dr. DRURY, seconded by Dr. MORTON, it was decided to hold the next meeting of the Division on or about July 9th to consider the report and supplementary report of the Council, and the provisional agenda for the Annual Representative Meeting.

School Medical Officers for the Halifax Education Committee.

As the present whole-time school medical officer to the Halifax Education Committee is about to take up other duties, it was thought that the question of appointing part-time medical officers might suitably be brought forward, and it was decided to ask the Education Authority to receive a deputation from the Division on the subject.

Vote of Thanks to Retiring Chairman.

On the motion of Dr. DRURY, seconded by Dr. PRIESTLEY LEECH, a cordial vote of thanks was passed to the retiring chairman, Dr. J. Crossley Wright.

Association Notices.

ELECTION OF MEMBERS OF COUNCIL BY GROUPED REPRESENTATIVES.

NOTICE is hereby given that Nominations for candidates for election of Members of Council by grouped Representatives for the year 1913-14 will be received by the Medical Secretary up to the end of the first hour of the proceedings of the Annual Representative Meeting, on Monday, July 21st, 1913. Each Nomination must be on the prescribed form, copies of which will be forwarded by the Medical Secretary on application.

Separate forms have been prepared: (I) for Nomination by a Division (through its Representative), and (II) for Nomination by a Representative of a Constituency included in the Group, and these applying are requested to state for which purpose the form is desired.

The voting papers will be issued at the Representative Meeting to each Representative or Deputy Representative of a Constituency in the United Kingdom in attendance at the Meeting.

By order of the Council.

ALFRED COX.

Medical Secretary.

June 19th, 1913.

CHANGE OF BOUNDARIES OF DIVISIONS AND BRANCHES.

THE following change has been made in accordance with the Articles and By-laws of the Association, and takes effect from the date of publication of this notice :

Alteration of Areas of Cambridge and Huntingdon and West Suffolk Divisions and of Cambridge and Huntingdon and East Anglian Branches.

That the Urban District of Newmarket be transferred from the area of the Cambridge and Huntingdon Division of the Cambridge and Huntingdon Branch to the area of the West Suffolk Division of the East Anglian Branch, and that the boundaries of these four bodies respectively be adjusted accordingly.

Representation in Representative Body.—No necessity for modification of the present grouping of the Cambridge and Huntingdon and Isle of Ely, and West Suffolk, Divisions arises from the carrying into effect of the above change.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—Dr. Duncan Davidson, Honorary Secretary (15, Priory Row, Coventry), gives notice that a special meeting of the Coventry Division will be held at the Coventry Hospital on Tuesday, July 1st, at 8.30 p.m. Agenda: Recommendation of Ethical Committee; consideration of SUPPLEMENT of June 21st; letters from Medical Secretary; recommendations of Local Medical Committee, if any.

BORDER COUNTIES BRANCH.—Dr. Livingston, Secretary, gives notice that the annual meeting of the Branch will be held in the Town and County Hotel, Carlisle, on Friday, June 27th.

CAMBRIDGE AND HUNTINGDON BRANCH.—Dr. G. S. Haynes, Honorary Secretary, gives notice that the sixty-ninth annual meeting of the Branch will be held in Cambridge on Wednesday, July 16th. President-elect, Joseph Griffiths, M.A., M.D., M.C., F.R.C.S.

DORSET AND WEST HANTS BRANCH.—Dr. Frank Fowler, Honorary Secretary (29, Poole Road, Bournemouth), gives notice that the summer meeting will be held at the Town Hall, Wareham, on Wednesday, July 9th, at 3.30 p.m. Dr. Charles March will read a paper, *A Problem in Diagnosis*. Any members having cases or short papers they would be willing to read are requested to communicate with the Honorary Secretary. Luncheon will be arranged at the Red Lion Hotel at 1.30; price 2s. 6d. The Rev. Canon Blackett has kindly promised to show members the churches and wall of the town after luncheon. Drs. Courtenay and Bell invite members to tea after the meeting.

EAST ANGLIAN BRANCH.—Dr. B. H. Nicholson, Honorary Secretary (East Lodge, Colchester), gives notice that the annual meeting of the East Anglian Branch will be held at Ipswich on Thursday, July 10th. Members wishing to read papers, etc., should communicate with Dr. Nicholson.

EAST YORK AND NORTH LINCOLN BRANCH.—Dr. Edward Turton, Honorary Secretary (1, Albion Street, Hull), gives notice that the annual meeting of the East York and North Lincoln Branch will be held at Beverley on Friday, June 27th, at 4 p.m. Business: (1) Report of Branch Council. (2) Treasurer's Financial Statement. (3) Election of President-elect, Vice-President, and Honorary Secretary and Treasurer. (4) Address by the new President, Dr. J. Mitchell Wilson. (5) Any other business proper to annual meetings of the Branch.

EDINBURGH BRANCH.—Dr. Michael Dewar and Mr. E. Scott Carmichael, Honorary Secretaries (24, Lauriston Place), give notice that the annual meeting of the Edinburgh Branch will be held in the Royal College of Physicians' Hall, Queen Street, on Thursday, June 26th, at 4 p.m.

EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION.—Dr. M. J. Oliver, Honorary Secretary (St. Boswells), gives notice that the annual meeting of the Division will be held in the Railway Hotel, Newtown St. Boswells, on Friday, June 27th, at 3 o'clock p.m., for the election of officers, the consideration of the annual report of the Executive Committee and financial statement; the discussion of various matters concerning the Insurance Act, including certificates, duties of Medical Service Subcommittee, expenses of Local Medical Committees, payment for services to temporary residents, and for instructing the Representative on the Representative Body.

METROPOLITAN COUNTIES BRANCH.—Drs. W. Griffith and R. E. Crosse (Honorary Secretaries) give notice that the annual general meeting of the Branch will be held at 429, Strand, W.C., on Tuesday, July 1st, at 4 p.m. The business will include a report as to the election of new officers, and the annual reports of Council and of representatives of the Branch on the Central Council. On the motion to adopt Model Ethical Rules for Branches, Dr. F. J. Smith gives notice that he will propose an alteration to the Model Ethical Rules by substituting the words "British Medical Association" for the words "Medical Profession" in Rule 1. President's Address: The Profession and the Public. [The Model Ethical Rules are printed in the SUPPLEMENTS of September 21st and 28th, 1912, pages 325 and 350.]

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—Dr. A. G. Southcombe, Honorary Secretary, gives notice that the

adjourned annual general meeting will be held in Balfour Hall, Dunstan Street, Kingsland Road, on Wednesday, July 9th, at 3.30 p.m. The chief items of business before the meeting will be: (1) Report of Central Council (SUPPLEMENT, May 3rd). (2) Agenda for Representative Meeting (SUPPLEMENT, May 10th). (3) Report of Council upon reorganization of the Association (SUPPLEMENT, June 21st). (4) Supplementary Agenda for Representative Meeting (SUPPLEMENT, June 21st and July 5th); members are especially desired to preserve those SUPPLEMENTS and bring them to the meeting. (5) Instructions to Representatives. (6) Poor Law medical appointments—(a) Dr. Major Greenwood will call attention to the position in (a) Shoreditch and (b) Bethnal Green, and move a resolution; (ii) consideration of appointment of a deputation to the (c) Hackney Union Guardians. (7) The Chairman will report the results of the appeal and levy.

METROPOLITAN COUNTIES BRANCH: WANDSWORTH DIVISION.—Dr. Hugh McD. Parrott, Honorary Secretary, gives notice that the annual meeting of the Wandsworth Division will take place on Thursday, July 10th, at 3.15, at Stanley's Restaurant, 235, Lavender Hill, Clapham Junction. Members of the Wimbledon Division are invited to attend at 4 p.m.

MIDLAND BRANCH: LEICESTER AND RUTLAND DIVISION.—Dr. R. Wallace Henry, Honorary Secretary (6, Market Street, Leicester) gives notice that a meeting of the Division will be held in the Council Chamber, Hinckley, on Friday, June 27th, at 4 o'clock, when there will be a discussion on local industrial diseases, in which Drs. Jenkins, Garratt, Young, Horron Davies, Johnston, and Sevestre intend to take part. Dr. Sessions Barrett has kindly invited members attending the meeting to tea, at 3.30 o'clock, at Appleton House, and would be glad if those who intend to be present would communicate with him.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—Dr. J. Munro Moir, Honorary Secretary (4, Ardross Terrace, Inverness), gives notice that the annual meeting of this Branch will be held at the Highland Hotel, Strathpeffer Spa, on Friday, June 27th, at 11.30 a.m.

NORTH OF ENGLAND BRANCH: NORTH NORTHUMBERLAND DIVISION.—Dr. R. B. Robson, Honorary Secretary, gives notice that the annual meeting of the North Northumberland Division will be held at the Alwick Infirmary on Thursday, June 26th, at 3.30 p.m. Business: Election of officers, mileage question, etc.

SOUTHERN BRANCH.—Dr. James Green, Honorary Secretary (Brandon House, Mile End, Portsmouth), gives notice that the fortieth annual meeting will be held at the Institute, Shanklin, Isle of Wight, on Thursday, July 3rd, at 1.30 p.m., Dr. F. W. Jollye, President, in the chair. Agenda: Election of officers for 1913-14, annual report of Council, balance sheet, general business. An address will be delivered by Dr. J. Cowper, of Shanklin, the President for the ensuing year. Dr. Cowper invites members of the Branch to luncheon at Daishe's Hotel at 2.15 p.m., and to a garden and tennis party, to which ladies are also invited, at 4 o'clock. The Arthur Webster Memorial Hospital and the Scio Hospital can be visited during the afternoon. Those members who wish to play golf are invited to do so by the Shanklin and Sandown Golf Club, and, if possible, a match will be arranged between the club and the medical visitors. Intending players will please communicate with Dr. Cowper not later than June 27th. Those gentlemen who intend to accept the President's hospitality will oblige by sending word to that effect to Dr. G. Benington Wood, Newlands, Sandown, Isle of Wight, not later than June 28th.

STAFFORDSHIRE BRANCH.—Dr. Harold Hartley, Honorary General Secretary (Basford, Stoke-on-Trent), gives notice that the fortieth annual meeting of the Branch will be held at the Victoria Hotel, Wolverhampton, on Thursday, June 26th, at 5.25 p.m., when an address will be delivered by the President-elect, Mr. W. F. Cholmeley, F.R.C.S. The Agenda: Report of the Council and the financial statement will be presented; officers for the ensuing year (President-elect, Secretary and Treasurer) will be elected, and the place of holding the next annual meeting decided.

YORKSHIRE BRANCH.—Dr. Adolph Bronner, Honorary Secretary (33, Manor Row, Bradford), gives notice that the annual meeting of the Yorkshire Branch will be held at the Clayton Hospital, Wakefield, on June 25th, for the election of Vice-President, Secretary, and Treasurer. Members intending to read papers, make any communications, propose new members, or show cases or specimens are requested to notify the Honorary Secretary at once. The annual dinner will take place at the Bull Hotel, at 6.30 p.m.

A cricket match has been arranged in connexion with the Annual Meeting, on Saturday, July 26th—The Profession v. Brighton College. Play will commence at 11.30 on the College Ground. Any gentlemen wishing to play are requested to send their names as soon as possible to Mr. Geoffrey Bate, 8, Patmeira Avenue Mansions, Hove. In the afternoon the Head Master (the Rev. W. R. Dawson) and Mrs. Dawson will be glad to entertain members and their friends to tea, and the college will be open for inspection.

ELECTION OF COUNCIL, SESSION 1913-14.

BRANCHES IN THE UNITED KINGDOM.

| Malaya and Hong Kong and China Branches.. .. . | Dr. J. MITFORD ATKINSON. |

CENTRAL COUNCIL ELECTION, 1913-14.

ANALYSIS OF VOTING.

THERE were three contests in the election of the Central Council, these taking place in the South-Eastern, Lancashire and Cheshire, and Metropolitan Counties Branches respectively. The transferable vote was again employed in these elections, and it is of interest to note that this method of voting has been adopted and applied by the Insurance Commissioners for England for the election of medical representatives to serve on insurance committees, and will again be used at the end of this month in the election of representatives of insured persons.

Under the system of the transferable vote the elector has one vote which he records by placing the figure 1 against the name of his favourite. The transferability of the vote is secured by permitting the elector to mark the name of his second choice with the figure 2, his third choice with the figure 3, and so on. The elector's vote may then be transferred to his second choice when his first choice does not require it for his own election, and to later choices in due sequence where necessary. In these elections it appeared that many of the electors thought that they would benefit their first choice by recording a preference for him alone. This is not the case. The vote is retained for the elector's first choice so long as he can make effective use of it, and it is only passed to the second choice when it can be no longer of any benefit to the first preference.

The South-Eastern Branch Election.

In the South-Eastern Branch there were four candidates for one seat, and the votes recorded were as follows:

| | | | | | |
|------------|-----|-----|-----|-----|--------------------|
| | | | | | First Preferences. |
| Mr. Lord | ... | ... | ... | ... | 198 |
| Dr. Scott | ... | ... | ... | ... | 177 |
| Dr. Benham | ... | ... | ... | ... | 81 |
| Dr. Heggs | ... | ... | ... | ... | 70 |
| Total ... | | | | | 526 |

Mr. Lord, although at the head of the poll, did not receive an absolute majority of all the votes cast, and could not on the first count be declared elected. In accordance with the principle of the second ballot, the candidates lowest on the poll—Drs. Benham and Heggs—were excluded from the contest, and their votes transferred to the second preferences of their supporters. The votes of both were transferred in one operation because the total of these two candidates amounted only to 151, which was less than the number of votes polled by Dr. Scott, the candidate next highest on the poll. It was found that Mr. Lord had been marked as next preference on 58 papers and Dr. Scott on 50, whilst on 43 the electors had shown no preference either for Mr. Lord or for Dr. Scott. The result of the transfer was as follows:

| | | | | | |
|-----------|-----|-----|---|----|--------------|
| | | | | | Total Votes. |
| Mr. Lord | ... | 198 | + | 58 | = 256 |
| Dr. Scott | ... | 177 | + | 50 | = 227 |

The former was accordingly declared elected.

The Lancashire and Cheshire Branch.

In the Lancashire and Cheshire Branch there were three candidates for two seats. The first preferences recorded were:

| | | | | | |
|------------|-----|-----|-----|-----|-----|
| Dr. Helme | ... | ... | ... | ... | 498 |
| Mr. Larkin | ... | ... | ... | ... | 281 |
| Dr. Brown | ... | ... | ... | ... | 56 |
| Total ... | | | | | 835 |

As there were two candidates to be elected, any candidate receiving over a third of all the votes was sure of election. The "quota" or number of votes necessary for election was therefore a third of 835 plus 1 vote—that is, 279 votes. As both Dr. Helme and Mr. Larkin had received more than this number they were declared elected, and no transfer of votes was necessary.

The Metropolitan Counties Branch.

In the Metropolitan Counties Branch election there were six candidates for four seats. The first preferences were as follows:

| | | | | | |
|----------------------|-----|-----|-----|-----|-------|
| Dr. F. J. Smith | ... | ... | ... | ... | 353 |
| Dr. Charles Buttar | ... | ... | ... | ... | 259 |
| Dr. Greenwood | ... | ... | ... | ... | 179 |
| Dr. M. G. Biggs | ... | ... | ... | ... | 101 |
| Dr. B. G. Morison | ... | ... | ... | ... | 96 |
| Mr. Montgomery-Smith | ... | ... | ... | ... | 73 |
| Total ... | | | | | 1,061 |

In this case, where there were four vacancies, the "quota" necessary for election was one more than a fifth of the votes recorded, or 213. Both Dr. Smith and Dr. Buttar had obtained more than this number of votes, and were accordingly declared elected. Their excess votes were distributed in strict proportion to the second preferences shown on their papers. The method by which this was done may be explained by giving the details of the transfer of Dr. Smith's surplus, which amounted to 140 votes. All Dr. Smith's papers were re-examined and sorted accordingly to the next available preferences. Dr. Buttar, being already elected, was not an "available" preference, and any papers on which Dr. Smith was marked 1 and Dr. Buttar 2 were carried on to the third preference. The total number of papers showing preferences was 319, divided as follows: Dr. Biggs 44, Dr. Greenwood 177, Mr. Montgomery-Smith 64, and Dr. Morison 34. From these 319 transferable papers Dr. Smith could spare 140, and the returning officer calculated by means of rule-of-three sums the numbers he could spare for Dr. Biggs, Dr. Greenwood, Mr. Montgomery-Smith, and Dr. Morison respectively. The numbers were 19, 78, 28, and 15. These were added to the previous totals of the candidates named, and the state of the poll became:

| | | | | | |
|----------------------|-----|-----|-----|---------------|-------|
| Dr. F. J. Smith | ... | ... | ... | 213 (elected) | |
| Dr. Charles Buttar | ... | ... | ... | 259 (elected) | |
| Dr. Greenwood | ... | ... | ... | 257 | |
| Dr. M. G. Biggs | ... | ... | ... | 120 | |
| Dr. B. G. Morison | ... | ... | ... | 111 | |
| Mr. Montgomery-Smith | ... | ... | ... | 101 | |
| Total ... | | | | | 1,061 |

As Dr. Greenwood's total now exceeded the quota, he was declared elected. The surpluses of Drs. Buttar and Greenwood were next transferred in succession, with the following result:

| | | | | | |
|----------------------|-----|-----|-----|---------------|-------|
| Dr. F. J. Smith | ... | ... | ... | 213 (elected) | |
| Dr. Charles Buttar | ... | ... | ... | 213 (elected) | |
| Dr. Greenwood | ... | ... | ... | 213 (elected) | |
| Mr. Montgomery-Smith | ... | ... | ... | 154 | |
| Dr. Biggs | ... | ... | ... | 140 | |
| Dr. Morison | ... | ... | ... | 128 | |
| Total ... | | | | | 1,061 |

Three candidates had been elected, and one seat remained to be filled. The principle of the second ballot was again acted upon, and the lowest candidate was excluded from the poll, his votes being transferred to the next preferences indicated on his papers. In this transfer Mr. Montgomery-Smith, who had improved his position materially at each count, obtained the largest number of votes and was elected to the last seat, the final state of the poll being as follows:

| | | | | | |
|-------------------------|-----|-----|-----|---------------|-------|
| Dr. Smith | ... | ... | ... | 213 (elected) | |
| Dr. Buttar | ... | ... | ... | 213 (elected) | |
| Dr. Greenwood | ... | ... | ... | 213 (elected) | |
| Mr. Montgomery-Smith | ... | ... | ... | 185 (elected) | |
| Dr. M. G. Biggs | ... | ... | ... | 157 | |
| Non-transferable papers | ... | ... | ... | 80 | |
| Total ... | | | | | 1,061 |

In the Metropolitan Counties Branch there were eight spoil papers, owing to electors marking candidates with crosses instead of with figures. Further, in this as in the other two elections, many electors did not make full use of their right of marking preferences. In the distribution of Dr. Morison's papers no less than eighty were non-transferable, owing to an insufficient number of preferences being marked. It should be realized that a second preference cannot possibly injure the position of the candidate to whom the first preference has been given, and there would then be less hesitation in placing all the candidates in the order of preference.

National Insurance.

LOCAL MEDICAL COMMITTEES.

COUNTY OF CHESHIRE.

THE fourteenth meeting of this Committee was held on June 15th at the Altrincham Hospital, Dr. GARSTANG being in the chair and eighteen members present.

Dr. HODGSON, on behalf of the Drug Subcommittee, reported that the new agreed tariff had been submitted in proof for revision; that the Committee had decided that the ordinary doses of the drugs should be printed; and that an effort should be made to influence the Commissioners to agree to the inclusion in the list of certain dressings (ribbon gauzes, etc., and sterile packets of gauze) and of pessaries and trusses. Certain vaccines and serums and a number of drugs and splints suggested by the Committee had already been accepted.

Treatment of Absentees.

The following reply of the Commissioners to the letter addressed to them on this subject (printed in SUPPLEMENT of May 3rd, p. 400) was received:

National Health Insurance Commission (England),
Buckingham Gate, London, S.W.,
May 13th, 1913.

Sir,—In reply to your letter of the 26th of April, I am directed by the National Health Insurance Commission (England) to thank you for your suggestions regarding the scale of fees to be adopted for calculating the remuneration of practitioners in respect of the medical attendance of temporary residents, and for the various observations submitted by you regarding the scheme for dealing with such cases outlined in Memorandum 161/I.C.

I am at the same time to inform you that the case value to be transferred will be the entire case value for the period on which the calculations are based, and that the amount transferred will not be a portion thereof proportionate to the length of absence from home.

The terms of your letter as to the amount to be transferred being a fraction of the case value proportionate to the length of the absence appear to involve some confusion as to the precise nature of "case value" itself. "Case value," while necessarily ascertained by the experience of working over a fixed period, such as a year, does not itself involve any consideration of duration of time. It is the average amount payable for a "case" of illness of average length and severity during the year. If, adopting your own illustration, it is assumed that ten persons are ill during the year out of a total number of thirty, their illnesses will vary from slight ailments involving only one or two attendances to serious or even chronic diseases, and the case value of 21s. will be the average remuneration payable for the entire treatment, representing an average of all the actual cases of varying severity in the area. Inasmuch, therefore, as "case value" represents average remuneration for the entire treatment of an average case of sickness, it is not measured by duration of treatment.

Further, as the persons temporarily removing from the area in question are presumably of the same average standard of health as those in the area, it may be assumed that the cases of illness which take place among them are of the same average severity as those which are treated in the area. Thus, the whole case value, being the amount payable for a case of average severity in the area, will be required to defray the cost of treatment of cases occurring outside the area, and the fact that the illness of an individual temporary resident may be below the average of severity will be counterbalanced by the fact that other temporary residents will have illnesses of more than average severity, the total averaging to the same degree of severity as that represented by "case value."

I am further to point out that the payment of 7s. referred to in the Memorandum to which you allude is the capitation fee payable in respect of each insured person for whom the doctor is at risk during the whole year. In addition, however, to those insured persons who actually fall ill, and in respect of whom case value is transferred, there will normally be other insured persons who remove without falling ill and in respect of whom the doctor is not at risk during the period of their absence. The case value transferred in the case of one person is, under average conditions, precisely equivalent to the amount which would have been transferred, if under the old arrangements all persons removing for however short a period,

had given notice whether well or ill and had been temporarily removed from the list of their doctor. Persons who move temporarily will not under the new system be taken off the doctor's list and they will thus continue to be credited with remuneration in respect of them in circumstances in which under the previous system they would have ceased to receive remuneration. Such adjustment in the doctors' lists are expressly referred to in the explanatory Memorandum as to Medical Benefit cited by you; and the transfer of case value merely effects the adjustment which would have been necessary on the old system if notice had been properly given.

With regard to the fact that in the case of insured persons temporarily absent from home a case value will be transferred, whereas in the case of persons constantly travelling the capitation fee will be paid into the central fund, I am to point out that in the former case the payment will be made only where the insured person actually receives medical treatment; whereas in the latter case the capitation fee will be paid into the central fund whether or not the insured person is ill, thus securing that the equivalent of a case value will be available in respect of each constant traveller who receives treatment during the year.—I am, Sir, Your obedient Servant,

E. MACGOWAN.

Dr. Lionel J. Picton,
Saddler's Close, Holmes Chapel, Cheshire.

The Committee was not of the opinion that the reply removed the objections of the profession to the proposed deduction from the promised capitation fee. The Commissioners' argument would only be sound if temporary absentees were never ill in their own home area. The Committee accordingly resolved to notify the Joint Commission and the Insurance Committee that in the county of Cheshire green vouchers would not be accepted, and temporary absentees would only be treated as private patients.

Membership of District Insurance Committees.

It was reported that a doctor who had been introduced to a district by the friendly societies to oppose the local profession in treating the uninsured was nominated by the District Insurance Committee upon one of its subcommittees as a co-opted member. Dr. Hodgson had fought this matter at the County Insurance Committee, and induced the latter to decline to confirm the minutes of the District Committee. The Commissioners had been consulted, and took the view that the District Committee had the right to make any appointment it chose; therein they traverse the by-laws which they have approved, which subject the decisions of District Committees to the County Committee. The County Medical Committee approved the action of the County Insurance Committee.

Conference at Brighton.

Drs. Garstang (Chairman) and Picton (Honorary Secretary) were appointed to represent this Committee at the Conference of Representatives of Local Medical Committees at Brighton.

Co-ordination of Committee with British Medical Association Divisions.

It was decided that for the present matters raising questions of professional discipline in connexion with arrangements for contract practice amongst uninsured persons should be referred to the appropriate Division of the British Medical Association.

BIRKENHEAD.

Temporary Residents.

THE following questions were recently submitted by the Honorary Secretary of the Committee, Dr. J. Ratchiff-Gaylard, to the Insurance Commission for England:

1. If after the words "temporary resident" (page 5, line 6,* Memo. 161/I.C.) the words "receiving treatment" may be correctly read in?
2. If the Central Fund to be constituted will be made up of individual "case value" sums in respect of temporary residents *actually receiving treatment*; or of all temporary residents who have obtained vouchers whether used or not?
3. If such "case value" amounts will be calculated upon the period actually spent outside the area of permanent residence?

* In SUPPLEMENT, April 19th, p. 334, par. 5, line 7.

The Commissioners replied to the questions on June 2nd. The answer to question 1 was as follows:

In paragraph 5, line 6, the words "receiving treatment" would correctly be read in after the words "temporary residents" as implied in paragraphs 7 and 12.

The answer to question 2 was as follows:

The Central Fund will not include "case value" in respect of temporary residents who have obtained vouchers, but have not used them for the purpose of obtaining treatment.

The answer to question 3 was to the same effect as that given in reply to the Local Medical Committee of the County of Cheshire in the letter from the Commissioners set out in full at page 575.

After the receipt of the reply from the Insurance Commissioners, the following resolution was adopted by the Birkenhead Local Medical Committee, and forwarded to the Insurance Commission for England and to the Local Insurance Committee, with the statement that the practitioners on the panel in Birkenhead would only attend insured persons presenting form Med. 28 (b)—the green voucher—as private patients; and, further, would not permit any deduction being made from their capitation payments for the purpose of constituting a Central Fund.

Resolution.—The practitioners on the Birkenhead panel, being strongly of opinion that the schemes embodied in Memos. 159 and 161/I.C. is not an equitable one, decline to be parties to any agreement, or arrangements for the treatment of temporary residents under the conditions therein disclosed.

They are further of opinion that such proposed arrangements, if carried into effect, would constitute a breach of the agreements already signed.

LANCASHIRE COUNTY.

A Local Medical Committee for the County of Lancaster has been constituted, and the names of the representatives are as follows:

| District. | Name. | Address. |
|-----------|------------------------------|---------------------------------------|
| 1 | Dr. Bowman ... | Ulverston. |
| 2 | Dr. F. H. Oldham ... | Morecambe (Chairman). |
| 3 | Dr. J. Harrison ... | Garstang. |
| 4 | Dr. W. H. Buckley ... | Poniton-le-Fylde. |
| 5 | Dr. Petyt ... | Longton. |
| 6 | Dr. G. E. Orme ... | Clitheroe. |
| 7 | Dr. H. Henry ... | Blackburn. |
| 8 | Dr. James Craig ... | Church, near Blackburn. |
| 9 | Dr. A. E. Normington ... | Nelson. |
| 10 | Dr. Duckworth ... | Croston. |
| 11 | Dr. W. J. Leighton ... | Chorley. |
| 12 | Dr. T. W. Heywood ... | Darwin. |
| 13 | Dr. Stewart ... | Haslingden. |
| 14 | Dr. T. Campbell ... | Platt Bridge, near Wigan (Secretary). |
| 15 | Dr. J. C. Eames ... | Stoneclough, Manchester. |
| 16 | Dr. D. P. M. Farquharson ... | Radcliffe. |
| 17 | Dr. J. A. Ashcroft ... | Littleborough. |
| 18 | Dr. M. Hutton ... | Oldham. |
| 19 | Dr. S. M. Green ... | Prescot. |
| 20 | Dr. Murray ... | Penketh (Warrington). |
| 21 | Dr. M. J. Halton ... | Leigh. |
| 22 | Dr. E. Higson ... | Swinton. |
| 23 | Dr. M. Mamourian ... | Ashton-nder-Lyne. |
| 24 | Dr. H. H. Hitchon ... | Heywood. |
| 25 | Dr. | |

Dr. Helme (Manchester), as direct representative of the profession on the Lancashire Insurance Committee, was elected member of the Committee *ex officio*.

The first meeting of the Committee was held on May 27th, when the following resolutions were carried:

1. The Medical Committee, having carefully considered the whole question of sick certificates in the case of insured persons, is of opinion that it would be seriously detrimental to the interests of the patient and of the public to place upon certificates the nature of the disease.
2. The Medical Committee is of opinion that the requirements of the certificate for continued incapacity might be satisfied by the doctor initialling the pay sheet.
3. The Medical Committee has no objection to medical officers of public institutions being placed upon the panel for the treatment of officials whilst resident in the institution, provided that the appointment be made by the honorary staff, but strongly disapproves of institutions receiving the capitation grant in respect of such officials, as such moneys should be paid to the appointed officer.

Statement of Nature of Disease upon Certificates.

On Thursday, May 29th, the Medical Committee met a deputation from the Lancashire Insurance Committee to consider the question of stating the nature of the illness on certificates.

The resolutions quoted above were handed to the deputation, and after some discussion the Medical Committee as a compromise submitted the following form of certificate as acceptable to the medical profession of Lancashire:

I certify that I have this day examined . . . and that ^{he}/_{she} is incapable of following ^{his}/_{her} usual employment by reason of sickness not, in my opinion, an industrial disease, and not caused by ^{his}/_{her} misconduct.

Signed.....

Date

BRADFORD.

The payment of the sums due to doctors on the Bradford panel in respect of those insured persons who had chosen a doctor, up to April 14th, was made on May 29th.

Allocation.—There has been no allotment of insured persons who have not chosen a doctor. The Local Insurance Committee and the Local Medical Committee agreed that doctors on the panel would attend any unallotted insured person who presented an unsigned card, but that no doctor need accept such a case if more than half a mile from his house, unless he should be the nearest panel doctor. The Committee undertook to do everything in its power, by advertisement and otherwise, to get the unallotted to choose a doctor. The doctors are to be paid for the unallotted in proportion to the number each has on his list, and in the event of a distribution of unallotted persons they are to be distributed in the same proportion.

Transfers.—It has also been arranged that, in the event of an allotted person removing from the address at which he resided when his card was signed to a residence more than one mile from his doctor's residence, the insured person and the doctor will agree whether or not the said insured person is to remain on the doctor's list or be transferred to another doctor in the district to which he has gone. This arrangement has proved advantageous both to doctors and insured.

Temporary Residents.—The Bradford Local Medical Committee approved of the scale of fees for temporary residents, but strongly disapproved of the method by which it was suggested to raise the central fund.

WEST SUFFOLK.

The sixth meeting of the West Suffolk Local Medical Committee was held at Bury St. Edmunds on June 12th.

Temporary Residents.—Letters from the State Sickness Insurance Committee, advising refusal to accept the arrangements proposed in Memos. 159 and 161/I.C., were read and considered. The Committee decided unanimously to follow this advice, and the Secretary was instructed to send the notices supplied by the British Medical Association announcing this decision to the Commissioners and to the County Insurance Committee. The Chairman and Secretary were requested to draw up a notice explaining the situation and announcing their decision, and to send a copy to every practitioner on the panel.

Conference of Local Medical Committees' Representatives.—A letter from the Executive Committee of the Annual Meeting of the British Medical Association at Brighton inviting Representatives to this conference was read, and the invitation was cordially accepted. Drs. Wood and Batt were appointed to serve.

Proposed Deputation to Commissioners.—A letter from the Commissioners expressing their willingness to meet a deputation from the Local Medical Committee was received. It was decided, however, that as the representations now being made by the State Sickness Insurance Committee covered all the ground which the deputation was to discuss, the need for it no longer existed. The Secretary was instructed to inform the Commissioners accordingly, and to thank them for their letter.

ESSEX.

The seventh general meeting of the Essex Local Medical Committee was held on June 12th, when the resignations of Drs. Margaret Rorke, H. Bonnefin, and Clarence Wright were accepted with regret (Dr. Bernard Scott resigned May 8th). The vacancies caused had been filled

by elections in No. 1 and No. 2 District Medical Committees, and Drs. J. O. Goldie, P. R. Blake, John Brown, and C. E. Brunton were welcomed by the Chairman (Dr. Leigh Day).

A Treasurer Committee of three was appointed (Dr. Leigh Day, Dr. J. D. Wells, Dr. Harding H. Tomkins), and secretaries of district medical committees empowered to collect subscriptions for the finance scheme as an alternative to direct payment in order to expedite collection. The Secretary, having had letters complaining of the paucity of information concerning the doings of the Local Medical Committee received by practitioners, wishes to point out that reports have been published (see BRITISH MEDICAL JOURNAL, SUPPLEMENT, March 8th and 22nd, and April 19th); that to circularize individual practitioners funds are indispensable; and that if districts will call meetings and invite local members of Local Medical Committees (as has been done in South-West Essex), information should be available. He again invites letters (address 492, Lee Bridge Road, Leyton, N.E.) on any difficulties from all individual practitioners, which will be analysed and laid before the Local Medical Committee. In this way effect could be given to the desires and opinions of the profession.

The questions of repetition of mixtures, income limit, representation on District Insurance Committees, payment of army contract doctors, and consultation of the Local Medical Committee by the Insurance Committee on all matters of medical benefit, though repeatedly laid before the Insurance Committee, remained unsettled. The drug tariff, with slight additions, was accepted last month. The payment of doctors dispensing in part or wholly for insured persons, amounts and dates of payment for panel work, Memorandums 159 and 161/I.C. were considered, and a letter addressed to the Insurance Committee thereon. The consideration of Memorandums I.C. was referred to the 21 District Medical Committees by circular letter. Resolutions from District Medical Committees concerning consultation of Local Medical Committee, irregular payment of panel doctors at arbitrary dates, inadequate representation on District Insurance Committees, and other matters were discussed, and representations on these subjects forwarded to the Insurance Committee.

An Emergency Committee of three (Drs. Day, Wells, Tomkins) was appointed to act between the monthly general meetings.

An invitation to send two Representatives to the Conference of Local Medical Committees at Brighton on July 24th was responded to by electing Drs. J. D. Wells and Harding H. Tomkins to attend. This conference was the outcome of a letter addressed to the State Sicknes Insurance Committee of the British Medical Association and Organizing Committee early in March by Dr. Harding H. Tomkins, with the consent of a Committee of Medical Unions of East and North-East London, Essex, etc., requesting such a conference with a view to the national organization and consolidation of the entire profession, as it was hoped later to embrace every medico-political society—the British Medical Association included—in one co-ordination of interests, and so utilize the scattered societies, which now tend to disintegrate the power of the profession. Dr. Tomkins will welcome any points desired to be raised if sent before July 1st to 492, Lee Bridge Road, Leyton, N.E.

The Local Medical Committee hopes that all practitioners will take a personal and active interest in matters affecting the profession, and, by attending meetings of the District Medical Committees, secure the passage of resolutions expressing their opinions, which, if sent to the Secretary of the Local Medical Committee, can be collected and analysed so as to embody them in comprehensive resolutions of the Local Medical Committee, which, as opinions of the profession of Essex, will be enhanced in importance and be more likely to have weight with the Insurance Committee and Commissioners.

OXFORD.

A MEETING of the Oxford Local Medical Committee was held in the Town Hall, on June 11th, when Dr. ORMEROD was in the chair, and eight other members were present.

Temporary Residents.—A discussion took place on Memorandum 161 I.C., and after the whole question had been thoroughly debated it was unanimously decided to

instruct the Secretary to sign the draft letter issued from the British Medical Association and send a copy to the Commissioners and the Local Insurance Committee.

Conference at Brighton.—It was also decided to send a representative to the conference at Brighton, and Dr. Rivers-Wilson was elected.

Meeting of Practitioners on the Panel.—At a full meeting of the panel which followed, the above decisions were unanimously agreed to. The panel also decided to ask the Insurance Committee to issue identification cards to all the insured, such cards to be produced by the insured when applying to his doctor for treatment. The pharmacopocia drawn up for the London panel was adopted. It was decided to recommend to the Insurance Committee that at the allocation the residue of the insured who had not selected their doctor should be equally divided amongst every member of the panel, and where any member had as big a list now as he could deal with his share should be dealt with by mutual agreement amongst the members of the panel willing to take them.

BUCKS.

A MEETING of the Bucks Local Medical Committee was held on May 30th at the Royal Bucks Hospital. Dr. BAKER took the chair and fifteen members were present.

Responsibility of Employers.—The ruling of the Committee was asked for in a case in which a mistress had sent for a doctor to attend her servant, who was an insured person, and who knew nothing about the summons. After discussion the following resolution was carried unanimously:

That in a case when the doctor is sent for by the employer, unless at the express wish of the patient, the employer should bear the responsibility for the fee, especially when the message is out of hours.

Model Rules.—It was decided to press for the issue of model rules.

Allocation of Patients.—It was resolved:

That when the clerk to the Insurance Committee has completed the register cards of the persons who have not chosen a doctor, he be requested to divide them into the districts, eighteen in number, corresponding to the suggested panel areas.

The Secretary of the Medical Committee would then communicate with a member of the Committee, requesting him to act as secretary and arrange a meeting of all the practitioners practising in that district for the purpose of allocating these persons.

Temporary Residents.—This matter was discussed and the principle of deducting any sum from the amount agreed upon—namely, 9s. a year—was objected to and the views entertained by the British Medical Association supported.

Chemists' Subcommittee.—Dr. BAKER reported the result of a meeting with the Pharmacists' Committee.

Income Limit.—A discussion took place on the advisability of pressing for the 50s. wage limit instead of waiting for the new committee. It was agreed that facilities should be allowed for any well-to-do persons to make their own arrangements; that doctors should suggest this to them when they brought their tickets to be signed.

KIRKCALDY.

A MEETING of the Kirkcaldy Local Medical Committee was held on June 10th. Dr. C. LESSLIE CURROR was in the chair, and eleven members were present out of a total of fifteen.

Temporary Residents.—It was decided to act on the lines suggested in the letter from the British Medical Association, and the Secretary was instructed to write to the Commissioners and the Insurance Committee, informing them that the profession declined to allow any money to be deducted from the present panel fund for this purpose, and would treat all temporary residents as private patients.

Aged and Disabled Members of Friendly Societies.—A request from the Insurance Committee that the Local Medical Committee should reconsider the terms of 7s. per annum was declined.

Excessive Ordering of Drugs.—The information asked for at the meeting on April 29th was laid before the meeting. After careful consideration it was unanimously agreed that the excess was due to the nature of the prescribing of one practitioner. It was decided to request

the practitioner concerned to be present at a subsequent meeting, when he could have an opportunity of making an explanation. It was also decided to ask the chemist to be present at a joint meeting on the same evening.

INSURANCE NOTES.

TEMPORARY RESIDENTS.

THE following is the form of a draft letter suggested by the State Sickness Insurance Committee for use by Medical Committees in communicating to Local Insurance Committees the objections of the profession to the method of providing payment for medical attendance and treatment of temporary residents set out in Memorandums 159 and 161/I.C.

.....June, 1913.

Sir,

I am instructed by the.....Local Medical Committee to inform you that the Committee has given consideration to the method recently proposed by the Insurance Commissioners in their Memorandums 159 and 161/I.C., for the payment of medical attendance on temporary residents, out of a central pool formed by deductions from the amounts due to the medical practitioners on whose lists the names of these temporary residents normally appear. The.....Local Medical Committee cannot consent to these deductions from the amounts promised to the practitioners in this area for the attendance upon the insured persons on their lists, as such a method appears to be sanctioned neither by the agreements made by practitioners nor by the Regulations.

As in the opinion of the Committee Regulation 22 does not concern temporary residents, and as it has been admitted that the method proposed in that Regulation would be inequitable as applied to temporary residents; and as it is admitted that the method suggested in Memorandums 159 and 161 cannot be enforced without the consent of the members of the medical profession and the chemists concerned, my Committee would urge that the only fair method of dealing with this problem would be by the provision of a Central Fund financed entirely apart from the 8s. 6d. per head now set apart for medical benefit. Until some such provision has been made the.....Local Medical Committee, speaking on behalf of the doctors on the local panel, gives notice that persons holding green vouchers can only be attended as private patients.

I am,

Yours faithfully,

.....
Honorary Secretary,
.....Local Medical Committee.

SUPPLY OF DRUGS TO INSURED PERSONS.

THE report has been issued of the Departmental Committee appointed at the end of February to inquire into the question whether, having regard to the interests of insured persons in obtaining an efficient and rapid supply of drugs, medicines, and appliances, and to the conditions under which these articles were supplied before the passing of the Insurance Act, any alteration is necessary in the conditions laid down by Section 15 (5) (iii) of the Insurance Act. Dr. J. S. Whitaker was the chairman, and the other members were Mr. Walter Davies (National Conference of Friendly Societies and Chairman of the Manchester Insurance Committee), Mr. J. C. Ledlie (Privy Council officer), Sir Claud Schuster, and Dr. Lauriston Shaw.

The Committee examined twenty-five witnesses, and now reports that it would be inadvisable to amend the subsection in the manner suggested so as to permit of arrangements for the dispensing of medicines for insured persons being made with persons other than persons, firms, or bodies corporate entitled to carry on the business of a chemist and druggist under the provisions of the Pharmacy Acts. But should it be deemed desirable that persons who are not qualified under the Pharmacy Acts but have been engaged in business as drug store proprietors should be permitted to enter into arrangements with Insurance Committees for dispensing medicines which do not contain scheduled poisons, the Committee recommends that the amendment of the Insurance Act should be framed not so as to confer a statutory right upon persons who do not at present possess it, but so as to authorize an Insurance Committee to enter into arrangements with persons known

to it to have been bona fide engaged in business as drug store proprietors.

The Committee recommends that the Insurance Act should be so amended as to permit a person, firm, or body corporate, who or which has entered into arrangements with an Insurance Committee for the dispensing of medicines for insured persons, to employ in such dispensing, not necessarily under the supervision of a registered pharmacist, any person who shall have satisfied such conditions as may be prescribed by the Privy Council. These conditions should include a thorough practical knowledge of dispensing, the possession of a sufficient degree of general intelligence and education, and some knowledge of chemistry and of the nature and physical properties of drugs. The Committee further recommends that care should be taken to secure that the dispensing of medicine for the insured by persons who are not registered pharmacists nor specially qualified as dispensers shall in fact be carried out under the direct supervision of registered pharmacists. The Committee is, however, of opinion that it is desirable that steps should be taken to carry into effect, as regards qualified military dispensers and certified assistants to apothecaries under the Apothecaries Act, 1815, the powers conferred on the Council of the Pharmaceutical Society by Subsection (b) of Section 4 of the Poisons and Pharmacy Act, 1908, and that to this end definite proposals should be submitted by the War Office and the Society of Apothecaries to the Pharmaceutical Society.

COMMITTEE OF INQUIRY.

Provisional regulations, dated June 10th, 1913, as to the procedure for inquiries with respect to medical practitioners were issued on June 19th. The provisional regulations are made by the National Health Insurance Joint Committee acting jointly with the Insurance Commissioners and the Welsh Insurance Commissioners. They are designed to carry out the provisions contained in paragraph 54 (Inquiry as to Practitioner) of the Regulations for Medical Benefit issued in December, 1912 (see SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL, December 7th, 1912, p. 635).

The Provisional Regulations provide that the Commissioners shall send to the practitioner a copy of the statement of complaint and a list of the documents proposed to be put in evidence. The practitioner personally or by an agent is authorized to inspect and take copies of any documents. The Commissioners take power to hold an inquiry to ascertain whether the continuance of a practitioner on a panel would be prejudicial to the efficiency of the medical service of the insured, even though no representation to that effect had been made to them. The Committee of Inquiry would be constituted in accordance with the second subparagraph of paragraph 54 of the Regulations for Medical Benefit, and would consist of two medical practitioners and one other person, who must be a barrister-at-law or a solicitor in actual practice.

Appended to the Provisional Regulations are two schedules. The first schedule contains form of notices to the practitioner and to the complainant of the intention to hold inquiry, for intimating to the practitioner the alleged facts and grounds on which the inquiry is based, of notice of inquiry to be sent to the Insurance Committee where it is not the complainant, and of notice to the practitioner of the case for inquiry and of the date appointed for holding it. The second schedule contains rules for procedure at the inquiry. The Committee will have power to hear witness and to adjourn the inquiry from time to time.

LONDON.

It will have been observed that the London Insurance Committee has had under consideration on several occasions various suggestions for improving the conditions under which practitioners willing to do so might give medical attendance to insured persons in London. The matter was referred to a special subcommittee, which included representatives of the medical profession on the Insurance Committee. We understand that this subcommittee has now completed its work, and that its report, which, it is stated, embodies various important modifications in the present conditions, will probably be available for publication in our next issue.

We are informed that there is an impression among members of the medical profession in South London that protests against the discussion of the subject of free choice of doctor contained in the article published in the *BRITISH MEDICAL JOURNAL* of May 24th have been refused publication in the *BRITISH MEDICAL JOURNAL*. We desire to remove this impression. Two letters on the subject were received, and two letters only—one from Dr. J. J. Gorham, which was published in the *SUPPLEMENT* of May 31st, p. 481, and another from Dr. Kennish, Representative of Wandsworth and Wimbledon, which was not published because it was understood to be a private communication. A reply was addressed to Dr. Kennish, but, no doubt owing to an illness from which we regret to hear he has been suffering, the matter was not then cleared up. We desire to say that any communication from doctors who have not joined the panel in London or elsewhere will receive every consideration.

Hackney and Stoke Newington.

At an open meeting of practitioners on the panel resident in the boroughs of Hackney and Stoke Newington, held on June 6th, the following resolution was passed:

That, in the opinion of practitioners on the panel in the boroughs of Hackney and Stoke Newington, we refuse to grant insurance certificates on the first day of illness.

The Chairman, as requested by the meeting, has sent a copy of this resolution to every practitioner on the panel in the boroughs.

THE NATIONAL MEDICAL UNION.

A general meeting of the National Medical Union was held in Manchester on June 4th. The business dealt with included the adoption of rules, and the consideration of some points in the future policy of the Union. In the absence of Mr. G. A. Wright, F.R.C.S. (the President), Mr. W. Coates, C.B., occupied the chair. The Executive Committee's report stated that the membership of the Union continued to grow, and testified to a growing disinclination among men on the panels to continue in the service owing to their conviction of the impossibility of carrying out satisfactory work under the Act. Numbers of letters from different parts of the kingdom have been received in which the writers expressed the hope that they would be able to resign service at an early date, and their intention, in that event, of joining the union. The adoption of the draft rules, prepared by the Executive Committee, was moved from the chair. By the rules, service in any capacity under the Act would be a bar to membership of the National Medical Union. Dr. Trotter, of Huddersfield, moved an amendment to the effect that only those "who accepted service on any panel or list, or in any position of profit to which they have been appointed by any Insurance Act authority" should be excluded from membership. Dr. Blumer (Stafford), Dr. Prebble (Blackburn), and Dr. Taylor (Bradford) spoke in favour of the amendment. Drs. Wheeler Hart, Fairclough, Brassey Brierley and others supported the excluding rules. Dr. Porter, Honorary Secretary of the Edinburgh Medical Guild, said that it comprised a majority of the practitioners in and around that town, and was strongly opposed to the acceptance of work of any character in connexion with the Act. The amendment was lost, and the rules as drafted were adopted. It was resolved that a complete list of members of the union should be printed and circulated among the members; and that as full a list as possible should be compiled of all non-panel practitioners in the kingdom. The Executive Committee was instructed to consider what measures should be taken to inform insured people of the validity of non-panel certificates, and to check the action of many insurance agents throughout the country who were instructing the insured patients that they must go to panel doctors. It was also decided that communications should be sent to all societies of non-service doctors with a view to the affiliation of such bodies with the National Medical Union.

THE POSITION OF WOMEN UNDER THE ACT.

A well attended conference, organized by the Faculty of Insurance (a body representative of approved societies) was held in London on June 14th, the general subject being the position of women under the National Insurance

Act. The proceedings, which were prolonged, related in the main to such subjects as the misuse of the maternity benefit, the propriety of forming separate societies for women, the position of women as visitors and officials under the Act, and the extent, if any, to which there is a tendency among women either definitely to malingering or to remain too long on the sickness list. There was a very considerable variation in the views expressed on these subjects, but in regard to the maternity benefit there seemed to be a general admission that so far the sums granted have been considerably misused and that one factor in this circumstance has been undue delay in paying out the sum authorized. Several speakers held that even when the husband was known to be a worthless person there would be no advantage in administering the benefit through a society. The allotted sum should be paid to the mother promptly in cash. In regard to separate societies, evidence was brought forward to the effect that it is to the interest of men to keep women out of their societies and the interest of women to get into them; while it was also argued that ordinary friendly societies meet at places like public-houses where women would not attend, and that if women had their own societies with women officials, the latter would keep a watchful eye on their members. Most of the speakers admitted that women members of approved societies had so far been a cause of unduly heavy expense. Previous to the coming into operation of the Act there was very little experience, it was pointed out, in regard to women as members of friendly societies, and like many other insured persons, they did not realize that they must stand or fall by their own particular society; they had an idea that they had practically an unlimited source from which they could draw sickness benefit. It was exceedingly difficult to check the claims of women, and, apart from definite malingering, a danger was introduced by the fact that the weekly earnings of many women did not exceed the sickness benefit which they might draw. Hardships introduced by the Act in regard to domestic servants and nurses were mentioned by Miss Amy Hughes and Lady St. Helier, while it was also stated that difficulty had been experienced in getting women to fill posts under the Act which were open to them. Several speeches included allegations to the effect that at present medical men were far too ready to provide sickness certificates. The meeting concluded with an offer by the Faculty of Insurance to form a women's committee if this were desired.

PREScription OF PROPRIETARY MEDICINES.

The Medical Benefit Subcommittee recently reported to the Plymouth Insurance Committee that it had passed the following resolution:

That, as some doctors on the panel are ordering expensive drugs, and the charge on the drug fund appears likely to be much heavier in Plymouth than in Devonport, cases of what might be considered unduly expensive prescriptions be brought before the Subcommittee for consideration.

In reply to observations by medical men, it was explained that the Subcommittee had no thought of deciding whether particular drugs were rightly included in a prescription or not; what was meant was that the doctors were prescribing proprietary articles, and that the same drugs could be prescribed in a less expensive form.

LANCASHIRE.

Medical Certificates.

At a meeting of the Lancashire County Insurance Committee on June 9th, the question of the form of medical certificates to be given to insured persons was discussed. The question arose on consideration of the following resolution passed by the Medical Benefit Subcommittee, which was said to be regarded by the subcommittee as a reasonable compromise:

It shall be treated as a breach of a doctor's agreement if he knowingly gives an insured person a certificate for sickness or disablement benefit under the Act, (1) in respect of an industrial disease, (2) if the illness is caused by the patient's own misconduct. The doctor shall state on the certificate the nature of the disease in every case of a disease notifiable to a local authority, and also in every case unless in his opinion to do so would militate against the patient's recovery; but if in such a case he refrains from stating the nature of the illness on the certificate, he shall, if requested, give his opinion of it in writing to a medical man who may

be employed by or on behalf of an approved society. The doctor shall state on each certificate whether in his opinion the illness has arisen from natural causes or from an accident.

It was plainly stated that the proposal was not likely to be accepted by the Medical Committee. The panel doctors had offered to give a certificate stating that the disease was not an industrial disease and not due to the patient's own misconduct, but apparently that did not satisfy the Insurance Committee. It was said that if approved societies knew the nature of an illness they would be in a better position to assist the doctors and to detect malingering. The Committee eventually decided by 18 votes to 14 to approve of the general principle of the resolution of the Medical Benefit Subcommittee given above, and appointed a deputation to meet the County Medical Committee to consider the question on this basis.

LEICESTERSHIRE.

Payment for Accident Cases.

The Leicestershire Insurance Committee last week considered a report by the Medical Benefit Subcommittee as to the remuneration of medical men in cases where insured persons met with accidents in mines and quarries. Figures were given showing the high incidence rate of accidents of a more or less serious character, and it was stated that, prior to the passing of the Act, medical practitioners in contract practice received special fees in respect of attendance in accident cases. These payments were being dropped now. The Committee decided to recommend the Insurance Commissioners that payments in respect of mining and stone quarrying be made out of the floating sixpence, and allocated amongst the doctors performing the additional work, or that a special fund be created to meet such cases.

Sick Nursing for Insured Persons.

A conference of Insurance Committees, approved societies, and nursing associations in Leicestershire has approved a scheme to provide for the sick nursing of insured persons. The scheme provides for the provision of necessary funds by means of a levy by approved societies of 3d. per insured member. Approved societies in Leicestershire are to be asked to give the scheme a provisional trial.

MEETINGS OF INSURANCE COMMITTEES.

LEEDS.

Free Choice of Doctor.

At a meeting of the Leeds Insurance Committee on June 16th, Dr. EWING said that on April 15th he had given notice of the following resolution:

That, as the general arrangements made to facilitate the treatment of insured persons will terminate on April 30th, every facility will be given by the Committee to enable the insured persons to now place their names on the list of the doctors of their choice; and the doctors will be encouraged to reduce their list, if found unworkable, or take on fresh names if deemed advisable.

He had expected that the Insurance Committee would be called to consider it, but no such meeting had been held. Everybody, he said, had believed that the arrangements were only temporary, and that after April 30th the insured person would be free to choose the doctor he preferred. He felt that both the insured persons and the doctors had been taken in from beginning to end, and he knew hundreds of insured persons who were not going to the doctor who had signed their pink tickets, but to their own practitioners. He hoped the Committee would express to the Commissioners its feeling on this betrayal. Dr. EWING moved the resolution of which he had given notice.

Dr. BELL, who seconded, said that there had, beyond question, been a great misunderstanding on the point.

The CHAIRMAN, in reply to Mr. KELLY, said that he considered that no good purpose would have been served by calling the Committee together, as it was merely an administrative body, and no expression of its opinion could have altered the Regulations, and added, in reply to Dr. EWING, that he believed it was true that the public were not aware that insured persons could not choose another doctor for twelve months until Dr. Ewing had written to that effect to the press.

Mr. KELLY said that hundreds of friendly societies' officials, and himself amongst the number, did not know.

The Clerk said that a transfer could be effected if a mutual agreement were arrived at between the two doctors concerned and the insured person, but Mr. KELLY said that doctors were unwilling to make a change, and several speakers maintained that the doctors were responsible for the present position.

Alderman JOSEPH CLARK said that some doctors were being penalized for remaining loyal to their association.

Dr. EWING, in replying on the discussion, said that the doctors who did not go on the panel at first might have been foolish from a business point of view, but they acted rightly. He urged that all insured persons were led to believe that they would have absolute free choice of doctor after April 30th.

The resolution was carried by 16 votes to 8, and the Clerk was directed to forward it to the Insurance Commissioners as a recommendation that the Regulations should be altered.

Medical Referee.

On the motion of Mr. KELLY, seconded by Dr. BELL, a proposal to appoint a medical referee with a view to preventing malingering was referred to the Medical Service Subcommittee.

Sanatorium Benefit.

Alderman J. CLARK, in moving the minutes of the Sanatorium Subcommittee, said that the City Council was being asked to provide over one hundred more beds, and the Association for the Prevention and Cure of Tuberculosis twenty beds. He believed that eventually much more would be required from the Council if it took all the cases; it was proposed that if new buildings were erected by the Corporation they should be built on sites belonging to it.

REPORTS OF LOCAL ACTION.

IRELAND.

MEDICAL CERTIFICATION.

THE Dublin papers have published what is stated to be an official announcement with regard to the measures taken by the Insurance Commissioners in Ireland with reference to medical certification in the county boroughs of Dublin, Limerick, and Waterford. It was announced that fifteen doctors had been appointed as salaried officials in Dublin, and their names were given as follows:

Surgeon-Colonel Adye-Curran, Dr. F. G. Adye-Curran, Dr. A. Atoch, Dr. J. Burgess, Dr. M. F. Donovan, Dr. H. W. Mason, Dr. R. Moore, Dr. J. J. O'Kelly (at present Medical Officer of Letterkenny Dispensary District), Dr. O'Sullivan, Dr. E. Purcell, Dr. J. Sheppard, Dr. R. S. Stephens, Dr. S. Stitch, Dr. G. B. White, and Dr. Nora Williams. Two of these—namely, Dr. Mason and Dr. Sheppard—withdraw, and Dr. George M. Keating has, we are informed, been appointed to one of the vacancies so created.

It is said that the duties of these doctors will be to act as medical advisers to approved societies and to the Insurance Committees in respect of those insured persons resident in the City of Dublin and the urban districts of Rathmines, Rathgar, and Pembroke, who may be considered to be improperly claiming to be entitled to, or improperly in receipt of, sickness benefit under the Insurance Act.

It is believed that included in their duties will also be the obligation to give to insured patients all the certificates required in connexion with the administration of sanatorium benefit as well as certificates for sickness benefit, but this is not certainly known, and there may be some misapprehension. It is, however, understood that they will constitute a board of medical advisers to whom certain functions will be assigned with regard to cases of malingering.

We understand that Dr. Mason assigned as his reason for withdrawing that he could not act as medical adviser in opposition to the wishes of the profession. It is considered that the course of action indicated by these appointments represents an attempt on behalf of the Commissioners to frustrate the efforts of the profession to obtain proper remuneration for certification.

In the county borough of Limerick the Commissioners have given notice that they have appointed Dr. T. J. Lloyd and Dr. F. M. Kirwen for the purpose of furnishing

free of cost to persons resident in the county borough of Limerick the certificates required in connexion with the administration of sickness and sanatorium benefits. The notice further sets out the names of approved societies in Limerick the members of which have been assigned to one or other of these medical practitioners. In the county borough of Waterford it is reported that Dr. D. Kennedy and Dr. R. A. H. Williams have been appointed to discharge similar functions.

The Commissioners are proceeding to make arrangements with respect to those other areas where panels have not been formed, and in areas where the panel system is in operation Committees of Complaints and Committees of Inquiries are being established, and in certain areas it is also proposed to appoint medical referees. The Derry County Insurance Committee at a meeting in Coleraine last week temporarily appointed Dr. Adams, jun., Garragh, their medical adviser, at a salary of £200 yearly.

INSURANCE ACT IN PARLIAMENT.

MEDICAL BENEFIT.

Sickness Claims and Malingering.

MR. GODFREY LOCKER-LAMPSON asked the Secretary to the Treasury (1) whether he had seen the report of a meeting of the Kent Insurance Committee on May 29th, wherein it was stated that the rate of sickness experienced was more than double that expected, and that in a district near Maidstone the rate went up to four times that expected; if so, what steps he proposed to take for the protection of approved societies; (2) whether the Insurance Commissioners had received representations from the approved societies under the National Insurance Act as to the prevalence of malingering; if so, whether he proposed to appoint medical referees for the purpose of checking malingering; and (3) whether the sickness claims received by approved societies under the National Insurance Act were in excess of those expected on the basis of the Government actuaries' calculations; and, if so, whether the excess arose from malingering.—Mr. Masterman said it was too early at present to make any generalization as to the actual claims for sickness benefit in comparison with the actuaries' estimates. He had seen a report of the meeting of the Insurance Committee referred to, from which it appeared that references were made to the rates of sickness in certain areas, but he was not aware that any general official statistics were available. As was to be expected, there was evidence that the claims on some societies, and in some districts, were above the normal, but such evidence as was at present available for the country as a whole did not point to any general excess over the actuarial expectations. The primary responsibility for checking malingering must, of course, rest upon the approved societies who administered the sickness benefit. The whole question, however, including the appointment of medical referees, was now receiving the most careful consideration of the Commissioners, who were obtaining information as to the character and extent of the problem.

Supply of Medicine.

Mr. Tyson Wilson asked (1) whether any decision had yet been come to regarding the appointment of inspectors of pharmacies; and (2) whether the auditors appointed to audit the accounts sent in by chemists who had supplied medicine under the provisions of the Insurance Act would have to possess a special knowledge of the price of drugs and the business of a chemist.—Mr. Masterman said that the matters referred to were under consideration, but he was not yet in a position to make any announcement in regard to them.

Reserves for Aged Persons.

Mr. Worthington-Evans asked whether the reserves necessary to give medical benefit to insured persons over the age of 70 were being accumulated; and, if so, whether by the Insurance Committees or by the approved societies.—Mr. Masterman said that the actuarial calculations allowed for the accumulation of the necessary reserve to provide medical benefit for surviving members of approved societies entitled to it after the age of 70. The reserve was, therefore, being accumulated out of the ordinary contributions received by societies in respect of their insured members.

Medical Aid Societies.

Sir J. D. Rees asked whether, in South Wales, medical aid societies were being formed into which insured persons were brought and medical men imported, who joined the panel as whole-time servants of such societies on a fixed salary, the Local Insurance Committees encouraging insured persons to make their own arrangements, under Section 15, subsection (3), with such medical aid societies, and to provide for their dependants by deductions from wages; whether such medical aid societies were paid by the Insurance Committees the sum due for medical attendance to insured persons, such payments being then pooled, and medical men being required to attend insured persons and their dependants for 6s. 6d. a head; and whether the Act contemplated, and the Government approved of, such a scheme.—Mr. Masterman said that two Insurance Committees had in a few instances allowed insured persons to make their own arrangements with medical aid societies attached to certain works in South Wales. In these circumstances the Insurance Committees proposed to make a contribution to the cost of providing medical attendance for the insured in conformity with Section 15, subsection (3), of the Insurance Act and Section 49 of the Regulations with respect to the administration of medical benefit. The sum contributed by the Insurance Committee would in no case be greater than the amount for which the medical society undertook the treatment of the insured person. The payment made in respect of dependants was not within the purview of the Insurance Committee.

MATERNITY BENEFIT.

Women in Poor Law and Other Institutes.

Mr. G. Locker-Lampson asked whether, under the Insurance Act, single or married women entering Poor Law institutions for the purpose of treatment during maternity were entitled to claim the full maternity benefits; and whether, if this were so, he would take steps to prevent persons claiming treatment at the expense of the rates, with a view to reducing the cost of Poor Law administration.—Mr. Masterman said that under Section 12 of the Act maternity benefit was not payable to or in respect of a woman while she was an inmate of one of the institutions referred to in the first part of the question. The sum which would otherwise have been payable must, however, be paid to, or applied in whole or in part to the relief or maintenance of her dependants, if any; and in so far as not so paid or applied, was payable to the woman or her husband as the case might be when she left the hospital, either in kind, or in instalments, or in a lump sum, as the society might determine. The latter part of the question should be addressed to the President of the Local Government Board.

Desertion by Husband.

Mr. G. Locker-Lampson asked the Secretary to the Treasury whether a married woman, not an insured person, who was deserted by her husband just before the birth of her child, could obtain the maternity benefit; and, if not, whether he would deal with this matter in the forthcoming amending bill.—Mr. Masterman said he thought that in the circumstances mentioned the society, which had discretion to administer the benefit otherwise than in cash, would be justified in using the money to make provision for the wife. The question of proposing a clause in the amending bill to enable the society to treat the benefit, in cases of desertion, as in every respect a benefit for the wife had been under consideration.

SANATORIUM BENEFIT.

Estimated Cost of Sanatorium Benefit.

In reply to Mr. G. Locker-Lampson, who inquired as to how the estimate of 1s. 3d. per insured person was arrived at, Mr. Masterman said that the experience in the sphere of tuberculosis, as distinct from other diseases, possessed by friendly societies and the authorities of sanatoriums, before the passing of the Act was too limited to be of much practical value in arriving at an estimate of the amount required to be provided by the Act for sanatorium benefit. A further difficulty was that tuberculosis was at the time not a notifiable disease. The figure was arrived at by a calculation based on the mortality statistics, and such experience as was available of the cost of treatment.

At a later date Mr. Godfrey Locker-Lampson asked the Secretary to the Treasury whether he had had an opportunity of testing the adequacy of the amount allowed per head under the National Insurance Act for the treatment of consumptives as compared with the actual cost to the Post Office Society, in which members were only admitted after satisfactorily passing a medical examination; and, if so, whether it was shown that the cost to that society, even with selected lives, has been substantially in excess of the figure (1s. 3d.) fixed under the National Insurance Act?—Mr. Masterman, after referring to his previous reply, said that in the case of the particular society referred to, the higher cost of administration, due to the society being only concerned with the administration of a single benefit, vitiated any comparison between the cost to the society and the cost to an Insurance Committee under the scheme of the Act.

Grants for Sanatorium Schemes.

Mr. Astor asked the President of the Local Government Board what was the total amount of the grant made available by the Chancellor of the Exchequer in a letter, dated July 31st, 1912, to Mr. Hobhouse which had already been distributed to local authorities by the Local Government Board; and what was the total which it was estimated would have to be paid by the Treasury to local authorities through the Local Government Board ultimately when treatment was provided for all persons in England who were neither insured nor dependants?—Mr. Burns replied that the sum of £125,000 included in the Estimates for this purpose had not yet been voted, so that it had not yet been possible to make any grants to local authorities on maintenance account in aid of their sanatorium schemes. It was not practicable at present to make any reliable estimate of the possible ultimate charge.

In further reply to questions by Mr. Astor and Mr. Worthington-Evans in respect of the £1,116,000 available for England for providing of dispensaries, sanatoriums, and hospitals for the treatment of tuberculous persons, Mr. Burns said that capital grants amounting to £11,491 had been made to authorities in England in aid of expenditure already incurred in providing tuberculosis dispensaries and sanatoriums for the treatment of tuberculosis. These grants had been paid to the county council of Devon and the corporations of Birkenhead, Birmingham, Eastbourne, and Leicester. Further grants, amounting to £36,900, had been promised to various authorities in aid of expenditure already incurred or now being incurred, and large capital grants had also been promised to more than fifty other authorities whose schemes had been approved by the Board. The whole capital grant available for England had been provisionally allocated to counties and county boroughs on the basis of population.

WOMEN VOLUNTARY CONTRIBUTORS.

In reply to Mr. Worthington-Evans, Mr. Masterman said that out of 20,500 voluntary contributors, 5,600 were women.

CORRESPONDENCE.

THE AMENDMENT OF THE ACT.

DR. P. R. COOPER (Bowdon) writes: Like Dr. Palm (SUPPLEMENT, June 14th, 1913), I am greatly disappointed with the so-called amendments as published in SUPPLEMENT, June 7th. Apparently the State Sickness Insurance Committee have swallowed the Act whole, and, forgetting its basal wrongness of principle and the rightness and dignity of their previous attitude, they are now content with a few comparatively petty alterations.

The medical men who have stuck to their principles and ideals in maintaining the freedom and status of the profession are quietly dropped, despite the fact that many of them have risked (and lost) very largely, if not their all, in their fight for liberty, and for a scientific and worthy profession, rather than be drawn into a mere scramble for fees, irrespective of the sacred responsibilities of our calling.

I agree with Dr. Palm that it is radical and not symptomatic treatment which is called for in the amendment of this Act, not only in the interests of the medical profession, but of all concerned.

Already, as I foretold, the amount of malingering fostered by the Act threatens to bankrupt it, or rather to bankrupt the friendly societies, who are finding the "fruit" by no means so "refreshing" as they were led to suppose; and insistent demands are being made for the appointment of medical referees, as if this would solve the problem! A more fatal error cannot well be conceived. It is no disparagement to the acumen of any medical referee to point out that if a patient alleges he has a pain in his head, back, or any other part of his anatomy, the most expert medical man that ever lived cannot prove that he has not, although the doctor may very strongly suspect malingering. Even the less educated of people nowadays are well aware of the incontrovertibility of this simple fact. There is only one effective way to check malingering, and that is to make it to the individual's interest to keep well, or, being ill, to get well as quickly as possible. This can be done—as has been practically demonstrated—by adopting the private deposit system of the National Deposit Friendly Society, which also carries with it the other great desideratum of real free choice of doctor by the insured; but as I have so often referred to this in your columns, I will not trespass further on this subject at present.

The excellent stand made by the London practitioners encourages the hope—*pax* Dr. Lauriston Shaw—that it is not too late even now for a more enlightened and less arbitrary and despotic scheme of national insurance to be evolved, and I think the State Sickness Insurance Committee would be well advised to pursue a broader-minded policy and again insist upon certain fundamental cardinal points. Of these the question of the amount of remuneration to medical men might well be left in the background, whereas the conditions of service and opportunity for sound scientific work are vital matters.

THE DISTRIBUTION OF UNALLOTTED FUNDS BY THE LONDON INSURANCE COMMITTEE.

DR. W. OWEN WILLIAMS (Stepney) writes: The proceedings of the above Committee, as reported in the SUPPLEMENT of June 14th, cause considerable apprehension amongst practitioners on the panel, who made possible the working of medical benefit in London. The disputed sum (£34,000) represents 400,000 insured persons who failed to exercise their choice of doctor during the first quarter. Certain members of the Committee contend that, inasmuch as these persons did not receive treatment by practitioners on the panel, the latter are not entitled to any money in respect of such insured persons. A more preposterous proposition was never advanced by men occupying a responsible position. It displays colossal ignorance of the elementary principles of insurance. A surprising fact is that Dr. Evan Jones, a directly-elected representative of the medical profession on the Committee, should lend his support to this cool proposal to deprive his professional brethren of hard-earned money which is equitably due to them.

The unallotted portion of the panel fund for the first quarter undoubtedly belongs to those practitioners who rendered service during the corresponding period, and to no one else. It is not the fault of panel practitioners that the unassigned residue were not allocated at the end of the quarter. Had the allocation of persons been proceeded with, the amount of medical service rendered would not have been greater, inasmuch as *all* insured persons falling ill were treated by practitioners on the panel, the residue being healthy lives. The attendance-rate during the first quarter, in proportion to each doctor's list of acceptances, was relatively high, for the simple reason that all the chronic cases of illness had to be treated, besides acute diseases and slight temporary ailments. In default of the allocation of the healthy residue at the termination of the first quarter, the money representing such insured persons should rightly go to the doctors on the panel.

I have a dim recollection that Dr. Evan Jones was once upon a time an exponent of adequate remuneration. One regrets to repeat a platitude—that under any system of contract practice the contributions of *all* ("the well" and "the ill") pay for "the ill." If a portion of the accumulated funds representing "the well" be deducted, then the remuneration of the doctor will correspondingly be inadequate.

With regard to the negligible number of insured persons

who, according to Dr. Evan Jones, have paid their own medical bills, he should know that they have absolutely no claim to any contributions paid by them in respect of medical benefit unless they were granted permission to "contract out."

THE POSITION IN LONDON.

Dr. J. H. KEAY (Greenwich) writes: To offer any correction of the innumerable false statements made by correspondents of the JOURNAL and in the press as to the working of the Insurance Act would be an endless task. Dr. Worth has, however, contrived in a few lines to make so many statements that are utterly wrong and misleading as to the working of the Act in London that I cannot help referring to them and giving to practically all an absolute and entire contradiction.

1. He tells us that it is necessary to have 3,000 men on the panel in London in order to work the Act. As there are, roughly, 1,400,000 insured, that means for less than 500 a medical man is required. As every one who has had any experience of general practice well knows, such a contention is entirely untenable, and only shows to what straits men are driven to find reasons for opposing the Act.

2. He tells us that up to recently the number of doctors on the panel was 1,244. This is misleading. At the commencement there were over 700. The number to-day is 1,378. This information Dr. Worth could readily have obtained if he had asked for it. It is probably quite true that among this number there are some who have more on their list than they can properly attend to. At the same time, it is equally true that there are a much larger number—myself, for example—who can attend more than have applied to be placed on their list.

3. He further tells us that "a good number are tired of it already, and therefore are unlikely to renew their agreements." Personally I do not know of these men, but, judging from what has transpired in the past, I do not think they are numerous. Since the panel was formed in London there have been fifty-eight withdrawals. I have before me the list, and find that already eleven of this number have been removed by death, others have left the districts, some have thought it useless to continue because of the small number of the insured who applied to them, but only three have given as their reason dissatisfaction with the working of the Act. The fact is, that, now that it is found that the work is so much less than was confidently predicted, the number of doctors on the panel is likely to increase in pretty much the same way as it has in the past.

4. In these circumstances it must be evident that Dr. Worth's further assertion that the London Insurance Committee is in a hopeless muddle is entirely contrary to fact. There are medical men in London who have done their level best, by publishing wrong statements in the newspapers and otherwise, to make it a muddle. They have entirely failed, and will continue entirely to fail, while in not a single borough in London has it been found necessary to secure the services of a whole-time medical man.

The facts are as stated, and I challenge Dr. Worth or any of those who are of the same mind to refute the figures or contradict a word I have written. This being the case, were it not more reasonable that medical men in London should take the course adopted in practically all parts of the country and accept the inevitable, whether they like it or not? If the profession is divided there is immediate risk of objectionable institutions being approved, of an even worse form of contract practice than has ever existed in the past, and of much besides.

Vital Statistics.

HEALTH OF ENGLISH TOWNS.

In ninety-six of the largest English towns 9,037 births and 4,027 deaths were registered during the week ending Saturday, June 14th. The annual rate of mortality in these towns, which had been 13.4, 13.5, and 12.1 per 1,000 in the three preceding weeks, further declined to 11.8 per 1,000 in the week under notice. In London last week the death-rate did not exceed 11.4, against 13.4, 12.9, and 11.6 per 1,000 in the three preceding weeks. Among the ninety-five other large towns the death-rates ranged from 2.9 in Gillingham, 3.5 in Enfield, 3.6 in Ilford, 4.6 in Ealing, 5.6 in Bournemouth and in Smethwick, and 6.0 in Hornsey to 16.4 in Middlesbrough, 16.5 in Dewsbury, 17.4 in West Bromwich, 18.7 in Stoke-on-Trent, 21.2 in Dudley, and 23.9 in Stockton-on-Tees. Measles caused a death-rate of 1.3 in Stoke-on-Trent and in Salford.

1.7 in Walsall, and 2.0 in Dudley and in Aberdare. The mortality from the remaining infective diseases showed no marked excess in any of the large towns, and no fatal case of small-pox was registered during the week. The causes of 38, or 0.9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; of this number 15 were registered in Birmingham, 3 in Liverpool, and 2 each in Ipswich, Leicester, Sunderland, and Gateshead. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1,441, 1,430, and 1,427 at the end of the three preceding weeks, had further declined to 1,418 on Saturday last; 186 new cases were admitted during the week, against 193, 177, and 202 in the three preceding weeks.

HEALTH OF SCOTTISH TOWNS.

In the sixteen largest Scottish towns 1,205 births and 617 deaths were registered during the week ending Saturday, June 14th. The annual rate of mortality in these towns, which had been 16.3, 16.7, and 15.9 per 1,000 in the three preceding weeks, declined to 14.2 in the week under notice, but was 2.4 per 1,000 above the rate recorded in the ninety-six large English towns. Among the several towns the death-rates ranged from 7.3 in Falkirk, 8.9 in Perth, and 9.6 in Coatbridge to 15.6 in Kirkcaldy, 16.0 in Aberdeen, and 29.7 in Hamilton. The mortality from the principal infective diseases averaged 1.5 per 1,000, and was highest in Hamilton and Aberdeen. The 302 deaths from all causes registered in Glasgow included 19 from measles, 15 from whooping-cough, 3 from diphtheria, 1 from scarlet fever, and 1 from infantile diarrhoea. Seven deaths from measles and 4 from diphtheria were recorded in Aberdeen; 2 from measles and 4 from infantile diarrhoeal diseases in Dundee; and 2 from whooping-cough in Kirkcaldy and 2 in Hamilton.

HEALTH OF IRISH TOWNS.

DURING the week ending Saturday, June 14th, 701 births and 426 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 667 births and 393 deaths in the preceding period. These deaths represent a mortality of 18.5 per 1,000 of the aggregate population in the districts in question, as against 17.1 per 1,000 in the previous period. The mortality in these Irish areas was, therefore, 6.7 per 1,000 higher than the corresponding rate in the ninety-six English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 30.5 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 20.8, as against an average of 18.5 for the previous four weeks, in Dublin city 22.8 (as against 19.4), in Belfast 17.5 (as against 17.1), in Cork 17.0 (as against 19.0), in Londonderry 15.3 (as against 15.3), in Limerick 12.2 (as against 17.6), and in Waterford 19.0 (as against 21.4). The zymotic death-rate was 0.9, as against 1.3 in the previous week.

Naval and Military Appointments.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT ASTON R. DALE, to be Captain, May 29th; Cadet Sergeant THOMAS J. KELLY, from the Dublin University Contingent, Officers' Training Corps, to be Lieutenant on probation, May 26th.

MEDICAL RESEARCH.

The following official notice has been issued by the Chancellor of the Exchequer:

NATIONAL HEALTH INSURANCE.

Scheme for Research.

The Right Hon. D. Lloyd George, as Minister responsible to Parliament for National Health Insurance, has appointed the following persons as a Committee with executive functions, to be known as the Medical Research Committee, for the purpose of dealing with the money made available for research under the proviso to Subsection (2) of Section 16 of the National Insurance Act, 1911:

- The Right Hon. Lord Moulton of Bank, LL.D., F.R.S. (Chairman).
- CHRISTOPHER ADDISON, M.D., F.R.C.S., M.P.
- WALDORF ASTOR, M.P.
- Sir T. CLIFFORD ALLBUTT, K.C.B., M.D., F.R.C.P., F.R.S., Regius Professor of Physic, University of Cambridge.
- CHARLES JOHN BOND, F.R.C.S., Senior Honorary Surgeon, Leicester Infirmary.
- WILLIAM BULLOCH, M.D., F.R.S., Bacteriologist to the London Hospital and Professor of Bacteriology in the University of London.
- MATTHEW HAY, M.D., LL.D., Professor of Forensic Medicine and Public Health, Aberdeen University.
- FREDERICK GOWLAND HOPKINS, M.B., D.Sc., F.R.S., Reader in Chemical Physiology in the University of Cambridge.
- Brevet Colonel Sir WILLIAM BOGG LEISHMAN, M.B., F.R.S., Professor of Pathology, Royal Army Medical College.

These first appointments are for three years in each case; in and after 1916 three members, to be selected in manner to be prescribed, shall retire at intervals of two years, their places being filled (whether by reappointment or otherwise) by the Minister responsible for National Health Insurance.

The duties of the Committee will be to formulate the

general plan of research and inquiry at the outset and for each year, to make arrangements for carrying it out, and to supervise its conduct so far as may be necessary, and in particular to secure adequate co-ordination of the various parts of the scheme. The Committee will also deal with the collection and publication of information, and of the results of statistical and other inquiries so far as suitable or necessary. For this purpose it will determine, subject to the assent of the Minister responsible for National Health Insurance, the expenditure of the money available each year, the total of the sums available under paragraph (b) of Subsection (2) of Section 16 of the Act being about £57,000 per annum. Before the Minister responsible for National Health Insurance gives his final assent to the Medical Research Committee's scheme for any year, he will receive criticisms and suggestions in regard to it from the Advisory Council for Medical Research.

This Advisory Council has been appointed for the purpose by Mr. Lloyd George, as Minister responsible for National Health Insurance, after receiving suggestions for suitable names from each of the universities of the United Kingdom, from the Royal Colleges of Physicians and of Surgeons, from the Royal Society, and from other important public bodies interested in the question. It includes representatives of the four National Health Insurance Commissions, and the other principal Government departments concerned in medical work. The first appointments are for three years in each case; in and after 1916 one-third of the members, to be selected in manner to be prescribed, shall retire at intervals of two years, their places being filled (whether by reappointment or otherwise) by the Minister responsible for National Health Insurance.

The duty of the Advisory Council will be to consider the scheme of the Medical Research Committee, when referred to them as above explained, and to afford to the Minister all such criticisms and suggestions in regard to it as they may think desirable to submit to him from the point of view of securing that adequate consideration is given to the different problems arising and the various kinds of research work going on in the different parts of

the United Kingdom and in other portions of the Empire, in America, and in foreign countries, and also to the general scope of the research work to be undertaken under the Committee's scheme.

The membership of the Advisory Council for Medical Research is as follows:

The Right Hon. LORD MOULTON OF BANK, LL.D., F.R.S.
(Chairman).

Miss L. B. ALDRICH-BLAKE, M.D., M.S.
Sir W. WATSON CHEYNE, Bart., C.B., F.R.C.S., F.R.S.
Sir WILLIAM S. CHURCH, Bart., K.C.B., M.D.
SIDNEY COUPLAND, M.D.
DAVID DAVIES, M.P.
SHERIDAN DELÉPINE, M.B.
Sir JAMES KINGSTON FOWLER, K.C.V.O., M.D.
Sir RICKMAN J. GODLEE, Bart., F.R.C.S.
Sir ALFRED PEARCE GOULD, K.C.V.O., F.R.C.S.
DAVID HEPBURN, M.D.
ARTHUR LATHAM, M.D.
Sir JOHN McFADYKIN, M.B.
W. LESLIE MACKENZIE, M.D.
J. C. McVAIL, M.D.
W. J. MAGUIRE, M.D.
S. H. C. MARTIN, M.D., F.R.S.
ROBERT MUTR, M.D.
ALEXANDER NAPIER, M.D.
Sir GEORGE NEWMAN, M.D.
ARTHUR NEWSHOLME, C.B., M.D.
J. M. O'CONNOR, M.B.
Sir WILLIAM OSLER, Bart., M.D., F.R.S.
A. C. O'SULLIVAN, M.B.
MARCUS S. PATERSON, M.D.
Sir ROBERT W. PHILIP, M.D.
Sir WILLIAM H. POWER, K.C.B., F.R.C.S., F.R.S.
H. MEREDITH RICHARDS, M.D.
LAURISTON E. SHAW, M.D.
ALBERT SMITH, M.P.
J. LORRAIN SMITH, M.D., F.R.S.
T. J. STAFFORD, C.B., F.R.C.S.I.
T. H. C. STEVENSON, M.D.
HAROLD J. STILES, F.R.C.S. Edin.
Sir STEWART STOCKMAN, M.R.C.V.S.
W. ST. CLAIR SYMMERS, M.B.
Miss JANE WALKER, M.D.
NORMAN WALKER, M.D.
J. SMITH WHITTAKER, M.R.C.S., L.R.C.P.
Sir ARTHUR WHITTLEGGIE, K.C.B., M.D.
G. SIMS WOODHEAD, M.D.

ATTENDANCE ON UNINSURED DEPENDANTS.

We have received the following letter, and have appended to it a report of an application for an injunction in a case of alleged touting by friendly societies heard on June 23rd in the Chancery Court at Liverpool, and also a note on a scheme to form a medical aid institute "under the National Insurance Act" at Newport Pagnell, a small town in Buckinghamshire with a population of a little over 4,000.

Sir,

The cessation of the dispute between the profession and the friendly societies in Swansea, while perhaps gratifying to the actual dependants, cannot be regarded with satisfaction by the profession at large when the terms of settlement are carefully reviewed.

The struggle has been bitter and prolonged, and doubtless all concerned are thankful that a truce has been called; but considered from the point of view of the highest interests of the profession, it cannot be said that the settlement arrived at is likely to be favourably accepted by the profession at large, or that the last word has been spoken on a very perplexing problem—the attendance on uninsured dependants in working class communities.

The remuneration agreed to, 10s. 6d. a family per annum, is obviously inadequate to ensure anything like a satisfactory standard of medical service for the uninsured dependants, and it is quite apparent that both the profession and the insured workers are depending on the contributions from the Insurance Funds to make up the deficiency.

This is a consequence of the Insurance Act which was never intended, and constitutes a grave injustice to the medical profession. In addition it cannot but have prejudicial effects on the medical service under the Insurance Act, and on the work of friendly practice. An inclusive payment per annum of 10s. 6d. a family of uninsured dependants, estimating at only one visit a month a family, works out at considerably less than 1s. a visit (including medicine), a totally inadequate payment for satisfactory work. It compares very unfavourably

with the payment made under the Insurance Act, which it was understood was now the recognized standard rate for contract practice generally (children under 16 at half rates), and it is a payment which, I feel sure, will not be accepted by the general profession doing similar work in industrial communities throughout the country.

It is not my intention or desire to blame the profession in Swansea for accepting such terms. Apparently their acceptance has been more or less forced upon them by the opposition of competition from without and probably the still more disruptive competition from within, but all the same it is in the highest degree regrettable. If it becomes known in working-class districts that by combination and the collective use of medical payments due under the Insurance Act the profession may be so exploited that entire families of dependants can be medically attended for 23d. a week, the outlook for the working-class practitioner will be worse than even before.

The profession in Swansea owe their disappointment to the opposition and menace of the so-called medical aid associations and suchlike combinations of insured workers and to the support given to these by members of their own profession. Against both of these the members of the British Medical Association must proceed without delay and with the full strength of a united Association.

The General Medical Council should be called upon to make employment under such exploiting medical companies—at any rate those formed since the introduction of the Insurance Act—a proceeding "infamous in a professional respect" on the part of any practitioner.

Up to the present its attitude towards medical aid associations has been much too tolerant, and its disciplinary measures against practitioners working under them have had little or no deterring effect. Medical aid associations use with impunity methods to procure members, and form a practice which would immediately bring a private practitioner under the ban of the General Medical Council. Like trade unions, in some respects they have placed themselves above the common law of the profession.

It is futile, for example, to make "systematic canvassing" (if this implies only "persistent canvassing") by medical aid associations the only ground for interference on the part of the General Medical Council.

A vigorous preliminary canvass, with accompanying trumpet blowing locally, is all that is needed in many populous districts to work up a large membership. A medical officer is then advertised for, and ultimately procured. His qualifications, experience, etc., are of no account, so long as he is only a doctor. Systematic and continuous canvassing may then be dispensed with. The association once formed is held together by pressure from within by methods known only to its members and officials. Established in a district such associations bolster up an inferior and degrading system of medical practice, offer a standing obstacle to fair and honest competition in the medical field, and continue an abiding menace to the freedom and prestige of the profession, and the well-being of the public medical field.

It is necessary also that the medical profession be protected against the unscrupulous and dishonourable within its ranks. That there are men in our profession ready to oust honest practitioners from their practices and become the "kick-about" of lay committees under medical aid associations experience goes to show. It is deplorable, but only too true. But surely the profession is strong enough and healthy enough to rid itself of such parasites, or to remove the conditions under which they thrive.

This is a matter for which we cannot blame the Insurance Commissioners; nor, on the other hand, seek their protection. The ethical standards and conditions of practice which exist in the profession are of our own making, and the Commissioners cannot, with all the goodwill in the world, do other than accept them as they are. Over such medical aid associations as are "approved institutions" they have certainly a controlling power, but these are few in comparison with the many quasi-medical institutions of recent growth over which they have little or no control.

No, we must put our own house in order and clear out the rats that infest it.

Let the Association, then, place this question in the medico-political programme at the July meeting, and declare its wishes respecting it in a manner that will command attention.

Then will the General Medical Council be roused to take speedy and effective steps to end a state of things which is a disgrace to our profession.

J. CHARLES.

Stanley, co. Durham.

ACTION TO PREVENT ALLEGED TOUTING BY A FRIENDLY SOCIETY.

At the Chancery Court in Liverpool on June 23rd, before Vice-Chancellor Stewart-Smith, K.C., in an action brought by Dr. Leonard Youatt, of Prescot, against Thomas Wright, William Beesley, Thomas Byron, and William Ashcroft, the plaintiff applied for an injunction until the trial of the action to restrain the defendants from procuring, or attempting to procure, by means of canvassing, touting, or otherwise, persons to be patients of the plaintiff in such manner that if the same were done with the sanction or acquiescence of the plaintiff it would amount to infamous conduct in a professional respect on his part within the meaning of Section 29 of the Medical Act, 1858.

Mr. R. Lawrence, on behalf of the plaintiff, stated that formerly the plaintiff and the four other medical practitioners at Prescot attended the members of the friendly societies in that district on the terms of receiving a fixed sum a member per annum, the member being free to select which doctor he would consult. After the passing of the Insurance Act an association composed of representatives of the friendly societies was formed for the purpose of negotiating with the doctors the terms on which medical attendance should be given to the juvenile members who did not come under the Act. Mr. Wright was the secretary and the other defendants members of the executive of the association. Not being able to come to an agreement, the defendants resolved to advise their juvenile members to go to one particular doctor, the object, it was alleged, being to injure the practice of the other four and thus induce them to consent to less favourable terms than they were demanding. At the end of April Mr. Wright gave notice to the five doctors terminating their contracts for attending juvenile members, and since then these persons had been told to go to Dr. Youatt. This was done without the sanction or consent of that gentleman. In his opinion it amounted to canvassing or touting for patients, and was a serious breach of medical etiquette, and if he acquiesced in or took advantage of it he would be guilty of infamous conduct in a professional respect and liable to be struck off the *Register*. This view was supported by affidavits made by an officer of the British Medical Association and by another doctor. Dr. Youatt was therefore compelled to take energetic steps to dissociate himself from the action taken by the defendants, and he was put to much trouble and annoyance, as well as suffering pecuniary loss, because he had to investigate every case of a patient coming to him in order to ascertain whether they were sent by the societies or had come of their own motion. He asked the defendants to give an undertaking not to repeat the conduct he complained of, but they had declined to do so. The matter was not one which must be regarded from a legal aspect alone. The point of view must be that of the medical profession, the decision what was professional misconduct being dependent upon the opinion of the Medical Council and not upon the opinion of the Court, except to this extent—that it must not act so unreasonably that the Court would say it did not act with bona fides.

Mr. Maberly, for the defendants, said the societies had to provide medical attendance for their members; they had been placed in a difficulty because of the demands made by the doctors, and they had told their members who wanted to know what they must do in a future illness, "Go to Dr. Youatt." They had no power to compel the members to do so, and, if he wished, Dr. Youatt could refuse to receive them. Until the recent breach he attended a good many of them. What had been done was merely to give advice.

The Vice-Chancellor pointed out that if it were made clear to the plaintiff whether the patients came from the societies, he could exercise his discretion as to whether he would treat them. But if it was not made clear, he would be put to much trouble in making inquiries. Was a ticket given which could be shown to Dr. Youatt?

Mr. Lawrence said if tickets were given bearing Dr. Youatt's name, it would be expressly doing what was contrary to medical etiquette. He wished to protect his client from the risk of any suggestion that he was acquiescing in it.

The Vice-Chancellor said it was clear from the proceedings that anything in the shape of advertising was done entirely in defiance of Dr. Youatt's wishes. He had done everything that a reasonable man could do, and Mr. Lawrence would be justified in not pressing his motion for an injunction.

Mr. Lawrence remarked that after that expression of opinion he would allow the motion to stand over, on the understanding that the case would be brought on for trial as speedily as possible.

PROPOSED MEDICAL INSTITUTE AT NEWPORT PAGNELL.

From a report in the *Northampton Echo* it appears that steps are being taken in Newport Pagnell apparently by a body called "the protest committee" to establish a medical institute in the town, where it would appear there is already a dispensary of this nature. At a public meeting on June 10th it was stated that the protest committee had proposed to adopt certain amendments of the dispensary rules, including (1) the abolition of the wage limit, (2) members and officers to have equal representation on the committee, which should be presided over by an independent chairman, the committee to decide as to a person being eligible for membership, (3) contributions—members over 16 years 6d. per month, under 16 years 3d. per month, no family to pay more than 1s. 3d. per month (this, it was stated, was an increase on the present rates of 25 per cent.).

The doctors have not accepted these conditions. Mr. Pride, who was introduced as a person who had been concerned in the foundation of several medical institutes, said that such organizations paid a doctor a fixed salary, and there were no class distinctions, no inquisition into the earnings of members, and the payment for each was about 4s. for adults and 2s. for children. Eventually the following resolution was adopted unanimously:

That this meeting authorizes the protest committee to fix a scale of charges for the medical benefits for the wives and families of insured persons and others not eligible for State insurance, as nearly as possible equivalent to the present dispensary charges, and issue circulars on these lines asking the public to support the establishment of a medical institute by selecting the medical practitioner to be introduced to carry on the above work as their panel doctor, under the National Insurance Act, in November next.

We give the resolution as it appears in our contemporary, but it appears to require some explanation, although we assume that it may be taken as a further illustration of the tendency discussed by Dr. Charles in his letter.

LOCAL MEDICAL COMMITTEES.

BIRMINGHAM.

A MEETING of the local profession was held at the Medical Institute on June 20th, at 3 p.m., when over fifty practitioners attended.

Mr. ALBERT LUCAS, who was in the chair, reported that the Medical Committee elected on January 7th, 1913, was recognized on March 29th, and that thirteen meetings had been held, to the last five of which the medical representatives on the Local Insurance Committee—Mr. J. F. Jordan, Drs. Brash, Pain, and Thomas Wilson—had been invited. The three officers of the Committee had been appointed to serve on the Local Medical Service Subcommittee.

The following recommendations of the Medical Committee were fully discussed and approved:

1. *Income Limit.*—Panel doctors are asked to report to the Committee insured persons on their lists whose income exceeds £160 per annum. If there are a considerable number, as no income limit has yet been fixed, the Insurance Committee may ask these persons to make their own arrangements.

2. *Arrangements with the Midland Pharmaceutical Association.*—The following arrangements have been made:

(1) Chemists have agreed to dispense all medicines in bottles graduated in tablespoons; over 10 oz. the doctor to order in two-tablespoonful doses.

(2) Chemists have agreed not to charge for copying the present prescription forms, but a new form in triplicate without loose carbon paper has been approved for future use, to do away with the 1d. copying fee.

(3) Elastic webbing bandage, 2½ in. wide, at 7d. per yard, can now be supplied.

(4) Medicated gauzes will be supplied in 10 oz. sealed packets.

(5) No doctor is to write "Rep. mist." or chemist to dispense prescription unless written in full.

(6) No prescription to be repeated by chemist for a cash payment. Any allegation of infringement of this rule to be reported to Insurance Committee.

(7) Medicines dispensed and dressings used by medical practitioners in emergencies and in all urgent cases after 10 p.m. to be paid by a capitation charge from drug fund of 1s. per 100 insured persons on each doctor's list per quarter. This payment to be retrospective.

(8) Doctors not to order proprietary articles excessively.

3. *Certificates.*—A uniform fee of 6d. to be charged for all extra certificates. Where complaint is named certificate only to be given to sick person or his or her representative.

4. *Payment for Temporary Residents.*—The Committee, on behalf of practitioners, had notified the Local Insurance Committee and the Commissioners that they object to any deduction from the agreed capitation fee of 7s. per annum. Practitioners are requested not to treat insured persons with a green voucher, except as private patients.

5. *Expenses of Committee.*—The Committee has recommended:

(a) That panel doctors be asked to pay towards the expenses of the Committee for 1913:

5s. for the first 1,000 or portion of 1,000 persons on their list.

2s. 6d. for each additional 500 or portion of 500.

(b) That all local practitioners not on the panel be asked to pay 5s.

(c) That the expenses for locumtenents of the representatives on the Insurance Committee be paid when applied for.

(d) That the secretary be given an honorarium.

6. *Maternity Benefit.*—Drs. Trumper, Wilkinson, and Thomas Wilson have been appointed representatives of the medical profession on the Committee of the Birmingham Maternity Association. At a meeting of this Committee held on May 7th the following general points were discussed and unanimously agreed to:

(1) With a few exceptions the whole of the midwives in Birmingham be invited to join the association, and that a list of those midwives be sent round to the approved societies, the patient being allowed to choose her own midwife.

(2) The midwife to be paid the sum of 15s. direct by the approved society as part of the maternity benefit under the Act. Each midwife to pay to the association the sum of 1s. 6d. per case, the whole of which will be given to the fund for paying the doctors who may be called in.

(3) That a general statement be circulated recommending that women requiring services at confinement should engage a doctor at least three months beforehand, if not a doctor then a midwife.

(4) If one of the midwives on the list is selected, she is entitled to call in, if necessary, the nearest doctor, whose services will be paid for by the association. The scale of fees to be the same as those adopted by the Birmingham Central Division in March, 1905, and accepted by the guardians of Birmingham.

The advantage of the association to members of approved societies are many. In the first place the woman would have the services of a midwife whose work would be under supervision. The midwife would be able at once to call in a doctor if necessary, whose fee would be paid by the association. Only 15s. of the maternity benefit would be expended on the midwife or doctor, however serious the case might be, therefore in such cases the insured person would have a clear 15s. with which to provide other necessities. The association would also be in close touch with the maternity hospital and could, no doubt, arrange for taking in special cases at once.

The following is a complete schedule and scale of fees adopted by the Central Division, March, 1905, with suggested alterations by the Medical Committee, for payment of fees by the Birmingham guardians to medical practitioners called in to assist midwives:

A.—In the case of a pregnant woman.

- (1) Where the midwife suspects a deformed pelvis.
- (2) Where there is loss of blood.
- (3) Where the pregnancy presents any other unusual features (as, for example, excessive sickness, persistent headache, dimness of vision, puffiness of face and hands, difficulty in emptying the bladder, incontinence of urine, large varicose veins, rupture), or where it is complicated by fever or any other serious condition.

Fee.—5s. for first visit and 2s. 6d. for subsequent visit. If first visit be between 9 p.m. and 9 a.m., 10s. 6d.

B.—In the case of a woman in labour.

- (1) In all presentations other than the uncomplicated vertex or breech.
In all cases of breech presentation in primiparæ.
In all cases of flooding and convulsions.
Also whenever there appears to be insufficient room for the child to pass, or when a tumour is felt in any part of the mother's passages.

Fee.—£2 2s., which should include five subsequent visits.

- (2) If the midwife, when the cervix is dilated, is unable to make out the presentation.
- (3) If there is loss of blood in excess of what is natural, at whatever time of the labour it may occur.
- (4) If an hour after the birth of the child the placenta has not been expelled and cannot be expressed (that is, pressed out), even if no bleeding has occurred.
- (5) In cases of rupture of the perineum or other serious injuries of the soft parts.

Fee.—£1 1s., to include five subsequent visits.

C.—In the case of lying-in women and in the case of newly-born children. Whenever, after delivery, the progress of the woman or child is not satisfactory; but in all events upon the occurrence of the subjoined conditions in:

- (1) The mother.
 - (1) Abdominal swelling and signs of insufficient contraction of the uterus.
 - (2) Foul-smelling discharges.
 - (3) Secondary post-partum hæmorrhage.
 - (4) Rigor.
 - (5) Rise of temperature above 100.4° F., with quickening of the pulse for more than twenty-four hours.
 - (6) Unusual swelling of the breasts with local tenderness or pain.
- (2) The child.
 - (1) Injuries received during birth.
 - (2) Obvious malformations or deformities, not inconsistent with continued existence.
 - (3) Concealed malformations, incapacity to suck or to take nourishment.
 - (4) Inflammation to even the slightest degree of the eyes, eyelids, or ears.
 - (5) Syphilitic appearance of the skin in certain parts.
 - (6) Illness or feebleness arising from prematurity.
 - (7) Malignant jaundice (*icterus neonatorum*).

(8) Inflammation about the umbilicus (septic infection of the cord).

Fee.—5s. for first visit and 2s. 6d. for subsequent ones, but if the case be one of puerperal septicaemia, or if the first visit is between 9 p.m. and 9 a.m., the fee to be 10s. 6d.

D.—In all cases, if during pregnancy, labour, or lying-in, a woman dies before the arrival of a doctor.

Fee.—10s. 6d. for visit.

The Honorary Secretary (Dr. E. Osborne) was instructed to send a copy of the suggested scheme of the Birmingham Maternity Association for the approval of the British Medical Association.

DERBY.

TEMPORARY RESIDENTS.

The Honorary Secretary of the Derby Local Medical Committee addressed a letter to the Insurance Commissioners in accordance with the resolutions of the Committee on this subject (see SUPPLEMENT, May 17th, p. 448). The following correspondence has since taken place:

National Health Insurance Commission (England),
Buckingham Gate, London, S.W.,
June 11th, 1913.

Sir,

In reply to your letter of the 10th of May, I am directed by the National Health Insurance Commission (England) to remind you that the sum referred to in your letter is the capitation rate of remuneration applicable only in respect of those insured persons for whose treatment the doctors in the area have been responsible during the whole year.

Under the system in force during the provisional period insured persons removing for however short a period, whether temporarily or otherwise, were required to give notice to the Committee to whose area they removed and were thereupon transferred from the lists of doctors in the old area to the lists of doctors in the new area. Under the old arrangements, therefore, the capitation fee payable to a doctor in respect of any given insured person was liable to be reduced by a sum proportionate to the period of his absence from the area of the doctor's practice, whether he required treatment during his absence or not. These adjustments are expressly referred to in the Explanatory Memorandum as to medical benefit referred to in your letter.

Under the new arrangements, however, insured persons changing their residence for a temporary period are no longer removed from the doctor's list, and the doctor accordingly continues to receive credit in respect of each such person on his list, notwithstanding the fact that he is not responsible for that person's treatment during his absence. In respect of every insured person temporarily resident outside the Committee's area who has fallen ill and has received treatment a transfer of "case value" is made; but the total sum transferred in the form of "case value" as regards any area is precisely equivalent to the total of the deductions to which the full capitation fees would have been subject under the old system owing to the temporary removal of insured persons from their doctor's lists during the periods of their absence from the area.

The new arrangement, therefore, subjects the doctors in any given area to no greater deductions than those to which they were previously liable. In place of a separate small deduction in respect of each insured person temporarily absent from the area whether ill or well, a larger deduction will be made in respect of those persons only who require treatment while temporarily absent; but the deductions in the latter case will be so calculated as to be equivalent to the sum of the separate deductions provided for under the previous arrangements. The net effect of the new system, therefore, is merely to vary the machinery of adjustment, not the amounts of the adjustments themselves; and the basis of the doctors' remuneration, as embodied in their agreements, is accordingly unaffected.—I am, Sir, your obedient servant.

(Signed) S. P. VIVIAN.

Dr. G. K. Smiley,
Honorary Secretary, Derby Local Medical Committee.

Derby Borough Medical Committee.

112, Kedleston Road, Derby,
June 23rd, 1913.

Sir,

Your letter of June 11th has been received and considered by my Committee, and I am instructed to reply as follows:

There are two main contentions which you seek to establish:

1. That the system described in Regulation 22 (Medical Benefit Regulations), by which the doctor loses credit for a patient as soon as that patient changes his residence to another area, applies to, or would be just and equitable if applied to, "temporary residents" who are absent from home for periods varying from one week up to twelve weeks; and

2. That the amount proposed to be deducted from the doctor's remuneration by the new method of "case value transfer" is precisely identical with what would be deducted were the system of Regulation 22 adopted for the "temporary residents."

The first contention seems to be largely a question of the intention and the interpretation of Regulation 22. As far as this Committee can learn from outside authorities, including the Scottish Commissioners, and your original explanatory circular, the Regulation refers to those insured persons who definitely change their residence from the area of an Insurance Committee to the area of another Committee, and does not refer to the temporary absence from home for a few weeks of an insured person. This interpretation is in accordance with the established custom in all contract practice hitherto carried on by doctors when dealing with friendly society members. In this Committee's own opinion and in that of the doctors whom it represents, the Regulation does not apply to "temporary residents," nor is it just or equitable that the method described in that Regulation should be made to apply to those "temporary residents."

With regard to the second contention, this Committee utterly fail to see on what grounds or on what method of calculation the conclusion is based. Until they know more of this method of calculation they must refuse to accept the result, which you put forward as a statement of fact, without any proofs.

In conclusion, therefore, my Committee feel that they can only advise the doctors whom they represent to continue to act as they have formerly acted in their contract practice, and look to the individual "temporary resident" for the remuneration which the green voucher purports to supply.—I am, yours faithfully,

G. KENNEDY SMILEY,
Honorary Secretary.

The Secretary,
National Health Insurance Commission (England),
London.

LANCASHIRE.

The following are the names of the Statutory Medical Committee, Area No. 9, Lancashire County:

| | |
|---|-------------------------|
| Dr. Agnew, Padiham (<i>Chairman</i>). | Dr. Hodges, Burnley. |
| Dr. Normington, Nelson (<i>Honorary Secretary</i>). | Dr. Stuart, Nelson. |
| Dr. Bromley, Padiham. | Dr. Findlay, Nelson. |
| Dr. Joynson, Padiham. | Dr. Pim, Barrowford. |
| Dr. Rogers, Burnley. | Dr. Wilson, Brierfield. |
| Dr. Callam, Burnley. | Dr. Dickie, Colne. |
| | Dr. Doyle, Colne. |
| | Dr. McCauley, Colne. |

Many meetings have been held, and the last was held on June 5th, at 4 p.m., in the Bull Hotel, Burnley, when the Secretary's report from the Preston meeting was read and fully discussed. Area No. 9 is in agreement with Area 21, and considers it inadvisable to state the nature of illness on the certificate, and instructed the Secretary to support that view at the Local Medical Committee meeting at Preston.

STAFFORDSHIRE.

A MEETING of the Staffordshire County Medical Committee was held at Stafford on June 3rd.

The following recommendations of the Executive Committee were considered and adopted without dissent:

That all doctors on the county panel be requested to resume the practice recently discontinued by recommendation of this Committee, of providing prescriptions in duplicate for the use of the chemist.

That all doctors on the county panel abstain from ordering proprietary medicines unless the requirements of the case will be met *only* by the use of such proprietary preparation.

The Secretary was instructed to send a copy of the resolutions to every doctor on the panel, with such explanation as might be necessary, pointing out in the case of the first that it was the outcome of a conference with the representatives of the County Pharmacists Association, and in the case of the second, drawing attention to Section 46 of the Insurance Regulations, in which the penalties for excessive prescribing are set forth. By carrying out

the spirit of the recommendations it is hoped that the whole of the "floating sixpence" will be secured to the medical profession.

BEDFORDSHIRE.

The fifth meeting of the Bedfordshire Medical Committee was held at the Bedfordshire County Hospital on June 20th. Dr. J. W. BONE in the chair, and fourteen others were present.

Status of the Committee.

The CHAIRMAN announced that no reply had been received from the National Insurance Commissioners in answer to the Secretary's letter applying for the permanent recognition of the Medical Committee, to which so far only temporary recognition had been granted. The Secretary was instructed to communicate with the Commissioners requesting permanent recognition.

Proceedings of the County Insurance Committee.

The CHAIRMAN detailed to the meeting the decisions affecting the practitioners of the county arrived at by the Bedfordshire Insurance Committee:

(a) The model rules for the administration of medical benefit had been printed and circulated to the practitioners concerned. The hours agreed upon by the Medical Committee were accepted, and it was decided that there should be no surgery attendance on Sundays or Bank Holidays, and that there should be one half holiday per week, the day chosen in the towns being that adopted for early closing.

(b) The application for an income limit was refused.

(c) A list of unallotted panel patients would be drawn up after the lapse of a certain time, and it would be left for the doctors to divide them up among themselves.

(d) A further payment of 7d., in addition to the 1s. 2d. already paid to the doctors, had been passed by the Committee. It appears that the balance of the floating 6d. and the fees for unallotted patients will not be distributed before the end of the year.

Prescription Book.—The CHAIRMAN demonstrated the "Carbac" triplicate prescription book, and it was decided to adopt the pattern for Bedfordshire. Dr. J. G. DURRAN remarked on the hardships inflicted upon practitioners resident near county boundaries, since they might be called upon to adopt as many different patterns of prescription books as the counties in which their work lay. The only remedy was the adoption of a universal pattern. He promised to bring the "Carbac" to the notice of the Buckinghamshire Medical Committee.

Expenses of Committee.—The CHAIRMAN announced that the County Insurance Committee had consented to the collection of a levy of $\frac{1}{2}$ per cent. from those practitioners who signed a form agreeing to it, and that this sum would be deducted "at the source" and handed to the treasurer of the Medical Committee, a small honorarium being paid to the clerk for the trouble of collection.

Temporary Residents.—The CHAIRMAN outlined the proposals of the Commissioners with regard to the administration of medical benefit in the case of temporary residents as set forth in Memorandum 159 I.C. The correspondence from the British Medical Association on this subject was then submitted to the meeting and discussed, and on the motion of Dr. KILHAM ROBERTS, seconded by Dr. WAUGH, it was unanimously resolved:

That the policy of the Association be supported—that is, that medical men should refuse to consent to any deduction being made from their panel fees, and that all green vouchers should be refused.

It was also unanimously agreed that this decision should be announced to the authorities forthwith on the forms supplied by the Association. It was further decided that all the practitioners on the panel for Bedfordshire be circularized of this action.

Conference of Representatives of Local Medical Committees.—Dr. J. W. BONE was invited to represent the Bedfordshire Medical Council at the conference of Representatives of Local Medical Committees to be held at Brighton on Thursday, July 24th, during the Eighty-first Annual Meeting of the Association.

Model Rules.

Letters containing complaints were read from two practitioners, and the Secretary was instructed how to deal with the points raised.

The CHAIRMAN announced that he had been in communication with the Clerk to the Bedfordshire Insurance

Committee with a view to printing cards of the model rules, hours of attendance, and holidays, to be hung up in the surgery of each panel practitioner, and had been informed that the Committee could not accede to this request as it had no funds for the purpose. It was thereupon decided that the Medical Committee print the cards and also a supply of leaflets, and distribute them to the practitioners concerned.

PLYMOUTH.

At meetings of Plymouth Local Medical Committee, held on May 29th and June 18th, the following matters were discussed:

Constitution of the Local Medical Committee.—The question having been raised whether there was fair representation of the panel on this Committee, it was shown that the condition is as follows:

| | |
|--|----|
| Total doctors in practice in Plymouth and residing in Plymouth | 68 |
| Doctors on the panel and residing in Plymouth | 29 |

| | |
|--|----|
| CONSTITUTION OF THE LOCAL MEDICAL COMMITTEE: | |
| General practitioners on the panel | 7 |
| General practitioners not on the panel | 6 |
| Consultants or specialists | 4 |
| Total | 17 |

Medical Benefit for Temporary Residents.—On May 29th a resolution was passed and forwarded to the Commissioners and to the Plymouth Insurance Committee to the effect that in the opinion of the Local Medical Committee any deduction from the 7s. capitation fee constitutes a breach of the agreement entered into by the doctors on the panel. On May 18th a memorial signed by all the doctors on the panel in Plymouth with one exception came before the Local Medical Committee, in which they stated their intention to refuse to allow any deduction from the 7s. capitation fee in order to make a pool in accordance with the method suggested in Memorandum 159 I.C., and declining to attend visitors holding green tickets except as private patients. It was decided to send a copy of the memorial to the Insurance Committee, together with the printed letter on the subject recently issued by the British Medical Association.

Committee of Panel Doctors.—It having been suggested by one panel doctor that a meeting of the panel should be called by the Clerk to the Insurance Committee in order to form a committee, the Clerk to the Insurance Committee was informed that in the opinion of the Local Medical Committee it was not necessary or desirable to set up another committee, and that this Committee was arranging a panel subcommittee which was intended to ensure full representation of the views of doctors on the panel.

List of Panel Practitioners.—The new list having been submitted to the Committee, it was pointed out that the method of exposing the names, qualifications, addresses, and surgery hours of panel doctors on large posters in post offices and chemists' shop windows was not in accordance with the ethics of the profession. It was decided to notify the Insurance Committee that the Local Medical Committee strongly disapproves of the practice, and would be willing to suggest other and less objectionable ways of making known the names, etc., of doctors on the panel.

MIDLOTHIAN.

MATERNITY BENEFIT.

The Midlothian Medical Committee became aware that certain officials of approved societies were representing to persons insured through their societies (1) that the Commissioners have issued a table of charges fixing the fees payable to doctors in connexion with accouchements; (2) that the highest fee so payable is 15s.; and (3) that no insured person need pay more than that sum in all.

The Committee found that the basis of these representations was a leaflet issued by the English Commissioners, and refers only to England, where in consequence of the Midwives Act, which does not apply to Scotland, it had been deemed necessary to make a scale of charges, which, however, applied only to cases in which a midwife had been employed and, finding difficulty, called in a doctor.

Acting on the instructions of the Committee, the Secretary, Dr. Alex. M. Easterbrook, addressed a letter to the

Scottish Commission on May 6th, pointing out the above circumstances and asking the following questions:

1. Notwithstanding the Act, is not the fee for attendance by a doctor on the wife of an insured member at a confinement still a matter of private contract between that insured person and the doctor?
2. Is any power given by the Act to approved societies to determine the amount of such fee?
3. Even although the approved society mortgages only a portion of the 30s. of maternity benefit as a fee for the doctor is it not still competent for the doctor to recover the balance of his fee should the portion so mortgaged be insufficient to meet it?
4. Is there any regulation of the Scottish Commissioners fixing the doctor's fee in these cases?
5. Are the Commissioners empowered by the Act so far as it applies to Scotland to fix doctors' fees in such cases?

To this communication the following reply was received:

National Health Insurance Commission (Scotland),
83, Princes Street, Edinburgh,
May 28th, 1913.

Sir,

I am directed by the Scottish Insurance Commissioners to acknowledge your letter of 6th instant, in which you refer to a point arising in connexion with the administration of maternity benefit, and put forward five queries relating to the same subject.

In the first place, with regard to the point raised in your letter, I am to advert to Section 18 (1) of the National Insurance Act, in which it is provided that if, in the case of a midwife being selected by a mother to attend her, a duly qualified medical practitioner is subsequently summoned in pursuance of the rules made under the Midwives Act, 1902, the prescribed fee shall, subject to regulations made by the Insurance Commissioners, be recoverable as part of the maternity benefit. In accordance with this provision, the English Insurance Commissioners have issued regulations dated 10th January, 1913, prescribing the fees of duly qualified medical practitioners summoned in pursuance of the rules made under the Midwives Act. The Midwives Act, however, and the rules made under the Midwives Act do not run in Scotland, and the Scottish Commissioners have not issued regulations dealing with the point under notice. In Scotland, if a midwife has been selected by a mother to attend her, and a medical practitioner is subsequently summoned to treat any emergency or complication which may have arisen, the fee payable to the practitioner for his services is for arrangement between parties.

In the second place, with regard to your five queries, I am to reply:

1. The total amount of the fee payable for attendance by a doctor at the confinement of the wife of an insured person entitled to maternity benefit—or of an insured person, if a woman entitled to maternity benefit in her own right—is a matter of private contract between the insured person and the doctor.

2. Approved societies are not empowered by the National Insurance Act to determine the total amount of the fee payable by the insured persons specified in Answer 1.

3. An approved society may at its discretion make arrangements for administering a portion of maternity benefit by a direct payment to the doctor in consideration of his attendance at the confinement of a member—or of the wife of a member, as the case may be—entitled to maternity benefit. If such payment, in the view of the doctor, is not sufficient remuneration for the services rendered by him, the fact that such arrangements have been made and given effect to will not debar the doctor from claiming from the insured person such further remuneration as under the circumstances he may consider warranted. On the other hand, the doctor cannot demand a larger sum from the society than that fixed by the society.

4. The Scottish Insurance Commissioners have not made Regulations fixing the fees payable to doctors for attendance at confinements under maternity benefit.

5. The National Insurance Act does not provide for the making of such regulations by the Commissioners.

I am, Sir, your obedient servant,

(Signed) JOHN JEFFREY,
Secretary.

To this letter Dr. Easterbrook replied in the following terms:

Memorandum 159 I.C. was duly considered by the Midlothian Local Medical Committee, and it was resolved by the Committee "that it could not agree to any deduc-

tion being made from the capitation fee, which was promised as a minimum to each practitioner on the panel as an inducement to accept service under the Act. It was further resolved that it should be intimated to the Commissioners that, in the opinion of the Committee, it is unfair to ask the profession at this time to submit to such proposed deduction." I would further refer you to the letter of Dr. Alfred Cox, Medical Secretary to the British Medical Association, to the National Health Insurance Joint Committee, dealing with the subject, which appears upon the first page of the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of May 24th, 1913, and which letter more fully embodied the views of the profession.

SELKIRKSHIRE.

By kind invitation of Dr. Somerville, a meeting of the Selkirkshire Local Medical Committee was held at his residence, The Grange, Galashiels, on June 16th. Every member of the Committee, with one exception, was present.

Conference of Local Medical Committees' Representatives at Dundee.—Dr. Muir (Chairman), whom failing, Dr. Tyrrell (Secretary), was appointed to attend a conference of representatives of Local Medical Committees at Dundee on July 4th, and was specially instructed to bring under the notice of the conference the necessity of having uniformity of all certificates for medical benefit under the Insurance Act, and to have a minimum of clerical work by the profession in granting these certificates. The exclusion of treatment of venereal diseases and abortions was also considered necessary in any amendment of the Insurance Act.

Temporary Residents.—The meeting unanimously decided to instruct the Secretary to fill up and sign the draft letter issued from the British Medical Association, and send a copy to the Local Insurance Committee and the Commissioners.

Vote of Thanks.—After the meeting tea was partaken of, and a walk through the grounds and a vote of thanks to Dr. Somerville ended a most enjoyable afternoon, combining business with pleasure.

INSURANCE NOTES.

LONDON.

CONDITIONS OF MEDICAL SERVICE.

WE have received from the Clerk to the Insurance Committee for the County of London the statement printed in the opposite column.

Paragraphs 4 and 5 should be read along with form 43 I.C. for the use of insured persons desiring to make their own arrangements and embodying an undertaking to be signed by the doctor; this document was published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of March 1st, p. 214. It provided that remuneration for medical attendance should be at an inclusive rate per quarter, or calculated on a tariff of fees, the practitioner undertaking to furnish quarterly a statement of attendances and treatment. The conditions the practitioner is required by this document to undertake to fulfil were:

1. The keeping and furnishing of records in the form prescribed by the Insurance Commissioners, of the diseases of the insured person attended by me, and of any treatment of him, and of such further records as may at any time hereafter be agreed between the Insurance Committee and the Local Medical Committee.
2. The furnishing, at the request of the insured person, of such certificates as are required to be furnished by him for the purposes of the National Insurance Act in connexion with any claim for sickness or disablement benefit made by him in pursuance of the rules of the society of which he is a member, or of the Committee, as the case may be.
3. The giving of any domiciliary treatment which may be required in the event of the insured person being recommended for sanatorium benefit.

We understand that the intention of the London Insurance Committee is that the name of any practitioner undertaking to attend a limited number of insured persons shall be placed on the general alphabetical list for London, but not on the local or borough panel list, and that his name shall be marked by a star, showing that he is only willing to attend a limited number. This arrangement, we apprehend, will not satisfy those practitioners who desire that the attendance given under the Insurance Act to persons making their own arrangements should be on

the basis of private practice. At the same time, the provision of paragraph 5 will apparently meet some of the difficulties felt by some practitioners, for it is to be assumed that when the 400,000 insured persons who have not yet selected a doctor are allotted none of them will be assigned to any practitioner who has undertaken to attend only a limited number of persons.

Statement by London Insurance Committee.

The Insurance Committee for the County of London understand that there is considerable misapprehension in the minds of certain medical men with regard to various points connected with the administration of the Insurance Act. They think it well, therefore, to make the following statement:

1. In cases where a question arising between an insured person and a doctor involves purely technical, scientific, or medical details of the treatment by a practitioner, the Committee have decided that the matter shall be considered by a Special Committee consisting of the medical members of the Insurance Committee and of the Medical Service Subcommittee.

2. With regard to the question of inspection, the Committee wish it to be clearly understood that there is no intention either on the part of the Committee or, as they understand, on the part of the Insurance Commissioners, to appoint inspectors to inquire into the diagnosis and treatment of diseases by medical practitioners. The only appointments which the Committee are at present considering are those of part-time medical advisers with a view to inquiring into and deciding alleged cases of malingering in consultation with the doctor in attendance.

3. The Committee are anxious to do everything in their power to reduce the amount of clerical work required of practitioners on the panel.

4. All applications by insured persons to make their own arrangements in special circumstances with doctors, either on or not on the panel, are considered on their merits.

5. The Committee have been given to understand that private practice prevents a number of medical men from entering into agreements with the Committee for the treatment of any large number of insured persons, while they would accept small numbers. In order to meet such cases the Committee have arranged for medical practitioners to join the panel for the purpose of treating a limited number of insured persons and to suitably indicate their names in the panel, and the fact that they accept service under this condition.

The Committee have also expressed the opinion that it is undesirable that any practitioner on the panel should undertake the treatment of a larger number of insured persons than 2,000.

MEDICAL ADVISERS.

The General Purposes Subcommittee presented to the London Insurance Committee on June 26th a report in accordance with a resolution of the Insurance Committee adopted on May 22nd to the effect that it was desirable to appoint a medical adviser whose duties should include the examination of such applicants for benefit as may be referred to him by the Committee. The report of the subcommittee stated that there were approximately 1,400,000 insured persons in the County of London, and that among them were members of 862 different approved societies. The Committee was, therefore, of opinion that it would be necessary to engage more than one medical adviser to deal with questions arising as to malingering or invalidism, and recommended the appointment of four part-time medical advisers for six months. It advised that cases should be referred to a medical adviser by the Insurance Committee at the request of the approved society, and that the Committee should then arrange for the medical adviser to visit the insured person whose benefit was in question in company with the medical practitioner in attendance. The medical adviser would be consulted only on questions dealing with fitness or otherwise of an insured person, and would be required to report to the Insurance Committee any *mala fide* applicant for certificates. The Medical Benefit Subcommittee has concurred in the proposals, and the Finance Subcommittee has also concurred in them as a temporary arrangement. The recommendations formulated by the General Purposes Subcommittee were as follows:

(a) That, subject to the approval of the Insurance Commissioners, the employment be authorized, for a period not exceeding six months, of four part-time medical advisers.

(b) That a fee of 7s. 6d. be allowed for each examination by a medical adviser of an insured person as to his fitness or otherwise for work, the fee to include the issue of the necessary certificate.

(c) That, subject to the payment to the Committee of a sum of 2s. 6d. by an approved society in respect of each examination of an insured person applying for sickness benefit under the National Insurance Act, 1911, the services of a medical adviser be placed at the disposal of the approved society.

(d) That it be the duty of a medical adviser (i) to examine and check certificates referred to him by the Insurance Committee; (ii) to visit, in company with the medical practitioner in attendance, any insured person whose application for sickness benefit is in question; and (iii) to report on each case to the Insurance Committee.

SALFORD AND MANCHESTER.

At a general meeting of the medical profession of Salford, held on June 20th, it was resolved to continue the present system of medical attendance under the Insurance Act from July 15th to the end of the year. The Salford system is one in which there is an absolute free choice of doctor, patients changing their doctor whenever they think fit, and in practice it is found that they do so not infrequently. The money available for the doctors under medical benefit is pooled and distributed to the doctors on the panel by the Insurance Committee after the Local Medical Committee has scrutinized the doctors' accounts. Payment is nominally at the rate of 2s. for an attendance at the surgery, and 2s. 6d. for a visit, with extras for night calls, operations, anaesthetics, etc. The doctors are required to enter up in their day-books every service rendered, and at the end of each month to forward to the Local Medical Committee the whole of the sheets used from the day-book, including the tear-off slip, which was intended for the use of the Commissioners. The Local Medical Committee has thus before it all the work of every doctor, with his diagnosis of every case attended, and uses its discretion in cutting down anything which it considers over-attendance before allowing the accounts to rank for the division of the pool. In addition to this a grand average is obtained of the number of attendances that have been given to all insured persons throughout the borough, and any doctor whose attendances exceed this average is cut down to the average, though those below the average are not credited with anything more than what they have recorded in their day-books. Even after all these deductions have been made, the money available for the first quarter up to April 15th has only sufficed to pay the doctors 56 per cent. of their accounts if reckoned according to the nominal scale of fees. It need hardly be said that the system entails a vast amount of work of a character not always agreeable to the Local Medical Committee, as no doctor can be altogether satisfied to have his accounts cut down possibly in both the ways mentioned above, before ranking for a share in a pool which after all is only sufficient to pay 56 per cent. of the reduced accounts.

The position of the chemists in Salford is even worse than that of the doctors, as the amount available for the first quarter was only sufficient to pay them 46 per cent. of their accounts—less than the bare cost of materials supplied to the prescriptions of the doctors. Permission has now been obtained to apply a proportion of the floating sixpence so as to raise the 46 per cent., but this, of course, only goes a short way towards reducing the loss to the chemists.

A good deal of dissatisfaction is being expressed with the amount of clerical work required from the doctors, and especially as this is to be very seriously increased under the new system which the Commissioners propose to introduce. In addition to entering up the day-books, with a few modifications of no great importance, it is proposed that a card shall be kept for each patient containing the full year's account of each patient for the use of the Commissioners, the attendances being copied from the day-books on to the cards in each case. At the same time, the present tear-off slip of the day-books, which was at first intended for the use of the Commissioners, will still be required for the use of the Local Medical Committee, so that it may see the diagnosis in each case, and from that judge each month whether there has been any over-attendance. Thus there will be

a double system of entering up for each patient—once fully in the day-book almost as at present, and again on the card which the Commissioners propose to require; and the meeting of the profession passed a resolution protesting against the increase of clerical work which the new system of the Commissioners would entail. The factors which weighed principally with the Salford practitioners in their decision to continue the present system to the end of the year, in spite of all the objections to it, were, first, the greater freedom to the doctors owing to the absolute free choice of doctor by patient with similar freedom on the part of the doctors to refuse to attend any patient at any time; and secondly, the fact that the present system will provide statistics showing the amount of work required from insurance doctors, and the inadequacy of the money now available for both doctors and chemists. In addition to this, there is the rooted objection to the ordinary contract practice system.

At a meeting of the Manchester Insurance Committee on June 24th, the representatives of the Local Medical Committee reported that a postcard vote had been taken of the doctors in the Manchester area on the question whether the present system of payment per attendance should be continued or the capitation system adopted in its place, and that a very large majority of the votes were in favour of a continuance of the present system to the end of the year. The system in force in Manchester is in nearly all respects identical with that of Salford, alluded to above, and the same considerations have influenced the Manchester doctors in deciding to give the present system a full year's trial.

SCOTLAND.

ACTION BY AN INSURED PERSON AGAINST A DOCTOR.

FROM a report in the *Edinburgh Evening Dispatch* we learn that an action has been brought in the Glasgow Small Debt Court by an insured person in Glasgow against a doctor, claiming £3 11s., and alleging that as an insured person under the Insurance Act he required medical treatment in February, 1913, but that the defender failed to give him treatment between February 4th and 11th, and the pursuer had to call in another doctor not on the panel. The defender pleaded that the pursuer had no title to sue, and that the proper party to sue was the Glasgow Burgh Insurance Committee. The Sheriff has delivered judgement on this preliminary point, and said that the pursuer founded his title to sue on the averment of a contract completed between the defender and himself in the course of and through statutory procedure. The Sheriff thought that pursuer's interpretation of the legal position was correct, and therefore repelled the defender's plea and ordered proof.

IRELAND.

"MEDICAL ADVISERS."

It has been officially announced that the medical advisers recently appointed by the Irish Insurance Commissioners for the purposes of certification met in Dublin last week. Their duties and powers were fully explained to them, and they were specially instructed as regards their attitude towards other medical practitioners from the point of view of medical ethics, and the course to be adopted in dealing with cases of industrial disease, etc. A Board of Medical Advisers was constituted, and Surgeon-Colonel Adye-Curran and Dr. Seymour Stritch were appointed chairman and secretary respectively. Arrangements were made to secure central offices as a place of meeting for the board. The method of allocation of insured members was outlined, and it is anticipated that the services of the Medical Advisers will be available for approved societies and Insurance Committees as from July 1st.

SANATORIUM BENEFIT SUSPENDED IN DUBLIN.

The arrangement made by the Insurance Commissioners with regard to medical advisers was considered at the last meeting of the Insurance Committee of the County Borough of Dublin, when a resolution was adopted by 10 votes to 1 (three members of the Committee, including the Countess of Aberdeen, declining to vote) to the effect that the Committee was of opinion that it was impossible to carry out satisfactorily the sanatorium benefit clauses of the Act if applicants for benefit were to be compelled to secure certificates from some one of the medical advisers. The Committee, therefore, refused to undertake the responsibility of administering this portion of the Act. The result would appear to be that for the time being sanatorium benefit is suspended in Dublin.

IRISH MEDICAL ASSOCIATION.

Refusal to Work the Act.

The following resolutions were passed last week by the Council of the Irish Medical Association:

1. That since the Irish Insurance Commissioners have adopted a system of medical certification for sickness benefit, as well as a system of treatment and certification for tuberculosis for the insured, in opposition to the Irish medical profession, the County and Borough Insurance Committees representing employers and insured, we call upon all Local and County and Borough Medical Committees to refuse to assist the Insurance Commissioners in their determination to administer the Act in defiance of the views of those most concerned.
2. That we refuse to work the sanatorium part of the Insurance Act, in view of the action of the Insurance Commissioners in appointing medical men for certification for purposes of sickness and sanatorium benefits in opposition to the wishes of the Irish Medical Association.

CONJOINT COMMITTEE.

A meeting of the Conjoint Committee was held at the Royal College of Surgeons on June 18th, with Sir ROBERT H. WOODS, and subsequently Dr. R. J. JOHNSTONE, in the chair. The following members were present: Drs. F. W. KIDD, H. T. WARMACK, J. MILLS, KATHLEEN LYNN, E. THOMPSON, J. G. COOKE, J. S. DARLING, R. J. ROWLETTE, KATHERINE MAGUIRE, W. DOOLIN, D. FORDE, A. H. WHITE, and O'C. J. DE LA HOYDE. The Medical Secretary (Dr. M. R. J. HAYES) and Mr. C. H. GICK were also in attendance.

The minutes of the last meeting, held on April 26th, and of the special meeting held on May 9th, were read, confirmed, and signed.

Resignation of Representatives, Irish Medical Association.—In conformity with the resolution passed at the annual meeting of the Irish Medical Association, calling upon its representatives to resign their positions on the Conjoint Committee, resignations were received from the following: Drs. Stanley B. Coates, J. D. Ryan, J. W. Olpherts, G. A. Hickey, Thomas Heunessy, John M. Day, J. J. Curran, Leonard Kidd, O'C. J. De la Hoyde, and Dr. Donnelly. The Medical Secretary was directed to reply, stating that the resignations had been accepted with regret, but to point out to Dr. Donnelly that the resolution passed at the annual meeting of the Irish Medical Association had reference to its representatives, but not its members, as stated in his letter of resignation.

Limerick.—A letter was read from Dr. J. F. Devane, dealing with the importation of two doctors into Limerick to supply certificates for insured persons, and the following resolution was passed:

That this Committee sanctions the remission of fees for certificates by practitioners in Limerick in necessitous cases pending the settlement of the question.

Derry.—The position of the medical men in Derry was dealt with by Dr. COOKE, and the peculiar circumstances existing there having been considered, Dr. COOKE was instructed to convey the advice of the Conjoint Committee to his colleagues.

Conjoint Committee, 1913-14.—The arrangements for election of a Conjoint Committee for 1913-14 having been considered, it was resolved to send a concise statement of the work done by the Conjoint Committee during the past eighteen months to each member of the profession in Ireland, and to convene a delegates' meeting representative of the profession in Ireland, to which each Local Medical Committee be asked to send 5 or 7 representatives. A member of the Conjoint Committee would be *ex officio* a member of the meeting without the power of voting unless he were also a delegate to the meeting. The date of the meeting was provisionally fixed for Thursday, July 17th.

Salaried Medical Certifying Officers.—The action of the Insurance Commissioners in appointing salaried medical practitioners for the purpose of certification in areas where the panels had failed having been discussed, the following resolutions were passed and copies directed to be sent to the Insurance Commissioners:

That the Conjoint Committee regret the action of the Insurance Commissioners in appointing medical advisers in the county boroughs of Dublin, Waterford, and Limerick, and in threatening to adopt similar measures in other areas, and we condemn their action as a Government department in offering preferential treatment as an inducement to medical men to join the panels contrary to the expressed decision of the profession in their areas. That we regard

the action of the Commissioners in this matter as intimidatory, and in view of the altered circumstances, suggest that the Local Medical Committees should reconsider their action in advising their men to go on the panel for certification.

That we call upon the universities, colleges, and hospitals to use their influence in preventing recently qualified medical practitioners from accepting all appointments under the Insurance Act in opposition to the wishes of Local and Borough Medical Committees.

THE INSURANCE SCHEME.

STATE SICKNESS INSURANCE COMMITTEE.

A MEETING of the State Sickness Insurance Committee appointed by the Special Representative Meeting in November, 1912, was held at the house of the Association, 429, Strand, W.C., on Thursday, June 19th, Dr. J. A. MACDONALD, and afterwards Mr. E. B. TURNER, in the chair, and the other members present were:—*England and Wales:* Dr. R. M. BEATON (London), Mr. C. E. S. FLEMING (Bradford-on-Avon), Dr. E. R. FOTHERGILL (Brighton), Dr. HERBERT JONES (Hereford), Dr. CONSTANCE E. LONG (London), Dr. D. G. THOMSON (Norwich). *Scotland:* Dr. JOHN ADAMS (Glasgow), Dr. R. MCKENZIE JOHNSTON (Edinburgh).

Special Fund for Organization.

The Committee considered at length a report presented by a subcommittee on the subject of the formation of a special fund for the effective organization of the profession. The report was amended and forwarded to the Council with the recommendation that it should be submitted to the Annual Representative Meeting.

The report will be considered by the Council at its meeting on July 2nd, and the Committee placed on record its appreciation of the work of the Special Fund Subcommittee, and particularly that of the chairman, Dr. BEATON, who in returning thanks expressed his appreciation of the services of the Financial and Medical Secretaries in this respect.

CO-ORDINATION OF THE WORK OF LOCAL MEDICAL COMMITTEES.

At the suggestion of the CHAIRMAN a resolution was adopted advising the Council to recommend the Representative Meeting to express the opinion that no system of reorganization of the Association can be effective or complete which does not take into consideration the position of Local Medical Committees and devise some means of co-ordinating their work with that of the Association.

RULES AND STANDING ORDERS OF LOCAL MEDICAL COMMITTEES.

A set of model rules, a model constitution, and model standing orders for Local Medical Committees were submitted by the Amendments Subcommittee, and, after discussion and emendation, approved for submission to the Council.

WORKMEN'S COMPENSATION ACT CERTIFICATES.

The Committee instructed the members of the deputation appointed to meet the Insurance Commissioners with reference to the Insurance Act Amending Bill to raise the question whether an insured person in receipt of compensation under the Workmen's Compensation Act, and therefore not receiving sickness or disablement benefit, is entitled to require the practitioner on whose list his name appears to supply him with compensation certificates, and to obtain, if possible, a definite pronouncement upon the question.

SEAMEN'S NATIONAL INSURANCE SOCIETY.

The question of the administration of the Seamen's National Insurance Society, discussed at the meeting of the Committee on May 22nd, was further considered, and it was resolved that Section 48 (5) of the Act should be amended by the insertion of the words in italics:

The affairs of the Seamen's National Insurance Society shall be managed by a committee constituted in accordance with a scheme to be prepared by the Board of Trade with the approval of the Insurance Commissioners, comprising representatives of the Board of Trade, of shipowners, and of members of the

Society in equal proportions, and of representatives of the medical profession of the United Kingdom in the same proportion as is accorded the medical profession on Insurance Committees, half of whom shall be appointed by the Insurance Commissioners, and half by the British Medical Association, and the Society shall, notwithstanding anything in this part of the Act, become an approved society.

TUBERCULOSIS SCHEMES.

The MEDICAL SECRETARY reported that difficulty was being experienced in the matter of interpreting the policy of the Association so far as advertisements for tuberculosis officers were concerned, and that certain cases of difficulty had arisen, whereupon the Committee resolved to recommend the Council as follows:

That it be recommended to the Representative Body that all possible steps be taken by the Association to prevent the appointment at less salaries than £500 per annum of tuberculosis officers whose duty, whatever their designation be, includes the control of the clinical arrangements concerning tuberculosis cases, and whose relation as regards such cases to the local profession will be that of consultant.

It was also resolved that, pending fresh development, further action under Minute 63 of the Special Representative Meeting in January should be postponed, and that the Council should be advised to again refer the question of the administration of sanatorium benefit to a conference of representatives of the Association and of the Society of Medical Officers of Health which it was proposed to hold early next session.

The Committee considered a communication from Dr. T. C. Askin, asking whether the Committee approved the charge of 1s. for four days' medicine supplied by practitioners to dependants of insured, and also to insured persons suffering from tuberculosis, and pointing out that under the rules of the Seamen's Society the fee was 1s. for two days. The Committee expressed its disapproval of this method of payment of practitioners for the supply of medicine, and suggested that the best solution of the question would be that practitioners supplying medicine should receive payment on the scale of fees allowed to pharmacists under the Act.

MATERNITY BENEFIT: FEES TO PRACTITIONERS CALLED IN BY MIDWIVES.

Arising out of a communication received from the Kent County Insurance Committee, the State Sickness Insurance Committee resolved as follows:

That a reply be sent to the effect (a) that the Association considers the fees inadequate which are allowed under the Regulations in question of the Insurance Commissioners to practitioners called in on the advice of midwives; (b) that prior to the passing of the Insurance Act many local authorities had made provision for the payment of a fee of £1 1s. to practitioners called in in such cases, whereas, consequent upon the Regulations in question, there was no provision for the payment of any higher fee than 15s. for the same services; and (c) that the Association considered it to be the duty either of the Insurance Commissioners or local authorities to find some remedy for the situation thus created.

STAFF OF POOR LAW INSTITUTIONS.

A communication was read from the Poor Law Medical Officers' Association, and the Committee resolved to forward a communication to the Local Government Board, (i) drawing attention to the facts reported by the Council of the Poor Law Medical Officers' Association, (ii) stating that the British Medical Association is strongly of opinion that in all those cases where the medical officer of a Poor Law institution is required under any agreement with an Insurance Committee to attend as insured persons any of the members of the resident staff of such institution, the proper proportion of moneys paid by the Local Insurance Committee in respect of medical attendance and treatment of such insured persons should be paid to the medical officer of the institution who is responsible for such attendance or treatment.

TRANSFER OF PATIENTS.

In continuation of the consideration of the forms for the transfer of patients dealt with by the Committee at its meeting on April 17th (SUPPLEMENT, April 26th, p. 349), a letter was read from the Insurance Commissioners in reply to a letter addressed to them by instructions of the Committee. The letter from the Commissioners stated that the London Insurance Committee had adopted a

revised form of transfer from one practitioner to another which did not require any statement from the insured person as to his reasons for desiring to be transferred.

COMPENSATION CASES.

Seven applications to the Committee for grants from the Central Insurance Defence Fund were received. In one case a grant was made; in another, it was arranged to make a loan without interest; in another the applicant was requested to inform the Committee at the end of the year of any loss he might be able to prove to have been caused by action taken out of loyalty to the policy of the Association; and in the remaining cases it was resolved to ask the applicants to say whether they were really in such financial embarrassment as to necessitate a grant.

TREATMENT OF UNINSURED PERSONS.

The CHAIRMAN reported that he had on behalf of the Committee approved schemes for the treatment of uninsured persons submitted by the South Middlesex and Mid-Staffordshire Divisions. In another case the Chairman was authorized to approve of the scheme subject to satisfactory answers to certain inquiries.

CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL COMMITTEES.

An invitation to the members of the Committee to take part in the conference of representatives of Local Medical Committees to be held on July 24th in Brighton during the forthcoming Annual Meeting was received, and the CHAIRMAN reported that all the members of the Council of the Association had received a similar invitation.

FUTURE MEETINGS OF THE COMMITTEE.

At an early stage of the meeting Dr. MACDONALD drew attention to the fact that it would probably not be necessary for the Committee to meet again, but that various matters of detail might arise in the interval before the appointment of a fresh Committee. An Executive Subcommittee was appointed to deal with such matters, consisting of Drs. Macdonald, Beaton, McKenzie Johnston, Fothergill, Turner, and Flemming. Authority was given to the Chairman to summon a meeting of the whole Committee at any time should he consider it necessary.

INSURANCE ACT IN PARLIAMENT.

MEDICAL BENEFIT.

Payment for Drugs (London).

MR. HARRY LAWSON asked the Secretary to the Treasury whether in the county of London the payments made for the supply of drugs to chemists and pharmacists were much in arrear; whether the Insurance Committee for the county of London was justified in withholding payments for a quarter because the account rendered was sent in a few days after the expiry of the preceding quarter; whether he was aware that such delay inflicted hardships upon chemists because of the drain upon their trading capital; and whether the Insurance Commissioners had issued any regulations referring to such payments.—Mr. Masterman said that the Regulations which were incorporated in the agreements entered into by the chemists provided for periodical advances, although a final settlement could only be made at the end of the year, and advances up to 75 per cent. of the accounts rendered by the chemists up to the end of last quarter were promptly paid by the London Insurance Committee. With regard to the second part of the question, he was informed by the Insurance Committee that it did not withhold payments because the accounts were rendered a few days after the expiry of the preceding quarter.

Medical Benefit for Aged Persons.

MR. WORTHINGTON-EVANS asked whether the sum being accumulated out of the ordinary contributions for the purpose of providing medical benefit to insured persons after the age of 70 was being accumulated by the Insurance Committees, who at present had to provide the benefit, or by the approved societies or by the Insurance Commissioners; what was the amount of such reserve at any recent date; and whether it was separately invested.—Mr. Masterman replied that the Insurance Committees

received from societies in any year only the sums necessary to provide medical benefit for that year. The liability to accumulate the sum from which the Insurance Committees received payment in respect of medical benefit to persons over the age of 70 rested entirely upon societies. This liability was duly provided for in the actuarial calculations, but no particular part of the reserves of societies or of the contributions received by them was allotted to any one item of benefit.

Ireland.

In reply to Mr. William O'Brien, Mr. Masterman said that the report of Lord Ashby St. Ledger's Treasury Committee had not yet been published, and that it was not proposed in the bill to amend the Insurance Act to extend medical benefit to Ireland.

Seamen.

In reply to Major McCalmont, Mr. Masterman said that Section 48 (12) provided that members of the Seamen's National Insurance Society should for the purposes of the National Insurance Act be deemed to reside in England. He was not aware of any case in which a difficulty had arisen in the case of seamen whose homes were in Ireland.

Statement of Nature of Disease upon Certificates.

Viscount Dalrymple asked the Chancellor of the Exchequer whether friendly societies were carrying out the principles and intentions of the National Insurance Act when they withheld the payment of sickness benefit to patients whose doctors conscientiously refrained from specifying the nature of the disease upon their certificate, merely writing "illness" or "accident," as the case might be.—Mr. Masterman replied that he could not understand how a doctor could conscientiously refrain from giving the certificates which he had contracted to give in his agreement with the Insurance Committee.

On a later day, Viscount Dalrymple asked the Chancellor of the Exchequer whether the panel doctors had contracted to specify in their certificates the actual nature of the disease of an insured patient; and whether the approved societies were entitled to withhold sick benefit if the actual disease was not specified.—Mr. Masterman said: The panel doctors have contracted to furnish, at the request of the insured patient, such certificates as are required to be furnished by that person in connexion with any claim for sickness or disablement benefit made by him in pursuance of the rules of the society of which he is a member. And the approved societies are entitled, as trustees of the funds which they disburse, to require from an insured person claiming sickness or disablement benefit under the Act, sufficient evidence of his suffering from specific disease or bodily or mental disablement to satisfy them that he is legally entitled to receive the benefit which he claims.

SANATORIUM BENEFIT.

Scottish County Councils.

Mr. James Hogge asked the Secretary for Scotland how many county councils in Scotland had refused to meet the deficit in the circumstances detailed under Section 17 of the National Insurance Act in connexion with the treatment of tuberculosis.—Mr. Masterman said that only one county council in Scotland had refused to accept responsibility for sharing with the Treasury half of any expenditure on the treatment of insured persons and dependants over and above what was provided for this purpose from the National Health Insurance Fund.

Mr. James Hogge asked whether the Local Government Board had distributed any of the money grant towards the capital expenditure on sanatoriums to any county council in Scotland under Section 64 of the National Insurance Act; and, if so, how much and to which councils.—Mr. McKinnon Wood replied that no portion of the capital grant had yet been distributed. Before distributing any portion of the grant the Board required that a complete scheme for dealing with tuberculosis should be submitted to them. For various reasons no council, either of a county or one of the larger burghs, had yet been able to submit a complete scheme, but the councils were actively engaged on the preparatory work, and were in consultation with the Board. The Board was urging them to expedite the work so that schemes might be submitted for final approval as soon as possible.

Mr. Masterman, in reply to a question by Major Hope, said that one county council in Scotland had already agreed to pay half of any expenditure on the treatment of tuberculosis of insured persons over and above what was provided for the purpose from the National Health Insurance Fund, and other councils had the matter under consideration.

In answer to a further question by Major Hope, Mr. Masterman said that in all counties in Scotland Insurance Committees had provided adequate sanatorium benefit for insured persons. Six County Insurance Committees had further resolved to extend sanatorium benefit to dependants, and had transmitted to the Commissioners estimates of expenditure on sanatorium benefit for insured persons and their dependants in terms of Section 17 of the National Insurance Act.

Proposed Tuberculosis Dispensary in Islington.

Mr. Lough asked the President of the Local Government Board whether a draft scheme for the establishment of a dispensary for the treatment of persons suffering from tuberculosis was submitted by the Public Health Committee of the metropolitan borough of Islington to the Local Government Board in the early part of May, and, if so, what action, if any, had been taken by the Board upon it; and whether he was aware that inconvenience was being caused to the local health authority of Islington by reason of the delay in obtaining the Board's sanction to a scheme prepared in the interest of the public health of Islington.—Mr. Burns admitted that the facts were as stated in the first part of the question. The Local Government Board had invited the observations of the London County Council on the proposals contained in the draft scheme, and had also communicated with the Insurance Commissioners in the matter. He regretted that inconvenience should be caused to the borough council by any delay in coming to a decision upon its proposals, and the Board would communicate with the borough council as soon as it received a reply to the letters which it had addressed to the Insurance Commissioners and the County Council.

MATERNITY BENEFIT.

In reply to Mr. MacCallum Scott, Mr. Masterman said that an insured woman whose husband was over 65 when he became insured, and whose society did not undertake to pay him maternity benefit, was not entitled to claim maternity benefit in respect of her own insurance.

CORRESPONDENCE.

STATEMENT OF NATURE OF DISEASE UPON CERTIFICATE.

DR. ERNEST C. HADLEY (Birmingham) writes: Whether the nature of the illness should be inserted in invalidity certificates is a question of much importance at the present time. I may at once say that I am strongly opposed to so doing for the following reasons:

I. Because it is a breach of professional confidence to do so, even if the patient to whom one gives the certificate is specifically asked whether he has any objection.

A. Take, first of all the case of the patient who says that he does not object. It is still, in my opinion, a breach of professional confidence in most cases, and especially in the case of the uneducated, to do so because:

(i) Owing to the patients' confidence in their medical attendant, they trust him not to do anything prejudicial to their interests.

(ii) They do not or may not themselves understand the nature of the complaint from the nomenclature given to it in the certificate.

(iii) They may not recognize the complaint as one the knowledge of which in the hands of a third party may act to their detriment from a business or morality point of view.

(iv) In the case of women there are many complaints which, although not coming under the above headings, yet nevertheless appear indecorous in the hands of clerks, and which may cause unnecessary embarrassment to certain women of the better classes who have to personally present these open certificates.

B. Secondly, the patient may refuse to consent to have the diagnosis of his illness inserted in the certificate; in this case the doctor's line of action is, of course, quite clear, but the patient at once places himself in collision

with his society, which may try, quite illegally, to withhold or inconveniently delay granting him his sickness benefit.

II. Because the inserting of a diagnosis in a certificate (usually on the first day that the patient is seen by a medical man) is a temptation to that medical man:

(i) To insert a false diagnosis, to avoid the troubles to which I have above alluded, or, at all events, a misleading one, which is just as bad.

(ii) To insert the name of a symptom, perhaps an unessential one or one common to many diseases, as a diagnosis in order

(a) To appease the societies' demands.

(b) To protect their patients from an unpleasant diagnosis appearing in writing against them.

(c) To protect themselves from committing themselves rashly to an exact scientific diagnosis and from legal disabilities.

It is often very difficult or impossible for a medical man to arrive at an accurate diagnosis at the time when the certificate is required; not from want of knowledge—rather the reverse—but on account of pressure of time, want of convenience for complete examination, or lack of sufficient observation. In whatever way one looks at this question, there can be no doubt that the mistaken demand for a diagnosis on first certificates leads to inaccurate, unscientific, and false certification.

It is still necessary to view this question from the societies' point of view, and ask, Why do they ask so insistently for a diagnosis upon these certificates? I believe the following to be a few of the chief reasons:

1. To check the doctor in giving certificates for inability to work without committing himself to a reason in the form of a diagnosis. From this it is clear that societies have not yet learnt the valuelessness of such diagnoses.

2. To check malingering by having each patient labelled with some complaint.

3. Pure and unadulterated idle curiosity and inquisitiveness.

For the reasons given—and there are many more—I consider it is clearly the duty of the medical profession to refuse to put any diagnosis upon ordinary “unable to work” certificates. If for any special reason a diagnosis or report is required by a society upon any particular patient, this should be given by the doctor as an extra with the written request or consent of the patient, and the information should be paid for by the party requiring it. Even in this case, if the patient refuses consent, then the doctor clearly cannot divulge the nature of the patient's complaint, and the matter must be left to be settled by the patient and his society as best they can, possibly by reference to a medical referee or otherwise.

May I therefore urge all Local Medical Committees to consider this question carefully, and pass as soon as possible some such resolution as follows:

That all approved societies be notified that the medical profession in future will not insert any diagnosis upon “unable to work” certificates given for the purpose of claiming sickness benefit except in exceptional cases, and then only with the written consent, or at the written request, of the patient concerned.

Even in this latter event it is requisite that the patient should be fully informed by the doctor of the diagnosis which it will be necessary to put in the certificate, so as to give the patient an opportunity of withdrawing his consent or request should he desire to do so.

SHIPS' SURGEONS AND SEAMEN'S BENEFIT.

Dr. P. HEYWOOD HADFIELD (Newbury, Berks) writes: In the SUPPLEMENT of June 14th (p. 530) Dr. Bateman writes under the above heading. Apparently he is not fully informed as to the conditions of medical work at sea. Permit me to offer some notes on the Insurance Act as it affects the sea.

Previous to the Insurance Act all owners of foreign-going ships (carrying over a certain number of souls) were required under existing Acts to carry a duly registered medical man and to provide free medical attention, medicines, etc., for (a) all “steerage”—now usually called third class—passengers and (b) all members of the crew during the period of (a) the contract ticket and (b) employment under the articles. The steerage passenger is evidently not entitled to treatment on board ship under the Insurance Act, nor does he make during the voyage period any contribution; neither does the ship owner or the State on his behalf. I refer to the steerage passenger no more.

Members of the crew are on a very different footing, since—in addition to treatment to which they have been and still are entitled under the Merchant Shipping Acts and Employers' Liability Acts—they are now further entitled to benefits (ashore and afloat) under the Insurance Act. Since medical benefit is almost the only benefit under the latter Act—especially as the majority of sailors are unmarried—it is obvious that these two benefits are identical. The seaman in reality is worse off than before, as he now has to pay his weekly contribution for what he previously obtained for nothing—his only added benefit consists in the fact that he will now be entitled to medical benefit for that part of the year—a very short one—which he spends ashore. The shipowner is also worse off, as he has to pay the doctor—as before—and the employer's contribution: on that account he has been let off one penny as compared with the land employer. The State contribution also appears to vanish into thin air. (I do not propose to refer to the “complications”—for example, the contributions enforced from the owner in respect of Lascar, Chinese, and foreign employees entitled to no benefits under the Act, but for whom a contribution must nevertheless be paid.) The Seamen's National Insurance Society was invented for the Insurance Act under the aegis of the Board of Trade, and must be receiving an enormous revenue under the Act. It should therefore, since it has not to provide the normal amount of medical attendance to its members (who are at sea), and since it pays nothing to the ship surgeon, be in a position to offer its members great extra benefits. Such were promised, but, so far as I am aware, nothing has as yet materialized. Its members are even denied free choice of doctor, as they are informed that they must seek medical attendance from one of a list of doctors whose names are published at the “shipping offices.” So far as I have been able to ascertain, there is no satisfactory arrangement whereby a sailor who lives inland can obtain medical treatment while ashore.

Where does the ship surgeon come in? Well, he is just where he was before the Insurance Act—no better and no worse off. He gets now, as he got then, his £10 a month, and he does the same amount of work now as he did then. But since £10 a month, plus board and lodging, cannot be regarded as a *satisfactory* return for perhaps a thousand “contract” patients, it is obvious that he should be and could be better off. Since the contributions under the Insurance Act are in great part for the provision of medical attendance, and since the ship surgeon provides at least three-quarters of that attendance, it is only justice that some portion of the contributed funds should go to pay him for the work he does. As it is, the money is being side-tracked for other than medical purposes, and the medical profession at sea is being exploited.

The proposition that the ship surgeon—who does the work—should benefit under the Act seems to me so manifestly fair that I am inclined to hope that were it brought before the Chancellor by some authoritative body, some provision might result in the forthcoming Amendment Bill.

Who is to act on behalf of the ship surgeon?

There is a Ship Surgeon Subcommittee of the British Medical Association, though so far as the columns of the JOURNAL are concerned its doings are unglorified and unsung. Here is an outlet and a worthy one for its energies. I conclude my letter with my moral.

THE POSITION IN LONDON.

Dr. W. E. BARTON (Streatham, S.W.) writes to controvert Dr. Keay's sweeping assertion as to innumerable false statements in the BRITISH MEDICAL JOURNAL as to the working of the Insurance Act:—I have carefully read the correspondence every week and I can assure him that this assertion of his is the only “false statement” I have yet noticed. Dr. Keay is probably correct in stating that the number of doctors on the panel is 1,378, but let me point out to him that this includes 100 who are not resident in the districts where their services are required, besides medical officers of hospitals and institutions and others who are on the panel for a very limited number of patients, so that there are probably only about 1,200 general practitioners available to attend the rest of the 1,400,000 “insured” in the London area, giving an average of over 1,000 for each of these doctors.

With regard to the number each doctor can adequately attend, this depends entirely on the locality in which he resides, as it must be in direct ratio to his number of private patients. I believe I have had more experience of contract practice than the average general practitioner, and I can confidently assert that no man who has a fair private practice can give adequate medical attention to 1,000 insured people as well.

It is also a fact that many of the panel doctors are heartily sick of the work. Dr. Keay need only read his *BRITISH MEDICAL JOURNAL* to be convinced as to this.

It is also true that the London Insurance Committee is in a hopeless muddle; this can be proved by reading the statements made by Mr. F. G. Harris and Mr. Rockliff in the published reports of meetings of this Committee. More recently, in the *Times* of June 21st, a reference is made to the annual report of the General Federation of Trades Unions that this report expresses the opinion

That the medical and sanatorium benefits are not worth one-eighth of the money now being spent on them, as they neither make for the improvement of national health nor the prevention of the spread of tuberculosis.

Dr. Keay ends his letter by writing: "If the profession is divided," etc. Surely he is not so obsessed with his affection for the Insurance Act that he cannot realize that there is no *if* about it. The profession is divided, and it is through men like him that the unity of the profession was broken. The panel doctors sold their birthright of honour for a mess of pottage, and by their bitter wails we hear on all sides they are finding it a very indigestible, badly prepared, and extremely nauseating compound. And yet Dr. Keay asks the non-panel men to come to the rescue and join with him to prevent an even worse mess being doled out.

Dr. E. H. WORTH (Streatham, S.W.) writes: Dr. Keay, like myself and 99 per cent. of the profession, signed a pledge that we would not accept any other terms but those embodied in the celebrated cardinal points. He has accepted other conditions, and now, like the fox in the fable who having had his own tail cut off, is very anxious that we shall all "accept the inevitable" and have ours amputated, also. Speaking for myself, my word is my bond and nothing will make me sell my honour by breaking it, and now to detail.

1. It is necessary to have 3,000 men on the panel in London if the work is to be done properly. In the old club days 1,500 doctors were required to work them; there are now four times the number of patients in receipt of contract advice, therefore at least twice that number of doctors are necessary.

2. A well-known member at the last London Insurance Committee meeting gave the number of panel doctors as 1,244, and I believe him. (My letter was sent to you three weeks before you published it.)

3. I stated that a good number of panel doctors were tired of insurance work already. Dr. Keay does not believe me; if however he will turn to page 578 of the same *SUPPLEMENT* he will read as follows: "The Executive Committee of the National Medical Union stated that the membership of the union continued to grow, and testified to a growing disinclination among men on the panels to continue in the service owing to their conviction of the impossibility of carrying out satisfactory work under the Act. Numbers of letters from different parts of the kingdom have been received in which the writers have expressed the hope that they would be able to resign service at an early date."

4. My statement that the London Insurance Committee is in a hopeless muddle is a fact.

I therefore restate my claim that we London men are in a strong position, not one-quarter of us are on the panels, and never will be under present conditions.

The old London Medical Committee, called the fighting committee, is again in working order, and I trust will draw all panel and non-panel doctors to it. In Edinburgh and district the majority are non-panel men, and the Manchester Union is strong and healthy and increasing in numbers daily. I would like to see an amalgamation of the London Committee with the Manchester Medical Union and the Edinburgh Guild. We would then have a fighting force of probably 12,000 men.

Vital Statistics.

HEALTH OF ENGLISH TOWNS.

IN ninety-six of the largest English towns 8,612 births and 3,979 deaths were registered during the week ending Saturday, June 21st. The annual rate of mortality in these towns, which had been 13.5, 12.1, and 11.8 per 1,000 in the three preceding weeks, further fell to 11.6 per 1,000 in the week under notice. In London last week the death-rate was equal to 11.0, against 12.9, 11.6, and 11.4 per 1,000 in the three preceding weeks. Among the ninety-five other large towns the death-rates ranged from 5.9 in Southend-on-Sea, 6.1 in Ealing, 6.3 in Smithwick, 6.4 in Leyton, 6.5 in Hornsey, and 7.0 in Lincoln to 17.3 in Walsall, 17.7 in Stoke-on-Trent, 17.9 in Darlington and in West Hartlepool, 18.4 in Dewsbury, and 18.8 in Bootle. Measles caused a death-rate of 2.2 in Wolverhampton and 5.0 in Walsall, and whooping-cough of 1.5 in Edmonton and in Newcastle-on-Tyne, and 1.6 in Brighton. The mortality from the remaining infective diseases showed no marked excess in any of the large towns, and no fatal case of small-pox was registered during the week. The causes of 28, or 0.7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; of this number, 5 were registered in Birmingham, 3 in Gateshead, and 2 each in Portsmouth, Liverpool, St. Helens, and Carlisle. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 1,430, 1,427, and 1,418 at the end of the three preceding weeks, had risen to 1,439 on Saturday last; 273 new cases were admitted during the week, against 177, 202, and 186 in the three preceding weeks.

HEALTH OF SCOTTISH TOWNS.

IN the sixteen largest Scottish towns 1,209 births and 643 deaths were registered during the week ending Saturday, June 21st. The annual rate of mortality in these towns, which had been 16.7, 15.9, and 14.3 per 1,000 in the three preceding weeks, increased to 14.8 in the week under notice, and was 3.2 per 1,000 above the rate recorded in the ninety-six large English towns. Among the several towns the death-rates ranged from 8.5 in Clydebank, 12.0 in Kilmarnock, and 12.8 in Paisley to 18.8 in Greenock, 19.5 in Kirkcaldy, and 20.3 in Hamilton. The mortality from the principal infective diseases averaged 1.7 per 1,000, and was highest in Aberdeen and Hamilton. The 275 deaths from all causes registered in Glasgow included 12 from measles, 9 from whooping-cough, 4 from diphtheria, 4 from infantile diarrhoea, 1 from enteric fever, and 1 from scarlet fever. Sixteen deaths from measles and 2 from whooping-cough were recorded in Aberdeen; 3 from measles and 3 from whooping-cough in Hamilton; 3 from whooping-cough in Edinburgh; 2 from measles in Dundee; and 2 from diphtheria in Kirkcaldy.

HEALTH OF IRISH TOWNS.

DURING the week ending Saturday, June 21st, 613 births and 380 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 701 births and 426 deaths in the preceding period. These deaths represent a mortality of 16.5 per 1,000 of the aggregate population in the districts in question, as against 18.5 per 1,000 in the previous period. The mortality in these Irish areas was, therefore, 4.9 per 1,000 higher than the corresponding rate in the ninety-six English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 26.7 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 17.5, this being the same as that for the previous four weeks, in Dublin city 19.3 (as against 18.8), in Belfast 14.0 (as against 16.3), in Cork 17.0 (as against 16.5), in Londonderry 14.0 (as against 15.9), in Limerick 19.0 (as against 16.9), and in Waterford 38.0 (as against 25.2). The zymotic death-rate was 1.2 as against 0.9 in the previous week.

Naval and Military Appointments.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT-COLONEL J. THOMSON has left Queen Alexandra Military Hospital for duty at Aldershot.

Major H. S. THURSTON has been posted to the Dublin District.

Major F. J. WHELAN has been appointed to command the Station Hospital, Jhansi.

The following officers have been granted an extension of their Indian tour of service for one year: Brevet Colonel R. S. F. HENDERSON, K.H.P.; Lieutenant-Colonels H. J. FLETCHER and H. I. POOCK; Major E. V. AYLEN and W. A. S. J. GRAHAM; and Captains C. E. L. HARDING, F. T. TURNER, D. F. MCKENZIE, D. T. MACCARTHY, and H. W. FAHRENBROTHER.

Captain E. D. CADDELL has been appointed to command the Station Hospital, Aden.

Captain J. R. FOSTER has been appointed to command the Station Hospital, Seemuch.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT WILLIAM S. HYDE is confirmed in his rank. HENRY H. MCELHOLLAND, M.B., late cadet, Belfast University Contingent, Officers' Training Corps, to be Lieutenant on probation, May 29th.

The undermentioned to be Lieutenants on probation, May 27th: Cadet Sergeant KENNETH A. M. TOMORY, from the Edinburgh University Contingent, Officers' Training Corps; Cadet Corporal JOHN TAYLOR, from the St. Andrews University Contingent, Officers' Training Corps; HENRY P. CROW, late Cadet Glasgow University Contingent, Officers' Training Corps; DAVID MACKIE, late Cadet Glasgow University Contingent, Officers' Training Corps.

INDIAN MEDICAL SERVICE.

LIEUTENANT-COLONEL PATRICK HEHR, M.D., F.R.C.S.E., has been promoted to Colonel, March 25th.

Lieutenant-Colonel KANTA PRASAD, M.B., has retired, June 3rd.

Lieutenant-Colonel HENRY C. L. ARMIST has retired, June 13th.

INDIAN SUBORDINATE MEDICAL SERVICE.

To be Senior Assistant Surgeon, with the honorary rank of Lieutenant, March 10th; First Class Assistant Surgeons GEORGE T. BYERS, CHARLES REGINALD W. BANCROFT, PATRICK EDWARD O'DONOGHUE.

Meetings of Branches and Divisions.

[The proceedings of the Divisions and Branches of the Association relating to Scientific and Clinical Medicine, when reported by the Honorary Secretaries, are published in the body of the JOURNAL.]

CAMBRIDGE AND HUNTINGDON BRANCH: ISLE OF ELY DIVISION.

THE annual general meeting of this Division was held at March, on June 10th, under the chairmanship of Dr. H. C. MEACOCK; twelve other members being present.

Presentation to the Honorary Secretary.—Before the business of the meeting commenced the CHAIRMAN, on behalf of the practitioners of the Isle, presented to the Honorary Secretary (Dr. A. C. S. Waters) a handsome silver rose bowl, together with an illuminated address, in recognition of his services to the Division during the past year. Dr. WATERS, in reply, thanked the Chairman and members for their very kind and handsome gift, which had come as a complete surprise to him. He wished especially to thank Drs. Meacock and Tylor for the great help they had given him during the past year.

Election of Officers.—The question was raised as to whether Dr. Meacock could be re-elected chairman for a second term of office, the meeting being unanimous in its appreciation of the untiring services rendered to the Division by him during the most critical period in the history of the Association. Dr. MEACOCK thanked the members for their continued confidence in him, but preferred a chairman to be elected from the other end of the Isle. Dr. H. F. Curl, of Ely, was then unanimously elected chairman for the ensuing year. The following officers were also elected:

Vice-Chairman.—Dr. C. H. Gunson, Wisbech.

Honorary Secretary.—Dr. A. C. S. Waters (re-elected).

Executive Committee.—Drs. H. F. Curl, R. H. Barrett, F. H. Beckett, H. Clapham, F. A. Evison, J. H. Fegan, C. H. Gunson, C. H. Harding, P. A. Hendley, A. Hamilton, O. Horrocks, C. W. Howe, H. C. Meacock, C. E. Stephens, M. F. Tylor, J. J. Waddelow, A. C. S. Waters.

Insurance Act.—A letter from the Medical Secretary, referring to temporary residents, aged and infirm members of friendly societies, and certificates for sickness benefits in the case of patients attended by midwives, was referred to the Local Medical Committee for consideration.

Alteration of Boundaries.—The suggested alteration of boundaries of Divisions and Branches to make them coincide with insurance districts and areas was considered, and the opinion was expressed that where this could conveniently be arranged it would be of benefit to all concerned.

DUNDEE BRANCH.

ANNUAL MEETING OF DIVISION.

THE annual meeting of the Dundee Division was held on June 19th in University College, with Dr. C. S. Young in the chair.

Election of Officers.—The office-bearers for the year were appointed as follows:

Chairman.—Dr. R. C. Buist.

Vice-Chairman.—Dr. Charles Kerr.

Secretary.—Dr. Martin Smith.

Executive Committee.—Dr. A. P. Low, Dr. W. Corsar Anderson, Dr. J. Strathearn.

Representative in Representative Meetings.—Dr. C. S. Young.

Annual Representative Meeting.—The annual report of Council and the agenda for the Representative Meeting were considered and instructions given to the Representative.

ANNUAL MEETING OF BRANCH.

THE annual meeting of the Dundee Branch was held at the close of the Division meeting, when Dr. W. E. FOGGIE, Vice-President, took the chair. The office-bearers for the year were appointed:

President.—Dr. W. Kinnear.

Past President.—Dr. Charles Aymer, Bervie.

President-elect.—Dr. J. D. Gilruth, Arbroath.

Vice-Presidents.—Dr. G. A. Pirie, Dr. H. C. Colman, Broughty Ferry.

Secretaries.—Dr. R. C. Buist, Dr. Martin Smith.

Treasurer.—Mr. D. M. Greig.

Council.—Dr. A. P. Low, Dr. W. Corsar Anderson, Dr. J. Strathearn.

EDINBURGH BRANCH:

EDINBURGH AND LEITH DIVISION.

THE annual meeting of the Division was held on June 18th in the Gartshore Hall. Dr. JAMES RITCHIE, Chairman of the Division, presided, and 103 members attended.

Model Ethical Rules.—The model ethical rules of procedure were brought before the meeting, when the SENIOR SECRETARY read a letter from the Central Ethical Committee stating the most urgent importance of adopting these rules. Dr. JAMES SMITH moved and Dr. SMILA PATERSON seconded:

That these rules be allowed to lie on the table.

Dr. M. DEWAR moved and Dr. BORROWMAN seconded:

That these rules be discussed.

The motion was carried by a very large majority, only eight voting for the amendment.

Annual Representative Meeting.

The Report of Council and the provisional agenda for the Representative Meeting were then considered. The SENIOR SECRETARY read a letter from the Medical Secretary on the action of the Council in the interest of the non-panel doctors.

On the motion of Dr. STEVENS, seconded by Dr. F. PORTER, the following resolution was carried unanimously:

That every insured person shall have the right to be attended as a private patient by any registered medical practitioner willing to attend, without the necessity of any form of contract on the part of the practitioner, and without the loss to the insured of any of the benefits of the National Insurance Act; and that the British Medical Association be requested to incorporate this provision in their proposed amendments to the Act.

Dr. JAMES SMITH moved and Dr. TORRANCE THOMSON seconded:

That with regard to Motion 38 of the provisional agenda, this Division disapproves of any contract practice being undertaken outside of the National Act.

An amendment was moved by Dr. BOWIE and seconded by Dr. GREEN:

That this Division disapproves of that kind of contract practice which remunerates the medical attendant at a fixed sum per head per year.

Six voted for the amendment and 36 for the motion.

Dr. SHOOLBREAD moved and Dr. R. ROBERTSON seconded:

That this Division approves of contract practice provided the rate of remuneration be fixed on a reasonable and rational basis with free choice of doctor.

Sixteen voted for the amendment and 51 for the motion.

The original motion was then put to the meeting as a substantive motion, when 47 voted for it and 5 against.

Dr. ARCHIBALD MACKINTOSH moved and Dr. CORMACK SMITH seconded:

That Minute 45 of the Special Representative Meeting held in January, in which work under the National Insurance Act is said to be derogatory to the profession, be retained.

Dr. SHOOLBREAD moved and Dr. BARKER seconded:

That the word "derogatory" be deleted.

Thirteen voted for the amendment and 64 for the motion. Dr. JOHN CUMMING moved, Dr. E. F. ARMOUR seconded, and it was unanimously agreed:

That with regard to Motion 25 of the provisional agenda, referring to By-laws 16 and 18, that Clause 16 (d) and Clause 18 (c) be not adopted.

Dr. F. PORTER moved and Dr. T. J. THYNE seconded:

That this Division disapproves of the British Medical Association being formed into or being in any way associated with a medical trade union.

The direct negative was moved by Dr. F. K. KERR and seconded by Dr. R. ROBERTSON; 6 voted for the negative and 76 for the motion.

The annual report of the Executive was given by the SENIOR SECRETARY.

The following members were elected office-bearers for the year 1913-14:

Chairman.—Dr. R. A. Lundie.
Vice-Chairmen.—Dr. James Ritchie, Dr. F. F. Armour.
Senior Secretary and Treasurer.—Dr. G. Keppie Paterson.
Junior Secretary.—Dr. J. D. Comrie.
Representatives to the Representative Meeting.—Drs. T. J. Thyne, J. Stevens, F. Porter.
Representatives to the Branch Council.—Drs. J. M. Bowie, R. McKenzie Johnston, R. A. Lundie, G. Keppie Paterson, James Smith.
Executive Committee.—Drs. P. G. Borrowman, G. Dickson, J. Lamond Lackie, Archibald Mackintosh, W. H. Miller, R. S. Mowat, G. W. Simla Paterson, J. Playfair, W. Stewart, H. Torrance Thomson, A. Logan Turner, R. Thin.

LANCASHIRE AND CHESHIRE BRANCH:
 WARRINGTON DIVISION.

A MEETING of the St. Helens and Warrington Divisions was held at the Town Hall, Earlestown, on June 17th. Dr. DOWLING was in the chair, and eight other members were present.

Election of Representatives.—Dr. Bassett (St. Helens) was re-elected Representative. The Secretaries were empowered to find a deputy if necessary.

Annual Representative Meeting.—Notices of motions for the Representative Meeting were discussed, and the Representative was instructed to act as he considered best with regard to Nos. 15, 36, 37, 42. Resolutions were adopted supporting Nos. 16, 21, 22, 23, 25, 36, 37, 45, 58, and opposing Nos. 44 and 27. The Representative was instructed to support No. 11, providing that the subscription be not raised above a guinea and a half. The Representative was requested to support any practical suggestions for the co-ordination of the relation of Divisions and Insurance Committees, and was also requested to support the candidature of Mr. Garstang.

Vote of Thanks.—A vote of thanks was passed to Dr. Watkins for making arrangements for meeting in the Town Hall.

METROPOLITAN COUNTIES BRANCH:
 EAST HERTFORDSHIRE DIVISION.

THE first annual meeting of the East Hertfordshire Division was held at the Town Hall, Ware, on June 20th. Dr. A. J. BOYD presided, and thirteen other members were present.

Election of Officers.—The following were duly elected:

Chairman.—Dr. J. H. Gilbertson, Hitchin.
Vice-Chairman.—Dr. W. F. Clark, Cheshunt.
Honorary Secretary and Treasurer.—Dr. H. D. Ledward, Letchworth.
Representatives on Branch Council.—Dr. C. P. Charles, Hitchin; Dr. W. H. Sturge, Hoddesdon.
Ordinary Members of Executive Committee.—Dr. Boyd, Ware; Dr. Lawson Smith, Hertford; Dr. Odell, Hertford; Dr. Brittain, Hatfield; Dr. Fell, Buntingford; Dr. Windsor, Royston; Dr. Duckray, Bishop's Stortford.
Representative in Representative Meetings.—Dr. H. D. Ledward, Letchworth.
Deputy Representative.—Dr. J. H. Gilbertson, Hitchin.

Annual Report.—The HONORARY SECRETARY presented the annual report, which stated that the membership of the Division was now 59, a net increase of 10. There had been nine meetings of the Division during the year, with an average attendance of 24 members; in addition, two meetings had been held in each of the three wards, and the executive of the Provisional Medical Committee met five times. The chief work of the year had been in relation to the Insurance Act. An important matter outside that Act which was dealt with successfully was a proposal of the Standing Joint Committee of the county in reference to medical attendance upon members of the county police force; the county authorities proposed a partly contributory scheme without free choice of doctor, at an inclusive fee of 8s. 6d. a year with the Poor Law extras; owing to the joint action of the two Hertfordshire Divisions, the county authorities decided to bear the whole cost of the scheme, and to pay a capitation fee of 10s. a year with the Poor Law extras.

Annual Representative Meeting.—The provisional agenda of the Annual Representative Meeting was briefly considered, and the Representative was instructed to vote against any increase of the subscription to the Association, and also against the suggestion to convert the Association into a trade union.

Vote of Thanks to Chairman.—The meeting terminated with a very hearty vote of thanks to the retiring Chairman, Dr. A. J. BOYD (Ware), for his able conduct in the chair during the past strenuous year.

Garden Party.—After the meeting the members and their wives were entertained by Dr. and Mrs. BOYD at a garden party at the Manor House, Ware.

NORTH OF ENGLAND BRANCH:
 GATESHEAD AND CONSETT DIVISIONS.

THE annual meeting of the Gateshead and Consett Divisions was held at the Dispensary on June 18th. Dr. STEWART, Chairman, and fourteen other members were present.

Correspondence.

The Chairman (Dr. STEWART) gave a synopsis of several important communications from the Central Office of the British Medical Association relative to work under the Insurance Act, laying special emphasis on the portions dealing with "certificates" and the attendance on "temporary residents." This correspondence having previously been before the Local Medical Committee, the Chairman informed the meeting that a circular letter would shortly be issued to each member setting forth in concise detail the several recommendations in these memoranda.

Election of Officers.

The following officers were unanimously elected:

Chairman.—Dr. E. C. Moore.
Honorary Secretary.—James Patton.
Executive Committee.—Drs. Moore, Durant, Farquharson, Green, and Patton.
Branch Council.—The above members of Executive Committee, together with Drs. Speirs and Kempster.
Representative to Representative Meeting.—Dr. Ewen J. Maclean, Cardiff.
Deputy Representative.—Dr. Farquharson, Washington.

Presentations to Representative and Honorary Secretary.

The CHAIRMAN then made a presentation of a silver salver and fountain pen to the Representative, Dr. Durant, and a silver salver and rose bowl to the Honorary Secretary, Dr. James Patton, as an expression of the Divisions' appreciation of their exceptional services during the years 1911-1912.

The Chairman, in making the presentation, drew attention to the abnormal calls made upon these two gentlemen, and stated that the members felt that such services demanded recognition.

Drs. DURANT and PATTON replied, thanking the members for their gifts.

SOUTH-EASTERN BRANCH:
 HASTINGS DIVISION.

THE annual meeting of the Hastings Division was held on June 13th at Bexhill-on-Sea. Dr. WILLS, the Chairman, received the members at tea at 4.30 p.m., twelve members being present.

Election of Officers.—The following were elected as officers for the ensuing year:

Chairman.—Dr. Barker, St. Leonards-on-Sea.
Vice-Chairman.—Dr. Redmayne, St. Leonards-on-Sea.
Honorary Secretary.—Dr. G. Vickerman Hewland, St. Leonards-on-Sea.
Representative for Representative Meeting.—Dr. Geo. Locke, Hastings.
Representative on Branch Council.—Dr. F. W. S. Cullhane, Hastings.
Executive Committee.—Drs. A. E. Baker, G. A. Ballingall, A. W. Brodribb, W. Daunt, A. T. Field, A. H. H. Huckle, R. M. Johnson, A. H. Joseph, H. Stanley, and J. T. Wills.

Malignant Growth in the Uterus and Rectum.—Mr. DOUGLAS DREW read a paper on the treatment of malignant growths in the uterus and rectum. He pointed out the advances that had been made in the treatment of cancer of these organs by the radical operation of Wertheim for cancer of the uterus, and by the abdomino-perineal method of extirpating the rectum with the tissues in which infection was known to spread. The address was much appreciated, and a hearty vote of thanks was given Mr. Douglas Drew for his paper.

SOUTH MIDLAND BRANCH.

THE annual meeting of the South Midland Branch was held at St. Peter's Hall, Bedford, on June 12th, under the presidency of Dr. CONNING HARTLEY. Prior to the meeting

The President entertained the forty-three members present at luncheon. The following new members were elected: Dr. D. E. Walker (Guisborough, Northants), Dr. Hope (Byfield), Dr. J. H. Bayly (Bedford), Dr. Martin Coombs (Bedford), Dr. Penny (Wolverton).

Model Ethical Rules.—The Model Ethical Rules for a Branch were passed *unanimously*. It was also proposed and carried that a short summary be appended to all voluminous reports and draft rules sent out by the Central Association.

Branch Benevolent Fund.—The following committee was appointed to deal with benevolent funds in the Branch: Mr. G. H. Percival (Northants), Dr. Bower (Bedford), Dr. Baker (Bucks), with Mr. Blake-Ogders as Honorary Secretary.

Presidential Address.—The President (Dr. CONNING HARTLEY) delivered his presidential address on Personal Insurance and Pensions for Medical Men. He advocated strongly the endowment policy as a means of investment, which protects the medical man's family in case of his death, whereas if he lived to a certain fixed age a large sum was payable to him, or he could have the option of a pension for life. Such policy was also useful as a surety if the doctor had to buy his house or practice, and premiums were deducted from income tax like ordinary expenses of practice. Generally speaking, a medical man had no time or inclination to watch the fluctuations of the money market, so a safe investment by insurance became necessary.

Dysentery.—Sir PARDEY LUKIS read the paper on dysentery which is published at p. 1357.

BUCKINGHAMSHIRE DIVISION.

THE annual meeting of the Buckinghamshire Division was held on June 18th at the Royal Bucks Hospital, when the chair was taken by Dr. BENSON, and later by Dr. SHAW, and seventeen others were present.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. J. Shaw.
Vice-Chairman.—Dr. Deyms.
Honorary Secretary.—Dr. Larking.
Representative.—Dr. Bradbrook.
Deputy Representative.—Dr. Shaw.
Committee.—Drs. Benson, Henderson, Kennish, Perrin, Reynolds, and E. O. Turner.
Representatives on Branch Council.—Drs. Baker and Durran.

Dr. BENSON, on vacating the chair, thanked the members for their consideration during the past year, and expressed a hope that the coming one would be quieter. Dr. BRADBROOK said that he had now the honour of acting as Representative for five years, and he must distinctly say that it must be the last time.

Subscription to the Association.—The annual report was received and adopted. The report of the Council was considered, and the proposed increase in the subscription to the Association was discussed. Some thought it was necessary to raise the subscription to 30s. a year, and that, as a voluntary one was not the success expected, this was necessary to keep the Association free from debt. Others thought that a rise in the subscription would lead to a loss owing to resignations, and that the extra 5s. would not balance this. It was hoped that some means might be found whereby all members of the profession should contribute to such objects as the Defence Fund, and that a method might be found, by donations from the Local Medical Committees, to limit the calls upon the funds of the Association. An estimated deficit of £5,000 was not business. Finally the following resolution was carried by 11 votes to 4:

That endeavours be made to curtail expenses, and that the present time is not opportune for increasing the subscription to the Association.

Treatment of Tuberculosis.—Dr. HORNE WILSON then gave an address on the active treatment of tuberculosis. He dealt mainly with treatment advocated by Dr. Canac Wilkinson by tuberculin, stating that it was much less expensive than sanatorium treatment, and very satisfactory in its results. It was really Koch's treatment in a modified form. The reaction should never produce a temperature of more than 99.4°. The doses should be small, and given twice a week; then the dose should be increased until immunity was pro-

duced, and the patient should come again once every six months for three years to see if it lasted. The cures in suitable cases amounted to 70 per cent. A discussion took place, in which Drs. SHAW, PERRIN, BUXTON, LARKING, HENDERSON, and BURRA took part. It was pointed out that tuberculin treatment was difficult in the country when the patients had to come long distances. At present most of the cases dealt with under the Insurance Act were old ones and unsuitable for tuberculin. Sanatorium treatment combined with tuberculin was the best. A hearty vote of thanks was passed to Dr. Horne Wilson for his address.

The discussion of the subject of contract practice was postponed.

Tea was provided, and a very pleasant and instructive meeting was then brought to a close.

SOUTH-WESTERN BRANCH:

WEST CORNWALL DIVISION.

THE annual meeting of the West Cornwall Division was held at the Royal Cornwall Infirmary, Truro, on June 19th.

Presentation to Honorary Secretary.—A presentation of a silver kettle, a gold watch-bracelet, and a purse of gold was made to Dr. Mark Taylor from some of the members of the Division as an appreciation of his ten years' work as Honorary Secretary. Dr. TAYLOR suitably replied, and remarked that though at times the work had been hard, it had been a pleasure and enabled him to make so many lasting friendships.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman.—Dr. A. E. Permewan, Redruth.
Vice-Chairman.—Dr. A. Shaw, St. Austell.
Honorary Secretary and Treasurer.—Dr. L. J. Phillips, Redruth.
Representative on Representative Council.—Dr. Mark Taylor, Helston.
Deputy Representative.—Dr. F. Chown, Hayle.
Representatives on Branch Council.—Drs. Permewan, Shaw, and Phillips.
Ethical and Executive Committee.—Dr. Taylor, under heading *a* (By-law 18 in Report of Council); Drs. Permewan, Shaw, and Phillips, under heading *b*; Drs. Nesbitt, Wilson, Chown, F. Hichens, Whitworth, Sharp, Haughton, Gilchrist, and Goldie, under heading *c*; and Dr. H. Sutton, under heading *d*.

Treatment of Uninsured Persons.—A discussion then took place on the question of non-insured members of clubs, and it was decided to hold district meetings throughout the Division and obtain signatures to an agreement not to accept a fee less than 8s. 6d. a head per annum, with the exception of those persons over 65 years of age, who would be treated at the old club rates plus 2s. 6d. Government grant where that was payable.

Royal Medical Benevolent Fund.—An appeal for the Royal Medical Benevolent Fund resulted in £2 16s. 6d. being collected.

Annual Representative Meeting.—The provisional agenda for the Annual Representative Meeting was then considered and the Representative instructed thereon.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.

THE annual meeting of the Branch was held at the Infirmary, Kidderminster, on June 19th. Mr. C. S. MORRISON, President, took the chair, and there were eleven members present.

Annual Report.—The SECRETARY read the annual report of the Branch Council and presented the statement of accounts, both of which were adopted.

Election of Officers.—The following officers were elected:

President.—Mr. J. Lionel Stretton.
President-elect.—Mr. Herbert Jones.
Honorary Secretary and Treasurer.—Mr. S. Colin Legge (re-elected).

Mr. J. LIONEL STRETTON showed some very interesting cases and pathological specimens, and conducted members to view the operating theatre and aseptic furniture designed by himself, and subsequently entertained the members to tea.

Vote of Thanks.—A hearty vote of thanks was passed to the retiring President, Mr. C. S. MORRISON, for his services to the Branch during the past year.

**YORKSHIRE BRANCH:
HUDDERSFIELD DIVISION.**

THE annual meeting of the Huddersfield Division was held at the Huddersfield Royal Infirmary, on June 20th, Dr. IRVING was in the chair, and ten other members were present.

Annual Report.—The annual report was read by the HONORARY SECRETARY and adopted. It stated that the membership was 61, a decrease of 4 from the previous year, and there were 33 non-members in the area of the Division.

Local Guarantee Fund.—The sum of £35 15s. was raised by this fund to meet the extraordinary expenses in connexion with the meetings held to consider the Insurance Act; and on the motion of Dr. CHAMBERS, seconded by Dr. CROSLAND, it was resolved *nemine contradicente*:

That no further calls be made on the Local Guarantee Fund.

Vote of Thanks to Retiring Officers.—On the proposal of Dr. ED. WALKER, seconded by Dr. CROSLAND, a vote of thanks was passed to the retiring officers.

Election of Officers.—The following were elected officers for the ensuing twelve months:

Chairman.—Dr. C. R. Braithwaite, Golear.

Vice-Chairmen.—Dr. John Irving, Huddersfield; Dr. Geo. W. K. Crosland, Huddersfield.

Honorary Secretary and Treasurer.—Dr. A. L. McCully, 51, New North Road, Huddersfield.

Representative for Representative Meeting.—Dr. D. L. Cairns, Huddersfield.

Representative on Branch Council.—Dr. David Wilson, jun., Gledholt, Huddersfield.

Executive Committee.—Drs. H. C. Baldwin, J. H. Chambers, J. W. Draper, W. Macdonald, Mr. C. D. Pye-Smith, Drs. P. Rattray, R. H. Rigby, Edward Walker, H. W. Williams.

Model Ethical Rules.—The model ethical rules approved by the Annual Representative Meeting were adopted.

Association Notices.

QUARTERLY MEETING OF COUNCIL.

THE Quarterly Meeting of the Council will be held at Eleven o'clock in the forenoon of Wednesday, July 2nd, in the Council Room at 429, Strand, London, W.C.

By Order,

GUY ELLISTON,

June 26th, 1913. *Financial Secretary and Business Manager.*

ELECTION OF MEMBERS OF COUNCIL BY GROUPED REPRESENTATIVES.

NOTICE is hereby given that Nominations for candidates for election of Members of Council by grouped Representatives for the year 1913-14 will be received by the Medical Secretary up to the end of the first hour of the proceedings of the Annual Representative Meeting, on Monday, July 21st, 1913. Each Nomination must be on the prescribed form, copies of which will be forwarded by the Medical Secretary on application.

Separate forms have been prepared: (I) for Nomination by a Division (through its Representative), and (II) for Nomination by a Representative of a Constituency included in the Group, and those applying are requested to state for which purpose the form is desired.

The voting papers will be issued at the Representative Meeting to each Representative or Deputy Representative of a Constituency in the United Kingdom in attendance at the Meeting.

By order of the Council,

ALFRED COX,

June 19th, 1913. *Medical Secretary.*

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian, at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are

stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

BRANCH AND DIVISION MEETINGS TO BE HELD.

BERMINGHAM BRANCH: COVENTRY DIVISION.—Dr. Duncan Davidson, Honorary Secretary (15, Priory Row, Coventry), gives notice that a special meeting of the Coventry Division will be held at the Coventry Hospital on Tuesday, July 1st, at 8.30 p.m. Agenda: Recommendation of Ethical Committee; consideration of SUPPLEMENT of June 21st; letters from Medical Secretary; recommendations of Local Medical Committee, if any.

CAMBRIDGE AND HUNTINGDON BRANCH.—Dr. G. S. Haynes, Honorary Secretary, gives notice that the sixty-ninth annual meeting of the Branch will be held in Cambridge on Wednesday, July 16th. President-elect, Joseph Griffiths, M.A., M.D., M.C., F.R.C.S.

DORSET AND WEST HANTS BRANCH.—Dr. Frank Fowler, Honorary Secretary (29, Poole Road, Bournemouth), gives notice that the summer meeting will be held at the Town Hall, Wareham, on Wednesday, July 9th, at 3.50 p.m. Dr. Charles Mercier will read a paper, A Problem in Diagnosis. Any members having cases or short papers they would be willing to read are requested to communicate with the Honorary Secretary. Luncheon will be arranged at the Red Lion Hotel at 1.30; price 2s. 6d. The Rev. Canon Blackett has kindly promised to show members the churches and wall of the town after luncheon. Drs. Courtenay and Bell invite members to tea after the meeting.

EAST ANGLIAN BRANCH.—Dr. B. H. Nicholson, Honorary Secretary (East Lodge, Colchester), gives notice that the annual meeting of the East Anglian Branch will be held at Ipswich on Thursday, July 10th. Members wishing to read papers, etc., should communicate with Dr. Nicholson.

METROPOLITAN COUNTIES BRANCH.—Drs. W. Griffith and R. E. Crosse, Honorary Secretaries, give notice that the annual general meeting of the Branch will be held at 429, Strand, W.C., on Tuesday, July 1st, at 4 p.m. The business will include a report as to the election of new officers, and the annual reports of Council and of representatives of the Branch on the Central Council. On the motion to adopt Model Ethical Rules for Branches, Dr. F. J. Smith gives notice that he will propose an alteration to the Model Ethical Rules by substituting the words "British Medical Association" for the words "Medical Profession" in Rule 1. President's address: "The Profession and the Public." The Model Ethical Rules are printed in the SUPPLEMENTS of September 21st and 28th, 1912, pages 325 and 350.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—Dr. A. G. Southcombe, Honorary Secretary, gives notice that the 14th annual general meeting will be held in Balfour Hall, Dunstan Street, Kingsland Road, on Wednesday, July 9th, at 3.30 p.m. The chief items of business before the meeting will be: (1) Report of Central Council (SUPPLEMENT, May 3rd). (2) Agenda for Representative Meeting (SUPPLEMENT, May 10th). (3) Report of Council upon reorganization of the Association (SUPPLEMENT, June 21st). (4) Supplementary Agenda for Representative Meeting (SUPPLEMENT, June 21st and July 5th); members are especially desired to preserve those SUPPLEMENTS and bring them to the meeting. (5) Instructions to Representatives. (6) Poor Law medical appointments—(a) Dr. Major Greenwood will call attention to the position in (a) Shoreditch and (b) Bethnal Green, and move a resolution; (ii) consideration of appointment of a deputation to the (c) Hackney Union Guardians. (7) The Chairman will report the results of the appeal and levy.

METROPOLITAN COUNTIES BRANCH: WANDSWORTH DIVISION.—Dr. Hugh McD. Parrott, Honorary Secretary, gives notice that the annual meeting of the Wandsworth Division will take place on Thursday, July 10th, at 3.15, at Stanley's Restaurant, 235, Lavender Hill, Clapham Junction. Members of the Wimbledon Division are invited to attend at 4 p.m.

SOUTHERN BRANCH.—Dr. James Green, Honorary Secretary (Brandon House, Mile End, Portsmouth), gives notice that the fortieth annual meeting will be held at the Institute, Shanklin, Isle of Wight, on Thursday, July 3rd, at 1.30 p.m. Dr. F. W. Jollye, President, in the chair. Agenda: Election of officers for 1913-14, annual report of Council, balance sheet, general business. An address will be delivered by Dr. J. Cowper, of Shanklin, the President for the ensuing year. Dr. Cowper invites members of the Branch to luncheon at Daisie's Hotel at 2.15 p.m., and to a garden and tennis party, to which ladies are also invited, at 4 o'clock. The Arthur Webster Memorial Hospital and the Scio Hospital can be visited during the afternoon. Those members who wish to play golf are invited to do so by the Shanklin and Sandown Golf Club, and, if possible, a match will be arranged between the club and the medical visitors. Intending players will please communicate with Dr. Cowper. Those gentlemen who intend to accept the President's hospitality will oblige by sending word to that effect to Dr. G. Benington Wood, Newlands, Sandown, Isle of Wight, not later than June 28th.

British Medical Association.

EIGHTY-FIRST ANNUAL MEETING,
BRIGHTON, JULY, 1913.

THE SECTIONS.

The scientific business of the meeting will be conducted in sixteen Sections, which will meet on Wednesday, July 23rd, Thursday, July 24th, and Friday, July 25th.

The President, Vice-Presidents, and Honorary Secretaries of each Section constitute a Committee of Reference for that Section, and exercise the power of inviting, accepting, or declining any paper, and of arranging the order in which accepted papers shall be read. Communications with respect to papers should be addressed to one of the Honorary Secretaries.

A paper read in the Section must not exceed fifteen minutes, and no subsequent speech must exceed ten minutes.

Papers read are the property of the British Medical Association, and cannot be published elsewhere than in the BRITISH MEDICAL JOURNAL without special permission.

The following additional information has been received since our last issue:

SECTION OF CLIMATOLOGY AND BALNEOLOGY.

The following papers have been accepted:

- HOBHOUSE, Dr. E. Some Remarks on the Climate of Brighton.
ACKERLEY, Dr. R. Massage in Fibrositis and other Painful Affections.
POSTER, Dr. Michael. Some Balneological Methods used in Italy.
BOYD, Mr. Shepherd. Notes on Egypt and the Nile as a Health Resort.
GORDON, W., and THOMAS, Drs. Distribution of Cancer Cases in two Registration Districts of North-East Cornwall.
BUCKLEY, Dr. C. Rationale of the Plombières System of Treatment.
BROWN, Dr. Durward. Panniculitits.
WOODCOCK, Dr. H. de C. Tuberculosis from the Climatological Point of View.

SECTION OF DERMATOLOGY.

The following programme has been arranged:

Wednesday.—Discussion on the Fungous Affections of the Glabrous Skin: To be opened by Dr. H. G. ADAMSON, followed by Dr. Alfred Bolam, Dr. G. Pernet, and others.

Thursday.—Discussion on the Nature, Varieties, Causes, and Treatment of Lupus Erythematosus: To be opened by Dr. J. M. H. MACLEOD, followed by Dr. Robert Wild, Sir Malcolm Morris, Dr. Alfred Eddowes, and others.

Papers.—The following papers will be read:

- PERNET, Dr. George. On Veronal Rashes.
MEACHEN, Dr. Norman. A Preliminary Note upon the Treatment of Tuberculosis of the Skin by means of Copper.
BUNCH, Dr. J. L. On the Treatment of Skin Affections by Solid Carbon Dioxide.
WALSH, Dr. David. Circulatory Disorders in Relation to Alopecia Areata and other forms of Baldness.
GARDNER, Dr. F.
DAVIS, Dr. Haldin. On Ointments.
WILLIAMS, Dr. A. W. On the Treatment of Chronic Ulcer of the Leg.
DOBE, Dr. S. E. The Use and Action of X Rays in Psoriasis and other Skin Diseases.
HOBSON, Dr. L. J. The Treatment of Common Skin Diseases at the Harrogate Spa.
TOMKINSON, Dr. J. G. An Unusual Form of Keloid.

Abstracts of the papers introductory to the two formal discussions will be found in the SUPPLEMENT for June 7th, p. 507.

SECTION OF DISEASES OF CHILDREN.

The following is the programme:

Wednesday. Discussion on Affections of the Heart in Childhood: To be opened by Dr. POYNTON and Dr. CAREY COOMBS.

Papers:

- LANE-CLAYTON, Dr. Janet. Some Statistical and Experimental Data as to Infant Feeding.
MUMFORD, Dr. The Heart in relation to Athletic, Gymnastic, and Swing Exercise in Adolescent Boys.

NICHOLL, Mr. J. H. The Surgery of Childhood; a Plea for the more Extensive Use of the Out-patient Department for Operations on Children. Coupled with an account of the Organization necessary for After-care.

Thursday.—Discussion on the Choice of Methods in Dealing with Paralytic Deformities in Children: To be opened by Mr. T. OPENSHAW, C.M.G., followed by Professor Foerster, Breslau (Posterior Root Section in the Treatment of Spastic Paralysis), and Messrs. Robert Jones, Edred Corner, Laming Evans, F. W. Goyder, Kellett Smith, R. Ollerenshaw, W. J. Midelton, and H. H. Rayner.

Friday.—Discussion on the Diagnosis and Treatment of Acute Inflammatory Affections of the Abdomen in Children: To be opened by Mr. C. B. LOCKWOOD, followed by Messrs. Edred Corner, R. H. A. White Locke, C. H. Milburn, Keogh Murphy, W. J. Tyson, and F. C. Pybus.

Papers:

- SMITH, Mr. Kellett. The Necessity for Selection and for Skilled Supervision in the Treatment of Spinal Deformities by Exercise.
BANKART, Mr. Blandell. The Treatment of Poliomyelitis.

Discussion on Acute Inflammatory Affections of the Abdomen.—In opening the discussion Mr. LOCKWOOD will lay special stress on the question of diagnosis and the relative importance of various clinical phenomena. He will afterwards deal with the indications for operation, and finally adduce some illustrative cases.

Discussion on Affections of the Heart. Abstracts of the opening papers will be found on p. 507 of the SUPPLEMENT for June 7th.

SECTION OF GYNAECOLOGY AND OBSTETRICS.

Discussion on the Methods of Dealing with Uterine Malpositions.—The following paragraph indicates the line that will be taken by Professor CORBY:

Two of the most important causes of retrodisplacements of the uterus are relaxation of the posterior vaginal wall and increased weight of the uterus. The dorsal position and making the posterior wall tense are useful when replacing the uterus; a special method of using the sound. Treatment for keeping a replaced uterus in position: (1) by pessaries; (2) by vaginal operations; (3) by abdominal operations. The vaginal operations must frequently include (a) lessening the increased weight of the uterus, which is mainly due to enlargement of the cervix—resulting from cervicitis; and (b) by shortening the posterior vaginal wall to make it tense, and, if necessary, dealing similarly with the anterior wall. Ventri-suspension and ventrifixation are often, but not always, successful in keeping fundus forwards. The dangers of these operations. Notes of cases of ventrisuspension. In one of them kidney disease developed. Was this the result of pressure of the gravid uterus on the bladder and ureters? The results and dangers of shortening the round ligaments are similar to those of ventrisuspension and ventrifixation. The causes and treatment of prolapse of the uterus are almost identical with those of retrodisplacements.

SECTION OF LARYNGOLOGY, RHINOLOGY, AND OTOTOLOGY.

Additional paper:

RICHARDS, Professor Owen (Cairo). Rhino-scleroma.

We are informed that the paper mentioned on page 539 of the SUPPLEMENT for June 14th on the re-education of the powers of hearing will be discussed by Mr. RICHARD LAKE, and that Dr. HOWARD HUMPHRIS is its joint author.

SECTION OF MEDICAL SOCIOLOGY.

The following programme has been arranged:

Wednesday.—Discussion on Eugenics: To be opened by Mr. EDGAR SCHUSTER, M.A., B.Sc., Dr. HARRY CAMPBELL, and Dr. STEWART MACINTOSH, followed by Dr. R. R. Rentoul, Sir James Barr, Mr. E. J. Lidbetter, and Miss A. H. B. Kirby (Secretary, National Association for the Feeble-minded).

Thursday.—Discussion on Crime and Punishment: To be opened by Dr. JAMES SCOTT, Dr. C. A. MERCIER, and Sir H. BRYAN DONKIN, followed by Dr. F. J. Smith, Mr. A. O. Jennings, LL.B. (Registrar, High Court of Justice), Major Atherley (Chief Constable for the West Riding), the Rev. W. D. Morrison (late Chaplain H.M. Prisons), Mr. Hugh

Elliott, the Rev. C. B. Simpson (Chaplain Inspector H.M. Prisons), and Dr. Drury Pennington.

Friday.—Discussion on Hospitals in relation to the State, the Public, and the Medical Profession: To be opened by Professor BENJAMIN MOORE, Mr. I. G. GIBBON, D.Sc., Professor W. PFEFFER, Dr. ADOLF GOTTSSTEIN (Charlottenburg), and Professor GROER (Jena), followed by Dr. Christopher Addison, M.P., Sir Henry Burdett, Mr. C. A. Parker, and Mr. W. P. Wright (Grand Master, Independent Order of Oddfellows). Mr. C. F. Masterman, M.P., Chairman of the Joint Committee of Insurance Commissioners, has also intimated his desire to be present if his engagements permit.

The following paragraphs indicate the lines that will be taken by the openers of the formal discussions:

(1) *Discussion on Eugenics.*—Mr. EDGAR SCHUSTER: (a) A consideration of the questions to which it is desirable to obtain an answer, in order to organize an effective control over the racial qualities of future generations; (b) an endeavour to indicate the problems for the solution of which the active co-operation of the medical profession is more particularly necessary. Dr. HARRY CAMPBELL: Theoretically it is possible to breed a race of man perfect in form and supreme in moral and intellectual endowment. Practically such a consummation is impossible; nevertheless some effort should be made to maintain a high standard of human fitness by a due observance of the more obvious facts of heredity. It is not at present advisable to put any legal restraint upon biologically right marriages. Natural selection is still stringently operative in civilized communities, and may safely be relied upon to prevent the human race from getting appreciably below the present standard of fitness. What is needed, above all, is that the public should be educated in the fundamental principles of evolution. The great truths of science have not yet been incorporated into our religious and ethical codes. Dr. STEWART MACKINTOSH: The British people is divisible into two primary elements—native and intrusive. Many of the intrusive elements evince definite signs of imperfect adaptation, except in most favourable circumstances, to the climatic conditions of the British Isles. This is because the climate of their areas of evolution and characterization differ from British climate in material respects. There are also local types among the British people, which, being specialized for local conditions, are deficient in powers of adaptation and acclimatization to strange environments. During the past century changes in national habits and occupations have brought about reassignment of national elements, and disintegration of old-established communities and reassemblage of their units in alien environments are prime factors in the phenomena of degeneration. Popular consciousness of the resulting danger is evinced by such cries as "Back to the Land," "to the Simple Life," "to Nature." How far are such ideas feasible? The simple traditions suitable to a simple age no longer meet the needs. Greater complexity of life requires a corresponding increase in conscious control of social organization and environment. The eugenics movement is a welcome sign of advance in this direction. Recognition of the biological basis of social phenomena is of supreme importance. The profound influence of man's migration has not hitherto received due attention and consideration. Its effect on children requires particular study.

Discussion on Crime and Punishment.—Dr. JAMES SCOTT: (a) It is difficult to frame a satisfactory short definition of crime. (b) It is an offence against social order. (c) Is it a disease? (d) Is punishment of crime necessary? (e) What are the objects of punishment? (f) Who should be punished? (g) Past and present methods of punishing. (h) Punishment according to the nature of the offence, with little or no regard to the offenders: and the converse method. The points considered most suitable for discussion are those marked (c), (e), and (g). Dr. C. A. MERCIER: Crime is a consequence of the social state. It consists in acts dangerous or detrimental to society, and arises from the preponderance of selfish over social desires, which preponderance is evidence of the imperfect socialization of man, due to the comparatively small number of generations that he has lived in societies. Crimes are of three kinds: Treasons, or direct attacks on the fabric of society; private crimes,

which tend to destroy society by piecemeal attrition; and racial crimes, which interfere with the renewal of society by the production and rearing of children. Crime being destructive or detrimental to society, society must suppress crime or perish. The criminal, being an extra-selfish person, must be reformed by an appeal to his selfishness—that is, by proving to him that the consequence of crime will be unpleasant to him. Sir BRYAN DONKIN: It is assumed (1) that the State is justified in coercing law breakers with a view to the protection of the community. (2) That not only the harm done to society, but also the character and condition of the criminal must be taken into account in correction and treatment. (3) That the controversy concerning "free will" and "determinism" does not concern the practical penologist. (4) That all men are potential law breakers. In all punishments the element of retaliation is inevitable even if the object in view is reformation. Any State treatment of crime involves coercion and loss of liberty. The two questions that require discussion on this basis are: (a) The desirability of improving the criterion of legal responsibility for criminal acts. The best criterion is that given by Dr. Mercier in his book on criminal responsibility. It is applicable to cases of mental defect as well as to others, and recognizes attenuative responsibility in the interests both of the public and of the criminal. (b) The functions of the State in relation to the reform of the criminal by such work, for example, as that represented by the Borstal institutions.

Discussion on Hospitals.—Professor BENJAMIN MOORE: The hospital of the future must be designed to meet three objects correlated together: (1) Prevention of disease, (2) treatment, (3) advance of knowledge. There must be unification of the present partial systems under (1) Public health and municipal authorities, (2) Poor Law authorities, (3) voluntary bodies. The absence of unification and of a common direction of interests leads to drifting in policy, wasteful overlapping, and neglect of many cases, to the great public danger of the community. The new unified system need not lead to the loss of voluntary help from present workers, nor the loss of aid from private donors. The finances of the national or municipal system may come from three sources: (1) Municipal, (2) State funds, (3) voluntary donations. The functions and limitations of voluntary aid or beneficence are pointed out, and it is claimed that charity in kind or money, being quite inadequate for the upkeep, must be made to disappear or take a new channel. The control must follow the source of finance, but it is pointed out that this need not mean any considerable change in the personnel of the committees directing the hospitals. The hospital of the future must form the centre and head quarters of the unit of medical service fighting disease in the district. All or nearly all, medical men in the district must work in relationship to the hospital and have access to it. All work done in the hospital must be done in future not as a charity, but as an essential part of the physician's or surgeon's daily work. Mr. I. G. GIBBON: (1) General hospitals are provided by public authorities in Germany, especially by local authorities. In addition, there are many hospitals provided by religious and philanthropic bodies. There has been a very large increase of hospital accommodation in recent years. This is attributed partly to the spread of insurance. The provision of hospital accommodation is still increasing. The conditions at the general hospitals differ considerably in different places. Some of the hospitals are very large; thus the Eppendorf Hospital at Hamburg has 2,200 beds. Payment has to be made for treatment. There are different rates of charges according to the maintenance provided. Insurance societies give hospital benefit. Payment for treatment has generally to be made by the Poor Law department, failing other means. In some places a medical director is in charge of the whole of the hospital. In some he has charge only of the medical work, the other branches being under a lay director. The large hospitals have separate departments, each with its medical officer (subordinate in some respects to the principal medical director) and assistants. Medical officers may have outside consultative practice in addition to their hospital work. (2) The cost of providing hospitals has gone up to a disturbing degree. There are signs of reaction against the high capital expenditure. Information

is given of the cost of building in a number of cases. The cost per bed, without cost of land and equipment, ranges in the instances given from £94 to £450. (3) The cost of maintenance of a patient per day ranges from about 3s. to 5s., excluding capital costs and building maintenance, but is higher in some cases. Capital costs alone add 9d. or 1s. more. Of the cost per bed, from 1s. to 2s. for salaries and wages (excluding payments in kind). The number of persons employed at a number of hospitals for which particulars are given ranged in most cases from 100 to 200 per 100,000 days of maintenance of patients in the year. (4) The number of doctors employed generally ranged from 8 to 12 per 100,000 days of maintenance in the year. Salaries differ much. Medical directors may receive from £125 to £600 a year, with residence in some cases. Assistants receive from £50 to £100 a year, with board and lodging; senior assistants receive more. The *Leipziger Verband* (doctors' organization) passed a resolution in 1908 that assistants should have a commencing salary of not less than £60 a year, with board and lodging, and annual increments of not less than £10. Medical officers may receive additional payments from patients in the superior classes; they may also have a private consultative practice. Assistants also may to some extent receive fees additional to their salary. (5) Nurses are often engaged through associations. In several cases the nurses are supplied by religious orders or associations. This materially reduces the expenses, especially in the case of Roman Catholic orders. Payments may be made partly, in some cases only, to the order or association. The tendency, however, seems to be to rely on lay associations. Training is given for twelve or eighteen months. Twelve months' training is required for the State examination. Probationers generally receive little pay beyond their keep. Qualified nurses receive from £18 to £30 or £35 a year, according to place and length of service, with higher salaries for those in the highest positions. In a number of instances quoted the average annual payment per nurse ranged from £7 to £52. (6) The rates charged to patients differ considerably in different localities. As a rule there are three classes. The rates are from about 6s. to 12s. per day in Class 1; from about 4s. to 7s. in Class 2; and from 2s. to 3s. in Class 3. The rates in Class 1 more than cover expenses; those for Class 2 are below expenses; those for Class 3 are much below. Additional payments may have to be made for some special forms of treatment. (7) Most of the patients are treated in the lowest class. Insurance societies use the hospital freely, and a considerable proportion of patients are treated at the cost of the societies. Very striking is the large proportion of patients who are treated at the cost of the Poor Law; more than half the total number of days of maintenance of patients are in many cases so charged. The total receipts for the treatment of patients generally meet only a part of the expenditure, even excluding capital costs, often comparatively only a small part; less than one-half at many places. The charge on the public funds is therefore high, being as much as an average of over 2s. per patient per day, and in several instances over 3s. (8) The main conclusions are stated, and it is pointed out that the German system, which is not wholly satisfactory, is not necessarily suitable for other countries. Account has to be taken of national and local conditions and developments. The problem is dealt with in some of its aspects in the author's book on *Medical Benefit in Germany and Denmark*. Professor PFEIFFER, Dr. GOTTSSTEIN, and Professor GRÖBER: These authors deal with the following questions: (1) Are there any private hospitals controlled by the medical profession only? If so, under what conditions are they governed? (2) Have there been any large voluntary hospitals (that is, hospitals that have been supported only by private persons) that have become State hospitals and are now receiving payment from the State? If so, what has brought about this change? (3) Is there State control, insurance society control, and (or) control by the medical profession of State hospitals; and, if so, to what extent in each case? (4) Are the doctors that form the staff of State hospitals consultants only, or are they general practitioners, or both? If general practitioners hold these posts at the same time as the consultants, how is this viewed by the consultant, and how is friction

avoided? How is the staff chosen? Is it elected by a lay committee or by the other members of the staff; or are all the eligible doctors in the district allowed to attend the patients in the hospitals? How is the staff paid? Is it by salary or an honorarium; and has this salary or honorarium any relation to the number of patients attended? Are there any advantages obtained either (a) inside the hospital or (b) amongst the residents in the town from being a member of a staff? If so, what are they? Are the number of beds apportioned to each member of the staff limited? That is, should there be provided an increased number of beds, is the staff thereby automatically increased? (5) What is the procedure which has to be followed in order to admit an insured person to the benefits of the hospital? Is it done by a letter of recommendation from (a) a subscriber to a hospital, (b) a doctor, (c) an insurance society, (d) the State, (e) the Poor Law, or by personal payment? (6) Is there any differentiation made in the State hospitals between the patients? That is, are acute cases separated from chronic; or special diseases separated from general diseases; or those requiring special skill from those requiring general treatment? (7) Are special wards or beds in the wards provided for insured persons? Is the administration of such wards or beds kept entirely separate from the wards or beds provided for other persons? By administration is meant the expenses incurred as well as the appointment of the doctors to be attendants to these beds. (8) Are there any conditions attached to the grants made to these hospitals by (a) the State, or (b) insurance societies? And, if so, what are these conditions? Have these grants any relation to the number of patients treated? (9) Is there any midwifery attendance given under the rules of the State hospitals to insured women or the wives of insured men? If so, is the attendance given in the homes of the women as well as in the hospitals? Who actually gives the attendance? Is it medical students, members of the staff, or midwives, or all three? What are the other arrangements that are made? (10) What has been the effect of the formation of State hospitals on (a) the patients and the public generally; (b) the status of members of the medical profession; (c) the progress of medical research?

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

The following programme has been arranged:

Wednesday.—Discussion on Sleep and the Treatment of Sleeplessness: To be opened by Sir GEORGE H. SAVAGE, to be followed by Drs. W. H. Butler Stoddart, Constance E. Long, J. R. Lord, and D. G. Thomson.

Thursday.—Discussion on Vertigo, its Significance and Treatment: To be opened by Dr. J. S. RISIEN RUSSELL, followed by Drs. E. Farquhar Buzzard, Harry Campbell, Leonard Guthrie, Ashley Mackintosh, Aldren Turner, W. B. Warrington, and Mr. Sidney Scott.

Friday.—Papers:

BOYD, Dr. William, and BRUNTON, Dr. G. L. On the Occurrence of Micrococci in the Blood and Cerebro-spinal Fluid of Two Cases of Mania.

KLEIN, Dr. S. R., New York. Determination of Urea in Epilepsy Before and After the Attack.

WINGFIELD, Dr. Hugh. Suggestion in the Treatment of Alcoholism.

BROWN, Dr. William. Case of Extensive Amnesia of Remote Date Cured by Psycho-analysis and Hypnosis.

EDER, Dr. M. D. The Present Position of Psycho-analysis.

The following paragraphs indicate the lines that will be taken by the openers of the formal discussions:

Discussion on Sleep and Sleeplessness.—Sir GEORGE SAVAGE: Various theories as to the cause of and necessity for sleep. The evidence in favour of any true hypnotoxin as a general cause of sleep is not sufficient. Opposed to such a view are (1) the power of voluntary sleep, and (2) the sleep of hypnotic suggestion. That sleep is only partial as far as the brain is concerned is shown by memory in dreams and the persistence of organic nerve relations during sleep. Observation on hibernating animals and on the brains of animals killed by sleep deprivation point to some changes in the frontal areas in these extreme cases of sleeplessness. There are various kinds and qualities of sleep. Sleep is not an essential for all living animals. The need of sleep varies greatly with habit, with temperament, and with age. Sleep differs in quality of refreshment; dreamy sleep is not necessarily less refreshing than dreamless sleep. Sleepiness may

depend on (1) bodily, or (2) brain disorder. Conditions found in sleeping sickness and in general paralysis. Sleeplessness may depend on physical or psychological causes—(1) bodily disease, (2) brain disease, (3) mental disorder. There is much sleep hypochondriasis. Persons sleep more than they think they do. Treatment of sleeplessness may be divided into the general and the therapeutical. Brief reference to the chief drugs—(1) the opium series, (2) the simple chemical series (bromides), (3) the compound chemical series. Particular reference will be made to the use of hypnotic suggestion with cases in which it has been used.

Discussion on Vertigo, its Significance and Treatment.—**Dr. RISIEN RUSSELL:** Severe vertigo is most commonly due to affection of the ear; vertigo of moderate severity may be due to a variety of different conditions. *Aural Vertigo*—What are the essential diagnostic features of aural vertigo? *Ocular Vertigo*—Is vertigo due to ocular defects ever so pronounced as to be confounded with the more severe varieties due to gross intracranial disease or aural affection? *Gastric or Hepatic Vertigo*—Can gastric or hepatic derangements cause vertigo of such severity as to be confounded with that due to aural or intracranial disease? *Vertigo due to Arterio-sclerosis of the Cerebral Vessels*—Vertigo due to arterio-sclerosis may simulate in some respects vertigo of aural origin, or by reason of concomitant symptoms present features similar to those of intracranial tumour. Vertigo may be a premonitory symptom of a gross vascular lesion of the brain, or may be associated with an apoplectic seizure. In a special though rare group of cases of arterio-sclerosis of the cerebral vessels without evidence of paralysis or lesion of the cerebellum, there may occur vertigo of such sudden onset as to indicate its vascular origin. It may be so severe as to necessitate the exclusion of aural affection and epilepsy. *Vertigo in Epilepsy*—The vertigo occurring in epilepsy is most liable to be confounded with that of aural origin. *Vertigo in General Diseases of the Nervous System*—Vertigo is most frequently met with in disseminated sclerosis. Although deafness is often associated with tabes it is seldom accompanied by vertigo.

SECTION OF SURGERY.

The paper by **Mr. J. K. DALZIEL** on Neuralgia Stimulating Visceral Lesions relates, not as stated in a previous issue, to the fifth nerve, but to the twelfth nerve.

A cricket match has been arranged in connexion with the Annual Meeting, on Saturday, July 26th—The Profession v. Brighton College. Play will commence at 11.30 on the College Ground. Any gentlemen wishing to play are requested to send their names as soon as possible to Mr. Geoffrey Bate, 8, Palmeira Avenue Mansions, Hove. In the afternoon the Head Master (the Rev. W. R. Dawson) and Mrs. Dawson will be glad to entertain members and their friends to tea, and the college will be open for inspection.

Honorary Local Treasurer—

H. H. TAYLOR, F.R.C.S.,
36, Brunswick Square, Hove.

Honorary Local Secretary—

LEONARD ARTHUR PARRY, M.D., F.R.C.S.,
5, The Drive, Hove.

PROVISIONAL PROGRAMME.

The following is the provisional time table for the Brighton meeting:

FRIDAY, JULY 18TH.

10 A.M.—Annual Representative Meeting.

SATURDAY, JULY 19TH.

9.30 A.M.—Representative Meeting.

MONDAY, JULY 21ST.

9.30 A.M.—Council Meeting.

11 A.M.—Representative Meeting.

TUESDAY, JULY 22ND.

9.30 A.M.—Representative Meeting.

2 P.M.—Annual General Meeting.

8.30 P.M.—Adjourned General Meeting, President's Address.

WEDNESDAY, JULY 23RD.

9 A.M.—Roman Catholic Service at St. John Baptist Church.

9 A.M.—Council Meeting.

10 A.M. to 1 P.M.—Sectional Meetings.

12.30 P.M.—Address in Medicine.

3.30 P.M.—Service at St. Peter's Church.

4 P.M.—Secretaries' Conference.

7 P.M.—Secretaries' Dinner.

8.30 P.M.—Soirée by the Mayor of Brighton.

THURSDAY, JULY 24TH.

8 A.M.—National Temperance League Breakfast.

10 A.M. to 1 P.M.—Sectional Meetings.

12.30 P.M.—Address in Surgery.

2.30 P.M.—Conference of Representatives of Local Medical Committees, to be continued on following days if necessary.

7.30 P.M.—Annual Dinner.

FRIDAY, JULY 25TH.

9 A.M.—Council Meeting.

10 A.M. to 1 P.M.—Sectional Meetings.

8 P.M.—Popular Lecture.

8.30 P.M.—Reception by the Brighton Division.

SATURDAY, JULY 26TH.

Excursions.

* Academic dress to be worn.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on June 19th, with Sir FRANCIS H. CHAMPNEYS in the chair.

Register of Cases.

A letter from the M.O.H., Newport, Monmouthshire, asking the opinion of the Board as to whether a register of cases kept by more than one midwife in common should be so arranged as to distinguish the records of each individual midwife was further considered, along with a letter from the Matron of the Monmouthshire Training Centre for Midwives, who expressed her willingness to distinguish the records of each individual midwife. The Board decided that the complaint of the M.O.H., Newport, had been met, and that a copy of her letter be sent to him.

Certificates of Training.

A letter was read from the Honorary Secretary of the Association of Inspectors of Midwives forwarding a copy of a resolution passed at the annual meeting of the association in April, 1913, with reference to the approval of midwives for the purpose of signing the certificates of practical training for candidates for the examination, and with reference to the form of the certificate of attendance on cases. The Board resolved to reply that the Board's rule is to hold every principal answerable for his or her subordinates.

Amendment of Midwives Act.

A letter was considered from the Town Clerk of Stoke-on-Trent urging the amendment of Section 5 of the Midwives Act, 1902, so as to provide for the assessment of contributions from Local Supervising Authorities on some principle more equitable in operation than that arising from apportionment on the basis of the number of midwives giving notice of intention to practise in any given area. The Board in reply pointed out that it had recommended the incorporation in the amending bill of a clause in accordance with the suggestion now made, and that it would not fail to support it by all means in its power.

Maternity Benefit: Fees of Practitioners called in by Midwives.

A letter was considered from the Clerk of the Kent Insurance Committee calling the attention of the Board to a difficulty experienced by midwives in getting medical help in cases of emergency for women entitled to medical benefit. The Board replied that it had no power over the assignment of fees under the Insurance Act, and that the responsibility of advising medical aid was laid upon the midwife by the rules.

Vacancies and Appointments.

VACANCIES.

WARNING NOTICE.—Attention is called to a Notice (see Index to Advertisements—Warning Notice) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

ABERDEEN COUNTY.—Tuberculosis Officer. Salary, £500 per annum.

ABERDEEN UNIVERSITY.—Additional Examiner in (1) Diploma in Public Health, (2) Medical Jurisprudence and Public Health, (3) Medicine, (4) Midwifery.

ABERYSTWYTH INFIRMARY AND CARDIGANSHIRE GENERAL HOSPITAL.—House-Surgeon (male). Salary, £130 per annum.

ALTON: LORD MAYOR TRELOAR CRIPPLES' HOSPITAL.—Assistant Resident Medical Officer. Salary at the rate of £100 per annum.

BANBURY: HORTON INFIRMARY.—House-Surgeon. Salary, £100 per annum.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham Road, S.W.—Resident and Junior Resident Medical Officers (males). Salary at the rate of £60 and £40 per annum respectively.

BIRKENHEAD BOROUGH HOSPITAL.—Junior House-Surgeon (male). Salary, £80 per annum.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Third House-Surgeon. Salary, £75 per annum.

BOLTON INFIRMARY AND DISPENSARY.—Third House-Surgeon. Salary, £90 per annum.

BOURNEMOUTH: ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House-Surgeon. Salary, £80 per annum, rising to £100.

BRENTWOOD: ESSEX COUNTY ASYLUM.—Two Assistant Medical Officers. Salary, £160 per annum, rising to £200, and on promotion to £400.

BRIDGWATER HOSPITAL.—House-Surgeon. Salary at the rate of £100 per annum.

BRISTOL: COSSHAM MEMORIAL HOSPITAL, Kingswood.—House-Surgeon. Salary, £100 per annum.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Junior Resident Officer. Salary, £80 per annum.

BRISTOL ROYAL INFIRMARY.—Obstetric and Ophthalmic House-Surgeon. Salary at the rate of £75 per annum.

CANCER HOSPITAL, Fulham Road, S.W.—Senior and Junior House-Surgeons. Salary at the rate of £80 and £70 per annum respectively.

CANTERBURY: KENT AND CANTERBURY HOSPITAL.—Junior House-Surgeon. Salary, £90 per annum.

CARDIFF: UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Lecturer in Histology and Embryology. Salary, £200 per annum.

CHESTER GENERAL INFIRMARY.—House-Physician. Salary, £90 per annum.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House-Physician. Salary, £90 per annum.

COVENTRY AND WARWICKSHIRE HOSPITAL.—House-Physician and Junior House-Surgeon. Salary, £90 per annum, increasing to £100.

DENBIGH: NORTH WALES COUNTIES ASYLUM.—First and Second Assistant Medical Officers. Salaries, £275 and £175 per annum respectively.

DEVONPORT: ROYAL ALBERT HOSPITAL.—Assistant House-Surgeon. Salary, at the rate of £75 per annum.

DIWSBURY AND DISTRICT GENERAL INFIRMARY.—House-Surgeon. Salary, £120 per annum.

DORSET COUNTY COUNCIL EDUCATION COMMITTEE.—Dental Surgeon. Salary, £260 per annum.

DURHAM COUNTY ASYLUM, Winterton.—Third and Fourth Assistant Medical Officers (male). Salary, £180 per annum each, rising to £200 and £220 respectively.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Resident Medical Officer (male). Salary, £100 per annum.

EDINBURGH: ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—Four Resident Medical Officers.

ESSEX EDUCATION COMMITTEE, Chelmsford.—School Inspector. Salary, £250 per annum, rising to £300.

EXETER: ROYAL DEVON AND EXETER HOSPITAL.—Assistant House-Surgeon. Salary at the rate of 100 guineas per annum.

GATESHEAD DISPENSARY.—Assistant Medical Officer. Salary, £200 per annum.

GLASGOW: VICTORIA INFIRMARY.—Director of Clinical Research Laboratories and Pathological Department. Salary, £350 per annum.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House-Surgeon. Remuneration at the rate of £80 per annum.

GREENWICH UNION.—Junior Assistant Medical Officer of the Infirmary and Workhouse. Salary, £125 per annum.

HALIFAX EDUCATION COMMITTEE.—School Medical Officer. Salary, £300 per annum.

HALIFAX: ROYAL HALIFAX INFIRMARY.—Second House-Surgeon (male). Salary, £100 per annum.

THE
British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1913.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

INDEX TO THE EPITOME FOR VOLUME I, 1913.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Eye, Ophthalmia and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. Cancer of Head of Pancreas.

CHAUFFARD (*Journ. des praticiens*, November 16th, 1912) relates the history of two cases of cancer of the head of the pancreas, the symptomatology of which, although presenting differences in detail, was identical in fundamental points. The first case was a man of 53 years of age, of good history and vigorous habits. The illness began with symptoms of ordinary dyspepsia, with loss of appetite, distaste for meat, fat, and soups, and a burning sensation in the stomach. Vomiting occurred at intervals. Wasting began to be noticed, and latterly became very marked. Jaundice appeared and remained constant and intense, with intolerable itching up to the day of his death. The faeces were clay-colored, becoming rose-tinted after being exposed some time to the air, this being due to oxidation of chromogen. The amount of urica eliminated by the urine, contrary to the usual experience in visceral cancer, was almost normal. The liver and gall bladder on examination were found to be much enlarged, but no tumour could be felt on palpation. Chemical examination of the faeces showed a great diminution in the percentage of acid fats and soaps, but a great increase in the neutral fats, the latter from a normal of 25 per cent. rising to 88 per cent. The patient now had a severe attack of pain in the region of the gall bladder—evidently an access of cholecystitis which lasted for several hours, but was finally relieved. He developed another symptom which in the opinion of the author is very rare—a persistent and excessive salivation. Vomiting of a sooty-black material now became constant, and the patient died in a state of collapse. On autopsy the surface of the liver and the hepatic parenchyma was dotted over with small secondary lesions. The second patient first complained of sensation of weight after eating, sour taste in the mouth, nausea, but no vomiting. He was attacked by girdle-like pains, especially at night, and bearing no apparent relation to any food taken. Icterus developed and again became extreme, but in this case there was no pruritus. Wasting became a marked feature. The liver and gall bladder were again much enlarged. The author goes on to say that the symptomatology is in these cases dominated by the close association of the liver and pancreas, and, further, that cancer of the pancreas usually being very indurated in character, compression of the biliary and pancreatic ducts is the rule. According to the author, the girdle-like pains in the last case are to be explained by the close contiguity of the solar plexus and the semilunar ganglia. This is more especially in evidence when the body of the pancreas is involved. Glycosuria may be present, but it has been frequently noted that a pre-existing glycosuria disappears when cancer of the pancreas is established. The disappearance of sugar in the urine of a diabetic without valid dietetic or therapeutic reason must be looked upon with suspicion. The differential diagnosis from cancer of the ampulla of Vater may be made by two indications. In cancer of the ampulla the jaundice is less stable and less constant; there is as a rule blood in the faeces. In cancer of the pancreas this is not the case. The author, while pointing out the risks of surgical interference, states that a laparotomy with freeing of adhesions very often not only relieves pain, but the intolerable itching also. The chances ought to be fairly put to the patient's friends.

2. The "Fourth Disease," or Duker's Exanthem.

F. VALAGUSSA (*Rivista Ospedaliera*, Rome, 1912, ii, 327) gives a brief description of this disorder, described by Duker in 1900, and in 1885 by Filatow as rubeola scarlatinosa. He then goes at some length into von Pirquet's views on the mode of production and significance of the rashes seen in the specific infectious fevers and in serum disease; von Pirquet regards the incubation period as the time demanded by the tissues for the formation of the specific antibodies, and the specific eruptions as evidence that the antibodies have combined with the antigens (or toxins giving rise to the production of antibodies) secreted by the infecting agent (bacterium, protozoon, etc.) that is the cause of the specific disease. He assumes that the antibodies cause agglutination of the infecting organisms, and so give rise to multiple cutaneous capillary embolisms, and so to the rashes characteristic of small-pox, scarlet fever, and other disorders. Valagussa

then details the uncertainties that exist as to what it is that is the infecting agent in scarlet fever, and describes the experiments that have been made with regard to its transmission to apes, rabbits, and other animals; he concludes that scarlet fever, like small-pox, is caused by an ultramicroscopic organism. His observations at Rome lead him to believe that cases of the fourth disease sometimes precede but more often follow outbreaks of scarlet fever. Twice he has seen two or three cases of the fourth disease followed after seven to ten days by typical cases of scarlet fever in other patients; he has seen the fourth disease occur in children who had had scarlet fever from forty days to seven months before in 12 instances (1909-11); and, conversely, he has noted the occurrence of scarlet fever in 19 children who had had the fourth disease from eleven days to two months previously (1909-12). He concludes that the two diseases are closely connected and due to the same infecting agent, but represent different degrees of reaction to it on the part of the body. He finds albuminuria between the fifteenth and the twenty-first days of the disease in 16 per cent. of the patients with the fourth disease; out of 42 patients with it, 35 had acetoneuria, 5 of the 35 also had diaceturia. The frequent or even constant occurrence of acetoneuria in scarlet fever is, he says, well known. He regards the fourth disease as a *forme fruste* (as the French would say) of scarlet fever, and asserts that it should be made notifiable, because it may spread scarlet fever.

3. Tumour of the Hypophysis.

ROZABAL (*Revista de Med. y Cir. Pract.*, September 14th, 1912), at the May session of the Academia Medico-Quirúrgica Española, showed two brothers with all the symptoms regarded as characteristic of tumour of the pharyngeal portion of the pituitary body, and consequent deficient action of that part of the organ. In the family history there was nothing of interest beyond the facts that both parents were of short stature and that the mother had experienced repeated abortions. This latter fact notwithstanding, the Wassermann reaction was negative in both parents and children. The elder boy, 14 years of age, commenced to suffer from dimness of vision at about 3 years of age. This gradually increased until he was able to distinguish objects only in limited portions of the field of vision. Soon it was noted that he was growing very bulky, especially about the belly and thighs. At the same time he ceased to grow in height. The external genital organs remained in a rudimentary condition. When first seen by Rozabal his height was 1.17 metre, much adipose tissue everywhere; the thighs and pubis were of the feminine type, the genital organs no more developed than in a boy of 4 years of age. There was double optic atrophy, and he counted fingers with difficulty at a distance of a metre. The arterial tension was 13.0, urine normal, hands extraordinarily small. The appearance and history in the case of the brother, 11 years of age, were similar but somewhat more advanced. There was typical hemianopsia. Both patients had a supernumerary digit on each foot, and the younger in addition a penile hypospadias. A radiograph of the sella turcica showed nothing worthy of mention. This combination of signs—increase of fatty tissue, cessation of growth, atrophy of the genital organs—forms the syndrome of Frölich, and is regarded as a consequence of tumour of the pituitary body with hypofunction of the gland. In some respects it is the reverse of acromegalia, nearly always due to hyperfunction of the gland. The author considers, in view of the usual relative benignity of tumours in these cases and the teratological alterations which were present—supernumerary toes, hypospadias—that there was probably in these two cases a cyst formed by an invagination of the ectoderm at the level of the pharyngeal portion of the hypophysis. These are the first cases of the syndrome of Frölich which have been reported from Spain.

SURGERY.

4. Tetany following Thyroidectomy.

FRANCIS J. SHEPHERD (*Ann. of Surg.*, November, 1912) follows up a brief historical sketch of the work done in investigating the causes of tetany after thyroidectomy

with the statement that the weight of opinion tends to prove that post-operative tetany is dependent on the removal or destruction or injury of the parathyroids. There are two theories of the functions of the parathyroids: (1) That an antitoxin is developed by the parathyroids which neutralizes certain waste products of tissue metabolism, so that when the parathyroids are destroyed a toxic material is formed in the blood which causes tetany (Berkeley); (2) that the calcium metabolism of the cells of the body is controlled by the parathyroids and that their removal causes a rapid disappearance of the soluble salts of calcium from the blood (W. G. McCallum). The latter theory is not strictly held now even by its author, but it is thought that there is something in it from the fact that fractures in animals whose parathyroids have been removed heal much more slowly than in normal animals, and that after removal of the parathyroids the skeleton, as a whole, takes on changes resembling rickets in young animals and more like osteomalacia when the animals are old. The parathyroids are to be regarded as organs of vital importance to the economy. It is hardly possible to recognize them during operation on the thyroid in the human subject. The author reports a case in a woman of 34, who had had goitre for twenty-one years. Operation was performed, all the thyroid except the upper pole of the left lobe being removed. Parathyroids were carefully looked for, but not seen. On the third day symptoms of tetany appeared (fornication, sense of weight and oppression, giddiness, numbness in legs, stiffness and flexion of fingers and toes, acute pains in legs). On the fifth day drachm doses of calcium lactate were administered every three hours, and in six hours there was marked amelioration of the symptoms. The drug was taken intermittently, and whenever it was stopped the symptoms again presented themselves. Parathyroid extract also was administered. It was found that the combination of calcium lactate and parathyroid extract suited best, and that the former alone did better than the latter alone. After six months the patient still had some sense of oppression in the head, which was corrected by calcium lactate taken in 20-grain doses twice a day. The results of the case show that calcium will cure temporarily any case of tetany due to insufficiency or removal of the parathyroids. The author refers also to other means of treatment, such as hypodermic injections of nucleo-proteid principle of parathyroid (Beebe) and transplantation of parathyroids of animals into muscle or into bone marrow (Kocher).

5. Diverticulitis Simulating Appendicitis.

A case of inflammation of Meckel's diverticulum simulating appendicitis is reported by C. Schwenk (*Berl. klin. Woch.*, November 18th, 1912). A married woman, aged 21, who had not previously suffered from abdominal disease, suddenly developed severe pain in the region of the appendix while walking. She had swallowed two gramophone needles the day before. At first the pain was intermittent; later it spread to the whole of the abdomen, but was still most severe on the right side. She vomited frequently, was constipated, and experienced pain on micturition. Thirty-six hours after the onset the clinical picture was in every respect characteristic of appendicitis. The temperature was 101.8° and the pulse 100. There were abdominal tenderness and distension, and on the right side the percussion note was distinctly tympanic. Rectal examination showed tenderness about the pouch of Douglas. The diagnosis of hysterical fever was negatived by the objective phenomena, and by a skiagraph which showed a needle in the ileo-caecal region. Laparotomy revealed slight and recent infection of the peritoneum and intestine. The serous coat of the latter presented small lacunomata. The appendix, which contained no foreign body but was somewhat injected, was removed. Palpation of the small intestine in the ileo-caecal region revealed nothing. When the pelvis was raised so as to expose the urogenital organs, a small cylindrical tumour, resembling a recent hydrops of the Fallopian tube, was detected. It was covered by a serous membrane, and from its blind end villi projected. It proved to be an 8 cm. long Meckel's diverticulum situated 1 m. from the ileo-caecal valve. Its distal end was club-shaped and occupied by the needle, both ends of which protruded freely. Amputation of the diverticulum was not feasible so the needle was withdrawn, and the wounds it left were carefully closed by several rows of sutures. The wounds healed by first intention, and the patient was discharged on the seventh day. The author emphasizes the relation of Meckel's diverticulum to acute abdominal disease, and recalls the case, published by Müller, in which the discovery of a gangrenous diverticulum was too late to save the patient's life.

6. Ligneous Phlegmon.

FAZANO (*Gazz. degli Osped.*, October 27th, 1912) reports 12 cases of ligneous phlegmon, a condition first described by Reclus, most of which cases occurred in the cervical region, but subsequent experience showed that it is not confined to this region, but may occur in various parts of the body, including the abdominal cavity, and it is especially in this latter region that such hard masses may be mistaken for malignant disease. Two of the author's cases, occurring in association with chronic appendicitis, well illustrate the great difficulty in differentiating the two conditions. Various organisms have been found in association with these tumours, but no one organism is constantly to be found; it seems probable that in every case the organisms are of attenuated virulence. Predisposing causes are bad general health, trauma—in fact, any of the usual causes of irritation, but it may occur in healthy subjects as some of the author's cases show. The only pathognomonic sign is the extreme hardness of the mass, which may appear as a diffuse induration or a definite nodular tumour. The skin, as a rule, is not adherent at the outset, but usually becomes so later. Slow absorption may take place, or eventual softening and the formation of pus. Pain and tenderness are usually very slight or even absent, and fever is slight and evanescent. The diagnosis is extremely difficult, even where such a condition is suspected, and time alone can clear the matter up. The greatest difficulty occurs when it is a question as to whether the mass is a malignant tumour or not, and immediate operation may in some cases be necessitated. The two cases of tumour in the right iliac region above referred to are very instructive from this point of view. Amongst the author's cases were examples of cervical phlegmon, gluteal, the dorsal aspect of the foot (in sequel to a foreign body), the abdominal parietes (the result of a buried suture), etc. Unfortunately there is no certain sign which enables one quickly to recognize these ligneous phlegmons from other indurated masses; only a careful consideration of all the factors and a watching attitude enables one to solve the problems eventually. The presence of hyperleucocytosis is in favour of phlegmon.

7. Pseudo-lumbar Puncture in Enuresis.

ALLASIA (*La Pediatria*, October 31st, 1912), believing that the success of the lumbar puncture in the treatment of essential enuresis in children is due to the psychical effect rather than to the puncture *per se*, has treated a series of cases by what he calls pseudo-epidural puncture. He carries out all the details of the ordinary lumbar puncture, but instead of injecting the physiological solution into the spinal canal, he merely injects it into the subcutaneous tissue. He says his results were quite as good in this method as in the more severe mode of treatment. All cases where the enuresis might possibly be due to such causes as adenoids, morbid urine, etc., were excluded, and only essential or idiopathic cases taken. Brief details of 23 cases are given, and these had 35 pseudo-lumbar punctures. In 16 no results were observed, in 2 the enuresis ceased for one night, in 8 for a few days, in 3 for some weeks, and in 3 for some months. Looked at in another way, 12 of the 23 cases got no benefit, 6 had slight and transitory relief, 5 were relieved for long periods. These cases, compared with another series of true lumbar puncture, led the author to believe that the main factor when relief follows is one of mental suggestion, and the contrary is that essential enuresis is a neurosis.

OBSTETRICS.

8. Pituitrin and the Ductless Glands in Obstetrics.

REYNOLDS of Philadelphia (*Amer. Journ. Obstet.*, October, 1912) has made use of pituitary extract in order to determine its action on the mammary glands, cardio-vascular system, and uterus. He publishes some cases where it undoubtedly proved to be a powerful galactagogue and a stimulator of uterine contractions in from fifteen to thirty minutes after intramuscular injection. It causes a rise in blood pressure and slowing of the pulse, the highest pressure occurring between twenty and thirty minutes after the injection. Lastly, it does not cause an inflammatory reaction at the site of the injection or any noticeable nervous symptoms. On the other hand, Reynolds insists that pituitary extract is inactive in the presence of fever. In three instances which he reports in abstract the extract was used in the febrile period with negative results, whilst in all the extract proved active when employed

after the temperature had fallen. The first patient had twice attempted to terminate the pregnancy within the previous two months. Labour occurred close upon term. pelvic inflammation developed on the sixth day, and an abscess was opened in the right groin. No milk could be drawn from the breasts. Two weeks after abatement of the fever, 1 c.cm. of pituitary extract was injected one evening into the deltoid. On the next morning a thin watery secretion ran rather freely from the nipple, and $\frac{1}{2}$ drachm of milk was withdrawn by the breast pump; this secretion lasted for four days. The second case, where gonorrhoeal infection complicated the puerperium, was somewhat similar. There was no milk in the breasts from birth; at the end of the third week the temperature was normal, pulse 114, systolic pressure 98, and diastolic 85; then 1 c.cm. of the extract was injected into the upper arm. Thirty minutes later the pulse was 96, systolic pressure 105, and diastolic pressure 95. On the next day the injection, of the same amount into the same part, was repeated. Six hours later $1\frac{1}{2}$ drachms of milk were withdrawn from the left breast and 1 drachm from the right. In the last case labour was induced in a multipara suffering from eclampsia. The breasts secreted hardly any milk. At the beginning of the third week, the patient being restored to general good health, the extract was given as in the second case. Not only did milk begin to be secreted, but the patient was soon able to suckle her child. In patients where there had been no fever from the first the extract proved an active galactagogue from the first, and it checked uterine haemorrhages. Sajous (*ibid.*) dwells on the beneficent influence of thyroid extract on lactation and on the share of the thyroid and parathyroids in the physiology of pregnancy. Adrenal haemorrhages in the fetus, detected in 45 per cent. of necropsies on nurslings, deserve consideration. Sajous believes that thyroid extract given to the pregnant mother protects the fetus from changes which lead to adrenal complications after birth. The other ductless glands, including the pituitary body and the ovaries, belong, like the adrenals, to the chromaffin system and are closely related to one another through the sympathetic system which plays an important part in the many functional relationships which they so plainly show. Krusen (*ibid.*) is of a similar opinion. Lutein is undoubtedly the internal secretion of the ovary, and its extract may give relief in ovarian insufficiency.

GYNAECOLOGY.

8. Menstrual Psychoses.

11. KÖNIG states that it has been recognized for ages that a large number of women present psychic anomalies during the menstrual period which pass off when the period ends and leave the woman quite sound. An analysis of these records reveals the inclusion of a number of distinct conditions, but although many of the supposed anomalies of menstruation can be classified under recognized mental disturbances, a number remain which correspond to what Krafft-Ebing called "psychosis menstrualis" (*Berl. Klin. Woch.*, August 26th, 1912). The author first discusses the distinction between hysterical and non-hysterical mental disturbances appearing during menstruation. Given a marked ease, in which hysterical signs and a hysterical habit are discernible, it is reasonable to suppose that the psychosis is in part, at all events, dependent on the hysteria, and therefore the prognosis will be less favourable than when it is not so influenced. The same may be said in regard to epilepsy. He objects to the view that every case of menstrual psychosis need have an ascertainable basis. Of course this condition will only be found in a person who possesses a certain degree of psycho-physical degeneracy, but it is unreasonable to require a more definite basis for changes in a predisposed individual during a time when the normal individual undergoes an alteration in bodily habit in mood and in capability for work. The author divides the cases into (1) those psychoses which occur periodically with regular intervals before the first menstruation and which do not recur after the first period; (2) ovulation psychoses, occurring either once, or several times, or at each period; and (3) the so-called epochal menstrual psychosis. Instances of the first and third groups are rare, the author having only come across one of each, but those of the second group are very common. They include the hysterical, epileptic, and the non-classified cases. The disturbance may be pre- or post-menstrual, or may occur during the period. The more common forms are the

maniacal, the melancholic, and the hallucinatory, the latter resembling a condition of amnesia very closely. A number of these cases lose their initial characters and pass over into chronic psychoses, either of the catatonic or of the maniacal-depressive type. After discussing the justification of associating these forms of psychosis with menstruation, which has been questioned by some psychologists, he turns with caution to the prognosis. In general terms he states that the earlier the condition sets in the worse is the prognosis. This, of course, does not apply to those cases included in the first group of the classification. An exception is found in the so-called pseudo-menstrual climacteric insanity. In such cases, although the onset takes place in advancing years, the prognosis is bad. He cites some cases as illustration for the prognosis. The author further adds a few words on the etiology of these conditions, about which he admits very little is known.

THERAPEUTICS.

10. Salvarsan and the Nervous System.

SPIEHOFF analyses the question of the frequency of neuro-recurrence in the treatment of syphilis on the basis of his wide experience with salvarsan and other medications (*Munch. med. Woch.*, May 14th and 21st, 1912). Finger has stated that since salvarsan has been introduced the frequency of recurrent symptoms of nervous implication has increased markedly, and this he ascribes to the treatment. Spiethoff agrees that more cases of nervous symptoms occurring during the course of syphilis after treatment have been seen since salvarsan has been introduced, but he also finds that they are more common when small doses of salvarsan are used, and he has come to the conclusion that they occur in inverse proportion to the size of the dose. In his cases he has registered 0.97 per cent. of neuro-recurrences. If only those cases are included in which observation was carried out for a fairly long time, the frequency is found to be considerably greater, but when analysed in relation to the intensity of the dose he is able to show that while 25 per cent. of the cases which were given two injections of an alkaline solution intravenously, and which were kept under control for at least four months, showed neuro-recurrences, only 12.5 per cent. were met with when three injections were given. The phenomenon was not seen at all when a more energetic treatment was followed. He gives details of the symptoms under discussion in his cases. He states that the prognosis and treatment of these symptoms do not differ from similar symptoms observed before the salvarsan era. He finds salvarsan extremely useful in combating these symptoms, and indeed, goes as far as saying that in one of his cases (optic neuritis) the removal of the symptoms would not in all probability have cleared up so completely with mercury as it did with salvarsan. In the course of these observations he finds that a comparison of the analyses of the spinal fluid yields more exact information than Wassermann's test does, both in regard to diagnosis and treatment. The cell counts and the determination of the albumen content by Nonne's method of precipitation often reveal signs of increase of the disease, when the complement deviation test of the serum of cerebro-spinal fluid gives no information at all. In speaking of the salvarsan treatment of tabes he feels justified in recommending its trial in all cases. An existing nervous lesion independent of syphilis, such as epilepsy, is not affected one way or the other by salvarsan, and he especially points out that fits are not produced by the injections. In syphilitic affections of the central nervous system he gives salvarsan and mercury when the signs are localized to one or two cerebral nerves, but when the process is more diffuse he prefers to start with mercury, and later on to give salvarsan in gradually increasing doses, when tolerance is established. He records two cases of very severe symptoms following the injection of slightly acid solutions of salvarsan for primary and secondary syphilis respectively, in one of which a fatal termination occurred. In conclusion, he expresses the opinion that in spite of Finger's, Kavaat's, and Levy Bing's publications, salvarsan should be given in full doses even when there are signs of spinal irritation. Lumbar puncture forms the best means of treating the headache arising in these cases.

11. Blerotin.

F. BERGER (*Wien. med. Klin.*, No. 17, 1912) describes an antigonorrhoeal internal remedy put on the market,

in capsule form, under the name of blenotin. Each capsule contains sandal oil 0.16 gram, myrrh 0.02 gram, camphor 0.02 gram, hexamethylenetetramine 0.12 gram, boric acid 0.11 gram, champignon extract 0.02 gram. The author describes cases illustrative of the action of blenotin in acute gonorrhoea of the anterior part of the urethra, of gonorrhoea cystitis, and of gonorrhoea in infants. The effects are those to be expected from such a combination of remedies already well known in urological practice. The effect of sandal oil in the pure form was clearly seen, but the sandal oil caused no gastric disturbance or kidney symptoms. As a rule, in patients complaining of bladder trouble, the appetite improved with the disappearance of the local symptoms. The effect of blenotin in anterior urethritis was excellent. The secretion in a few cases had already begun to diminish by the second or third day, but more usually after a week's time; it dried up altogether frequently in ten to fourteen days. In one case described the discharge had ceased after only five days. As a rule, gonococci had also disappeared by the tenth to the fourteenth day. In favourable cases clear urine was passed after from ten to twelve days. In order to test the preparation more satisfactorily, the author, in the cases described, gave blenotin alone without local treatment. Judging from the results obtained, he has no doubt that blenotin would prove a most useful aid in the treatment of posterior urethritis, and might even, if taken early, be a prophylactic against spread of the gonorrhoeal process to the posterior part of the urethra. The cases of gonorrhoeal cystitis were a good test of the efficacy of the remedy. In these cases the very severe strangury, which was accompanied by scalding and tenesmus, had usually disappeared in from four to ten days, and objective improvement kept pace with the subjective change. A complete clearing of the urine was seen on an average in twelve days. The author warmly recommends blenotin as a result of his own trial of it.

12. X-ray Treatment of Hyperidrosis.

In a paper read before the Société de Radiologie Médicale de Paris (*Bull. et mém.*, June, 1912), Belot speaks favourably of x-ray treatment in localized hyperidrosis, more particularly palmar and plantar ephidrosis. The type of hyperidrosis most amenable to this treatment is that in which the condition exists independently of emotional stimulus, although it is, of course, intensified by the emotions. In purely emotional hyperidrosis, the x rays are of slighter value. The increased sensibility of the tissues in conditions of excessive sweating makes treatment difficult, and the rays may produce troublesome reactions without any beneficial result. In special cases of this kind the author resorts first of all to a course of internal medication, and only turns to the x rays after the modification of the soil. In all cases when the trouble is of an emotional character, general treatment should be associated with the local applications—douches and aurodynes for the nervous disorder, alkalines and iodide for the arthritic diathesis if it exists; and tonics (such as arsenic, phosphates, etc.) for the anaemia. Electrotherapy (faradization of the spinal cord) is also useful. The function of the x rays is to induce partial but not total atrophy in the cells of the glandular elements, and to resist the hyperactivity which is the cause of the condition. It is important to divide the x-ray dose equally over the area, and for this purpose the region is partitioned off into segments. On the plantar surface, for instance, the heel, the hollow of the foot, and the toe portion are separately irradiated. In treating the palm some means has to be adopted to keep it immobile and level, and the distance of the thenar eminences and of the fingers from the focus of the tube is carefully taken. The dose, directed through aluminium filters, varies with the individual. A full but not a heavy dose (maximum 4 Holzknicht units) is given, being smaller in the case of the female, especially the female blonde, than in the case of the male. A second and rather smaller irradiation is given eighteen or twenty days after the first; and the state of the skin, the evolution of the reaction, and the persistence of the hyperidrosis, determine the subsequent treatment. Generally five or six sittings suffice; one should never go beyond eight or ten. After three or four irradiations some secretory change is usually noted, but the evolution of the atrophic phenomena is not immediate. Plantar hyperidrosis is more rebellious than hyperidrosis of the hands or the axilla, but there are few instances of trouble from the reaction, a passing redness only being noted in the more sensitive skins.

13. Iodine in Whooping-cough.

CAVAZZANI (*La Pediatria*, February, 1912), after ten years' experience of the above mode of treatment, says that iodine is a valuable drug in the treatment of whooping-cough. The value of iodine in tuberculosis and in various infective diseases has been recognized by many authors, and the present author speaks highly of its use in typhoid. It is contraindicated in acute infections—for example, pneumonia, acute nephritis, measles, scarlatina, acute rheumatism, and influenza. In whooping-cough it is said to diminish the attacks of whooping, to shorten the disease and make it generally milder. During the last ten years, the author says, he has seen no severe case such as he used to see before he began the iodine treatment. It does not act as a direct specific. He administers the drug as follows: He dissolves the metallic iodine in KI and water in the proportion of 1 part of iodine to 15 parts each of KI and water. Of this mixture he gives 4 to 6 drops per diem in sweetened milk to a child of 1 year, increasing up to 10 to 15 drops in children over 5 years. Given in this way, he has not observed any intolerance. It does not matter in what stage of the disease it is given. Apparently, in addition, he sometimes gives quinine or camphor monobromide.

PATHOLOGY.

15. Colorimetric Quantitative Estimation of Albumen.

THE methods of estimating albumen in urine in use in clinical practice are quite unreliable. It has been shown repeatedly by capable investigators that Esbach's test yields results which differ very considerably from the real content of albumen. M. Claudius calls attention to this and to the experience that the ordinary heat test is not available for clinical purposes (*Muench. med. Woch.*, October 8th, 1912). He now describes a colorimetric method of quantitative estimation of albumen, which yields accurate results and which he claims is easy to carry out. It is based on the principle that if a solution of albumen also contains a dye and the albumen is precipitated, the coagulum absorbs part of the dye, leaving the filtrate less strongly tinted than before. The degree of decolorization will indicate the amount of albumen precipitated. The test is carried out as follows: A reagent is made up of trichloroacetic acid, tannic acid (which not only assists the precipitation of the albumen, but also acts as a mordant), and acid fuchsin. The urine to be tested must be either neutral or slightly acid, and perfectly clear. The acidifying may be attained with acetic acid, and the clarifying by filtration. It is then diluted with equal parts of a 2 per cent. aqueous sodium chloride solution. By means of a 5 c.c.m. pipette, exactly 5 c.c.m. of the reagent and 5 c.c.m. of the diluted urine is dropped into a 15 or 20 c.c.m. flask. The pipette should be rinsed before the urine is measured. The flask is then closed with a cork and well shaken. The albumen soon separates out and is agglutinated. This is filtered off through a dry filter, and the filtrate is collected in a dry, clean test tube. A graduated tube is then taken and filled up to a point marked "5" with the diluent, and a second tube with the normal fluid. The diluent consists of a solution of trichloroacetic acid and picric acid, and is of exactly the same colour as that of a "normal" or standard tube. The normal colour fluid is a mixture of 1 part of reagent and 200 parts of diluent; 50 c.c.m. of the filtrate is now delivered into the diluent by means of a capillary pipette, care being taken that the amount is absolute. The mixing is attained by sucking the fluid up the pipette and blowing it out again several times. The colour of the mixture is now compared with that of the normal fluid. If the colour is deeper than that of the normal fluid, diluent is dropped by means of a dropper until the colours correspond. If it is weaker, the test must be repeated with a weaker dilution of urine in sodium chloride solution. The graduated tube containing the mixture is so arranged that the upper level of the fluid indicates the parts of albumen per 1,000. The smallest differences represent $\frac{1}{4}$ per cent. The accuracy of the test was controlled by comparing the results of tests with albuminous urines, the control being worked out by gravimetric analysis. The differences were found to be minimal. The author also gives the results obtained with the same samples of urine by Esbach's test, which showed an error of nearly 50 per cent. The apparatus necessary for the test and the reagents are obtainable from Drübner and Co., Leipzig.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

15. Nervous Sequelae of Cerebro-spinal Meningitis.

SAINTON (*Journ. des praticiens*, October 19th, 1912) states that, whatever the micro-organism, there is a common symptomatology in these cases. At a variable time from the date of recovery, (a) sensory, (b) motor, (c) psychical disturbances arise. The first of these is the most frequent, and deafness is probably more common than any other sequela. It results in all probability from atrophy of the auditory nerve, or partial destruction of the cochlea. Ocular sequelae are less common and generally improve. There may be paralysis of the third or sixth pair of nerves. In other cases there is pupillary inequality, mycosis, mydriasis, or more rarely optic atrophy. With regard to motor disturbances, the general rule is to find spastic paralysis, with exaggeration of reflexes. Sometimes there is tremor and nystagmus. Persistent aphasia has also been noted. Voison has seen a case followed by epilepsy, and a case related by the author had a similar result. There was a crisis which began with an aura of gastric origin, nausea and vomiting, loss of consciousness, and epileptic convulsions. An examination of the cerebro-spinal fluid between the crises was normal, and made immediately after a crisis showed a slight lymphocytosis. The general condition in this case was good. The psychical disturbances are variable. There is generally a change of disposition, and in some cases a state of dementia results. In these cases a state of extreme hydrocephaly was revealed at autopsy. Sometimes the malady, though cured clinically, may remain latent. The best means of preventing these sequelae appears to lie in the use of antimeningococcic serum. In bad cases it ought to be injected directly in contact with the nerve centres.

16. Herpes Zoster and Varicella.

THE relation of herpes zoster to varicella is commented on by P. Heim (*Berl. klin. Woch.*, December 9th, 1912), who observed the following cases: A doctor's wife became feverish on May 5th. Next day she had stabbing pain in the left side of the chest, where a number of red spots appeared. Seen the same evening, this eruption was characteristic of herpes zoster. At this period only one child—a 6-year-old girl—was at home, but four days later a 3-year-old son came home. On May 16th—ten days after the mother's eruption appeared—the girl developed typical varicella of moderate severity, the maximum temperature being 100° F. On May 22nd the boy developed varicella in a severe form, the temperature being 103° F. for several days, and the body being covered throughout by the eruption. In his right axilla, over an area the width of two fingers, the vesicles were smaller than elsewhere, and were arranged like those of herpes zoster; here, too, the child complained of pain. Evidently both children must have been infected by the mother, for only six days intervened between the outbreak of their eruptions, and the average incubation period of varicella is fourteen to seventeen days, and never under eight days. The mother's eruption ceased exactly at the middle line, and new vesicles appeared in the same area on the third and fifth days of her illness. She had never suffered from varicella, although, at the age of 4, she had not been isolated from two sisters who had contracted the disease. Bokáy, in 1880, observed two children of the same family one of whom suffered from typical herpes zoster of the chest. The other developed typical varicella ten days later. In the course of the following twenty-one years he saw eight other similar cases, the periods between the appearance of herpes and of varicella ranging from eight to twenty days. On three occasions the herpes was followed by two, three, and four cases respectively of varicella. One of his cases is of special interest. A patient was admitted to hospital with lumbar-femoral herpes on October 29th. On November 9th another patient suffering from a tumour of the spleen developed varicella. In none of Bokáy's nine cases of varicella was any source of infection other than herpes demonstrable. The author also observed the simultaneous occurrence of epidemics of herpes zoster and varicella in Budapest in 1912, and he believes that the hitherto unknown germ of varicella may, under certain conditions, cause a localized eruption like that of herpes zoster, and that, with further development, it may again cause a varicella-like eruption.

17. Tuberculosis in Infancy.

COZZOLINO (*La Pediatria*, October 31st, 1912), discussing some of the difficulties in the diagnosis of pulmonary tuberculosis in infancy, points out that neither radiocopy nor tuberculin reactions give decided evidence between a rather prolonged post-influenzal febrile condition and a tracheo-bronchial tuberculosis, and he gives cases of this from both points of view. Schick's sign (expiratory stridor) remains still a valuable diagnostic sign of enlarged tracheo-bronchial glands, even when associated with manifest pulmonary tuberculosis. Pulmonary tuberculosis starting in the tracheo-bronchial glands is not necessarily fatal in the first year of life. The daily (and prolonged) administration of fairly large doses of cod-liver oil to tuberculous children does not necessarily give rise to exudative manifestations. The differential diagnosis between bronchiectasis and pulmonary tuberculosis in infancy is decided more often on clinical signs and symptoms than on laboratory tests. Unfortunate mistakes may be made in either direction if too much stress is laid on the results of laboratory tests alone.

18. Loss of Weight in New-born Infants.

MENSI (*La Pediatria*, September 30th, 1912), taking the weights of the children admitted into hospital during the first nine months of 1911, and all artificially fed, found that in 32 admitted on the second day after birth the mean loss of weight was 108 grams, in 94 admitted on the third day the loss was 320 grams, and in 71 admitted on the fourth day the mean loss was 215 grams. The loss of weight was usually proportional to the absolute weight of the body. The length of the period during which weight is lost depends largely on the quality of the first food, whether human or artificial, but also to some extent on the "quotient of energy" of the child. Whether this physiological loss of weight is due to lack of water taken in or to abnormal elimination of water and tissue waste is uncertain. The author, in some observations on tissue change in a baby 2 days old, found that the elimination of CO₂ varied from 13 to 16 mg. per kilogram; insensible perspiration he puts down at 100 per cent., accepting the usual figures, and in general accepts the theory that the loss of weight is largely due to loss of water. There is also some loss of nitrogenous matter, but this is of less consequence. The author next discusses the relation between loss of weight and the development of jaundice, and from his figures it appears that the icteric children had lost less weight than normal up to the time of the appearance of the jaundice. As regards the viscosity of the blood, this was found to be higher in the jaundiced children. From testing the iodophile reaction of the blood and the resistance of the blood corpuscles the author found even in the pre-icteric stage the blood pressure was lower than normal. The percentage of urine passed in relation to liquid ingested in 3 normal children was 44, 55, and 57 per cent., whilst in 5 icteric it fell to 27, 28, 35, 44, and 52 per cent. respectively.

SURGERY.

19. Incandescent Light in the Treatment of Atonic Wounds.

LAQUERRIÈRE AND LOUBIER (*Arch. d'électr. méd.*, November 25th, 1912) have treated several cases of obstinate atonic wounds with the ordinary incandescent lamp. For this treatment they reserve the term "luminotherapy," as distinct from "phototherapy," in which the rays of the arc lamp are used. These superficial wounds had shown no inclination to heal after the application of dressings and other treatments. Daily exposures of from twenty to thirty minutes to the lamp were given, the lamp being of 32 candle power and placed in a reflector. In one case a suppurating wound on the dorsal surface of the ring finger following an accident had refused to cicatrize for a month, and the whole of the finger was oedematous and the nail had disappeared. By the tenth sitting with the lamp the oedema had diminished and the wound had a better aspect; by the twenty-sixth there only remained a very small tenacious patch, and this finally disappeared by the fortieth. In a second case painful wounds on the foot had followed upon a burn, and had refused to respond to

ordinary treatment. White light in this instance gave rise to severe itching after the sittings, but on using a lamp the glass of which was tinted blue the light was well tolerated and resulted in a marked sensation of relief. From the fifth sitting the amelioration was considerable, and after the twelfth sitting the healing was so well advanced that only ordinary dressings were deemed necessary to complete it. As instances of the deeper action of luminotherapy and the trophic character of the radiations the authors cite two cases of osseous rarefaction, one affecting the index finger and the other the astragalus, both of which improved greatly under this simple treatment.

20. Operative Treatment of Acute Circumscribed Phlebitis.

K. BÜDINGER (*Wien. klin. Woch.*, No. 32) has, he believes, been the first operator to treat by operation cases of acute circumscribed phlebitis. The customary conservative methods of treatment of this condition are tedious, and as a rule are followed by incomplete recovery; one or more phleboliths or venous knobs are left behind, and both give rise to symptoms and may easily form a starting point for fresh inflammatory processes. The author takes certain precautions against embolism. There is no mechanical, energetic, preliminary cleansing of the operation site. Any pressure on the inflamed veins is absolutely avoided, and the site is merely painted gently with benzine, or with iodine tincture, which is equally free from danger. Infiltration anaesthesia is not employed. The operative measures are as gentle as possible. An incision, 1 to 2 cm. in length, is made into each palpable nodule directly through the wall of the vein into the thrombus, and the thrombus removed either with forceps or, if it is firmly in position, with a spoon; but removal by the spoon must not be by scraping movements. Sometimes a long thrombus can be drawn out from the venous nodule. If, at the operation, it is found that purulent softening has already begun, large pieces of the veins can often be removed without any force of pull being required, the vessel having been first divided at either limit of the inflammatory area. Bleeding is never severe. The wounds are not stitched up nor plugged, but simply covered with a sterile bandage. The patients are allowed to stand on the day after the operation and also to walk a little. As a rule the wound is already healed on the eighth day, when the dressing is first changed.

21. Anaesthesia by Intramuscular Injections of Ether.

GUIBÉ (*Journ. des praticiens*, November 2nd, 1912) discusses critically this method of anaesthesia as advocated by Descarpentieries. The method is described as follows: A syringe holding from 20 to 50 c.cm. is used with a long platinum needle, and the patient's eyes being bandaged to prevent the irritation of the rays of light, multiple injections are given into the muscular tissues of the buttock at intervals of a few minutes. The dosage depends upon three factors: (1) The susceptibility and receptivity of the patient; (2) the degree of anaesthesia required; (3) the duration of the anaesthesia. For an average woman 60 c.cm. of ether in six doses of 10 c.cm. each are used, this amount being increased in emotional and nervous subjects. Anaesthesia can be prolonged by additional injections. According to the originator of the method, at the time of injection there is severe but transient pain, followed immediately by swelling of the parts. The patient feels an indefinable malaise, and his breath smells of ether. The anaesthesia follows the usual course, and in about twenty minutes is complete. Consciousness returns gradually, and in an average case is quite restored in about half an hour. According to the author, the disadvantages of the method greatly outweigh any possible advantages it may have. Cases which are not suitable for general anaesthesia may be quite satisfactorily dealt with by spinal anaesthesia. The initial pain, he says, is very severe, and persists locally after anaesthesia is over. But the inconstancy of result is a more serious drawback. The anaesthesia is often incomplete or too short, and it is often necessary to complete it with chloroform or ethyl chloride. There is also a variability in the rate of absorption, according to the tissue into which the injection is made, with the result that there is not enough ether circulating in the blood at one time to establish proper anaesthesia. Another notable objection to the method is the impossibility of arresting the anaesthesia at will. It may be prolonged for some hours after the operation is over—a consideration which might prove serious after certain operations. In the author's view, the advantages of the method are

too slight and the inconveniences too grave to recommend it for any other than very exceptional use.

22. Coxa Vara of Infancy and Congenital Luxation of the Hip.

PETIT DE LA VILLÉON (*Gaz. hebdom. des sc. méd.*, 1912, xxxiii) draws attention to a sign which he considers, in the absence of radiography, is diagnostic of coxa vara—namely, internal hyporotation. The patient is examined in the following manner: The child is laid on the healthy side, the suspected thigh flexed to a right angle on the pelvis, and the leg to a right angle on the thigh. The surgeon faces the child and seizes the condyloid process of the femur, the knee is kept above the table, the femur resting in an horizontal plane and parallel to that of the table. The surgeon then performs internal rotation of the femur, and at the maximum of this movement measures the angle made by the leg; if this represents 45 degrees the articulation is normal, if 90 degrees = congenital luxation, if 25 degrees or under = coxa vara.

OBSTETRICS.

23. Expectant Treatment of Eclampsia.

WRITING from Zweifel's clinic in Leipzig, Lichtenstein seeks to place the so-called expectant treatment of eclampsia on a sound scientific basis and to explain its rationale (*Muench. med. Woch.*, August 13th, 1912). Hitherto the active treatment of this condition by rapid emptying of the uterus and by decapsulation of the kidney was carried out because the various statistics appeared to show that the best results were obtained by these procedures. The cases were divided in these statistics into "early" delivery cases, in which the uterus was emptied after the first or at latest the second eclamptic fit, and the "late" or "rapid" delivery cases, in which delivery was not carried out until after the third attack. Now Lichtenstein points out that since Dürrssen's statistics were published, in 1893, eclampsia during the puerperal period has been excluded from the statistics. Eclampsia occurring after the birth of the infant, however, represents some 20 per cent. of all the eclampsia cases, and this form of the disease has a mortality of 20 per cent., which is as high as that of the late delivery cases, and about three times as high as the early cases. If emptying the uterus *per se* has such a marked effect on the course of the eclampsia, he argues, how can this be accounted for? Again, in a certain number of cases pregnancy is interrupted as a prophylactic measure when eclampsia is threatening. In 13 cases of this kind, 9 attacks of eclampsia occurred before the uterus was emptied and 4 during the lying-in period. This led Lichtenstein to regard the cases which do not break out until the lying-in period in the same light as the early delivery cases and to group them together in the statistics. The result was that the morbidity and mortality of the former group (that is, early cases plus puerperal cases) are as high as those of the late delivery cases. The obvious conclusion was that immediate delivery is not necessary. On the other hand, he recognizes that the results of the active treatment are better than were the old narcotic treatment results. On analysing the process he came to the conclusion that the improvement did not depend on the fact of the emptying of the uterus but on the manner in which it was emptied. Taking the average amount of blood lost at a normal birth at 400 c.cm., he finds that this amount is exceeded in the operative delivery of eclamptic patients in 52 per cent. of the cases, as against only between 4 and 5 per cent. of the spontaneously delivered eclamptic patients; 40 per cent. of the eclamptic patients lost more than 500 c.cm. after operative delivery, as against none of the spontaneous deliveries. Women in whom the eclampsia passed off after the delivery lost about half as much again blood as those in whom it continued, and about four times as much as those in whom the fit began after the birth. These facts led him to the conclusion that the quantity of blood lost is more important than the emptying of the uterus of the ovum. He therefore introduced a new method of treating eclampsia patients in April, 1911. This consisted in bleeding combined with anaesthesia, according to the directions given by Stroganoff. The method is carried out by bleeding to the extent of 500 c.cm., when the patient is either not in labour or only in the first stage. If she has borne the child, or if the birth can be completed rapidly, the bleeding is carried out immediately after the birth. After the bleeding is completed, the patient is given morphine and chloral. and

later ether anaesthesia. The room is kept quiet, no external stimuli are permitted to reach the patient, and no heat is applied, in order that sweating may be prevented, which would have the effect of concentrating the blood too much. Forty-five patients were treated in this manner. The amount of blood abstracted per patient was 710 c.cm. The infantile mortality was 40 per cent., as against 38 per cent. in the 400 cases treated by the active method. The mortality of the viable children, however, was 25 per cent., as against 36 per cent. in the previous cases. The delivery was completed spontaneously in 53 per cent., as against 22 per cent. The fits stopped in 60 per cent. of the cases at once, which is about the same ratio as with the active treatment. The average number of attacks per case was 5.1, as against 13 in the eclampsia cases of the previous fifteen years. The maternal mortality was 11.1 per cent. The mortality of the patients during the previous ten years treated by the active method was 18.5 per cent. The highest year gave a mortality of 33.33 per cent., while only one year showed a mortality percentage of less than 11.1. In analysing the causes of death in the 5 cases, he found that one patient died of double pneumonia, after having been given a powder. A second died of peritonitis; in this case two attempts had been made prior to admission to hospital to deliver with forceps. In a third, the cause of death was probably pneumonia. In 40 per cent. of the cases the eclampsia cleared up "intercurrently"—that is, before the child was born. This is a very high proportion. The author also adds the results obtained by others who have adopted this method of treatment, which were also favourable. He does not enter into a discussion of the theoretical significance of the facts brought to light, but reserves this for another communication.

GYNAECOLOGY.

24. Physiological Function of the Ovary.

A. LOUISE MCILROY (*Journ. of Obst. and Gyn. of the Brit. Emp.*, July, 1912) has carried out a series of experiments on rabbits, rats, and guinea-pigs to determine the physiological function of the different constituents of the ovary, and especially of the interstitial cells, and some additional experiments as to the influence of uterine secretion upon the ovaries. The operations were done under aseptic precautions, with the animals placed upon a modified Trendelenburg table. In the first five experiments double oöphorectomy was performed, the animals being allowed to live after operation for periods which varied from 62 to 400 days in the different cases. In the two cases in which the animal was pregnant at the time of the operation abortion took place in one case after three, in the other after four days. In all cases atrophy of the uterus occurred, the rate of atrophy being directly proportionate to the time the animal was kept alive after the operation. The muscular wall showed the atrophic changes first, the glands persisted for some time but gradually disappeared; the epithelium lining the uterus was always found to be still present, though the cells were more flattened than normal. No cyclic sexual phenomena appeared to occur after double oöphorectomy. The mammae and external genitals atrophied. Six operations were performed to find the effect of the removal of the uterus and Fallopian tubes, and six to find the effect of retention of uterine secretion upon the ovaries and general nutrition of the animal; in no case were either the ovaries, the general development, or the nutrition influenced. There is no evidence that the uterus is responsible for the phenomena of menstruation or pro-oestrus more than that it is the channel for excretion of substances generated or controlled by the ovary itself. In the next two experiments one ovary was removed, in one of them the uterine horn of the opposite side was ligatured at both ends and in the other the uterine horn on the same side, and there was thus retention of uterine secretion. It appeared that compensatory hypertrophy of the other ovary follows removal of one ovary even in the absence of pregnancy or oestrus and in the presence of retained saline fluid from the uterus. Two other experiments in which double oöphorectomy was performed and both uterine horns ligatured also showed that uterine secretion has no inhibitory effect upon the growth of the ovary and it does not counteract the atrophy of the uterus after removal of both ovaries. In the last six cases double oöphorectomy was performed and ovarian grafting carried out. In one case a small piece of cortex of human ovary

was grafted on to the kidney of a rabbit; in this case the uterus was atrophied when the animal was killed 200 days later, the mammae were small and there was no evidence of the graft. In the other five, pieces of the cortex of one of the ovaries removed was transplanted in one case on to the uterine wall, in two others on to the right kidney, in another on to the peritoneum of the abdominal wall, and in the last into uterine muscle. The animals were kept alive for from 60 to 200 days after operation. Special note was taken of the influence of the interstitial cells as contrasted with the follicles on the graft. The conclusion arrived at was that ovarian grafts prevent atrophy for a time, but ultimate degeneration takes place in the transplanted tissue followed by atrophy of the uterus. The rate of degeneration varies with the site of implantation, the more vascular the site the longer the persistence of the graft. Degeneration takes place first in the cells of the corpus luteum. The follicles show cystic degeneration. The interstitial cells persist much longer than the follicles, and they appear to control the nutrition of the uterus, as atrophy takes place when these cells are degenerated and no atrophy when they are present even without any trace of follicles.

THERAPEUTICS.

25. High-frequency Treatment of Vesical Tumours.

BACHRACH (*Wien. med. Woch.*, No. 31, 1912) advocates the endovesical treatment of tumours of the bladder by means of the high-frequency current. He points out that the invention of the cystoscope made endovesical surgery possible, and led to the introduction of several useful instruments combining the principles of the snare and the cautery. Nevertheless, opinions are still divided on the respective merits of the endovesical treatment and the abdominal operation. The mortality after the abdominal operation, especially under a local anaesthetic, is practically *nil*, while, on the other hand, recent improvements in technique have extended the scope of the endovesical method. The author employs the instrument introduced by Beer of New York, and obtainable from the firm of Wappler in that city. It consists of a single electrode made of six fine copper wires twisted into a cable, which is passed through the cystoscope, and used in the same fashion as a ureter catheter. The bladder is filled with a sterile fluid, the cable is passed in and pushed in a little way into the substance of the tumour, and the current is then passed for twenty or thirty seconds. Round the electrode a white slough forms, in the middle of which, after withdrawal of the instrument, a black charred spot can be seen. The current is applied in three or four places at each sitting. In a few days the necrosed portion separates and is passed out in micturition. Three or four sittings, each lasting about four minutes for every application of the current for thirty seconds, suffice to remove a large papilloma. The patient feels absolutely no pain so long as the spark touches only the new growth—a fact which safeguards the more sensitive vesical mucous membrane from serious injury, while it admits of the thorough removal of the growth. The author points out that the well-known tendency of papillomatous tumours of the bladder to recur and finally to take on a malignant character is met more effectually by the searching influence of the high-frequency current than it can ever be by the snare and cautery. The high-frequency current is relatively a radical cure. Another advantage which he claims for this treatment is not only its simplicity but the fact that tumours situated in certain regions difficult of access, such as the vertex or the neck of the bladder, can be handled far more readily with the cable than by any modification of the snare. He thinks, however, that the snare may often be helpful, both in shortening the treatment by removing large pedunculated masses, leaving only their base to be treated with the cable, and also in removing portions of the growth for microscopic examination. The high-frequency current can also be used to check haemorrhage in cases of carcinoma, and is valuable in the treatment of inflammatory growths both in the bladder and in the posterior urethra. The author describes cases illustrating the apparently permanent removal of repeatedly recurring tumours with signs of malignancy, but admits that his own 15 cases are too recent to allow him to speak with certainty of the permanence of the cure. He says, however, that Beer has collected 187 cases, extending over a period of two years, in which the results of this treatment are thoroughly satisfactory.

26. Treatment of Tetanus by Intradural Injections of Magnesium Sulphate.

THEODOR KOCHER (*Corr.-Bl. f. Schweizer Aerzte*, September 10th, 1912) has successfully employed a modification of Meltzer's method in the treatment of tetanus. A carter, aged 56, was seen on November 29th. A fortnight previously, during stable work, he cut his left thumb. The wound was cleansed and sutured on the following morning. Eight days after the accident the wound had suppurated, and the sutures were removed. On November 27th trismus appeared. This was followed by lumbar pain and rigidity, which spread to the shoulders, arms, and legs. On admission to hospital there were marked opisthotonos, dysphagia, and profuse sweating. The temperature and pulse were normal. The wound was cleansed and painted with iodine. Ten c.c.m. of tetanus antitoxin were injected hypodermically near the wound, and towards night a similar amount was injected intravenously. Two hypodermic injections of 2 per cent. carbolic acid (Bacelli's method) were also given. But, in spite of treatment, the tonic spasms increased, and the face became cyanosed. On November 30th, at noon, 2 c.c.m. of a 25 per cent. solution of magnesium sulphate were injected into the lumbar subarachnoid space. The muscular rigidity soon decreased. In the evening a second subarachnoid injection of magnesium sulphate and a third injection of 10 c.c.m. of tetanus antitoxin were administered; 500 c.c.m. of sterilized water were injected subcutaneously. On December 1st the rigidity was less, but spontaneous micturition was impossible. An intradural injection of 3 c.c.m. of a 25 per cent. magnesium sulphate solution, and also hypodermic injections of morphine and carbolic acid, were given. On December 2nd micturition was normal. Injections of carbolic acid and chloral were given. On December 4th the rigidity again became marked, and 5 c.c.m. of the magnesium sulphate solution were again injected. Fifteen minutes later the rigidity decreased, first in the legs, then, in order, in the abdomen and arms. An hour later the patient could sit up, and soon the muscles were fully relaxed. Later in the day some rigidity recurred. On December 5th, on the increase of rigidity, 5 c.c.m. of the magnesium solution were injected. The rigidity decreased within half an hour. The treatment was repeated with the same good result on December 6th and 7th. On December 8th four doses of 15 gr. of calcium chloride were given. On December 14th the muscular rigidity had almost disappeared, but there was again retention of urine with suppression of the patellar reflexes. The patient was discharged cured on the thirtieth day after admission to hospital. In two further cases of tetanus with severe attacks of tonic spasm and opisthotonos, which occurred as often as twenty times in fifteen minutes, intradural injections of magnesium sulphate were equally successful in combating the muscular spasms; recovery followed in both cases. In the first of these cases after the seventh injection of 5 c.c.m. of the magnesium sulphate solution unconsciousness supervened and respiration ceased. Tracheotomy was performed, a cannula was introduced nearly as far as the bifurcation of the trachea, and oxygen was insufflated. Sufficient space existed between the walls of the cannula and trachea for the exit of the gas or air. The cyanosis subsided, but the respirations remained at two or three in the minute during an hour. Consciousness was recovered twenty-four hours later. Tetanus antitoxin was also employed. This method of treatment is based on the researches of Meltzer and Auer, who found that magnesium sulphate and chloride when injected subcutaneously in the proportion of 1.5 grams per kilo of body weight produce deep sleep with muscular relaxation and abolition of all reflexes except the conjunctival and trigeminal. Doses exceeding 2 grams per kilo are followed by arrest of respiration, the heart continuing to beat for a time and the blood pressure being maintained. Hence resuscitation is possible by artificial respiration, providing O'Dwyer's apparatus for intralaryngeal insufflation under pressure is used. Local applications of 25 per cent. magnesium sulphate solution to nerve trunks produce complete nerve block, both conductivity and excitability being suppressed. Sensory nerves are more rapidly affected than motor. Mathews and Brooks conclude that magnesium salts, like curare, paralyse the motor nerve endings before the respiratory centre. However this may be, physostigmine, which is physiologically antagonistic to curare, is also antagonistic to magnesium, and invariably stimulates the respiratory centre. If respiratory paralysis is threatened, the danger may be rapidly moved by Arnd's method of washing out the lumbar sac with sterile normal saline solution; the

only disadvantage is temporary paralysis of the bladder. The position of the patient at the time of and after the injection is of great importance. The action of the magnesium is at first local. Hence, if the body is raised almost vertically and the neck is flexed, the evil effects on the respiratory centre may be avoided. But if the upper part of the body is involved, and especially in cephalic tetanus, it is desirable to extend the action of the salt to the medulla oblongata. For this purpose the legs may be raised above the body for a time. This was done in the writer's third case for two hours after an injection, with the result that two hours' profound sleep in complete muscular relaxation resulted. Kocher believes the strength of the solution recommended by Meltzer to be unnecessarily strong. Fifteen per cent. proved ample. Of this solution as much as 10 c.c.m. may be safely injected. Two injections may be given daily, though owing to a cumulative action not at too short intervals. Thus two doses of respectively 7 and 10 c.c.m. were given within five hours. Deep sleep, from which the patient could not be awakened, and stertorous breathing resulted. If the urgency of the symptoms rapidly necessitates a second dose, the amount injected should be reduced by half.

27. Effects of Various Drugs on the Bacteria of the Skin.

S. HIDAKA (*Wien. med. Klin.*, No. 34, 1912) makes a further communication as to his experiments with regard to the effect of different dermatological treatments on the bacterial contents of the skin. His first contribution appeared in the same journal, No. 44, 1911. In each experiment he has applied the same treatment at three different sites, and he has further increased the value of his results by repeating each experiment six to eight times, and taking an average of the results obtained. The different preparations tested were oleum rusci, acid. pyrogall., resorcin, acid. salicyl., chrysarobin, ichthyol. sulphur precip., tumenol and sulfoform. They were applied as far as was possible both in the form of ointments, as a paint, and in alcoholic and oily solutions. The paint contained 10 per cent. of the drug to be tested made up with zinc oxydat., talc venet., glycerin and aq. dest. The ointments used all contained 10 per cent. of the particular drug used. The results arrived at were that: (1) Oleum rusci, pyrogallic acid, and ichthyol had the strongest action in diminishing the number of bacteria, while resorcin, chrysarobin, etc., had less effect; (2) the action of these drugs when applied in the form of the paint or in alcoholic solutions was considerably more powerful than when given as ointments or in oily solutions.

PATHOLOGY.

28. Cammidge's Reaction.

ZUCCOLA (*Rif. Med.*, November 16th, 1912) gives the result of his researches upon the nature and origin of the crystals found in the urine by Cammidge's reaction. He first tried the effect of various substances which are said to be the more or less direct source of the crystals. And, first, to fifteen healthy subjects showing no Cammidge reaction he gave 15 grams of glycerine, and found that, if crystals were present, they were not of the Cammidge type, so that he concluded that the crystals in question in the true Cammidge reaction were not due to glycerine. So, also, with pentoses isolated from fresh pancreas by the Salkowski method, the crystals produced did not behave exactly as they do in the ordinary Cammidge reaction. The author infers that if it is a pentose which gives the reaction this cannot be entirely derived from a direct destruction of nucleo-proteins derived from the pancreas. To further elucidate this he experimented with the other pentoses—namely, arabinose and xylose—but found that the osazones formed from these differed in several ways from the typical Cammidge osazone. Similar negative conclusions were arrived at with regard to saccharose, glucose, levulose and sorbinose, mannose and galactose. The net result of these researches was negative—that is, it is not possible to say exactly what substance it is which gives the Cammidge reaction. Assuming it to be a hydro-carbon, one source of difficulty lies in the determination of the fusion point of the crystals and in getting them pure; errors also arise from the differing solubility in H_2SO_4 , partly due to the relation between the size of the crystal and the size of the drop of acid. Not every saccharoid capable of combining with phenylhydrazin will give a true Cammidge reaction. Probably the pseudo-reaction after the administration of glycerin is due to the syrup (glucose and saccharose) mixed with it.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

29.

Visceroptosis.

CAWADIAS (*Journ. des praticiens*, November 23rd, 1912) discusses this subject fully. This condition, originally referred to as the syndrome of Glénard, has now, he points out, associated with it the name of Stiller, who has shown the relationship of these cases to a special diathesis. The term "visceroptosis," he maintains, is not sufficient. In considering this syndrome it is necessary to consider the soil which engenders it, its mode of commencement, and the manner in which it terminates. Stiller has termed it the "asthenic diathesis," which is congenital, and characterized by hypoplasia of the nervous system and of the digestive system. The evolution of the condition is without any marked symptoms, and is frequently only discovered by accident, or accidental causes precipitate the symptom complex of neurasthenia, digestive troubles, and visceral ptoses. At puberty, for example, any one of these may be accentuated, also during pregnancy. The three elements coexist and are mutually aggravating, forming the most perfect vicious cycle in gastro-intestinal pathology. The neurasthenic element is characterized by headaches, neuralgias, physical asthenia, intellectual and moral depression. The gastro-intestinal condition is variable, although the rule is a state of hypochlorhydria with gastric atony. There is generally constipation. On standing behind the patient and grasping the abdomen with both hands round the body, we find that raising the flaccid abdominal wall gives relief, while, on disengaging the hands again, the discomfort returns. All the abdominal organs are affected in varying degree, although radiography has shown that a state of gastroptosis is not so usual, the most usual condition being, in the author's opinion, elongation of the atonic stomach vertically. The condition is progressive, and presents remissions and paroxysms. The patient becomes hypochondriacal and finally melaancholic. The movement of gases in the intestine frequently creates strange delusions. The skin of the abdomen is dry and falls into folds, while a network of superficial veins covers the surface. At this stage floating kidney may be readily felt, whilst the transverse colon may be noted to have fallen to the inter-iliac line and stomach clapping may be induced at the level of the umbilicus. Remissions occur, especially in the nervous and digestive troubles; the visceroptosis alone persists. Sometimes crises of spasmodicity occur, during which the nervous system is notably excited, the stomach hypersthenic, and the intestine painfully contracted. The diagnosis is difficult in neurasthenia with secondary symptoms of dyspepsia. In the syndrome of Glénard-Stiller there is usually a long history of vague nervous and digestive troubles dating back to childhood. This with the presence of visceral ptosis is decisive. With regard to treatment: Children born of parents suffering from this disease ought to be put under a careful regimen of diet and exercise from the beginning. The neurasthenic state is best dealt with by hydrotherapy, electricity, and the use of glycerophosphates by injection. Psychotherapy is a very necessary adjunct in these cases also. The physician must gain the confidence of his patient and reassure him as to the seriousness of the visceral ptoses. The author does not approve of the treatment of the digestive trouble by sur-alimentation. He believes in aiming at a normal dietary as far as possible. The visceroptosis is to be healed by suitable abdominal exercises and massage. The application of a carefully chosen abdominal belt is of much use. At the commencement of treatment rest in bed is of great benefit. The nerve balance is restored and the abdominal organs regain in some measure their normal position. Surgical intervention is not generally called for.

30.

Angina Pectoris and Tobacco.

MOURIQUAND AND BOUCHAT (*Arch. des mal. du cœur, des vaisseaux, et du sang*, October 12th, 1912) relate the history of a man, 54 years of age, who was suddenly seized with an attack of angina pectoris, and died during the crisis. His father had died at 55 from heart disease. The patient's heart had been good, there having been no disease of childhood except an otorrhoea, which had left him rather deaf. There was no history of gonorrhoea, no signs of alcoholism, and no history of articular rheumatism.

He denied emphatically having had syphilis, and an examination of the genital organs seemed to bear this out. He had been in the habit of smoking thirty to forty cigarettes a day, as well as several cigars. About two months before his decease he had complained of dyspnoea and palpitation on any effort, these being accompanied latterly by a sense of thoracic and precordial constriction. At this time, on examination, there were no cardiac bruits to be heard, while the sounds were hard and vibrating. There was no pain on pressure over the pericardium and the pulse was regular. All the other organs seemed sound functionally. KI gave relief for some time, but latterly he became intolerant of it. He began to cough and the expectoration was blood-stained. Towards the end there was galop rhythm. On autopsy the heart was found to weigh 380 grams. There was slight sclerosis of the mitral valve, but no narrowing or insufficiency. The aortic valve was healthy. On the ascending portion of the aorta several gelatiniform plaques, about the size of a lentil, were seen. The orifice of the right coronary artery was scarcely visible, while the left was still more difficult to see, and was narrowed by one of the plaques spoken of. The authors then discuss various experiments on rabbits, in which tobacco was administered as nicotine in an infusion. The results of a number of investigations showed that in the rabbit tobacco in this form is causative of atheromatous degeneration. Demonicized tobacco similarly given rarely resulted in atheroma. In the authors' opinion, these experiments are inconclusive, because other agents, such as adrenalin, salts of lead, ergotin, all bring this about. The experiments do not prove, therefore, that in man tobacco is a cause of atheroma. They do not, indeed, believe that it does. Atheroma alone rarely causes stenosis of the coronary arteries or of the aorta, and the authors' conclusion is that there is no such thing as fatal angina pectoris of tobacco origin only. All the evidence goes to show that the gelatiniform plaques referred to are identical with those noted in syphilis. No stigmata of specific disease were found, but they agree that the fatal crisis in the case of the patient referred to was due to the presence of a coronary lesion of specific origin, and that the tobacco undoubtedly hastened the end by the vaso-constrictive effect of the nicotine. The gelatiniform plaques were as typical as possible, and the histological report showed that they were such as are found in syphilitic aortitis—that is to say, a fibro-hyaline thickening of the endothelium and evidences of inflammatory lesions in the tunica media resulting in destruction of the elastic fibres. The lesions produced by nicotine, on the other hand, are not so much inflammatory as degenerative. In spite of the clinical findings, the pre-existing lesions found on autopsy settled the issue in this case.

31.

Acromegaly.

CHAMBERS, BRUCE, AND MACKENZIE (*Med. Bulletin, Univ. Toronto*, July, 1912) report a case of acromegaly in a woman, aged 39, in whom enlargement of the hands and face was first noted about three years previously, and gradually increasing headache, dizziness, and failing eyesight during the past nine months prior to admission to hospital. The patient presented features of the masculine type, with sluggish speech and mentalty. There was a forward curvature of the upper part of the spine, and the subcutaneous tissue all over the body was thickened. The face was abnormally large and asymmetrical, the left side being more prominent than the right. The lower jaw projected forwards so that the lower incisors were half an inch in front of the upper. The ears were large, and the supraorbital, temporal, malar, parietal, and frontal prominences were enlarged. The hands were very large, with short, stubby fingers, coarse skin, and very prominent thenar and hypothenar eminences. The sternum at the level of the fourth rib was about 3 in. in width, and in the sitting posture the costal margin reached the iliac crest. She slept badly, and was generally mentally depressed, with occasional hallucinations as to seeing persons and animals and hearing noises and voices. The fields of vision and visual acuity were diminished, smell was lost, and hearing defective. Movements were sluggish, but there was no paralysis, and all the reflexes were present though depressed, especially on the left side. X-ray examination showed

Irregularities and thickenings of the bones of the skull, and general enlargement of the bones of the hands. Under 20-grain doses of potassium iodide three times a day the failure of the eyesight, diminution of the visual fields, and mental deterioration gradually increased, and the following operation was performed with a view to removal of the tumour of the hypophysis by the oronasal method. After a preliminary tracheotomy the upper lip was separated from the superior maxilla through an incision in its mucous membrane about five-sixths of an inch from the muco-cutaneous junction. The middle and lower turbinates, the vomer and perpendicular plate of the ethmoid were removed, and the septum divided and displaced laterally. After removal of the anterior wall of the sphenoidal sinuses the floor of the sella turcica was broken through and a reddish tumour exposed. Owing to free haemorrhage from the nose removal of the tumour was not attempted at this stage, but the sphenoidal and nasal cavities were packed with gauze saturated with adrenalin, which effectually controlled the haemorrhage. Unfortunately the tracheotomy tube was then removed, for about six hours later, owing to haemorrhage entering the larynx, the patient died before the tube could be replaced and relief therefrom obtained. The autopsy revealed the fact that had the patient survived it would have been quite easy to remove the tumour at a later stage. The operation would be most safely accomplished in two stages, the preliminary stage consisting of removal of the septum, anterior wall of the sphenoid, and middle turbinates, thus allowing the sella turcica and the tumour to be dealt with at the second stage without being handicapped by haemorrhage; 40.7 per cent. is the mortality in reported cases up to the present.

SURGERY.

32. Artificial Pneumothorax.

FAGINOLI (*Ital. Med.*, October 19th, 1912) gives his experience in 40 cases of phthisis treated by the production of artificial pneumothorax since February, 1911. In technique the danger of gas embolisms can be avoided by carefully watching the manometer and only admitting the nitrogen when the oscillations of the columns are free and ample (8 to 12 cm.) and synchronous with the respiratory movements. Secondary infection of the pleura as a result of the puncture is so rare as to be almost negligible. In nearly 2,000 infiltrations the author has had no seriously unfavourable results, and this he attributes largely to the observance of the following points: (1) The needle must be introduced slowly and steadily; (2) the gas should not be introduced until the manometric conditions above mentioned are fulfilled; (3) the gas in the apparatus ought to be at zero pressure and enter the pleura by spontaneous aspiration. The puncture was usually made in the eighth or ninth intercostal space in the mid-axillary line. Sometimes the patient suffers acute pain when the gas enters, but this is unusual. In one case a severe attack of pleural eclampsia followed, but was soon over and not repeated in succeeding operations. Emphysema (subcutaneous) was noticed once or twice and herpes zoster once. In 5 of the 45 cases it was impossible to produce a pneuothorax owing to the dense pleural adhesions. Caution is necessary in attempting too much where there are extensive adhesions, as haemoptysis may occur. Of the 32 cases where the treatment was systematically carried out 27 had bilateral lesions and 5 monolateral. One of the chief and most constant of the benefits resulting was the quick diminution and disappearance of the fever, most marked, as one would expect, in the monolateral cases. Another good result was the notable decrease in the amount of excretion, but tubercle bacilli were always found in such sputa as there were. A steady increase in weight and disappearance of night sweats were the rule. Only in 3 of the 27 bilateral cases was any improvement noted in the untreated lung. Some of the patients were treated in addition with tuberculin, but without any notable advantage. Sixteen of the cases have left the sanatorium, and 8 of these have returned to work. What the final result may be in all of these cases time alone can say, but as far as they go they show that with care the treatment is almost innocuous and clearly beneficial. The treatment was continued for periods varying from four to seventeen months.

33. Metastatic Tumours in the Skin.

IN describing a case in some detail and discussing the questions raised by it, M. Askanazy is able to demonstrate that the study of cancerous growths affecting the nerves

and their endings in the skin has been markedly neglected (*Berl. klin. Woch.*, November 11th, 1912). The patient was admitted into hospital in the last stages of a mammary carcinoma. The history was peculiar in that the primary growth was still comparatively small and had not implicated much of the surrounding tissue. The patient found that her general health was rapidly giving way, and that numerous small nodules appeared within twenty-four hours in the skin of various regions of the body. She felt a sensation of "drawing," and within the following few hours a nodule would appear in the same site. That this occurred in fact was confirmed by clinical observation. The removal of the primary growth failed to arrest the course of the disease, and the patient died after a short stay in hospital. Histological examination of excised cutaneous nodules and of the same after death showed that in each case the new growth was a secondary scirrhous carcinoma growing in the lymphatic spaces around a nerve, often implicating a Vater-Pacini body, and always avoiding the blood vessels. The infiltration into the nerve tissue was usually defined, but in no instance was there a trace of inflammatory reaction. It is notable that the nodules scarcely increased in size after the first appearance.

34. Foerster's Operation for Gastric Crises in Tabes.

CHARBONNEL (*Gaz. hebdom. des. sci. méd.*, 1912, xxxiii) resected the seventh, eighth, and ninth posterior dorsal roots in a man of 38 suffering from severe gastric crises as a result of tabes dorsalis. At the moment of section the breathing and pulse became accelerated, and after the operation there was a temporary retention of the urine and passing paralysis of the lower limbs. The result was not satisfactory, and the author thinks this was probably due to the insufficiency of the operation, and if another occasion offers he proposes to resect the fifth to the eleventh roots on both sides. Franke's operation consists of stretching the fifth to the twelfth intercostal nerves on each side, and Charbonnel considers this the operation of choice. Koenig injects deeply into the muscles of the back each side of the median line between the sixth and tenth dorsal nerves 100 c.cm. of a 0.5 per 100 solution of novocain, and Charbonnel considers this should be first tried, and, if it fails, recourse should be had to Franke's operation, leaving Foerster's operation as a *dernier ressort*.

35. How Pyelography may be Misleading.

THE method known as "pyelography," which consists of making radiographs of the renal pelvis after collargol has been injected, may on rare occasions lead to error. This is illustrated in a case of movable kidney with painful crises, brought forward by Reynard and Nogier (*Arch. d'électr. méd.*, November 25th, 1912). The presence of calculus in the renal pelvis being suspected, a radiograph without collargol was first made, and gave a negative result. Then it was thought possible that the hypothetical calculus was one of those which consist almost entirely of uric acid, and therefore are more or less transparent to x rays in the ordinary way, only being rendered visible by contrast with the different degree of opacity of the collargol. After injection the renal pelvis was seen distended with collargol, and in the centre was a small contrasting shadow, which was thought to be a calculus. An intervention was made, but no calculus was forthcoming, and the trouble was found to be due to a movable kidney. In the opinion of the authors, the opaque shadow surrounded by collargol was probably due to the extremity of a Malpighian pyramid, rather larger than usual, which was so situated that it did not allow the collargol to fill the whole of the renal pelvis uniformly. They suggest that in pyelography only those shadows remote from the calices should be regarded as characteristic of calculus.

36. Ocular Complications in Impetigo.

THE occurrence of keratitis in cases of impetigo contagiosa has received scant mention in ophthalmic literature. Stelwagon notes that lesions of the conjunctiva may exceptionally complicate the skin eruption. Bazer records a case in which a boy was affected with impetigo on the face, arms, and neck. In the right eye in the limbus corneae neighbourhood were numerous pin head-sized, clear blisters, whose contents contained cocci. Hansell in *Ophthalmology* for January, 1912, records another case. A delicate girl suffered from a pustular eruption, and also from an ulcerative keratitis. Although these cases are rare, it is quite common for an eye surrounded by impetiginous crusts to be affected with a conjunctivitis which disappears when the skin disease is cured.

OBSTETRICS.

37.

Pituitrin as an Oxytocic.

MALINOWSKY (*Zentralbl. f. Gynäk.*, No. 43, 1912) reports very favourably on pituitrin, and publishes charts showing the rhythm of uterine contractions—normal, violent, and tetanic—excited by doses of this material. His researches were conducted in the Obstetrical Department of the University of Kasan. In suitable doses pituitrin acts promptly on the uterine musculature. Intrauterine pressure rises greatly after injection, the action of the body beginning in about five minutes; it does not matter whether the upper arm, thigh, or the abdominal wall be chosen. The effects of 1 c.cm. of pituitrin last for about one hour. The duration of each pain is perceptibly diminished, and so are the intervals between the pains. After a moderate dose the pains show a normal rhythm—increment, acme, and subsidence. "Sturmwehen," however, are noted after almost every administration of pituitrin, and are violent according to the amount injected; these tetanoid contractions last for about eleven minutes, but Malinowsky seems to consider them to be a physiological curiosity, as he has never found them to do any harm to mother or child. Pituitrin acts most favourably in the second stage of labour and at the end of the first. In the earlier state of dilatation of the cervix pituitrin sets up true tetanic contractions, lasting over one-quarter of an hour in certain cases under observation. They were primiparæ with membranes unruptured and cervix but little dilated, or multiparæ with marked rigidity of the os externum. Yet in both types the uterine contractions returned to their normal character and rhythm as labour advanced. In primiparæ after rupture of the membranes tetanus of the uterus was not observed. The fetal heart sounds during the tetanic spasms fell to 60-50 beats per minute, but rose as labour progressed, and the child was born alive without any signs of asphyxia. One cubic centimetre is quite enough for a dose; repeated smaller doses are less satisfactory. The strongest dose not liable to produce ill effects is about 1.3 c.cm. The dose can always be repeated; the second, whether given whilst the effects of the first persist or after they have subsided, never fails to act on the uterine muscle. The third stage is, as a rule, uncomplicated; "the placenta was always expelled spontaneously," and atony of the uterus after delivery not observed in the cases under Malinowsky's care. Pituitrin appears to be contraindicated where the mother is subject to cardiac and renal disease. Altogether Malinowsky considers pituitrin to be an excellent oxytocic, and the injection is painless. But, he repeats, caution is necessary in the earliest stage of labour and in cases of rigid os, independently of pelvic contraction or impediments due to the fetus.

GYNAECOLOGY.

38. Hyperæmic Treatment of the Uterus.

ACCORDING to Felix Turan (*Wien. med. Woch.*, April 27th, 1912), the treatment of chronic metritis and endometritis has undergone radical changes in the last few years, owing to the futility of the ordinary local methods. Among the list of failures must be included the treatment by suction exerted on the cervix. Some writers, it is true, claim good results from this procedure, but as they have combined it with other methods, their testimony is unconvincing. Nor is it likely that an unhealthy condition of the uterus can be cured by a procedure the action of which is limited to the cervix. This procedure, which has been tested by several authorities during the past seven years, consists of introducing into the vagina a speculum, which embraces the cervix in an airtight space. When this is exhausted the cervix becomes flushed with blood, while the rest of the uterus is unaffected. Another disadvantage of this method is the pain it causes. The duration of the treatment is consequently limited to a maximum of fifteen minutes, which, according to Bier and other authorities, is totally inadequate. A further drawback to the suction treatment of the cervix is the oedema of the external os which it causes, and which obstructs the free flow of fluid from the uterine cavity. Therefore, though this procedure is safe and easy, it is unsatisfactory. Yet, if suitably prescribed, Bier's treatment seems a rational method of rectifying those disturbances of the uterus which are due to disorders of the circulation, and for the past seven years the writer has been perfecting his method by which suction is directly applied to the interior of the uterus. A catheter

is used, the metallic uterine end of which is longitudinally fenestrated. To suit the requirements of every case, several sizes are necessary, and the intrauterine end varies in length from 3 to 6 cm. At the junction of the intrauterine with the intravaginal end there is a rubber ring which prevents the escape of air through the external os and which holds the catheter in place. The vaginal end is 10 to 12 cm. long and is made of semi-elastic material. It is connected with that limb of a mercurial manometer in which the mercury has been previously drawn up by suction. The manometer, therefore, serves both as a suction pump and as a gauge. Before the catheter is introduced the external genitals are carefully cleaned, a speculum is introduced, and the cervix is pulled down by forceps. It is seldom necessary to dilate the cervix beforehand for, in chronic endometritis, it usually admits a thin catheter without difficulty. When it has been introduced, the vagina is packed with gauze to steady it. The degree of suction is read off the manometer, the connecting tube is clamped, and is then disconnected from the manometer, the projecting vaginal end of the catheter being secured by a safety pin to the patient's clothing. She is now free to recline for a little, and to walk about gently if she wishes. When the process is completed for the day, the catheter is withdrawn by a quick jerk, care being taken not to open the clamp before the catheter is removed, otherwise air will enter into the uterus. After use the catheter contains mucus, and when the suction has been powerful and the patient hæmophilic it also contains traces of blood. After the first introduction, the procedure, which is painless in skilled hands, takes but little time. The treatment should be repeated daily at first, and later every other day, usually sixteen to eighteen repetitions are advisable. The treatment should be suspended during menstruation, and abandoned if it causes embarrassing hæmorrhage. Irritability of the uterine appendages is also a contraindication. On the first occasion the treatment is maintained for fifteen minutes only. As the patient becomes used to it it may be gradually prolonged to several hours every time. The writer began with a negative pressure of 60 to 70 mm. of mercury, but finding that this frequently induced severe hæmorrhage he reduced the pressure to less than 50 mm. No serious hæmorrhage has occurred since. None of his 52 patients suffered any injury or discomfort from the treatment, nor was infection of the uterus by the catheter ever observed. The avoidance of this complication is attributed to the scrupulous cleanliness practised. The writer's material includes 33 cases of chronic endometritis and 19 miscellaneous cases, including such conditions as amenorrhœa, infantile uterus, habitual abortion, and sterility. Of the 33 cases mentioned, 10 were treated by congestion alone. The results were highly satisfactory in most cases, the patients gaining in general health and weight and the uterine discharge changing from a mucopurulent to a serous nature, and finally ceasing altogether. Conditions such as erosions and menorrhagia also showed marked improvement.

THERAPEUTICS.

39. Scarlet Fever and Intravenous Injections of Salvarsan.

LENZMANN (*Wien. med. Klin.*, November 17th, 1912) has tried the effect of salvarsan on 20 cases of scarlet fever, all of which were severe, and some very severe. At first very small doses were given, 0.05 gram as an initial dose, to persons of 16 to 18 years of age, lest the large quantities of toxins present in the system should give a special sensitiveness to salvarsan and its poisonous action should be increased. These small doses had no effect on the general condition, but also no effect on the course of the disease. The author now gives to patients of 15 years of age and upwards an initial dose of 0.2 gram and repeats the dose on several consecutive days. To children of from 3 to 8 years the initial dose is 0.1 gram, and from 8 to 15 is 0.15 gram. In quite small children, for whom intravenous injection may be impracticable, the author injects a weak alkaline solution subcutaneously, the patient being under chloroform. The effect of salvarsan was quite typical. The fever, instead of keeping up for the first four days, began to fall quickly. Thus in one severe case of hæmorrhagic scarlet fever the temperature on the evening of the second day was down to 38.9 C. (102. F.); after a renewed rise it came down on the third day as low as 38.8 C. (101.8 F.); on the fourth day to 38.2 C. (100.7 F.), and on the fifth to normal. In the cases as a whole the fever might be described as

showing a step-like descent like that seen in the defervescence after typhoid. After each dose the fever rises for from two to four hours, and then quickly falls. After the first dose the fall is only a total one of 5 to 6 points, and lasts only for a few hours. After the second dose there is again a short rise and then a fall of from 1 to 2 degrees. A third injection brings it to about 38° C. (100.4° F.). On the fifth day it comes down to normal. With regard to other symptoms in the author's cases, the rash quickly lost its vivid colour and came out only sparingly on the arms and legs. Subjectively the patient felt much better during the intervals of lower temperature. In two very severe cases the condition by the second day had very greatly improved, vomiting and diarrhoea had disappeared; in the hæmorrhagic case nose bleeding ceased on the third day. The speedy improvement in the throat symptoms was of even greater significance. After the first injection there was clear improvement in the symptoms on swallowing; on the third day the tongue had cleaned and pain on swallowing disappeared. In no case did necrotic processes develop, however severe the inflammatory symptoms had appeared to be in the prodromal stage and on the first day before the injection. The only complication in any of the cases was the development of an otitis media in the hæmorrhagic case on the eleventh day. No harmful side-effects were observed. In cases in which the pulse was soft or irregular the dose on the second day was only half the initial dose; but the initial dose was returned to on the third day if the fever were lower. As a rule the nearer the patient was to defervescence the better able he became to bear a large dose. Possibly larger doses than these recorded here could be safely given, but further investigations are needed. The author concludes that: (1) Treatment of scarlet fever by intravenous injections of salvarsan or by subcutaneous injections of weak alkaline solutions exercise a favourable influence on the cause of the disease; (2) dangerous complications seem to be avoided as a result of its use; (3) with careful dosage the treatment is harmless.

40. Vaccines in the Treatment of Pertussis.

LADD (*Arch. of Pediat.*, August 1912) records a series of cases of pertussis treated with a vaccine prepared from Bordet's bacillus. Resembling the influenza bacillus in size and shape it is usually present in the viscid exudate expectorated from the bronchi during paroxysms of coughing, and the strongest evidence of its being the causative factor of whooping-cough is afforded by the agglutination and complement fixation reactions first observed by Bordet, and since confirmed by numerous investigators. After growing the organisms on blood-agar in the incubator for twenty-four hours the growth is washed off with sterile salt solution, and a bacterial count made of the number of organisms per cubic centimetre. After killing the organism by heating in a water bath at 60° C. the emulsion is diluted with salt solution to the desired bacterial count per cubic centimetre. The cases selected were typical of the disease, and the blood counts showed the relative increase in mononuclear cells. A minimum interval of five days was given between each injection, and no harmful effects were produced, there being neither constitutional symptoms nor local reaction. At first doses of 20 million were given at each treatment even to an infant, but later injections of 40 million were given four times to babies of nine months. No other treatment was adopted, and all recovered without complications on an average in five weeks from the commencement of the treatment, which was usually started in the third week of the disease. The vaccine certainly appeared to have a favourable effect in cutting short the attacks, and it is at least worthy of a further trial.

41. The Rational Treatment of Phthisis.

SARGURIN (*Journ. des praticiens*, October 12th, 1912) expresses the opinion that, amidst the innumerable list of serums, vaccines, and tuberculins, the true foundation of all anti-tuberculosis therapeutics may be lost sight of. These are (1) a pure atmosphere, night and day; (2) regulation of both exercise and rest; (3) a sufficiency of good nourishment; (4) hardening of the organism by all reasonable methods. The latter comprises all hygienic measures capable of exalting the resistance of the individual, raising the vitality of his tissues, and restoring the functions of assimilation and dissimilation. The patient must accustom himself to cold and changes of atmosphere, fearing neither wind nor rain. This hardening treatment is of benefit in a great number of persons actually tuberculous, and should be still more valuable as a prophylactic in those who are likely to be susceptible to tuberculous attack. The author admits that outrageous exaggerations of the rational method of treatment have been tried, and

with unfortunate results. To apply the method indiscriminately to all tuberculous persons is bad practice. The treatment of all cases of tuberculosis is essentially individual and particular. The dietary, too, must not be lost sight of, ought not to be too rigid in any respect, and may range from suralimentation on the lines of a purely flesh dietary to a more or less severe vegetarian dietary. In the author's view this treatment is obviously more suited for patients under sanatorium conditions than in ordinary life. He asserts that tuberculo-therapy is losing ground even amongst its warmest partisans. The rational method of treatment is bound to become more and more perfected.

PATHOLOGY.

42. Rhythmical Contractions of Isolated Heart-muscle Cells outside the Organism.

THE work of Carrel, Braus, Harrison, Burrows, and others in the attempt to cultivate animal tissue cells outside the body has received a material addition by the introduction of improved technique. M. T. Burrows (*Muench. med. Woch.*, No. 27, 1912) records the technique which he has been experimenting with in the cultivation of heart-muscle cells, and then proceeds to give an account of the results of his observations. Growth is divided into two distinct periods. First, there takes place a lively migration of cells from the original piece of tissue, and next the cells undergo division and differentiation. The first period begins toward the end of the first day and lasts about five days, while the second period progresses slowly and is prolonged. In some cases as early as the fifth day, while in others on the fourteenth day, rhythmic pulsation of the cells is seen. This is in the divided and differentiated cells. This rhythmic movement is seen not only in the growth derived from young embryos, but also from those of fourteen days old embryos. The isolated cells are spindle-shaped, and the contraction is seen distinctly, the relaxation being sudden and most striking. The important part of these observations appears to depend on the fact that on the fourteenth, fifteenth, and sixteenth days the pulsation of the migrated cells remained synchronous with that of the main piece, but after this the migrated cells pulsated at a different tempo. It thus appears that the cultivated heart cells possess a spontaneous contractility, and that the myogenic theory of the heart beat receives a powerful support by these observations.

43. Synthetic Antigens for the Meistagmin Reaction in Malignant Tumours.

G. IZAR (*Wien. klin. Woch.*, No. 33, 1912) describes the attempts made at the Pathological Institute of the University of Catania to remove the difficulties which arise in carrying out the meistagmin reaction as a result of the variability of the antigen. The experiments were in three directions. Attempts were made: (1) To purify the antigen by successive precipitation from methyl alcoholic solutions by means of various precipitants; (2) to use synthetic preparations as antigens instead of antigens such as the methyl alcoholic tumour extracts of Ascoli and Izar, the pancreatic extract of Micheli and Cattoretti, or the lecithin extract of Köhler and Luger; (3) to substitute for the customary proof of reaction, proof by complement fixation with purified synthetic antigens, or by the occurrence of hæmolytic substances as a result of the setting free of hæmolytic substances on the use of suitable antigens. The results are described under the three different heads. The preparation obtained from successive precipitation of pancreas antigen in methyl alcoholic solution by means of treatment with acetone, ethyl alcohol, ether, benzol, and petrol ether, proved no more stable than the initial alcoholic extract, but while the initial extract was insoluble in acetone the later product was soluble—a circumstance which is of interest in view of the solubility in acetone of Köhler and Luger's lecithin extract. The following antigens, prepared according to Fischer's method, proved to be usable: myristil (Witte), peptone, myristil-albumose from Witte's peptone, myristil-albumose prepared by digestion of calf's pancreas with trypsin and with pepsine and hydrochloric acid, myristil-destin-elastine-caseine-kyrine. Instead of myristil acid was also used the fatty acids of oleic and palmitic acids freed from calf pancreas, from human sarcomata, from carcinomata, and from cocoa butter. Complement fixation with the purified antigens proved to be equally strong both with tumour and non-tumour cases. The experiments with regard to hæmolytic substances proved more hopeful, but further investigations are required.

AN EPTOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

41. Dropsy of the Whole Biliary System.

DROPSY of the gall bladder and bile ducts is discussed by Silas Lindquist (*Uppsala Läkareföreningens Förhandlingar*, vol. xvii, Nos. 4 and 5), who summarizes the observations on this condition since it was first described by Corrovoisier in 1890. Twenty-two cases have been recorded, and the author contributes the following: 'Towards the close of her eighth pregnancy, a woman, aged 38, developed colitis, with alternate diarrhoea and constipation. Violent attacks of pain near the lower costal margin were accompanied by nausea and perspiration. The attacks grew worse, and the stools became grey. The light yellow urine contained albumen, granular casts, leucocytes, and bile pigments. After the completion of labour, a large, tender swelling was found in the right abdomen, which was much distended. Under its thin wall the outline of the colon and of part of the small intestine was visible. In the epigastrium the lower border of the liver was easily palpable, and it merged gradually into the tender swelling, which extended down to the middle of Poupart's ligament. The spleen was palpable below the left costal margin, and the pouch of Douglas was tender on palpation per rectum. The temperature was 101.5. Laparotomy revealed an enormously enlarged liver and a much distended caecum, the gas in which was withdrawn by puncture to facilitate exploitation. The surface of the liver, which was livid, was perfectly smooth, glistening, and covered by a network of white, almost transparent vessels. The gall bladder and bile ducts were dilated, but contained no stones. In the right half of the peritoneal cavity and about the liver was a cloudy, slightly haemorrhagic fluid, which contained the colon bacillus. The duodenum, pancreas, and stomach appeared normal; but close to the middle line, beside the aorta, and at the level of the pancreas, was an enlarged lymphatic gland of the size of a thumb. On puncture, the gall bladder yielded an almost transparent, watery, and slightly viscid fluid. The walls of the bladder were thickened and oedematous, and its ducts were found, on probing, to be open. Cholecystostomy was performed. The fluid which escaped from the gall bladder was sterile, and it gradually acquired a yellow tinge. The patient, who also suffered from chronic bronchitis, made a slow recovery. Brønner traces dropsical fluid in the gall bladder and bile ducts to lymphatic glands within their walls. The bile ducts and the neck of the gall bladder are supplied with glands which, under normal conditions, secrete a fluid which mixes with the bile and constitutes, according to Laugenbuch, only 0.1 per cent. of the contents of the gall bladder. Cholelithiasis induces glandular hypertrophy in the wall of the gall bladder, and Ternqvist, who examined the fundus of the gall bladder in 12 healthy cases and in 35 cases of cholelithiasis, found in the first class no deep-seated glands, but they were present in 20 cases in the second class. Probably both gall stones and infection stimulate the growth of glands which secrete freely. When stenosis of the bile duct is complete, bile escapes by the lymphatic and blood vessels, and is replaced by secretion from the hypertrophied glands in the walls of the gall bladder. Why dropsy of the whole biliary system is so rare it is difficult to explain, and in the author's case, in which there were no gall stones nor stenosis of the bile ducts, the marked stasis in the biliary system is at first sight inexplicable. The author suggests that pregnancy was the primary cause of the stasis, for disorders of the liver and of the biliary system are of common occurrence in pregnancy. But it is not clear whether pregnancy acts merely by mechanical obstruction caused by the proximity of the uterus and liver, or whether it injures the latter by toxins or microbes.

45. Ulcerating X-Ray Dermatitis.

G. DARIER (*Ann. de dermat. et syph.*, October-November, 1912) describes a case of ulcerating x-ray dermatitis, the interest and importance of which centres in the fact that the lesions developed with extreme and obstinate chronicity, after a latent period of nearly twelve years. The patient was a woman aged 49, who in 1899 was treated for a supposed tumor mammae by the Roentgen rays. She received in all more than thirty sittings of fifteen minutes' duration each. They were given over a period of four months—twice weekly for three months, and then

once a week for one month or longer (December, 1899). She has never had x rays since. In June, 1900, six months after the last exposure, she developed a superficial x-ray dermatitis, which gradually gave place to a plaque of scleroderma associated with some loss of substance, and great pain and hyperaesthesia (February, 1901). After treatment with zinc paste and other mild measures she was discharged cured (November, 1901), and it was not till July, 1911, that is, eleven years and seven months after the last x-ray exposure, that the condition described by the author as an ulcer surrounded by three concentric zones of pathologically altered skin, set in. These zones, he states, are an expression of the diminishing destructive intensity of the rays from the centre (— the normal ray) to the periphery, and are typically the result of weak but very numerous and closely approximated applications. The interesting feature of the case is the fact that from November, 1901, until July, 1911, the patient was quite well, and that then, without assignable cause on her part, the ulcer slowly developed. It required six months to heal up. In his complete histological survey of the case Darier excludes epithelioma—a common sequela in an x-ray burn—and describes the microscopical findings in each zone. Briefly summarized from periphery to centre they were (1) excessive keratinization and epidermal hypertrophy, with slight round cell infiltration in the papillae of the corium, in zone 1. (2) Degeneration, more or less marked, of the epidermis, and necrosis of the papillary body (zone 2). (3) Complete destruction of the epidermis, and fibrosis in the papillary layer with marked dilatation of the vessels in the corium, in sections near the centre of the ulcer itself (central zone 3).

46. Haemophilia Neonatorum in a Family of Four Infants.

PITFIELD (*Archives of Pediatrics*, October, 1912) records four cases of haemophilia neonatorum occurring in brothers, whose parents were both healthy, with no tendency to bleed. The first boy, soon after a natural birth, became very yellow, vomited black material, and passed tarry stools, and the condition was accompanied by fever and rapid loss of weight. Though at the end of eighteen days the icterus was intense, he finally completely recovered. The second boy became jaundiced three days after birth and subdural haemorrhages followed, as manifested by coma and convulsions, from which he eventually recovered, but his mental and nervous health remained defective until somewhat improved five years later by a cranioplastic operation for the release of some dural adhesions, which occupied the site of the old subdural haemorrhages. The third boy was icteric when born, and became profoundly so when 48 hours old, dying from subdural haemorrhages before living three days. In addition to the subdural haemorrhages, the autopsy disclosed haemorrhages into the liver. With this history of haemophilic jaundice ascending in degree of malignancy in these three children, large prophylactic doses of calcium chloride were administered to the mother and acid fruits excluded from her diet during her pregnancy with the fourth child, and ether was used instead of chloroform at the labour. The fourth boy weighed 8½ lb. at birth and did not exhibit the slightest tendency to bleed from the cord or from mucous membranes. In five hours a faint icterus appeared, which, by the end of twenty-four hours, had become marked, and minute petechial haemorrhages were seen in the skin. Serum obtained from the veins of the nurse were injected. During the second and third day 72 c.cm. of blood were injected in doses from 4 c.cm. to 15 c.cm., and at the end of three days the petechiae and jaundice had disappeared, and the child looked and remained normal.

47. The Bismuth Meal.

A. T. HERTZ (*Arch. Roentgen Ray*, November, 1912) states that Rippmann and he have found that the weight of the bismuth mixed with the food produces a very slight degree of distention of the stomach, which is greatly increased in cases of atonic dilatation. It also tends to drag the caecum and the end of the ileum downwards. It is clear, therefore, that the smaller the dose of bismuth used in examinations of the alimentary canal, the more accurate will be the results obtained by means of the x-rays. Except in very stout individuals, 2 oz. of a bismuth salt is ample for all practical purposes. The use of 6 oz. trebles the error.

SURGERY.

48. Treatment of Cancer of the Stomach by Radium.

Two interesting cases in which radium has been applied successfully in cancer of the stomach are described by Julien (*Arch. d'électr. méd.*, December 10th, 1912). A combined method of external and internal application was employed, the internal application being made by bringing the radium simply to the surface of the tumour. One of the patients had a tumour in the pyloric region the size of a small mandarin orange. His state of extreme cachexia not permitting an operation such as gastro-enterostomy, radium was applied after laparotomy under cocaine. The tumour, situated on the anterior face of the stomach, was found to be much more flattened than the palpation had suggested; therefore the idea of introducing a radium tube into the mass of the tumour had to be abandoned for fear of penetrating the stomachal cavity. The radium tube used was one of the kind employed by Dominici, and contained 1 eg. of pure radium sulphate, with an external activity of 12,000. This was placed in a Nélaton's soft-rubber catheter, the extremity of which was closed with silk. The catheter was held in position by two loops of catgut, which, however, permitted the tube easily to be displaced when necessary. The tube remained in position upon the tumour for fifty hours. During the first half of that time, at the end of each period of six hours or so, the tube was lowered vertically 1 cm. by means of a silver-wire attachment. During the second half of the time it was made to ascend by stages in the same manner. Thus the tumour was divided into four zones, each of which was irradiated for about twelve hours in half periods of six hours each, save the lowermost zone, which was irradiated for twelve consecutive hours. In addition to this internal application, two tubes of radium (1 eg. of pure radium sulphate each, external activity, 12,000 and 11,000), sheathed in silver, were placed upon the abdomen. The operation was normal, and there was reunion by first intention. By the tenth day the tumour was proved by palpation to have entirely disappeared. There only remained, in the region which it had occupied, a sensation of resistance, clearly submuscular. In a second case a similar tumour was discovered, and an identical operation was practised, save that two tubes were introduced instead of one, each containing 1 eg. of pure radium sulphate. The time of application was seventy-five hours. Externally no fewer than six applicators were used, including three tubes of various activities, and three varnish apparatus. In this case also the consequences of operation were normal. By the tenth day the tumour had considerably diminished. The pulsations transmitted by the abdominal aorta were no longer visible, as they had been previously, although they were demonstrable on palpation. The general state also was better. A month later a second external application was made, and the tumour diminished further. Within a few months, after yet another application, the tumour entirely disappeared, and the patient, whose digestive troubles had continued for five years, resumed a normal life.

49. Death in Local Narcosis.

G. RITTER (*Wien. med. Klin.*, No. 30) describes the death of a girl 16 years of age during local anaesthesia, before the beginning of an operation for goitre. The goitre caused tracheal compression, and there was moderate tachycardia, but otherwise the patient was healthy. A dose of 1.5 gram of adalin per os, followed half an hour later by 0.015 gram of morphine subcutaneously, had been given at 10 o'clock on the morning of the operation to relieve the patient's nervousness and excitability. She was brought into the operating theatre about 11.15 o'clock, and at that time she was placid, and, in answer to questions, said she felt tired; but she was fully conscious. At about 11.30 o'clock the customary dose of 50 c.c.m. of a 2 per cent. solution of alypin was injected into the site of operation. Ten minutes after the end of the injection unconsciousness suddenly set in, accompanied by twitchings of all the muscles, gasping respiration, cyanosis, and small irregular pulse. The eyes were widely opened, the pupils narrow, and the corneal reflex absent. The attack passed off after thirty to forty seconds, but consciousness did not return, and the pulse remained irregular and smaller than before. The attacks recurred at the beginning at intervals of a few minutes, and then even more frequently. In spite of the most assiduous and energetic treatment the patient died after about eight hours. The author considers that death in this case was probably due to the combined effect of the narcotics employed and of alypin. The case is, so far as he knows, unique.

50.

Ocular Leprosy.

OCULAR leprosy is an exceedingly rare state in England; but whereas the circulation of this JOURNAL comprises the whole British Empire, in parts of which leprosy is not uncommon, a summary of Dr. Fernandez's paper which appears in *Ophthalmology* for January, 1912, will not be out of place. Dr. Fernandez writes from Cuba, where leprosy is on the increase. Ocular complications are frequent in leprosy, and sight is often completely destroyed. Fernandez, acting as oculist to the Leprosy Hospital in Cuba, has found eye symptoms in 150 patients out of 250 examined. Loss of eyebrows and eyelashes is found in all advanced cases, and later the hair also disappears. Often these leprosy changes are not limited to alopecia; ulceration and necrosis of the lids follow, and distortions of the tarsus are frequent, causing both ectropion and entropion. Tubercular lepromata appear in the conjunctiva, and these extend into the cornea, giving rise to a leprosy keratitis. This causes opacity of the whole cornea, and, in contradistinction to leprosy affecting other parts of the eye, is apt to be exceedingly painful. This keratitis is not amenable to treatment and perforation is common. Calderaro states that Hansen's *Bacillus leprae* is frequently present in the limbus. True lepromata of the cornea itself are rare. The leucomata left by the leprosy ulceration are astonishingly white and are associated with a thinning of the cornea, two phenomena which seem to be characteristic of corneal leprosy. Leprosy iritis is common and is very painful; it is always an iridocyclitis. The retina and choroid are only very rarely affected. It is perfectly proper to extract an ordinary senile cataract in a case of leprosy.

51. Coxa Vara Cervicale of Infectious Origin.

ROCHER (*Gaz. hebdom. des sc. méd. de Bordeaux*, 1912, xxxiii) describes the case of a boy, 16 years of age, who at the age of 10 suffered from arthritic symptoms following acute scarlet fever. The case was treated as one of coxalgia for many years, and was accompanied by painful crises with stiffness, shortness of the limb, and limitation of movements, pain on pressure applied to the head of the femur, and slight atrophy of the limb. Radiography revealed flattening of the superior part of the head of the femur, with enlargement. The treatment consisted of immobilization by means of bandages, thermo-therapy, revulsions, and an extra sole to the boot. The author narrates this case to show that coxa vara can be caused by an infectious malady, as Froelich maintains.

OBSTETRICS.

52.

Puerperal Fever.

ACCORDING to Brandt (*Norsk Magazin for Laegevidenskaben*, October, 1912) the incidence of puerperal fever at the present time is overrated, as the diagnosis is frequently made on insufficient grounds. Only a carefully conducted necropsy provides reliable evidence for or against puerperal fever, as the following case shows. A primipara, aged 26, underwent a normal confinement at full term. The temperature throughout the puerperium was subfebrile, and a swelling was detected extending from the right border of the uterus to the right iliac fossa. The patient coughed considerably, and there were signs of pulmonary tuberculosis in the left apex. The child died twenty-six days after birth, and the mother died three days later. The necropsy showed the cause of death in both cases to be tuberculosis, and the swelling in the pelvis to be due to tuberculous salpingitis. The following case aroused much interest in Christiania in 1911, as the patient's husband reported the authorities of the maternity hospital to the Minister of Justice for gross negligence. The patient was a 2-para whose first confinement had been complicated by placenta praevia and severe haemorrhage, the child being stillborn. At the second confinement, which lasted 21½ hours, no internal examination was made. A living child was born, and only one suture was required for a slight wound of the perineum. On the evening of the third day the temperature rose to 100.2° in the axilla, and on the eighth and ninth days it was 95.5°; otherwise it was subnormal. The slight rise of temperature was attributed to a "cold," for on the fifth day herpes labii appeared. The mother and child were discharged on the fourteenth day apparently quite well. Shortly afterwards the mother felt unwell, but her physician detected no illness. Another physician was summoned, who found fever, and a swelling to the left of the uterus. He attributed the death, which occurred a

month after the patient's discharge, to puerperal fever. But this diagnosis is reprehensible, for the history of the case is not characteristic of such a state, and it is more likely that an old inflammatory focus, possibly a pyosalpinx due to the placenta praevia of the first confinement, flared up after the second confinement. Many other instances are recorded of perforated gastric and duodenal ulcers, of appendicitis, miliary tuberculosis, gonorrhoea, extragenital thrombosis, osteomyelitis, etc., which were the causes of fever in the puerperium. But, after the exclusion of these cases, the incidence of true puerperal fever is still deplorably high. In Norway alone the yearly toll is 100, in Germany it is about 5,000, and in France about 8,000. When Semmelweis succeeded in reducing the mortality from puerperal fever to 0.5 per cent., he prophesied that a further reduction would be impossible. To day the mortality from this cause is still 0.2 per cent. in Norway, and 0.3 in France and Germany. Assuming the conduct of labour to be blameless, owing to the skilled use of antiseptics and the avoidance of internal examinations, the causes of puerperal fever at the present time are: (a) Autoinfection by the blood stream from a distant focus, such as a tonsillitis, a mastitis, or an otitis media; and (b) autoinfection from germs already present in the uterus and its appendages before labour. Tonsillitis is common in the puerperium, and Brandt has noticed the coincidence of fever among the maternity patients and epidemics of tonsillitis, with or without diphtheria bacilli, among the nurses. In the following case the only source of infection detected was a whitlow. A 4-para, aged 30, was admitted to hospital after labour had lasted for some time and the liquor had escaped. Pulse and temperature were normal, and labour was terminated in four hours. No internal examination had been made. Defaecation on the fifth day was followed by abdominal pain and high fever; the lochia also became offensive. Next day a whitlow of the right thumb was detected. Death occurred on the thirteenth day, and the necropsy showed parametritis, peritonitis, and a small fragment of placenta within the uterus. It is a popular belief that phlebitis in the puerperium is due to infection during labour, but this is not necessarily so. A 2-para, aged 36, who suffered from painful varicosities of the veins of the legs during her second pregnancy, underwent a normal confinement, no internal examination being made. On the day of her confinement periphlebitis of the saphena veins on both sides was detected. Thrombosis of both veins followed, there was severe pain and oedema in both limbs, and the patient was confined to her bed for three months. In this case to associate the phlebitis with infection during labour is absurd, for the former already existed when infection might have occurred. Puerperal fever caused by faulty technique, by infection from a distant focus in the patient's body, and by autoinfection from germs already present in the uterus is common enough, but it is often diagnosed when a host of other diseases are to blame.

GYNAECOLOGY.

53. Adnexal Infection.

DE BORIS (*La sem. mèd.*, No. 48), in a paper on adnexal complications following confinement, describes a condition which he calls lymphangitis of the superior border of the broad ligament. Clinically there are three forms—the algic, the exudative, and the suppurative. The first is characterized by a slight rise of temperature on the third day, offensive lochia which are not at first discoloured, and moderate pain in the right iliac fossa. The condition clears up in two or three days. The second form is characterized by the presence of a tumour, generally on the right side; the onset is similar to that of the first form, though the fever is more marked; shivering is rare, and constitutional disturbance is slight. The uterus always remains mobile, but involution is delayed. The lochia, generally offensive, become chocolate coloured on the fifth day and eventually purulent—a state of things which the author considers is not due to salpingitis. In from eight days to a month and a half the exudation is completely absorbed. The third form differs from the second in that the tumour is larger, the lochia are fetid, the temperature is markedly remittent, and there are rigors. At the same time the general state is relatively little altered as compared with a septicæmic infection. Pathologically and clinically the conditions resemble the classic entity of phlegmon of the broad ligament or periuterine phlegmon, but there is a difference: the uterus in the conditions under consideration preserves its mobility,

and the infection seeks for choice the upper part of the broad ligament; in periuterine phlegmon the infection is localized at the base. The diagnosis is easy, but on the right side there may be confusion with appendicitis; however, an appendicitis giving rise to so large a tumour would probably be accompanied by vomiting, meteorism, and violent pains. As regards treatment, one has to guard against operating simply because there is a tumour; most of the cases will clear up under medical treatment, of which the most essential item is the application of ice to the abdomen.

THERAPEUTICS.

54. Intestinal Movements under the Influence of Aperients.

F. MLYER-BETZ AND T. GEBHARDT have published in considerable detail the results of their investigations of the intestinal movements under the influence of various purgatives and aperients in healthy persons by means of x ray illumination (*Munch. med. Woch.*, August 13th and 20th, 1912). They state that this work could scarcely have been carried out without the excellent observations of Magnus and Padtberg on the cat having preceded. It is important in a short abstract to give the important data which form the subject of the communication, but the reader who is interested in the same will be well advised to refer to the original article. After describing the method of procedure, they give an account of typical experiments usually conducted on young patients whose digestive apparatus were natural. They divide these into four classes. In the first they deal with senna and aloes. The stomach and small intestine are not affected by these drugs. The action, limited to the large intestine, is not a stormy one, but consists of a combination of increased peristalsis with what has been termed by Schwarz as "small movements of the colon." The contents are well intermixed and the passage through the colon into the sigmoid flexure and rectum is a rapid one. Variations and minor points in the action of these two purgatives are both described in the text and illustrated by diagrams. In the next class castor oil is dealt with. In this case, although vomiting was at times noticed, no increased peristalsis of the stomach could be detected. The action on the small intestine is best marked when the oil reaches the already full gut, and in the course of from three to four hours causes the whole contents to be thrown into the colon. The movements in the small intestine are partly rolling peristaltic movements and partly rhythmical segmentative movements. The mass reaching the colon remains practically fluid and the normal real caecum movements are not observed. The haustra are not well marked and the intestine is filled with gas, probably from secretion. No "small colon movement" is present and the discharge of the mass into the sigmoid and rectum takes place suddenly as the result of increased onward peristalsis. The third group of purgatives, that of the drastics, is represented by jalap. The results obtained correspond to a great extent with Padtberg's colocynth experiments. The increased secretion in the small intestine leads to a complete filling of the gut. In about three hours the contents of the small intestine is discharged. The normal caecum activity is absent and the rapid passage through the large intestine of the fluid motion is characterized by repeated filling and sudden emptying of the ampulla. The fourth group is that of the salines. In this case the marked watery secretion of the intestine leads to an almost uniform passage of the fluid motion throughout the whole intestinal tract. The action is similar to that of jalap. The authors further have investigated the action of calomel. This drug stimulates every segment of the intestine. In the small intestine rolling movements are produced, and, while the secretion is not increased, the peristalsis often becomes stormy. This is best seen in the large intestine. They find that calomel is endowed with the power of emptying the intestines better than any other drug, and state that if it were not for the danger of an undesired absorption of the poison it would be the best and most searching purgative that we possess.

55. Alarming Symptoms after Hormonal Injections.

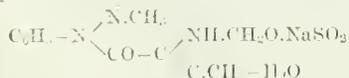

THE number of accidents following injections of hormonal has recently been increased. W. Wolf (*Munch. med. Woch.*, May 14th, 1912) reports the case of a man, aged 23 years, who had been subjected to splenectomy a year previously, on account of rupture of the spleen. An operation for a

ventral hernia having been performed, the author proceeded to give an injection of hormonal into the median vein two days later, to deal with symptoms pointing to peritonitis. These were distension of the abdomen, feeling of fullness and absence of flatus and faeces. He had only given 3 c.cm., when the patient suddenly turned pale, the pupils became dilated, the lips cyanotic, and the expression of face betokened fear. He complained of a severe headache. No pulse could be felt. The injection was interrupted, and after camphor, wine, etc., had been administered he gradually got better. The collapse was most alarming while it lasted. H. Bierenbach (*Munch. med. Woch.*, May 21st, 1912) injected 20 c.cm. of hormonal into the gluteal muscles. The patient was in good circumstances, and the injection, which was undertaken for obstinate constipation, was carried out in her private house. At first no signs were noted, but after a minute or two the face became red and she complained of severe headache and giddiness. Then she became intensely pale, the pulse was dicrotic, small, and soon disappeared, and consciousness was lost. He could only just hear the cardiac sounds. Not having any trained assistance at hand and being limited to what was to be found in a private house, he gave her champagne, hot coffee, and massage over the heart. Consciousness returned after about twenty minutes, but the headache persisted for some hours. Five hours later two motions were passed, and since then a stool has been passed each day or each alternate day. Bierenbach states that the accident was most alarming to witness. D. Frischberg (*Munch. med. Woch.*, April 30th, 1912) records the case of a man who underwent an operation for appendicitis. During the following four days complete obstruction of the bowels developed with signs of peritonitis. Other means having failed to bring relief, 20 c.cm. of hormonal were injected intravenously with all precautions. The injection had scarcely ended when the patient complained of severe headache and pressure: the pulse became almost obliterated, the face very pale, a rigor ensued and the temperature rose to 105.8° F. Camphor and other restoratives were applied and the attack passed off, but the patient suffered from the headache and other symptoms for some time. The effect of the hormonal was exceedingly good, the flatus and motions passing within a short time. A similar, but not quite so severe, experience was made by H. Bovermann (*Munch. med. Woch.*, July 9th, 1912) in a woman, on whom he had performed an operation for cancer of the gall bladder. In this case the action of the hormonal was excellent, but the symptoms developing one and a half hours after the injection were most alarming. Two deaths have been recorded, the first by Madlener, and the second, recently, by Jurasz (*Deut. med. Woch.*, No. 22, 1912), and R. Mohr (*Berl. klin. Woch.*, June 24th, 1912) warns the practitioner that a most alarming collapse, which may be fatal, may occur in any case in which hormonal is injected. He attributes the collapse to a sudden lowering of the blood pressure, and he raises the question whether the action is due to a specific hormone. In some animal experiments, he has found that quite small doses of adrenalin sufficed to remove all the action of hormonal, which suggests that there was no direct action increasing peristalsis.

56.

Melubrin.

MELUBRIN or the phenyl-dimethyl pyrazolen amido-methane sulphonate of sodium having the formula:

or, in other words, antipyrine, with one hydrogen group substituted by amido-methane sulphonate of sodium, is manufactured by Meister, Lucius, and Brünig, of Höchst. It is a white crystalline powder, possessing but little taste, and is soluble in water to the extent of 1 part by weight in 1 part of water. Solutions of melubrin are not stable, and it is therefore advisable to prescribe it in dry form. A few favourable reports of its action having been published, the preparation has been tested in the General Municipal Hospital in Friedrichshain, Berlin, in Professor Stadelmann's wards. F. Hoppe (*Berl. klin. Woch.*, May 27th, 1912) now gives the results of this trial. In acute rheumatism satisfactory results were obtained. The temperature fell, profuse sweating broke out, the pain, swelling, and redness of the joints disappeared or were materially reduced in three days' medication. Return of pain and other symptoms was at times noted, but a fresh exhibition of the drug rapidly removed the same. As a rule, the dose given was 1 gram three or four times a day, but at times the daily maximum was increased up to 8 grams. No signs of salicylism were

met with, even when full doses were employed. In about 6 cases the drug failed to reduce the pain and swelling of the joints and at times even the temperature. In these cases salicylic acid or aspirin succeeded in removing the refractory symptoms. Hoppe states that while they had not observed any beneficial action in cases of endocarditis, no harm accrued in giving the preparation even in the presence of well-marked heart disease. The only result obtained in chronic rheumatism was a slight and temporary diminution of the pains. It also failed to act in gouty arthritis. It acted well in sciatica. The antipyretic action was tested in cases of pneumonia. In a few the fever was uninfluenced, while in other cases it was reduced to some extent. In pulmonary tuberculosis it was given three times a day in doses of 1 gram. The temperature was reduced, but the sweating was so profuse that the patients refused to continue with it. The dose was then modified by dissolving 5 or 6 grams in 200 c.cm. of water and giving up to a tablespoonful of this solution seven times a day. In 4 cases it acted well, without any objectionable sweating or loss of appetite. The urine of patients who had received melubrin yielded a violet coloration with perchloride of iron, and in some cases it possessed strong reducing properties. The reducing substance proved to be glycolonic acid. A disadvantage of melubrin as against salicylic acid is its price, which is 57 marks 50 pfennings pro kilogram.

PATHOLOGY.

57. The Staining of *Spirochaeta Pallida*.

TRIBONDEAU (*Bull. de la Soc. Franç. de Derm. et Syph.*, November, 1912) says there are three desiderata for the successful staining of the organism: (1) The material should be obtained from the infiltrated tissues around the chancre and not from its surface where other micro-organisms abound. (2) All substances which are stainable with silver nitrate, such as, for example, haemoglobin, should be eliminated as far as possible. (3) The method of fixation and impregnation with silver should be as energetic as possible as the *Treponema* stains with difficulty. Three solutions which can be kept in stock for months are requisite—a fixative, a mordant, and a silver nitrate solution. (a) The fixative consists of:

| | |
|-------------------------------|-----------|
| Formalin, 40 per cent. | 2 grams |
| Pure acetic acid | 1 gram |
| Distilled water | 100 grams |

(b) The mordant is:

| | |
|------------------------|---------|
| Tannic acid | 5 grams |
| Distilled water | 100 " |

(c) And the silver solution, made alkaline by Fontana's method—that is:

| | |
|--------------------------|----------|
| AgNO ₃ | 1 gram |
| Ag. destill. | 20 grams |

To 15 c.cm. of this solution add ammonia drop by drop until the sepia precipitate produced completely disappears. To the alkaline solution thus obtained the remaining 5 c.cm. of AgNO₃ are gradually added until the solution remains slightly opaque after shaking. This solution (c) keeps active and constant for several months. Technique: (1) The syphilitic material obtained after drying of the chancre with cotton-wool and scarification of the edges till slight bleeding occurs is spread on a slide in the ordinary way and dried in air or the incubator at 37° C. It must not be fixed by heat. (2) Fixation and dehaemoglobinization are achieved by irrigation for one minute with the fixative (a), and the action is perfected by a few drops of absolute alcohol, which are allowed to dry on the inclined slide. (3) The mordant (b) is allowed to act over a flame till just steaming for thirty seconds. (4) Wash in tap water thirty seconds. (5) Pour off excess of water, and without drying add the ammoniated silver solution, which must be allowed to act over a flame as in (3) for thirty seconds. (6) Wash in distilled water and dry on blotting paper. It will be seen that the time occupied by these manoeuvres does not exceed five minutes. The films should have a yellowish tint when finished. They should not be mounted in balsam or left for long under cedar-wood oil or xylol, or the stain will fade. The *Treponema* is easily seen, especially where it overlies the red blood corpuscles. The *Sp. refringens* and *balantidis* are distinguished by their darker tint and morphological characters. It is claimed for the method that it is easy, certain, and rapid, that dried specimens can be examined with success even a year later, and that it requires no special skill or expensive apparatus.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

58. Harmless Adventitious Cardiac Murmurs
in Children.

W. SCHLIEPS (*Jahrbuch für Kinderheilkunde*, September, 1912) has investigated the incidence of adventitious cardiac murmurs among children, 273 of whom were examined. None who had suffered from articular rheumatism, scarlet fever, or diphtheria was included in this investigation, yet a hundred cases of systolic murmur were found. All the children were repeatedly examined at different times, in different positions, and both before and after exercise. Cardio-pulmonary murmurs constituted 63 per cent. of all the murmurs. The distinction between this murmur and that of organic heart disease is made by observing the soft, blowing character, the irregularity, and the changeableness of the former. The two latter characteristics may appear spontaneously or may be elicited by certain acts. Thus, the murmurs not merely come and go, but they become loud or soft, according as respiration is varied and the posture of the body is changed. Murmurs which are heard in one position, and which disappear in others, are always cardio-pulmonary in children, and are never due to valvular disease. The importance, therefore, of examining a heart in various positions cannot be overrated. Of the 63 cases of cardio-pulmonary murmur, it was audible in 27 cases only when the child was standing. In 14 cases it was audible only in the horizontal position, and in 6 cases it was equally audible in both positions. In 16 cases it was audible, but not equally loud, in both positions. Sometimes a cardio-pulmonary murmur does not appear till several deep breaths have been taken, and many children in whom such a murmur was detected on the first examination were found on subsequent examinations to show no murmur. This was due to the fact that on the first examination the child's lungs were examined before the heart, and the child was instructed during the examination of the lungs to take deep breaths. On subsequent occasions only the heart was examined, and thus the deep respiratory movements which elicited the murmur were omitted. While cardio-pulmonary murmurs constitute two-thirds of all adventitious cardiac murmurs, there is another class of adventitious murmur which makes up the remaining third, and to which the writer applies the term "atonic murmur." He found it in 27 of his patients, and it was almost invariably associated with pallor, emaciation, and muscular flabbiness. This murmur, which is systolic and loudest over the apex, differs in many respects from the cardio-pulmonary murmur. Thus its intensity is but little affected by deep respiration, changes of position or exercise. The cause of this murmur is a local or general loss of tone by the heart. This loss of tone differs from the simple cardiac dilatation to which the murmur was formerly attributed. It is sometimes difficult to distinguish atonic murmurs from those of endocarditis and myocarditis; but the distinction between atonic and cardio-pulmonary murmurs is easily made. Only when the two forms are combined in the same person are they difficult to distinguish. When a systolic murmur gives place to a clear first sound on psychic stimulation, compression of the abdominal aorta, or elevation of the lower limbs, no serious disease of the heart exists. The absence of any cardio-vascular irregularity, subjective or objective, either at rest or after exercise, is further proof of the unimportance of a systolic murmur. Difficult cases do, however, exist among children in whom severe heart disease may cause little discomfort. In such cases the pulse is an invaluable guide, for it reveals serious cardiac disease when its rate is markedly increased and its rhythm altered by bodily exercise. The cardio-pulmonary murmur calls for no treatment. The atonic murmur, however, requires treatment which aims at restoring weight, energy, and colour to the patient. Diet that is merely fattening should be replaced by one containing little milk and a liberal supply of meat, cheese, and fruit. Combined with suitable exercise this régime often banishes cardiac murmurs with astonishing rapidity. Drugs and confinement to bed are pernicious factors to be most strenuously avoided.

59. X-ray Indications of a Malformed Liver.

In a paper read before the Société de Radiologie Médicale de Paris (*Bull. et mém.*, No. 39, 1912) Aubourg describes

a case in which subsequent *post-mortem* examination bore out the essential truth of the x-ray picture. It was noted, on examining a patient's abdomen by means of the x rays, that the upper and external part of the hepatic shadow appeared abnormally clear. This clear space, obviously below the diaphragm, was similar to the pulmonary transparency above. The surface affected was about the size of the palm of the hand, and it was taken to be a case of hepatoptosis with an intestinal loop insinuated between the liver and the diaphragm. The patient was examined four times by means of the x rays, and the radiological picture was the same in every case, being modified neither by direct palpation nor by the retraction of the abdominal wall. The patient died later, and it was then found, on opening the abdomen, that the liver was malformed, and that its general position was oblique. An examination of the right lobe posteriorly showed that, instead of presenting a convex surface, it was depressed to within 10 cm. of the oesophagus, and formed a concave furrow, with which the kidney was not directly in contact. It was evidently a malformation, because, at the summit of the hepato-renal space, the liver showed a deep vertical notch, and into this space during life a portion of the intestine had slipped, corresponding to the lower part of the right lung. The interest of the autopsy lay in the fact that this was the first case of the kind which was discovered radiologically and subsequently demonstrated *post mortem*. The autopsy proved, however, that the condition was not one of falling liver but of a malformation of that organ. Once again it was not the x-ray picture that was at fault but its interpretation.

60. Rheumatic Neuritis.

PIERRET (*Echo méd. du Nord.*, 1912, xvi) describes three cases, two of the arm and one of the leg, of neuritis following rheumatic fever. The disease showed itself by muscular atrophy, pain produced by or increased on pressure, hypoaesthesia, and diminished electrical excitability. The disease is a rare one, and can occur during the acute attack or during the period of convalescence. Alcoholism may act as a predisposing cause. The most marked characteristic is rapid muscular atrophy. Glossy skin is sometimes met with, and sensory troubles are frequently superadded. The prognosis is usually favourable. There is no reaction of degeneration. The duration of the disease does not exceed two months. The best treatment is by salicylates and the galvanic current.

61. Septic Rheumatoid Affections.

THE etiology of rheumatic affections has long been a matter of dispute—a number of observers claiming that the affections are caused by streptococci, while others claim that the cocci are present only as secondary infective organisms. J. Schürer discusses the part played by the streptococci, and especially by *Streptococcus viridans*, in atypical forms of septic arthritis (*Munch. med. Woch.*, November 5th, 1912). Choosing cases in which salicylates failed to act, he investigated the blood bacteriologically. The first patient had suffered from swelling and pain of joints three weeks before admission. Nearly all the joints were affected; the temperature varied between 100° and 102° F.; anaemia was present, and, while salicylates failed to relieve, antipyrin and its derivatives acted fairly well. The blood was examined by sowing some 20 c.cm. on dextrose-agar, ordinary agar, and broth. The third test revealed some small greyish-green colonies on the dextrose-agar plates, which proved to be *Streptococcus viridans*. A horse was immunized with these organisms and the serum was applied therapeutically, but without beneficial result. The affection proved refractory to all forms of ordinary treatment, and therefore the tonsils were enucleated. In one large abscess was found. At first, even this did not appear to influence the course of illness, but later some improvement was seen. Ultimately the patient improved considerably, the pains were no longer present, but there was marked stiffness of the previously affected joints. The second patient complained of joint pains and swelling on the fifth day of a febrile sore throat. A soft systolic murmur was heard at the apex. *Streptococcus viridans* was cultured from the blood in the third week of illness. Salicylates proved of little value, while antipyrin brought slight relief; 100 c.c.m. of the serum prepared from the

cocci of the first patient was injected intramuscularly. This caused a diminution of the joint affection, but the temperature remained heightened. Both tonsils were extirpated, which was followed by the disappearance of all the symptoms. A third case of a similar nature is also recorded. The author is of opinion that since he has found streptococci in three cases of septic rheumatic affection within a short space of time, it is likely that systematic examination of the blood will prove that this organism is a common cause of these cases.

SURGERY.

62. Biliary Peritonitis without Perforation of the Biliary System.

THE escape of bile into the peritoneum without any gross lesion of the biliary system is discussed by P. Wolff (*Berl. klin. Woch.*, December 9th, 1912), who has observed three such cases. One patient, who had suffered from typhoid fever three years earlier, suddenly developed violent abdominal pain. When admitted to hospital, fifteen hours later, his abdomen was distended, rigid, and tender. As the pain was most severe in the region of the appendix, the abdomen was opened at this point. More than one litre of mucous, dark-green bile escaped from the peritoneal cavity, both the parietal and visceral linings of which were somewhat inflamed. After the healthy appendix had been excised the abdominal wound was enlarged upwards to facilitate the exploration of the gall bladder and ducts. The former was filled with bile, its serous coat was normal, its walls were not thickened, and it contained no stones. Palpation of the biliary passages revealed nothing abnormal. The operation was hastily completed owing to the patient's weakness. A tube and a gauze tampon were inserted near the common bile duct, on the assumption that a perforation might have occurred in it or in the duodenum. The patient recovered. Another patient, who had suffered for some time from abdominal symptoms, suddenly developed violent pain in the abdomen. Twenty hours later he was admitted to hospital, where symptoms of appendicitis led to an exploratory laparotomy. Several litres of mucous, dark-green bile escaped from the peritoneal cavity. After the removal of the healthy appendix the other organs were examined, and a small perforation, of the size of a lentil, and covered by a fibrinous deposit, was found on the anterior surface of the duodenum, a few centimetres from the pylorus. Apart from slight inflammation, the gall bladder and bile ducts were normal. The perforation was closed, a drain was inserted, and an uneventful recovery was effected. A third patient had suffered for two days from vomiting and abdominal pain when seen by the author. There was retention of flatus and faeces, and the abdomen was much distended. Perforation of the appendix and peritonitis were diagnosed; but when the abdomen was opened a large quantity of cloudy, bile-stained, purulent fluid escaped, and the appendix proved to be healthy. The gall bladder contained many stones, and between it, the liver, and duodenum were many adhesions. Nowhere, however, could a perforation be found. The gall bladder was freed from adhesions, sutured to a small opening in the abdominal wall, opened, and drained. Death followed two days later. At the necropsy the stomach and the upper portion of the small intestine were found much dilated. A coil of the ileum was rotated on its own axis, and lay compressed within the pelvis. The gall bladder and cystic duct contained many small stones, but neither of these organs nor the common bile duct showed any ulceration. The stomach and intestine showed no perforation. The author recognizes two forms of biliary peritonitis. In the one bile oozes through the wall of a diseased gall bladder; in the other it escapes through a perforation in the biliary system or in such organs as the duodenum and stomach, into which bile may flow. In the first form the process is obscure. Simple catarrh or chronic inflammation alone is insufficient to cause biliary peritonitis, for while the former is common, the latter is very rare. For the same reason stasis alone cannot account for the condition; and though gall stones were found in the author's third case they caused no obstruction. Doberauer holds that the gall bladder after recovery from typhoid fever may become permeable to bile; but the author discredits this view, even in his first case, in which he thinks the bile must have escaped through a perforated duodenum. This explanation applies also to the second case. In the third case the author doubts whether the peritonitis was caused by the state of the biliary system,

or vice versa. He inclines to the latter view, though he cannot show how a primary peritonitis can cause a transudation of bile through the walls of the biliary system.

63. Dislocation of the Patella about a Horizontal Axis.

MALLOCH (*Med. Bull. Univ. Toronto*, July 1912) records the case of a boy, aged 14, in whom, as the result of striking his knee against the handle of a hand-car, the patella was rotated about a transverse axis, with its lower border directed forwards and the upper border backwards, so that its cartilaginous posterior surface faced downwards and its anterior free surface directly upwards. There was no lateral displacement or vertical rotation. As an immediate result of the accident the knee was locked in complete extension and the joint distended with fluid. There was no bruising or abrasion of the skin, and in the situation of the patella a marked narrow bony transverse ridge was felt, passing downwards, from which the ligamentum patellae could be seen and felt as a tense band. Above the ridge was a saucer-shaped depression, capable of holding a hen's egg, the floor of which was formed by the anterior muscular fibres of the quadriceps. The ligamentum patellae was stretched but intact, and there was no separation of its periosteum. Even under ether reduction failed, but on opening the joint and affording escape to 3oz. of blood clot and synovia reduction was easily accomplished. The patient was an active, healthy, rather loose-jointed boy, and the patella was normal in shape and size. Since reduction was so easily accomplished upon the entrance of air into and the escape of blood from the joint it would appear that the bone was held in its abnormal position by the pressure of the effused blood, and possibly aspiration would have done equally well as incision.

64. Aseptic and Antiseptic Treatment of Wounds.

P. SICK enters minutely into the question of the possibility of dealing aseptically with wounds, and comes to the conclusion that true asepsis is impossible, at all events for wounds and for the skin (*Deut. med. Woch.*, November 7th, 1912). Antiseptic measures are required for the preparation of ligatures. He finds that it is wiser and very common to use a non-irritating drying antiseptic, such as noviform gauze, for those regions in which experience teaches the surgeon the wound is unlikely to remain hermetically sealed without. The use of a very small quantity of such an antiseptic not only does no harm, but actually is productive of good. On the other hand, the free use of antiseptic douches and other solutions or of antiseptic powders has proved harmful to wounds. In wounds of some hours' standing, especially if they be infected and inflamed, antiseptic tamponage lessens the virulence and inhibits the growth of the imprisoned microorganisms, while the absorption of the secretion into the tampon and its frequent removal assists the bactericidal action of the tissue fluids in destroying the germs. This can be demonstrated in all cases, save in tetanus, glanders, and rabies wounds. He has found that iodoform, isoform, and vioform, as well as the milder bismuth preparation, noviform, are of high value for these purposes.

OBSTETRICS.

65. Caesarean Section.

AT the International Congress for Midwifery and Gynaecology, held in Berlin in September, 1912, Henkel (*Muench. med. Woch.*, October 1st, 1912) reviewed the recent advances in Caesarean section, and reported 33 cases in which transperitoneal cervical Caesarean section had been performed. The only fatal case in his series was that of a patient in the ninth month of pregnancy, who had lost much blood from a central placenta praevia. The patient, who had been repeatedly examined, and whose cervix scarcely admitted one finger, was sent to hospital, where a stinking tampon was removed. The operation was successfully performed, and the patient remained afebrile till the nineteenth day, when fever set in. Death occurred four days later. Professor Henkel had left her perfectly well, and was astonished on his return from his holiday to find her dead. Death was due to a phlegmon, which had developed between the bladder and the anterior wall of the cervix. Had it been incised and drainage been effected through the vagina, the patient would probably have survived. This death should therefore be attributed to post-operative neglect rather than to the original

operation. With this exception, the operations were satisfactory, although in only three cases were the membranes intact at the time of operation. In many cases labour had begun outside the hospital, to which the patients were admitted after rupture of the membranes. In several cases four days had elapsed between the rupture of the membranes and the operation. Some of the patients were already febrile, and diplococci and streptococci were demonstrable in the uterine secretion; others, again, had been examined more than fifteen times, by students without rubber gloves, after rupture of the membranes. In the case of a primipara with a contracted pelvis there was a transverse presentation with prolapse of an arm. The membranes had been ruptured four days before admission, and the child was dead. The narrowness of the pelvis was not so extreme as to render the passage of the child by this route impossible, but the fear of rupture of the uterus and of other injuries led to the choice of Caesarean section, the result of which was excellent. While the prognosis for classical Caesarean section in those cases in which the membranes have been ruptured for some time and fruitless efforts have been made to hasten labour with unclean hands is bad, it is relatively good for transperitoneal cervical Caesarean section. Professor Henkel's material was largely composed of infected cases, but the exact proportion of infected to sterile cases remains unknown, for at the time of operation it is frequently impossible to classify patients in this respect. That purulent peritonitis may exist without causing any local symptoms is shown by the following case: A woman, aged 18, had suffered from fever and rigors for some days. The abdomen was neither distended nor tender. No rigidity of the muscles was detected and no vomiting occurred. Extraperitoneal cervical Caesarean section was attempted, but a tear was made in the peritoneum, through which pus escaped. Had this condition been detected only after death, it is certain that it would have been traced to the operation. There are, however, cases in which signs of a generalized infection are unmistakable at the time of operation, and for these the only treatment which offers a chance of recovery is the removal of the uterus.

GYNAECOLOGY.

66. Pseudomyxoma Peritonei.

WILSON (*Journ. of Obstet. and Gyn. of the British Empire*, October, 1912) has met with six typical cases of the above condition. These occurred amongst 144 cases of glandular pseudo-mucinous cysts of the ovary, giving the unusually high proportion of over 4 per cent. Pseudomyxoma of the peritoneum occurs most frequently between the ages of 40 and 60, and is most frequently found in multiparae. Menstruation is usually not affected, but a large proportion of the women have already passed the menopause. The onset, symptoms, and physical signs do not differ remarkably from those of the ordinary glandular cyst of the ovary. The growth is generally rapid; pain is often absent; there is neither tenderness nor notable evidence of irritation of the peritoneum. General emaciation is common. The physical signs are those of a large ovarian cyst, the outlines being not very well defined, and the consistence elastic. The very free mobility of the uterus floating in free fluid, as in ordinary cases of ascites, is never present in these cases. In none of Wilson's patients was any symptom or sign elicited that pointed to a previous rupture or perforation of the cyst wall, and in none of them was the true diagnosis suspected until the abdominal incision was made. The ovarian cyst in these cases is a multilocular one, the loculi being filled with the characteristic gelatinous material, and divided by very delicate transparent connective tissue septa lined by columnar secreting epithelium, which is the source of the gelatinous material. The Fallopian tube is generally normal and unaffected; the mesosalpinx is usually free, but may be found opened up by the growth of the ovarian cyst. A dermoid loculus may be found in the midst of the ovarian cyst, a concurrence which is not very uncommon in glandular ovarian cysts in general. Towards the distal pole of the ovarian tumour the capsule becomes more delicate and thin, until finally it gives way, and the jelly-like material oozes gently into the peritoneal cavity. The tenacious consistence appears to prevent the material from sinking into the lower part of the cavity and pelvis; the jelly seems rather to have a tendency to be carried to the upper part of the cavity, where it is commonly found between the diaphragm and

the upper surfaces of the liver, spleen, and stomach. The parietal peritoneum is thickened, opaque, and has lost its gloss; where the gelatinous material is more closely in contact with it the surface is often found velvety or granular, and occasionally small transparent prominences are seen in some parts of the peritoneum. Some observers have considered the gelatinous mass to be the product of a specific peritoneal affection, but the author considers that what happens is that the peritoneum attempts to absorb or to encapsule the jelly-like substance, which acts as a foreign body; a chronic inflammation is the result, and the term "chronic pseudomyxomatous peritonitis" is justified in the majority of cases. The affection leads in no very long time to death. Puncture of the cyst is highly dangerous. The only method of treatment that affords a chance of success is removal of the cyst and, as far as possible, of the whole of the gelatinous effusion. The only effectual method of performing the latter task is by copious flushing with normal saline solution. This fluid causes the masses to swell up and become loosened, and it is to the use of it that the author attributes the relatively good results in his cases. One case in which boracic lotion had been used died on the ninth day from ileus, but the other five made a good recovery. Of these, one, in whom there were true metastases, remained well for more than two years, and then died of a psoas abscess; of the others, three remain well after eight, seven, and two years respectively, while the fourth was operated on less than a year ago.

THERAPEUTICS.

67. Intravenous Serum Treatment of Pneumonia.

W. WEITZ (*Wien. med. Klin.*, No. 26, 1912) describes the treatment of pneumonia by intravenous injections of Neufeld-Händel pneumococcus serum. Neufeld and Händel found in experiments on animals that in pneumococcus infections only large doses of serum could be depended upon against large amounts of culture; smaller doses had no corresponding value for weaker infections, and on further diminution of the dose the serum soon ceased to have any effect. They therefore recommend that intravenous injections of large amounts of serum should be substituted for subcutaneous injections, because by the subcutaneous method only small quantities of the antibodies gradually enter the circulation. The author has treated 38 cases—3 women and 35 men—on these lines. The men were usually of the labouring class; many of them were hard drinkers. No children were treated, and only 2 patients of more than 60 years of age, otherwise the patients were fairly evenly distributed amongst the different age-periods. The injections were made into the cutaneous veins of the forearm, after anaphylaxis had been guarded against by ascertaining that the patients had not previously received serum treatment. The single dose of serum was usually from 20 to 30 c.cm., and later 40 c.cm. was frequently given as an initial dose; occasionally only 10 c.cm. was given. In 3 cases a single injection only was made, but usually two or three injections at twelve-hour intervals, and in some of the more protracted cases as many as ten injections were made. No harmful effect of the serum on heart or respiration was observed. Serum rashes occurred in 6 cases, but were never severe. The ordinary treatment of pneumonia was given in addition to the serum treatment. One patient was subjected to the injections on the first day of illness. In this case the doses given were inadequate to prevent steep rises of temperature succeeding the falls of temperature which followed the injections, but the temperature became finally normal at the end of the fifth day of illness. In 16 cases the treatment was begun on the second day; 12 of these ran a clearly abortive course, the temperature beginning to fall steadily on the third day, and becoming normal usually on the fourth; in 2 cases the temperature was already normal on the morning of the third day of illness, in 1 after a single injection of 30 c.cm. of serum, in the other after a single one of 20 c.cm. The effect of the serum was specially noticeable in the case of a man 65 years of age who was admitted to hospital showing signs of dangerous cardiac weakness, of an exceedingly stout woman 50 years of age, and of a man 57 years of age with severe diabetes—all three of them cases in which spontaneous recovery was unlikely to occur. One case only in which the injections were begun on the second day ended fatally, and in this the action of the serum was shown in the disappearance of pneumococci from the

blood and in a very marked destruction of the pneumococci in the affected lung. In 3 of the "second-day" cases there appeared to be no cutting short of the illness as a result of the serum treatment. In 2 cases in which treatment was begun on the second day, one of them being a case which had run an abortive course, and in one case in which treatment was begun on the third day, exudative pleurisy developed. In 6 cases treatment was begun on the third day; 6 recovered, 4 of them running an abortive course, 1 died from a streptococcus sepsis, the origin of which was not very clear. In 8 cases treatment was begun on the fourth day; 2 died, both of them cases of mixed infection. In 5 of the 8 the temperature was favourably affected by treatment and became normal on the sixth day of illness—that is, two days after the beginning of treatment. As a rule, the serum treatment was not begun later than the fourth day. In 5 very severe cases it was tried as late as the fifth day, but 4 out of the 5 patients died. In 2 cases it was begun on the sixth day, both patients being free from fever on the eighth day. The author's conclusion is that the Neufeld-Händel pneumococcus serum injected into the veins has a specific action in a majority of cases of pneumonia, and should be extensively made use of, especially in early cases.

68. The Serum Treatment of Hydrocele.

CARFORIO (*Rif. Med.*, September 7th and 14th, 1912) has treated 73 cases of hydrocele by injections of hydrocele fluid. For the most part the fluid of the patient's own hydrocele was used, but in a few cases hydrocele fluid from other human subjects was injected. One thing comes out clearly in the report of these cases—namely, the innocuous character of the treatment. No bad effects were observed. The hydrocele was usually not emptied, but a certain quantity withdrawn, and then a small amount (usually about 5 c.cm.) of this injected into the subcutaneous tissue. In the 7 cases where the hydrocele was symptomatic of inflammatory or neoplastic lesions of the testes the results were negative, but that is only what one might expect. Of the remaining 66 cases, 8 showed marked thickening of the vaginal sheath, 56 were typical idiopathic hydroceles, 10 were tuberculous. About 300 punctures were made in all, and in only 4 cases was there slight local reaction. Immediate cure (= complete reabsorption of the fluid) occurred in 96 per cent., but relapse was very frequent (80 per cent.), but after a second injection lasting cure occurred in 42 per cent. of the cases. The more recent the case the better the result. The number of injections necessary for complete absorption varied from 1 to 5, and was dependent on the size, age, and previous history of the hydrocele. No relation seemed to exist between the rapidity of the cure and the amount of fluid injected. Hydrocele fluid taken from other hydroceles did not seem to act at all. The *modus operandi* of the cure cannot be explained, as in merely local reactions—for example, in bilateral hydroceles, where only one side was injected—the good effect was noted on both sides. Possibly it acts by stimulating the renal epithelium and inducing some obscure immunizing action. The method is technically extremely simple, and although it is by no means a cure for every case of hydrocele, short of the more heroic surgical procedures, it seems an advance on mere tapping.

69. Bismuth in Gastric and Duodenal Ulcers.

AARON (*Amer. Journ. of Med. Sciences*, October, 1912) discusses the treating of gastric and duodenal ulcers with bismuth, the protection afforded by the subnitrate being both physical and chemical. From its consistency, fine distribution, and high specific gravity, bismuth forms a layer over the ulcer, mechanically protecting it from injury, its chemical action producing a mucous secretion, so that the protective layer is a muco-bismuth mixture. The drug must never be regarded as a substitute for rest in the treatment of ulcer, its main indication being as a reinforcement in treatment, and when the ulcer becomes chronic, relapses, or causes pain. It is most effectual in cases of overacidity, the chief requirement in its use being to cover the ulcer with a large and resistant protective layer which can be renewed and supplemented at regular intervals. As soon as subjective symptoms are relieved the daily dose may be tentatively reduced according to the clinical indications. It should be administered finely suspended in a liquid medium, 10 to 20 grams of the subnitrate being taken in a tumbler of warm water on an empty stomach which has been cleansed three-quarters of an hour previously by 150 c.cm. of Carlsbad or Vichy water, or it can be administered suspended in olive oil.

The treatment must be adapted to each individual case, since occasionally the bismuth treatment may prove to be unsuitable, and some observers prefer the subcarbonate to the subnitrate, and bismuth subgallate is a useful substitute.

PATHOLOGY.

70. Spontaneous Recovery from Cancer.

THERE are, according to A. Theilhaber (*Deut. med. Woch.*, June 27th, 1912), 200 published cases of spontaneous recovery from cancer in which the evidence is convincing. The disease in most of these cases was far advanced before recovery was made, and it is probable that the cases in which patients recovered spontaneously from cancer that was too early to be clinically recognizable, are numerous. But, apart from such early cases, there are many others in which cancer was diagnosed and recovery was effected. Though in many of these cases the diagnosis was doubtless incorrect, there probably were several among them of true cancer. Such cases are, however, seldom published, on account of the physician's distrust of his original diagnosis. The conception of the incurability of cancer is still firmly rooted, and the public's attitude towards cancer in this respect is to-day what it was towards consumption a generation ago. It is common for surgeons operating for cancer of the uterus to find that, even after extensive removal of cancerous deposits, there yet remain others which are beyond the range of the knife. The prognosis in such cases is usually hopeless, but not necessarily so, and in three cases of this description the writer observed complete recovery. The first of these was operated on in December, 1905, and the last in May, 1908. In the following case, seen by the author early in 1912, the diagnosis of cancer was confirmed by a microscopic examination of an excised portion of the growth. The patient, a married woman 56 years old, whose menopause had occurred four years earlier, complained of irregular uterine haemorrhage which had lasted for a year. The external os was dilated, and there were many ulcerating nodules in the cervix. The uterus was somewhat enlarged and no longer movable. Swellings were detected in the parametrium on both sides of the uterus, that to the left being adherent to the uterus and the pelvis. There was also a tumour behind the uterus in the pouch of Douglas. A profuse and offensive discharge escaped from the cervix. Treatment consisted of euretting and cauterizing the growth. Eight days later hyperaemia of the uterus was induced by hot hip baths and intravaginal treatment with hot air and hot douches. For six weeks—at first every day and later every other day—0.05 gram of caecodylate of soda was given subcutaneously. Five injections of a uterine extract were also given. The patient, who had been very debilitated and anaemic, improved steadily. The discharge grew less, till it completely ceased and the swellings about the uterus disappeared. After five months the ulcers in the cervix had cicatrized and the external os and the uterus had regained their normal dimensions. A corresponding improvement in the patient's general health was also effected, and she felt perfectly well. The author's treatment of inoperable cancer and of post-operative growths is based on the assumption that local anaemia and malnutrition of the tissues favour the growth of cancer. He therefore stimulates circulation in the diseased area by general and localized treatment. The former consists of sea bathing or residence in a mountainous district. The latter includes hot-air baths and douches, as well as injections of fibrolysin. The following case also illustrates the success of his methods: In May, 1910, a married woman was found to have advanced cancer in the breast. The growth was adherent to the pectoral muscles and the axillary glands were invaded. A radical operation was performed, the affected muscles and glands being excised. But four weeks later the arm was painful and oedematous, and there was a swelling in the axilla. The site of the operation was daily treated by Bier's method of hyperaemia. The pain, oedema, and swelling in the axilla disappeared in a few weeks. But the two latter returned a few months later. They disappeared again on treatment with hot air, and one year and nine months after the operation there were no signs of relapse. The author therefore concludes that not only does cancer disappear of itself, but it is also amenable to non-operative treatment in certain cases. He does not, however, dogmatize on his system of treatment, nor does he push it to the exclusion of operative measures.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

71. Cerebral Symptoms in Phthisis without Meningitis.

THE appearance of marked cerebral symptoms in phthisis is, according to E. Querner (*Berl. klin. Woch.*, November 11th, 1912), often interpreted as tuberculous meningitis, and when they disappear and the patient recovers, the physician points to the case as illustrating the fallacy of regarding tuberculous meningitis as incurable. True enough, a few cases of recovery from tuberculous meningitis have been recorded in which tubercle bacilli were found in the cerebro-spinal fluid, but the classical symptoms of tuberculous meningitis may also exist without any lesion of the brain or meninges. It is therefore impossible to diagnose tuberculous meningitis only from clinical observations, and proof positive of this condition is obtainable only by a necropsy or the demonstration of tubercle bacilli in the cerebro-spinal fluid. The writer reports the two following cases: A workman, aged 29, had suffered from phthisis for over a year. He was a heavy drinker and had a nervous temperament. The temperature was high, the pulmonary disease was actively progressive, but the urine was normal. On his admission to hospital he showed no signs of any nerve lesion. A month later he developed a slight attack of otitis media, his liver becoming at the same time swollen and tender. Between two and three weeks later signs of cerebral disease appeared. Kernig's and Oppenheim's signs were positive, and there were general peripheral hyperaesthesia and delirium. There was cervical rigidity, and the pupils failed occasionally to react to light. Cerebro-spinal fluid withdrawn by exploratory puncture contained blood, but no tubercle bacilli. Death occurred after the cerebral symptoms had lasted for nearly three weeks. The necropsy revealed no cerebral abnormality except a slight excess of cerebro-spinal fluid and dilatation of the ventricles. A joiner, aged 63, suffered from phthisis and alcoholism. He was febrile, his pulmonary disease was actively progressive, and his left lung was compressed by a pleural effusion, 1,500 c.c.m. of which were withdrawn. This eased his respiration. Soon afterwards cerebral symptoms appeared. Delirium, cervical rigidity, peripheral hyperaesthesia, Oppenheim's and Kernig's signs, and finally general convulsions were observed. This condition lasted for fourteen days, at the end of which the patient died. No anatomical lesion of the brain or meninges was demonstrable at the necropsy. The question naturally arises, How do the classical signs of tuberculous meningitis arise in such cases? The author agrees with the explanation given by Lyonnet, who found that the cerebro-spinal fluid of patients suffering from tuberculous meningitis, when injected into tuberculous guinea-pigs, caused the same reaction as tuberculin. He concluded that the symptoms of tuberculous meningitis are due to the presence in the cerebro-spinal fluid of a tuberculin, and that the severity of the symptoms is proportional to the toxicity and quantity of this substance. This view accounts for the lack of conformity between the severity of the symptoms and the anatomical changes found *post mortem* in cases of tuberculous meningitis. Lyonnet further describes a condition which he calls *encéphalopathie tuberentineuse*. This is due to the same tuberculin in the cerebro-spinal fluid as that which evokes the symptoms of tuberculous meningitis, but it is unaccompanied by any anatomical lesion of the brain or meninges. He includes in this class cases of epileptiform convulsions in tuberculous patients, as well as many cases which have hitherto been quoted as illustrating the curability of tuberculous meningitis.

72. Hypernephroma in the Nervous System.

COLLINS AND ARMOUR (*Amer. Journ. of Med. Sci.*, November, 1912) record a case of Jacksonian epilepsy caused by a metastasis of hypernephroma, in which there was no objective sign indicative of extensive and advanced disease. The patient, a man aged 45, and of previous good health, developed typical Jacksonian epilepsy, with twitching of the left thumb and index finger, parasthesia of the left hand and forearm, followed on five occasions by unconsciousness and generalized convulsions. Loss of power and dexterity gradually developed in the left upper arm, and to a slight degree in the left half of the body, together with loss of sense of position in the left hand and

fingers, and absence of the left plantar reflex. There was an inconstant astereognosis of the left hand, and slight increase of the tendon jerks of the left half of the body. A mild somnolency was the only symptom, aside from the Jacksonian attacks, which he ever developed. Five months after the initial symptom the patient had a series of convulsions and died, a week prior to which a slow rhythmical tremor of the left thumb and index finger, consisting of adductor movements at the rate of about one per second, developed. A large whitish tumour was found in the right flank, and this had invaded the upper pole of the right kidney, surrounding the adrenal, and extending into the under surface of the right lobe of the liver. Metastases up to $\frac{3}{4}$ in. in diameter were present in many parts of the liver, and there was a small metastasis $\frac{3}{4}$ in. in diameter in the wall of the duodenum. The only other metastasis, $1\frac{1}{2}$ in. in diameter, was found in the right cerebral hemisphere, involving the arm area, and especially the hand area. Beyond causing frequent aversion to food the primary tumour never gave any indication of its presence. Microscopically, its structure and that of the metastases in the liver and duodenum resembled that of the adrenal cortex, but this resemblance was lost in the metastasis in the brain. In this last the cells were large, polyhedral, staining deeply, and with nuclei in many stages of degeneration, while many of the cells had taken on phagocytic function, and were seen to have ingested red and white blood cells. The extraordinary absence of general symptoms of brain tumour was probably due to the fact that it had not caused much increase in intracranial pressure. Congenital in origin, later in life these hypernephromas may grow rapidly, as in this instance, with invasion of tissues and dissemination of metastases, which are usually found in bone, there being very few recorded instances of a metastasis in the brain.

73. Neuritis of External Popliteal Nerve following Typhoid Fever.

RUDOLF (*Med. Bull. Univ. Toronto*, July, 1912) reports a case of neuritis of the external popliteal nerve following typhoid fever in a woman aged 30. When admitted to hospital the patient was in the eighth day of a typical typhoid fever with rose spots, enlarged spleen, and positive Widal. The course was severe, with considerable diarrhoea and a temperature occasionally reaching over 106°. A week later she was given a vaccine of 200 million bacilli, which was twice repeated in larger doses at six and five day intervals. Nephritis and uraemia developed, followed by two severe haemorrhages from the bowel, after which she began to improve, and at the end of eight weeks from the commencement she was convalescent, the temperature having been normal for some days. She then casually complained that her left foot felt numb and that she was unable to move the toes. On examination the foot lay limp and flaccid with complete inability to dorsiflex the foot or the toes, but the foot could be pointed downwards and the toes could be flexed on the sole. An area of complete and definitely limited anaesthesia was present over the area supplied by the musculo-cutaneous and anterior tibial nerves, and all the muscles on the anterior and external aspects of the leg were involved. Higher up the nerve was not affected, as shown by the absence of anaesthesia about the knee supplied by two cutaneous branches, and there was no evidence of any nerve involvement elsewhere. The patient a few months later was reported as being much better and able to walk a mile, though there was still a little foot-drop and inability to dorsiflex the toes. The anaesthesia was limited to a small area between the great and second toe, the surface supplied by the anterior tibial nerve. Such cases of affection of a single nerve are rare, as the condition, when it does occur as a complication of typhoid, is usually multiple.

SURGERY.

74. Anaesthesia of the Arm.

ANAESTHESIA of the arm induced by injecting a 2 per cent. solution of novocain-suprarenin into the brachial plexus is described by D. Kulenkampff (*Deut. med. Woch.*, October

3rd, 1912), who has practised this method in 140 cases. For the first 70 cases he gave 10 c.cm. of the solution to adults, and 5 c.cm. to children. For his later cases he doubled these doses so as to hasten anaesthesia. The injection causes so little pain that it is unnecessary to give morphine beforehand; but it may be useful when the anaesthesia wears off two to three hours after the operation. Under this combined treatment many patients suffer no pain. The injection is made above the clavicle, and the brachial plexus is sought at the level of the first rib, which, being immediately behind the plexus, prevents the needle penetrating to a dangerous depth. Both the patient and operator are seated. The position of the subclavian artery is ascertained by palpation, and the needle is inserted external to it. Fear of wounding this artery sometimes leads to the insertion of the needle exterior to both brachial plexus and artery, the wounding of which by a fine needle is not necessarily dangerous. In fact, the author has punctured it with impunity, as his needle is very fine. The distance between the skin and first rib is 1 to 3 cm.; and in their passage over the latter the nerves of the brachial plexus form a compact bundle, in which the median is superficial to the radial nerve. A cork which is fitted on to the needle is fixed flush with the skin when the needle has been arrested by the first rib. The length of the needle is thus adjusted to prevent its passage beyond the first rib in the course of probing for the nerves. These are sometimes struck before the first rib is reached, paraesthesia being induced after puncture of the deep fascia. This symptom usually appears first in the hand and middle finger, and later in the thumb. But when the rib is reached without paraesthesia the needle is withdrawn for about 1 cm., and its direction is slightly altered, before it is again thrust as far as the cork permits. Only partial anaesthesia is obtained by injecting the solution near, but not into, the nerves. Considerable practice and patience are sometimes necessary, for the nerves may slip away from the point of the needle. Again, the solution must not be injected till paraesthesia has been induced; otherwise slight anaesthesia will result, and the operator will be deprived of the reaction of paraesthesia, which is his best guide to the plexus. Complete paralysis and anaesthesia of the arm are induced from one to three minutes after the injection, and the anaesthesia lasts for one and a half to three hours. In some cases the sympathetic system was involved: the face flushed, the pupils and eyelids contracted, and sweat broke out on the injected side. No permanent paralysis or other disaster followed the injections, which, the author claims, secure safe and simple anaesthesia.

75.

Mastoiditis.

NICOLL AND FIELDER (*Archives of Pediatrics*, August, 1912) record a case of mastoiditis followed by general sepsis with symptoms of tetanus, which presented extreme difficulty in diagnosis in spite of every facility for careful study. A girl, aged 4, was vaccinated a fortnight previously, and twelve days later she became drowsy, unable to open the mouth or take solid food, and on the following day convulsions set in at irregular but frequent intervals. On admission to hospital she was unconscious, cyanotic, and with jaws fixed, any attempt to open them setting up a clonus. Pupils were equal and reacting, and the eyes tended to turn to the left. There were no paralyses, no Kernig, no Babinsky, the reflexes were exaggerated, and ankle and patellar clonus easily obtained. There was moderate rigidity, and the hands, fingers, and wrists were in position of tetany. The vaccination presented a perfectly normal appearance, and both the vaccine therefrom and from the stock used were negative by culture and animal inoculation when tested for tetanus; 17,000 units of tetanus antitoxin were given intravenously without improving the condition, and 30 c.cm. of clear fluid under moderate pressure were obtained by lumbar puncture. Two days later 9,000 units of antitoxin were given intramuscularly, and Babinsky sign was present on the left side. Aural examination showed slight redness and bulging of the left tympanic membrane, paracentesis of which produced free bleeding but no pus, and the following day the ears appeared normal. The unconsciousness gradually deepened, and cyanosis became more marked, a blood culture showing haemolyzing streptococci in abundance. Death occurred eight days after admission. *Post-mortem* examination revealed an abundant whitish exudate giving Gram-positive diplococci and streptococci in pure culture in both middle ears and the mastoid cells, and cultures of the spleen showed streptococci. Although the diagnosis of tetanus was beginning to be doubted a few days before death, seeing that the patient became unconscious so early, the true cause was not suspected. The

case shows clearly how mastoid disease may exist without any local evidence, and also that such a condition, with the subsequent occurrence of general sepsis, may cause lockjaw and other symptoms indistinguishable from those usually due to localized lesions in the meninges.

OBSTETRICS.

76.

Heart Disease and Pregnancy.

THE majority of observers have come to regard the existence of heart disease during pregnancy, parturition, and the puerperium as a particularly dangerous condition. Felber and Jaschke took up an unusual position in this respect, and Jaschke in particular formulated the doctrine that the course of a pathological affection of the heart is not materially influenced by the fact of pregnancy. Klages (*Muench. med. Woch.*, No. 24, 1912) gives the details of a case of a woman who showed all the signs of aortic disease during her first pregnancy. This case, the author considers, supports the views put forward by Jaschke, especially in regard to the presence of a serious complication in all cases which terminate fatally during pregnancy. The woman was 27 years of age, and was admitted into hospital on December 2nd, 1911, in the belief that labour had commenced. There had been some pains. It was found that there was a loud systolic murmur at all the orifices, more especially over the aortic orifice; the second pulmonary sound was somewhat accentuated. The pulse was strong, regular, and not frequent. There was some albuminuria, with granular and hyaline casts, blood corpuscles, and epithelium in the urine. In the evening the patient had an attack of dyspnoea, with slight cyanosis, pulse 140 to 150, very irregular, and some oedema. The attack lasted a quarter of an hour. The urine became somewhat sparse, and during the night two further attacks took place. No urine was passed until about 50 c.cm. was drawn off by catheter at noon on the following day. The fetal heart sounds were not distinct, but the mother's condition was fairly comfortable during the day. An attempt was made to improve the cardiac action, in order that the birth might be completed as rapidly as possible. On the next afternoon the patient became drowsy and occasional convulsive movements were noted. A distinct improvement was noted after this, and the pulse became more regular and stronger. What were believed to be fetal heart sounds were indistinctly heard on the left side. During the night the patient suddenly complained of a feeling of fear and after a short period of extreme cyanosis, died. A *post-mortem* Caesarean section revealed a child that had been dead for some hours. The *post-mortem* examination was conducted in the Pathological Institute, and it was then found that there were multiple gummata of the heart wall with perforation and sacculation. The gummatous process had implicated the aortic endocardium, and the heart was dilated, hypertrophied, and showed fatty degeneration. It thus appears that the unhappy termination could not be ascribed to the effect of pregnancy on the cardiac affection.

77.

Treatment of Puerperal Phlebitis.

VANVERTS and PAUCOT (*Echo méd. du Nord*, 1912, xvi) consider the two following forms: I. Phlegmasia alba dolens. II. Utero-pelvic phlebitis. I. (a) Prophylaxis. This consists of rigorous asepsis during childbirth and reparation of perineal or vaginal wounds. Hagapoff recommends slight elevation of the lower limbs for six days, commencing at the fourth, after parturition. (b) Curative—which consists of palliative measures, local and general. Complete rest is indicated, with slight elevation of the affected member, hot baths, hot-air baths, and fomentations. Pinard advises slight vesication with ammonium hydrochloride; others prefer calmatives, as belladonna and opium. The general treatment comprises drugs, as quinine and strychnine, and a dechlorhydrated diet. The authors do not advise the patient to get up until thirty days at least after the last elevation of temperature, and a flannel bandage should be applied. II. Utero-pelvic phlebitis. The general treatment of pyaemia should be adopted, and care be taken that there is nothing retained in the uterus. Serum-therapy has proved successful in some cases. *Surgical*: The authors consider that surgical intervention is justified in cases where there are no extravascular lesions and where the affection is localized; intervention is always a serious matter. Out of 82 cases collected by the authors from the literature 49 died. The operations practised are of two kinds: (a) Ligature of the veins through the vagina,

extraperitoneally or transperitoneally through the abdomen; the authors prefer the last method. (b) Direct treatment of the phlebotic focus by drainage extraperitoneally.

GYNAECOLOGY.

78. X Rays in the Treatment of Uterine Fibroma.

LAQUERRIÈRE AND LOUBIER (*Arch. d'electr. méd.*, August 25th, 1912) described seven gynaecological observations in which radio-therapy yielded interesting results. In one case of uterine fibroma, although the dosage was very small, the growth diminished considerably in size, such diminution taking place before any modification of the menses. Afterwards a definite menopause was established. In another case, in which the dosage again was feeble, there was diminution in size and arrest of haemorrhage without amenorrhoea. In a third case, a woman of 53 years, the uterus returned to a normal size, and the retarded menopause was obtained. In a fourth case, a young woman, the action on the uterus was independent of the action on the ovaries, an ovariectomy having been done long before. The treatment stopped the leucorrhoea, the dysmenorrhoea, and the oozing of blood during the intermenstrual periods. The fibroma did not disappear, but it became more mobile and less accessible to palpation. In a fifth case, in which, together with fibroma, there were inoperable complications, great local and general improvement followed upon radio-therapy. A sixth case demonstrated that even in a woman of considerable age (47) an exceptional resistance to the inhibitory action of the X rays on the ovaries might be encountered. For five months the abundance of the menses was in no way modified, and a very large total dose—some 26 Holzknecit—had to be given at each of the four points at which the rays were directed before the menopause was established. Finally, in another case, in spite of prolonged treatment, and of a dosage well up to the limit of what is tolerable for the epidermis, the X rays did not cause amenorrhoea in a woman of 27 years.

79. Inflammatory Affections of the Uterine Appendages.

TÖPFER (*Berl. klin. Woch.*, September 2nd, 1912) discusses the treatment of inflammatory conditions of the uterine appendages, with especial reference to Solm's operation, and comes to the conclusion that these affections should in every case be treated conservatively at first, unless large, easily reached collections of pus render surgical interference necessary. If these means fail after repeated and persistent trials, operative treatment should be considered. The social position of the patient and the degree of suffering must influence the gynaecologist in his decision. In the less severe cases in which the uterus is freely movable and adhesions are not numerous double salpingectomy, performed vaginally, is the best operation. In more severe cases the abdominal or combined operation is needed. A portion of the ovary must be left. The employment of Solm's method of dealing with the stump extrauterinely, closing the true pelvis completely, and by draining through the vagina, exudation from the stump and adhesions can be avoided and a complete cure can be achieved. Töpfer states that a radical operation has now become unpermissible, save in very rare cases, and then only in old patients.

THERAPEUTICS.

80. Heliotherapy in Tuberculosis.

ROLLIER (*Wien. klin. Woch.*, No. 28, 1912) discusses the history of the sun treatment of tuberculosis: he lays stress upon the special efficacy of the treatment when carried out in mountain climates, and then describes his own experience of the method at Leysin. It is above all in surgical tuberculosis that heliotherapy has given its most striking results, and after observation of 700 cases of surgical tuberculosis treated at Leysin during the last nine years Rollier maintains that recovery can be obtained in all forms of the disease, at every stage and at every age period. In all cases the author recommends a full sun-bath as well as local sun-baths. The beginning of the treatment is gradual, more and more surface is exposed to the sun for increasing periods of time daily on a fixed plan until the complete bath is reached, as a rule, on the seventh day. By this cautious progress the development

of an erythema solare is prevented, and a too intense reaction to local treatment is guarded against by similar means. The rate of recovery appears to vary with the rate at which pigmentation proceeds. No unpleasant side-effects resulted from the treatment in the author's cases and the patients' general condition greatly improved. Blood examinations were made to determine the effect of the treatment on erythrocytes and leucocytes. As a rule in cases of closed tuberculosis and good general condition the number of erythrocytes increased on the first to the third day and reached a maximum of 5,500,000 to 7,500,000. The more serious the prognosis the more slowly the maximum was reached and the higher it was. With the onset of clinical recovery the number fell to an average of 5,500,000. With regard to white corpuscles, it appeared to be true that in all open forms of tuberculosis and in a few closed ones there is an increase in polynuclear leucocytes at the expense of the lymphocytes, large mononuclear forms, and transition forms; as the case proceeds towards recovery the condition is reversed, the leucocyte curve falls and the lymphocyte curve rises. The use of irremovable plaster-of-Paris splints is not compatible with the treatment and is abandoned. In spondylitis immobilization is brought about by a linen girdle made fast to the bed and by axillary bandages. The patient lies on his abdomen, so that the bandages have only to be loosened to expose the back to the sunlight. The anterior surface of the spine and the pelvis are treated with the patient on his back. Spontaneous absorption of chronic abscesses frequently occurs. In coxitis and gonitis heliotherapy is combined with continuous extension. The author finds that a spontaneous recovery of joint function in surgical tuberculosis is a directly characteristic result of heliotherapy. It occurs without any attempt being made to bring it about by either active or passive movements. One of the first effects of sun treatment is the relief of pain, especially in all cases of tuberculous peritonitis, osteitis, and arthritis, and the relief was usually apparent almost immediately in cases of tuberculous cystitis or disease of the adnexa. In tuberculous adenitis the action of the sunlight is particularly a solvent one; the glands are either absorbed and disappear spontaneously, or they are softened and recovery occurs after one or two punctures. The eliminating action is especially noticeable in the case of sequestra, and the author has had a large number of cases of spontaneous extrusion of sequestra in different localities with subsequent healing. Cases of tuberculous peritonitis, and especially of caseous tuberculous peritonitis, responded particularly well to the treatment, as did those of ileo-caecal and other intestinal fistulae. Tuberculous disease of the urogenital tract is also especially mentioned as being amenable to treatment. The results reported in the series of cases were controlled by the use of X rays. The cases are tabulated with full details. Of 450 cases of closed forms of tuberculosis, 393 recovered, 41 were improved, 11 were stationary, and 5 died. Of 200 cases of open forms of tuberculosis, 137 recovered, 29 improved, 14 were stationary, and 20 died. In the list of deaths are included all those cases in which death has occurred up to the present time after the return home of the patient. The cases date back to the year 1903. A large number of the patients treated were those for whom all other methods had failed, and some were in a condition of cachexia on arrival, and already showed signs of amyloid disease. In 4 out of 5 of the cases of closed forms of tuberculosis in which death occurred the patients also suffered either from tuberculosis of the lungs in the second or third stage or from ulcerative intestinal tuberculosis. Six cases of relapse occurred in the whole series.

81. Vaccine Treatment of Gonorrhoea.

DROBNY (*Vratchebnina Gazeta*, June 17th, 1912) has tried vaccines in 136 cases of gonorrhoeal infection, including acute, subacute, and chronic urethritis, acute and chronic cystitis, acute and chronic epididymitis, acute orchitis, chronic prostatitis, chronic folliculitis, chronic pyelitis, vesiculitis, cavernitis, chronic polyarthritis, and chronic pyelitis. The dose of the vaccine used was established by means of the opsonic index, but he does not think this estimation necessary during treatment; the clinical signs are a sufficient guide. The initial dose was 20 to 25 million cocci, increased by the same amount up to 100 million. In only one case was 200 million reached. In children the dose was from 2 to 8 million. Injections were given twice a week, to the number of 15 in most cases. After this, the gonococci had disappeared from the discharge. As the result of his observations, Drobný concludes that

vaccines have a specific action in cases where the gonococci have penetrated into the tissues, such as prostatitis, epididymitis, and arthritis, but that they have no action on affections of the mucous membrane, such as urethritis and cystitis. In spite of this, however, he recommends treatment to be begun as early as possible, in order to avoid gonococcal complications. He concludes that a combination of vaccine with ordinary treatment shortens the duration of the disease and leads to a more complete cure.

82. Deaths after Salvarsan.

HIRSCH (*Muench. med. Woch.*, July, 1912) reports two cases of death after intravenous injection of salvarsan. Both cases occurred after the second injection. In the first case, a healthy young man with primary syphilis, an intravenous injection of 0.5 gram salvarsan was well borne, but a second injection of the same dose, made after twelve days, was followed by fever, vomiting, and diarrhoea, and two days later by icterus, dryness of the throat, enlargement of the liver, and albuminuria. On the following day there were tremors of the legs and severe cramp, extending to the whole body; the pulse became imperceptible, breathing stertorous, and the pupils were dilated. Death took place after three or four similar attacks. In the second case, a healthy young woman with secondary syphilis, two intravenous injections of 0.3 gram and 0.4 gram salvarsan, together with two courses of salicylate of mercury injections caused no bad symptoms. But, two months after the second injection of salvarsan, the patient became suddenly unconscious, with dilated pupils, icterus, and cramps of the extremities, soon followed by death. As the predominant symptoms in these cases (gastro-intestinal symptoms, icterus, cramp, and dryness in the throat) are all characteristic of arsenical intoxication, the author considers that the cause of death was arsenical poisoning, in persons with a hypersensitiveness to this drug.

83. Treatment of Rickets.

A NUMBER of observers have come to the conclusion that rickets and osteomalacia are manifestations of one and the same disease, the difference consisting in the fact that the former is a disease of childhood and the latter one of adult life. Babs and Neas have recently recommended pituitrin in the treatment of osteomalacia, and it has therefore occurred to Klotz (*Muench. med. Woch.*, May 21st, 1912) to try extract of pituitary gland in rickets also. He started with the consideration of the fact that while thyroid gland contains a considerable quantity of iodine, suprarenal gland a considerable quantity of sulphur, and so on, pituitary gland contains a considerable quantity of phosphorus. The retention of phosphorus and calcium is increased in rickety children by medication with phosphorus cod-liver oil. Phosphorus alone does not affect the storing up of calcium, but, on considering the composition of cod-liver oil, it becomes probable that a fair proportion of the phosphorus exists in the form of nuclein phosphoric acid and glycerine phosphoric of nuclein and lecithin respectively. In order to gain a better insight into the action, he treated some of his cases with lecithol extract of malt, which contains 2.5 per cent. of pure lecithin. Improvement not only in the general condition but also in the power of walking was recorded on taking this medication. This improvement was maintained only as long as the preparation was given, and the symptoms returned when it was stopped. In all the experiments with pituitary extract and lecithin was limited to 5 cases. He used a special extract of pituitary gland, called hypophysochrom. In 4 of the cases the children were able to stand after from seven to fourteen days after the treatment was started; they began to walk in seven, fourteen, twenty-one, and twenty-one days respectively, and all could walk nearly alone within forty-two days. An improvement in respect to the general condition was also recorded. The excellent results obtained in these few cases inclines the author to the view that in rickets one is dealing with disturbances of phosphorus and not calcium metabolism. He is of opinion that further investigations are required before the pharmacology of the pituitary gland can be regarded as in a satisfactory state.

84. Treatment of Phlebitis by Urotropin.

RÉFON AND RICHER (*Boum. des praticiens*, October 19th, 1912), while noting the importance of urotropin as a urinary and biliary antiseptic, call attention to the possibility of its value in certain vascular infections, notably in phlebitis. Whereas no benefit resulted in a

case of tuberculous phlebitis or in phlebitis accompanying malignant disease, rapid improvement resulted in bad cases of varicose phlebitis, and in two cases which were post-influenzal, as well as in one following enteric fever. In three or four days the condition had almost disappeared. The dose was 1 gram per diem, taken morning and evening. The authors offer no explanation of this improvement, but suggest that the matter is worthy of inquiry, especially in cases of puerperal phlebitis.

PATHOLOGY.

85. The Danger of X-ray Applications on the Abdomen.

A SERIOUS warning against extensive x-ray irradiation of the abdomen appears in an interim report by Regard, Nogier, and Lacassagne (*Arch. d'électr. méd.*, October 10th, 1912) on lesions of the alimentary canal observed to follow such irradiation in animals. The findings are put forward with some urgency, owing to the manner in which x-rays are now applied to the abdomen in uterine fibroma, splenomegaly, and neoplasms of the alimentary canal itself. With non-filtered rays the seat of danger is the skin, but with the thick filters and powerful apparatus now employed to ensure strong doses in the deeper parts another danger arises, greater, though less apparent, than that of radiodermatitis, namely, the danger of setting up severe lesions of the digestive passages. The experiments of these investigators have been carried out on dogs. It is admitted that among animals of different species there are differences in the sensitivity of the digestive mucous membrane. The rabbit, for instance, appears to have a membrane much less sensitive than the dog. But there is such a similarity between the dog and man, both in the structure of the mucosa and in the alimentary régime they undergo, that a parallel is justifiable. Particulars of six experiments upon healthy dogs are given. In the first experiment a bitch with gravid uterus received a single dose of x-rays over the abdominal region corresponding to the major portions of the intestine. An aluminium filter 2 mm. in thickness was used; the distance of the focus from the skin was 250 mm.; the duration of exposure one hour, and the incident dose exceeded 11 on the scale of the Bordier radiochromometer, or 10 Holzknicht units. The animal died within thirty-six hours. Autopsy revealed a uterus with commencing abortion without haemorrhage, and an intense congestion of the alimentary canal with small but diffuse haemorrhage. The proximate cause of death was uncertain, but the remote cause was undoubtedly the irradiation. In another experiment a dog received over the posterior half of the abdomen a weak dose (corresponding to Bordier I, or the tint B of Sabouraud-Noiré, or 5 Holzknicht units) under 2 mm. of aluminium. It died twenty-three days later, after showing some loss of weight. Two days before death, in company with two other dogs, neither of which showed any after-effects, it ate a quantity of chicken bones. At the autopsy signs of commencing peritonitis were observed, and it was supposed that the irradiation had lowered the resistance of the intestinal mucosa, and that a traumatism caused by the chicken bones had provoked an acute infection. A third dog received irradiations at intervals over an extensive region of the abdomen during a period of thirteen months. Each of the five doses given through various thicknesses of aluminium, brought about temporary digestive troubles, and the animal died a month after the last irradiation, which was much stronger than the others. The subsequent investigation placed it beyond doubt that the rays had given rise to severe lesions, microscopic in character, of the digestive mucosa, and that these lesions caused the cachexia to which the animal succumbed. The authors conclude that x-rays, sufficiently filtered so as not to be absorbed too readily by the skin and abdominal wall, exercise on the gastric and intestinal mucosa of the dog a powerful and selective cyto-caustic action. The glands of the gastric fundus appear to be most susceptible in this respect, and in the small intestine the glands of Lieberkühn can be made to disappear in the course of a few days with a strong dose. Extreme care is therefore necessary in applying x-rays over any extensive area of the abdomen, and the importance of this is emphasized by the difficulty of securing effective localization under such circumstances, and the virtual impossibility of doing so when treating neoplasms of the alimentary canal itself.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

86. Hospitals and Typhoid Carriers.

BRANNAN (*Amer. Journ. Med. Sci.*, September, 1912) conducted an examination of the faeces and urine in 119 cases during convalescence from typhoid fever, and in 48 cases during the active stage, an average of two examinations being made in each case. About 1 case in 5 gave positive findings during the active stage of the disease, and 1 in 8 during convalescence. In Bellevue and its allied hospitals no typhoid patient is discharged unless bacteriologically free, at least two successive negative examinations being required in each case, and it is believed that this measure of precaution will arrest the great majority of typhoid carriers, though it is recognized that patients discharged as bacteria-free after only two negative results may still be potential carriers. Instructions in the simple rules of cleanliness should be given to each patient on discharge, especially to those who will become engaged in the preparation or distribution of food, and, as far as possible, they should be prevented from following occupations involving the handling of food and drink. The hospital should further notify the health authorities in order that they may take the necessary precautions to protect the public. Of 140 individuals, 25 were intending, on discharge from hospital, to follow such an occupation, thus showing how impossible it would be to compel a change of work, and emphasizing the importance of instructing them carefully how to avoid conveying infection. Regulations for the control of typhoid carriers are in force in some European countries and in the English army, and of the various lines of treatment which have been adopted in an endeavour to sterilize carriers, army surgeons report the following results from the five different methods tried: (1) Lactic acid bacilli cause only a temporary disappearance of the typhoid bacilli; (2) acidifying the urine fails to cure the bacilluria; (3) the administration of antiseptics causes decided diminution in the number of bacilli both in faecal and urinary carriers, and this effect is markedly enhanced by a concurrent treatment with low diet, aperients in faecal cases, and diuretics in urinary cases; (4) x-rays are beneficial in gall-bladder infection; and (5) vaccines cause only a temporary disappearance, though they might possibly have a better chance if combined with diuretics in urinary carriers, and x-ray treatment in gall-bladder cases.

87. Acute Haemorrhagic Nephritis in Phthisis.

IN spite of the rarity of acute haemorrhagic nephritis in phthisis, F. Tobiesen (*Ugeskrift for Læger*, September 26th, 1912) has collected 21 cases from two Danish hospitals. When haematuria occurs in phthisis, it may be due to tuberculosis of the kidneys or to haemorrhagic nephritis. The author is convinced of the correctness of the latter diagnosis in all but two of his cases. In one no casts were found in the urine, but uneventful recovery occurred. In the other, tubercle bacilli were, indeed, once found in the urine, but not during the haematuria. As the symptoms were not those of renal tuberculosis, the tubercle bacilli found had probably been excreted by the kidneys from the circulating blood, where these germs have often been demonstrated in phthisical patients. The haematuria is probably due to toxins formed in the diseased lung, and not to the bacillus itself, for it may follow an injection of tuberculin. In support of this view Holst has recorded the case of a young man suffering from tuberculous effusions into the pleura and peritoneum. Potassium acetate was given to aid diuresis, the increase in which was followed by a fatal attack of haemorrhagic nephritis. Many of the author's patients suffered from serous exudates, the resorption of which, Holst argues, floods the kidneys with toxin. There is little doubt that the kidneys of patients who thus react by haematuria have abnormally low powers of resistance to begin with. All but 2 of the 21 patients were in the third stage of consumption, and in 5 cases the haematuria was preceded by haemoptysis. Probably the latter causes the rapid spread of the pulmonary disease, and thus favours the formation of much toxin. The haematuria often disappeared with astonishing rapidity, especially when the condition of the lungs improved. Many patients, on the other hand, died during or

soon after the haematuria. The necropsies in these cases showed enlargement of the kidneys. The cortex on section was swollen and brawny, the pyramids were dark red, the tubules were lined by partly degenerated epithelium, and contained hyaline and blood casts. The outline of many of the blood vessels was blurred, and some of the glomeruli were swollen and invaded by numerous round cells. In cases of old-standing phthisis the kidneys also showed amyloid disease.

88. Conjugal Specific Chronic Meningitis.

BABINSKI (*Journ. des praticiens*, December 14th, 1912) refers to several cases which he says come under this heading. The first is that of a woman who suffered from violent headaches, vomiting, and a certain weakness of intelligence. There was papillary congestion and other indications of intracranial pressure. The cerebro-spinal fluid showed a lymphocytosis, and the Wassermann test was positive. Under the influence of iodo-mercurial treatment she much improved. Her husband, on examination, was proved to be suffering from tabes. Another case was that of a woman of 31, who developed interstitial keratitis. There was abolition of the left knee-jerk, and dilatation and immobility of the pupils. An examination of the cerebro-spinal fluid showed lymphocytosis, and the blood serum gave a positive Wassermann reaction. The history of the case was that the father had contracted syphilis during the pregnancy of his wife. The child was infected but the mother escaped. A third case was that of a little girl who had partial epileptic crises, and suffered also from hemiparesis of the left side. Lumbar puncture showed a lymphocytosis, and the Wassermann reaction was positive. The father had contracted syphilis five years before. He contaminated his wife and they both contaminated the child. This is a case of familial rather than hereditary transmission. According to the author, it is well to examine all the members of a family when one of them displays nervous manifestations of an organic character. The perpetuation of nervous affections in the transmission of syphilis is a striking fact, and it has been suggested that the virus of syphilis is selective as to the nervous system in certain cases. It is certain that if two individuals have contracted syphilis from the same source, one may develop organic disease of the nervous system and the other escape. It is desirable to examine thoroughly suspected subjects, as, for example, the wife of a man who suffers from tabes. The treatment in these cases ought to be thorough, and the author makes a point of submitting all cases of tabes in his practice to mercurial treatment. It has been noted of late years that the general aspect of tabes dorsalis has been less grave than formerly, and this is to be attributed in large measure to early antisyphilitic treatment.

89. Alastrim.

JACOBS (*Schweiz. Rundschau*, No. 6, December 21st, 1912) describes under this name a mild form of epidemic very similar to small-pox, but differing from it in the following particulars: (1) In an epidemic at Sao Paulo the mortality was about $\frac{1}{3}$ per cent.; (2) the disease is less dangerous in children than in adults; (3) there is no secondary fever, pustulation is quicker, and the fetid smell of small-pox is absent; (4) cicatricial formation is wanting, after the pustule dries a smooth irregular scar remains, with borders as if nibbled by insects; (5) although vaccination is a prophylactic against alastrim, cases have been observed in which persons vaccinated shortly before (one to two years) suffered from alastrim, and of 15 persons who had passed through an attack of alastrim six months previously 7 (46.6 per cent.) reacted positively to vaccination. Most patients complain at the beginning of pains in the neck, the tonsils become red but not much swollen. In the following days pains are complained of throughout the body, vomiting, loss of appetite, headache, and fever are noticed, and the urine is high coloured. The incubation stage lasts from ten to fourteen days. The eruption begins almost always on the face and spreads to the arms, chest, abdomen, thighs, back, and, lastly, the palms of the hands and the soles of the feet. Purulent changes take place in the papules and vesicles in from three to five days, and the scab falls off in about ten days. Pustules may form on the conjunctiva, and in almost all cases are found on the mucous membrane of the lips, gums, and pharynx. The

severity of the disease and the prognosis depend on the numbers and confluence of the pustules, and the cases may accordingly be divided into mild, where the pustules are irregularly distributed throughout the body; moderately severe, in which cases the pustules are confluent on the face and fairly thickly set over the whole body; and severe, in which they become confluent over the whole body, and cause death nearly always in old and feeble individuals. Of the author's 49 cases the mortality did not reach 4 per cent. The origin of the disease is Africa, where it is called Amaas. Aragao considers that varicella, alastrim, and variola are all derived from a common ancestor, and should be placed in one group.

SURGERY.

90. Hour-glass Constriction of the Stomach.

AN interesting case of gastric stricture, which incidentally illustrates the value of radioscopic examination, is described by Barjon and Rey (*Arch. d'électr. méd.*, January 10th, 1913). The patient had been subject to dyspeptic troubles for a number of years, and this condition, which dieting and rest had temporarily relieved, was succeeded by a more acute one, with severe gastric pains and black vomiting. The crises began regularly about four in the afternoon, and lasted until supper time. A radioscopic examination with the aid of bismuth was made, and it was then apparent that the stomach was divided into two portions, one of which was almost entirely above the umbilicus. The upper independent cavity communicated with the lower by an extremely narrow passage, and, after being filled, this lower cavity in its turn began to contract, and emptied at the true pylorus. There was, however, some degree of retention, because further screen examinations, made five and nine hours afterwards, showed that a notable quantity of bismuth remained. The curious phenomenon was that each cavity seemed to maintain its independent contractility, and that each had its own pylorus. When the upper cavity was in contraction the lower one was in repose, and when the lower cavity contracted, the upper remained slack. On surgical intervention the x-ray picture was confirmed, the stomach being divided into two portions by the medio-gastric stenosis, thus presenting the familiar hour-glass appearance. There were signs of an ulcer in process of healing. The constricted part of the stomach was lightly adherent to the pancreas. It was detached gradually, a medio-gastric resection was made, the narrowed part being removed, and a suture on three planes reunited the two cavities. On examining the removed portion, it was found to be exceedingly narrow, about 1 cm. in diameter, and only admitting the little finger on forcing. A good recovery was made, and when the patient left the hospital, three weeks later, the stomach was found to have taken almost its normal form and dimensions; there remained only a slight medio-gastric narrowing, rendered more apparent by the contractions of the walls, and appearing to be due to some degree of cicatricial retraction at the place of suture. A further examination was made three and a half months afterwards, and the stomach was then found to be entirely normal in form and calibre, the pylorus giving a perfect evacuation. The authors state, on the basis of this and of another somewhat similar case, that the radioscopic examination is of the greatest utility in making the diagnosis precise, and in giving operative indications. The presence of multiple ulcers is an indication for gastrectomy, lesser measures being habitually insufficient.

91. Mediastino-pericarditis.

DUNN AND SUMMERS (*Amer. Journ. Med. Sci.*, January, 1913) record their observations on a case of mediastino-pericarditis treated by cardiolysis. The patient, a man aged 29, with negative family history, had diphtheria followed by paralysis when 11, and this was the only disease that he had ever suffered from. Three years prior to observation he complained of "bloating," tiring easily, and shortness of breath on exertion, which rapidly grew worse, so that almost from the beginning he had been entirely incapacitated. Dyspnoea and orthopnoea were marked, the face dusky red, and the veins of the neck and face were turgid, with a marked diastolic collapse. Violent pulsation was present in the precordium, consisting of a slow systolic retraction with a rapid vibratory diastolic thrust, with systolic retraction of the left costal arch. Broadbent's sign was present, the respiration rapid and upper thoracic in type, and a marked

diastolic shock could be palpated. The area of cardiac dullness was increased, and did not change with change of position. A loud systolic murmur, best heard at the apex, was present over the whole of the precordium, and a second diastolic heart sound over the entire right ventricle, the heart's action being irregular and rapid. The left lower pleural cavity was obliterated, and the lower border of the left lung in the precordium did not move with respiration. Under treatment in hospital compensation was restored, the heart's action became regular, the murmur disappeared, and the cardiac sounds, from being blurred, became clear. Ten days later cardiolysis was performed with a view of untethering the heart from the costo-pericardial adhesions and allowing the enlarged organ freer play. A musculo-cutaneous flap down to the ribs was raised, and the third, fourth, fifth, and sixth ribs, with their cartilages, were resected flush with the sternum, thus exposing the pericardium and left pleura in an area measuring 5 in. vertically and $4\frac{1}{2}$ in. horizontally. The pericardium was found to be adherent to the chest wall, and the pleura thickened and adherent. With the exception of a mild bronchopneumonia, which did not disturb compensation, convalescence was uneventful. The onset was insidious, and, with the exception of diphtheria at 11 years of age, there had been no illness to which the condition could be attributed. In mediastino-pericarditis the descent of the diaphragm during inspiration pulls at the heart, chest wall, root of lungs, and posterior mediastinum, and respiration is defective, inspiration producing a worse condition than expiration, since the heart and large vessels are fixed to their surroundings. An important diagnostic sign of adherent pericarditis is the absence of forward movement of the chest. For the success of the operation it is essential that there should be present diastolic shock, systolic retraction at the apex, and ability of the cardiac muscle to compensate.

92. Radiographic Indications for Pylotomy.

IN making a radiological examination as a preliminary to pylotomy, Arcelin and Raïn (*Arch. d'électr. méd.*, January 10th, 1913) insist upon the necessity of the perfect immobility of the kidney. Long exposures, made with inadequate apparatus, have given results which have been confused by movement, and small calculi, which would have been quite visible on a short exposure, have escaped detection. The progress of radiographic technique has now made it possible to obtain renal records within a fraction of a second. The authors state that at their own hospital in Lyons, with a rectifier on the alternating current, they are able to obtain excellent radiographs of the kidney in from one-third to one-tenth of a second, and that even those who do not possess the more powerful outfits may, by the use of intensive coils, secure good radiographs in two or three seconds. An intensifying screen is necessary, as it is only this which permits of such radiographs being made within the period of apnoea. Radiological diagnosis of calculi is not to be trusted when respiratory movements take place during exposure. The authors estimate that with these rapid exposures it is possible to see the contour of the kidney in 80 per cent. of the cases, and under such conditions it is easy to say whether or not the calculus is at the site of the renal pelvis. In the remaining 20 per cent. the renal contour is invisible, whatever the technique employed, and these cases constitute a still unsolved problem. One authority affirms that when the radiograph shows the shadow of a calculus to be placed in such a manner that the distance which separates its inner border from the median line does not exceed 5 cm., one may conclude that the calculus is placed in the pelvis of the kidney, with the reservation that this shadow must lie between the transverse processes of the first and second lumbar vertebrae. The present authors state, however, that many calculi of the renal pelvis by no means fulfil these conditions. Out of seventeen calculi for which they have operated by pylotomy, only four have come within these limits. Some calculi of the renal pelvis project their shadows to the level of the first lumbar vertebra, others to the level of the third. Some, in children, almost touch the shadow of the spinal column; others, in adults, are as much as 75 mm. from the median line. When the contour of the kidney is visible, the radiologist can give the surgeon certain complementary information as to the exact position of the calculus, and by radiographing at different times the mobility or fixity of the kidney and the calculus may also be studied. If a radiograph indicates a calculus of the renal pelvis having ramifications up to the calices, the authors are of opinion that pylotomy is contra-indicated.

OBSTETRICS.

93. Pituitrin in Obstetric Medicine.

UDACTA (*Revista de Medicina y Cirugía Practicas*, October 14th and 28th, 1912) reported to the Spanish Gynaecological Society two cases of uterine haemorrhage treated with pituitrin. The first was a woman two months pregnant, who had been passing coagula and large pieces of "flesh" which macroscopically appeared to be placenta. Three days after being first seen she had a slight haemorrhage, and about six minutes after its appearance she was given a hypodermic injection of pituitrin. Fifteen minutes later she felt pain, and expelled from the uterus a quantity of blood. Forty-two minutes later there came away a coagulum and a mass of placental tissue. That was the last of her symptoms, and she has remained well since. In the second case the patient's uterus expelled the placenta after the first injection of pituitrin. In the discussion Botin said that he had experience of the action of pituitrin in 4 cases. In 3 of them the result was excellent; in the fourth case there was no result. He referred to the great difficulty in the experimental study of the action of the extract of the pituitary gland in the living animal. The operation for its removal was so severe that it was difficult to distinguish the effects of its removal from the effects due to the severe traumatism necessary in removing it. The recent introduction by Parache of the orbital method of reaching the gland involved much less injury to neighbouring parts, and may have better results. The injection of pituitrin causes first of all a tetanic contraction of the uterine muscle, which after a short time ceases, and is succeeded by other contractions altogether resembling those of normal labour. Attempts to avoid the initial tetanic uterine contraction by giving smaller doses have not been successful. So far, pituitrin appears to be quite harmless to both mother and fetus. One peculiarity of its action is that tolerance seems to be very quickly established, so that even the second injection acts less energetically than the first, and the third than the second. For this reason, the drug should not be used in the first complication which occurs (unless this is really serious), as otherwise a later moment of greater danger will find us deprived of its full power of assistance. It results from its power of increasing the normal intermittent contractions of the uterus that it can often be used in uterine inertia before the child's birth, and in this way replace the use of the forceps. Mañeco remarked that our knowledge of the drug was still much too incomplete to justify any enthusiasm about it. This might lead to its falling unduly into discredit. He believed that in the reactionary relaxation of the muscular fibres of the uterus following its use haemorrhage was to be feared. For this reason he always repeated the injection if the pains faltered towards the end of the labour. In every case an exact diagnosis of the cause of the delay in the course of parturition was essential. To use pituitrin, for example, in a case of pelvic contraction could only lead to a calamity. More study of the effect of the drug on the contractions of the uterus, by means of the tocodynamometer, was required.

GYNAECOLOGY.

94. The Relation between the Lungs and Genital Organs in Tuberculous Women.

VON BARDELEBEN (*Arch. gén. de méd.*, September, 1912) writes: Genital tuberculosis is generally the result of pulmonary tuberculosis. On the other hand, clinical observations teach us that the prognosis of pulmonary tuberculosis is considerably worse when genital tuberculosis coexists with it. That is why, at autopsies, the latter is very often found to be accompanied by extensive pulmonary tuberculosis, whereas opportune extirpation of the genital focus very often cures an incipient pulmonary tuberculosis. During pregnancy the placenta or the placental site is, in most cases, the focus of this reciprocal and retroactive effect. It frequently harbours large numbers of circulating tubercle bacilli, and these, on separation of the placenta, again become mobile. The greater the chance of tubercle bacilli circulating in the blood, as in active pulmonary tuberculosis, the worse the effect of gestation, and, vice versa, it is much more rare for tuberculosis to be unfavourably influenced by pregnancy when there is small chance of the bacilli circulating, as in an inactive latent pulmonary tuberculosis. These facts are proved by anatomical examinations of placentas, and therapeutic operations have given the same results.

Artificial abortion alone is only of use in those cases where hardly any tubercle bacilli are found in the placenta (uncomplicated catarrhal affections of the apices of the lungs up to the fourth month of pregnancy), but it is insufficient in cases where many tubercles are found there. In these latter cases the results are as good as in the former if, in addition to removing the fetus, excision of the placental site is performed. Equally, local puerperal and post-puerperal affections disappear after excision of the placenta. The ovaries take no part in the aggravation of pulmonary tuberculosis during gestation; on the contrary, their total extirpation aggravates those cases in which simple artificial abortion is indicated. In the class of case where abortion alone is not sufficient, excision of the placental site is preferable to extirpation of the uterus, which, however, gives good results.

95. Carcinoma of Cervix at the Age of 18.

CRAIGIN (*Amer. Journ. Obstet.*, January, 1913), at a recent meeting of the New York Obstetrical Society, related a case which he reports as the youngest instance of carcinoma of the uterus ever under his own observation. A girl had been subject for several months to menorrhagia, which was mitigated by rest, ergot, and other measures. A large cauliflower growth projected from the cervix, and a portion was removed and examined at the Crocker Cancer Research Laboratory and by experts elsewhere. There could be no doubt that it was a true carcinoma. Craigin saw her in consultation on April 26th, 1912. On May 4th he performed Wertheim's operation, and when the patient was seen on September 16th, 1912, there was no evidence of recurrence.

THERAPEUTICS.

93. Acetonuria and the Treatment of Diabetes.

VON NOORDEN (*Wien. med. Woch.*, No. 28, 1912) discusses the significance of the presence of acetone in diabetic urine and its practical bearing on treatment. He remarks that although acetone is constantly found in the urine in cases of diabetic coma, its presence is often physiological and does not necessarily indicate danger. Premising that the chemistry of the production of acetone is not fully understood, he says that its forerunners, β -oxybutyric acid and diacetic acid, are formed principally in the liver by the incomplete oxidation of fats. Normally, under the as yet imperfectly understood influence of glycogen, the fatty acids are oxidized with the formation of carbonic acid and water, but when, even in a healthy person, owing to withdrawal of carbohydrates from the diet, glycogen is not produced in sufficient quantity, a faulty metabolism of the fats takes place, and ketones (an intermediate stage in their combustion) appear in their blood. If this starch-free diet be continued, a kind of tolerance is established, and apparently the liver manufactures glycogen out of fats and other materials not usually so converted, for in a few days the superabundant ketones disappear. In diabetes the liver cells lose, to a greater or less extent, their power of storing up glycogen, which is hurried away and converted into sugar almost as fast as it is formed. The faster the glycogen is thus destroyed the greater is the production of ketones. In applying these considerations to treatment and prognosis, the author divides cases of glycosuria into mild and severe. Mild cases he defines as those in which a partial or complete withdrawal of carbohydrates from the diet secures the disappearance of sugar from the urine, while in severe cases it is not possible to get rid of the sugar unless not only carbohydrates, but also, to a great extent, albuminous substances, are excluded. He distinguishes two types of mild cases. In the first the urine of a patient on ordinary diet contains 3 or 4 per cent. of sugar, but no acetone. A restriction of the amount of carbohydrate food by removing the stimulus which that gives to the sugar-producing liver cells, rests them, removes their hypersensibility, and soon causes a diminution in the output of sugar. After a few weeks starchy foods may safely be taken again in moderation; but, as an immediate result of the restriction of carbohydrates, acetone will appear in the urine. This should not be regarded as a danger signal of impending coma, but as a physiological phenomenon. The restricted diet should be continued, and in a few days the acetone will disappear. In the second type of case the patient has followed a regimen for some time, but has not been entirely deprived of starchy foods. On his taking to a strict diet the sugar disappears without any access of ketones, for the liver cells have

become accustomed to the paucity of starch, and its complete withdrawal makes but little difference in the formation of glycogen. Acetouria does not, in the author's opinion, necessarily call for any alteration in the treatment, and he has long since ceased to give alkalis in these mild cases. It is to be observed, however, that there are patients with slight glycosuria who, whether on strict diet or on a moderate allowance of carbohydrates, continually pass a few decigrams of acetone. Some of these cases are harmless, especially in old age or pregnancy; but when in young people the amount of acetone exceeds 0.2 gram daily, even though no sugar be found in the urine after a moderate amount of starchy food, the prognosis is grave. In these cases sugar will be present in the blood although it is not eliminated by the kidneys, and in spite of the acetouria the strictest diet should be ordered, together with alkaline medicines. The severe cases are also divided by the author into two types. In the first, in spite of a fairly restricted diet, the urine still contains sugar and a small quantity of acetone, but the patient remains in apparently good health except for certain complications such as furuncles, visual disturbances, and neuralgia. These cases always tend to grow worse, and attempt should be made to bring them back to a less severe grade by gradually reducing the amount of starchy food. At first the output of sugar will diminish, but the acetone will increase. A change from strict diet to one of egg and vegetable, and then to oats for a few days, will correct the excess of acetone, and the strict diet can then be resumed. One day's complete abstention from food will sometimes inaugurate a change for the better. The author holds that although the addition of carbohydrates to the food will for a time diminish the output of acetone, yet it is not right thus to endanger the future of the patient; but every effort should be made to combat the tendency to ketonaemia, not by the convenient method of giving carbohydrates, but by systematically resting the sugar-forming process in the liver. Of the second type are those cases in which, in spite of every effort, sugar is constantly present in the urine, and the withdrawal of carbohydrates only leads to a formidable increase in the amount of acetone. The author believes that the glycogen formed in the liver from the carbohydrates brought to it by the portal blood has a fleeting influence on the metabolism of fats before it is hurried away, and, though it cannot entirely prevent the formation of ketones, if the carbohydrates are supplied in abundance, there will always be enough glycogen present to check their too rapid formation. The diet, therefore, must contain carbohydrates, but about once a week the patient should have a "hunger day," during which he lies in bed and takes nothing but tea, clear bouillon, and brandy and soda-water. Discussing the use of alkaline medicines, the author remarks that they do not prevent the formation of ketones, but they neutralize the fatty acids and favour their elimination from the blood. He thinks they should be used freely in severe cases. With regard to levulose, although this form of sugar admittedly forms glycogen most readily, the author has not found it of much practical value; but he lays stress on the good effect of large quantities of alcohol given on the occasional hunger days, and he claims that impending coma may often be warded off by a strict oatmeal diet for a few days.

97.

Adalin.

NAVER WALTER (*Wien. klin. Woch.*, No. 26, 1912) describes his experience of adalin as a narcotic and sedative. Adalin is a white, crystalline, rather bitter powder without odour, which is soluble only slightly in cold water, more in warm water, and most in fats. It is prepared by the firm of Bayer and Co. The chemical formula is

Thus, in adalin, bromine is combined with the ethyl and acetyl groups. The author has used adalin in 60 cases, which included cases of tuberculosis, insufficiency of the cardiac muscle, arterio-sclerosis, typhoid fever, sciatica, chronic alcoholic poisoning, cardiac neurosis, bronchial asthma, neurasthenia, hysteria, Basedow's disease, anaemia, and syphilis of the central nervous system. He has found adalin a very efficient narcotic. As a rule, a dose of 0.75 to 1.0 gram (11.6 to 15.5 grains) given in hot tea was followed within three-quarters to one hour by a sleep which lasted from eight to ten hours. The patients woke up feeling refreshed. The sleep was not deep and could easily be broken, but the patient readily fell asleep again. There were no severe side-effects. In 3 cases

there were headaches and a sense of heaviness. Adaptation of the dose to the individual case is always needed. Thus, in one case of obstinate sleeplessness, a dose of 0.5 gram (7.7 grains) proved too large and induced a sleep of more than twelve hours' duration, with sleepiness on the following day, while in other cases 1.5 gram (23.2 grains) is the minimum effective dose. With continuous use doses smaller than the initial one become effective, and adalin can be given for comparatively long periods without any sign of its losing its effect. Illustrative cases are given in which adalin was successful where other narcotics had failed. The author finds adalin as a rule more certain in its action than narcotics such as veronal and trional; in two cases only veronal proved the more effective. The action of bromine preparations was weaker than that of adalin. Adalin is especially useful in sleeplessness of nervous origin, in a whole series of cardiac neuroses, and in organic heart disease.

98.

Death after Neo-Salvarsan.

LÉVY (*Ann. des mal. vén.*, October, 1912) reports a case of death after injection of neo-salvarsan. The patient, an apparently healthy man, but said to be somewhat alcoholic, received four injections of neo-salvarsan (0.45, 0.60, 0.60, 0.90 gram) for primary syphilis. The first three injections were well tolerated; but six days after the fourth injection the patient suffered from intense dyspnoea, and died on the fourteenth day. No autopsy was made. The author attributes the death to arsenical intoxication, predisposed to by alcoholic degeneration of the liver. He mentions the experimental work of Bitter and others which shows that salvarsan has a particularly noxious effect on the liver.

PATHOLOGY.

99.

The Nature of the Tuberculin Reaction.

F. MEYER AND K. E. F. SCHMITZ have investigated a number of points in connexion with the mode of action of tuberculin, and publish their results in the *Deut. med. Woch.*, October 17th, 1912. Yamanouchi has attempted to transfer the susceptibility of tuberculous animals to normal animals by the injection of the serum of the former. The animal thus passively immunized was injected with tuberculin, in order that a reaction might be attained. Various observers obtained varying results, and the diagnostic importance of the procedure has not been proved. Starting from this idea, the authors first injected the serum of rabbits which had been rendered tuberculous with bovine tubercle bacilli into normal rabbits. After twenty-four hours a trial injection of tuberculin made from bovine bacilli was injected. The results were inconstant, sometimes a rising of temperature following and sometimes no such rise occurring. The next series of experiments consisted of the injection of a mixture of tuberculous serum and tuberculin with and without normal guinea-pig's serum (complement). With the serum of a freshly infected rabbit a well marked reaction was obtained, while when the serum of an animal which had been tuberculous for a long time was used the reaction was slight. In the next place they mixed tuberculin with the blood of a tuberculous rabbit and also with the red blood corpuscles. A very well marked reaction was obtained in this manner. They further determined that the washings of the blood corpuscle-tuberculin mixture after sharp centrifugalization could produce the reaction, and also that the tuberculous rabbit from which the serum or blood was obtained reacted sharply to tuberculin. As a result of these and other experiments, they give the following explanation for the nature of the tuberculin reaction. Small quantities of tuberculin when injected are taken up by the red blood corpuscles and carried to the tuberculous foci. In this situation receptors which have the greatest affinity to tuberculin are present in more or less recent cases, but at a later period other receptors are found in the blood cells. The focal receptors attract the corpuscles and tuberculin, and in this manner the local reaction is produced. The combination of receptor and tuberculin produces a toxin which on becoming free causes a general reaction. In progressive cases the receptors of the blood are so saturated with tuberculin that a freeing on renewed injection of tuberculin does not take place and therefore the reaction is negative. On the other hand, after prolonged treatment with small doses, the body responds by the formation of increasing quantities of toxin which induces a non-sensibility to tuberculin. This may perhaps be attained by the production of a true antitoxin.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

100. Atropine Reaction in Cardiac Disease.

TALLEY (*Amer. Journ. of Med. Sciences*, October, 1912) discusses the prognostic significance of the atropine reaction in cardiac disease, the throat dryness and impaired vision resulting from $\frac{1}{30}$ to $\frac{1}{25}$ of a grain hypodermically, soon passing off without any other untoward effect. This method of releasing the vagus action, and of comparing the effect on normal and diseased hearts, led to the use of the reaction in the study and treatment of cardiac disease, and showed its prognostic significance in cardiac cases, especially auricular fibrillation, and how it may be used in the study of digitalis action, since it was found to be unusual for cases giving small reactions to respond well to digitalis. Patients with rheumatic mitral disease developing auricular fibrillation with rapid pulse-rate, gave large atropine reactions, the pulse-rate, with the vagal influence abolished, depending upon either stimulus production or conduction. Cases of auricular fibrillation show marked slowing under digitalis, many small beats disappearing, the remainder being more even in height and the diastolic pauses more regular. Under atropine many of the small beats reappear at the expense of the diastolic pauses as the pulse accelerates. The atropine reaction in the normal heart is probably from 30 to 40, and a reaction of 20 or less, in a heart not recently subjected to exhausting disease, points to degeneration of the cardiac muscle, and makes the chance of improvement under treatment unpromising. Cases of auricular fibrillation, with responses normal or above, are promising subjects for treatment, two reactions, one before and one on full digitalis, enabling a determination possible as to whether the vagal or the cardiac tissue factor is the greater. Those cases with a large cardiac tissue factor are usually the ones sufficiently improved by treatment to return to their occupations.

101. The Detection of Occult Gastric Bleeding.

ONE of the chief difficulties in deciding whether small, easily overlooked quantities of blood are passed into the intestine from the stomach consists in distinguishing between exogenous from endogenous blood in the faeces. I. Boas (*Deut. med. Woch.*, October 31st, 1912) finds that many patients object to be kept without meat diet altogether for several days, and inasmuch as it is a matter of trust in ambulant patients that they carry out instructions rigidly, he has devised a method of overcoming this difficulty. If hydrogen peroxide is added to meat the haemoglobin splits off the odd oxygen atom from the peroxide, and this freed oxygen decolorizes the pigment entirely. He therefore instructs his patients to take from 100 to 125 grams of minced or scraped meat (veal or chicken for choice), and add to it 100 c.c.m. of a 3 per cent. hydrogen peroxide in a porcelain dish. This has to be stirred until the colour is quite removed and a snowy white meat results. A plentiful froth must be produced. The meat is then transferred to a sieve and well washed under the tap to remove all the peroxide. It is then made into croquettes. First the patient is told to take a suitable purgative—for example, Carlsbad salts, rhubarb, magnesia, or some aperient bitter water—and then to take no other meat for two or three days, save the decolorized meat. At the end of this time the analysis of the faeces may be undertaken, and any blood found will certainly be endogenous.

102. Congenital Syphilis.

TILBRIEN, BABONKEIX, AND DAUFRELLE (*Bull. de la Soc. de Pédiatrie*, December, 1912) publish an interesting case of hereditary syphilis on the father's side, with symptoms analogous to those seen in congenital muscular atrophy. The child was 19 months old; born at term, breast-fed, and able to sit up at 7 months, when convulsions began, followed a little later by apparent failure of sight. On examination there was marked muscular atony, so much so that the limbs could be bent in extraordinary ways, as though the joints were dislocated; the patient was unable to sit up or to control the head. There was, however, no paralysis, no choreic movements, no fibrillary twitching, no atetosis. The muscles of the eyes, the tongue, and deglutition acted normally. Tendon reflexes were present, but skin reflexes absent; Babinski's sign was elicited. Sensibility seemed to be intact, and there were no

vasomotor symptoms. There was grey atrophy of both papillae, of the post-neurotic type, with marked diminution of vision. The child could not speak and was mentally backward. The electrical reactions showed under-excitability of the trapezius and the pectorals, both to galvanism and faradism. No R.D. Lumbar puncture showed moderate lymphocytosis. There was marked obesity, the spleen was enlarged; the head was large, with projecting frontal bosses, and the anterior fontanelle was open. Wassermann reaction was positive; the teeth were normal. In the matter of diagnosis the condition most resembled the congenital muscular atony of Oppenheim, but in this disease the amyotony is observed from the first days of life, active movements are very limited, there is always abolition or diminution of tendon reflexes; ocular phenomena have never been observed, and the intelligence is intact. In view of the obesity, a symptom often associated with disorders of internal secretion, the authors consider that all the phenomena may be explained by a specific lesion of the hypophysis. Injections of biniodide brought about a considerable diminution of the atonic phenomena and a marked improvement of vision.

103. Laryngeal Tuberculosis.

OPPIKOEFER (*Schweizerische Rundschau f. Med.*, 1912, No. 6, December 21st), writing on this disease, says it is commonest between 20 and 40 years of age; men are more frequently affected than women, owing to the greater use in the former of tobacco, alcohol, etc. The disease is nearly always secondary. About 20 to 30 per cent. of cases of pulmonary tuberculosis suffer from the same disease in the larynx. Infection is chiefly from the sputum, but may occur through the blood or lymphatics, or from direct inhalation. The most frequent appearance of the larynx is that of infiltration or ulcer formation; miliary tumours are rare. The infiltration at the beginning is usually solitary, and situated on the true or false vocal cords, or on the posterior wall of the larynx. Later on, if the disease progresses, ulcers form, which may be superficial or penetrate into the muscular tissue and even the perichondrium. Later on extensive perichondritis, oedema, abscesses, and cartilaginous necrosis result. The perichondritis is more frequent in the arytenoid than in the other cartilages. The disease shows itself by hoarseness, loss of voice, or paralysis of a vocal cord, pain on coughing and swallowing, and shortness of breath, but it should be noted that the disease can progress without any symptoms. The prognosis is always serious, but cure can result if the lung condition improves; if the pulmonary disease progresses, there is little hope of any improvement in the larynx. The author considers the various remedies that have been recommended for the treatment of the disease, both local and general, but does not consider that any real remedy has yet been found.

104. Influence of Pregnancy on Psoriasis.

PETRINI says (*Bull. de Soc. Franç. de Derm. et Syph.*, November, 1912) it is well known that psoriasis may make its first appearance during pregnancy, or immediately after a confinement; but in the author's case the lesions, which were of the intractable papulo-squamous disseminated type, disappeared completely with conception, only to return with the birth of the child. The patient assured him that a similar freedom from eruption had coincided with every one of her previous four pregnancies, and that she always felt well, and put on weight at these times. The author has not been able to find a report of a similar case in the literature, and emphasizes the great rarity of the syndrome by calling attention to the frequency with which psoriasis disappears during periods of sickness, only to recur with renewed vigour when the patient is restored to normal health.

SURGERY.

105. Renal Tuberculosis.

F. SUTER publishes the permanent results of 60 cases of renal tuberculosis treated by nephrectomy (*Munch. med. Woch.*, November 5th, 1912). He states that in 53 out of the 60 cases the patients sought assistance on account of

a disagreeable sensation during micturition and of an increased frequency of the same. In the 7 remaining cases the patients came to the doctor either on account of pain in the kidney or for some independent condition, and in the latter case the diagnosis was made by accident, on the analysis of the urine. In discussing the differential diagnosis, he points out that the use of a separator for the collection of the urine from one or other kidney may only be relied upon when the urine from the one kidney is quite normal, while that from the other is purulent, and when the cystoscopic appearances coincide with the results of the urine analysis. Of the 60 persons operated on 5 died, yielding a total mortality of 8 per cent., 1 died twenty-four hours after the operation and 4 died at a later date, the cause of death being pulmonary tuberculosis, puerperal fever, anaemia, and miliary tuberculosis. Of the 55 patients who are still living, 5 need not be further considered, since the operation has been performed within the last six months, 28 (56 per cent.) are completely cured, and 17 (34 per cent.) are considerably improved. The remaining 5 were little or only temporarily improved; 5 of the considerably improved patients still complain of bladder symptoms (due to scars, etc.) but the urine is quite clear. Particulars of the not improved cases are given. In critically surveying the cases, the author finds that the capacity of the bladder is of great importance for the chances of recovery. The capacity at the time of the first examination of those cases which were cured had an average of 270 c.cm.; it was 150 c.cm. in the case of the "considerably improved" patients, and 130 c.cm. in the "little improved" cases. The third class shows a high average, as the result of one case in which the bladder was capable of holding 400 c.cm. at the time of the operation. The rest only yielded an average of 60 c.cm. The prognosis is always favourable if the surgeon can begin the treatment when only one kidney is affected and when the bladder is not implicated. It is stated that the chances of cure are better in women than in men. In 16 cases the kidney was totally destroyed and caesarean; of these cases 8 recovered completely. He cites some histories in support of his contention that the risk of postponing the operative treatment in the hope that Nature will effect a cure is too great to be justified. Nephrotomy has not yielded satisfactory results in his hands, and while x rays and tuberculin may be required when an operation cannot be carried out, the treatment for one-sided renal tuberculosis is nephrectomy.

105. Rhizotomy for Gastric Crises in Tabes Dorsalis.

FRAZIER (*Amer. Journ. of Med. Sciences*, January, 1913) advocates rhizotomy for the relief of gastric crises in tabes dorsalis in suitable cases where other measures have failed, because the procedure is physiologically sound and has been followed by good results in a considerable percentage of cases, those hitherto recorded showing entire relief in 30 per cent. and a partial relief in 56 per cent. A man, aged 40, had suffered for three years from attacks of violent pain and vomiting recurring every four to six weeks. There was no evidence of any lesion of the upper abdomen, as ascertained at a previous operation for suspected cholelithiasis, but the symptoms of tabes dorsalis were well defined. Through a unilateral laminectomy the seventh, eighth, ninth, and tenth sensory dorsal roots were divided, with the exception of the tenth on the right side owing to difficulty of exposure. Some weakness in the right leg and retention of urine ensued, which passed off before the patient left hospital, and he has since reported as having remained entirely relieved from pain and vomiting, and as having gained steadily in weight. Contrary to German and French usage, the performance of the operation at one sitting is advocated unless contraindicated by the condition of the patient, and the anaesthetic is best administered by intratracheal insufflation. Although in the case recorded unilateral laminectomy was sufficient for adequate exposure of the roots, bilateral exposure facilitates and shortens the operation and does not afterwards materially interfere with the strength of the back or the patient's comfort. Experience points to the fact that the seventh to the eleventh (inclusive) dorsal roots should be severed, and probably the fifth and sixth, as recurrences or partial successes have been attributed to the fact that too few roots have been cut, and subsequent further rhizotomy has effected a cure. The above procedure will of course be useless in cases of pneumogastric origin in which root resection is contraindicated. Although among the 30 cases gathered from the literature there were five deaths, the mortality from the operation need not be excessive if care be taken in the selection of suitable cases, bearing in

mind that in many instances of tabes dorsalis the patients are anything but fit subjects for operative intervention.

107. Transplantation of Bone Marrow.

In a preliminary notice, O. M. Chiari records some experiments which he has carried out on the transplantation of bone marrow (*Muench. med. Woch.*, November 12th, 1912). Having first attempted to implant the medulla of the sternum or of the femur into the space under the fascia of the rectus abdominalis or into a preperitoneal pocket, without success, he turned his attention to the spleen as a possible site for the transplantation. He removed a portion of the medulla of the femur of a rabbit and inserted it into the parenchyma of the spleen of the same animal through a narrow canal prepared by a blunt probe. The capsule was then sutured over the wound, and the abdomen closed. Some technical difficulties were met with on account of the haemorrhage arising from the spleen and other causes. The whole animal, with the exception of the splenic region, was then exposed to x-rays with the object of producing a general damage to the bone marrow still *in situ*. Apart from an abortion, no harm was apparent from the rays, and after five months, during which time the rabbit remained well, it was killed. The examination showed that the piece of marrow was not only still alive, but proliferation of medullary cells (erythroblasts, myelocytes, etc.) was found. There was a small splinter of bone at the lower edge. It appears that the piece of marrow of the size of a millet seed had grown to that of a pea.

108. Ulcus Cruris Varicosum and Syphilis.

ZINSSER AND PHILIPP (*Zeit. f. Dermat.*, December, 1912) state that the differential diagnosis of varicose and syphilitic ulcers of the leg are elementary points with which every student is familiar. The pre-existence of varicose veins, the tendency for the involvement of the lower third of the leg, and the congested, often eczematous, condition of the parts surrounding the typical irregular, shallow, dirty-looking ulcer in the former condition, as opposed to the still more typical punched-out circular or reniform luetic ulcer, which tends to be grouped in the upper third of the leg, and often presents the off-described wash-leather slough on its surface, are points too well known to require further description. The authors of this article are concerned with cases in which the points above stated are not sufficiently obvious, or in which typical varicose ulcers occur in syphilitic patients. As an aid to diagnosis they have availed themselves in a number of cases of the services of a radiographer, who found in a surprisingly large percentage of the cases photographed periostitic changes which could only be ascribed to syphilis. These changes were present in some cases in which the clinical appearances entirely agreed with the diagnosis of varicose ulcer. Most of such cases occur in old people, whose memory for anything which may throw suspicion on the possibility of a luetic taint incurred in their youth is proverbially unsound. As a further support, therefore, to their theory the Wassermann reaction was performed in 36 cases, and in 28 of these proved positive. The underlying syphilitic bases of such cases can hardly, therefore, be negatived, and they are in all probability due to specific inflammatory conditions—as, for example, endophlebitis or phlebitis obliterans—which may precede or go hand in hand with the adjuvant varicose condition of the veins. The practical bearing of the discovery is of great importance, and suggests that in every case in which the ordinary treatment for varicose ulcer fails an antiluetic one should be also tried. In every case in which the authors followed the therapeutic indication, except those which had undergone marked secondary changes—over thirty years' persistence—cure or alleviation followed. Salvarsan was not administered.

OBSTETRICS.

109. Treatment of Flooding in Pregnancy and Labour.

PAUL BAR (*Bull. de la Soc. d'Obstét. et de Gyn. de Paris*, July, 1912) has issued a full statistical report of his public experience of haemorrhages associated with gestation, which he analyses at some length. He groups his series into three subdivisions. First, he reviews haemorrhage in pregnancy from vicious insertion of the placenta. He finds that women who have been subject to severe and repeated bleeding run little risk of death if there be already no infection, provided that no infection is allowed

to occur during any obstetrical manœuvres or operations in the course of the labour and the removal of the placenta, and all hæmorrhage at the same time checked, as a very little bleeding in these cases may prove fatal. Bar declares that lacerations of the cervix caused by hasty dilatation are especially dangerous. Secondly, he discusses the subdivision, including retroplacental hæmorrhage, in pregnancy. He advises caution, whether labour be not threatening, or whether it is beginning. He relates two cases of embolism, one where the uterine wall was the seat of a true apoplexy, and one where there was sepsis in the puerperium and infection of the urinary tract; all four died, but the fourth case was imprudently removed from the maternity and died at home. Diagnosis of retroplacental hæmorrhage is by no means easy in many instances, and Bar relates a case where all clinical symptoms pointed to this complication. Labour had set in, and black clots were expelled, whilst the cervix was long and rigid and undilated. He performed Caesarean section. The uterine wall was not ecchymosed, and when the dead child was extracted no trace of retroperitoneal hæmorrhage could be detected. It proved best, according to Bar's experience of this series, to deliver through the natural passage should the cervix be sufficiently dilated or readily dilatable. If the cervix be in a less favourable condition an abdominal operation is indicated. Bar insists that the "classical" or conservative Caesarean section is only justifiable if the general condition be good, all evidence of infection absent, and ecchymoses in the muscular wall of the uterus absent or but little marked; otherwise, hysterectomy is necessary. Vaginal Caesarean section is reserved by Bar for exceptional cases where great haste is imperative, and hysterectomy, therefore, not quite advisable. Bar includes in his third group hæmorrhages of the *post-partum* class. When due to uterine atony surgical aid is rarely called for. As a rule, hæmorrhages due to laceration of the cervix are checked by the tampon. But when this is not the case, and when on drawing down the cervix with the volsella the bleeding vessel cannot be seen and secured, sutures *en masse* are unsafe. It is better, Bar insists, to operate from above so that the divided vessels can be quickly ligatured.

110. Rupture of Uterus: Avulsed Fetal Head in Broad Ligament.

BRETSCHNEIDER (*Zentralbl. f. Gyn.*, No. 43, 1912) reported two cases of ruptured uterus in private practice at a recent meeting of the Leipzig Obstetrical Society. In the first, the injury was caused by turning shortly after the membranes had ruptured; the laceration extended from the fundus down to the posterior fornix. Abdominal section was promptly undertaken, and the laceration was closed by suture. The operation was performed in a cottage; the patient made a good recovery. In the second case, breech extraction was attempted in labour at the sixth month. Much force was used, and the head was torn off as the trunk was extracted. Great hæmorrhage ensued, and the patient was sent to the Leipzig maternity. The os externum, rigid and but little dilated, and the cervix were laid open. Then the head was extracted, the uterine walls had been lacerated along the right side, but the rupture was incomplete in so far as it did not involve the serous coat. Thus the peritoneal cavity was not opened. The fetal head had been pushed out into the right broad ligament, and was invested by its layers. The bladder and right ureter were not damaged. The cervix was united by suture to the body of the uterus, and the wound drained. The patient recovered.

GYNAECOLOGY.

111. Cysts of the Mesentery, Chylous and Others.

PROUST AND MONOD (*Rev. de gynéc. et de chir. abdom.*, September, 1912) have prepared a full monograph on this type of cystic tumour, based on an example of true chylous cyst removed by Proust, and carefully examined by pathologists. The patient was 67 years of age, and the growth, "like a ball rolling about in the belly," had been noted by her for about six months. It caused pains so that she could not walk. It was as big as a fetal head at term, resistant, dull on percussion, and not very movable. Ovarian cyst was diagnosed, though the fornices were quite free, and movements of the cyst did not affect the cervix. On opening the abdomen the tumour was found to lie in the folds of the mesentery, but neither could be separated without damage to the mesenteric vessels. The intestine over the tumour was therefore resected, but after the removal of the tumour with its mesenteric capsule,

Proust found that the remaining intestine adjacent to the excised segment appeared insufficiently protected by the mesentery. On that account he removed nearly 8 in. of intestine above the upper cut end. Then a latero-lateral anastomosis of the two ends was made. Nevertheless there was still great difficulty in bringing the divided borders of the mesentery together, and in fact it proved impossible to close the breach by suture, so that nothing more could be done except to introduce a drainage-tube with two strips of gauze into the gap. Flatus passed by the rectum on the third day; then black vomit (not analysed) was ejected at intervals up to the seventh day. The gauze was removed on the ninth, and the drainage tube on the twentieth. The patient was in good health, and quite free from abdominal pain two months after the operation. The cyst contained 750 c.cm. of a viscid milky fluid, which proved on examination to be mostly chyle—that is to say, it resembled lymph in composition, but contained much fat. Lecithin, as well as cholesterine, was detected in this cystic fluid, the authors noting that Noel Paton has shown that both exist in normal human chyle. As for pathology, the authors divide these tumours into (1) lymphatic cysts, including those containing chyle; (2) serous cysts, developed by adhesion of opposite sides of the mesentery; and (3) epithelial cysts of congenital origin, either from Meckel's diverticulum or aberrant germs of the intestinal canal, or from Wolffian relics, or from dermoid elements. The last subvariety may be a simple intramesenteric or retroperitoneal tumour, or a complex tridermic growth either grafted from a dermoid ovary or representing fetal inclusion. The main feature of importance to the surgeon operating on any type of mesenteric cyst is the fact that resection of the involved small intestine is usually necessary—that is to say, it must be performed whenever the capsule of the cyst, the two folds of the mesentery, are adherent so that the blood vessels are certain to be damaged and the nutrition of the gut cut off if the tumour be enucleated. The authors admit that enucleation is the best method when the mesentery is non-adherent, as is often the case with small serous and lymphatic cysts.

THERAPEUTICS.

112. Mechanical Treatment of Skin Disease.

SCHIFF (*Wien. med. Woch.*, No. 26, 1912) remarks on the great advance made in the treatment of skin diseases during the last twenty years, first by the light of Finzen, then with the x rays and radium, and later by massage and by the studies of Bier on hyperaemia. As pointed out by Unna, the effects of treatment can be observed experimentally on the skin at once and with certainty, and this applies not only to the chemical remedies which he used, but also to various mechanical means, so that more rapid progress has been possible in the therapeutics of skin diseases than in any other branch of healing. The author contrasts with primitive apparatus the modern application of heat and cold to the tissues, instancing the diathermic method, in which by means of a high tension current heat can be originated in the tissues themselves. As other triumphs of electrical treatment he mentions its use by Shoemaker, Wiukler, and Ehrmann to promote absorption, to check inflammation and congestive erythema, to kill parasites, and to allay tenderness and irritation in such conditions as anal fissure, cracked nipples, burns, and herpes zoster. The value of the Roentgen rays, he says, is established in the treatment of lupus, of mycosis fungoides, and of favus; in the removal of naevi, angiomas, and keloids, and possibly even of cancerous growths; and in the relief of hyperidrosis and hypertrichosis. Radium emanations have proved useful in slow-healing ulceration due to tubercle, syphilis, or other causes; in Aleppo boil; and in excessive pigmentation. The use of massage has been extended by Jaquet with good results to the relief of all forms of pruritus, of eczema, seborrhoea rosacea, and even of the most severe forms of acne. In opposition to the teaching of Hebra, who forbade the use of water in many skin diseases, Lassar has proved the great value of hydrotherapy in over 10,000 cases of eczema, particularly in the bullous and moist forms; and continuous baths have been used with success in pemphigus, psoriasis, ichthyosis, lichen ruber, pityriasis rubra, and in extensive burns. Apart from the effect of water itself sublimate baths in syphilis, calcium sulphide baths in scabies, and hot Japanese baths in leprosy afford examples of special balneotherapy. Hot air has been shown by Holländer to be valuable in the treatment of lupus and of primary

syphilides; and the results of Bier's congestive treatment of diabetic skin diseases and of local bacterial inflammations are well known. In conclusion, the author considers the mechanical treatment of skin diseases to be the treatment of the future, as the chemical treatment is the treatment of yesterday. The discriminating physician of to-day will use each in its place; but to attain success with the mechanical treatment the practitioner must possess, not only a knowledge of disease, but also a practical acquaintance with the technical details of every form of apparatus he would use.

113. Hypodermic Injections of Oxygen in Pulmonary Tuberculosis.

The idea of treating phthisis by oxygen originated with Priestley himself. The method of injecting the gas subcutaneously was invented by Spallanzani, who showed that the skin of batracians absorbs more than their lungs, and that the cellular tissue absorbs all the oxygen which is injected into it. Inhalations of oxygen were employed in pulmonary affections in 1780 with good effect, but some bad results caused a violent reaction against them, and their use in phthisis, except as a desperate remedy, was altogether abandoned after 1789. Bayeux (*Arch. gén. de méd.*, September, 1912), having observed the good effects of subcutaneous oxygenation in dyspnoea, conceived the idea of applying the method in pulmonary tuberculosis. He used it in 36 cases; 7 cases are reported in detail; all had serious and well-marked symptoms, and the result in each case was excellent. Of the remaining 29 cases, 11 suffered from tuberculosis with slight symptoms, and all were cured; 12 were long-standing cases with cavitation, and of these 3 were sent home relieved of their acute symptoms and all the others are on the road to cure after three months' treatment; 2 cases, still under treatment, are not expected to recover, but their dyspnoea has disappeared as a result of the injections; 4 cases died whilst undergoing the treatment, 3 of them having been relieved of their dyspnoea, night sweats, and insomnia, whilst in one the effect was *nil*. For the administration of the gas the author has evolved an apparatus which permits of very precise instillations and of exact regulation of the rapidity of the flow; the rate of flow is regulated in litres per hour by means of a graduated disc. If it is necessary to stop an acute asphyxia, as much oxygen as possible is injected in the shortest time possible; but in dealing with a chronic case the treatment is not so simple. In the latter type of case the author lays down the following rules: (1) Never exceed a speed of 1 litre in twelve minutes. (2) Rarely give a dose of more than $\frac{1}{2}$ litre a day. (3) In cases of moderate severity be content with an injection every three days, changing the site of the puncture—buttock, lumbar region, external region of the thigh, outer third of abdominal region—with each injection. The amount to be given varies with the age and state of the patient: for infants 100 c.c.m., for children 150 c.c.m., for adolescents 300 c.c.m., for adults 500 c.c.m. The graver the condition the more often must injections be made; which is not to say that more gas must be administered, for the writer has observed that slowness of absorption of the oxygen is in direct relation to the gravity of the tuberculous intoxication, a fact which he has found valuable in prognosis.

114. Sozoiodol in Diphtheria.

R. WEISSMANN (Reprint from the *Fortschritte d. Medizin*, No. 40, 1912) states that to form a better idea of the value of the various medicaments which he has used in his practice, he has turned up his case books of past years and has attempted to learn a lesson from them. He first used a preparation called sodium sozoiodol in May, 1897, and he briefly relates his experience. It is used for ulcers, soft sores, etc., in the form of a coarse powder, and in the form of a finely divided powder for affections of the nasopharynx and the larynx, either with some indifferent vehicle or mixed with some other active medicament. It is further employed in solution for catarrhal affections, especially for gonorrhoea and for syphilis. It is also useful in ophthalmic practice in from 1 to 6 per cent. solution. He has used sodium sozoiodol in 335 cases since 1897. Of these 13 were cases of scarlatina, 13 of acute or chronic catarrh of the nose, 22 cases of pharyngeal catarrh, 42 cases of faucial diphtheria, 108 cases of follicular tonsillitis, and 137 cases of catarrhal tonsillitis. He obtained highly satisfactory results, using an improvised insufflator, in his tonsillitis cases. In his inflammatory cases, besides the sozoiodol treatment he gave purges and alsounctions with Credé's ointment. He states further that the results in scarlatina were very satisfactory. In diphtheria he claims to have obtained the best results. He much prefers

the less rough treatment of sodium sozoiodol insufflation to the old energetic plan of painting the throat. The moment the diagnosis is made he uses his sodium sozoiodol and also gives colloidal silver, either in the form of Credé's ointment, or as an enema to be retained, or as an intravenous injection. Of his 42 cases only one child died. In the remaining cases the membrane disappeared in two days in 4 cases, in three days 8 times, in four days 9 times, in five days 19 times, and in six days in 1 case. He regards this treatment as more than a local therapy. The sooner the membrane is cast off, the less toxin will be absorbed, and he attributes to the early disappearance of the membrane the rapid manner in which his patients recovered. In conclusion he states that sodium sozoiodol is non-toxic, and that he has not observed any undesired or unpleasant symptoms which could be attributed to the drug.

PATHOLOGY.

115. Potentia Generandi after Bilateral Tuberculous Epididymitis.

WHILE neither bilateral tuberculous epididymitis nor subsequent castration affects potentia coeundi as a rule, it has generally been supposed, according to P. Bull (*Deut. med. Woch.*, October 3rd, 1912) that the former condition entailed sterility. This assumption is discredited by the following case: A carpenter, aged 35, noticed at the age of 12 that his testicles were abnormally large. In October, 1904, he married at the age of 27, and a child was born exactly nine months later. In January, 1906, the right testicle was removed with the right epididymis, which was much enlarged, caseous, and the seat of an abscess. The left epididymis was not removed, although it was enlarged, firm, and nodular. This condition had been stationary for many years, and it was feared that complete castration would rob the patient of potentia coeundi. In January, 1907, and again in December, 1908, his wife was confined. When examined in 1910 and 1912, the semen lacked the smell and reactions of prostatic secretion, but it contained many motionless spermatozoa of normal appearance. It is obviously difficult conclusively to prove that the wife's husband is the father of her children, but the following points are in favour of this hypothesis. The semen contained spermatozoa which, though motionless under the microscope, may have been lively enough on emission. The first child was born exactly nine months after marriage, and the second child closely resembled her father. After the birth of her third child, the mother, of her own initiative, applied for anti-conceptual aid in relation to her husband.

116. A Simple Method of Preparing Haemin Crystals

NIPPE points out that the usual method of preparing haemin crystals for the recognition of blood has certain disadvantages (*Deut. med. Woch.*, November 21st, 1912). Haemin crystals are compounds of haemin with one of the halogens. It is possible at times to obtain crystals by treating the blood with glacial acetic acid, the chlorides in the serum supplying the halogen. As a rule, however, sodium chloride is added. If this be done in substance, since it is only slightly soluble in the acetic acid, a larger or smaller quantity of sodium chloride crystals may obscure the result. It is not uncommon for some of the chloride in solution to crystallize out. If the chloride is used in solution, the disadvantages are removed, but in this case only about one-tenth volume per cent. will be present. He therefore conceived the idea that if the halogens are dissolved in the glacial acetic acid, since the molecules exist in solution in a dissociated state and free chlorine, bromine or iodine ions are present, a satisfactory result would be obtained by using the potassium chloride, bromide, and iodide together. He therefore dissolved 0.1 gram of each in 100 grams of glacial acetic acid. Testing with sodium thiosulphate solution, he could prove the presence of free iodine and bromine in the solution. The test is carried out by placing a few drops of the solution with the blood traces on a slide, covering it with a cover glass and warming gently. A plentiful crop of crystals appears when blood is present. The excess of fluid can be sucked off or allowed to evaporate, and the preparation can be made permanent by sealing with Canada balsam. The crystals are clearly seen, tinted a light reddish-brown by the free bromine and iodine. He was able to demonstrate their presence from old, decomposed bloodstains, admixed with rust, from old carbon monoxide blood and various other blood-containing material.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

117. Tuberculosis and Zona.

THE frequently close association of a tuberculous infection and herpes zoster is emphasized by Bernardon in an article in *La Province médicale* of November 2nd, 1912. The author relates the case of a Colonial officer of the French army who after undue exposure to cold and wet was attacked by severe muscular and articular pains. The pain finally localized itself at the upper and inner aspect of the left buttock near the iliac crest, and a day or two later an erythematous rash appeared over the same area, followed by a vesicular eruption. The herpetic eruption was interesting as following the territory supplied by the small sciatic and the posterior branches of the lumbar nerves, and anteriorly the genito-crural nerve. The attack terminated in about three weeks. In this case the only previous suggestion of tuberculosis had been a slight attack of pleurisy some years before. Later on and apparently as the result of a traumatism of the lumbosacral region a haematoma formed, and, the patient's health being undermined at the time by malaria, a fistulous opening followed. This discharged freely, and there was evidence of considerable destruction of bones involving both sides of the sacro-iliac articulation. The patient gradually lost ground, developed amyloid degeneration of the kidneys, an intense and persistent diarrhoea, and succumbed. The author goes on to say that in his opinion zona is not itself a disease, but a syndrome which may be noted in a variety of circumstances. Intercostal herpes in the course of pulmonary tuberculosis is a well-known fact which has been emphasized by Potain and others. It has been pointed out that zona is due to a nervous localization of tuberculosis. In the author's view its occurrence reveals a state of tuberculosis in evolution not hitherto suspected by clinical or other means. It is of great prognostic value in doubtful cases.

118. Pneumococcal Infection.

FULTON (*Pediatrics*, October, 1912), in considering pneumococcal infection in infancy and childhood, reports a series of 6 cases in which the only treatment adopted was by pneumococcus vaccine and open air. Since it is generally conceded that the pneumococcus may find its way to any portion of the body, and there set up a primary local inflammation which may or may not become general, pneumonia may in some cases be merely a local expression of an infection which was general from the start. The constitutional symptoms of acute pneumococcal infection—namely, chill, high continued fever, tachypnoea, increased arterial tension, and signs of meningeal irritation—are characteristic irrespective of the site of local manifestation, and in cases where there is no definite pneumonia it is difficult, and at times impossible, to arrive at a diagnosis even after bacterial investigation. Pneumonia is the most common local expression of such a general infection, but since it is not the only factor to be dealt with the ordinary treatment of the pneumonia alone is not likely to be entirely successful. The 6 cases reported were treated in the open air with Parke, Davis, and Co.'s pneumococcus vaccine with markedly beneficial results in all but 1 case in which permission to try the vaccine early was refused. Whether the infection is in the lung or elsewhere treatment by vaccine is of value, the more so the earlier it can be used. A stock vaccine is better than an autogenous one, since the possibility of a rapid tolerance for an individual vaccine, with the consequent need for a series of autogenous vaccines, is avoided, a course which would not only take time but add very considerably to the cost. The experimental pneumococcus vaccine (Parke, Davis, and Co.) from its multitudinous source minimizes the possibility of such tolerance being established.

119. Vaccination and Small-pox.

POLLACI (*Rif. Med.*, August 24th, 1912) gives an account of an extensive epidemic of small-pox which occurred recently in Palermo (6,353 cases, 2,060 deaths), and particularly with regard to 2,979 cases treated by him in two lazaretti between July 27th, 1911, and June 27th, 1912. Of these 2,979 cases, 1,653 (52 per cent.) were unvaccinated, 1,272 (42 per cent.) vaccinated, and 54 (1 per cent.) revacci-

nated. There were 1,636 men and 1,343 women. Most of the cases were admitted in the third or fourth stage of the disease. The mortality amongst the non-vaccinated was 32 per cent., amongst the vaccinated 17 per cent., and in the revaccinated 7 per cent. Figures are also given in reference to age, sex, and clinical variety of the disease. In addition, there were some 1,766 persons of all ages, who for various reasons (contacts, nurses, attendants, etc.) were admitted; 982 of these were successfully vaccinated, 717 gave negative results, and 267 doubtful. Beyond a few cases of slight roseola, no ill effects followed the vaccination. Of the 181 persons in immediate attendance on the sick, not one contracted the disease. Of the remaining 1,585 (2 per cent.) caught small-pox, and all recovered. Taking all the cases, men show a slightly greater proclivity to small-pox and a small excess (2 per cent.) in mortality. As showing the influence of vaccination on the types of disease, it was found that whereas confluent and obstinate types affected the non-vaccinated in the proportion of 25 per cent. and 24 per cent., the vaccinated were only attacked in 9 per cent. and 19 per cent., and the revaccinated 0.67 and 0.53 per cent. On the other hand, the mild varioloid type attacked 12 per cent. of the vaccinated and only 2 per cent. of the unvaccinated. As in all statistics of this class, it is important to bear in mind the difference between morbidity and mortality in estimating the value of vaccination. Seeing that the morbidity of small-pox is greater in early life and that vaccination immunity probably does not last more than five years on an average, the benefits of vaccination should be seen most convincingly in the early years, and the author's figures help to prove his statement.

120. Hypokinetic and Dyskinetic Constipation.

THE observations of the normal faecal movement and distribution by means of *x* rays have led the way to a more minute study of the various forms of constipation. G. Schwarz (*Munch. med. Woch.*, October 1st, 1912) records his observations in cases of chronic constipation. He divides these cases into two groups, the first of which shows some forty-eight hours after the intake of the contrast meal no formation of what he designates the globus pelvius, and an abnormally large amount of continuity. In the *x*-ray observations it is seen that the colon is often very long and much convoluted. The second group shows a globus pelvius after forty-eight hours, but the faecal column becomes greatly segmented, and there is an increased retrograde action. The author gives brief clinical accounts of each type, and illustrates the cases by pictures representing the appearance as seen by means of the *x*-ray illumination. The first group he calls hypokinetic. The motility of the colon is not disturbed, but that of the caecum, sigmoid flexure, etc., is markedly so. The second group he calls dyskinetic. Here the function is disturbed in the colon, and partakes of the type of an exaggeration of the normal power of detachment of portions of the faecal column.

121. Diagnosis of Enlarged Thymus.

PAIK AND MCGUIRE (*Archiv. of Intern. Med.*, September 15th, 1912) criticize the percussion methods of Jacobi and Boggs for diagnosing enlargement of the thymus. Jacobi presupposes a movement of the thymus in an antero-posterior direction, while Boggs assumes an up-and-down movement, and both aim at the determination of a movable dullness based on the hypothesis that the organ is movable. Anatomically the thymus is loosely fastened inside its own capsule, which latter, however, is most intimately attached to all the thoracic structures. At an autopsy its attachment to the sternum must be freed before the sternum can be removed, and any attempt to lift the thymus out of the thorax necessitates the pericardium, with the heart and diaphragm, being lifted also. The attachments could not be more universal, nor those posteriorly more firm, than they are, so that it is difficult to regard the gland as movable. In a series of 29 autopsies both methods were investigated by inspecting the thymus through a window cut in the upper part of the manubrium. The organ was found to be invariably in close apposition to the sternal wall (*contra* Jacobi), and immobile when the procedure, as performed by Boggs himself on the living subject, was carried out (*contra* Boggs). The lower limit of the thymus dullness corre-

sponds to the margins of the lungs, and the theory that the lower border of the thymus dullness rises when the thymus is drawn upwards is no more reasonable than would be the idea that the waistcoat opening moved upward when the shirt is drawn upwards. So long as the lung margins remain stationary the lower border of the thymus dullness remains stationary also, even supposing that portions of the thymus below that opening were drawn up into the dull area. It is concluded, therefore, that percussion methods of the thymus, based on the theory of its mobility, are founded on a false anatomical hypothesis.

SURGERY.

122.

Simple Cysts of Bone.

EVER since Virchow first drew attention to the occurrence of cysts in bone, numerous writers have narrated cases. The relation of simple cysts with osteitis fibrosa was discussed by Maclaure over a year ago, and he concluded that the pathology was very complex and many new observations were required. In the *Archives provinciales de chirurgie* (October, 1912) P. Canaguier contributes a long article on the subject. Simple cysts of bone are to be regarded as quite definite entities. The cyst is not a concomitant of other diseases nor dependent upon them, but is the principal lesion of the bone. Thus definitely limited it is found that there are not many cases on record: 97 being the total number known. A case in the author's practice may be taken as typical: A girl of 7 years presented a swelling in the upper end of the humerus, regarded as a painless tumour which did not interfere with use of the arm; at 9 years she fell and sustained a fracture at the upper extremity of the humerus, this fracture had all the classical signs except pain, the bone became consolidated in six weeks; at ten years the same accident happened, and again the force causing it was slight; at 12 years again the same lesion occurred. On each occasion the size of the limb at the seat of swelling subsided immediately very markedly. After the third fracture the child was brought to hospital. Three months later at operation the periosteum and muscles were easily separated from the bone, and the first stroke of the gouge penetrated a bony wall not thicker than a playing card. The cavity contained serous fluid and no other tissue. A septum separated it from the head of the humerus; when this was perforated the head was found to contain red pulpy material. A few weeks later resection of the affected portion of the humerus, about half of the bone, was performed preserving the articular surface of the head, and a graft consisting of freshly removed tibia of a young goat was inserted. Suppuration ensued, but the graft held and union at both ends took place; the final result was fairly satisfactory. Practically all these cases of simple cysts of bone have the same symptoms, the same etiology, the same evolution. As to etiology, trauma plays an important part. Trauma is frequently the first fact to draw attention to the condition, but there is a number of cases, about two-thirds of the whole, in which injury was known to precede the cystic formation. It is usually in the growing period of bone that these cysts are found. Their seat of predilection is in the juxta-epiphyseal part of long bones. This author does not agree that they do not cross the epiphyseal line into the epiphysis. The contents of the cyst are as a rule serous fluid which does not contain cellular elements or organisms. As regards symptomatology, these cases only present themselves when fracture has occurred. Pain is seldom present; the fracture occurs spontaneously, or is produced by slight causes. Radiography shows a clear space in the head of the bone, indicating that there is only a shell of bone. The growth of the cysts is slow; they are usually benign. Diagnosis frequently depends entirely on the findings at operation. Treatment resolves itself into (1) attempts to cure the cyst by curettage, filling up the space with an antiseptic paste or resection of the cyst-bearing portion of bone, and (2) preserving the utility of the limb by means of bone grafts. Several theories have been advanced to explain the pathology. Virchow regarded the cyst as resulting from the breaking down of a sarcoma, and there seems to be a certain number which have a true sarcomatous basis, but they are apparently benign. Recklinghausen's theory of osteitis fibrosa is at the present time the favourite explanation; according to this theory, this special form of osteitis is characterized by the formation of fibrous tissue in the medulla with cysts and giant cells. But it may be that the cyst formation is associated with a local inflammatory process. Other theories are the parasitic and the traumatic.

According to the latter, intraosseous hæmorrhage occurs: this is sufficient to provoke medullization of the bone, and ultimately a cyst is formed. The author believes that osteitis fibrosa is at the bottom of the whole group of bone cysts, but does not think that that condition is the sole explanation. His conclusions are that simple cysts of bone are not all of the same pathogenesis, and that they may be derived (1) from tumour, generally sarcoma; (2) from osteitis fibrosa; (3) from a chronic attenuated inflammatory process; and (4) from a traumatism which may act by the formation of a hæmatoma within the bone, or by favouring the starting of an inflammatory process, or osteitis fibrosa.

123. Fascia Lata in Dura Mater Plastic Operations.

MAUCLAIRE (*Arch. gén. de chir.*, October 25th, 1912) points out that organic grafting is still experimental. So far the greatest success has followed grafting of fascia lata and tibia, both of which have been employed by this author. The results of the employment of fascia lata to re-enforce abdominal aponeurosis in the radical cure of inguinal hernia in subjects where the abdominal wall was very weak have been encouraging. So also have been the results after operation for umbilical and incisional (post-operative) ventral hernia; while in femoral hernia a graft of fascia lata with a fragment of muscle has been successfully used as a stopper to close the femoral opening. Maclaure narrates a case in which loss of substance of the dura mater was made up by a piece of fascia lata. A patient had received a bullet in his head, and as a consequence of two exploratory operations, of which the second proved a success, a considerable aperture was made in the dura mater so that suture was impossible. A piece of fascia lata 4 cm. square, with a little portion of adherent muscle, was placed muscle side innermost over the opening in the dura mater between that membrane and the bone; the disc of bone was then placed over it. The healing was uncomplicated. This, or a similar operation, has already been frequently performed. Perhaps the most interesting observations are those by Rehn, who sought to repair the loss of dura-mater by implantation of fatty tissue. The object is to obtain hermetic closure of the breach, and to preserve the nutrition of the graft without formation of adhesions to brain or to the cutaneous flap. Fat seemed to be suitable for this purpose. The pieces transplanted in man persisted for several months, and the adhesions with the pia were very slight. In one case Rehn transplanted a piece of fat the size of the palm of the hand, 1 cm. thick, to replace the portion of dura mater resected. The loss of bone was also made up by an osteoplastic flap. Kirschner prefers to employ fascia lata, and has a list of 17 cases operated by this method. Healing was always satisfactory, and in the cases operated on for epilepsy of cortical origin the fits ceased to occur after the wound had healed. Where a large graft was used the fascia lata amply resisted cranial pressure so that no hernia cerebri formed. It is too soon to state definitely that absolute cure has resulted, but experiment seems to show that fascia lata comes nearest to the ideal grafting substance, although it does not possess endothelium on its inner surface which is applied to the surface of the brain. The objection to peritoneum which may be obtained from hernial sacs is that the endothelium tends to be readily destroyed by faults of nutrition and to form adhesions. In addition, it is to be noted that autotransplantation is more likely to succeed than homotransplantation. A piece of fascia lata may act as a bridge, and the endothelium from the cut edges of the dura mater may (it has not yet been proved) grow inwards, and ultimately cover the inner surface of the graft very much in the same way as the epidermis grows concentrically to cover an ulcer of the skin. The transplanted material must form an impermeable barrier, and the subdural space must be hermetically sealed. Fascia is the only tissue which can be sutured with such an object.

124. Removal of Lacrymal Gland in Epithelioma of Inner Canthus.

MAUCLAIRE (*Arch. gén. de chir.*, November 25th, 1912) was called upon to operate on a case of epithelioma of inner end of left eye. In removing the tumour it was of course necessary to remove the lacrymal puncta and ducts for a certain distance. He feared the patient might suffer from obstinate permanent epiphora; so, to obviate that risk, he decided to remove the whole lacrymal gland, both its palpebral and orbital portions. This was easily and successfully accomplished. One month afterwards there was no epiphora; the cornea was sufficiently moist and efficiently lubricated by the conjunctival glands.

OBSTETRICS.

125. Intramammary Injections of Air in
Eclampsia.

A REPORT on 3 cases of eclampsia successfully treated by injections of air into the breasts is given by C. F. Licht (*Ugeskrift for Læger*, July 18th, 1912), whose procedure was based on the observation that an afebrile disease which occurs in cattle before, during, or after calving time has for some years been successfully treated by distending the udder with air, injected by a bicycle pump. This disease usually attacks strong cattle which are good milkers, and its symptoms are paresis, loss of consciousness and, in some cases, cramps. Originally the disease often ran a fatal course, but after Schmidt in 1897 introduced the treatment by injection of a solution of potassium iodide into the milk ducts, it became easy to cure, and lost its dangerous character. Now the potassium iodide has been replaced by air, the effect of which is so rapid that veterinary surgeons boast of giving an injection, retiring to smoke a pipe, and, when this is done, finding the cow already cured. This result is attributed to the destructive action of air on hypothetical toxins in the udder. The writer noted that this disease and eclampsia presented the following features in common: Relation to gestation, absence of fever, the toxic character of the symptoms, and the special liability of strong subjects with large mammary glands to contract the diseases. The first patient to be treated was a well-built primipara, aged 23, who had suffered from vomiting during pregnancy, and had suddenly developed cramps, three attacks of which occurred before admission to hospital. Ten minutes later, another attack occurred. There were cyanosis of the face, foam about the mouth, and clonic contractions of all the limbs. The fetal head occupied a high level in the pelvis, and was movable. The cervix admitted one finger. There were no fetal movements or heart sounds. Subcutaneous injections of pituitrin and sea-water were given, and about 300 c.cm. of air were injected into each breast at five or six different points, as it was impossible to pass the needle's point directly into the milk ducts. During this procedure another attack occurred. This was the last. Sixteen hours after the injections were given the mother was delivered of a dead child. A few days later the temperature began to rise, and death occurred thirteen days after the completion of labour, the patient showing signs of sepsis and renal disease. The second patient, a 4-para, aged 32, developed oedema, nausea, vomiting, and headache in the eighth month of pregnancy, when she was admitted to hospital. Twenty minutes later a typical eclamptic attack occurred, which lasted for ten seconds, and was accompanied by loss of consciousness and twitchings of the face and limbs. Two similar attacks followed in rapid succession. The pulse was 136, and the urine contained albumen. The treatment included injections of salt water and pituitrin, and 200 c.cm. of air were injected into each breast. No more attacks occurred, and after the birth of a dead child the mother recovered. The third patient was a 10-para, aged 37, who towards the close of her pregnancy developed headache, vomiting, dimness of vision, partial loss of consciousness, oedema of the legs, but no cramps. The urine was dark and cloudy, and it contained a large quantity of albumen. Treatment as already described was adopted, the amount of air injected being 900 c.cm. This was followed by improvement of the mental condition and sleep after the patient had long been restless. A living child was born, and no relapse occurred. The injections of air were easily administered and caused little discomfort. Resorption was completed in eight to fourteen days. There is but little danger of air embolism, as there are no large blood vessels in the neighbourhood, and the presence of the needle's point in a blood vessel can be detected by aspiration. The writer attributes the cessation of the eclamptic symptoms in all his cases to the injections of air and not to the saline solution, little of which had been absorbed when the symptoms began to disappear.

GYNAECOLOGY.

126. Dystocia from Cicatricial Atresia of Os.

ROUVIER and BENHAMOU (*Bull. de la Soc. d'Obstét. et de Gyn. de Paris*, etc., July, 1912) are greatly opposed to extreme operative measures advocated at the present day in cases of labour impeded by cicatricial contraction of the os externum. More than one living obstetrician has undertaken abdominal Caesarean section, yet even

Küchenmeister's scissors, the bistoury, or multiple small incisions are by no means indispensable. The dangers of neglect and delay are the possibility of severe laceration of the inferior segment, not very common, or the detachment of a circular piece of the cervix, an extremely rare complication; yet experience has shown that these dangers may be avoided by simple dilatation of the os externum with the finger, as Naegle taught eighty years ago. Bureau, more recently, made use of vaginal injections at 118° in a labour where there was great stenosis and rupture of the uterus seemed imminent. The patient was a multipara. As he was getting ready a bistoury to make small notches in the edge of the contracted os externum the cicatrix yielded and the child was delivered spontaneously. Rouvier and Benhamou relate their own experience. Their patient, 27 years of age, had suffered from some complication following her second confinement four years previously. The head presented, and no instrument, it seems, was used; but in a few months free haemorrhages occurred, which were checked by a medicated tampon, but what compound or chemical was used did not transpire. Benhamou examined the patient and discovered sclerosis of the cicatricial type; the cervical canal appeared to be impermeable, yet she became pregnant, and the treatment, dilatation with laminaria tents, had to be discontinued. No tent had as yet been successfully passed through the canal of the cervix. At term the membranes ruptured prematurely, and three days later pains set in. Rouvier found an orifice of the size of a pin's head, and managed to pass a blunt probe through it. After a little manipulation he introduced his forefinger, rotated it in the cervical canal, and then passed in his middle finger. Almost immediately the cervix opened widely, and two hours later a robust infant was born. Six months afterwards the uterus appeared normal and the cervix somewhat indurated but permeable. This case shows, the authors insist, that, guided by a probe, the finger can usually be used as a dilator. It is only where the cervix is destroyed by cicatricial changes that Caesarean section is required.

THERAPEUTICS.

127. Psychotherapy in Gastropathy.

CRÉSPIN (*Progr. méd.*, October 5th, 1912) emphasizes the importance of taking into account the psychical factor in the treatment of many gastric disorders. In these cases the medical psychologist has an advantage which his more stereotyped confrère does not possess. The latter is too often obsessed by the necessity of finding some organic lesion to account for the illness, he omits to note the mental factor and directs his treatment solely to the local condition which he assumes exists. The author describes several cases, all suffering from gastropathy in varying degree. The history of each case shows an emotional or nervous origin. A false idea of the situation takes possession of the patient's mind, and, owing to a frequently debilitated nervous system, becomes deeply rooted. This was accentuated in each case originally by the unconscious aid of a medical man who ordered local treatment only. The author dwells upon the necessity of gaining the confidence of these patients; he insists that no detail of their lives is too insignificant for examination, that the assistance of the family and friends of the patient must be sought. The history of one of these cases is in practical correspondence with all the others. The patient was a girl of 16, whose parents were farm servants and in good health. Her illness began two years before, when she received a slight blow on the pit of the stomach. Her health began to fail rapidly. For some days she suffered from a heavy, deep-seated pain, after which followed bilious vomiting and loss of appetite. She had a marked aversion from food, partly because of the fear of making herself worse. She saw a medical man, who advised a very restricted diet, especially as regards meat of any kind. She followed his advice literally, but got no better, and had to give up work. On examination there was found to be marked hyperaesthesia over the epigastric region, even gentle stroking causing pain. The stomach was not unduly dilated, although there was some aërophagy, and the x rays showed that motility was normal. An examination of the gastric contents showed no alimentary debris, and fluid rich in HCl. The conclusion was that a slight hypersecretion existed without any pyloric obstruction. This hypersecretion was not in evidence when the stomach was more or less full. In the author's view, a lack of the usual utilization of the gastric juice is the main cause of the trouble. Irritation of the mucosa

and pyloric spasm followed. The patient had a positive fear of eating, especially meat, which she has come to consider a poison in her case. She took great interest in the various methods of examination employed, and, gaining confidence, was gradually brought to believe that to eat a little meat would do her no harm. Following a return to normal diet the gastric symptoms abated, and the patient's belief in her cure was established. The author emphatically states that this was no case of hysteria. The gastropathy arose from an emotional incident—a traumatism. The cure was certainly by persuasion or suggestion, but whereas hysteria can be cured similarly in certain cases, this happens much more immediately and dramatically than in the case under review. Here the result was obtained after many weeks' effort to convince the patient of the error of her belief. The author concludes by pointing out that these gastropathies are not necessarily mere chimeras of the patient's imagination, for certain emotions can result in real gastric disorder which must be dealt with accordingly.

128. Salvarsan in Oriental Sore.

O. V. PETERSEN (*Munch. med. Woch.*, November 12th, 1912) has employed salvarsan in doses of from 0.4 to 0.6 gram intravenously in cases of Leishmaniasis with good effect, and in view of the fact that out of 36 cases treated in this way 16 were cured, 4 were discharged nearly cured, 11 were materially improved within a short time of observation, 3 could not be traced, and only 2 proved un-influenced, concludes that the drug has a specific action on the causal protozoa. He points out that the dosage should be decreased proportionately for children or weakly adults. He has only had a small experience with the ointment and oily preparations of salvarsan, but the results obtained up to the present are promising. His experience reaches him that if no effect is obtained within two weeks a second injection should be given, and he sees no objection to a third or fourth injection being employed if necessary, but the occasion has not occurred in his experience. He, however, recognizes that the more obstinate forms, in which the sore does not become ulcerated, may require repeated injections. He calls attention to the fact that Oriental sore goes under a large number of names, including Delhi sore, *kokandha*, *pidu-bios*, etc.; but the condition called "tropical ulcer" is a totally different disease and must be distinguished from Oriental sore. He considers that the local treatment of the ulcerating surfaces in Oriental sore with methylene blue should be further investigated.

129. Balsams in Gonorrhoea.

RIBOLLET (*Ann. des. mal. vén.*, December, 1912) considers that the administration of balsams in the early stages of gonorrhoea increases the duration of the disease, and often causes complications. He points out that the balsams have no bactericidal action on the gonococci, and only diminish the pain and the suppuration. But to diminish suppuration in the acute stage of gonorrhoea is to counteract the natural means of evacuation of the gonococci, the latter, instead of becoming absorbed by the phagocytes, remain in the urethra and penetrate into the mucous membrane and urethral glands. He therefore recommends that balsams should not be given till the gonococci have disappeared. Among the complications which he considers may be due to early administration of balsams are gonorrhoea, rheumatism, stricture, and chronic inflammation of the glands of the urethra and prostate. Balsams are, however, useful in the decline of the disease when gonococci have disappeared from the discharge, especially in cases of posterior urethritis, with dysuria or haematuria. Balsams should be given in large doses at first, and then gradually decreased. The author considers santal inferior to copaiba or cubebs.

130. Thorium in Leukaemia.

NAGEL-SCHMIDT calls attention to two peculiar observations which he has made in the course of the treatment of leukaemia with thorium X. The clinical history of the patient does not offer any special interest, the more so as the improvement attained was still of short duration when the communication was written (*Deut. med. Woch.*, September 26th, 1912). The spleen was greatly enlarged and extended almost to the right iliac spine. X-rays failed to influence this tumour. About sixteen hours after the first injection of thorium, the patient noticed that his abdomen had become suddenly quite soft. The spleen could be palpated deeply, without any pain being produced. This softness passed off in about half an hour, and the con-

dition was then precisely the same as before. The second point of importance was as follows: At the time of the first thorium injection, the patient was extremely anaemic and only showed 30 per cent. haemoglobin. The effect of this on the anaemia was not marked, and in the time following the cachexia increased, the appetite was lost, and the patient became thin and weak. As the haemoglobin sank to 25 per cent., he prescribed iron, starting it at the time of the second injection of thorium. The effect was striking. The general condition improved visibly, the haemoglobin content of the blood rose to 50 per cent. and later to 65 per cent., the appetite became normal, and the patient was able to take walks. The author leaves these two observations uncriticized, and reports them in order that others may watch for similar occurrences.

131. Modern Tuberculin Treatment.

B. MÖLLERS (*Berl. klin. Woch.*, October 14th, 1912) analyses the development of the tuberculin treatment of tuberculosis and on the basis of his own experience, as well as of the opinions of other authors, expresses his views in regard to this question. He concludes that the most reliable method of treating tuberculosis is a combined "open air dietetic" and tuberculin treatment. Early cases, he states, may be treated by means of tuberculin as "out-patients," provided that the cases are carefully selected. The characteristic of the modern tuberculin treatment is the gradual, almost insensible, increase of dosage from small to large doses. General reactions should be avoided. He is convinced that the method of application is of greater importance than the choice of the variety of tuberculin in determining the effect of the treatment. He urges further that the treatment may never be carried out in a schematic manner, but that each case must be treated on its merits, special attention being paid to the course of the disease and to the degree of susceptibility to tuberculin. The tuberculin should be injected subcutaneously. He finds that a single course of tuberculin is not sufficient to effect a cure, but that many courses should be given, during the course of months, if not years. He pleads for the general use by medical practitioners of tuberculin, in order that a comprehensive effort may be made to cope with the disease.

PATHOLOGY.

132. Malignant Embryonic Adenoma of the Liver in Infancy.

A PREVIOUSLY healthy and well-nourished female child began to grow pale and lose weight at the age of 6 months; six weeks later the mother noted a swelling in the abdomen, and brought the child to the hospital a fortnight later, when it was seen by A. Peiper (*Jahrbuch f. Kinderheilk.*, Berlin, 1912, 3 F., xxv, 690). He found it a thin and very pale infant, with a soft, lumpy, almost fluctuating abdominal tumour, continuous with the liver and reaching down on the left side to the pelvis. Exploratory laparotomy showed some ascites and a soft haemorrhagic growth apparently originating in the liver; the wound was plugged, the opening sewn up; the child died four days later, aged 8½ months. *Post mortem* the liver was found to be much deformed, especially in the left lobe, by a diffuse, marrowy, whitish tumour, particularly well seen on the inferior surface of the liver. The gall bladder and bile ducts were free from growth; the other abdominal organs, the heart, the lungs, and the brain were normal. There was no sign of cirrhosis of the liver, though its tissue was atrophic where pressed upon by the neoplasm. Microscopically the tumour showed cells of three main types, with intermediate transitional forms. First, cells with deeply staining nucleus and scanty protoplasm, sometimes showing amitotic cell division, closely resembling embryonic liver cells before they have been arranged and differentiated into either liver cells or bile-duct cells; secondly, cells arranged into columns and alveoli much as liver cells are, but richer in nuclei, in places degenerated, rarely producing any biliary secretion; and, thirdly, cells resembling and arranged as imperfectly formed bile ducts. Haemorrhages were seen throughout the new growth; no giant cells were observed. Peiper discusses a number of more or less similar cases of malignant hepatic disease culled from the literature, and concludes that in his instance the cancer was produced by carcinomatous degeneration of the (embryonic) liver (Anlage), and he thinks it comparable to the case of an eleven months female infant with hepatic cancer described in 1900 by Weber. Many quotations from the literature are given.

AN EPILOGUE OF CURRENT MEDICAL LITERATURE.

MEDICINE.

133. Fatal Pachymeningitis Five Years after Injury.

The medico-legal expert has frequently to decide whether pachymeningitis is traumatic or not, and E. Kasmeyer (*Deut. med. Woch.*, October 24th, 1912) considers that true hæmorrhagic pachymeningitis may follow an injury to the skull, that it may be slowly progressive, and that it may be fatal several years later. In support of this view he reports the case of a bailiff's assistant who, at the age of 20, was kicked on the forehead by a horse. It is not clear whether he was stunned or not, at any rate he was able to walk away without assistance. Afterwards, he suffered from loss of appetite and occasional headaches, when the weather changed. Five years after the accident he caught a severe cold. His head ached violently, but he continued his work till a fortnight later, when he had a rigor and went to bed. He became delirious, and showed symptoms of meningitis when admitted to hospital. Here a furrow was detected in his forehead, just over his left eye, almost deep enough to contain the little finger. The left eyebrow was scarred and distorted. The pupils, which were equal, reacted very slowly to light. The tongue protruded, and the patient was very sensitive to pressure upon his neck and shoulders. There was no albuminuria, but the reflexes were exaggerated on both sides. Icebags were applied to the head and neck, and morphine was given for the increasing restlessness. The temperature, which had been normal on admission, rose to 104.7, complete coma set in, and the patient died. The diagnosis of meningitis was confirmed by a throat swab and an exploratory lumbar puncture, both of which yielded typical pneumococci. At the necropsy small quantities of yellow pus were found in many sulci beneath the pia mater, the glistening appearance of which was in many places lost. The dura and the pia were firmly adherent to each other under the depressed portion of the skull, which presented four nodules corresponding to the furrow on the outer surface. When the membranes were separated from the brain at this point, 2 to 3 c.cm. of yellow pus were found. Here, too, the cortex of the brain was partially destroyed. The dura mater, detached from the skull at this point, was seen under the microscope to contain numerous capillary blood vessels, some of which were recently formed and ended blindly. In several places extravasations of blood or deposits of pigment were seen. The deeper layers of the dura consisted chiefly of dense fibrous tissue. The author explains the origin of the progressive hæmorrhagic pachymeningitis in the following way: The capillaries of the dura were ruptured by the kick; the clot formed became organized, and the new vessels which appeared, degenerated and ruptured. This process involved the pia and the cortex of the brain, which thus became locally eroded. When, therefore, germs invaded the body, they found in the injured area a *locus minoris resistentiæ* whence they spread to other parts of the brain, and to the cerebro-spinal fluid.

134. Intermittent Spinal Claudication.

RECKORD (*Amer. Journ. Med. Sci.*, November, 1912) mentions two cases of intermittent spinal claudication, a condition due to defective blood supply of the lumbar enlargement, whereby only sufficient blood is received for the physiological processes in the passive state, the supply being inadequate for the increased demands during activity. A man aged 43 complained of weakness in the left leg, and burning sensation and pain in the lumbar region, which began suddenly while cutting grass three years previously, with weakness in both legs, and though he continued working the stiffness and weakness kept pulling him up from time to time. While walking all power left his left leg, and he fell unless supported; but in a few minutes the power returned, and he was able to proceed. There was also an accompanying transitory loss of power in the left arm, and the foot became cold, getting warmer again as he recovered. He was attacked about once a day with jerking of his left leg, which became forcibly flexed on the thigh, and the great toe moved backwards and forwards. These attacks took place lying or sitting, but if he stood and bore some light weight the movements stopped, and if he bore much weight the leg suddenly gave way. After lying down and on waking he could

urinate freely, but during the day the urine was slow in coming, and dribbled intermittently at first. He complained of a sense of weakness in the region of the second lumbar vertebra. The left upper extremity was normal with the exception of daily attacks of numbness, radiating from the shoulder to the fingers, without any pain. The left lower extremity showed impairment of muscular force and power, and at times the leg was as if dead. The patellar reflexes were exaggerated, especially after walking, and there was a moderate Babinski. The second case was that of a man aged 47, whose chief complaint was pain in the back, and severe pain in the knees when walking down steps. After walking for a few minutes the legs became stiff and powerless, which passed off after a short rest. The reflexes were all greatly increased, but there was no ankle clonus, and upon exertion there was violent trembling of the legs. The pupils were unequal, with feeble reaction to light, and there was some slight swaying with the eyes closed. The gait was spastic in both legs. The diagnosis of this condition from peripheral intermittent claudication depends upon the absence of pain and circulatory disturbances, and the presence of vesical and rectal symptoms. Males are more frequently affected than females, and one side is generally affected sooner than the other. The course of the disorder may be rapid or insidious, but it tends to go on to spastic paraplegia if untreated. The organic reflexes are affected from the commencement, the most common symptom being precipitate micturition, and the Babinski sign is generally present. The ensuing paraplegia may resemble a hemiplegia, as the two sides are usually affected unequally.

135. X-ray Localization of a Focus of Pulmonary Gangrene.

BÉCLÈRE has brought before the Société de Radiologie médicale de Paris (*Bull. et mém.*, No. 39, 1912) a case in which a focus of pulmonary gangrene was revealed radioscopically in a bronchitic subject. The fluorescent screen placed in front of the thorax revealed at the pulmonary hilum a shadow, the contours of which were rather indistinct, while at the centre was a little horizontal line surmounted by a transparent area. The appearance was suggestive of a collection of pus with gas above. On shaking the patient, the phenomenon of the Hippocratic succussion, clear though slight, was obtained. An examination from the back showed the contours much more clearly, with the line of liquid more strongly marked. It appeared, therefore, that the lesion was nearer to the dorsal than to the anterior region. By examining in different directions, the shadow of the focus was enabled to be dissociated from the shadow given by the vertebral column, and the matter was clinched by an examination in the sagittal position, which showed the focus to be well in the rear. A second radioscopic examination was made five days after the first, and, the lesion being more accentuated, it was determined to operate. Under radioscopic and radiographic guidance, the operation was completely successful, and the cavity drained.

136. Pyloric Obstruction.

PISEK AND LE WALD (*Archives of Pediatrics*, December, 1912) discuss pyloric obstruction in infants, with a comparative study of the normal stomach, and indicate an additional means towards an early establishment of diagnosis in order to be able to determine positively whether or not any given case shall be treated medically or surgically. From an x-ray study of normal stomachs of infants at varying ages fed with bismuth milk mixtures, with the baby in a vertical position, the natural contour of the organ *in situ* was found to assume varying forms, as shown in twenty-two x-ray pictures figured. Liquid foods begin normally to be expelled from the stomach into the duodenum within a minute or two after ingestion, and this fact is helpful in the diagnosis of conditions of pyloric obstruction. If it becomes possible by such a series of bismuth radiographs to demonstrate accurately that milk is retained longer than would be the case in the normal stomach it becomes possible to determine the type of obstruction. Thus cases of true tumour with so small a lumen as to practically occlude the passage of food into the duodenum would be operated upon while the general condition remained good, whereas in cases of spasm without tumour formation the time, and the amount, of

food passing through the pylorus can be estimated, and thus the advisability of resorting to medical rather than surgical treatment determined. Every suspected case of pyloric obstruction, therefore, should be studied radiographically before deciding what line of treatment is best.

SURGERY.

137. Traumatic Appendicitis.

RECENT literature on the subject of traumatic appendicitis is collected and discussed by G. Benestad (*Norsk Magazin for Lægevidenskaben*, December, 1912), who contributes the following case: A forester, aged 22, who had previously been perfectly well, was carrying one end of a log on his shoulder, while his companion, who carried the other end, let it fall without warning. Stumbling and falling backwards and to the left, the patient was struck by the log on the right side of the abdomen. The blow was rather painful, and the log lay for a little while on the abdomen, between the costal margin and the crest of the ilium. The patient could not work for a quarter of an hour, and he suffered some discomfort for several hours. After bicycling on the same day, he vomited his supper and a few dark coagula of blood, of the size of coffee beans. During the following night, he suffered from violent abdominal pain which was at first general, but which was later confined to the ileo-caecal region. At the end of a week, during which the pain had gradually subsided, the patient returned to work. Four similar attacks of pain recurred during the following two and a half years, their manifestations being the same on each occasion, except for slight variations in the intensity of the pain. An operation was performed after the fifth attack had subsided, and tenderness had disappeared everywhere except on deep palpation over McBurney's point. The caecum was slightly adherent to the anterior abdominal wall from which it was detached. The neighbouring coils of small intestine were now found matted together, and too firmly adherent to be separated from each other. The 7 cm.-long appendix formed a crescent about the lower end of the caecum to which it was slightly adherent. Its distal end was club-shaped, and its walls were thickened. Its lumen was completely occluded 2 cm. from the base by a stricture, distal to which was a little mucus, but no faecal concretion. No ulceration could be detected. The patient recovered. The author points out that since Neumann in 1900 published his observations on the relation of trauma to appendicitis, about 100 cases of traumatic appendicitis have been recorded. But some writers still deny its existence, and Sprengel insists on the occasional relation between trauma and appendicitis being purely accidental. Other writers concede a causal relation between the two conditions; but they confine the diagnosis of traumatic appendicitis to those cases in which the appendicitis occurred only a few hours after the trauma. Such cases are rare. Far more common are the recorded cases in which a considerable interval existed between the trauma and the appendicitis; and the incidence of traumatic appendicitis has further been extended by writers who include such factors as a hard day's work, horn blowing, and defaecation under the heading "trauma." Hence the estimates of the frequency of traumatic appendicitis vary widely, and range from 0.8 to 8 per cent. of all cases of appendicitis. The author's estimate is 2 per cent., but he admits that this is rather a speculative opinion. The diagnosis in cases of traumatic appendicitis is seldom made early, as the symptoms are usually interpreted as those of contusion only. The appendicitis being thus masked in its early stages, it is little wonder that the mortality is about 50 per cent., and five times greater than in other forms of acute appendicitis. A characteristic feature of traumatic appendicitis is the existence of two kinds of pain. The first is due to the trauma alone, and passes off in a few hours. The second is due to the activity of micro-organisms in the effused blood, and therefore arises only after an interval of some hours.

138. Surgical Anatomy and Surgery of Horseshoe Kidney.

CARLIER AND GÉRARD (*L'Echo méd. du Nord*, 1912, xvi) pp. 429-39 and 442-52) divide horseshoe kidney into the following varieties: (a) Symmetrical: (1) concavity below, (2) concavity above; (b) asymmetrical, kidney on I., with the hilum to the left or the right. They fluid out of 68,589 autopsies in various countries, 862 cases of horseshoe kidney; the isthmus connected the inferior poles of the two kidneys in 88 per cent. of cases, and in 91 per

cent. the concavity was superior. The isthmus passed in front of the aorta and veins in 90 per cent. The arteries to the kidney are increased in number in nearly all cases. Symptoms: There may be none of any kind during life. The most predominant is marked pain in the lower part of the abdomen and in the lumbar region. Pressure on the vessels may cause oedema of the legs and ascites. Hydronephrosis is the most frequent complication. The authors have collected all the cases (13) in which hydronephrosis and horseshoe kidney were associated and on which operation was performed. Only one ended in death. Lithiasis is less common than hydronephrosis. All recorded cases (9) occurred in adults or those advanced in years. Hydronephrosis or pyonephrosis are frequently coexistent. The symptoms are not characteristic. Radiography shows proximity of the calculus to the vertebral column. The operations that have been performed are: heminephrectomy, pyelotomy, and nephrolithotomy. Three cases ended in death after operation. Pyonephrosis has been observed as a complication. The symptoms here met with are those usually associated with this condition. Three cases had been published in which a calculus was not present. Tuberculosis is rare. Only five cases had been published, three in men. The symptoms are the same as are noted in tuberculosis of the kidney. Heminephrectomy, removal of the kidney, resection of the diseased portion, and *morellement* have been performed. Four of the five cases ended in complete cure. Solid tumours: Two cases, both of sarcoma, had been published. Cysts: Two have been reported; number one in a child 6 years of age, and one in a woman aged 59. Resection was successful in both instances. Horseshoe kidney without other pathological conditions is best treated by liberation of the two parts of the organ by section of the isthmus.

139. Fortanini's Method of Treating Pulmonary Tuberculosis.

LEURET (*Gaz. hebdo. des sci. méd. de Bordeaux*, 1912, xxxiii, December 15th, 22nd, and 29th) considers the subject of the production of artificial pneumothorax in three articles as follows: After describing his instrumentation and method of puncture, he details seven personal cases and three others under other medical supervision, and then considers the indications. These are unilateral serious tuberculosis, tuberculosis without any other serious visceral lesion, and a sound heart. Laryngeal phthisis is a contra-indication. The results are twofold—those that occur immediately after the operation and those that take place during the first days or weeks after the same. In the former category come severe pain with superficial breathing, small pulse, cyanosis of the lips, shivering, attacks of coughing, and vomiting. He has never seen sudden death, as described by some authors. Morphine seems to act as a prophylactic of these symptoms, but very slow admission of the air to the chest is the best preventive. In the second category come the marked change of the expectoration, which ceases to be purulent and becomes mucoid and decreases in amount, and the cough becomes less and disappears. The temperature becomes lowered after a rise for the first twenty-four hours and the signs of tuberculosis become less and less, but these latter do not in all cases show permanent improvement, and all the author's cases, save one, finally died from a return of the morbid process, so that the author finds that the treatment does not lead to a permanent cure.

OBSTETRICS.

140. The Serum Diagnosis of Pregnancy.

THE HALLÉ Professor of Physiology, Professor Emil Abderhalden, invites clinicians and practitioners to collect a large body of evidence to determine the diagnostic value of his serum test for pregnancy (*Deut. med. Woch.*, November 14th, 1912). If a solution of albumen be injected into the blood stream, the serum gains the power of breaking down the albuminous molecule, a power which it did not possess before. A destructive ferment is created *ad hoc*. Not only is this true for foreign substances, it is equally true for those body constituents which may be regarded as being only foreign to the blood. Each organ may be thus regarded. Abderhalden therefore came to the conclusion that the placenta would be a foreign substance in this sense to the blood, but experience has shown that chorionic tissue actually does find its way into the blood stream during pregnancy. Consequently the blood would form an antiplacental ferment in every pregnancy. This he demonstrates. The methods employed are two: The

first depends on the change in the light refraction of light of the serum after an albumen has been dissociated. The second is the dialysis procedure. In performing this it is necessary to test the membrane used very carefully, not only as to its capability of retaining all proteids, but also as to its capability of allowing a satisfactory amount of peptone to pass through within a given time. A piece of placenta weighing about 1 gram is finely cut up after being boiled. The process of boiling must be repeated until the water no longer gives a reaction with trichohydrinden hydrate. The piece of placenta and 1.5 c.cm. of the serum, which must be free from haemoglobin, are placed in the skin and the serum washed in with water. The fluid is covered with a layer of toluol. The skin is immersed in a suitable vessel, and so arranged that the outer water reaches a higher level than the inner fluid. This is then incubated for sixteen hours at 37 C. A control is put up without placenta. After the time has passed, the outer fluid is tested with trichohydrinden hydrate (or by the biuret test, but this is not so good). If a violet colour develops, some partially dissociated placenta has passed through the membrane, and therefore the ferment which can break down placenta must be present in the serum. Professor Aberhalden has tried the method in about 500 cases, and finds that it is positive in every case of pregnancy in various animals and in the human subject. He has obtained distinct reactions with the placenta of animals of a different species to that of the animal whose serum was tested, but the results are not so clear or constant as when the placenta of the same species is used. But he recognizes that the test might fail at times. It might be positive without pregnancy, although this would destroy all idea of a specific reaction. For these reasons, he wishes clinicians to use the test largely to determine its value for practical purposes.

GYNAECOLOGY.

141. Sterility and Tuberculosis of the Peritoneum.

HASTINGS TWEEDY (*Journ. of Obst. and Gyn. of the British Empire*, December, 1912) publishes a case of extensive tuberculous disease of both Fallopian tubes, together with miliary tuberculosis of the whole peritoneum. The patient's sole complaint was of sterility; examination revealed nothing abnormal, and the true condition was only revealed by operation. Tweedy comments that textbooks contain much information as to the conditions capable of diagnosis by bimanual examination, but no systematic endeavour has been made to tabulate the diseases which cannot be so discovered. Ovaries are often enveloped in a membrane, which suffices to prevent the escape of ova, and yet this condition gives no palpable sign. Normal tubes are so soft that they can rarely be palpated. No difficulty arises in feeling a tube which is tense with fluid; but if the fluid contents do not approach to its fullest capacity and at the same time the walls are soft, it is not possible to make an exact diagnosis. Subperitoneal myomata may escape observation, even though they attain the size of a small egg. Miliary tuberculosis without adhesions, and occlusion of the tubes without distension, cannot be detected. In sterility associated with retroversion the cure of the displacement by abdominal section affords the opportunity of observing and rectifying many previously unobserved abnormalities. In the absence of retroversion, when no disease has been detected, and after fair trial of the usual procedures, the author believes it is justifiable to open the abdomen. In dealing with diseased parts when found he endeavours to remove the diseased parts, to open the lumen of the tubes, to retain uninjured as much normal tissue as possible, to bring the resected ovary and tube stump into as close proximity as possible, and to tuck them away in a manner which will expose them least to adhesions with the intestines. The fimbriated ends constitute an important factor in impregnation, and no trouble is too great to preserve them. It frequently happens that their adherent walls can be separated and their lumens opened by the passage of a probe. To prevent subsequent sealing of the tubes by adhesions the author has sometimes stitched the ovary into the tube-mouth.

142. Crochet Needle in Bladder.

PAKOWSKY (*Bull. et mém. de la Soc. Anat. de Paris*, October, 1912) reports an instance of a foreign body in the female bladder which caused the development of a calculus and perforated the bowel, yet did not occasion any discomfort for three years. Then the patient, aged

36, became subject for six months to chronic cystitis. Ultimately she came under the care of Marion at the Hôpital Lariboisière. The stone being passed, a calculus as big as a walnut was detected, without difficulty: it lay in the neck of the bladder, encroaching on the urethra, and was quite fixed. Radiography confirmed the presence of a calculus. As the shade of a straight object could be defined running across the cavity of the bladder, it was clear that the stone had formed around a foreign body. The patient admitted that a bone crochet needle had been introduced into the bladder three years and a half previously. Cystoscopy also proved the presence of a calculus, but it was found impossible to get a view of the foreign body. Suprapubic cystostomy was performed. As the bladder was being insufflated air was heard escaping with a distinct noise, and it seemed to enter the peritoneal cavity. The bladder was opened and the calculus seized, but it was fixed, and could not be extracted until the projecting piece of bone was rotated upwards and backwards and pulled upon firmly. Then a communication with the intestine was detected: the greater part of the crochet needle lay in the bowel. The bladder was drained and the closing of the entero-vesical fistula left for operative treatment later on. No air or liquid faeces had ever passed out through the urethra.

THERAPEUTICS.

143. Pituitrin in Heart Failure after Diphtheria.

H. VON WILLEBRAND (*Tinska Läkarsällskapets Handlingar*, vol. liv, 1912) points out that the treatment of low blood pressure in the infectious diseases by injections of adrenalin is very successful, but that it is not perfectly satisfactory: for, as Straub has shown, only 6 per cent. of the drug reaches the circulating blood, while the remainder is disintegrated at the site of injection. Pospisichill accordingly gives 3 c.cm. of Parke Davis's preparation undiluted three or four times a day; but this amount may cause suppuration, and even extensive necrosis of the skin at the site of injection. Glycosuria is another transitory but disturbing sequel. On account of these flaws in the action of adrenalin, the author has substituted pituitrin on account of its powerful action on unstriated muscle. He employs Parke Davis's original preparation, 1 c.cm. of which contains 0.1 gram of glandular extract. Twenty cases of diphtheria complicated by weakness of the heart and low blood pressure were treated, and only in two did the drug fail. No glycosuria or other complication followed its use; and in several cases the effect of an injection was most striking. One patient, a girl aged 2 years, was admitted to hospital four days after diphtheria had developed. Her condition was alarming, the temperature being 98.6°, while the pulse could not be felt. Respiration was laboured and stridulous. Treatment consisted of intubation and the injection of 9,000 units of serum into a vein, and 6,000 units under the skin. Caffeine and camphor were also injected. On the fifth day of the illness the general condition was better, respiration was unobstructed, the pulse was 140, and its volume was fairly satisfactory. But on the sixth day she suddenly collapsed, and the pulse was scarcely palpable. Caffeine and camphor were injected, but were ineffective. A subcutaneous injection of 0.3 c.cm. of pituitrin was now given. The improvement which followed was almost instantaneous, and about four hours later the volume of the pulse was satisfactory, and its rate was 140. The tube was removed after a few days without difficulty, but nine hours later a sudden relapse occurred: the pulse was no longer palpable, and the general condition was most alarming. The injection of the same dose of pituitrin was so rapidly beneficial that the child sat up happily in her bed an hour later. During the next five days similar attacks were successfully combated by the same treatment, and its substitution by injections of caffeine and camphor on two occasions was most unsatisfactory, for they had apparently no influence on the weakness of the heart or on the blood pressure. The patient was finally discharged in perfect health. The author regrets that his observations do not include accurate measurements of the blood pressure, and he admits that pituitrin is only of use in coping with weakness of the heart and loss of tone in the blood vessels. The best treatment for the infection itself remains the injection of antitoxin. Fortunately, the severe collapse which may follow diphtheria is rare, and the commoner and slighter forms of vascular disturbances seen after diphtheria are speedily and effectively treated by such stimulants as caffeine, strychnine, and digitalis.

144. **Salvarsan in Syphilis.**

KANNENGIESSER publishes the results of the observations made in the Cologne Academy of Medicine in regard to the effect of salvarsan treatment of syphilis (*Munch. med. Woch.*, May 21st and 28th, 1912). After fully discussing the various points, he concludes that salvarsan, alone or in combination with mercury or iodides, is capable of removing the symptoms of syphilis in every stage, even when other methods of treatment have failed. The best method of application is by intravenous injection. In order to obtain permanent results, it should be given, in combination with mercury, in repeated doses, and the total amount given must be large. While he recognizes the impossibility of fixing a minimum total dose of salvarsan for the cure of syphilis, he suggests that from 3 to 4 grams of salvarsan, together with an unguent of about 180 grams of mercurial ointment, should suffice, in the majority of cases, to obtain permanent results. Wassermann's test should be used before and during the treatment, especially to enable the physician to push the injections when the patient showed a very marked reaction to begin with, and also to mark the point when the reaction becomes negative. After this further injections should be employed to render the result certain. A negative reaction following an insufficient treatment or a long time after the treatment has ended is no criterion of cure. The best procedure is that suggested by Genenrich and recommended by Milan to give provocative injection of salvarsan and then to control the serum. This is, however, difficult to carry out in practice. He is of opinion that the increased frequency of neuro-recurrences since salvarsan has been introduced is due to a certain effect of the medicament on the nerves, which creates a *locus minoris resistentiae* in those cases that are insufficiently treated. Sudden death after salvarsan has been injected occurs very rarely. In some cases the cause is entirely unknown, while in others there is some evidence that the salvarsan may be responsible. The risks are so small in comparison with the extraordinary curative action of the drug that they may be neglected. It may be possible at a later date to find a means of detecting the susceptibility of individuals toward salvarsan.

145. **The Treatment of Chronic Eczema by Heat.**

J. TÓTH (*Bert. klin. Woch.*, October 7th, 1912) has made personal experience of the beneficial effect of a thermic treatment of eczema, and recommends this method very warmly. The first application should be that of radiating heat. The affected part is exposed to the heat of an open fire, oven, or other source of heat, and the temperature acting should reach from 100° to 115° C. The part is slowly moved in front of the source of heat until the intolerable itching has either moderated considerably or leaves off altogether. The procedure is to be repeated three times a day. Later it is only required twice, then once a day, and, lastly, it need only be applied once in two or three days. The next procedure is the application of moist heat. Four or five litres of water are brought to boiling on a stove; a handkerchief or piece of linen is folded four or five times and dipped into the water. As soon as the excess of water has run off, the cloth is applied gently and rapidly to the affected part. As soon as the skin accustoms itself to the heat, the handkerchief may be applied more firmly and hotter to the skin. Acute eczema with scabs, etc., yield to this form of treatment in about five or six weeks. During the healing the itching can be kept within bounds and sleep can be assured at night. After a pause of several weeks it is necessary to begin over again, as recurrences nearly always take place. In spite of the very long time required for the treatment, the author believes that the results are better than by chemical means.

146. **Daily Lavage of the Rectum for Haemorrhoids.**

IN the course of a detailed account of the anatomy of the rectum, Professor Lenhossék (*Dent. med. Woch.*, May 30th, 1912) points out that its lower portion is lined with squamous epithelium, which extends up to a greater height than was formerly supposed. In fact, the junction of the squamous with the columnar epithelium does not occur, as was supposed, at the upper border of the annulus haemorrhoidal, but at the level of the sinus rectalis and the lower border of the ridge of Morgagni. While the columnar epithelium of the intestine is naturally protected against the action of the products of digestion, squamous epithelium appears to be less resistant in this respect, though under normal conditions it is unaffected

by contact with the faeces. But under abnormal conditions, such as sedentary life, its resistance is lowered, and the inflammation which occurs extends to the submucous tissues, including the blood vessels. Chronic phlebitis and the familiar varicosity of the haemorrhoidal veins follow. An important factor in this inflammation is, according to the writer, the retention of small particles of faeces in the folds of Morgagni or in those of the annulus haemorrhoidal after defaecation. That these particles are detached from the main mass of the faeces, and are retained within the rectum after defaecation, may be shown by the subsequent administration of an enema, when a considerable amount of residual faeces will be washed out. The bacterial and chemical poisons which these faeces contain must clearly favour irritation and inflammation of the lining of the rectum. As the mucous membrane above the sphincter ani is obviously beyond the reach of the ordinary toilette of defaecation, lavage of the rectum becomes necessary. The writer uses lukewarm water injected through a vulcanite nozzle from a syringe with a capacity of 100 c.cm. The process is completed by wiping the anus with moist and then with dry cotton-wool. The lavage may also be necessary before defaecation if constipation exists. The process soon becomes as much a matter of routine as the toilet of the teeth or hands. It is, of course, only necessary for the sufferers from haemorrhoids.

PATHOLOGY.

147. **Rupture of the Dura Mater in the Newborn.**

LEOPOLD MEYER AND E. HAUCH (*Arch. mens. d'obstét. et de gynéc.*, No. 3, March, 1912) describe the results of their investigations into the causes, extent, and frequency of laceration of the dura mater in newborn infants. After referring to Beneke's pioneer work in this direction, the authors give a brief anatomical description of the tentorium cerebelli and falx cerebri at birth, and detail the results of their experiments in the artificial production of laceration in these structures. They find that if bilateral pressure is exerted upon the fetal skull, the fibres of the tentorium are stretched, but that if force is exerted from before backward this tension is much increased, being aided by lateral displacement of the temporal bones. Forcible dislodgement backwards of the vertex produces tension in the antero-posterior fibres of the falx, with rupture of the same if the pressure is long sustained. If the cranial cavity is just filled with cotton-wool to replace the cerebral tissue laceration is more easily produced, as the tentorium and falx are fixed thereby. Meyer and Hauch have carefully examined the intracranial conditions in all stillborn children, or those dying shortly after birth, in the Rigshospital at Copenhagen from October, 1910, to April, 1911. In 1,200 births the foetal mortality was 64, and autopsy revealed ruptures of the dura mater upon twenty-eight occasions. In 15 of these cases the laceration was small, and did not account for death. The remaining 13, however, undoubtedly died as a result of the intracranial lesions; 6 were stillborn, and in all a complete laceration of the tentorium, with much haemorrhage, was found. Amongst the remaining 7 children, who were born alive but died shortly afterwards, two examples of severe trauma produced by purely natural forces occurred. In one case severe laceration of the tentorium and falx cerebri and much haemorrhage was found in a child born eight weeks before term. Delivery was spontaneous, and the presentation was the first vertex. On another occasion rupture of the superior longitudinal sinus occurred in a child born spontaneously one month before term, and who died fourteen hours after birth. The tentorium cerebelli is usually the seat of rupture, and considerable lesions may occur without any laceration of the falx. No injury to the inferior longitudinal sinus was noted. As to the cause of trauma, the authors note that in 66 forceps deliveries the application of the forceps in 20 cases was faulty. Amongst these, eight examples of serious laceration occurred. In 46 cases where proper application was made no case of trauma was noted. These observations confirm the old doctrine that a faulty application, especially one in the antero-posterior diameter, is very dangerous to the child. Trauma, again, is more frequent in footling or breech deliveries than with forceps. Lastly, in those cases where ruptures were found after spontaneous delivery, the children were always small and premature, the head under these circumstances not being sufficiently strong to withstand the natural forces of labour. The paper is accompanied by twelve excellent photographs and a tabulated series of cases.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

148. Serum Diagnosis in Congenital Syphilis.

STINER (*Corresp. Blatt.*, No. 16, 1912) discusses the light thrown on congenital syphilis by the Wassermann reaction. An examination of the blood of 45 women, mothers of syphilitic children, showed that the reaction was positive in nearly the same proportion (about half of the cases) in those known to have syphilis as in those who appeared healthy. From this he argues that the mother of a syphilitic child should always be regarded as syphilitic. He seeks to show that the child of a syphilitic father seldom infects the mother, and considers that the theory that the reacting bodies, but not the spirochaetes, may pass from the blood of the child into the circulation of the mother is disproved by the observations of Boas, who found that children whose mothers reacted positively to the test gave at birth a positive reaction themselves, although they were free from symptoms of the disease; but this reaction could not be obtained from the children's blood after a short time, though it persisted undiminished for months in the blood of the mother. This fact goes to show that the reacting bodies originate with the mother and pass to the child. In 102 cases of stillbirth the mothers reacted positively although 75 of them were apparently healthy, and in every case spirochaetes were found in the body of the fetus as well as in the maternal parts of the placenta. In these women also the Wassermann reaction persisted for months, which supports the view that the reacting bodies are produced in the individual in whom they are found. The writer argues that even a negative reaction in the mother with a positive reaction in the child should not be taken as proof of paternal transmission; for the mother may have previously received treatment, and so the Wassermann reaction may fail, and yet she may harbour spirochaetes and infect the child. On the other hand, the mother may have a gumma but no spirochaetes in the blood, and the child then escapes infection. Baisch considers that a positive Wassermann reaction depends upon the presence of spirochaetes, and concludes that the apparently healthy mothers of syphilitic children are spirochaete "carriers." This view receives corroboration from the fact that a woman who has had stillborn children by a syphilitic husband may bear syphilitic children to a second or third healthy husband, she herself remaining clinically healthy all the time. The early recognition of congenital syphilis is of the greatest importance in treatment, and, owing to the frequent absence, from various causes, of any distinct family history, the Wassermann reaction is here particularly useful. The writer suggests that the blood may conveniently be obtained by wet cupping in infants if there should be any difficulty in opening a vein. There is practically no other European disease which gives the reaction (except scarlatina), so that a positive result is a clear proof of syphilis; and a negative result, when symptoms suggestive of syphilis are present and the patient has had no previous treatment, excludes that disease with certainty. The writer also calls attention to the large proportion of mental disease, especially idiocy, due to syphilis; he thinks that a systematic blood examination would show the nature of these cases and would lead to a more rational treatment with some prospect of relief.

149. The Treatment of Phthisis by Artificial Pneumothorax.

MOLON (*Gazz. degli Osped.*, August 25th, 1912) gives his experience of the above treatment in 45 cases. In 12 of these it was not possible to induce pneumothorax owing to extensive pleural adhesions. In 3 the treatment had to be abandoned owing to the onset of complications. In 6 (severe cases with bilateral lesions) after a period of improvement the lesion on the non-operated side increased so rapidly that the treatment had to be abandoned. In 3 marked improvement followed, although owing to adhesions complete pneumothorax could not be induced. In 3 improvement was so marked that the patients left the hospital and refused further treatment. In 18 excellent results were obtained and treatment is still carried out. Four refused to continue treatment owing to the pain of the stretched adhesions. In the 33 in whom treatment

was carried out, 24 were unquestionably benefited. Pleural eclampsia was only observed in 1 case; the attack lasted half an hour and passed off without leaving any bad result. This may be avoided by giving an endopleural injection of stovaine. By watching for negative pressure in the water manometer one can know the pleural cavity is entered—occasionally a fallacy arises from penetration into a bronchus, in this case the manometer follows the respiratory curve. As a greater security against gas embolism the author suggests using oxygen for the first injection instead of nitrogen. Pleural adhesions give rise to the chief difficulty in this mode of treatment. The best regions for the introduction of the gas are the axillary and the infrascapular. A right-sided pneumothorax is better borne than a left. The amount of gas introduced varies from 100 c.cm. to 1,000 c.cm. according to the tolerance of the patient. Usually the pressure should not exceed +5 in the water manometer, at any rate at the beginning, but it may go up to +30, and having once accomplished compression of the lung a pressure of +1 or +2 suffices. Radioscopic examination is useful as an index of what is going on. Among the secondary phenomena noted are faintness, dyspnoea, tachycardia, pain, laryngeal spasm, bloody sputa, endopleural haemorrhage, cough, fever, cyanosis and pleural effusion. The best results are obtained in unilateral cases and the pneumothorax should be kept up for at least a year.

150. The Diagnosis of Chronic Appendicitis.

L. DREYER (*Muench. med. Woch.*, August 20th, 1912) finds that the diagnosis of chronic appendicitis or of appendicitis during an interval between acute attacks is often very difficult. In order to assist the diagnosis in doubtful cases he has employed inflation of the rectum. Air is pumped in through the anus. At first no special pain is complained of, but as soon as the air reached the caecum the patient complains of the same kind of pain as that experienced during an acute attack. The pain is frequently referred to the umbilical region. In inflating the bowel of patients not suffering from chronic appendicitis no complaints of pain were made. The author cites some typical cases in which this method assisted materially in forming the diagnosis, which was in each case confirmed by operation.

151. Tracheal Cough in Malaria.

MAX BUCH (*Finska Läkaresällskapet's Handlingar*, November, 1912) has frequently noticed attacks of coughing which occurred at certain hours every day in patients suffering from malaria. This complication, which occurred in 20 out of 150 cases, sometimes synchronized with the attacks of fever, and sometimes appeared when the attacks ceased. In 1 case of intermittent fever, the attacks of fever occurred twice a day, at 2 a.m. and at 5 p.m. Coughing began three hours after the onset of the fever and lasted for three to four hours. In another case the coughing began every evening at nine, and the fever lasted from twelve midnight till 3 a.m. Like other symptoms of malaria, such as giddiness, tinnitus, headache, etc., tracheal cough bears to the fever a definite relation which varies in different cases. The author was consulted by a boat-builder, aged 73, who suffered from a dry cough which awoke him every morning at 4, and continued till 6 o'clock. After this condition had lasted a week he developed at 9 p.m. a rigor accompanied by a violent, dry cough. Both ceased a little later, but he was again awaked at 4 a.m. by the usual cough. Subsequently every evening at 9 rigors and coughing occurred, and the patient felt weak and ill. The apex of the right lung was indurated, but there were no signs of active pulmonary disease, and there was no bronchitis. Pressure upon the trachea invariably evoked a violent attack of coughing, and the diagnosis of trachitis was therefore made. The author considers that a double malarial infection existed, and that the evening cough was a symptom of typical intermittent fever, while the morning cough was a manifestation of masked ague. This view he based on the development of the evening cough several days after the morning cough began, and on its curious reaction to quinine. This, if given just before, during, or just after an attack of fever, causes, as is now well known, more harm than good. As it is most beneficial when given from three to seven hours before an attack, the author gave 0.6 gram at 5 p.m. on

three successive days. After the first dose the evening cough ceased, but the morning cough remained. The same dose of quinine was now given at 11 p.m. on four successive nights. The morning cough ceased after the first dose, the patient again felt quite well, and pressure on his trachea no longer induced coughing. This test is, in the author's opinion, most valuable in the diagnosis of dry coughs apart from malaria. Examination of the pharynx and larynx may, if true, reveal the cause of such a cough: but when these appear healthy, and examination of the chest is negative, the physician is often in doubt as to the existence or not of pulmonary tuberculosis. The author has found that pressure on the trachea near the sternum induces coughing only when trachitis exists. In some cases in which coughing due to pressure on the trachea was anticipated, the patient complained only of pain, which healthy persons did not experience with the same degree of pressure.

SURGERY.

152. Paralysis from Extension Treatment of Fractured Femur.

THE treatment of fractures of the femur by continuous extension has, according to M. Weichert (*Berl. Klin. Woch.*, January 13th, 1912) raised the standard of improvement considerably; and while a shortening of 1 to 2 cm. was formerly considered a satisfactory result, nothing short of perfect union without any shortening is now successfully aimed at. This is due to extension by weight, the amount of which has been raised by Bardenheuer to 60 lb. in muscular men. Records of paralysis after this treatment have not yet appeared, but the author has observed 5 cases of paralysis of the external popliteal nerve since 1910, when he began to use heavy weights for extension. As he has treated 224 cases of fractured femur by extension, and as the paralyzes occurred only after heavy weights were used, he claims that they and not ignorance of technique are responsible for the consequences. It was at first thought that the paralysis might be due to pressure upon the external popliteal nerve against the fibula, but paralysis occurred in one case in which this possibility was excluded owing to a window having been cut in the bandage at the point where it traversed the head and neck of the fibula. Reducing the weights used minimizes the risk of paralysis, but this concession leaves the treatment of fractures of the femur at the old, unsatisfactory stage. The author has therefore returned to the use of heavy weights, and keeps the thigh raised and the knee flexed. With this procedure he has escaped paralyzes because he thinks flexion at the knee relieves tension on the sciatic nerve. The distribution of the paralysis was the same in every case, and the nerves involved were the musculo-cutaneous, the anterior tibial, and nervus cutaneus surae lateralis. The paralysis of the latter, which branches off from the external popliteal nerve above the popliteal space, is further proof of the condition being independent of pressure over the fibula. The injury to the nerves clearly occurred at a higher level, and the external popliteal nerve is more vulnerable than the internal, which has a better blood supply, and which is surrounded by more elastic tissues. In the first two cases no elevation or abduction existed, but these were present in the three latter cases. The first patient was a man, aged 47, whose fracture was subtrochanteric. The weight applied was 50 lb. There was no shortening of the limb, and the paralysis disappeared in nine months. The second patient was a man, aged 22, whose fracture was compound and involved the middle of the femur. The weight applied was 30 lb. The paralysis appeared a fortnight later, and after three months it had partly disappeared. The third patient was a man, aged 52, whose fracture involved the upper third of the right femur. There was considerable displacement, and the limb was 6 cm. shorter than its fellow. The fracture was set under an anaesthetic, and a weight of 36 lb. was applied. Owing to the patient's delirium, the bandages were frequently displaced. A week after the fracture paralysis occurred, and the fifth toe became cold and white. Gangrene of the fourth and fifth toes followed, and no improvement in the paralysis occurred. As this patient suffered from advanced arterio sclerosis, it is possible that the paralysis was due to interference with the blood supply rather than the nerve supply of the affected part. The fourth patient was a schoolboy, aged 11, whose fracture was transverse, and involved the middle of the right thigh. The limb was 4 cm. shorter than its fellow. Extension by a weight of 26 lb. was applied without any previous attempt to set the

fracture, but, owing to the lad's restlessness, the bandages had to be replaced thrice. The paralysis appeared five weeks after the fracture, when the bone had firmly set, and there was no shortening. The knee was stiff, and the muscles of the limb were much atrophied. Some time later the paralysis had almost disappeared, and only slight weakness of dorsal flexion of the big toe and slight loss of sensation in the area supplied by the musculo-cutaneous nerve were still demonstrable. The fifth patient was a man, aged 27, whose transverse fracture of the upper third of the left femur shortened the limb by 5 cm. Extension by a weight of 36 lb. was applied without previous setting of the fracture. There was no permanent shortening, but the paralysis which ensued had diminished to a slight degree only four months after the fracture. The author considers that this type of paralysis takes about a year to disappear, and that the best treatment consists of massage, exercises, galvanism, and hot air baths.

153. A Bismuth Preparation for Radiography.

A NEW formula for the preparation of the bismuth mixture is given by Réchou (*Arch. d'Electr. Méd.*, February 10th, 1913), who lays stress upon the fact that the ordinary solutions of bismuth carbonate and gum syrup have a tendency to form a double layer in the stomach. The bismuth carbonate, being heavy, is rapidly deposited, and the liquid vehicle, containing little of the carbonate, remains above it. The use of rice-milk with the carbonate gives rise to the same phenomenon. Under these conditions the shadow on the fluorescent screen shows the lower part of the stomach in clear relief, and leaves the other outlines indistinct. Thus, pathological irregularities pass unperceived, or are seen only in a fugitive manner. The following formula is said to produce a bismuth liquid which is homogeneous and gives no sediment:

| | | | |
|-------------------|-----|-----|-----------|
| Bismuth carbonate | ... | ... | 120 grams |
| Gum arabic | ... | ... | 20 grams |
| Gum tragacanth | ... | ... | 5 grams |
| Syrup (simple) | ... | ... | 150 c.cm. |
| Water | ... | ... | 350 c.cm. |

To aromatize the mixture, orange water is used. The patient can absorb about 550 c.cm., and a uniformly opaque stomachal shadow is given on the screen. In preparing the mixture the solid substances are pulverized together in a mortar, and to these is added, little by little, the mixture of water and syrup. The gum makes a perfect emulsion with the bismuth carbonate, the bismuth being slightly syrupy but very fluid. It has been found by experiments *in vitro* that bismuth prepared in this manner remains perfectly homogeneous for more than twenty-four hours, whereas with the ordinary preparation of gum syrup, water, and bismuth carbonate the last named will be almost completely deposited by the end of that time.

154. Franke's Operation for the Gastric Crises of Tabes.

INGELBAUS (*L'Echo Méd. du Nord*, 1912, lx) describes the history of this operation, which consists of stretching the intercostal nerves on both sides. The nerves usually chosen are the fifth to the twelfth. The operation has proved successful in numerous cases, but the result is not always certain, and death from pneumothorax has resulted.

OBSTETRICS.

155. Pituitary Gland in Midwifery.

IN view of the various opinions which have been expressed as to the therapeutic value of pituitary gland extract for the increase of the uterine activity during labour, and also as to the disadvantages of this medication, M. Eisenbach has recorded his own experience and draws certain conclusions from the same (*Muench. med. Woch.*, November 5th, 1912). In the first place, he seeks for an explanation of the reported inconstancy of the action of extracts of the gland. These could be (1) that the dosage employed by different obstetricians has varied too largely, (2) that the indications for its use are variously interpreted, and (3) that the preparations are not always equally active. In regard to the first point, he is of opinion that only when a large number of publications have been issued will it be possible to ascertain the optimum dosage. The second point depends on the capability of the uterus to respond to chemical stimulation. It is well known that the uterine muscle is much more susceptible to stimuli at the end of pregnancy than at the commencement, and

this fact will account for the failures when given for the purpose of bringing on an abortion. He has made the experiment twice, once in the third month on account of a missed abortion, and once in the fifth month, but in neither case with the desired effect. He gave pituitary gland extract in 28 other cases, including 12 in the first stage of labour, 4 in the second stage, and 12 in the third stage. Out of the 16 cases in which it was given during the labour up to the time of the birth, it acted well 11 times, but in 5 cases the action was not strong enough. Pituglandol made by Hoffmann-La Roche (stated to contain 0.1 gram of gland in 1 c.c.m. of extract) was given in doses of from 1 to 2 c.c.m. intramuscularly. The injections were repeated when necessary after one hour or more. He suggests that in the first stage, when these doses only produce a weak response, larger doses might be used, but he questions whether the cost incurred would be justified. After these doses no ill effects were noticed either in the mother or in the child, and there was no tendency to haemorrhage in the third stage. In regard to uterine inertia during the third stage, he states that in those cases in which massage and ergot failed to control the atonic bleeding he gave the extract with uniformly good results. He therefore feels justified in regarding pituitary gland extract as the best medicament that we possess for stimulating uterine contractions, but admits that it is not an absolutely reliable and certain drug. If suitable cases are selected and the doses are appropriate, it is capable of beneficially influencing cases of atonic inertia, and thus avoiding the use of forceps, dilators, etc. It is useless in artificial abortion, but does no harm to either mother or child.

155. Emotional Jaundice and Acute Yellow Atrophy in Pregnancy.

ROUVIER AND LAFFONT (*Bull. de la Soc. d'Obstét. et de Gyn. de Paris*, etc., April, 1912) refer to Blot and others, who have observed instances of emotional jaundice in pregnancy passing into icterus gravis and report a well-marked case under their own observation. A woman, aged 31, lost her child in the street when approaching the end of her fourth pregnancy. Her anxiety was intense until the child was found at the end of two hours. Almost immediately afterwards she began to show symptoms of jaundice. Next morning she was sent into hospital. There was uniform icterus, lemon-yellow in tint; the conjunctivae and the mucosae were involved. The liver was enlarged and tender, the urine mahogany-coloured, the pulse 90, and temperature 100°. Yet the general condition was good, and the patient related her recent experiences very clearly. Labour pains set in a few hours after admission, and early on the following morning she was delivered spontaneously of a male child nearly 6½ lb. in weight. It was slightly jaundiced, but the symptoms disappeared within a few days. The liquor amnii was greenish-yellow and abundant. There was very little blood lost during or after delivery, but the temperature exceeded 104°. For a few days the patient seemed to be improving, but on the fifth all the symptoms of acute yellow atrophy set in. There was delirium and rapid pulse, which soon could not be counted, and the patient died within a few hours. No necropsy was allowed.

GYNAECOLOGY.

157. The Relation of the Brain to the Ovarian Function.

CARLO CENI (*Archiv. ital. per le mal. nerv. e ment.*, vol. XXXVIII, August, 1912) experimented on a number of hens and pigeons to examine the relation of the brain to the function of the ovary. One hemisphere was removed, and the birds that survived the traumatic shock were killed after successive periods varying from a few months to three years, and their ovaries were examined histologically. The primary effect of the trauma was to cause them to cease laying eggs for several months. In the year following the operation they began to lay again, but in the second year some of them laid about half the number of eggs, others ceased laying entirely. The birds were otherwise in a healthy condition. The examination of the ovaries showed a premature progressive involution affecting the whole of the parenchyma. The writer considers that these changes are the expression of a permanent state of functional torpor of the organ, in consequence of which ovulation is more limited than under normal conditions, and finally becomes entirely arrested. This functional disturbance may be considered as a premature dynamic exhaustion of the sexual gland. The

conclusion drawn is that very intimate dynamic relations exist between the brain and the ovaries, and that the function of the latter is directly dependent on the anatomical and functional integrity of the former. The writer considers that his results have an important bearing on human pathology and on the question of limited reproduction in persons afflicted with neuropathic degeneration.

158. Dermoid Tumour of Both Fallopian Tubes.

NIGEL STARK (*Journ. Obst. and Gyn. Brit. Emp.*, October, 1912) was consulted by a woman aged 38, who had been married for ten years but was sterile. Menstruation was regular, free, and preceded by pain. The general health was good. On examination the uterus was found to be in the normal position and of normal size, but a fixed doughy swelling was definable in each lateral fornix. Neither was tender or painful. On opening the abdomen the swelling proved to be tubal, not ovarian; the right Fallopian tube was removed, whilst the swelling in the left tube was excised, the cut ends of the tube being afterwards united by suture, so that a shortened oviduct remained with its canal patent and the fimbriae intact. Both tumours were of the size of a Tangerine orange. The right involved the greater portion of the tube, the left lay in the outer third, not involving the infundibulum. They were cysts containing sebaceous matter, hair, and plates of very hard bone. Three other authentic instances of dermoid cyst of the Fallopian tube have been reported (Pozzi, Jacobs, and Noto); Stark's fourth instance of a tumour of the kind was peculiar in being bilateral.

THERAPEUTICS.

159. Idiosyncrasy to Arsenic.

Two cases of idiosyncrasy to arsenic in the form of sodium cacodylate are recorded by C. Staebli (*Deut. med. Woch.*, December 26th, 1912), who reviews the recent advances made in the study of the action of the various compounds of arsenic on the body. One patient, a man aged 52, suffered from malaria, general debility, and neurasthenia, for which sodium cacodylate was prescribed. The first injection of 0.05 gram, taken from a Bloch's ampulla, caused no disturbance. The same amount was introduced into the right forearm four days later. After twenty-four hours a rectal temperature of 101.8°, great weakness, pain in all the limbs and in the loins, and a sensation of pressure in the head were observed. The site of the injection was hot and brawny, and erysipelas was suspected. Next day, however, the temperature was almost normal, the general condition was better, and the local swelling was no larger. Scrupulous cleanliness was exercised, when, four days later, the same dose was given, but twenty-four hours later the same phenomena recurred, and the injections were therefore discontinued. The drug had been administered to many other patients without ill effects by the author, when he again observed symptoms of idiosyncrasy. The patient, a woman aged 36, who suffered from exophthalmic goitre, had been given twenty-four injections of 0.05 gram of Clin's sodium cacodylate on twenty-four consecutive days without ill effects. On August 14th the last injection was given. On August 24th she left the lowlands and came to St. Moritz, where, two days later, she was given an injection of 0.05 gram of the drug. Next day her temperature was 102.2°, and she complained of "rheumatic" pains throughout her body, anorexia, and headache. Her respiration was laboured and asthmatic. Although scrupulous cleanliness had been exercised, the site of the injection was hot and brawny. On the second day the patient was much better, and on the third day the temperature was normal and the swelling began slowly to disappear. As the needle had previously contained tuberculin, it was thought that a trace of this might have been injected with the sodium cacodylate, for the reaction was like that which follows an injection of tuberculin. This view was disproved by the repetition of the reaction on September 8th, twenty-four hours after the patient had injected half the usual dose of sodium cacodylate into her left thigh. The local but not the general reaction occurred. On September 9th the author substituted Bloch's for Clin's preparation, and injected 0.05 gram into the right thigh after careful disinfection of the skin. Next day the temperature rose to 102°, with a rigor in the evening. The other symptoms resembled those of the previous attacks, but were less marked. The site of the injection was again inflamed. The patient had completely recovered when, on September 16th, she was given an injection of 0.025 gram.

Twenty-four hours later the site of the injection was firm and swollen, and the temperature was slightly raised. The same dose, injected on September 20th, produced less fever, but a more violent local reaction than on the previous occasion. The cutaneous reaction to the drug was now tested by von Pirquet's method. After the skin had been cleansed and lightly scarified in three places, glycerine was applied to two places and sodium cacodylate to one. After eighteen hours the two former control places showed no reaction, while on the third place a reddened and infiltrated papule, 8 mm. in diameter, had appeared. This increased in size during the next thirty hours, and was still palpable two days later. The only explanation the author can give for the patient's erratic behaviour is that the passage from a low to a high level effected a change in the metabolism which rendered the tissues intolerant to the drug.

160. Treatment of Sleeplessness.

In dealing with the treatment of sleeplessness E. Meyer points out that a number of patients consult their medical advisers on account of "sleeplessness"; but on closer investigation it appears that the symptom which leads them to seek treatment is a limitation of the duration of sleep and the fact that they are unrefreshed in the morning (*Deut. med. Woch.*, September 12th, 1912). Simple disturbances of sleep practically do not occur unless associated with some body disturbance, either past or present. In a few cases the disturbance is periodic and is a kind of psychotic affection. It should be the duty of the practitioner to discover the other symptoms with which the sleep disturbance is connected. It is quite a common thing for nervous children to sleep badly. The exciting causes may be some extraordinary excitement, bodily exertion, or tiring and emotional causes. The treatment of severe cases of this kind should be directed to strengthening the nervous system and regulating the hygienic conditions of life. Psychic influences from the parents and the doctor do much good, but care must be exercised that neither severe, unkind treatment nor exaggerated mildness are employed. Narcotics are very rarely needed. The possibility of worms must be borne in mind in these cases. The disturbance in adults may be secondary to affections of the lungs, heart, or skin, or there may be a painful nervous disease, such as neuralgia, neuritis, rabes, or cerebral syphilis. At times organic diseases of the nervous system are manifested only by disturbance of sleep at first. It is not uncommon for a general paralytic to come to the medical practitioner on account of this symptom. The next category of cases belong to the poisonings. Chronic alcoholism, nicotine poisoning, intoxication with tea or coffee and the like may be responsible for the disturbance, and the author also points out that sleeplessness may arise in the course of morphinism. The disturbances of sleep in marked mental disturbances are well known. In functional neuroses—such as hysteria, neurasthenia, etc.—sleeplessness is not infrequently met with. The type of the disturbance in these cases is very definite. Finally, he mentions the sleeplessness of the climacteric. The treatment of the symptoms must consist first of all in the treatment of the primary condition causing it. In the second place, much good can be done by paying attention to the hygiene of sleep and of the bedroom. By small means the physician may be able to remove the symptom altogether in nervous patients. Next, hydrotherapeutic means may be adopted. Wet compresses, packs, partial baths, etc., are useful. Baths often work well in the sleeplessness of the climacteric. Hypnosis is often an excellent soporific, but as a rule the practitioner is not experienced in this. Electrotherapeutic measures may do good. In discussing drugs, he refers first to the various valerian preparations, and such drugs as aspirin, pyramidon, and bromides. Before giving hypnotics or narcotics, the physician should remember that he is merely dealing with a symptom; at times, however, it is impossible to get on without them. Morphine should never be used for sleeplessness; chloral hydrate had better also be avoided on account of its action on the heart. Paraldehyde in doses of from 3 to 5 grams, amyl hydrate, isopral, and veronal are mentioned, and it is said that trional and subphonal are not given as they used to be, on account of the production of haemato-porphyrinuria. The author further mentions medinal, bedonal, hypnal, hypnoval, malonal, veronacetin, and luminal, but does not discuss the risks attending their use, though he utters a warning against inducing a habit. He commends Bürgi's suggestion, to give the dose in two parts, and also to combine two drugs which act in a different manner.

PATHOLOGY.

161. The Metabolism in Barlow's Disease.

INFANTS suffering from Barlow's disease are not rare in Germany, but the patients come mostly from the upper and middle classes; this explains why their metabolism has not hitherto been investigated. F. Lust and L. Klocman (*Jahrb. f. Kinderheilk.*, Berlin, 1912, 3 P., xxy) believe themselves to be the first to examine it; their patient, the 18-months-old child of an extremely rickety woman, was the fruit of a Caesarean operation; was breast-fed for six months, cut its first teeth at 8 months, walked at 12 months. At 14 months the first signs of Barlow's disease appeared—restlessness, irritability, inability to walk or even sit up, swelling of the extremities; at 16 months the gums became discoloured and bled easily, epistaxis occurred, and there had been diarrhoea almost all the time when the infant came under observation two months later. At this time it weighed 14.8 lb. instead of the normal 25.3 lb., was very anaemic, made practically no voluntary movements, screamed when touched; the chest showed marked rickety deformity, there was much swelling in the neighbourhood of the epiphyses of the long bones of the arms and legs, crepitation could be felt in the shoulder-joints. Skin-grafts showed subperiosteal haematomas. The blood contained 3 million red, 2,400 nucleated red, and 11,000 white cells per cubic millimetre, with 40 per cent. of haemoglobin; of the white cells, 57 per cent. were lymphocytes, 32 per cent. polymorphonuclears. The authors set themselves to examine its metabolism for three periods of four days each; during the first period on a diet of boiled milk, oatmeal, and sugar, analogous to the diet which had been responsible for the onset of its disease; during the second period, three weeks later, on a similar diet, but with the use of unboiled milk; during the third period, a month later, by which time the child was clinically cured, on a diet like that given in the second period. The total ash, the N, the Cl, the P, and the CaO, were determined for the urine and faeces excreted during these three periods. The results of the analyses are rather surprising. The authors found that during the first period of four days there was an abnormally large retention of CaO and P, and a normal retention of Cl and of the total ash of the food. At the time of the second period of investigation the child was much better, and had gained 1 lb. in weight; during this period there was a much-increased secretion of the total ash and of all its separate constituents, as if the child was now eliminating a quantity of useless material stored up during its illness. The balance-sheet showed that while about 31 grams of total ash were taken in the diet, 48.3 grams were excreted in the urine and faeces. By the date of the third period of four days, when the child was clinically well, its weight had increased to 17 lb.; the phosphate and total ash balance-sheets now showed small positive balances, much below the normal in size. Hence, the authors conclude, Barlow's disease cannot be due primarily to a lack of mineral constituents in the food; it must rather be associated with an abnormal retention of mineral matter, and of lime salts in particular, in the system. Whether this retention is the cause of the disease or one of its effects they are unable to say; at any rate, the mineral metabolism of Barlow's disease is unlike that of rickets.

162. Syphilis of the Heart.

PIERRET AND DUHOT (*L'Écho méd. du Nord*, 1912, ix) describe 18 cases of various affections of the heart due to syphilis treated with mercury successfully, and find that the disease may be acquired or hereditary. It usually appears in the tertiary period, three to ten years after the chancre, and is met with most frequently between the ages of 30 and 40 years, slightly more frequently in men (60 per cent.). It may affect the myocardium in the form of gummata, chiefly in the left ventricle, the interventricular septum, and the right ventricle, more rarely in the auricle or interauricular septum, or as syphilitic myocarditis; it also gives rise to inflammation of the coronary arteries, the endocardium, or the pericardium; and Fournier has noted an etiological relationship between hereditary syphilis and cardiac or arterial malformations, especially persistence of the duct of Botalli. Persistent bradycardia is a frequent symptom, and a positive Wassermann reaction is extremely often noticed. When treated early cardiac syphilis is curable, but when untreated may lead to aneurysm of the heart and rupture. The best treatment is by injections of soluble salts of mercury intravenously, especially the cyanide; iodides and the usual treatment of cardiopathies are also in place. If these methods are unsuccessful salvarsan should be tried.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

163.

Tinnitus Aurium.

IN discussing the prognosis and treatment of tinnitus, Wittmaack (*Deut. med. Woch.*, September 26th, 1912) states that he does not regard a sharp distinction between objective and subjective noises as feasible. In the same manner, it is not always possible to distinguish between subjective sounds and otitic sounds. The characteristics which can be attributed to the sounds, however, should be noted in each case. After entering upon the subject of the presence or absence of rhythm in the sounds, which can be ascertained by requiring the patient to describe them fully and imitate them, he turns his attention to the etiology of the various forms of tinnitus. He commences with a large group in which no objective changes can be found in the ear. When the hearing is not reduced in sharpness, an organic aural basis of the tinnitus may be excluded. When the noises are rhythmical, the first possibility is to identify the rhythm with that of the arterial pulse. At times the noises are objectively audible by means of the stethoscope or otoscope. Under normal conditions the arterial pulse is not heard by the subject, but pathological changes in the peripheral circulation or in the heart may render it audible. Aneurysms in the neighbourhood of the ear or neck frequently produce intense and irritating noises. In these cases the pulsation may be seen or felt. But cases of this kind are rare. Again, tumours, such as a goitre, enlarged glands in the neck, etc., may cause the tinnitus. Should peripheral causes not be found, the heart must be examined to ascertain whether the noises are due to a definite heart disease or even to a temporary increase of the cardiac activity due to bodily exertions or to psychical excitement. An increase in pressure of the cerebral fluid, and also sounds produced in anaemia, must likewise be thought of. Less frequently the rhythm corresponds to that of the respiration. At times periodically recurring sounds of an irregular rhythm may be produced by the condition of contraction of certain muscles. In these cases a rapid tempo similar to the ticking of a watch may point to a spasmodic condition of the muscular apparatus of the Eustachian tube. The next group of cases dealt with in which no changes in the ear can be found includes those cases with arrhythmical noises. In many cases the noises are the only symptoms of the condition, or by far the most prominent one. The basis on which such noises are produced is most commonly neurasthenic. The author calls attention to the fact that a perfectly normal person hears very similar noises when in an absolutely noiseless room. The difference between the normal perception of noises perceived in a so-called acoustic chamber and those of neurasthenic tinnitus lies in the pathological tendency of the neurasthenic to exaggerated self-observation. The noises are not imagined. He discusses the probable production of the sounds in these cases. Somewhat similar are the noises in hysteria, only in these cases the psychical element is pronounced. In treating of the prognosis of tinnitus he states that much depends on the cause. When there is a neurasthenic basis an examination of the ear and any form of local treatment will probably do harm, and may alter the prognosis considerably. On the other hand, when the cause lies in the circulatory apparatus, cure may be effected at times, as, for instance, when there is an operable aneurysm. Should an aneurysm be present which cannot be dealt with surgically, symptomatic means may do some good. The same holds good in the cases of tumours, goitre, and the like. In the case of cardiac disease, the treatment will have to be directed entirely to the endeavour to compensate the cardiac defect. When the heart condition is amenable to treatment the noises may disappear. In neurasthenia the attention of the patient should be directed from his ear. Suggestion may be employed with advantage. Wittmaack finds it useful to place the patient in a room where some loud, rhythmical noise can be heard. The babbling of a brook or some similar noise in nature, or, failing this, the ticking of a loud alarm clock, may suffice to cover the tinnitus. The prognosis is unfavourable when the tinnitus is due to a combination of neurasthenia and arterial pulsation. Next he turns to tinnitus associated with organic changes of the ear. He discusses the production of noises as a result of inflammatory

processes of the middle ear or of the tube or its pharyngeal orifice. The most favoured view is that the noises are produced in the muscles or vascular apparatus. Common is, further, a fruitful cause of tinnitus. Passing on to catarrhal processes of the middle ear, the formation of adhesions and oto-sclerosis, he admits that the etiology is by no means clear. In the last named the noises frequently take on a pulsating character, which would lead to the supposition that they are produced in the vessels. Acute processes involving the middle ear yield better to treatment than chronic processes, and in the majority of these the otologist will not be able to do entirely without symptomatic remedies. In the last place, he deals with tinnitus arising in the course of disturbance of the internal ear. The treatment depends in these cases on whether one is dealing with an intoxication or infection, a nerve change or a constitutional disease. If a poison can be avoided, such as quinine, salicylic acid, alcohol, or nicotine, the prognosis is in so far good, provided that the damage done is not irreparable. Less good can be done when there is locomotor ataxy, general paralysis, leukaemia, cachexia, or arterio-sclerosis. In conclusion, he deals with what he speaks of as symptomatic treatment. Bromides and valerian are mentioned first. Next, iodides, sweating agents, arsenic, and thyroid substance are cited as yielding good results at times. Counter-irritation, hyperaemia, and hydrotherapeutic procedures are often worth trying. In desperate cases an attempt may be made by lumbar puncture, and, as a last resort, he cites the operative opening of the labyrinth and its destruction. The effect of these various remedies and the actual prognosis of each case will depend on the minute analysis of each case; and it may be possible, when all the participating factors have been considered, to combine several therapeutic measures with beneficial results.

164. Infection of the Kidneys by *Bacillus coli*.

A REPORT by Munich (*Archiv für klin. Chir.*, vol. 98, No. 3) on 60 cases of renal infection, in which bacteriological investigations were made, brings out the following points: As a rule the prognosis in acute unilateral *coli* infection of the kidneys is good, but it is doubtful when both kidneys are involved. The necropsy on two patients who succumbed to the infection showed the kidneys to be permeated with multiple miliary abscesses. The ultimate results of the infection were studied in 21 cases, which the author followed up for a considerable period. In 18 of these the *Bacillus coli* was the only germ found; in 1 case there was a mixed infection, and in 3 cases the nature of the infection was not stated. The treatment was conservative in 11 cases, nephrotomy was performed in 4, and nephrectomy in 6 cases. Subsequently the urine was sterile in 6 cases, in 6 a pure culture of *B. coli* was found, in 6 this germ coexisted with staphylococci, in 1 a pure culture of staphylococci, and in another a pure culture of streptococci, were found. Ten patients showed no symptom, 9 still suffered from occasional but slight attacks of pain in the region of the kidneys, and 2 suffered from severe and continuous renal pain. The author finds that nephrectomy gives good results in cases of severe unilateral infection. But most cases of slight and acute *coli* pyelitis and pyelonephritis require no operation, for they rapidly react to rest in bed, urotropin, and a liberal consumption of water. When fever, rigors, and unilateral pain persist, the author recommends catheterization of the ureter as the best aid to drainage; but he seldom practises lavage of the renal pelvis as advocated by Casper, for he finds this method is no improvement upon simple drainage. He advises nephrotomy when such threatening symptoms as fever and rigors persist, and he admits that when the disease is complicated by pregnancy, the induction of labour may be a necessity. Vaccine treatment he has not practised.

165.

Stenosis of the Duodenum.

ANDRUS (*Amer. Journ. of Med. Sciences*, September, 1912) finds, from a statistical study, that the acquired form of stenosis of the duodenum occurs more often than is generally supposed, and that there exists a somewhat close relationship between this condition and such causative affections as duodenal ulcer, carcinoma, disease of the head of the pancreas and of other adjacent structures. He reports the case of a woman, aged 56, who had

suffered for four years with attacks diagnosed as "acute gastritis." A fortnight prior to coming under observation she had been seized with acute pain and tenderness in the right hypochondrium, lasting about three minutes, and recurring three or four times daily without apparent relation to food. The pain was not referred, and jaundice followed the first attack, and a small mass, which did not move with respiration, was palpable. Gall stones were not present under x rays, but the pylorus was seen to be in relation with the gall-bladder region, suggesting adhesions. After about a fortnight's improvement, vomiting of large quantities of bile-stained fluid recurred without recurrence of pain. At operation the duodenum was found to be markedly adherent to the under surface of the liver and kinked, the stenosis being due partly to the cicatrix of an old ulcer and partly to the kinking from adhesions. From a statistical examination of 262 collected cases, 215 were due to benign causes, and therefore amenable to operation. The absence of meteorism; the presence of biliary, but never faecal, vomiting; the disappearance of the meteorism in the epigastrium after vomiting, and early anuria, are the symptoms recognized as being of major diagnostic importance in stenosis below the ampulla of Vater. In those cases due principally to kinking the diagnosis of duodenal obstruction is generally impossible, such a kink as a rule resulting from adhesions produced by an ulcer or other lesions, and colicky epigastric pains, recurring regularly three to five hours after meals, will usually be present. If the kink is above the ampulla of Vater, the symptoms will be practically identical with those of pyloric stenosis, but of more acute development. If the kinking be below the ampulla of Vater, oft-repeated vomiting of biliary secretion becomes a prominent symptom. When the obstruction is situated at the ampulla of Vater, the condition can usually be diagnosed during life, since the usual gastro-intestinal symptoms with chronic jaundice and progressive emaciation result from the absence of the biliary and pancreatic secretions, and marked dilatation of the stomach and duodenum above the stenosis usually occurs. When below the ampulla of Vater, in addition to the pain and vomiting of bile, the stools will be acholic and constipated, and analysis of the gastric contents will usually show an absence of free hydrochloric acid, due to the reflux of alkaline intestinal secretions from the duodenum into the stomach.

SURGERY.

166. Camphor in Surgery.

LAUREL (*Proc. med.*, January 4th, 1913) writes enthusiastically on the use of camphor dissolved in oil in a great variety of cases. He quotes Lemaire as having written upon the dosage of camphor and its toxicity even in small doses in certain cases. The author has not found it toxic even when given in massive doses in operations involving the peritoneum. There are two methods of administration: (a) subcutaneous, (b) intraperitoneal. Baudel quotes several cases of severe injury with shock, or shock following operation, in which 20 c.cm. of camphor in oil were given. In one case this was repeated three times in one day with marked improvement in the pulse and general condition. There were no toxic symptoms. In every case the breath had an odour of camphor some time after injection. The injections are painless and cause no local reaction. In the intraperitoneal cases, the value of Recklinghausen's discovery that a small quantity of oil in the peritoneal cavity diminishes absorption by the lymphatics and so prevents resorption of toxic materials, is enhanced by the use of camphor in oil, as the latter acts as a cardiac tonic as well as being an antiseptic; further, it diminishes the risk of adhesions. The author in his personal practice has injected as much as 1.0 grams of a 10 per cent. solution. His statistics fully bear out the benefits of the method.

167. Chancre of Thumb Complicated by Suppurative Arthritis of the Interphalangeal Joint.

LEBAR AND JOLEBANET (*Bull. de la Soc. Franc. de Derm. et Syph.*, January, 1913) state that an elderly woman contracted the infection on the dorsal surface of her right thumb four weeks after dressing and poulticing a malignant phagedenic ulcer, with secondary eruption and mucous tubercles, in her son. *Spirochaeta pallidus* were found in both cases. After five days the thumb became painful and swollen and on exploring the ulcer the probe penetrated the joint between the first and second phalanges, evacuating therefrom a small quantity of thin seropus.

The case was turned over to a surgeon, who opened the joint dorsally, and made a counterpuncture on the palmar surface. Healing was very rapid, and in ten days cicatrization was complete without loss of movement in the joint. A day or two later, a maculo-papular eruption made its appearance on the face, trunk, and limbs. The attempts to inject salvarsan had failed, owing to the smallness of the veins, and recourse was had to intensive treatment with mercury, and proto-iodide and biniodide by intramuscular injections, according to Jaquet's method, under which all symptoms subsided, so that in six weeks the woman was able to leave the hospital for out-patient treatment. The author raises the interesting question of the etiology of the arthritis. A suppurative arthritis complicating a primary chancre has no precedent in the literature of syphilis, and the possibility of a specially malignant spirochaete in this connexion cannot be excluded. More probably, however, the common organisms of suppuration (streptococci or staphylococci) must be held responsible, but it is very uncommon for an arthritis due to either of them to be cured without relief in so short a time. The third possibility is the infection of the joint with the organism originally responsible for the phagedaena in the son. It is very unfortunate that an examination of the pus from the joint was not made at the time of the operation.

168. Thiersch's Skin Grafts in Varicose Ulcers.

PETGES (*Ann. hebdom. des sci. méd.*, 1912, xxxiii) warmly recommends the above treatment, which he successfully employed in a case of extensive varicose ulceration of the leg in a man 59 years of age. The ulcers were first cauterized by silver nitrate, and after a week of this treatment were treated by iodine vapour produced by a special apparatus, and after three days the ulcers were ready for skin grafting. In a week the grafts had become firmly adherent, and the ulcers, which had existed for years, were healed in a month after commencement of treatment.

OBSTETRICS.

169. Obstetric Hints.

WRITING from the German obstetric clinic in Prague, H. H. Schmid (*Munch. med. Woch.*, August 23rd, 1912) gives some practical hints, which he thinks will be welcomed by the practitioner. In practically all difficult manipulations, such as version, reposition of a prolapsed arm or cord, and the like, the pelvis should be raised, as is done for spinal anaesthesia. He states that the manipulation becomes incomparably easier in this position than when the patient is lying on one plane. It must, however, be pointed out that the Continental obstetricians employ the dorsal and not the left lateral position. The second point which he touches upon is that of ether anaesthesia. He is of opinion that the dogma of the textbooks that chloroform only may be used in childbirth should be done away with. Chloroform tends to damage both the kidneys and the liver, and it is just these organs which are already more or less damaged during pregnancy. On the other hand, the heart is usually strong enough to withstand the extra strain of the parturition, and he is therefore in favour of selecting ether as the better anaesthetic of the two for childbirth. It can be given by the drop method, inducing a very light unconsciousness, even in very protracted labours. The third subject is that of the suture of the torn perineum. He states that in the majority of large obstetric clinics the obstetrician does not bother about such small details as the suturing of a perineum. It is, in his opinion, absolutely necessary to suture a second degree tear in stages, and to pay special attention to the exact apposition of the muscular layer and the fascia. In order to obtain satisfactory results, two things are necessary: First, the operator must be able to examine the tear carefully in a good light; and, secondly, the patient must keep quite still while it is being sewn up. Both conditions are very materially facilitated by the employment of Braun's local anaesthesia (3 per cent. novocain solution with 0.0005 per cent. suprarenin). Between 50 and 75 c.cm. of the solution is usually required. This renders the parts absolutely anaesthetic, and the operator can inspect the deeper parts of the wound and apply as many sutures as are necessary without causing the patient any pain. If the first point of insertion of the injection needle be through the wound, even the injection need not cause any pain. The wounds heal well by first intention. Further, he calls attention to

the coincidence of the appearance of dyspeptic symptoms in the infant and the getting up of the mother. He explains this coincidence in that while the mother is still kept in bed, the infant is put to the breast at the proper intervals by the nurse. When once the mother gets up she succumbs to the temptation of giving the baby the breast each time it cries, which naturally produces indigestion. In the last place, he recommends ozet baths for premature infants.

GYNÆCOLOGY.

170. Facial Palsy in Child delivered Spontaneously.

CARLSSON (*Zentralbl. f. Gynäk.*, No. 45, 1912) has reported and tabulated some researches to throw light on this complication. Facial palsy is the most common of all the forms of paralysis in the newborn child. In a large majority of cases it follows instrumental delivery, being due to direct pressure of the blade of the forceps on the facial nerve at its point of exit from the stylo-mastoid foramen. Yet it is occasionally observed after spontaneous birth. In that case there may be defective development of the nerve or arrested development of the petrous portion of the temporal bone. Otherwise the paralysis is caused by injury, during birth, to the facial nerve or its centre. Kennedy of Dublin was the first to describe an authentic case (1836), and Carlsson tabulates 36 instances of this condition. The table shows that the paralysis is nearly always peripheral, and is caused by pressure on the facial nerve at its exit from the cranium, just as in forceps cases. In at least 19, if not 20, the pressure was against the symphysis pubis: the twentieth case (Thomé) was complicated by an exostosis of the symphysis pubis, the pelvis being otherwise normal, so that it is not quite of the same type as the 19 previous cases, and, besides, the face presented. In 8 the fetal head was pressed against the promontory of the sacrum, the portion near the ear receiving the most direct pressure. In 4 there was much doubt, in 3 congenital lesions were suspected, although there had been local pressure, apparently, as well; the paralysis remained for months after birth, and no after-history was reported. Pressure from the shoulder was observed in one case; the mother had a very pendulous abdomen; the child was fat, and a deep depression in the integument lay close to the left ear, corresponding to the rounded left shoulder. The relative frequency of injury to the right and left facial nerve could not be ascertained, as reports were deficient as to this point in at least seven cases. In nearly all instances where the question of the pelvis was noted there was moderate contraction, the flat rachitic type predominating. The paralysis disappeared on the average in about a week.

THERAPEUTICS.

171. Phototherapy for Tuberculous Glands.

ISELIN (*Corresp. Blatt.*, No. 20, 1912) relates his experience in the treatment of 202 cases of tuberculous glands with x rays. The results were good; and he states that at Basle during the past three years surgical treatment in these cases has been almost abandoned. The researches of Grober have shown that tubercle bacilli may gain entrance to the lungs by way of the tonsils and retro-pharyngeal glands, and the author considers that the treatment of glands in which bacilli are lodged is therefore of the greatest importance. So long as the glands are single and not softened, he thinks thorough extirpation the best method, but when they are matted together or softened the conservative treatment with light is to be preferred. Direct insolation has proved beneficial in these cases; but it is only in certain places, such as Alpine heights or in hot climates, that it can be satisfactorily carried out. Moreover, experiments by Finsen and others seem to indicate that the effects produced at Leysin on the deeper tissues by insolation must demand some other explanation, for they have shown that not only pigment in or on the skin, but also the red colouring matter of the blood, greatly hinders the passage of the chemical rays. Thus, a piece of photographic paper buried in a dog's body to the depth of 3 cm. remained unchanged after the animal had been exposed to strong sunlight for an hour; and a strip placed behind the lobe of the ear was affected by light much more quickly if the blood were squeezed out of the tissues between two plates of glass. Roentgen rays have the advantage of being more penetrating than sunlight. Petthes has shown that at a depth of 4 cm. the

light retains 40 per cent. of its intensity, and this penetrative power may be increased by passing it through a thin plate of aluminium, which, moreover, filters off the rays most injurious to the skin. The sensitiveness of the skin also may be diminished by any means tending to deprive it of blood; while, conversely, the effect on a diseased area is more intense during the focal hyperæmia induced by a tuberculin reaction, or by Bier's congestion, or in any other way. It is not claimed that the bacilli are killed by the x rays; the intensity of light required for that would destroy the overlying tissues. The success of the treatment is only rendered possible by the fact (which has been verified experimentally) that the light has a more destructive action on glandular tissue and granulations than it has on the connective tissues. The process is slow, and its exact nature has not yet been satisfactorily explained, but the effect on the diseased structures is evident. A few hours after the treatment the parts affected become swollen, but a fortnight later matted glands become separated, abscesses shrink, and fistulae close up after one or two sittings. Caseous glands require about ten sittings, but end by disintegrating without previously undergoing any apparent structural change. The treatment of large masses is long and tedious, and may fail on account of the sensitiveness of the skin to the rays; but the results are better than those of extirpation, for scarring is avoided, and all infected glands are searched out and destroyed by the light. Weitever disputes the view that general infection may follow the destruction of tuberculous glands, but the author has seen this happen once, and temporary disturbance of the general health as an effect of the rays is common. However, the influence on the general health of the patient is usually very good, and the author suggests that the destruction of the tuberculous glands may give rise to some kind of auto-inoculation, instancing in support of this view the injection of sterilized caseous gland tissue by Patersen with the object of raising the opsonic index. In conclusion, the author considers that the use of x rays is of real value in these cases, superior to sunlight in its local effects, but inferior to it in its tonic effects on the whole body. He recommends, therefore, that if possible the treatment should include sun baths for the whole body, with local applications of x rays once every three or four weeks.

172. Arsenic and Pancreatin in Pernicious Anaemia.

L. BRIEGER (*Deut. med. Woch.*, November 14th, 1912) recalls a publication by himself and Trebing, in which they set out that the high antitryptic titre found in persons suffering from carcinoma could be reduced to the normal level by an internal medication with pancreatin. They further found that other carcinomatous patients resisted this action of the ferment. The indications of the previous observations were interpreted as suggesting that pancreatin might when combined with other medicaments prove of some therapeutic use in certain diseases. For example, they suggest the treatment of tuberculosis with tuberculin and pancreatin. Brieger now returns to this idea and states that after a high antitryptic titre was found in the blood of persons suffering from pernicious anaemia, an attempt was made to treat this disease with arsenic combined with pancreatin. The result was beneficial, although only temporary. He gives the clinical histories of three cases. Two of the patients died at a later date, after they had been discharged improved from hospital. The third patient was treated three years ago and is still under observation as an out-patient. She has remained well up to the present. The treatment has therefore to be repeated from time to time, a careful control being exercised in the interval. The high titre has been reduced to normal limits. Brieger repeats that this does not mean cure, since this reduction of the titre was attained in the case of several cancer patients, and was accompanied by a constitutional improvement, but the treatment naturally did not exercise any influence on the carcinomatous process, nor did it arrest the ultimate termination of the disease." He raises the question whether the pancreatin medication may not effect a catalytic action on the diseased tissues.

173. Joha, a Salvarsan Preparation.

SCHINDLER'S salvarsan preparation, joha, has been the subject of a number of favourable reports and a few unfavourable ones. In order to increase the total of cases recorded which have been treated with joha, H. Lindenhein gives his experience in some detail (*Berl. Klin. Woch.*, November 11th, 1912). He has given it in intramuscular injection to 36 patients—seventy-five single

injections. In one case, where he employed Lesser's technique of removing the barrel of the syringe after inserting the needle into the glutens medius, to see whether any blood issues from the needle, sudden dyspnoea, cyanosis, and signs of pulmonary embolus set in. These signs passed off after the administration of opium. In all subsequent cases he employed Schäfer's modification of drawing back the piston of the syringe before removing the barrel, so that if any vessel has been opened the exit of blood from the needle is ensured. He did not experience the same accident again. In one case in which the heart was dilated he experienced a severe cardiac collapse after the injection, and warns others not to inject any salvarsan preparation when there are any signs of cardiac affections. In all other cases the substance was absorbed without any alarming effects. In six cases a slight infiltration *in situ* was noticed. This can, he states, be avoided by directing the patients to rest for twenty-four hours after the injection. The initial dose given was 1 c.c.m. of joha, which is equivalent to 0.4 gram of salvarsan; later he has given 1.5 c.c.m. After a week's interval he gives a second dose of 1.5 c.c.m., so that the patient receives 1.2 grams of salvarsan. The usual combination with mercury salicylate, etc., and potassium iodide, is recommended. He finds from the clinical experience of his cases that joha exhibits all the favourable action of salvarsan, and exerts a rapid healing action on cutaneous and mucous manifestations and malignant syphilis. He finds that it can be employed without keeping the patient in bed, or even at home, and, given the proper technique, he claims that it is free from harmful results, always excluding cases of heart disease.

174. Electro-magnetic Arsenic Treatment of Cancer.

H. SPUDE (*Munch. med. Woch.*, 31, 1912) wishes to secure priority for himself in respect to what he calls the new electro-magnetic arsenic treatment of cancer. He has applied it in two cases, one of a facial "cancer" (a piece was excised for microscopical diagnosis and confirmed the diagnosis of "cancer"), and one of a cancerous tumour of the forehead. In both it was successful. The treatment consists in the local application of finely divided oxide of iron which is subjected to the action of an ordinary powerful electro-magnet with rapidly alternating polarization, thus causing the iron particles to vibrate. The second part of the treatment is the injection of atoxyl, either intravenously or locally. The author attempts to argue the *rationalité* of this treatment. He admits, however, that a purely chemotherapeutic treatment would be more ideal, but since such does not appear to be forthcoming at present, he calls attention to his method, which may yield good results.

PATHOLOGY.

175. Haematogenous Origin of Acute Appendicitis.

WIDAL (*Bull. de l'Acad. de Méd.*, October 22nd, 1912) raises this important question. He submits that a blood culture frequently gives evidence of a pre-existing bacteraemia in localized inflammatory conditions, and relates the case of a woman, aged 45, who was admitted to hospital with a diagnosis of typhoid fever. The patient had been suddenly attacked with fever, rigors, headache, and diarrhoea. There was no vomiting, however, and no epistaxis. The skin was of a subicteric tint, and sibilant and sonorous rales were heard over the lungs. There was slight delirium and an abundant eruption of typical rose-coloured spots all over the abdomen. The diazo-reaction was present. After a few days the typhoid stupor increased, the motions ceased, there was intense meteorism, marked abdominal rigidity, and a peritonitic facies. There was neither vomiting nor nausea. The patient succumbed in a state of coma. On autopsy there were none of the usual indications of typhoid fever in the small intestine. The sclerous present affected the appendix, the caecum, and the initial portion of the ascending colon. On incision into the appendix there were several typical gangrenous lesions, one of which had perforated. The inner surface of the appendix was for the most part covered by a black, putrid material. On the interior aspect of the caecum were found a number of ecchymotic spots. The mesentery was normal, as were the other abdominal organs. Great numbers of short, motile, Gram-negative organisms were found in the appendix. In one instance they seemed to have occupied the lumen of a capillary. Blood cultures taken in the case of this

patient before death resulted in the growth of motile bacilli which were Gram-negative. The appearance of the colonies upon gelatine was intermediate between *B. typhosus* and *B. coli*. Further investigation, including blood serum tests, identified the organism as *B. paratyphoid B*. The peritoneal fluid contained these and also a Gram-positive diplo-streptococcus. The gall bladder contained the same bacillus, which agglutinated 1 in 1,500 of the patient's serum. The author goes on to say that the case had the usual ending of a paratyphoid B septicæmia, and that it emphasizes the view of those clinicians who have been struck with the frequency of appendicitis in infectious diseases. It has been noted in connexion with morbilli, influenza, pneumonia, and scarlatina. Numerous observations, too, have shown that the entry of an appendicular infection may be by a premonitory angina, or even a subcutaneous suppuration. It has been suggested, as the result of some recent experiments, that the appendix acts as an agent for the elimination of organisms circulating in the blood. The author goes on to say that it is not suggested that every attack of appendicitis has its origin in a circulatory infection, but maintains that these results enlarge the field of the diagnosis of infectious maladies by means of blood culture.

176. Chronic Sclerosis in Youth.

DANIEL ROCHER (*Bulletins de la Soc. Anat. de Paris*, March, 1912) describes a pair of kidneys each about 30 grams or 1 oz. in weight. The clinical history is of importance. A girl, aged 16, was admitted into hospital with left pleurisy, and chronic psoriasis all over the body. She was in a torpid condition and died three days later after several uræmic convulsions. She had only left work for about a week, but no information about her antecedents or the beginning of her malady could be obtained. Two and a half pints of serum were found in the left pleura, and the opposite lung was full of white infarcts. The heart and liver were normal. The kidneys were difficult to find, they were sunk deeply back in the loins and had to be dissected out. They were pinkish-grey, with granular surface and adherent capsule. They were both extremely small; on cutting into them only three pyramids were detected, which in the left kidney were hardly definable, being mixed up with dense yellow sclerotic tissue. The cortex in both organs seemed completely metamorphosed and was indistinguishable. Under the microscope the signs of chronic atrophic nephritis were found very advanced, the tubes were scanty, dilated and separated by dense fibrous tissue, the glomeruli very scanty, whilst the arteries appeared unchanged, their coats showing no thickening. A few collections of tubes were detected in areas free from sclerosis, looking like adenomata. They apparently represented compensatory hypertrophy. The fatal result of the acute malady was not remarkable, but the kidneys must have been diseased for a long period, therefore it is remarkable that they carried on their functions for so long without causing constitutional disturbance.

177. The Acidity of the Urine in Lordotic Albuminuria.

NAVY named the albuminuria met with in children which disappears on lying down and reappears in the upright position "cyclic"; Kuttner called it "albuminuria minima," and Neubauer gave it the term "orthostatic albuminuria." Jehle pointed out that in numerous cases the excretion of albumen could be induced by giving the spinal column a lordotic position, and thus suggested the term "lordotic albuminuria." The diagnosis is rendered difficult by the fact that some observers have found blood cells and casts, while others maintain that these are not present in pure cases, and further that cases have been observed in which the albuminuria is intermittent in character, and also that a large number of cases can scarcely be classified in which various kidney and urinary symptoms are met with. E. Fränkel (*Dent. med. Woch.*, October 17th, 1912) has attempted to clear up some of the difficulty by studying the condition of the titration acidity of the urine in cases of lordotic albuminuria. He was able to demonstrate that in a certain number of children (thus affected an increase of the acidity can be recorded simultaneously with the albuminuria, after the spinal column has been placed in a position of lordosis. He has further found that if a sufficient dose of sodium carbonate is previously given no albumen is excreted after this experiment. On the other hand, when there is a distinct nephritis due to scarlatina, with or without lordotic albuminuria, sodium carbonate fails to prevent the albuminuria.

AN EPTOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

178. Endobronchial Treatment of Asthma and Bronchitis.

A REPORT on the treatment of 3 cases of bronchitis and 27 cases of asthma by the local application of drugs is given by C. Heilskov and L. Mahler (*Vgeskrift for Læger*, December 12th, 1912). The treatment was ambulatory only in 5 cases, and all the patients had undergone various other forms of treatment elsewhere in vain. Most had also undergone endonasal treatment with but little benefit. The following procedure was adopted. Half an hour before the treatment a hypodermic injection of 0.5 to 1 cg. of morphine was given. The pharynx and larynx were painted with a 10 per cent. solution of cocaine-adrenalin. The bronchoscope was introduced as the patient sat on a low seat, breathing deep and slowly. The solution, which was administered by a Brining's spray, usually contained the following drugs: Novocain 10 cg., adrenalin 1 gram of a 1 per cent. solution, sodium chloride 9 grams of a 0.9 per cent. solution. When the secretion of mucus is profuse the solution must be applied at intervals, during which the patient coughs up the accumulated secretion. The spray is slowly introduced as far as the bifurcation of the trachea, and as the spray traverses the different bronchi the solution is steadily blown out. In the course of about 120 insufflations the authors have observed no alarming symptoms. It was necessary to repeat the treatment sometimes as often as ten times. Of the cases of bronchitis, 1 was "successfully" treated, 1 was much improved, and 1 was unaffected by the treatment. Of the cases of asthma, 5 were subsequently free from attacks, the period of observation being over one year. In 10 cases there was improvement and in 12 no permanent improvement could be claimed although temporary relief was experienced. In 1 of these cases recovery was apparently effected after the fourth insufflation, but eight days later the attacks recurred and were refractory to further treatment. The patients included 13 men, 16 women, and 1 child. All experienced temporary relief, respiration became less laboured, and they could take deeper breaths for some hours after an insufflation. The expectoration, too, became temporarily profuse in several cases. Many explanations of the benefit derived from the treatment are forthcoming. Nowotny, who sees in asthmatic attacks the result of oedema of the mucous membrane and narrowing of the bronchi by accumulations of secretion, holds that cocaine and adrenalin reduce the hyperaemia and swelling of the bronchi, and that the bronchoscope acts mechanically as an expectorant. Ephraim, who regards asthmatic attacks as a result of spasm of the bronchial muscles, argues that the passage of the bronchoscope may cure asthma, just as the passage of a sound down the oesophagus may permanently cure oesophageal spasm. He considers, however, that anaesthesia and anaemia induced by the drugs are more important factors. The authors think that their good results depend on both factors; but when in 3 cases they introduced the bronchoscope without applying drugs through it, the subsequent improvement was as great as when drugs were also given.

179. Pyelitis in Children.

STILL (*Pediatrics*, October, 1912) describes the symptoms, diagnosis, and treatment of pyelitis in children. The fact that the disease is most prevalent in female infants under 2 years of age is consistent with the view that infection ascends through the urinary tract from faecal soiling of the vulva. Though occasionally the route may be via the blood, as is the case when seen in boys. Abrupt in onset, the child suddenly goes cold and blue, with or without an actual rigor, and is found to have an otherwise unexplained fever unless the urine has been examined, which is the one essential in diagnosis. Albumen may be so slight as to be overlooked by the nitric acid test, and consequently the test by boiling a layer should be used. Even with only a trace of albumen and an apparent absence of deposit, a few pus cells will be found microscopically, six, or even fewer, to the field being sufficient to account for a severe attack. Since only a spot or two of urine is needed for this purpose it is possible to obtain this, even in quite small babies, by arranging a mackintosh under the child, and it is best to examine from a shaken-up specimen rather

than from one which has stood, or been centrifugalized, since it is important to have a standard of comparison, not only of the presence of pus cells, but also of how many there are to a field. The urine is markedly acid, and under a one-sixth objective shows an average of six to thirty pus cells per field, and occasionally bacilli either singly or in clumps may be seen. When the disease has become chronic, and in older children, the diagnosis is often difficult unless the urine is examined, among the most common mistakes being tuberculous meningitis, cerebro-spinal meningitis, typhoid fever, a latent pneumonia, influenza, gastro-enteritis, or dentition. Rarely will it be necessary to obtain a catheter specimen, though care must be taken in children suffering from vulvo-vaginitis that the specimen is not contaminated from this source. Prognosis is good under treatment, which consists mainly in alkalization of the urine. The alkalinity must be maintained night and day for at least a week or ten days after all symptoms have subsided, and for this purpose potassium citrate in 5-grain doses should be given every two hours during the day, and every three hours by night. The urine should be frequently tested with litmus directly it is passed, and in order to keep up the alkalinity it may be necessary to increase the dosage up to even 20 grains every two hours. Should the larger doses disturb digestion, sodium bicarbonate or potassium may be substituted to maintain alkalinity when once this has been obtained by the citrate. Occasionally the alkalis fail, when urotropine or salol, or in obstinate cases an autogenous vaccine, may be tried; 10 to 15 minims of brandy may be needed every four hours if the large dosage of potassium citrate causes depression, and if any tendency to convulsions develops, $\frac{3}{4}$ to 1 grain of phenazonium, with 2 or 3 grains of sodium bromide, may be given to a child from 6 to 12 months old. This should be given in a separate mixture, so as not to interfere with the frequent administration of the potassium citrate.

180. Reflex Contractions of the Large Intestine.

LEBON AND AUBOURG have presented before the Société de Radiologie médicale de Paris (*Bull. et mém.*, January, 1913) a number of bismuth radiographs to illustrate the fact that direct excitation of the stomach and first part of the small intestine may increase the peristalsis of the colon. A subject who had been given a meal of rice containing 100 grams of bismuth carbonate in the evening was radiographed twice next morning, once at 9.45, without having taken anything previously, and again at 10.30, after the ingestion of two glasses of milk. The changes produced during this brief interval were indicated clearly by the form of the bismuth mass, and were shown to affect the ascending, transverse, and descending colon. By other experiments the authors show that these modifications of the colon are produced rapidly, and are not due to gaseous distension of the stomach, nor anything save reflex contractions of the large intestine. The ingestion of exciting substances demonstrates that the stomach is one of the generalized zones of colic contraction. The absorption of a cachet of quassia powder provokes this contraction, but the effect is much more rapid and notable if a tablespoonful of water with 2 mg. of quassin be taken, the appearance of the contents of the large intestine being modified within a few minutes. Caffeine and caffeine citrate act in the same manner, and the drinking of a cup of strong coffee sends the bismuth material in the ascending colon towards the iliac colon, without the production of antiperistaltic movement. The authors have also examined the large intestine after percussion of the lumbar vertebrae, and comparative radiographs show that this undoubtedly produces modifications of the large intestine. They add that vertebral reflexotherapy has given good results in constipation.

181. Radiographic Examination of "Typhoid Spine."

THE "typhoid spine," as it is called, or that complication of typhoid fever in which the patient complains of pain in the lumbar and sacral regions, has been studied radiologically by Anclair, Weissenbach, and Aubourg (*Bull. et mém. Soc. de Radiol. méd. de Paris*, January, 1913). Clinical examination in such cases frequently reveals antero-posterior and lateral deviations of the spine. The evolution is subacute, lasting usually from three months to one year, and terminating as a rule by resolution. As

a result of the radiological examination of typhoid patients having this vertebral complication, the authors divide the visible lesions into three orders: (1) Very small lesions of the vertebral body, such as are found in osteitis; (2) lesions of the intervertebral discs, characterized by the absence of a clear space between the vertebrae; (3) a lesion, appearing to be the result of a special process, which takes the form of a thick "muff" surrounding the spine, and by its opacity probably hides other lesions of the vertebral bodies or discs. This perivertebral thickening is not dissimilar from the appearance seen in certain forms of Pott's disease. The authors do not suggest that it is characteristic of typhoid spondylitis, for spondylitis of other infectious origin than that of Eberth's bacillus may give the same spinal aspect, but upon this point there is little information available. The curious feature in connexion with the vertebral appearance in typhoid, according to these authors, is that there are two phases of evolution. In the acute stage there are no distinct lesions visible, but only a certain deviation of the lumbar vertebrae. The perivertebral thickening above described only makes its appearance towards the end of the acute stage, and the authors are of opinion that the opacity is due to the infiltration of calcareous salts.

SURGERY.

182. Local Anaesthesia in Fractures and Dislocations.

TWO methods of inducing local anaesthesia in fractures and dislocations of the limbs are discussed by H. Braun (*Deut. med. Woch.*, January 2nd, 1913). For the arm, the best method is the injection of an anaesthetic, such as novocain-suprarenin, into the brachial plexus as it passes over the first rib. Carried out skilfully, this procedure ensures complete paralysis and anaesthesia of the whole arm; and it is available also for dislocation at the shoulder-joint. The other method is preferable in injuries to the lower limb, and consists of injecting an anaesthetic directly into the site of the fracture or dislocation. The author uses a 1 per cent. solution of novocain-suprarenin, which he injects after the lesion has been investigated by the X rays and other methods, and after the skin has been painted with tincture of iodine. The anaesthetic must be injected from several quarters and in many directions; and, when considerable displacement has followed a fracture, the ends of the fractured bone require separate anaesthesia. Similarly, when two bones in a limb are fractured, all four ends may require separate anaesthesia. After a dislocation the anaesthetic is injected around and into the joint. Anaesthesia soon becomes complete, and the muscles relax as under a general anaesthetic. The beneficial results of the latter are thus attained without that danger to life and struggling which the induction of general anaesthesia provokes. In the course of a year the author has treated about 50 cases of fracture and dislocation by this method. Many other cases of dislocation of the fingers and compound fracture of the arm were reduced or set after the brachial plexus had been anaesthetized. No accident followed either method, and a sepsis was followed by scrupulous cleanliness, and by not introducing the needle through unhealthy skin. A detailed account of two cases of dislocation at the hip are given, as this is a difficult joint to anaesthetize locally, and the test of the method's reliability is in other respects severe. In one case the dislocation was sciatic and recent. A long needle was introduced at two points in the gluteal region, and 25 c.cm. of the anaesthetic were injected over the head of the femur and 20 c.cm. into the acetabulum. The femur being dislocated, it was no longer a guide to the acetabulum, which was therefore sought by introducing the needle immediately behind the anterior superior spine of the ilium. The needle's point was now kept close to the ilium on its course to the acetabulum, and an innominate bone was held by the patient's side to act as a further guide. When the acetabulum was reached a small quantity of blood was aspirated. The injection was almost immediately followed by relaxation of the previously rigid muscles, and in ten minutes reduction of the dislocation was easily effected. The patient experienced no pain during the reduction, and the only source of discomfort was the tight grip of the operator's hands. In the second case an obturator dislocation had lasted forty-eight hours; 20 c.cm. of the anaesthetic were injected about the head of the femur, which was palpable below the adductor muscles. The acetabulum was reached by the same route as in the first case, and in a few minutes the limb was relaxed. There was, however, still some pain in the region of the great trochanter, and 10 c.cm. of

the anaesthetic were accordingly injected around the bone from the outer aspect of the thigh. Five minutes later anaesthesia was complete, and the dislocation was reduced at the first attempt.

183. Impassable Cicatricial Contraction of Oesophagus.

DELAGENIÈRE (*Arch. prov. de chir.*, December, 1912) points out that in the opinion of oesophagoscopists 2 per cent. of all cases of cicatricial contraction are impassable from above downwards. These cases are suitable for endo-stomachic treatment by retrograde dilatation, because the obstruction lies mostly at the lower end of the oesophagus. He has already reported cases dealt with by this route, and he now puts on record two more. The first was acute: the man was operated on fourteen days after having swallowed a quantity of ammonia. Unsuccessful attempts having been made to pass bougies from above downwards, laparotomy was performed, the stomach opened, and a rubber oesophageal bougie passed along the finger through the obstruction of swollen mucosa from below upwards towards the pharynx. A catheter of the calibre of the bougie was passed by means of the first instrument and kept in position, with the eye end in the stomach, and the stomach wound was closed. Jejunostomy was then performed, to allow of the feeding of the patient, because of the inflamed state of the gastric mucosa. The patient, however, succumbed a few hours later. The second case was operated on two months after the swallowing of the caustic solution, and by that time complete occlusion had occurred. Through the opening made in the stomach the lower end of the oesophagus was found to be simply a cicatricial mass with a central depression. A crucial incision was made in this mass and a sound passed from below upwards. The patient was meanwhile fed by the gastrostomy wound, and very slow gradual dilatation accomplished from above downwards, though the patient was unable to take ordinary food till about the fortieth day after operation. Three weeks after the first operation the gastrostomy wound was closed. Delagenière advocates the method because the opening in the stomach permits examination of its wall and the operator may decide at once whether gastrostomy or jejunostomy will best serve for feeding. Then absolute rest of the oesophagus may be obtained, so that an impassable stricture may become passable. Lastly, retrograde progressive dilatation may be practised through this opening. As regards technique, the author makes a fairly large opening into the stomach and tries by means of a speculum to see the oesophageal orifice. This manoeuvre may be rendered easier if a cushion or sand pillow be placed beneath the patient, as is practised in gall-bladder operations. To make the incisions in the cicatrix he uses a bistoury; the urethrotome of Albarran is also of value. The orifice is then dilated by sounds and one is passed into the now widened opening, its outer end being fixed in a small stomach wound made for the purpose; the large wound is then closed. Delagenière does not now use the silk thread method of Abbé, as he believes that when the stricture is rendered permeable by bougies sufficiently large, passed from below upwards, and the oesophagus put at rest by the gastrostomy, the stricture can be efficiently treated by dilatation from above.

184. Osteo-Synthesis for Fracture of Humerus.

BRAU-TAPIE (*Gaz. hebdom. des sc. méd.*, xxxiv, January 3rd, 1913) relates the case of a child, aged 6, who sustained a compound fracture of the lower extremity of the humerus. An ivory peg, about 2 mm. in diameter ($\frac{3}{16}$ in.) was introduced into the lower segment and directed upwards, posteriorly and externally, into the humerus. The wound was drained and a plaster bandage applied. Fifteen days later active and passive mobility of the joint to 90 degrees were possible.

OBSTETRICS.

185. Pituitary Extract as an Ecbolic.

E. HAUCH AND LÉOPOLD MEYER (*Arch. mens. d'obst. et de gynéc.*, No. 10, October, 1912) record some interesting results of an experimental inquiry into the value of pituitary extract in childbirth. They have employed pituitrin (Parke, Davis and Co.) in 0.5 c.cm. doses in 65 cases at the Rigshospital in Copenhagen, and state that the drug has quite fulfilled their expectations. No untoward results were noted in either mother or child, even when the dose was repeated, and the influence

upon the course of labour in the majority of cases was remarkable. Nineteen failures were encountered, but these included 7 abortions and 2 premature labours. Hauch and Meyer's experience is in accord with that of other authors, who have stated that pituitrin is less efficacious the earlier it is used in pregnancy. The drug is most useful when employed to stimulate pains following secondary uterine inertia. It is less useful in the case of primary inertia and will not induce labour. The authors quote in detail 6 cases where the extract has been successfully employed to terminate labour rapidly when delay was experienced during the second stage. In no case was forceps required. They have also successfully used it in a case of twin labour with prolapse of the cord. Both children were born alive. With regard to pelvic contraction, they note that the disproportion between the head and brim should not be too great. In some cases of fetal distress, however, pituitrin may be employed with advantage. Immediately the indication for artificial delivery occurs an injection may be given, and in many cases it will be quite unnecessary to use forceps. The authors also record their experience of the drug in cases of placenta praevia. As mentioned previously, pituitary extract is not of the same value at the commencement of labour, and hence it is not to be expected that it will prove an infallible remedy in placenta praevia, where symptoms occur usually before labour has begun. However, in 7 cases occurring at the Righospital, 4 successes are recorded, and the authors conclude that in cases of lateral placenta praevia, when labour has commenced, some measure of success may be attained if injection is combined with rupture of the membranes. Care is required, however, as in the majority of cases haemorrhage continues for some time after the administration of the drug, and it is necessary by external manipulation to force the head into the pelvis. Further trials are required before more definite statements can be made, but the results so far obtained are sufficiently encouraging to warrant continuation of this treatment in placenta praevia.

186. Prognosis and Prophylaxis of Albuminuria in Pregnancy.

LEPAGE (*Ann. de gynec. et d'obstet.*, October-November, 1912) discusses this question in full in all its phases. The obstetrical prognosis of a pregnancy with albuminuria, occurring in a subject where the complication has attended a previous pregnancy, is the more favourable the better she is watched and the better she follows the advice of her physician throughout gestation. Care is needed from the very beginning of pregnancy. When in a previous pregnancy there have been eclamptic attacks or premature detachment of the placenta requiring interruption of the labour, the urine must be examined once a week at least, and every month—especially in the seventh, eighth, and ninth months—the urine should be submitted to a complete analysis. Lepage considers that the patient may be profitably instructed how to test for albumen herself. The diet should be almost restricted to water and milk. Lacto-vegetarian diet is allowable when the complication during a previous pregnancy was relatively mild. Diet to effect dechloruration is needed in some cases. Piard's *régime blanc* (milk, puddings, white meat) is to be allowed when, although the patient has been subject to the characteristic intoxication, marked by albuminuria in one of her previous pregnancies, she has also passed normally through one or more besides. General hygienic measures are imperative, as chills, overwork, and fatigue involve great perils. Arterial tension must be noted, as it may be necessary to bleed the patient.

GYNAECOLOGY.

187. Tuberculous Dermoid Cysts of the Ovary.

CHATELONNET AND PIERRE-NADEL (*La Province méd.*, No. 28) publish a case of this very rare condition. The cyst removed by them had the usual contents of a dermoid. In the wall were multiple thickenings suggesting malignant degeneration. Microscopical examination showed that the greater part of the wall contained very thick inflammatory tissue presenting the usual histological characters of tuberculous lesions. Besides perfectly schematic Koster's follicles, there were softened grumous masses without histological characters, some of which were invaded by many polynuclear leucocytes. There was a tendency to encapsulation and cicatrization of the lesions, in short, a classical picture of nodular tubercle

was presented. Tuberculosis developing on a dermoid cyst is far more rare than malignant degeneration, and also than tuberculosis of a mucoid ovarian cyst. In nearly all cases the lesion is secondary to a tuberculous focus in the genital organs, but in this case the vagina, the uterus, the tubes, and the peritoneum were absolutely healthy; the other ovary contained a mucous cyst the size of an egg. Tuberculosis of the ovary is very exceptionally primary; most often it is the tube or the peritoneum that is the starting point, whence the ovary may become infected by the lymphatic channels or even directly through the rupture of a follicle. Gorizontor has demonstrated the truth of this by experiment; after inoculation genital tuberculosis developed far more often from peritoneal inoculations than from subcutaneous, intestinal, or pulmonary inoculations, and the most frequent seat was the cellular tissue of the ligaments, then the tubes and uterus, last the ovaries. This case, however, proves that tuberculosis of the ovary or its tumours may be primary, or rather, that it may be "locally" primary, for it is very probably secondary to some hidden deep-seated tuberculous focus, infection being conveyed by the blood stream. The writers throw out the hypothetical suggestion that the twin embryo which the dermoid cyst represents may have been tuberculous from the origin, perhaps hereditarily, either alone or at the same time as the subject which carried it.

THERAPEUTICS.

188. Treatment of Leukaemia with Thorium X.

W. FALTA, KRISER, AND L. ZEHNER (*Wien. klin. Woch.*, No. 12, 1912) report on 5 cases of leukaemia treated with thorium X. Thorium X may be administered in the form of a soluble compound either per os or subcutaneously, but the authors found that when administered per os the effect was less constant and less intense, so that, in the experiments described the subcutaneous method alone was employed. Experiments on guinea-pigs, rabbits, and dogs have shown that after a moderate dose of thorium X the number of leucocytes first rises and then quickly falls and remains lower than before for a considerable time, while otherwise the animals show no striking change; with very large doses the fall is very rapid, and leucocytes may altogether disappear from the circulating blood, the animals dying with symptoms of increasing weakness. All the experiments go to show that (1) thorium X has an intense selective action on the leucocytes, and (2) that with suitable dosage no other injury to the organism results. The selective action is similar to that seen with enormous doses of radium emanations and with strong Roentgen-ray applications, but exceeds either in effectiveness. The author next tried the effect of thorium X on the leucocytes in cases of advanced carcinoma in human beings and found it to be the same as in animal experiments. The first patient treated for leukaemia was a man 43 years of age, suffering from severe lymphatic leukaemia and tracheoma of at least three years' duration. The patient in the months before thorium X treatment was begun had been treated by raying, and at first had appeared to improve, but latterly the raying had no effect, and the number of leucocytes had risen to 1,000,000. At the beginning of the thorium X treatment the number rose still further up to 1,700,000, but then fell rapidly to 20,000, while the subjective condition also improved. In the course of three days the number rose again to 180,000, but after further injections came down to under 100,000; the spleen diminished in size, and became no longer palpable, and the glands became smaller and softer. About five days after the last injection severe pneumonia developed, and proved fatal after nine days. Observation of the other cases does not support the idea that the development of pneumonia depended on the treatment. The next case was of lymphatic leukaemia in a woman 52 years of age, whose symptoms dated from the beginning of 1909. In 1910 this patient had been treated by raying. When she came under the author's care the number of leucocytes was between 600,000 and 700,000, the lymphocytes about 95 per cent.; the spleen reached to the symphysis, and to the right beyond the umbilicus; the liver was increased, the abdomen distended and tense, and the patient could scarcely sit up as a result of weakness. Under treatment with thorium X the leucocytes fell so that after twenty-six injections the number stood at 200,000, lymphocytes 86 per cent.; the spleen was smaller and softer, the abdominal walls were soft, the patient's subjective condition was good, and she was able to help in the work of the ward. In two cases of myeloid leukaemia the results were equally

good, though in one of them the thorium treatment was begun five days only after a last Roentgen-irradiation, so that this may have conducted to the result. The cases are too recent for conclusions as to the permanency of the results or as to the relative value of thorium X and Roentgen-ray treatment: the most that can be said on the latter point is that in two instances in which Roentgen-ray treatment was no longer effective the use of thorium X led to improvement, but it is always possible that if thorium X after some time failed, Roentgen-ray applications might be effective. Thorium treatment allows of graduated dosage, and avoids the danger of injury to the skin from the rays, but whether it is likely itself to cause injury is not as yet known. Further observations are required.

189. Radiotherapeutic Treatment of Chronic Adenitis.

MAX ROQUES (*Arch. d'Electr. méd.*, July 25th, 1912) states that x-ray treatment acts very favourably in chronic adenitis due to micro-organisms. The inflammation rapidly clears up, and the aesthetic result is superior to that obtained by incision and drainage. All the varieties of peripheral glandular inflammation are more or less amenable to radiotherapy, but of course an advanced generalized condition or a severe intercurrent affection may negative or modify the x-ray treatment. The x-rays are also useful in intrathoracic adenopathies, the diminution or disappearance of the cough, hoarseness, and other symptoms testifying to the value of such a procedure. Except when the general state is extremely grave radiotherapy should be essayed in the case of intra-abdominal tuberculous glands, especially when operation is contra-indicated, but a special degree of watchfulness is required in view of the local and general reactions. The author enters minutely into questions of technique. He employs one (or more) of three standard dosages:

| | Milliamperage. | Time of Exposure. | Distance of Anticathode from Skin. |
|-----------------|----------------|-------------------|------------------------------------|
| Weak dose ... | 0.5 | 10-20 min. | 15 cm. |
| Mean dose ... | 0.8-1.3 | 20-30 min. | 15 cm. |
| Strong dose ... | 1.0-2.0 | 30-50 min. | 15 cm. |

Generally speaking, he prefers to administer a massive dose at one sitting, or in the course of two or three sittings within two or three days, followed by a rest of from twenty to twenty-five days. But he modifies his technique according to the clinical variety and phase of the case before him, and when the case seems to require it he uses, instead of the massive dose, a mean dose given about every eight days, or small doses repeated every two or three days. He employs also a large series of aluminium filters, varying in thickness from 0.1 mm. up to 1 mm. In intrathoracic adenitis, after having determined by means of the x-ray screen the situation of the principal glands affected, and having traced them on superimposed radiations, he uses the massive dose method, and takes advantage of four points of entrance for the rays—two lateral and one anterior and one posterior. In intra-abdominal adenitis, a smaller or the mean dose administered with eight day intervals is the more prudent. If there are several perceptible masses, each mass should be exposed in a complete sitting or in part of a long sitting, according to the indications furnished by the general state.

190. Rhodane.

L. V. DALMADY (*Wien. klin. Woch.*, No. 21, 1912) has made use of sodium rhodanide for the last seven years in the treatment of the lancinating pains of tabetics, of arteriosclerosis, and of angiospastic migraine, and has made trial of it in other conditions also. He gives the drug in a mixture made up with water and syrup, or in drops of a concentrated 1 in 10 solution. The single dose of sodium rhodanide is 0.15 to 0.25 gram (2.3 grains to 3.9 grains), and from 0.45 to 1.25 grams (6.9 grains to 19.5 grains) can be taken per day. No unpleasant side-effects were observed, except that in a case of bronchial asthma in which the drug was given experimentally a rhodane catarrh similar to an iodine catarrh developed. The cases of lancinating pains treated were those in which the pains were a prominent symptom and had proved resistant to the ordinary analgetics. With a few exceptions, the favourable effect, both on the pains and on the general condition, was unmistakable. It became evident from the third to the fifth day after the beginning of the treatment,

and could not, therefore, have been the result of suggestion. In some cases the attacks of pain were altogether stopped, but in the majority the attacks merely became fewer in number and the pain less severe. The treatment was continued at longest for a month continuously, and the effect was noticeable for two or three weeks longer. The danger of the drug losing its effect was lessened by this method of administration, but in one case the cure proved ineffectual when tried for the third time, and the patient had to fall back on the older analgetics. The author's impression was that the paraesthesias, and especially the girdle sensation, were favourably influenced. Rhodane treatment was tried in five cases of angiospastic migraine. In a typical case described the patient, who was 46 years of age, had suffered from severe migraine attacks since the age of 14, sometimes as often as three times in a week. After taking rhodane for ten days the patient had no attack for forty days, a longer free period than ever before. She then had a severe attack; treatment was begun again, and another free period of forty days followed. Since that time the patient has taken three or four rhodane cures yearly, each cure lasting from ten to fourteen days, and she has remained free from migraine. In a case of a peculiar neurosis of the sympathetic, in a man 35 years of age, rhodane proved successful where water cures, electric treatment, and bromides had failed.

PATHOLOGY.

191. Deaths after Neo-Salvarsan.

DARIER (*Bull. de la Soc. Franç. de Derm. et Syph.*, November, 1912) records two cases which occurred in young men aged respectively 31 and 28. The first was suffering from tertiary tuberculo-verruccose manifestations on both upper extremities, but otherwise was in robust health; the other was a weakly individual in the secondary stage, with pronounced pulmonary tuberculosis and albuminuria. Both cases had already received courses of mercurial injections. The neo-salvarsan was given intravenously to both patients, according to Ehrlich's directions. The first case received on September 25th 0.6 gram, and on September 26th 0.75 gram, without toxic manifestations. On October 2nd a third injection of 0.9 gram was given, and on October 6th, sixty-seven hours after the last injection, he died in convulsions, with a temperature of 105 F. The other patient, after receiving successively on September 28th, October 2nd and 5th, 0.45, 0.75, and 0.9 gram of the drug, died in a similar manner on October 14th, nine days after the last injection. In a lengthy survey and discussion of these two cases and six others of a similar kind the author comes to the following important conclusions: (1) Neo-salvarsan would appear to be more dangerous than salvarsan. (2) Neo-salvarsan can produce very serious nervous symptoms, notably encephalomyelitis and progressive neuritis of an arsenical type. (3) Exceptionally it may cause death with symptoms of acute arsenical poisoning. (4) These catastrophes are caused apparently by retention of the drug, due to inefficient or slow elimination, and at the present moment we have no criterion which can certainly enable us to prevent occasional accidents. It is obviously impossible to refuse administration to every case in which there would appear to be lesions of the kidney or liver. His advice is to begin treatment with small doses (a minimum of 0.2 gram or 0.3 gram at first), and to increase the dosage by reasonable amounts, with minimal intervals of five or seven days, and to be sure that the preceding injection was not followed by any symptom of intolerance, and to ascertain that the urinary excretion of arsenic is proceeding normally.

192. Thomsen's Disease, or Myotonia Congenita.

DÉJÉRINE (*Journ. des praticiens*, 1912, lvi) describes a case of this rare disease in a patient, a man 44 years of age. All the signs of the disease were well marked. The author, with Sottas, was the first to make an autopsy on such a case, but found no lesion of the nervous system. The muscles were enlarged, and vacuoles existed in the fibres, with an increase of the nuclei of the sarcolemma, and a hyperplasia of the interstitial tissue. The author considers that the muscle is the seat of the muscular phenomena, and the latter are the result of an abnormal development of striated muscles. For a complete consideration of the disease Erb's monograph should be consulted.

AN EPIITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

193. Tuberculin in Febrile Phthisis.

IN a paper illustrated by numerous temperature charts, J. W. Samson (*Berl. klin. Woch.*, November 25th, 1912) reports favourably on the use of very small doses of tuberculin in febrile phthisis. Hitherto some authorities, including Sahli, Bandelier, and Röpke, have occasionally obtained good results by this method, but others have reported unfavourably on it. The author holds that though small doses of tuberculin have been given they have not hitherto been small enough, and that doses as small as 0.00001 mg. of old tuberculin or 0.0001 of Koch's bacillary emulsion are not ineffective. The first and last doses which he gave in one case were 0.0001 and 10.0 mg. of old tuberculin. In another case the first and last doses of bacillary emulsion were 0.0001 and 0.8 mg. In another case the initial dose of bacillary emulsion was as small as 0.00001 mg. The tuberculin treatment of febrile phthisis differs in many respects from the treatment of afebrile cases with tuberculin, for not only must the initial dose be very small, but no attempt must be made to reach those large doses to which early cases of afebrile phthisis may ultimately attain. The disappearance of fever is often the only effect of the tuberculin, and the author is careful to point out that a fall of temperature is not necessarily synonymous with the arrest of the disease. He confirms the observations of other workers that the temperature generally persists at the same level until several injections have been given, when it falls to normal. This is the case with slight and moderate fever in the first and second stages of the disease. In the third stage this effect is only obtained in a few cases. By his cautious dosage the author aims at avoiding reactions of which the focal reaction, indefinitely prolonged, is most harmful. He has observed as the result of relatively large doses a state of "protracted focal reaction" with increased physical signs over the lungs, increased cough and expectoration, and more than the usual number of bacilli in the sputum. By the adoption of his minute doses these symptoms are avoided; and if the temperature is further raised by an injection it is not repeated till the temperature has fallen to its former level, when a similar dose is given. This dose is now repeated, and only when it causes no reaction is it increased. Intervals of only three to five days are allowed between each injection so long as no reaction occurs. It matters little what form of tuberculin is used, but it may be advisable to avoid old tuberculin in advanced laryngeal tuberculosis for fear of a focal hyperæmic reaction. In addition to the two forms of tuberculin already mentioned, the author recommends Fritz Meyer's sensitized bacillary emulsion. In the process of gradually raising the dose of tuberculin, special care is necessary at the transition between solutions of different strength, for reaction to tuberculin depends not only on the actual amount but also on the concentration. The view that small doses of tuberculin render the body hypersensitive is a common fallacy due to a confusion between intolerance to vaccines and serum anaphylaxis. Only by large or too frequent doses of tuberculin can its therapeutic action be destroyed. The patients suitable for this form of tuberculin treatment are those whose fever has persisted in spite of hygienic and dietetic treatment, and who are unsuitable for the artificial pneumothorax treatment. Patients whose fever disappears on treatment with tuberculin fall into three groups. In one the pulmonary disease grows less and its permanent arrest may be effected. In another the pulmonary disease remains stationary, but the weight, appetite, pulse, and general vitality show marked improvement, and life is much prolonged. In a third group the disease is progressive in spite of a normal temperature. Life is, however, prolonged by some months, which are passed in relative comfort. A similar condition is sometimes found among patients who, without any specific treatment, became afebrile shortly before death. In both cases the cessation of fever induces a feeling of well-being and health, the attainment of which in the moribund is alone sufficient warrant for the treatment.

194. Acute Abdominal Aortitis.

MINET, LECLERCQ, AND HOLLEAU (*L'Echo méd. du Nord*, 1912, 1x) consider this disease under the following headings: (1) *Symptoms*.—(a) Accessory. Pain is habitually

the first symptom to occur, and increases quickly in severity. It takes on the form of violent cramps in the stomach, intestine, liver, or kidney, and simulates disease of these organs. It may radiate to the lower limbs. The dorsal position seems to aggravate it. Nausea, vomiting, constipation, flatulence, diarrhoea, and even hæmorrhage may occur with it, but are very variable. Intense dyspnoea, vertigo, intermittency of the heart, which feels as if it stopped between the stomach and the abdomen, had also been noticed. (b) *Essential*. Pain most often just above the umbilicus, painful on pressure, enlargement of the aorta, which can sometimes be detected, and deviation and mobility of the vessel, usually to the left side, with marked pulsations and contraction of the right rectus muscle, form a symptomatic triad to which Potain has drawn attention. Hypertension of the dorsalis pedis artery is very frequent, and Teissier finds that the degree of aortic irritation is generally proportional to this hypertension. Elevation of the temperature nearly always occurs during the attacks of aortitis, and persists for a variable length of time. (2) *Complications*.—Gastric crises characterized by violent pains in the stomach, nausea and vomiting are frequent. Intestinal crises are more rare, and manifest themselves by pain in the bowels and diarrhoea. Mucous-membranous enterocolitis seems to have some narrow relationship to abdominal aortitis. Nephritis is rare, and likewise appendicitis. Emboli are extremely infrequent. Asphyxia of the foot, with threatening gangrene, has been noticed. (3) *Evolution: Prognosis*.—The disease sometimes sets in suddenly, and sometimes insidiously. Cure is sometimes rapid, and sometimes the symptoms last for weeks or months. An acute case never becomes chronic. The prognosis is usually favourable, but death has occurred. Aortitis of the abdominal aorta is less serious than that of the thoracic part. (4) *Diagnosis*.—Abdominal pain at the level of the aorta, or deviation and incurvation of the vessel, and hypertension of the dorsalis pedis, permit of the diagnosis of acute aortitis. Tabetic crises very similar to aortic crises can be excluded by the presence of other signs of tabes. In cases of aortic aneurysm and abdominal crises from various diseases the absence of hypertension of the dorsalis pedis will generally give a clue to the diagnosis. (5) *Etiology and Pathogeny*.—Primary acute abdominal aortitis is very rare, and it is said to have occurred after cold, fatigue, and trauma, and infections, as influenza, typhoid fever, scarlet fever, etc. It is more commonly the result of secondary causes by propagation from one of the neighbouring organs. The majority of the symptoms are of reflex origin from the periaortic and pericardiac plexuses, or from the large sympathetic. (6) *Treatment*.—Rest in bed. Very warm fomentations, belladonna plaster, blisters, leeches, have their advocates. Aspirin, sodium salicylate, amyl nitrite, trinitine, bromides, especially the salt of strontium (1 to 2 grams per diem), belladonna, valerian, have all been recommended. Convalescence can frequently be hastened by mineral water, especially at Royat, Plombières, or Châtel-Guyon.

195. Thrombo-phlebitis in Typhoid.

CONNOR (*Archiv. of Intern. Med.*, December 15th, 1912) regards many of the obscure late interruptions of the normal course of typhoid as having a common underlying cause in thrombo-phlebitis. Although the incidence of this complication is usually placed at 2 per cent., an earlier recognition of milder and less characteristic manifestations will show that venous thrombosis occurs in from 10 per cent. to 15 per cent. of all cases of typhoid. The development of the condition is gradual and commences long before its classical symptoms develop, so that these latter appear only late in the process, which is much more extensively disseminated than the actual symptoms indicate, and even with the frank symptoms of the trouble quite circumscribed there is usually a widely scattered thrombosis. Notes of 63 cases are given, clearly pointing to the conclusion that a very large proportion of the pulmonary and pleural complications of typhoid are embolic in nature, especially those in which the embolus is small, the symptoms mild and transient, and the prognosis good, the signs occurring several days before any of the usual local symptoms of phlebitis can be discovered. It was further noted that, in cases complicated by phlebitis, multiple chills, for which no satisfactory

cause has hitherto been assigned, were frequent, and in those cases where no phlebitis was recognized symptoms suggestive of pulmonary embolism occurred, so that it was difficult to escape the conclusion that these obscure multiple chills bear some direct relation to the thrombotic process in the peripheral veins. Another occasional complication occurring late or during convalescence is a condition of painful and exquisitely tender toes, and, although the causal relation between phlebitis and this condition is not proved, the association of the two is so frequent as to warrant an assumption that such association is not merely accidental. From the transient character of the symptoms and the lack of trophic changes, it can hardly be attributed to an actual neuritis, and it is probable that there is a primary thrombosis of the veins in the region of the heel, and that the subsequent periphlebitic exudate irritates the closely adjacent plantar nerves, and such a cause may underlie many of the cases of localized neuritis which frequently complicate typhoid fever. There is no entirely satisfactory explanation of the cause of the fever in latent phlebitis, though intravenous injections on animals with sterile finely divided paraffin are regularly followed by a rise of temperature. The temperature which precedes a thrombo-phlebitis should be looked for several days before the first apparent manifestation of the condition, and it may be concluded that many of the unaccountable rises of temperature occurring during convalescence from typhoid, and most of the protracted and irregular types of post-typhoid fever, are due to thrombo-phlebitis.

SURGERY.

196. Fatal Post-scarlatinal Perirenal Haematoma.

W. HERRING (*Deut. med. Woch.*, January 2nd, 1913) records the case of a lad, aged 7, who suffered from pain in the umbilicus and left testicle three weeks after developing scarlet fever, the course of which had hitherto been normal. The pain in the testicle increased and spread upwards till the whole of the left inguinal canal and the lower part of the abdomen on the left side were painful. The temperature was 100.4 and the pulse 80. There was progressive anaemia and rapid respiration, but there was no loss of consciousness. Two days after the onset of these symptoms the pulse was 150, the temperature was subfebrile, and the abdomen was somewhat distended, being markedly rigid even on light palpation on the left side. The urine contained neither albumen nor blood. The spermatic cord and the neighbouring structures were swollen and tender. This condition, combined with vomiting and absence of motions and flatus, led to the diagnosis of incarcerated ommental hernia followed by intestinal obstruction and peritonitis. But an incision over the left cord showed no hernia. The testicle, however, was suffused with blood and was as large as a pigeon's egg. A little bloodstained serous fluid was found in the tunica vaginalis. An exploratory laparotomy was now made, when bloodstained, sero-fibrinous fluid was found in the peritoneal cavity, the lining of which was covered with a fibrinous deposit. Though the intestines were distended, no hernia or constriction of the intestine was demonstrable. The parietal peritoneum bulged over the left kidney, and was livid from this point down to the pelvis. A needle was introduced and dark red fluid blood was aspirated from the swelling. As drainage of this haematoma by the abdominal route was considered unsatisfactory, the abdomen was closed, and the flank was incised over the left kidney. The lumbar muscles, the retroperitoneal tissues, and the fatty capsule of the kidney were suffused with fluid and coagulated blood. Death followed three days later. The necropsy showed diffuse, purulent peritonitis and a normal appendix. Except for slight hyperaemia of the cortex and slight haemorrhagic injection of the right renal pelvis, the kidneys were normal. Neither at the operation nor the necropsy could the site of the haemorrhage be found, and the author thinks that a capillary haemorrhage must have occurred, either in the left suprarenal body or in the neighbouring structures. He also traces the paralytic, progressive, intestinal obstruction to the haemorrhage, which must have been due to the scarlet fever.

197. Non-tuberculous Cold Abscess and Non-acute Staphylococcal Abscess and Osteomyelitis.

ABADIE (*Arch. prov. de chir.*, December, 1912) contributes a paper which he entitles "Cold Abscess and Chronic Osteitis from Staphylococcal Infection: Tuberculous Acute Abscess and Acute Osteitis." Surgeons are too apt

to regard cold abscess as synonymous with tuberculosis, and to look upon all acute abscesses and osteitis as staphylococcal. Non-tuberculous cold abscess does exist. He cites four cases, two in his own practice, where abscesses, which clinically were designated "cold," appeared several years after an acute attack of osteomyelitis, good health being experienced in the interval. The pus was found to contain staphylococci, but a previous and long-cured infection need not necessarily have been present. The staphylococcus may, without early acute infection, of its own accord give rise to a cold non-osteopathic abscess. Abadie quotes a case narrated by Schwarz and Kahn and another in his own practice which were multiple in their localizations. Abadie's patient was a child of 4 years who, two and a half months before, had suffered from measles followed by imperfect recovery. A week before admission into hospital multiple abscesses, symmetrical, painless, and of slow growth, formed in the neck and lumbar region. Incision of the lumbar swellings was made; the pus contained staphylococci. A staphylococcal invasion may be silent; a tuberculous invasion may, on the other hand, be acute. Broca has pointed out already that hydrarthroses of rapid acute formation, simulating acute staphylococcal or streptococcal infection, may develop in the knee, and may (after inoculation of guinea-pigs with the exudate) prove to be tuberculous. This evidence may be confirmed by later development of "white swelling." Indeed, there may actually be pus—an acute suppurative tuberculous arthritis. Abadie does not admit that an organism must necessarily give rise in every case to the same clinical characteristics. The virulence of a particular species of organism is far from being constant. In proportion as the evolution of the disease is prolonged, the virulence of the initial infective agent will become attenuated. It is evident then that late torpid staphylococcal manifestations are to be explained by a slow attenuation of the virulence of the organism. Again, the coefficient of resistance of the body plays a part. Regarding tuberculosis (quoting Calmette with approval) it may be that the majority of individuals have been infected from infancy by the digestive tract. This attenuated infection manifests itself mostly by mesenteric gland reaction, and confers relative immunity. New invasions will not be more tolerated by the organism but will provoke defensive reaction, tending to the expulsion of the infecting agents and damaged tissues. It will be well in every case of apparent cold abscess to make microscopic examination, and also inoculation experiments, before deciding that it is tuberculous.

198. Diaphragmatic Hernia.

VOGEL (*Amer. Journ. of Med. Sciences*, February, 1913) reports a marked case of congenital diaphragmatic hernia unaccompanied by any subjective symptoms, death resulting from an independent lesion. A man, aged 47, was admitted to hospital suffering from stenosis of the large intestine with peritonitis, ending fatally, and the history included no symptoms of the remarkable condition revealed at the autopsy. On opening the thorax the colon was found occupying the left chest through a left-sided diaphragmatic defect. The spleen was about in the position of the heart, which was pushed over to the right, its left border being 2.5 cm. to the right of the median line. The left lung was collapsed, and the left chest was filled with omentum, caecum, transverse and descending colon, the latter being straight, and running directly to the brim of the pelvis. The stomach was above the diaphragm with the duodenum passing through the hernial opening, which occupied the posterior and lateral portions of the diaphragm and was about 15 cm. in diameter. Such hernias may be classified under three headings: (1) True hernias, consisting of protrusions of abdominal viscera through congenital or acquired openings, with pleura and peritoneum to form a sac; (2) false hernias, in which there is no true sac; and (3) diaphragmatic eversion, due to relaxation of a portion of the diaphragm itself. The condition is much commoner than is generally supposed, and it may exist indefinitely without giving rise to symptoms. If sufficiently large the physical signs are usually significant, and dextrocardia with signs suggesting pneumothorax should always lead to a suspicion of some form of diaphragmatic hernia, and to a radiographic study of the thorax, several examinations at different times and positions, and with and without bismuth being necessary. In traumatic hernias operation is indicated as soon as the existence of a fresh wound in the diaphragm is ascertained, and the prognosis is good when a prompt operation is performed. In chronic hernias prophylaxis of incarceration is the main object, surgical interference being indicated only in the event of incarceration occurring.

OBSTETRICS.

199. Direct Transfusion after Placental Haemorrhage.

GUI, in the *Bull. de l'Acad. de Méd.* of October 29th, 1912, relates a case in which this operation was carried out successfully. The patient had had five normal accouchements; the first half of the sixth pregnancy was normal also. She then complained of severe pains in the right lumbar region. On examination there was evidence of marked increase in size of right kidney. There was a good deal of pus in the urine. She was put upon a lacto-vegetarian diet, but with no effect. Labour came on, and there was some bleeding, but on rupture of the membranes this ceased externally as the head engaged. There was every evidence that the haemorrhage was due to detachment of the placenta. The pulse became small and accelerated. A dead child was delivered soon after. There was formidable haemorrhage after delivery, and the placenta was found completely detached. It was removed, as were all intrauterine clots. Meantime the patient had collapsed. She was exsanguine, and her pulse 140. All the usual methods of restoration were tried, but produced only momentary benefit. Finally recourse was had to direct transfusion from the radial artery of the patient's husband into the median cephalic vein of the patient. This was carried out according to the procedure of Carrel, slightly modified. In a few minutes the lips of the patient, who by this time was quite insensible, began to be faintly coloured; her eyes opened, and her pulse became perceptible again. The radial artery of the donor was rather small, and the transfusion was continued at his request for an hour. The pulse gradually fell to 92 per minute, and ultimately the patient made a good recovery. In this case the massive injections of normal saline which would have been necessary were contraindicated on account of the renal insufficiency. Other isotonic serums might have been used, but the difficulty of preparation and sterilization render such quite inappropriate in a case of this kind. The author does not believe that in grave cases of puerperal haemorrhage the effect of saline infusion is as powerful as direct transfusion. The volume alone of the latter could not so powerfully raise vascular tension, and in the author's view the mode of action is not clear. This method is the procedure of choice in such an emergency, and is preferable to the use of special cambric, and, further, there is no risk of the formation of clots.

GYNAECOLOGY.

200. Extruterine Pregnancy.

FAKRAH COBB (*Annals of Surgery*, December, 1912) has made an investigation into the question of the management of grave emergency cases of extruterine pregnancy with the object of obtaining information as to the wisdom of immediate operation in desperate cases of rupture with severe haemorrhage, as in a recent discussion delay was advised in some cases. He studied 137 cases of tubal and interstitial pregnancy in Massachusetts General Hospital from 1902 to 1910. His conclusions are: (1) More than one-third of all cases of extruterine pregnancy occur in women who have never before been pregnant. (2) Pelvic inflammation or salpingitis is not an essential or even frequent causative factor. (3) Most of the cases of complete rupture with alarming haemorrhage occur in the early weeks, often in the first month; these are the cases which are rapidly fatal unless operated on. Cases that have gone two months or more are those which furnish the greatest number of non-emergency cases. (4) Cases of sudden severe rupture, in which signs of marked intra-abdominal haemorrhage are present, often simulate other grave abdominal emergencies. (5) In grave emergencies, with signs of extreme haemorrhage, operation should be done at once without waiting for a possible reaction. (6) In the less severe cases of tubular rupture, without signs of marked haemorrhage, a correct diagnosis is often difficult or impossible. (7) The menstrual history cannot be relied upon; many of the most alarming cases had skipped no period. (8) The character and location of the pain may vary within wide limits. (9) Tubular abortions are nearly as frequent as tubular ruptures. The author insists upon a very minute technique: absolutely everything in connexion with the operation should be in readiness before it is begun. Shock and collapse, until the haemorrhage is stopped, should be combated by morphia subcutaneously and artificial heat. The anaesthetic should be ether. At the first signs of muscular relaxation the patient should be placed in the Trendelenburg position and abdomen opened in the middle line. Without attempt-

ing to evacuate the blood and clots first, one ovarian artery and then the other should be caught with long clamps. As soon as this is done intravenous salt infusion should be started, strychnine given, and the blood and clots washed from the abdominal cavity with generous use of hot salt solution. The tube in which the pregnancy is located should be doubly ligated and removed and the abdominal wall closed by through-and-through silkworm gut sutures without drainage. The patient should be in bed in fifteen minutes from the time the anaesthesia is started.

THERAPEUTICS.

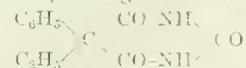

201. The Therapeutic Value of Camphor.

HEARD AND BROOKS (*Amer. Journ. of Med. Sciences*, February, 1913) investigated clinically and experimentally the therapeutic value of camphor. During the last three weeks of a case dying from an infection secondary to a suppurative cholecystitis, there were several acute attacks of alarming circulatory breakdown occurring during the course of a clinical auricular fibrillation, and apparently due to the action of the infective agents upon the myocardium and vasomotor apparatus. The hypodermic injection of camphor was followed in more than one instance by a marked temporary improvement in the character of the pulse and in the general condition of the patient. Considerable divergence of opinion exists as to the safe dose of camphor, some fearing to give more than 2 to 5 grains, while others claim that ten times those amounts can be administered without bad effect, the explanation of this variation probably lying in the metabolism and excretion of the drug. When absorbed it quickly unites with glyconic acid and is thus rendered inert, being subsequently excreted in the urine as campho-glyconic acid. A variable portion may escape such combination and be excreted uncombined by the lungs, and to this portion is attributed the physiologic action of the drug. Schultz explains the toxic effect in poorly nourished infants on the assumption that there is not sufficient available glyconic acid to combine with the camphor, and consequently the uncombined portion becomes greatly increased; whereas in well nourished infants no intoxication followed the administration of relatively large doses, because there was enough glyconic acid to unite with all the camphor. If this theory is correct, care should be exercised in giving camphor to patients with a poor glyconic acid content. The drug restores the heart after poisoning with chloral, muscarine, strychnine, etc. Clinically the investigation was limited to a study of the effects of hypodermic injections of the drug, dissolved in oil, upon the circulatory system of human subjects presenting varying conditions of the cardio-vascular apparatus. Records of the pulse and of systolic and diastolic blood pressure were made at frequent intervals, covering an average period of two hours. Polygraphic tracings were taken in several of the fibrillation cases before, during, and after the use of camphor, but in no instance was any alteration in the type of the radial or venous pulse observed. The laboratory results were in agreement with the clinical findings, camphor injected subcutaneously in oil, in doses as large as 50 grains, producing no definite effects. While it may be an active agent in certain disorders in which there is an abnormally small glyconic acid content, and may act favourably upon cardiac muscle poisoned by chloral, muscarine, or strychnine, it cannot be relied upon as a cardiac stimulant, nor feared as a toxic agent, in doses and under the conditions studied.

202.

Luminal.

F. BAYER AND CO. of Elberfeld have associated themselves with Merck of Darmstadt in bringing out a new sedative and hypnotic, called "luminal." The need for new hypnotics and soporifics is recognized, especially in neurological and psychiatric practice, since the larger variety at hand the better is the chance of avoiding a habit for the one or other. Besides, each drug has its special indications, and usually fail in some patients, so that other drugs have to be tried. Luminal is the phenylethyl-barbituric acid, having the formula:

The preparation can be had as a powder or in tablet form, or in the form of the sodium salt for subcutaneous injection. The acid is little soluble in cold water, while the sodium salt is readily so. The dosage advised varies according to the case from 0.2 to 0.6 gram; 0.3 for women

and 0.4 gram for men is said to have approximately the same action as 0.5 gram of veronal. P. Schaefer (*Berl. klin. Woch.*, May 27th, 1912) has used it in infirmary practice, and recommends it as a sedative and as a simple hypnotic. He has found it capable of relieving pain of organic origin. He states that its action is more powerful than the majority of ordinary sedatives. But he warns the reader not to give it in cases with severe changes in the heart and vessels exist, such as arterio-sclerosis. He gave it to one patient with chronic bronchitis and arterio-sclerosis in doses of 0.4 gram. Later he gave 0.5 gram, and the sleep was so deep that a hypostatic pneumonia and cardiac weakness set in from which the patient died on the fifth day. He is of opinion that the patient might not have died so soon if the luminal had not been given. A. Wetzel (*Berl. klin. Woch.*, May 13th, 1912) has used it in the Heidelberg psychiatric clinic, and is specially pleased with the effect of the subcutaneous injections. He gave it in a variety of mental conditions, comparing the result with that of other hypnotics. The dose given varied between 0.3 and 0.4 gram. The only undesired effect met with was the occurrence of vomiting, which was seen in some cases. The best results were obtained in patients who were fairly quiet but who slept badly. These patients often refuse to take medicines by mouth, and the subcutaneous application of the drug in 20 per cent. solution is extremely handy. The sleep induced is a very natural one. Graeffner (*Berl. klin. Woch.*, May 13th, 1912) reports that when given with a warm drink at night time sleep is induced in about half an hour and lasts for many hours. In the following nights sleep is obtainable without a fresh dose. It can be given as a suppository. Unpleasant side-effects were not met with save a slight degree of giddiness and prolonged sleepiness. He advises 0.2 gram as the initial dose, which can be increased up to 0.4 or 0.5 gram if necessary. He found that it was useless in cases where the cause of sleeplessness was pain, thus differing in this respect from Schaefer. O. Juliusburger (*Berl. klin. Woch.*, May 13th, 1912) has had an experience of this drug in 120 patients. In mild cases of sleeplessness he found 0.2 to 0.3 gram sufficient, but in more complicated or obstinate cases he gave up to 0.6 gram and at times even up to 0.8 gram. He never had any difficulty in decreasing the dose, even after he had given 0.6 gram for twenty-two or twenty-three nights. At times luminal failed to produce the desired effect, but in some of the cases it acted very well when given later. In the excitable stages of general paralysis it acted well. It was also of much use in epilepsy and delirium tremens. He points out that in the treatment of the morphine and alcohol habit it acted extremely well. He is of opinion that luminal is calculated to replace hyoscine to a certain extent.

203. Pituitrin in Osteomalacia.

C. Koch (*Wien. med. Klin.*, No. 25, 1912) reports on 3 cases of osteomalacia treated with pituitrin. The first was a severe typical case whose origin was possibly a pregnancy which had ended in abortion five years earlier. The patient was given 2 c.cm. of pituitrin subcutaneously every day, and had completely recovered when a total of 190 c.cm. had been injected. At first no result of the treatment was perceptible, and there was thought of changing the treatment, but improvement began to be visible after 12 c.cm. had been given, and in spite of frequent relapses recovery occurred as stated above. The second and third cases were not such typical ones, but the characteristic symptom of pain on pressure along the whole length of the bones could be demonstrated so clearly that the diagnosis was at any rate a very probable one. The cases resembled one another, in that in each the nervous system was markedly involved. In both cases a prompt action was obtained in Case II after 5 c.cm. of pituitrin, in Case III after 3 c.cm. of pituitrin, which appears to resemble pituitrin in its action. It is characteristic that though narcotics and antirheumatic remedies had no effect in removing the acute pain, a striking improvement, especially in the subjective condition, followed when only a few cubic centimetres of pituitrin had been administered. With regard to side-effects, in one case the first two injections, but not later ones, were followed by severe occipital headache, which lasted for about six hours, and then gradually disappeared, while occasionally, also in this case the earlier injections were followed by temporary exacerbation of the bone pains. In the second case there was an outbreak of miliaria crystallina at the back of the head and the elbow-joint after the first injections, together with an increased secretion of sweat; and the rash persisted for some days. These two cases suggest that

in osteomalacia there may be a specific reaction to pituitrin, which disappears after the first few doses. The first patient began to complain of pain at the site of injection after the injections had been going on for some time, and the addition of a small quantity of novocaine was found to be necessary. These cases showed the harmlessness of pituitrin or of pituitrin as compared with adrenalin in the treatment of osteomalacia, while the effect upon the disease appeared to be similar, or perhaps even better, than that of the adrenalin preparations.

PATHOLOGY.

201. Serum Diagnosis of Echinococcal Infections.

BENNO HAHN finds that the ordinary methods of diagnosing echinococcal infections are very apt to fail (*Muench. med. Woch.*, No. 27, 1912). After reviewing the individual signs of echinococcus and the frequency with which these various signs are absent, proceeds to give an account of his observations with Ghedini's serological method. Ghedini claimed absolute specificity from the complement-deviation reaction, but this has recently been questioned. Hahn therefore considers it of importance to record the results of his studies in this direction. The antigens with which he worked included the fluid from echinococcal cysts of human origin and from the pig and ox. He also used alcoholic and aqueous extracts from the cyst walls of these various infections. Lastly, he made alcoholic and aqueous extracts of *Taenia saginata*. The patient's serum was inactivated by heating to 56° C. for thirty minutes, greater heat proving destructive to the antibody. Guinea-pig's serum served as complement, a 5 per cent. suspension of sheep's blood corpuscles were utilized as the corpuscles for haemolysis, and the amboceptor was a dried haemolysis prepared in the Behring Werks in Marburg. It is unnecessary in this place to enter into the quantitative details of the tests put up. Of the five patients who were suffering from echinococcus infections, Nos. 1, 3, and 4 gave positive reactions with alcoholic and aqueous extracts of human cyst wall, with aqueous extract of ox cyst wall, and with aqueous extract of *Taenia saginata*, but negative reactions with all the other antigens, negative reactions with Wassermann's test, and no reaction when no antigen was employed. No. 2 gave the same positive reactions, and also with the alcoholic extract of pig's cyst wall, and with ox cystic fluid; the other tests proved negative. No. 5 yielded a negative reaction with all antigens before operation, but after the removal of the cysts a positive reaction was obtained when the antigen was either the alcoholic or aqueous extract of human cyst wall, aqueous extract of ox cyst wall, or *Taenia saginata*. Three patients infected with *Taenia saginata* yielded a positive reaction with alcoholic and aqueous extracts of human cyst wall, aqueous extract of ox cyst wall, and aqueous extracts of *Taenia saginata*; 15 normal persons and 15 syphilitic persons were also tested. In all cases a negative, or at most a very doubtful, reaction was obtained with the serum of these persons. He therefore concludes that Ghedini's complement test for echinococcus proves the presence of this or of *Taenia saginata*. The best antigen appears to be an aqueous extract of the cyst wall, while the cystic fluid does not contain sufficient antigen to be of use. If an alcoholic antigen is employed, it is necessary for the syphilitic reaction to be negative, as the test in this case may not be specific. A negative reaction does not exclude an infection.

205. The Leprosy Bacillus in the Lymph Nodes of Leper Contacts.

SOREL (*La presse méd.*, No. 100, 1912, p. 1016) examined both in lepers and leper contacts those lymph nodes which are accessible to puncture, such as the inguinal, epitrochlear, and cervical. In 8 out of 19 lepers he found leprosy bacilli in these nodes. He examined also in this manner 15 persons living with 7 lepers, and in one case, the sister of a leper, he found leprosy bacilli in the 1st inguinal nodes, although she herself presented no visible evidence of the existence of leprosy. Marchoux, who presented Sorrel's note to the Société de Pathologie Exotique of Paris, remarked that these researches, like those of Liebenf, tend to establish an analogy between the leprosy of man and of the rat in the first stage of the disease. In man, as in the rat, leprosy can exist in the latent state and remain isolated in the lymph nodes for a long time, and even, it may be, for life.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

206.

Barlow's Disease.

DE SAGHER (*Ann. de méd. et chir. infant.*, March, 1913) refers to the difficulties of diagnosis in this disease. The classical picture is typical enough, but in many cases the symptoms are so masked and incomplete that the condition is not easy to recognize. Nearly all the cases reported to the Society of Pediatrics (Paris) have been wrongly diagnosed at first. The children have been treated for Pott's disease, coxalgia, osteomyelitis, and syphilitic pseudo-paralysis. In a case cited by Guinon the syndrome was represented only by pains in the legs. "When a child is brought to you with a painful paraplegia, think of Barlow's disease, says Hutinel; do not wait for symptoms of scurvy to make your diagnosis." The diagnosis is arrived at by elimination: when examination of the spine and the reflexes has excluded Pott's disease, when examination of the joints has shown that they are free and are not the seat of the pain, when there are no signs of coxalgia or of infantile paralysis, Barlow's disease must be considered, especially if the child has been artificially fed. The disease occurs for the most part among the children of the well-to-do, for the reason that the lower classes cannot afford patent foods; also, the writer thinks, because the latter class are in the habit of early giving their children bread, potatoes, and fruit, which, however unsuitable in other respects, are antiscorbutic. Lesage believes that the mild form is common, and even concludes that if an infant of over 6 months becomes suddenly peevish and cries when its lower limbs are touched, it is suffering from the disease. One often sees a child who has begun to walk become extremely sensitive in the lower limbs and refuse to walk. Change the diet and the child walks. To prevent this mild form de Sagher has devised a prophylactic treatment which he prescribes for all artificially-fed children. From the age of 6 months he gives from two to six teaspoonfuls of grape juice, at the seventh or eighth month he adds one to three teaspoonfuls of compote, preferably of banana. These foods, besides their antiscorbutic properties, have the advantage of combating constipation, and their iron content cannot but be beneficial at an age when the reserve of this metal in the liver is becoming exhausted.

207. Indications for an Artificial Pneumothorax in Phthisis.

N. VON JAGIC (*Wien. med. Woch.*, February 1st, 1913) states that the pneumothorax treatment of phthisis has been adopted in so many cases and for so long, that it is now possible to lay down definite indications for its employment. He excludes all cases of slight and moderate disease in which there is still a prospect of recovery under ordinary hygienic and dietetic treatment. Extensive disease of both lungs, active intestinal and amyloid disease are also contraindications; but albuminuria without other signs of nephritis is not necessarily a contraindication. Pleural adhesions and rigid-walled cavities prevent collapse of the lung, and are in consequence unfavourable to the treatment; but their existence cannot be demonstrated till attempts to collapse the lung have failed. The most suitable case is that in which one lung is extensively and actively diseased and the other is healthy. This ideal is seldom realized, for phthisis is almost invariably bilateral. Good results are, however, obtained in cases presenting slight infiltration or apical catarrh in the healthier of the two lungs. When the whole of the upper lobe of this lung is involved, the treatment may be unsatisfactory. Haemoptysis localized to one lung may be promptly arrested by an artificial pneumothorax when all other measures have failed. Obstinate fever and laryngeal tuberculosis may improve under the treatment, provided the condition of the lungs is satisfactory. The most suitable age for the treatment is from 15 to 35, but good results have been recorded of children only a few years old. Cardio-vascular complications do not necessarily prohibit the induction of a pneumothorax. The author expresses astonishment at the want of discomfort following displacement of the heart and blood vessels by a pneumothorax; and in one case he found complete dextrocardia unaccompanied by distress on walking. The right ventricle may become hypertrophied under these conditions, but necropsies have also

shown that no hypertrophy of the heart follows the presence in the chest for several months of a large pneumothorax. Possibly the heart of the consumptive is often incapable of hypertrophy.

208. Spasmodic Dysphagia of Neuropathics.

HARTENBERG (*Journ. des praticiens*, 1912, xxvi) treats these cases as follows: All spiced food or alcoholic drinks should be forbidden, hydrotherapy and 1 or 2 grains of KBr per diem, a $\frac{1}{4}$ mg. of hydrobromate of scopolamine subcutaneously injected during the spasm, the continuous current in the region of the spasm for twenty minutes 20 to 30 milliamperes, and psychotherapy, assuring the patient that the treatment will be successful. Generally two weeks are necessary to bring about a cure.

209. Paraldehyde Poisoning.

AFTER commenting on the extensive use of paraldehyde as a hypnotic, L. Fornaca and G. Quarrelli (*Berl. klin. Woch.*, December 23rd, 1912) point out that toxic effects are rare though such large quantities as 150 grams have been taken within thirty-six hours by one patient. The same amount was taken in one dose by Mackenzie's patient, who slept heavily and was perfectly well twenty-four hours later. In the author's case, however, delirium, resembling that of chronic alcoholism, was observed. The patient, a doctor 48 years old, had been perfectly healthy till, at the age of 32, he fractured his right parietal bone. Subsequently he suffered from severe insomnia, for which he used in succession chloral, sulphonal, trional, and veronal, the latter being taken daily in doses of 5 grams for five years. At the age of 42 he began to take paraldehyde in daily doses of 2 grams. During the next five years this dosage was gradually raised to 15 grams a day without interference to his work. Two months before admission to hospital he suffered from alternate fits of depression and excitement, accompanied by tremor of his hands and disturbances of speech. This condition drove the patient to larger doses of paraldehyde. In one week he took 500 grams. Alarmed by his condition he swallowed over 100 grams of paraldehyde, and then went to a hospital, where he was admitted in a semi-conscious condition. The smell of paraldehyde filled the whole room, and for eight days he was delirious. At the height of the delirium his temperature was 104 and his pulse was 134. He perspired profusely, and once exhibited an epileptic attack. After the delirium culminated on the fourth day the patient improved steadily, and on the ninth day he was again normal. On the twentieth day he returned to his work, which he performed satisfactorily. The authors found that the hot pack, small doses of paraldehyde, and large doses of bromide were of little use during the delirium. Injections of morphine also proved useless; but opium, in the form of pantopon, was most beneficial; 6 cg. of this drug was injected in three doses on the fourth day, and it was increased until 10 cg. were given in 24 hours. The authors attribute the epileptic attack to heredity (the mother had suffered from such attacks since the birth of a child), to the old fracture of the skull, and to the acute toxic state of the patient.

SURGERY.

210.

Latent Erysipelas.

A. SCHLESINGER (*Deut. med. Woch.*, January 16th, 1913) records two cases of erysipelas remarkable for their long incubation period. One patient was a nurse, aged 40, who had previously been well, and whose left hand had been scratched by a woman dying from a septic abortion. Though disregarded, the scratch healed quickly. But a fortnight later the left elbow became painful, and a month after the infection the patient felt ill and suffered severe pain in the arm. The ulnar nerve and its immediate neighbourhood were tender, but not swollen. Neuralgia of the ulnar nerve was diagnosed, and iodine, alcoholic compresses, aspirin, and pyramidon were prescribed. Only transitory relief was effected, and the patient was confined to her bed with a temperature of 99.3° in the evening. Six weeks after infection the temperature was higher, and there was a tender swelling over the ulna. Periostitis was now diagnosed, but rest and antineuralgic drugs were

prescribed in vain. Two months after infection the swelling was more extensive and superficial, although up to this date the skin and subcutaneous tissues were not involved. The morning and evening temperatures were 99.5° and 100.4° respectively. At this period a circumscribed, raised, and red patch appeared in the skin over the tender swelling. In three days this patch had grown to the size of a small plate, and was characteristic of erysipelas. Simultaneously with the development of this rash the deep-seated pain and swelling in the forearm disappeared. During the following fortnight the rash spread over the neck, head, and back, and then slowly faded away. The temperature at this period ranged between 99.5° and 101°. At no time was it indicative of typical erysipelas, and it is possible that the effect of the germs on the temperature was modified by their delayed incubation. No doubt they had multiplied in the tissues some weeks before they gave rise to a typical eruption, for an inflammatory reaction began over the ulna a fortnight after infection; but even this period is extraordinarily long, for the usual incubation period of erysipelas is one to two days, and the longest period hitherto known is, according to Tillmann, eight days. The suddenness with which pain and swelling ceased in this case as soon as the rash appeared on the arm distinguishes it from that common group of cases in which a deep-seated phlegmon precedes by a few days a typical eruption of erysipelas without any diminution of the swelling and pain in the underlying structures. The second patient was a girl, aged 7, whose tuberculous cervical glands were excised under local anaesthesia. The cavity left after their removal was plugged with a tampon, and a few ligatures were applied. The tampon was changed on the sixth day, when the wound was painted with tincture of iodine. On the twelfth day deep infiltration of the wound began, and was interpreted as the result of pent-up pus. The wound was therefore re-opened, but no pus was found. Tincture of iodine was applied during the next few days, during which the infiltration increased. On the twenty-sixth day the temperature was 100.4°, and the swelling in the neck was as large as a child's fist. On the thirty-second day, when the temperature was 102.2° in the evening, a small red and sharply circumscribed spot appeared over the swelling. Next day it was as large as a small plate, and during the following weeks it spread over the neck, face, and head. Finally, with a fall of the temperature to normal, it faded away completely. Evidently in this case also the germs deserted the deeper structures as soon as they invaded the skin and subcutaneous tissues, for with the appearance of the rash the deep swelling in the neck vanished.

211. Sacro-iliac Displacement.

YOUNG (*Amer. Journ. of Med. Sci.*, July, 1912), in considering sacro-iliac displacement, points out that when the ligamentous attachments preserve their normal tone a certain degree of movement at the articulation is compatible with health, and consequently it follows that, should anything tend to disturb this tonicity, or in any way interfere with the associated musculature, increased movement will result. Some of the more common affections have their origin in an abnormal sacro-iliac articulation or in the neighbouring nervous structures, and an obscure case of sciatica, lumbago, etc., may often have its origin in a too movable articulation, which may also be weakened by a direct trauma or the impoverished health following long illnesses. The simplest type of the affection is strain, which usually becomes corrected when the musculature adjusts itself; but a continuance of the faulty position gives rise to a displacement or rupture of the ligaments with marked instability in the joint. In more pronounced cases there may be complete dislocation, which does not permit of voluntary replacement, and the accompanying neuralgias are the result of some pathological condition of the joint. It should always be borne in mind that the resulting ligamentous changes may become a fertile field for the invasion and development of an infecting process—for example, tuberculous arthritis. Pain, limitation of motion, abnormal mobility, and changes in attitude are the usual characteristic symptoms, and the best method of testing abnormal mobility in the joint is to ask the patient to stand with the knee fixed and then to raise and lower the heel in rapid succession. Spontaneous reduction may take place, but when this does not occur it can be effected by placing the patient prone and producing forced extension with traction of the limb, or the patient may be placed between two chairs, situated at an interval of about a foot and a half, while the surgeon makes downward pressure over the site of the articulation. An efficient belt should be worn, the principle involved in

any such apparatus being the exertion of pressure by a pad upon the sacrum, either at its upper or lower part, according to the case. After-treatment consists in developing the affected parts by exercises, massage, vibration, and electricity continued over a long period of time.

212. Sudden Death from Embolism Subsequent to an Undetected Fracture of the Neck of the Femur.

JULIEN (*Echo méd. du Nord.*, 1913, xvii, January 19th) describes the case of a man, aged 48, who fell from a height, who died suddenly fourteen days after the accident. *Post-mortem* examination revealed a fracture of the neck of the femur undetected during life, fibrinous clots in the right heart and pulmonary artery, and slight congestion of the lungs.

OBSTETRICS.

213. Suffocation in a Suckling.

J. HJORT (*Norsk Magazin for Lægevidenskaben*, February, 1913) records the case of an eight-day-old child whose death he traces to aspiration of milk into the bronchi. Towards the end of suckling at 10 a.m., the child gurgled, but continued to suck the nipple for a short time. There was no regurgitation of milk, as often happened at the end of a meal. On being put back into the cradle, the child whimpered continuously instead of going to sleep as usual. At midday the face and hands were cyanosed, and respiration was laboured. An hour later the author found the skin everywhere cold and cyanosed. Though regular, the heart sounds were feeble, and no pulse could be felt. No air entry was audible over the lungs. Warm bottles, warm baths, cold douches, artificial respiration, and injections of camphor partially restored the child, whose cyanosis diminished. At 2 a.m. on the following night air entry was audible over the lungs, the pulse could be felt, and the child slept peacefully. But the previous symptoms recurred an hour later, and death occurred at 4.30 a.m. The necropsy showed a few punctate haemorrhages in the skin of the head, but no haemorrhage into the bones of the head, the meninges, or brain, although they were filled with blood. There were a few haemorrhages into the pericardium and pleurae. The lungs contained much blood, but there was no pneumonic infiltration. The alveoli contained air, and all the bronchi, including the smallest, contained a greyish white, viscid fluid, in which there were no solid particles. In the trachea it was frothy. It was not apparently analysed. The umbilicus was healthy, the thymus was normal, and there was no oedema of the glottis. The author can find no record of a similar case.

214. Rupture of the Uterus in the First Months of Pregnancy.

JULLIEU (*Écho méd. du Nord*, 1912, lx) records three cases of this occurrence in women 36 (two) and 30 years of age. One of the former died suddenly from embolism on the sixth day after operation, and the other two recovered. The author believes that vaginal hysterectomy is the ideal operation.

GYNAECOLOGY.

215. Pyosalpinx in Virgins.

DE ROUVILLE, of Montpellier (*Rev. de gynéc. et de chirurg. abdom.*, November, 1911) discussed the question of pyosalpinx in the virgin at the last meeting of the Association française de chirurgie. He has examined and reported several instances where both virginity and tuberculosis were authenticated. He insists, however, that there are cases where pyosalpinx exists in virgin patients where it is equally clear that neither tuberculous, gonococcal, or puerperal infection caused the suppuration. He operated on a maiden lady, aged 46, subject for four years to symptoms of pelvic inflammation. There was a big double pyosalpinx, which was removed together with the body of the uterus. The disease was of the familiar type associated with local infection, and there was no trace of tubercle, but the pus was free from the gonococcus, and from the well-known bacteria of puerperal infection. Under the usual tests and inoculations nothing could be made out, and when cultured colonies of a staphylococcus and a diplococcus appeared, neither of which could be identified, M. de Rouville concludes that pyosalpinx

may be due to other causes than the three already universally recognized. We might add that a dirty syringe, septic material in the fluid which it throws up into the patient's genital tract, or some gynaecological instrument, may convey infection in these doubtful cases. For obvious reasons we require more aid from the bacteriologist for determining the significance of pyosalpinx in single women.

216. Roentgen Rays Treatment of Uterine Fibromyomata.

DE BORIS (*La Semaine Méd.*, No. 40) discusses the above method of treatment. The results, he says, are truly remarkable. The first effect of x rays is often to increase the metrorrhagia or the abundance of the periods; this effect is apparently due to stimulation of the ovaries and is more marked with small doses. The second effect is scantiness or amenorrhoea, with disappearance of pain due to diminution in the size of the tumour. The local effects are more or less marked and more or less easy to obtain according to the age of the patient, the results being far more brilliant in women past 40 than in women with more active ovaries. According to Gauss it requires an average of 366 minutes' irradiation to obtain amenorrhoea from the age of 31 to 40, 240 from 41 to 50, 204 from 51 to 55, and 142 from 56 to 60. Most observers have noted amelioration of cardiopathies, but, on the other hand, others have observed a number of phenomena concomitant with the treatment, the most constant being vesical tenesmus and intestinal contractions. The writer holds, with the majority of radiologists, that the symptoms of artificial menopause are less marked when it is brought about by this means than when it is the result of surgical operation. The therapeutic effects are undoubtedly due to the action of the rays on the ovaries, and it has been shown that the rays have an elective action on the germinative epithelium. The treatment has the advantage over ovariectomy that it does not radically suppress the ovaries so that their internal secretion is to some extent conserved; also that it acts on the myoma itself. As to constancy of the results opinions differ, some observers claiming 99 and 100 per cent. of good results while others only claim from 60 to 70 per cent. On the question of safety the writer considers that the method is free from danger provided always that it is in competent hands. Albers-Schönberg has inaugurated a technique of which the principal points are: The use of bulbs of moderate hardness, a focal distance of 38 cm., a total exposure of eighteen minutes divided into three sittings (one a day), an interval of at least fourteen days between each series of sittings, a skin filter, a current of 2 to 3 milliampères, and a quantity of rays not exceeding a total of 6 to 7.5 units Kienböck for the three days. Bordier and Gauss, by using filters of aluminium, are able to give larger doses (10 units Kienböck), thus shortening the treatment and avoiding the initial recrudescence of menorrhagia and metrorrhagia. By the method of small doses the treatment takes at least six months, often more; with large doses it takes from seven weeks to three and a half months. Much difference of opinion obtains as to whether malignant degeneration of the tumour is a contraindication to the treatment; but the diagnosis of malignancy is very difficult, and according to Döderlein is impossible. That being so the writer holds that, supposing radiotherapy fulfils its promises, it ought to be used, since the risks of cancerization on the one hand and the operation mortality on the other are about equal. Two more positive contraindications are gangrene of the myomata and mucous polyps; the first requires urgent treatment, and the second are easily and effectually removed. Submucous myomata, which act as foreign bodies in the uterine cavity, should be treated by hysterectomy. Concomitant infections of the adnexa are generally considered a contraindication, but Menge thinks that recent infection is a doubtful contraindication, whilst old infection may be ignored. For the rapidly growing myomata of young women, with abundant haemorrhage, many authorities prefer hysterectomy, but de Boris advises that radiotherapy should first be tried, seeing that, when successful, it brings about a less violent menopause. The treatment has the advantages that it is almost absolutely safe, and that it avoids the shock and the other risks and drawbacks of an operation. On the other hand, it is very expensive owing to the short life of the bulbs, and it takes a long time. Another disadvantage is the difficulty of diagnosis; and lamentable mistakes may be made by irradiating cysts, fibromas, cancers of the ovary and the uterus, not to mention salpingites. The results of radiotherapy are very promising, but as yet it is impossible to say whether they will be maintained. Many successes appear to be quite definite, but among young women recurrences are frequent. Much

work has yet to be done before a final judgement can be given and a precise list of indications and contraindications can be drawn up.

THERAPEUTICS.

217. Cerebral Congestion after Neo-Salvarsan.

PORKEL (*Ann. des mal. vén.*, November, 1912) reports a case of cerebral congestion occurring three days after the third injection of neo-salvarsan, and lasting two days. The patient, a man, aged 23, with secondary syphilis, received three intravenous injections of neo-salvarsan in five days, a total of 2.55 grams of the drug. The symptoms of cerebral congestion were rise of temperature, rapid pulse, congestion of the face, paraphasia, rubeoliform rash on body, dilated pupils, transient convulsions of the arms. These symptoms, which lasted two days, were treated by ice to the head, blisters to the neck, leeches to the mastoid region, adrenalin, and potassium bromide. Under this treatment the patient recovered; but, as the author remarks, similar symptoms, and even fatal haemorrhagic encephalitis, have been many times reported after intravenous injections of salvarsan, and he thinks the same may occur after neo-salvarsan if it is given in large doses or even in small doses repeated at too frequent intervals. In the case reported freshly-distilled water was used. This is interesting in view of Wechsleman's explanation of the symptoms as being due to the use of stale distilled water containing bacteria.

218. Molyform.

E. LAMPÉ AND H. KLOSE (*Wien. med. Klin.*, No. 20, 1912) have investigated by animal experiment the bactericidal action of molyform. They had previously known that paper and other materials soaked in molyform solution became resistant to destructive influences, that in chemical works those who worked with molybdic acid never suffered from toxic eczemas, and those who had acquired obstinate skin diseases in other departments quickly recovered if working with molybdic acid, and that cholera vibrios and typhoid bacilli were destroyed by $\frac{1}{2}$ to $\frac{3}{4}$ per cent. molyform solution. Molyform is a fine white powder of astringent taste, soluble in water up to 10 per cent., and giving the specific reaction for molybdic acid and its salts. The authors tested molyform on sixteen guinea-pigs. The dose given varied from 0.09 to 0.1 gram per kilogram of body weight. The following case is a typical one: An intravenous injection of molyform was given to a guinea-pig severely infected with streptococci. Within three hours the temperature fell to normal, and the animal was once more running about. Injections were also made into each of thirty dogs. With a dose of 0.09 gram per kilogram the effect was similar to that observed in guinea-pigs. A dose of 0.25 gram per kilogram proved fatal to dogs within twenty-four hours, the animals being attacked by diarrhoea and vomiting, followed by clonic-tonic contractions of the muscles of the whole body. Intravenous doses of 0.12 gram per kilogram gave rise to symptoms of the same nature as with the larger dose, but did not prove fatal. The drug was excreted chiefly through the kidneys, the urine giving the molybdic acid reaction an hour after the injection. Marked phagocytosis followed the injection of molyform. The authors concluded as a result of their experiments that molyform possesses very great antiseptic properties, and can be given in relatively large doses without injury. Their experimental conclusions were confirmed by clinical tests. They employed for clinical purposes either pure molyform, a 5 per cent. molyform ointment, a 3 per cent. watery solution, 5 per cent. molyform gauze, or 10 or 20 per cent. powder. The authors found that molyform applied to healthy granular tissue greatly quickened the growth of epithelium. Catarrh of the bladder even of years' duration quickly yielded to local treatment with molyform solutions; in gynaecological work it proved a mild but most efficient deodorizing antiseptic. The irritation of carcinomatous ulcers could be kept in check by molyform. The authors never saw any harmful side-effects, and especially never any kidney irritation from the external use of the drug, and they therefore felt justified in injecting it into closed tuberculous abscesses. In one case in which iodoform glycerine had failed, two injections of 15 c.c.m. of a 3 per cent. molyform solution caused the pus in a tuberculous ulcer to be replaced by pure serum, and later complete healing followed. Chronic eczemas, acne, and other skin affections which had proved resistant to treatment healed rapidly under molyform ointment. Further investigations are needed as to the action of

intravenous injections of molyform in general septic processes; the authors tried the treatment in two already hopeless cases, and thought the results encouraging. They strongly recommend an extensive trial of molyform in surgical, gynaecological, and dermatological practice.

219. Serum Treatment of Chronic Purpura.

ELSNER AND MEADER (*Amer. Journ. of Med. Sci.*, February, 1913) record two cases of chronic purpura with the results of treatment with animal serum. The first case, that of a woman aged 45, had presented for three years the characteristic signs of chronic purpura, the lesions being indiscriminately distributed and not limited in type, with repeated circumscribed gangrenous patches following purpuric macules. From a pustule covering a small purpuric spot a vaccine was prepared and three injections given, the necrobiosis being favourably influenced, but there was no effect upon the general condition. Several injections of animal (rabbit) serum were administered over a period of eighteen months, the effect being distinctly symptomatic in controlling the haemorrhagic lesions, and in addition decidedly tonic and exhilarating, though not in any way curative, since at the end the patient was still suffering from chronic purpura, while thoroughly realizing that no other remedy was so effective in controlling the symptoms as the injection of animal serum. In the second case, that of a woman aged 56, alarming symptoms of anaphylaxis followed the third injection of rabbit serum, but there was no recurrence after the fourth, the patient having completely recovered from the chronic purpura, of which there had been no sign of recurrence nine months later. In order to prevent anaphylaxis similar cases should be injected during ten-day periods, the number and dosage of the injections being dependent upon the effects of safe initial and second doses. The doses in these cases varied from 1 to 17 c.c.m., and in both cases a general improvement and increased weight followed almost immediately. In sporadic haemophilia and acute purpura the results with animal serum are permanent and the cure definite, the prognosis in chronic cases being less favourable as far as permanency is concerned. Rabbit serum is preferable to other serums for such treatment, but in an emergency antidiphtheric serum may be substituted until a fresh serum can be obtained. Though the rationale of the serum treatment of haemorrhagic diseases is not at present quite clear, it was observed that the blood platelets became very numerous after a series of small doses of serum, and this was accompanied clinically by considerable improvement in the patient's condition.

220. Treatment of Typhoid Fever in Children.

DELÉARDE (*Écho méd. du Nord*, 1912, 1x) recommends the following treatment. When the temperature does not exceed 39 C. no remedies are necessary. The best drinks are milk, bouillon, and eau d'Evian at regular intervals in doses of 100 to 150 grams. If the evacuations are slight a mild purgative, as castor oil or a little magnesia, is all that is necessary. If diarrhoea exceeds five to six motions in the twenty-four hours, benzonaphthol and sodium bicarbonate, $\bar{a}\bar{a}$ 0.25 gram, four times a day, in cachets, should be given, or salol 0.20 gram, sodium borate 0.10 gram, thrice daily. Cold baths are badly supported by children, and should only be given for five minutes at a time when the temperature reaches 40° C. It is better for the water to be at a temperature of 30 to 32 F., and a warm drink of tea or coffee should be given. Cold applications, as a rubber bag of ice, are also of value. Where pulmonary or cardiac complications occur sinapisms, repeated twice a day for ten to fifteen minutes, should be applied to the chest, and oil of camphor 1 in 10 in doses of 1 c.c.m. four times in twenty-four hours in a child of 5 or more should be injected subcutaneously, or the following prescription instead: Sulphate of sparteine 0.50 gram, neutral sulphate of strychnine 0.005 gram, distilled and sterilized water 10 c.c.m. Each cubic centimetre contains 5 cg. of sparteine and a demimilligram of strychnine; 2 cg. of sparteine should be injected once a day. When the temperature has ceased to rise above 37 C. in the evening for two or three days farinaceous food may be commenced with eggs and fruit.

PATHOLOGY.

221. Diphtheria Bacilli in Urine.

CONRAD AND BIERAST found diphtheria bacilli in the urine of about one-third of all the patients examined.

They only proved that the bacilli were true Klebs-Loeffler bacilli in 6 cases. R. Koch has followed up this subject, and published the results of his investigations (*Deut. med. Woch.*, No. 50, 1912). He examined the urine of 26 patients, working up some 111 samples of urine. In 4 samples, derived from 2 patients, diphtheria bacilli were found. In 10 further samples, derived from 5 patients, bacilli suspiciously like diphtheria bacilli were found, but they were unable to cultivate them in pure culture, or in some cases they obtained an avirulent, uncharacteristic strain. In the urine of scarlatina patients who were not suffering from diphtheria, 4 samples out of 19 contained a diphtheroid organism. These were not pathogenic to animals. The positive finds were derived from early cases in which death from cardiac and vascular paralysis followed at an early date.

222. Radiographic Study of Acromegaly and Gigantism.

X-RAY examination, say Marqués and Peyron (*Arch. d'électr. méd.*, January 10th, 1913), may be of service in clearing up some of the vexed questions relating to acromegaly. From the etiological point of view, there are some who claim that acromegaly and gigantism have no connexion with each other, and others that gigantism is the acromegaly of adolescence. From the anatomophysiological point of view, it is still uncertain whether the modifications of the pituitary gland are of primary or secondary importance. Again, in order to make the clinical syndrome clear, many facts still remain to be established, particularly with regard to the antecedents and family connexions of acromegalics, and to the cases of incomplete acromegaly and of acromegalo-gigantism. As to the radiographic features of acromegalic cases, Bécclère has instanced the dilatation of the frontal sinus, the thickening of the cranial walls, and the expansion of the pituitary fossa, or Turkish saddle, at the upper surface of the sphenoid bone. The present authors state that in cases of typical acromegaly the radiograph will illustrate with great clearness the expansion of the Turkish saddle, and that it is possible sometimes to perceive on the negative the shadow of the hypertrophied pituitary gland. In the case of incomplete forms of this dyscrasia it is worth while to take successive radiographs of the skull, these being useful either for diagnosis or prognosis. The authors give particulars of cases in which an increasing expansion of the Turkish saddle has been concurrent with an increase of the functional troubles; and of other cases in children in which there were some signs of acromegaly in the features, though the "drumstick" deformity of the phalanges suggested a hypertrophic pneumatic osteoarthropathy. In these cases the radiograph of the head showed an expansion of the Turkish saddle, which was a point in favour of the diagnosis of acromegaly. The authors conclude that, in addition to the typical cases, account must be taken of certain complex forms, which they place in three groups: (1) Incomplete acromegalics, the patients having all the physical signs but few or none of the functional ones, or inversely; the radiograph in these cases shows an abnormal development of the Turkish saddle. (2) Acromegalo-gigantism, including cases of giants possessing some physical and some functional signs of acromegaly; the radiograph in these cases also shows an expansion of the Turkish saddle. (3) "Acromegalism," by which term the authors propose to designate the group of signs found in the descendants or collaterals of acromegalics. They have studied several families in which one or other parent was clearly acromegalic, the children presenting certain characteristic deformities.

223. Experimental Lesions of the Central Nervous System.

J. T. MACCUDRY AND H. M. EVANS have studied certain experimental lesions of the central nervous system with the aid of the intra-vitam stain, trypan blue. They found (*Berl. klin. Woch.*, September 2nd, 1912) that freshly-killed nerve cells are vitally stained. The stain affected both the nucleus and diffusely the protoplasm. Even the processes are coloured and stand out in relief against the unstained matrix. In damaged cells, the stain appears in granular form in the protoplasm. In the injection of the virus an unavoidable wound is created, and in examining the cells of this wound they found that the glia cells which have been killed show the same changes toward the vital staining as do the nerve cells. All the granular cells met with are exquisitely contrasted by the staining, and the endothelial cells of the vessels bordering on the wound also reveal well-stained granules in their protoplasm.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

221. The Psychic Aspect of Cerebral Arterio-Sclerosis.

THE scantiness of the literature on the subject of psychic disturbances in cerebral arterio-sclerosis is commented on by Jarl Hagelstam (*Finska Läkaresällskapets Handlingar*, November, 1912), who reports some illustrative cases. One patient, a woman, aged 58, had been nervous from childhood, and had suffered from giddiness for many years. She had incurred many troubles of late years, and had developed increasingly frequent headaches. Occasionally she suffered from causeless weeping and complete amnesic aphasia of short duration. Although she had previously been energetic, lively, and enterprising, she became depressed, and in some ways childish, without showing gross stupidity. After this condition had lasted, with remissions, for about three years, the patient suddenly collapsed on to a chair, and was unable to walk for some days. She was perfectly conscious, and no weakness of the lower limbs could be detected. Later, slight ataxia of the right arm and leg were noticed, as well as paraesthesia of the right arm, and a sense of numbness in the right leg. After a period of five years, during which the patient felt very ill, and persistently predicted her speedy death, she suddenly became restless and partially unconscious. A severe headache occurred which terminated in coma and death. The necropsy showed marked atheromatous degeneration of arteries of the brain, and foci of softening, from the size of a pin's head to that of a lentil, which were most numerous in the basal ganglia. Not a trace of arterio-sclerosis could be found in the heart and the main blood vessels. In another case, a woman aged 62, whose temperament had always been nervous and restless, became very excited after repeated and prolonged mental trouble. She felt constantly giddy, and complained of singing in the head. As these symptoms were aggravated by the slightest movement she kept to her bed, where she remained for about two years. She could, however, both stand and walk, and the strength and mobility of her legs seemed unimpaired. She constantly complained of "her terrible illness," and her capacity for critical reasoning became slowly less. But there were no paralyses or sensory disturbances, and no signs to suggest a focal, cerebral lesion. The tension of her arteries was high, the second heart sound was accentuated, and slight oedema of her hands and feet were sometimes noticed. Her condition grew worse in spite of slight transitory remissions, slight facial paralysis appeared, and partial loss of consciousness was followed by death. The necropsy showed a very marked degree of atheroma of all the arteries of the brain, including the most minute. Areas of softening, of the size of a bean, and evidently of no recent origin, were found in the lenticular nucleus and the thalamus of both sides. Arterio-sclerosis of the coronary arteries, and an early stage of granular kidney were also found. In his analysis of the symptoms of the "nervous" form of diffuse arterio-sclerosis of the cerebral vessels, Dr. Hagelstam attaches most importance to a sense of giddiness and noises in the head as aids to diagnosis. Headache is a less constant symptom, though intermittent headache is not uncommon. General depression, restlessness, and a sense of severe illness are characteristic symptoms of the disease in its more advanced stages; and there are usually signs of slight mental derangement. These conditions, combined with slight and transitory signs of a focal cerebral lesion, constitute the clinical picture of a disease which is more common than is generally supposed.

225. Induced Albuminuria in the Detection of Latent Nephritis.

SCALIA (*Riv. Med.*, January 11th, 1913) has made observations on 84 persons suffering from various diseases (excluding acute infections) whose urine had previously shown no trace of albumen, by attempting to induce albuminuria in them by means of injections of pure egg albumen. He refers in some detail to the work of others on similar lines, and then gives an account of his own experiments. The dose injected was usually 2 c.c., and only one injection was given. This as a rule gave rise to no disturbance, and only in a few cases—16 in all—induced

any albuminuria. If albuminuria followed it was always slight and of short duration (about eight hours as an average), and did not appear earlier than eight or later than twenty-two hours after injection. The type of albuminuria was monocyclic with a maximum intensity at the beginning of elimination. In persons already affected with marked albuminuria the injection of white of egg made very little change in the amount of albumen. In diseases not materially affecting the body as a whole the egg albumen injections were usually negative in their results, but in diseases affecting various organs and producing secondary effects, a latent weakness of the kidneys was often evoked. This was especially so in the case of hepatic disease, where the egg albumen test frequently disclosed a lowered resistance of the kidney. Albuminuria induced in this way may be the only evidence of renal change.

226. Treatment of Obesity.

GALISCH (*Sem. méd.*, No. 50) recommends the following régime in cases of obesity. In the morning the patient takes a cup of tea with buttered bread, and if he is too hungry to wait for luncheon he takes an egg with a small piece of bread and butter at ten o'clock. At one o'clock the meal consists of meat, vegetables, salad, and a compôte. In the afternoon he takes coffee with a little biscuit or white bread with butter. In the evening he gets simply a small piece of bread and butter. At the first breakfast and the midday meal the amount taken must be sufficient for the patient to leave the table completely satisfied. For the first two or three days the patient feels very hungry in the evening; but this quickly passes off, and he soon gets into the habit of eating more at the first two meals, this excess of alimentation being counteracted by the exercise and work done during the afternoon. The régime is founded on the idea that it is the food taken in the evening and followed by the repose of night which particularly contributes to the formation of adipose tissue, and also on the fact that the obese generally prefer their evening meal. All Galisch's patients who have undergone the treatment have lost one or two pounds a week. When the normal weight has been attained some increase may be allowed in the evening meal, but the patients should be weighed constantly, and if there is any relapse they must return to the previous diet.

227. Gastro-Intestinal Arterio-sclerosis.

FRAGONI (*Riv. Critic. di Clin. Med.*, An. xiv, 1913), in a lengthy contribution, raises several very interesting questions in relation to the above subject. The effects of arterio-sclerosis in other parts of the body are well known and definite, but in the gastro-intestinal region there is much room for further knowledge, and there is no reason for supposing that this region should escape any more than any other. In the etiology the same causes which produce arterio-sclerosis elsewhere are efficient in the gastro-intestinal region: in the German cases (and most of the cases hitherto described are German) beer and smoking seem to play rather a predominant part, and for the same reason the male sex is preferred. A good deal of discussion is given to the pathological anatomy and a special appendix devoted to the mesenteric arteries, which are described as anatomically and functionally anastomotic vessels, but practically terminal, which means that only under exceptionally favourable conditions can anastomosis take place after blockage. Clinically the author groups the cases into gastric arterio-sclerosis—(1) pseudo-gastralgic angina, (2) gastro-rrhagia, (3) dyspeptic and intestinal, (a) enteralgia, (b) thrombotica. Differential diagnosis, as one may suppose, is extremely difficult, and it is largely by a process of exclusion that one arrives at a definite diagnosis. Reading the long list of symptoms, any one of which might be due to some other cause, it is hard to disentangle a clear picture of gastro-intestinal arterio-sclerosis as an entity in itself, and perhaps one could not expect that, but there is much interesting evidence to show that this should be borne in mind as a possible cause of certain gastro-intestinal phenomena. In regard to unexplained hæmatemesis, cramp of the stomach, colic, etc., the suggestion of arterio-sclerosis may well throw light in a dim region of speculation and possibly avoid the surgical solution of looking inside to see. A very full bibliography is appended.

SURGERY.

228. Spontaneous Gastro-enterostomy discovered Radiologically.

A RARE gastro-intestinal condition in which x-ray diagnosis "has had all the value of laparotomy without chloroform or incision" is reported by Douarre (*Arch. d'électr. méd.*, March 10th, 1913). The patient had suffered from digestive troubles for four years, accentuating as time went on, and giving rise to crises increasingly frequent and severe. These culminated in an extremely acute attack, occurring six months before radioscopic examination. This attack, which lasted for four or five hours, and was accompanied by a sensation at the stomach only to be compared to burning with a hot iron, was followed by a diminution of the symptoms, except that of constipation, and in subsequent months, although there was still pain after every meal, it was much less acute than formerly. Ultimately a radioscopic examination, made after the ingestion of gum bismuth, revealed a stomach apparently normal in situation, form, and mode of filling. It was noted, however, that in spite of particularly energetic contractions in the prepyloric region, no portion of the bismuth appeared to clear the pylorus and pass into the duodenum during the five or ten minutes of observation. On studying the method of evacuation more thoroughly there was seen to be a diverticular shadow, like a triangle, appended to the lowest part of the stomachal cul-de-sac, and a brief observation of the movement of the bismuth at this point was sufficient to suggest an abnormal communication between the stomach and a portion of the intestine. The general image of the stomach having excluded all idea of medio-gastric biloculation, there remained the alternative of a communication between the stomach and the small intestine or a gastro-colic fistula. Repeated radioscopic examination, as well as the clinical findings, negated this second hypothesis, for the small intestine evidently fulfilled its part in the digestive function. At no period of the examination, however, was any appreciable trace of bismuth found in the duodenum, and the evacuation from the stomach took place very slowly, some of the bismuth remaining in that organ more than twenty-four hours after ingestion. It appeared, therefore, that, owing probably to a cicatricial constriction of the pylorus, the stomach was emptied almost entirely by this natural gastro-enterostomy. The commencement of the evacuation, which did not follow immediately upon the ingestion of the bismuth liquid, made it evident that the perforation acted as a true muscular orifice, analogous to what is produced in surgical gastro-enterostomy, permitting the passage of the stomachal contents only under the influence of contractions or of a relaxation. Another anomaly in this case was a twist in the tract of the transverse colon, probably due to inflammatory adhesions, this being responsible for the persistent constipation. Altogether the x-ray findings made it possible to reconstitute the clinical history of the patient. The digestive troubles and painful crises were attributable to one or more ulcerations in the prepyloric region, and these crises increased in intensity up to the day when spontaneous perforation occurred.

229. Treatment of Generalized Acute Peritonitis.

JACOULET (*Rev. Franc. de méd. et de chir.*, 1912, No. 16) divides the treatment under the following headings: *Pre-operative*: The patient should be placed in the semi-sitting posture, a large bladder of ice placed over the abdomen, and six to ten drops of a 1 to 1,000 solution of adrenalin injected subcutaneously. *Operative*: Usually local anaesthesia is sufficient; 1 per 200 solution of novocain with some drops of 1 per 1,000 adrenalin should be injected, and, if a general anaesthetic be required, ether or ethyl chloride, and never chloroform. The lines of incision depend on the diagnosis. If the origin be an appendicitis, the abdominal wall at the external edge of the rectus should be incised; if perforation of the stomach or duodenum, the incision should be made above the umbilicus. If the cause of the peritonitis be doubtful, the incision for appendicitis should be made, and, if the appendix be healthy, the incision should be prolonged upwards, and the duodenum, pylorus, and gall bladder examined, and, if necessary, a new incision made. Drainage in all cases is necessary. *Post-operative*: Immediately after the operation the patient should be placed in the semi-sitting position, and continuous proctoclysis carried out with a solution of sodium chloride 7 grams, calcium chloride 7 grams, water 1,000 grams; this should be continued drop by drop for three days or more. Thirty to 40 c.cm. of a solution of 1 to 10 of oil of camphor in the

twenty-four hours make an excellent adjuvant to the treatment, and it is good practice to inject intraperitoneally before closing the wound after operation 200 to 300 c.cm. of the same solution carefully sterilized. If operative intervention and the other treatment just described are futile, enterostomy or caecostomy should be performed.

230. Rectal Ether Narcosis.

FEDERICI (*Gazz. degli Osped.*, August 1st, 1912) reports the case of an emphysematous man, aged 67, who was operated upon for inguinal hernia. As he was not considered a good subject for a general anaesthetic by the mouth, it was decided to administer ether per rectum, and, after a preliminary injection of 1 g. of morphine and atropine, and washing out the rectum, 1 litre of a 5 per cent. solution of ether in physiological solution was given per rectum. Beyond a slight burning feeling in the rectum and towards the descending colon, no discomfort was complained of, and the operation was finished without the patient feeling any pain. The breath smelt of ether. After the operation, the patient did not suffer from any local trouble in the rectum, no diarrhoea, no proctitis, and the abdomen was normal. No vomiting was observed either during or after operation. Increased frequency of micturition (every three-quarters of an hour) was noticed for three or four days, but this gradually disappeared before the eighth day, when the patient died. During life no albumen or sugar had been detected in the urine. At the *post-mortem* examination, however, both kidneys were in a state of chronic interstitial nephritis, whilst in the left kidney there was evident acute diffuse haemorrhagic parenchymatous nephritis. The lungs were both congested, and there was some old leptomeningitis. The cause of death was the state of the kidneys, which the author is inclined to attribute to the ether.

231. Smooth Pigmented Naevi, or an Unusual Form of Xeroderma Pigmentosum?

BALZER ET BELLOIR (*Bull. de la Soc. Franc. de Dermat. et Syph.*, January, 1913) report the case of a girl, aged 15, who since the age of 5 weeks has presented the appearances for which she is now attending the Saint Louis clinic. The lesions, which were originally few in number and discrete, have during the last few years become more numerous and confluent in places. They were first noticed circumlabially and chiefly under the nostrils, and consisted of small pigmented points of a brownish colour, flush with the skin, and of the size of a pin's head. The mucous membranes were similarly affected and that from the commencement. At the present time the lips, chin, and nose, chiefly in the middle line, and part of the forehead are the sites of numerous pinhead macular spots of a greyish-yellow, grey, or black colour. Those at the lip margins are more marked and dark in colour, and their elements are particularly obvious on the mucous surfaces, both of lips and cheeks. The tongue is free. There are no epitheliomatous lesions to be seen anywhere on the body. In discussing the diagnosis it is important to note that no members of the family are suffering from xeroderma (a common affection in families, a member of which presents xeroderma pigmentosa), also that the lesions are mucous as well as dermal, and that they appeared originally altogether at the same time. These points are in favour of pigmentary naevi. The other possibility requires careful observation especially at the present age, for it is certain that the pigmentations have for some time past been on the increase. Radium applications are being tried.

OBSTETRICS.

232. Prolapse of the Placenta.

MÜNCHMEYER (*Archiv f. Gynäk.*, xxxiii, 1888), some twenty-five years ago wrote on this rare condition. Reported cases are accepted with great diffidence by obstetrical authorities because it is always possible that the placenta was actually attached in part at least to the cervix, in other words that in more than one instance the case was really "placenta praevia" wrongly interpreted. The question is important for the practitioner and midwife. Hence it is interesting to read the report of a case under observation last year in Leopold Meyer's maternity department at Copenhagen (*Monatsschr. f. Geb. u. Gyn.*, May, 1912). The medical superintendent, Dr. J. P. Hartmann, published the case last spring. It was associated with a grave complication. The patient, 25 years of

age, had been subject to kidney disease ever since an attack of diphtheria sixteen years previously. She had borne two children. During her second pregnancy when she was under close observation the urine was highly albuminous. The child was born alive at term, and the patient went into the medical wards of the Copenhagen Hospital after convalescence from the puerperium. The third pregnancy was associated with great aggravation of the renal disorder. Once more the patient was admitted into a medical ward. She had reached about the sixth month of gestation. A little blood and, it was believed, liquor amnii came away, and as there were hypogastric pains the patient was transferred to the maternity. The urine was highly albuminous and full of casts, and there was oedema of the legs and eyelids. Some coagula came away. The placenta could be readily defined presenting at the os externum. Hydrostatic dilators were introduced as placenta praevia was not unreasonably diagnosed. No liquor amnii escaped, but neither was there any bleeding. Pains were induced, but they were very weak. The pressure was increased cautiously, but the pains did not strengthen, and the patient's condition grew very bad, the oedema increasing perceptibly. As the bag was withdrawn a quantity of liquor amnii came away, strongly blood stained, followed by a clot of the size of a fist; yet there was no flooding. The fundus was pressed, and then the placenta began to pass into the vagina till it presented at the vulva. The membranes were torn widely open, and immediately an arm prolapsed. Hartmann turned and then delivered the fetus, without difficulty, by expression. A cotyledon, spontaneously torn off, came away after an intrauterine injection. There had been practically no flooding during the induced labour, but the patient died a few hours after delivery. Advanced chronic tubal nephritis, with extensive characteristic changes in the viscera were discovered at the necropsy. The placenta was full of white infarcts and circumscribed coagula. Its maternal aspect was compressed by a wide layer of old coagulum. On examining the uterus the true nature of the obstetrical complication became evident. The placental site lay on the inner aspect of the fundus posteriorly, and did not come near the cervix at any point. Thus the placenta had become detached from its favourable insertion, and had been pressed downwards or had slipped downwards when the uterus was in a state of relaxation, and ultimately presented. The remarkable absence of flooding in association with a placenta lying across the os externum should be borne in mind. Hartmann adds to his report a second case under observation in a garrison hospital. A woman in her second pregnancy miscarried in the sixth month. The pains at the beginning were associated with flooding. On admission into hospital it was found that the waters had come away, the membranes protruding from the vagina. The placenta lay in the vaginal canal. The fetal head now presented, expression failed, and the obstetrician, Ammentorps, turned and delivered. A little blood came away afterwards, but the uterus contracted badly, so that the tampon was applied. The patient, 28 years old and apparently healthy, recovered. Hartmann gives a good summary of researches on the subject. As the complete detachment of the placenta, from its site high up in the uterine cavity, the necessary preliminary to prolapse, entails haemorrhage, there must always be risk to the mother. Complete detachment allowing unhindered uterine contraction is less serious than partial detachment. The peril to the fetus is, for an evident reason, extreme, yet in more than one case the child was saved, though delivered five or even ten minutes after its placenta. Hartmann observed the same phenomenon in a case of true placenta praevia. The placenta was detached, and not till ten minutes later could the child be extracted. To his great surprise, it was alive.

GYNAECOLOGY.

233. Results of Hysteropexy.

BAZY (*Rev. de gynéc.*, June, 1912) reviews hysteropexy according to clinical evidence and comes to the conclusion that it is not only useless but also dangerous. Some operators bring together the round ligaments and fix them to the parietes. Being very extensible, the uterine so treated is not prejudiced should pregnancy occur, but the ligaments under such conditions are not elastic and do not undergo involution after childbirth. Hence, as secondary operations have shown, a long tough band runs from the uterus to the parietes. Even when no pregnancy occurs this band often develops in course of time. It is a standing danger to intestine. But Bazy

shows that a graver complication may develop. The band, becoming longer and longer as the uterus drags on it, tends to split into its original component parts, the right and left round ligaments. Then two rigid bands run from the uterus to the parietes, doubling the danger to the intestine as far as they are concerned, and adding a third and greater danger of obstruction, for a deep and narrow fossa forms between them, a most unnatural disposition which interferes with the rising of the distended bladder below, and itself becomes a sac into which intestine will insinuate itself, and undergo incarceration or strangulation. Metrorrhagia, common after direct suspension of the uterus, has been noted by Bazy in a case where he detected this unnatural fossa. The dangers of direct suspension are even greater. Between the fundus fixed to the parietes and the point on the parietes to which it is applied and sutured, a cord gradually develops, the fundal or suspensory ligament of F. E. Taylor. It may exceed two inches in length, and it is a source of obstruction: indeed, it is wonderful that strangulation does not always develop. Kreutzmann, in 1902, reported seven cases of acute obstruction after the ordinary ventral fixation. Bazy admits that Doran and Wallace practised methods where no space was left under the band running between the uterus and the parietes. The former surgeon brings together the peritoneum on the inner aspect of each round ligament, uniting them by suture. A yet more theoretically perfect operation is the union of the isthmus or lower part of the uterus to the parietes. It is important for us to bear in mind Bazy's experience in a secondary operation for salpingitis after an "isthmic hysteropexy." The latter had been performed two years and ten months previously. He found that the band which developed between the isthmus and the point on the parietes to which it had been fixed had undergone a remarkable change. The tissues of the band at the lowest part of its attachment to the uterus had atrophied, whilst more fibrous or cicatricial tissue had developed along the upper part of its attachment. Thus a gap had formed below the band, just the complication which "isthmic hysteropexy" is supposed to avoid. On the other hand, the upper part of the band had come to lie close to the fundus. These two changes, mainly the result of steady dragging of the entire uterus, had reduced the operation to a simple "fundal hysteropexy." A coil of intestine had already forced its way under the "fundal ligament," and filled the vesico-uterine pouch, a most perilous condition. M. Bazy concludes that operations for the direct or ligamentary fixation of the uterus to the abdominal wall can be and ought to be absolutely discarded. They can or may be rejected because, in his opinion, they are simply no good. Where there is prolapse the uterus soon sinks down again, dragging on the dangerous newly-made bands of adhesions. In cases of retroflexion, ventral fixation without doubt gives temporary relief, but Jagle finds, as the result of secondary operations, that this fixation is not constant. After-histories about operations for disorders, mainly sources of discomfort, may be misleading, as the patient may continue to feel comfortable, though pelvic exploration shows that the parietal union has begun to yield. Some surgeons advocate well-known extraperitoneal operations on the round ligaments, but as they are distensible but not elastic bad results may ensue should the patient become pregnant. Plastic operations on the pelvic floor are, according to Bazy, the right steps towards radical cure of distressing displacements of the female organs. Most flexions and prolapses, the gynaecologist must by the way admit, cause little discomfort. In old subjects hysterectomy alone ensures cure. Lastly, ventral fixations ought to be discarded, because they are dangerous. Intestinal obstructions have been frequently reported, and perhaps more often not reported or overlooked, and Bazy adds that severe metrorrhagia is a common result of an operation of this type.

THERAPEUTICS.

234. The Pathogenesis of Mercurial Stomatitis and Colitis.

ALMKVIST (*Dermat. Zeitsch.*, November, 1912, December, 1912), in a long series of clinical and experimental observations, provides additional proofs of his original explanation of this important toxic action of mercury, and replies to the criticisms of other writers in a very convincing manner. According to him putrefactive processes in the mouth, dependent mainly on pyorrhoea, cause erosion and a loose, congested condition of the mucous membrane in the meshes of which H₂S is generated and freely absorbed.

The capillaries which supply the mouth are charged with mercury which, meeting in this situation with the H_2S , will be converted into the sulphide, which is deposited in the tissues and capillary walls as a black precipitate which can be demonstrated microscopically and chemically. Mercury sulphide is very toxic, as he has experimentally shown, and the damage done to the vascular system locally can therefore readily be accounted for. Further erosion leading to ulceration is the result, and if there is much circulatory disturbance the organisms which abound in this cavity of the body become so virulent and the body resistance so weak that even gangrene may ensue. To Sabbatani's suggestion that the local selective action of mercury on the mouth is due to the ionic concentration of Hg in the saliva owing to the low protein and high chloride content of the latter the author returns what would seem to be an unanswerable reply—namely, that mercury perchloride (1 to 4,000) and mixtures of mercury and iodiform locally applied have not only prevented but have actually cured mercurial stomatitis, and that such has been for quite a long time the chief therapeutic measure used in the St. Görán Hospital in such cases. The colitis is explained in much the same way, and it is noteworthy that in animals such as dogs, in which the intestinal putrefactive processes are not marked, colic and diarrhoea with watery and blood-stained stools are exceedingly difficult to produce.

235. Excretion of Formaldehyde; Burnam's Test.

COMMENTING upon the very general use of the preparations of formaldehyde, L'Esperance, in the *Boston Med. and Surg. Journ.* (vol. clxvii, No. 17), points out that it is too often assumed that because the drug is decomposed in the kidneys of one patient it will necessarily do so in the case of all. Some cases of coluria improve greatly under urotropin, others again show no improvement. This has been hitherto attributed rather to the peculiarity of the micro-organism concerned than to the patient. The work of Burnam brings forward disquieting evidence to the effect that only one patient in two is able to break up urotropin in such a way that formaldehyde appears in the urine. The routine administration of urotropin, for example in typhoid fever, must be accompanied by evidence of the necessary reduction into formaldehyde in order to justify the practice. Formaldehyde to be of any value as a urinary antiseptic must be present in the proportion of 1 in 5,000. Burnam's test is reliable and quickly performed. It is carried out as follows: To 10 c.cm. of urine in a test-tube is added (1) of a 5 per cent. solution of phenylhydrazine hydrochloride, 3 drops; (2) of a 5 per cent. solution of sodium nitro-prusside, 3 drops; (3) of a saturated solution of sodium hydrate, a few drops poured down the side of the test-tube. As the latter diffuses through the urine, if formaldehyde is present, a deep purplish black colour is seen, changing quickly to dark green, gradually becoming lighter and finally becoming pale yellow. In a urine containing no formaldehyde, on the other hand, the same test gives a reddish colour gradually changing to light yellow. Measured by this test only 50 per cent. of these patients excrete formaldehyde. This was noted in all conditions of age, sex, normal and abnormal states of the kidney, and was constant. About an hour was the average time in which the drug appeared in the urine, and it continued to be excreted for from four to six hours. No symptoms were reported by the patients not excreting formaldehyde. Of those who showed formaldehyde in the urine—as indicated by the Burnam test—the symptoms varied from slight hæmaturia and a burning sensation along the urinary tract to a vague sense of malaise. These symptoms ceased with a discontinuance of the drug. The test was applied to 250 patients taking urotropin by the mouth. The conclusions to be drawn are: That formaldehyde appears in the urine in only 52 per cent. of patients taking urotropin; that the reaction of the urine is of no importance; alkalis taken in combination with urotropin have no effect; the duration of the excretion of formaldehyde lasts for a varying period up to six hours; that increased dosage does not affect excretion in negative urines; that patients not excreting formaldehyde have no symptoms however much urotropin is taken.

236. Elimination of Salvarsan.

CAFFARENA (*La Pediatria*, No. 4, 1912) found that salvarsan was eliminated through the milk whether it was given endovenously or intramuscularly; if given through the veins elimination takes place for two or three days; if given intramuscularly it takes from ten to twelve days; hence if an effect is desired on the suckling infant it is better to give the drug by the intramuscular method, and

all the more as after endovenous administration to the mother bad effects have been noticed in the child. Probably this is due to the setting free of a large amount of endotoxin as a result of the very rapid destruction of spirochaetes which follows direct venous ingestion of salvarsan. Indirect antisypilitic treatment of the child through the mother would not suffice for a severe case of congenital syphilis; in such a case some direct treatment, whether by injection or otherwise, of the child is necessary.

237. Treatment of Purpura by Radiotherapy.

TRIBOULET, ALBERT WEIL, AND PARAF (*Bull. de la Soc. de Pédiatrie*, November, 1912) reported the case of a girl of 7 suffering from purpuric patches, with vomiting, abdominal pains, and violent attacks of epistaxis. No family history of hæmophilia, coagulation normal, spleen enlarged. Antidipltheritic serum, adrenalin, peptone, hemostyl, splenic extract, mercurial inunctions, were all tried successively without benefit. Four applications of x rays (two to the spleen and one to each femoral diaphysis) rapidly brought about a cure, and when seen two months after her discharge from the hospital the patient remained perfectly well. X rays have not previously been employed in conditions of hæmophilia and purpura, and *a priori* the treatment would seem irrational, since it has been shown that leukaemic patients so treated suffer from intense anaemia with considerable diminution in the number of red corpuscles. But it must be remembered that this result is brought about by very strong doses; mild doses, on the contrary, stimulate the cells of the hæmatopoietic organs. Asher and Bayer have demonstrated that small doses of the rays applied to the spleen act on the metabolism of the iron, bringing about its conversion into hæmoglobin. In the case here reported the maximum total dose at each irradiation was 2 units H.

PATHOLOGY.

238. The Detection of Fat in Stools.

ALTHOUGH the estimation of fat in the faeces is of great clinical value, many authorities have admitted that the difficulty of carrying out the tests with accuracy renders its employment useless. L. Saathoff describes a simplified method of recognizing fat in stools microscopically and estimating the quantity present (*Muench. med. Woch.*, October 29th, 1912). Every motion contains fat. F. Müller has found that during fasting as much as 1 gram out of a total of 3 grams of dried matter is passed daily, while a normal person is said to pass about 30 grams of solid matter—dried faeces, absolutely freed from water—daily, of which 6 grams is fat. It is, however, significant that the amounts contained in the faeces of different individuals vary considerably. Fat is present in faeces chief in the form of potassium soap, to a less extent as fatty acids, and only to a very small extent as neutral fat. Attempts to melt the fatty substances and to estimate the quantity from the size of the fat drops under the microscope were found to be unreliable. The fact that Sudan III, a diazo dye, is frequently used to render fat visible in histology induced Saathoff to work out a method with this substance. The fat is dyed a yellow or red colour when treated with saturated (30 per cent.) solutions. The method is as follows: A piece of faeces of about the size of a pea is roughly rubbed down on a microscope slide. If the motion is thin or fluid, it may be advisable to heat the slide over the spirit lamp until a tenacious consistence is attained. Two or three drops of Sudan III solution are now applied, and the whole well rubbed together. The Sudan III solution is prepared by mixing 90 c.cm. of glacial acetic acid and 10 c.cm. of a 96 per cent. alcohol and dissolving as much of the dye as can be placed on a threepenny-bit in this. As soon as the mixture with the faeces is homogeneous and equally stained red, a cover-glass is placed on it and pressed firmly to leave only a thin film. The slide is then heated for half a minute over the flame, but not so hot that boiling takes place. It is then placed under the microscope for examination with a high magnification. All the fat is now visible, either as yellow or any colour up to intense red globules. These are readily recognized in contrast with the pale yellow background. The stained fat loses its colour on cooling, and colourless crystals appear. Reheating revives the intense colouring. The author has set up a general scheme whereby the approximate quantity of fat in a stool can be estimated in this manner. He gives some results of his observations with the method.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

239. Arterio-sclerotic Neuritis.

THOUGH barely recognized, neuritis due to arterio-sclerosis is, in the opinion of O. Foerster (*Wien. med. Woch.*, January 25th, 1913), not uncommon, for he has observed it in sixteen cases during the past six years. In all these cases general arterio-sclerosis existed before the neuritis, and the blood pressure was abnormally high. In most cases the arteries were thickened and tortuous, the heart showed signs of myocarditis and steno-cardia, a systolic murmur was audible over the aorta, and the urine contained a little albumen. Transitory glycosuria, which was independent of the patient's diet, was also frequently observed. In none of the cases was any other cause of the neuritis demonstrable. Wassermann's reaction was invariably negative, and such factors as alcohol and infectious diseases were also absent. Five of the patients were about 50 years old and 5 were between 60 and 70, and 6 were between 70 and 80. The condition is not, therefore, invariably a late sequel to arterio-sclerosis in elderly people. Hitherto the records of arterio-sclerotic neuritis have almost exclusively been of cases of polyneuropathy, the nerves of the legs and arms, as well as the cranial and intercostal nerves, being involved simultaneously or in rapid succession. But most of the author's cases showed strict limitation of the neuritis. In 6 cases the nerves of the crural plexus were involved, and pain was felt in the outer aspect of the thigh and, later on, its anterior aspect. At first this pain occurred only after walking, and it ceased with rest. Later, it became continuous, and was troublesome at night. But though the pain might be excruciating, it was not accompanied by tenderness on pressure over the muscles or nerves of the affected area. The author repeatedly reiterates this observation, which he finds of great importance in differential diagnosis. There was also no paravertebral tenderness, but the patellar reflexes were absent. In one case in which the neuritis was unilateral, the absence of patellar reflex was bilateral. In some cases atrophy of the iliopsoas, quadriceps extensor, and adductor muscles was accompanied by altered reaction to electrical stimulation. Motor paralysis, when present, invariably occurred later than the pain. Two out of the 6 cases in which the crural plexus was involved were unilateral, 3 were first unilateral and then bilateral, and 1 was bilateral from the beginning. In another group of 13 cases the sciatic plexus was involved. The original diagnosis was commonly sciatica, and the patients complained of pain in the hips, the buttocks, and in the back of the thigh and leg, down to the external malleolus. But neither the sciatic nerve, its branches, nor the muscles they supplied were tender. Lasègue's sciatic sign and paravertebral tenderness were also absent. In some cases there was paraesthesia of the foot, and in every case the Achilles reflex was absent. Atrophy of the muscles supplied by the peroneal and tibial nerves was common, but muscular weakness was frequently not noticed till the patient had walked for some time. In 1 case violent pain and paraesthesia in both limbs, absence of patellar and Achilles reflexes, involvement of the bladder, and positive Romberg without motor paralysis, formed a group of phenomena suggestive of tabes. The disorders of the bladder observed in 3 cases were probably due to neuritis of the pudendal plexus. But it is also possible that they were due to arterio-sclerosis of the brain. None of the dorsal nerves was involved; but in 3 cases slight pain and paraesthesia were observed in the arms, and in 1 case marked neuritis of the left arm was followed by atrophy of many of the muscles of the forearm. In 2 cases there was bilateral trigeminal neuritis without pain on pressure. With these exceptions, the cranial nerves were intact. The course of the disease was very erratic, remissions were frequent, and a transition from a mononeuropathy to a polyneuropathy was often seen. Complete recovery was also observed. Many of the patients died of arterio-sclerosis of the brain after the neuritis had existed for a long time.

240. Angina of Ludwig.

RECLUS (*Journ. des praticiens*, March 8th, 1913) describes several cases of this disease. The first of these, which may be taken as typical of the others, was the case of a waiter, aged 25 years, who suffered for some time from severe pain in a diseased molar, and in whom there was

an enlarged submaxillary gland on the same side. The swelling spread rapidly, and finally involved the whole of the submaxillary area on both sides. The inflammatory area was of woody hardness, and the skin a rosy flush, but was noticeably free over the subjacent tissues. The mucosa of the floor of the mouth, which was the upper limit of the inflamed area, was difficult to see, on account of the trismus present, but appeared to be raised in a soft, cushion-like, almost gelatinous swelling. Under local anaesthesia a deep incision was made by means of the thermo-cantery, the platinum knife being heated to a white heat. A fetid, serous fluid, apparently gaseous, escaped freely. A tampon soaked in iodine strongly fortified with alcohol was then introduced, and the walls of the cavity were well bathed with it. As tincture of iodine decomposes almost immediately in contact with organic albuminoids, these dressings have to be changed frequently at first. The recovery was very satisfactory. In two other cases which the author details the dyspnoea associated with Ludwig's angina was very pronounced, and caused some anxiety, but a similar procedure had a successful issue. All of these cases showed the anatomical limitations of the inflammatory area of the disease. It is a space bounded in front by the posterior surface of the are formed by the inferior maxilla, below by the muscular band of the mylo-hyoid ensheathed in its aponeurosis, and above by the sublingual mucosa. In the author's opinion Ludwig's angina has nothing specific about it, and may be associated with a variety of infective agents, the streptococcus being perhaps the most common. It is apt to arise in cases of temporary debility, and a common feature in all the cases quoted was the existence of a carious tooth and an enlarged but almost painless submaxillary gland. An important point, and often a source of error for the clinician as to the gravity of the condition, is the fact that the rosy-tinted and glistening skin moves freely over the underlying tissues. The necessity for early and active interference is emphasized by the risk of grave toxæmia and asphyxia in these cases. Any delay may necessitate tracheotomy, which would have to be undertaken in the most unfavourable circumstances. With every day's delay the mortality of the disease rises rapidly. General anaesthesia in these cases is dangerous.

241. Erythema Nodosum in Children.

DURANTE (*La Pediatria*, September 30th, 1912) reviews the various theories as to the nature of erythema nodosum and comes to the conclusion that it is a specific disease, and not a manifestation of rheumatism, tubercle, etc. It is true no definite organism has as yet been isolated, but that is equally true, for example, of scarlet fever. The diseases most likely to be confounded with erythema nodosum are rheumatism, polymorphous erythema, and the erythema induratum of Bazin. That some patients develop tubercle subsequently to an attack of erythema nodosum does not make erythema nodosum a manifestation of tubercle any more than such a sequence of events would turn measles into such a manifestation, and tubercle not infrequently follows measles. A few instances of limited epidemics have been recorded, so that it is possible erythema nodosum is very slightly contagious. If we consider the onset of the disease, its uniformity of course, the constancy and unity of the elementary lesions, the possible complications, and the general clinical behaviour, there is as good a reason for believing it to be a definite morbid entity as for most other diseases. In the three cases reported by the author von Pirquet's reaction was negative in each case.

SURGERY.

242. Tuberculous Peritonitis and Trauma.

E. EDÉN (*Uppsala Läkareförenings Förhandlingar*, February 17th, 1913) records a case of tuberculous peritonitis following a fall. The patient, a girl aged 6, had been quite well till six months ago, when she began to waste and to complain of abdominal pain; a younger sister also complained of abdominal pain. The milk supply of the family came from tuberculous cows. Two days before admission to hospital the patient fell on the ground, and immediately

complained of violent abdominal pain, which did not, however, prevent her walking a few steps to her home. She had not fallen on any sharp object, and no external injury was demonstrable; but her abdomen was everywhere tender, and for two days she was treated at home with cold compresses. She refused food, vomited frequently, and, with the exception of one motion passed after the accident, her bowels did not act. In hospital her temperature was 99.8° and her pulse 120. There was no dullness on percussion or marked hardness of the abdomen, which was somewhat distended and tender. A laparotomy showed great distension of the intestines, the surfaces of which were dull, dry, and covered with a thin layer of fibrin. The pelvis contained a small quantity of blood-stained fluid. An abscess cavity large enough to contain an orange was found in the mesentery of the jejunum. The mesentery elsewhere contained many enlarged glands, but there were no adhesions between the coils of intestine or between the intestine and the abdominal wall. Enterotomy was performed on both the large and small intestine, and cheesy, blood-stained matter was removed from the ruptured and half empty abscess cavity, which was then plugged with a tampon. The tumour which had formed around the abscess was now excised, and was found to consist of typical tuberculous tissues. The patient recovered. The author considers that the fall ruptured the abscess and thus started the peritonitis. As a rule, when tuberculosis of an abdominal organ extends to the peritoneum, adhesions form locally and thus prevent the generalization of the peritonitis. Another rare feature of this case is the shortness of the interval between the commencement of the peritonitis and the operation. This explains the absence of adhesions, thick deposits of fibrin, and of the tuberculous nodules found in tuberculous peritonitis of old standing. Lüchse alone appears to have recorded a similar case.

243. Electrolysis of the Urethra, Prostate, Lacrymal Duct, and Oesophagus.

LAFOND-GRELLETY (*Gaz. hebdomadaire des sci. méd.*, 1913, xxxiv, No. 6) publishes the following results of electrolysis: *Urethra*: 46 cases of stricture; 8 cases in which no bougie would pass, 7 cures, 1 inoperable; 14 cases of stricture without discharge, all cured; 24 cases with discharge, 23 cured, in 1 the discharge continued. *Prostate*: 6 cases, 5 cures. *Lacrymal duct*: 4 cases, all cured. *Oesophagus*: 1 case of carcinoma of the oesophagus, much relieved.

244. Hemisporosis.

BALZER AND BELLOIR (*Bull. de derm. et syph.*, February, 1913) draw attention to hemisporosis as reported in the literature, and for fuller information refer the reader to the publications of Gougerot and Caraven, Schramek, Pinyo, and De Benmann, whose work, *Les Sporotrichoses*, was published in Paris last year. The case they reported concerned that of a fruit porter, who two months before attending hospital had suffered from furuncles of the neck. A month later there developed in the interscapular region a small, slightly painful swelling which quickly increased in size and broke down in fifteen days, the resulting ulcer, when first shown, being the size of a florin, with dusky red, irregular, soft, infiltrated margins, and discharging a sero-purulent fluid from under the yellow, crust-covered base. A smaller and similar lesion was found on the antero-internal surface of the right tibia. It was noted that the patient, whose Wassermann reaction was found to be negative, was in the habit of slinging his fruit basket round his bare neck, from which source he no doubt contracted the infection. Cultures of the typical organism—a mycelium with bulb-shaped protogonia (so called) and chains of circular deuteroconidia—were successfully grown on maltose agar in ten days. The cultures were also typical in appearance and consisted at first of small, greyish-white, downy discs, enlarging later to circular cerebriform patches of a rusty and chocolate brown colour. The authors suggest that in all cases of soft gummatous tumours, where the Wassermann reaction is negative, cultures should be made, as a positive find will save the patient from surgical interference or antisypilitic treatment. The lesions yield rapidly to the internal administration of potassium iodide in large doses.

245. Hydatid Cyst of Liver.

VERDELET (*Gaz. hebdomadaire des sci. méd. de Bordeaux*, 1912, xxxiii) describes the case of a woman 50 years of age operated for a hydatid cyst of the liver, in whom six months afterwards an echinococcus cyst occurred in the cicatrix. The cyst was removed and cure resulted. The author draws attention to the necessity of antiseptic precautions to prevent secondary infection.

OBSTETRICS.

246. Fatal Haemorrhage from Vagina and Vulva after Labour.

A CASE of haematoma of the vagina terminating in profuse haemorrhage and death is reported by R. Roemer (*Zentralbl. f. Gyn.*, January 25th, 1913). The patient, whose two previous confinements had been normal, was 23 years old when attended at her third confinement by a midwife. No instruments were used, but half an hour after the completion of labour violent pain like that of labour was experienced, together with a sensation of pressure in the lumbar region and about the rectum. These symptoms were ignored till the midwife saw a swelling of the size of a fist projecting from the vagina through the vulva. An hour later a medical man found this swelling as large as a child's head. Three hours *post partum* the patient was sent to the hospital, on her way to which the swelling burst and flooded the stretcher with about two litres of blood. She was now very anaemic, her pulse was 130, small, and of low tension, and the firmly contracted uterus extended to the umbilicus. The whole of the posterior vaginal wall was stripped from the underlying structures and was torn from above downwards, but the uterus and peritoneum were intact. Although the patient rallied under treatment with stimulants and subcutaneous injections of saline solution, death followed six hours *post partum*. The author attributes the haemorrhage to rupture of a large blood vessel in the paravaginal tissues during the passage of the child's head, and he reflects unfavourably on the delay which cost the patient her life. Had she been admitted sooner to hospital, had the bleeding vessel been found and ligatured, and had a tampon been inserted, death would, he thinks, have been avoided. This view is supported by the experience of Walther, whose patient complained of pressure about the anus within an hour of the completion of labour. Haematoma of the upper portion of the vagina was discovered, and active measures were taken which saved the patient's life. In another case described by the same writer a vaginal haematoma as large as a fist was not interfered with. Sepsis followed and the patient died. The mortality from vaginal haematoma is not, however, very high, and out of 50 cases collected by v. Winckel there were 6 deaths, 3 of which were directly due to the haemorrhage.

247. Pernicious Vomiting of Pregnancy.

WHITFRIDGE WILLIAMS (*Journ. of Obstet. and Gyn. of the British Empire*, November, 1912) has revised his views on this subject. He still holds to his original classification of reflex, neurotic, and toxæmic vomiting, and regards the toxæmic element in the first two forms merely as a predisposing factor. The toxæmic type occurs much less frequently than the neurotic, but considerably less frequently than the reflex variety; but its diagnosis is not so simple as the author had originally believed. Formerly he taught that the toxæmic form, being associated with profound degenerative lesions in the liver and kidneys, as well as with marked changes in metabolism, could be sharply differentiated from the others; that it was characterized by the increase in the proportion of nitrogen excreted as ammonia, and that when the ammonia coefficient exceeded 10 or 15 per cent. it should be regarded as an indication for the prompt termination of pregnancy. It now appears that the significance of a high ammonia coefficient is not specific, but may be a manifestation of starvation following neurotic vomiting, or of an acidosis due to various causes. Nevertheless for clinical purposes we can consider a case as toxæmic in origin whenever a seriously ill patient, presenting a high ammonia coefficient (20 per cent. or more), fails to improve after a few days' complete rest in bed, combined with suggestive treatment, energetic rectal feeding, and the administration of large quantities of saline solution per rectum and beneath the skin. Furthermore, the appearance of coffee-ground vomit, well-marked icterus, and a semi-comatose condition, justifies an almost positive diagnosis, provided chloroform has not been employed as an anaesthetic. If improvement does not promptly follow appropriate treatment the existence of toxæmic vomiting should be assumed, and abortion promptly induced. In the absence of genital lesions, a low ammonia coefficient indicates neurotic vomiting, which can be cured by suggestion and dietetic treatment, no matter how ill the patient may appear. In primiparæ vaginal hysterectomy is the most conservative method of emptying the uterus. Nitrous oxide gas or ether should be used for anaesthesia in preference to chloroform, since chloroform has a deleterious

effect upon the liver, and in cases of delayed chloroform poisoning similar hepatic lesions are found to those seen in cases of death from toxicæmic vomiting.

GYNAECOLOGY.

248. Radium and X Rays in the Treatment of Uterine Fibroma.

THE use of radium, either alone or associated with x rays, in the treatment of uterine fibroma has been the subject of an interesting discussion in the Société de Radiologie Médicale de Paris (*Bull. et mém.*, No. 42, 1913). The discussion was initiated by a communication made previously to the Société d'Obstétrique et de Gynécologie by Bouchacourt and Chéron, who advocated the radium method. The opinion of all the radiologists, however, was adverse to the excessive claims made for radium in this connexion. Haret, for example, questioned the statement of the authors of the paper to the effect that the radiation from a tube of radium inserted into the uterus was almost entirely absorbed by the uterine muscle and fibrous tissues. It was well known that in a radiograph of the pelvis no trace of the uterus was visible, owing to the penetrating character of the x radiation. Was it likely, therefore, that the radiation from a tube of radium, which was so very much more penetrating, could be arrested almost totally by the uterus? Nor would this authority accept the statement that the technique of radiumtherapy was easier than that of radiotherapy. Properly to employ either method required not only a knowledge of the various factors of dosage but a considerable experience. The authors had stated that at the beginning of x-ray treatment, using feeble doses, they had occasionally observed an increase of hæmorrhage, due to the excitation of the ovarian function, but the testimony of Haret was that, although he himself had given nothing but feeble x-ray doses, he had never witnessed this phenomenon in forty cases. Bécère endorsed Haret's criticisms, and dealt with the insinuation that radium was therapeutically much superior to the x rays because of its greater penetrating powers. The epithet "ultra-penetrating" in connexion with radium seemed to have the same talismanic value for some workers as the label "extra dry" possessed for certain palates when it appeared on bottles of champagne. Without doubt the gamma rays of radium surpassed greatly in penetrating power the rays emitted by the hardest x-ray tube, but the gamma rays did not constitute more than the tenth part of the total radiation. The extreme tenuity of the useful dose in the case of radium was compensated for by the lengthened time of exposure, but in order that this should not be dangerous it was necessary that the gamma rays only should come into play, and therefore that the salt of radium should be filtered through an envelope of lead at least 8 mm. thick—a condition very rarely fulfilled. The advantage of radium lay in the possibility of introducing it into cavities inaccessible to the x rays. It represented, in fact, a pocket edition of the x-ray tube. Other radiologists having expressed themselves to similar effect, the reply of Bouchacourt was directed mainly to the question as to whether or not x rays in feeble doses were capable of increasing the hæmorrhage by exciting the ovarian function. Personally he had observed twice a recrudescence of hæmorrhage in the days which followed the first weak irradiation, and he quoted the experience of Guillenimot, Falk, and others in support of his view. Belot summed up the discussion by saying that the gamma rays were much more penetrating than the most rapid x rays actually known, but the quantity of effective radiation for a given sample was feeble when compared with the quantity of x rays emitted by a tube, and by virtue of this very penetrability of the radium rays the amount of energy which they gave up to the cellular elements while traversing the tissue was small.

THERAPEUTICS.

249. Treatment of Seborrhoeic Alopecia.

THEODOR MAYER (*Wien. med. Klin.*, No. 33, 1912) discusses the treatment, general, dietetic and local, of alopecia seborrhoeica. Massage aims at increasing, at least temporarily, the local circulation, and at mechanically loosening the skin, which is often too tightly stretched. For the latter purpose the hands are laid flat on each side above and behind the ears and the skin moved by shoving movements, without rubbing, towards the vertex, so as to be thrown into folds. Such movements should be carried out twice a day, 100 times on each occasion. When there is already definite thinning of the hair this

procedure should be followed by tapotement carried to the point of beginning to induce redness of the skin. Local drug treatment aims at the removal of excess of fat and then at the application to the diseased hair follicles of drugs, such as sulphur, tar, resorcin, naphthol, etc., which have been found empirically to be useful. Lassar's hair cure appears to meet all the indications, and has been found by the author to be, in the majority of cases, the most useful. In it the head is lathered with tar soap, washed, and lightly dried; sublimate solution is next applied, the head then rubbed with naphthol spirit 0.3 in 2,000, and finally the hair, which may be too much dried, oiled with 2 per cent. salicyl oil. In specially severe cases concentrated tar oil, turpentine, vaseline, chrysarobin, or sulphur ointment can be applied. The defect of the treatment is the length of time needed for its application, and to meet this defect the firm of Arthur Wolf, Berlin and Breslau, has prepared sapalcol (sapo-alcohol), a medium for the application of the required drugs by the use of which the procedure is shortened. Sapalcol is a cream-like preparation put up in tubes, and it contains mixtures of fat acid, alkalis with spirit, a small quantity of a fatty body, and one or other of the drugs above mentioned. It becomes fluid almost immediately it is applied to the skin, and penetration is so complete that after slight massage the skin becomes dry and clean. Dry rubbing with sapalcol answers better than the use of the customary hair pomades, because sapalcol is not fatty, and its soap and spirit constituents help towards a more intense and penetrative action of the drug which it contains. Sapalcol is applied at night and any remnant of it washed off in the morning. The massage recommended above should be carried out before sapalcol is applied at night and after the hair has been washed in the morning. If a specially strong action is required the treatment can also be given during the day, or a spirituous hair wash used. Any excessive drying of the hair can be met by impregnation of the hair, but not the skin, with 2 per cent. salicyl oil (æ. salicyl. 1.0, tinct. benz. 2.0, ol. olivæ optim. ad 50). In the case of women with long hair the sapalcol treatment can be carried out easily with only a weekly, not a daily, washing of the hair. The sapalcol treatment of the majority of cases of seborrhoea is begun with sulphur sapalcol and continued with tar sapalcol, or the two preparations can be used alternately. Tar and afridol sapalcol are, it is claimed, specially indicated when there is much itching, naphthol sapalcol in cases in which a slight irritant action is required, and resorcin sapalcol where there is an accompanying acne. The author also warmly recommends the use of sapalcol prophylactically for the hair.

250.

Insipina.

D. E. P. NOGUERA (*Rivista di Medicina y Cirugia practicas*, October 21st, 1911) mentions as derivatives of quinine the best known tasteless up to the present—ether-ethylcarbonate-enquimine; the neutral ether carbonate—aristovina; and the α combination with salicylic acid—salovina. Quite recently, however, a new compound has been obtained—a sulphate of ether-diglicolico, to which the name "insipina" has been applied. It is a crystalline powder insoluble in water, alcohol, ether, and chloroform, but very soluble in acids. It has scarcely any bitter taste, is less toxic than any of the tasteless quinine compounds already mentioned, and contains 72.2 per cent. of quinine, that is, nearly as much as the sulphate of that alkaloid. Dr. Umberto Sylva, who has employed it in a large number of cases and in large doses (30 grains daily), has convinced himself that it is better tolerated than the salts of quinine. In cases of enteric fever in which there were evidences of cardiac weakness, small doses—less than 15 gr.—seemed to act as a tonic to the heart, increasing the force of its systole, the blood pressure, and diminishing the frequency of the pulse. Other statements made are as follows: Insipina is very readily eliminated by the kidneys, and its presence in the urine can be demonstrated by Bouchardat's reaction ten minutes after administration. The albumen, in cases of albuminuria, is not increased. Like quinine, it diminishes metabolism, and less nitrogen is excreted in the urine, but its action in this respect is only about half as energetic as that of quinine. Lastly, the observations of Werner (of the Institute of Tropical Medicine of Hamburg) has proved that insipina in malaria acts as rapidly and surely as quinine, but must be given in doses half again as large.

251. Relapses after Salvarsan in Syphilis.

GAUCHER AND LEVY-FRANCKEL (*Ann. des mal. vén.*, January, 1913) report on 52 cases of relapse after treatment of syphilis by salvarsan and neo-salvarsan, chiefly

from the St. Louis Hospital, Paris, partly from literature. They find that salvarsan, whether given during the primary or the secondary stage, only modifies the evolution of the disease by retarding the further symptoms, and that there is no relation between the apparent cure nor between the gravity of the relapse and the number and dose of the injections; for instance, a case of severe iritis occurred after twelve intravenous injections of 0.15 gram. They draw attention to the frequency of recurrent roscola and redux chancre, or chancre recurring *in situ*, after treatment during the secondary period. They also point out the danger of false security given to patients treated by salvarsan, especially as regards marriage. With regard to the effect on the Wassermann reaction, this may remain positive or become negative, but a positive reaction was obtained in some cases with Desmoulières's antigen (1 per cent. cholesterin added to an alcoholic maceration of powdered heredo-syphilitic liver extracted with ether) when the usual Wassermann was negative. The authors conclude that salvarsan is only indicated when mercury fails, and when the liver, kidneys, nervous system, eyes, and ears are sound, and that it "whitewashes" syphilis, but does not cure it.

252. The Therapeutic Value of Carbenzyme.

CARBENZYME is the name given by Freund and Redlich of Berlin for carbon which has absorbed pancreatic ferment and put up in sterile ampullae, each containing 0.25 gram. A. Stieker and S. Rubaschow have made some experimental investigations in regard to this preparation before proceeding to their clinical tests (*Berl. Klin. Woch.*, October 28th, 1912). Carbenzyme, they claim, is a reliable sterile preparation, which is much less influenced in its therapeutic action by chloroform, alcohol, potassium permanganate, etc., than the other trypsin preparations. It acts equally well when emulsified in glycerine as in sodium hydrate solution. It does not attach normal tissue, save fat, and digests dead and decomposing tissues and the contents of cysts. Injections of carbenzyme produce a marked reaction when there is an acute inflammatory process or when a pathological lesion leads to an increased tension of the tissues. Tuberculous pus is rendered more fluid, serous, and dark by carbenzyme. Albuminolytic processes continue in tuberculous suppurative lesions for about ten days. Clinically, the authors noted a beneficial influence on tuberculosis of the soft parts, on cold abscesses, tuberculous hygromata, and on softened lymphatic glands. In gangrene the dead tissue is digested, but the connective tissue capsule is left intact.

253. Treatment of Chronic Eczema.

TÖTH (*Sem. méd.*, No. 45) recommends the employment of radiant heat and boiling water in the treatment of chronic eczema, a method which he found successful in his own case after other means had failed. The affected region is exposed to the radiant heat from a stove, or from any other source, giving a temperature of 100 to 115°C. The limb is slowly passed before the source of heat five or six times till the itching provoked by the heat has disappeared or nearly so. This manoeuvre is repeated two or three times at each sitting of which there are three a day. As improvement appears the number of applications is gradually diminished to one every two or three days. The distance of exposure is determined by the intensity of the morbid process. After irradiation a folded napkin is wrung out of boiling water and applied gradually to the affected part: it is then again soaked in boiling water and applied more energetically, care being always taken to wring it out thoroughly. In cases of weeping eczema with the skin infiltrated, oedematous, and covered with rhagades and acute lesions of all kinds, these phenomena clear up in from five to six weeks under the treatment. The discharge improves in character in two or three days and the crusts disappear in about a fortnight. In several weeks improvement is so marked that one is tempted to believe that permanent cure is imminent, but in fact several relapses generally follow which, however, become less frequent and less severe. The treatment is rather long, but Töth is convinced that it gives excellent and permanent results. The special advantages of the method are that it is clean, that it is simple, and that it is soothing, particularly in regard to the itching and the acute eruptive phenomena.

254. The Treatment of Ophthalmia Neonatorum.

IN discussing the treatment of ophthalmia neonatorum, A. Lehle has compared the action of silver nitrate, silver acetate, and a preparation called sopolol, which is a combination of silver and formaldehyde-nucleinic acid

(*Muench. med. Woch.*, October 1st, 1912). This last-named preparation is manufactured by the Elberfeld Farbenwerke (formerly F. Bayer and Co.). It is employed in a 5 per cent. solution. The irritant action of silver nitrate is less marked when the silver acetate is used. But even the acetate does not fulfil the requirements of ophthalmia neonatorum completely. In 0.2 per cent. of the cases in which it was tried gonococci could be found three and four days after birth respectively, when the acetate was carefully instilled into the eyes at birth. No cases of late infection were met with. Sopolol was used in a large series of cases. In 8 per cent. there was a very mild irritation; only in 1.5 per cent. was redness and swelling met with. In 0.5 per cent. there was some purulent conjunctivitis. This indicates, according to the author, that the irritation from sopolol is much less than from the other silver compounds. Its bactericidal action was highly satisfactory; pain is not produced by instilling drops into the eyes, and it has proved to be quite harmless. He points out that it is quite stable. He therefore considers that it should replace silver nitrate in the prophylactic treatment of the eyes of newborn infants.

PATHOLOGY.

255. Inclusion Bodies in Scarlet-Fever Blood.

NICOLL, jun. (*Arch. of Pediatrics*, June, 1912), from further research upon inclusive bodies in scarlet-fever blood, records the results of his examination of 115 cases of scarlet fever with 80 controls. Since these bodies are of practical rather than scientific value the controls were selected as far as possible from such pathological conditions as the clinician is frequently required to differentiate from scarlet fever. Manson's stain (borax, methyl blue) is the most useful and best fulfils all requirements of diagnosis, the red blood cells taking up a bluish-green tinge, the nuclei of the leucocytes a very deep blue, the cytoplasm a very faint blue, and the inclusions a shade between the two. These bodies vary in shape and size and, in fresh cases of scarlet fever, from one to six or more are found in nearly all the polymorphonuclear cells. They generally tend to disappear after the first week of the disease. Of the 115 cases only 16 failed to show the inclusion bodies, 12 having been ill more than seven days, and one dying within twenty-four hours from a fulminating type of the disease. It may be fairly concluded that these bodies will be found up to and including the fourth day of the disease in every case of scarlet fever with the exception of the fulminating type, in which case the tissues have had no time to react. They will not be present in cases of antitoxin rashes, measles, German measles, various toxic rashes, and ordinary tonsillitis, but they are present in cases of general sepsis—a condition frequently confused with scarlet fever, and, unfortunately, therefore indistinguishable from it by the blood examination. In technique it is essential that a small drop of blood should be spread evenly and thinly, so that the leucocytes may lie flat and by themselves, and not be distorted or cramped. The smear is fixed in methyl alcohol, washed, and stained with Manson's stain for from ten to thirty seconds. Then, after further washing, it can be examined with oil immersion, thus affording a valuable method of differential diagnosis between scarlet fever and nearly all the conditions resembling it.

256. The Inhibition of Haemolysis by Syphilitic Serum.

M. POPOFF (*Deut. med. Woch.*, September 26th, 1912) has examined the capability of syphilitic serums in inhibiting the haemolysis of guinea-pig's blood corpuscles. It appears that normal serum, when added to saline fluid and a suspension of guinea-pig's red blood cells, causes the latter to become dissolved. Popoff found that this occurs regularly when 0.1 c.cm. of serum, 0.9 c.cm. of saline fluid, and 0.1 c.cm. of guinea-pig's blood cells (diluted to 1 in 5) are mixed. He also used 0.2 c.cm. of serum and 0.3 c.cm. In each case the saline fluid and blood cells are added. If the serum yields a positive Wassermann test, the haemolysis does not take place. On testing over 600 serums in this way side by side with the Wassermann test, he found that 75 per cent. gave inhibition to haemolysis and a positive Wassermann. The remaining 25 per cent. gave a haemolysis with his test. He tested some 161 normal serums, and in 2 cases he obtained partial inhibition of the haemolysis. Complete haemolysis was effected in all the others. He adds a few remarks on the partial absence of complement in normal and pathological serums.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

257. **Neuritis following Pneumonia.**

ALTHOUGH neuritis is a rare sequel of pneumonia according to Biermann (*Dent. med. Woch.*, January 23rd, 1913), he has lately seen three patients with this complication. One was a servant girl, aged 24, whose croupous pneumonia of the left lung was followed by crisis on the seventh day. Pain and weakness in both arms were noticed on the tenth day, and for the following three weeks the patient could not lift her arms to feed herself. The pain was practically limited to the shoulders and upper arms, whereas the hands and fingers showed partial anaesthesia. After five months the muscles supplied by the thoracicus major, axillaris, subscapularis longus, radialis, and medianus nerves on the right side showed paresis and atrophy. On the left side the nerves involved were the subscapularis longus, musculo-cutaneous, and radialis. The patient recovered in two years. Another patient was a farmer, aged 22, who developed pneumonia for the third time. About a fortnight later both arms became painful, and within twenty-four hours there was marked paralysis of both arms and shoulders. Considerable atrophy followed, and though the paralysis was not progressive it had not completely disappeared six months later. The cervical segments of the cord were probably involved, for there was slight inequality of the pupils on accommodation and reaction to light. Vasomotor and trophic disturbances, such as punctate redness of the skin and recurrent desquamation, combined with absence of symptoms referred to the bladder, and the slow cessation of the paralysis and atrophy, confirmed the diagnosis of neuritis. A certain degree of alcoholism in this case may have rendered the nerves specially susceptible to the toxin of pneumonia. The third patient, a married woman aged 47, developed pneumonia concurrently with the menopause. Pain in the lower dorsal vertebrae and lower ribs followed a little later, and was succeeded by violent pain in both legs from the knees to the toes. Burning and stabbing pains were felt in the soles of the feet and the outer aspect of the legs, which became very weak. Subsequently the muscles of the leg began to twitch and the first three fingers of the left hand showed slight loss of sensation. The right facial nerve was also slightly paralysed. With those two exceptions the disease was limited to the lower limbs. Here the muscles of the hip, the adductors and abductors of the thigh, and the extensors and flexors of the leg were intact. The peroneal muscles on both sides were weak, the gait was jerky, and the feet dragged. The Achilles reflexes were weak, but the patellar reflexes were normal. The patient improved slowly under treatment with sun and carbonic acid baths and phenacetin, 0.5 gram of which was given thrice a day. When discharged a few weeks later the patient could walk without a stick, and the only trace of the neuritis was slight loss of sensation in the soles of the feet.

258. **Pellagra.**

AFTER an extensive and intensive epidemiological study of pellagra in the south, Assistant Surgeon R. M. Grimm (Public Health Reports, quoted in the *Journal of the American Medical Association*, April 5th) thus summarizes his results:—*Race*: More cases were found among the whites than among the negroes. *Sex*: More cases were found among the females of each race than among the males. *Age*: More persons developed the disease at ages between 20 and 40 years than at other ages. *Case Mortality-Rate*: The case mortality-rate is higher among the negroes than among the whites, highest among the coloured females, and lowest among the white males. *Case Insanity-Rate*: The case rate of insanity incidence is higher among the negroes than among the whites, and higher among the males than among the females. *Marital Condition*: Among the married and widowed pellagrins the females predominate; the single pellagrins are equally divided among the sexes. *Environment*: More cases occurred under conditions of poverty than of comfort, and more under conditions of comfort than of affluence. *Location of Homes*: More cases developed in persons living in small towns and villages than among those living in the rural districts. *Relation of Cases*: More cases developed in the immediate vicinity of other

cases than otherwise. *Food*: The relationship existing between the cases of pellagra in this series and the character of the food supply admits, at present, of no conclusion. In investigations of this character, however, this relationship demands consideration. *Incidence*: Pellagra seems to have been on a gradual but constant increase in the districts visited, with the probable exception of the year 1912. *Prevalence*: Pellagra is more prevalent than is ordinarily supposed even by the physicians practising in pellagrous communities, and there are many persons in pellagrous communities who present symptoms of a mild pellagrous condition which do not ordinarily come to the attention of the physician on account of the mild character of these symptoms. It is added: "Since the deduction of a correct conclusion presupposes the existence of unquestionable premisses, no definite conclusion regarding etiology has been drawn from the results of the work. Premises based on work in other lines seem to be necessary before such a conclusion on this point can be drawn. The possibility of some insect playing a part in the dissemination of the disease does not seem inconsistent with the facts presented above." From Grimm's observations the relationship between pellagra and food seems to be a real one, but whether the character of the food may act only in predisposing to conditions which favour the development of pellagra, or whether certain articles of food act as the real exciting agent, or whether they act only as exaggerators of the symptoms (as the sunlight, for instance), is an open question. It is possible that certain articles of food may act in all three ways.

259. **Abnormal X-ray Reaction following Syphilis.**

REGAD (*Arch. d'electr. méd.*, September 25th, 1912) brings forward a case of severe radio-dermatitis following two very feeble applications of the x rays. The treatment was given for a pronounced freckling upon the dorsal face of both hands. (The patient had spent a quarter of a century in the tropical climate of Tongking, Indo-China.) At neither of the two sittings, which were separated by an interval of six weeks, was an "erythema dose" administered. Some inflammation was forthcoming, however, twenty-seven days after the second sitting, and left in its train a few days later an ulceration the size of a 2-franc piece on the back of each hand. One hand also showed a hard and painful oedema, and the fingers remained demiflexed. The patient energetically denied that he was a syphilitic, and the most scrupulous examination from this point of view was negative. It was concluded that life in the tropics, with the paludism and dysentery to which the patient was subject, had diminished the resistance of the organism and thus encouraged infection, due, perhaps, to soiled dressings. The patient passed out of the author's hands, and some months later the author learnt from a medical man attending him that although the ulcerations might be considered as cured, symptoms of general paralysis were supervening, and later that there had been a rapid evolution of this malady, from which the patient had died. It was then found that the patient was an old syphilitic and had admitted his full knowledge of the fact to his intimates. The author takes the case to be a further proof of the rôle played by syphilis in the abnormal reactions that occasionally follow radiotherapy in spite of the most careful technique, and he suggests that a congress of radiologists should discuss measures for their legal protection in such circumstances.

260. **Arterial Vibration in Corrigan's Disease.**

WEBER (*Journ. des praticiens*, January 4th, 1913) calls attention to a proceeding in the investigation of the hammer pulse of Corrigan which is more distinctive in its results than the ordinary clinical method of applying the finger over the radial artery. The palm of the hand is applied to the lower and anterior extremity of the forearm in such a manner that the fingers are bent round the posterior aspect; moderate pressure of the palm gradually applied over the arterial region gives evidence of a vibratory tremor resembling the purring of a cat in certain cases. This tremor is accentuated on raising the limb as in the ordinary demonstration of Corrigan's pulse. The same thing is experienced in the case of the lower extremity. The author relates a case of typical aortic

disease in which there was no thrill to the finger applied in the ordinary way, but in which, when the arm was grasped in the manner indicated, there was marked tremor. His conclusion is that, whilst the ordinary linear examination of the larger arteries is sufficient as indicating a marked tremor, the method may have negative results in the examination of the radial artery or the dorsal artery of the foot, and in such cases contact over a larger surface in the manner indicated frequently gives evidence of intense tremor, accentuated by elevation.

SURGERY.

231. Prolapse of the Rectum with Ulceration and Perforation.

GREIWARIK (*Gaz. hebdom. des sci. méd. de Bordeaux*, 1912, xxxiii) narrates the case of a man, 35 years of age, who had suffered for three years from prolapse of the rectum. Ulceration occurred in the peritoneal portion and ruptured the rectum through the opening of which the small intestine protruded. Taxis failed to reduce the protruding bowel, and owing to the condition of the patient operation was not performed. The patient died three hours afterwards; no autopsy was performed, and the author thinks death was due either to haemorrhage from a mesenteric vessel or reflexly from traction on the solar plexus.

262. Eczema Marginatum.

NICOLAN (*Ann. de dermat. et syph.*, February, 1913) cites personal observations of 35 cases (29 men, 6 women) during four years of work in his clinic. Only three times was there a history of family infection—in two cases husband and wife, in the third both parents and their two children. The lesions, which are almost invariably localized to, or at any rate primary in, the cruro-serotal region, are always sharply demarcated from the healthy skin and do not show any tendency to spread beyond the folds. In appearance they resemble often in colour, consistency, circinate edge and dry surface, the lesions of *tinca circinata*, with which they have doubtless been confounded in the past, but the fact that children are very rarely infected by the epidermophyton *inguinale* (the age of Nicolan's patients varied between 15 and 40 years) should suggest the correct diagnosis to the practitioner. The cases most difficult to diagnose are undoubtedly those which attack the interdigital clefts and the toes and plantar aspect of the foot. Where the suspicion arises, the cruro-serotal region should always be examined and a few scales placed in potash for microscopical purposes. Once the diagnosis is assured, the cure is only a matter of a week or two. The author orders a weak chrysarobin ointment. He describes the microscopical appearances and the cultural features of the fungus at considerable length. The latter grow best on a maltose agar (Chauvet) at room temperature and show evidence of growth in the shape of downy-white points in from five to eight days. They extend peripherally and assume a characteristic yellowish-green to grey tint in from thirty to forty-five days, by which time they have grown to a crateriform colony the size of about a two-shilling piece, the limit of their growth, and they then undergo pleomorphism. Under the microscope can be distinguished ribbon-like threads of mycelium composed of rectangular cells of variable length but of a constant breadth. Here and there these elements have undergone irregular development; they become vivid or inflated in appearance, and in places even present the appearance of watch-chains. The illustrations given by the author are exceedingly clear and instructive.

233. Cranial Spina Bifida.

PETIT DE LA VILLÉON (*Gaz. hebdom. des sci. méd.*, 1913, xxxiv, No. 6) describes a case of a girl 7 years of age suffering from a large tumour protruding from the posterior region of the head. Incision of the swelling removed a large quantity of cerebro-spinal fluid, and the swelling disappeared. A pedicle attached to the swelling was removed, and the whole sac dissected out. The child made a good recovery.

264. Fibroma of the Orbit.

TEULIÈRES (*Gaz. hebdom. des sci. de Bordeaux*, 1913, xxxiv, January 26th) divides fibromata of the orbit into those that arise (1) in front and (2) behind the capsule of Tenon, and describes a case of the former, in a woman 33 years of age, which arose as the result of a blow. It affected the periosteum of the orbital border. Removal showed all the appearances of a fibroma.

OBSTETRICS.

265. Extract of Pituitary Body in Labour.

THE treatment of uterine inertia during labour must be adapted to the condition of the uterine muscle and to the work which it has to perform. Uterine weakness must be distinguished from faulty pressing down by the abdominal muscles, and care must be taken that the weak pains which are supposed to indicate a primary inertia are not periodic pains of pregnancy. Pries (*Dent. med. Woch.*, September 12th, 1912) dismisses secondary inertia rapidly by pointing out that this usually results from some abnormal resistance, and is thus a sign of exhaustion of the muscle, which must be treated, like all other forms of exhaustion, by rest, provided that no vital indications exist for a speedy termination of the labour. For primary inertia, mechanical, thermic, and medicamentous measures may be adopted. The mechanical and the thermic measures are not dealt with in detail. The former remain the last resort, while the latter are unreliable. Among the medicines employed to enable the uterus to perform its work, only quinine and ergot are worthy of consideration. Recently a third active substance has been introduced—namely, the pituitary gland. The latter have proved themselves to be reliable and harmless substances, which yield good results in the first and second stages of labour, provided that no considerable resistance has to be overcome and that there are no indications for immediate delivery. The action in the third stage is uncertain and not so good as ergot. Further, he points out that pituitary preparations do not suffice for the induction and completion of abortions or premature labours. A great advantage of these extracts is that they are non-toxic and can be combined with cardiac stimulants, morphine and ergot. The ecbolic action is not impaired by such combination. He is of opinion that a general adoption of these preparations into general practice would limit the number of operative deliveries, which he regards as a great gain.

266. Condition of the Kidneys in Eclampsia.

A. ZINSSER is quite justified in calling attention to the fact that a large number of questions in connexion with eclampsia are awaiting solution (*Berl. klin. Woch.*, March 3rd, 1913). He has set himself two specific questions, and deals briefly with the replies. The first is, "Does the degree of damage to the kidney run parallel to the severity of the eclampsia?" In attempting to answer this question, he reviews the possibility of being able to ascertain the condition of a kidney during an attack of eclampsia. The indicators formerly relied on were: The excretion of albumen, the composition of the urinary sediment, and the amount of urine excreted. The more modern methods dealing with the tests of renal function can scarcely be put into action during the extremely brief time available during the eclamptic attack. It has been shown that eclampsia may set in before the amount of urine is diminished; and, further, that it may pass off before the oliguria or anuria ceases, and cases are on record in which no oliguria accompanied the eclampsia at all. In the same way albuminuria need not be an accompaniment of eclampsia. No indication of the prognosis of a case can be derived from the estimation of the nitrogen content of the urine, or from the amount of chlorides excreted. But Zinsser points out that in oedematous eclampsia after delivery, if the amount of chlorides in the urine suddenly and permanently sinks to a fraction of the normal quantity (under 6.1 gram) the prognosis is extremely bad, while as long as the amount remains permanently above average values, even a severe case of eclampsia may be regarded in a favourable light. Unfortunately this sudden drop in the chloride content of the urine takes place after the organism is severely damaged. The author regrets that we have no indication of the prognosis before this has occurred, so that a suitable form of treatment might be applied. The second question is, Can the damage to the kidney essentially influence the course of illness? or, in other words, Can we act on the kidney therapeutically in order to alter the course of the eclampsia? The reply to this is in the negative. He shows that the kidney is not the only organ damaged in the disease. The kidney may, during an attack of eclampsia, be quite capable of excreting nitrogen satisfactorily, and even when this is not the case, the shortness of the time prevents the retention of N bodies from being so marked as to control the condition. Arguing by the analogy of scariatalinaemia, he finds that the renal insufficiency for sodium chloride and water producing oedema stands prominent in the condition. The chlorides are markedly diminished in the urine, less water is excreted, and oedema takes

place. The convulsions are regarded as the signs of oedema of the brain. It would thus appear to be more rational to aim at the treatment of the oedema than of the defect of the kidney. Trephining the skull or lumbar puncture at times yield extraordinary results in aemia, and the same may apply for a few cases of eclampsia. But in the majority of cases of eclampsia it is quite useless to perform lumbar puncture or to decapsulate the kidney. All attempts to eliminate the hypothetical poison from the system by the kidney fail. It is therefore necessary to study the problem further in order to attempt to find a reliable prognostic indicator which can be relied on before the organism is past hope of assistance, and a rational therapeutic procedure which may free the organism from the noxious agent of eclampsia.

GYNAECOLOGY.

267. The Umbilicus in Women and New-born Children.

SOME observations on the relation of the umbilicus to fixed points bordering the abdomen have been published by Kakouchkin (*Roussky Vrach*, December, 1911; *Sov. med.*, May 29th, 1912). These points are the summit of the ensiform cartilage, the upper border of the symphysis, and the right and left anterior superior spines of the ilium. He detected great variation, as might be expected. Measurements were taken first from 173 women who had never borne children. Out of these 91 were from 17 to 25 years of age, and in them the average distance from the umbilicus to the ensiform cartilage was 17.5 cm., or 6 $\frac{3}{4}$ in.; from the umbilicus to the symphysis, 15.1 cm., or a little under 6 in.; from the umbilicus to the anterior superior iliac spine, 15.6 cm., or 6 $\frac{1}{4}$ in. right, and 15.2 cm., or 6 in. left; 72 were from 26 to 40 years of age, and in them the average of the first measurement was 17.2 cm., or over 6 $\frac{3}{4}$ in.; of the second 15.2 cm., or about 6 in.; and of the third, 15.1 cm., or a little under 6 in., right and left; 10 were from 41 to 64 years of age and the averages in this group were, for the first measurement 19.5 cm., or a little under 7 $\frac{3}{4}$ in.; for the second 18 cm., or 7 $\frac{1}{4}$ in.; and for the third measurement 19.3 cm., or 7 $\frac{3}{8}$ in., right and left. It is remarkable that asymmetry appears, according to Kakouchkin's statistics, to be distinctly marked not in the two older but in the youngest group, where the umbilicus was further from the right iliac spine than from the left. All dimensions appear to increase after forty. Next, Kakouchkin measured 150 uniparous women. The average of the first measurement was 17.3 cm., or over 6 $\frac{3}{4}$ in.; of the second 15.1 cm., or under 6 in.; and of the third 15.3 cm., or a little over 6 in., on both sides. This symmetry of the umbilicus and the iliac spines is noteworthy, especially in relation to the asymmetry in young nulliparae. Then 216 multiparae were measured. The first measurement, ensiform cartilage to umbilicus, was on the average 17.6 cm., or a little under 7 in.; the second, from the umbilicus to the pubes, 15.3 cm., or over 6 in.; whilst the third comes out unsymmetrical, as in young nulliparae—namely, 15.9 cm., or over 6 $\frac{1}{4}$ in.—from the navel to the right iliac spine, and 15.4 cm., or under 6 $\frac{1}{4}$ in., between the navel and the left spine. The distance, as in the young subjects, was greater on the right side. The averages of the total, or 539 subjects measured, is 17.5 cm., or over 6 $\frac{3}{4}$ in., for the first measurement, 15.2 cm., or a little under 6 in. for the second, and 15.7 cm., or under 6 $\frac{1}{4}$ in. for the third, on the right side, and 15.4 cm., or under 6 $\frac{1}{4}$ in., on the left. Kakouchkin seems to agree with Tillaux in making out that the umbilicus lies at a fairly even distance between the ensiform cartilage and the pubes. He finds, however, that the lower part of the abdomen is the part which undergoes the most distension in pregnancy. In multiparae all dimensions increase more than in primiparae, especially the third measurement, between the navel and the iliac spines. The distance, contrary to what was found in young nulliparae and in multiparae, was greater on the left side. This might, Kakouchkin thinks, be due to the dragging of the round ligament of the liver on the umbilicus, the recti at the same time tending to part along the middle line. The umbilicus approaches the ensiform cartilage and lies further from the symphysis as the waist develops. In the newborn, as is generally admitted, the umbilicus lies below the middle of the body. Kakouchkin finds that it lies relatively higher in the heavier infants, yet in females it lies higher on the average than in male newborn children, as in the former, which are relatively smaller, the upper part of the body is also relatively ill-developed. Kakouchkin would fain trace a distinct relation between

the topography of the umbilicus in the fetus and its presentation, at least at term. Obstetricians will note the latter qualification. In breech cases at term the umbilicus, in his experience, always lies higher in the abdomen of the fetus than in the fetus which presents at its head.

THERAPEUTICS.

263. Treatment of Arterio-sclerosis.

DISCUSSING the treatment of arterio-sclerosis, A. Strubell points out that the modern conception of the condition necessitates a fresh consideration of the suitable therapeutic measures (*Deut. med. Woch.*, November 7th, 1912). He distinguishes six stages of arterial disease. The first is v. Basch's pseudo-angiosclerosis, in which the blood pressure varies, and the electro-cardiogram is normal. The second shows a raised pressure; the cardiac action is sufficient, and the electro-cardiogram shows but little change. This indicates beginning angiosclerosis of the small vessels. The third stage is that of secondary insufficiency of the heart; the pressure is raised, the electro-cardiogram reveals a heightened auricular notch, there is dyspnoea, slight hypertrophy of the heart, etc.; the fourth stage is signalized by the implication of the cardiac muscle in the process. The pressure is raised, the terminal tremor is weaker and the auricular notch is much raised and dyspnoea is present. In the fifth stage, the blood pressure is much raised, there is a negative delayed tremor in the electro-cardiogram, markedly increased initial tremor, dilatation of the aorta, as seen by the roentgenogram, etc. Here the angio-sclerosis and arterio-sclerosis, the cardiac sclerosis and the aortic sclerosis are fully developed. In the last stage, which he terms that of manifest arterio-sclerosis, the kidneys are implicated and there is permanent albuminuria. It is obvious that the treatment of the later stages can only be symptomatic, and that the rational therapy must begin before any signs have shown themselves, in the form of a prophylactic treatment. Strubell therefore suggests treating apparently healthy persons with the view of preventing arterial degeneration. Bodily exercise must be prescribed for the sedentary person, regulation of the diet for the gourmand and the gourmet, syphilitic symptoms must be energetically combated, and the use of tobacco and alcohol must be kept within bounds. In regard to the psychic nervous element of the causation, he is of opinion that if we could induce people to avoid worry and annoyance, much would be gained. Failing this, balneo-therapeutic measures, including alternating current baths, carbonic acid gas baths, warm prolonged baths, and the like, all mollify the nervous system. Turning to the treatment of the various stages of the disease, he enters into a discussion as to the efficacy of iodides. Romberg has stated that iodides lower the viscosity of the blood. Deternann, on the basis of some careful experiments, denies this. He therefore asks what action can be expected from iodides. He maintains that this drug may not be given any longer without some well-defined knowledge of what it effects. In the first place, he objects strongly to the use of the potassium salt, which he regards as a highly toxic substance. His experiments with sodium iodide on the opsonic index show that an action on the immunizing processes is undoubtedly effected. It is an open question whether the iodide should be given in capsules or by subcutaneous injection. Of the organic iodine preparations, he has obtained good results with iodoval, iodglidine, and sajodin. Another means of reducing blood pressure is the drinking of the waters at certain spas, for example, Matienbad, Kissingen, Homburg, or Salzschlurf. Electric baths, massage, and such cardiac remedies as strophanthus or one of the digitalis preparations will be found useful when the heart muscle is either intact or but little affected. He also mentions that at times blood-letting may be able to prevent an apoplexy. In conclusion, the author is strongly of opinion that it is very unwise to forbid alcohol and smoking altogether in advanced cases. Small doses of the former in the form of a glass of wine acts favourably on the heart, and the smoking of a mild cigar may be useful in making expiration more easy. In any case, neither can do any harm, if limited to a reasonable degree.

269. Valloid.

E. P. NOGUERA, reviewing recent pharmacology and therapeutics in the *Rivista de Med. y Cirugia practicas* (October 21st, 1912) describes some new applications of valloid. This drug was introduced into medicine by Dr. Schwensen-ski of Berlin in 1897, who considered it a true chemical

combination of valerianic acid with menthol. It contains, however, 30 per cent. of free menthol, which makes it a powerful diffusible stimulant and antispasmodic. It is thus useful in hysteria, depression with cardiac weakness, and in all asthenic neuroses. Recently, however, it has been employed with great success by Baldeker and others as a cardiac stimulant and sedative in neurasthenic conditions, with which are associated attacks of palpitation and fainting; also in cardiac debility occurring in the course of other maladies (pneumonia, scarlet fever, influenza, etc.). It seems to be especially useful in the case of young children, in the vomiting of pregnancy, in seasickness and gastric neuroses. According to Baldeker, when given to children under 5 years of age in doses of 10 to 4 drops in syrup, an improvement in the pulse can be noted in twelve to fifteen minutes. In twenty to twenty-five minutes all the symptoms—cyanosis, dyspnoea, etc.—are markedly relieved. In the vomiting of pregnancy Sydney Hall has had excellent results from the administration of valiolol, and says that it should always be tried before artificial abortion is resorted to. Dr. Kendall of the Australian Navy, and Dr. G. Vandaela, Surgeon to the Red Star Line, have found it one of the best remedies they have tried in seasickness. Lastly, Stelkel of Vienna has found it valuable as a sedative in conditions of nervous or psychical excitement.

270. Salvarsan in Diseases of the Eye.

BENDA (*Wien. med. Woch.*, Nos. 26 and 27, 1912) gives his experience of the use of salvarsan in various syphilitic affections of the eye. He injected it intravenously in a faintly alkaline solution, and only very slight reactions were caused. In 30 cases of keratitis treated in this way he noticed no better effect on the course of the disease than he had been accustomed to obtain with mercury and potassium iodide. Out of 19 cases of irido-cyclitis the other eye became involved in 3—a complication which during the last four years the author had not known to follow the older form of treatment. In 3 cases of choroiditis the injections left the condition unaltered. In 6 cases of optic neuritis there was no improvement which might not fairly be attributed to the concomitant use of mercury. In one of these cases severe retino-choroiditis set in resembling that seen in hereditary syphilis. The author has never known this to result from the older form of treatment, and has only seen it three times in acquired syphilis, and then only in cases which had received no treatment. In 14 cases of optic nerve atrophy due to tabes no improvement resulted, while of 9 cases of paralysis of the ocular muscles only 3 showed improvement after salvarsan. The author's conclusions are that while the injections caused no injury to the eye, except in 3 cases, the effect of salvarsan in the secondary stage was no greater than that to be derived from mercury, and post-syphilitic affections were quite uninfluenced. This accords with the observation of Elsehnig that salvarsan has no sterilizing effect in generalized syphilis, and that the Wassermann reaction is no more affected by it than by mercury and iodine alone. The author, however, advises its use in all these cases, if only for its good effect in eliminating spirochaetes; but on account of the severe focal reactions which it may cause in the spirochaete "areas," he recommends that it should not be used in acute conditions until a preliminary course of mercury has to some extent reduced the inflammation.

271. Treatment of Asthma.

O. WEISS (*Deut. med. Woch.*, September 19th, 1912) is of opinion that a healthy condition of human blood is dependent on a healthy condition of the blood-forming organs, on a correct gaseous exchange of the blood and of the skin, on a proper excretory function, and on the regular action of the ductless glands. As far as asthma is concerned, he believes that the thyroid, pituitary gland, adrenal, and testes or ovaries play the most important part. He therefore conceived the idea of treating asthma with extracts of these organs. He employs a mixture of adrenal extract with pituitary gland extract. (For some reason not stated he recommends a special mixture, introduced under a protected name.) Each ampulla of his mixture contains 1.1 c.c.m. of extract, corresponding to 0.0008 gram of adrenal extract and 0.04 of pituitary gland (infundibulum) extract. The author claims that he has given this mixture in 3,000 doses, and has only experienced a failure in its action some ten times. These cases necessitated a repetition of the dose after twelve to fifteen minutes. The mixture is, in his opinion, absolutely harmless, and can be tolerated in ten times the dose he employs without ill effects.

PATHOLOGY.

272. The Hemianopic Pupil Reaction and Wilbrand's Prism Test.

Two tests are used to determine whether the lesion which causes a homonymous hemianopia is situated in the optic tract or above the chiasm. One is the hemianopic pupil reaction known as Wernicke's test; the other is Wilbrand's prism test. The exact course of the pupillary reflex fibres is undetermined, but it may be assumed that the centripetal pupillary fibres do not go beyond the primary optic ganglia; while Bechterew's theory of their decussation directly behind the chiasm into the grey matter on the floor of the third ventricle can no longer be maintained. The pupillary paths certainly traverse the greater part of the optic tract, and possibly continue on as Bernheimer's fibres into the external geniculate body. The presence of hemianopic pupil inactivity or hemianopic reaction, which Hess calls hemipinesis, has been held a valuable sign, localizing the lesion in a spot which impairs the function of some of the fibres forming the reflex arc for the pupil reflex; in other words, the presence of the hemianopic reaction places the lesion in the tract. Hess, however, concludes that it is of no practical importance. It is essential to use Hess's apparatus, otherwise diffused light vitiates the results. Hess obviates this error by a method of alternate illumination. Two equally illuminated surfaces are ultimately uncovered, so that first the blind and then the seeing half of the retina is exposed while the total amount of light entering the eye is hardly altered. The pupil is observed with a telescope. Wilbrand's prism phenomenon is carried out as follows:—A small circle of white paper is placed upon a black surface, and the patient is seated before it with one eye bandaged. He is asked to look at the spot, and a strong prism is placed before the eye in such a way that the image of the spot is thrown upon the blind half of the retina. We notice whether the eye at once moves to find the object again, and whether the movement is reversed when the prism is withdrawn. The presence of this reaction places the lesion in the cerebrum, the absence of the reaction locates it in the tract. Behr considers this reaction more accurate than hemipinesis. Bielschowski, Konorius, and Koelner have all obtained anomalous results. Jess, in a paper which is translated in the *Archives of Ophthalmology*, January, 1913, has investigated these tests in 8 cases. He finds the hemianopic pupil inaction test to be accurate in each case, but the prism test was useless for topical diagnosis. We have recently ourselves tried these two tests in two cases of hemianopsia, and in both they were found to be mutually confirmatory, and in accordance with other clinical evidence. It is obvious that both tests require careful investigation, for at present doubt must be thrown upon both of them.

273. Rivalta's Reaction in Sputum.

CASALI (*Rif. Med.*, July 27th, 1912) analyses the results of this test in 63 cases, mostly tuberculous. The test depends on the coagulation of albumen in the presence of very dilute solutions of sodium carbonate and acetic acid. In the case of sputa, 10 c.c.m. of the sputum is mixed with 10 c.c.m. of distilled water, stirred, and filtered; and a test solution is prepared by adding 2 minims of acetic acid to 100 c.c.m. of water and a solution of sodium carbonate (1 minim of a saturated solution to 100 c.c.m. of water). A drop of the filtrate is added to this solution and a precipitate looked for; if the reaction is positive, the filtrate is diluted with the sodium carbonate solution until the reaction vanishes. The 63 cases were examined in this manner, and the albumen also estimated by the Gantz and Herz method. It was then found that in many cases where the albumen reaction was well marked the Rivalta reaction disappeared after relatively few dilutions, and in other cases, where the albumen was scarce, the Rivalta remained positive up to strong dilution, in some cases even when albumen was absent there was a positive Rivalta's result. So that it looks as if the Rivalta reaction was not due to the albumen *in toto*, but to some substance (? englobulin, pseudoglobulin, phinoglobulin) present in different proportions in the sputa. Again, it is now found that the limit of dilution in tuberculous cases was always greater than 1 in 10. This was so definite that the author says that, excluding pneumonia, it is safe to diagnose pulmonary tubercle every time that expectoration subjected to Rivalta's test shows a limit of sensitiveness to dilutions 1 in 10, and he suggests that the protein giving this reaction is of vascular origin, due to the influence of the tubercle bacillus or its toxin, on the walls of the pulmonary vessels, allowing his protein to pass out of the blood to a degree greater than occurs in other respiratory diseases.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

274. Paroxysmal Haemoglobinuria and Lordosis.

L. JEHL (Wien. klin. Woch., February 27th, 1913) holds that under certain conditions lordosis may precipitate an attack of haemoglobinuria provided this condition is already imminent. In support of this view he records the case of a boy, aged 8 years, who had been weakly from birth. When 2 years old he began to walk and to suffer from attacks of haemoglobinuria, which were ushered in by rigors lasting for half an hour. The haemoglobinuria lasted only a day or two, and as it occurred during the winter, it was traced by the mother to chills. Three weeks before admission to hospital the boy became slightly jaundiced, and the haemoglobinuria was of daily occurrence. The heart was somewhat dilated, the aortic sound was accentuated, and the spleen was slightly enlarged. In hospital the urine was found to be dark red, the urobilin reaction was marked, and the spectroscope showed haemoglobin and methaemoglobin. There was also much albumen, and the sediment contained granular, amorphous debris and a few red cells and granular casts. On the second day the urine was lighter in colour, and there were only traces of albumen. On the fourth day the urine was at first normal, but during an examination the boy felt chilly and passed blood-red urine. Next day the urine was again clear until the boy got up and attended a demonstration in another room, when his temperature rose to 101.5, and marked haemoglobinuria and albuminuria appeared. During the next five days he was kept in bed, his temperature and urine remaining normal. But when he was fixed in a position of lordosis for a quarter of an hour the temperature rose to 101, marked haemoglobinuria and albuminuria appeared, and pain and lassitude were complained of by the boy, whose pallor was striking. The boy was kept in bed, and on the evening of the same day the urine was again normal. The experiment was repeated frequently with the same result. Later it induced the same degree of albuminuria, but less haemoglobinuria, and finally it induced albuminuria without a rise of temperature or haemoglobinuria. The author gives a detailed account of another child, aged 10½ years, who was subject to attacks of haemoglobinuria. The induction of lordosis caused albuminuria, but no haemoglobinuria; and this further confirmed the author's view that lordosis may be a secondary cause of haemoglobinuria, but that it is not a *sine quibus non* for this condition.

275. Acute Polyarthrititis due to the Colon Bacillus.

AFTER discussing the growing importance attached to the *Bacillus coli* as a cause of disease in man, A. Luger (Wien. med. Woch., February 22nd, 1913) reports the following case: A man, aged 45, who had contracted gonorrhoea in his youth, had been subject for some years to attacks of abdominal pain, nausea, and vomiting. The pain was most violent in the upper, right abdomen, and was on one occasion accompanied by a rigor and slight jaundice. The pulse during an attack was as slow as 48 and the blood pressure was 80. The urine was clear, acid, and normal except for an excess of urobilin. Cholelithiasis was diagnosed. After these attacks had ceased for four years the gonorrhoea returned, and was treated for a year and a half, at the end of which the joints, beginning with the left knee, began to swell. All the large joints and those of the fingers became exquisitely tender and painful, and passive and active movements were thereby much limited. There was no redness of the skin, which was swollen and doughy over the knees and wrists. The urine now contained much yellowish-red sediment and urobilin, traces of albumen, a few hyaline casts, many leucocytes and erythrocytes, but no bacteria. It was acid and the specific gravity was 1025. A blood count showed a moderate degree of leucocytosis. A week later bacteria were found in the urine but not in the blood. The arthritis persisted for many weeks with high fever of a septic character. Salicylates had little influence on its course, and rigors were common. During one of these the blood yielded five colonies of the colon bacillus on a blood-agar medium. The arthritis and fever lasted about two months, at the end of which the blood yielded no more bacteria, while the urine contained a few. The

author thinks the colon bacillus was present in the joints, and that the arthritis was not merely due to toxins, for it was severe, and resembled that in which typhoid bacilli have been demonstrated in the joints. Three explanations of the mode of infection in this case are plausible. The cholelithiasis may have been the primary cause, and the bacilli grown in the biliary passages may have spread to the blood, have been excreted by the kidneys, and have thus caused a descending *coli* pyelitis and cystitis; or the local treatment of the gonorrhoea may have started a *coli* cystitis, which was followed by infection of the blood stream, for it has been shown that the passage of a catheter may be sufficient to infect the blood with the colon bacillus. Finally, the germs may have migrated from the bowel to the bladder. The author considers, however, that the bacilluria was secondary to the bacillaemia.

276.

Indicanuria.

MORGAN (Amer. Journ. of Med. Sci., December, 1912) records observations upon 148 patients whose urine showed an excess of indican. The test employed was 10 c.cm. HCl, 10 c.cm. of a 1 per cent. solution of potassium chlorate, three drops of which were added to the urine and shaken up with 5 c.cm. of chloroform. The blue colour in the chloroform indicative of an excess of indican was arbitrarily graded as to intensity from +1 (sky blue) to +6 (very black blue). Indol results from bacterial digestion or putrefaction of proteids, the lower ileum being the chief laboratory for the process, and the colon the principal seat of absorption. The cases observed were about equally divided between the sexes, and usually the indican was incidentally present during treatment for other gastro-intestinal disorders, being in some transitory, in some recurrent, and in others more or less constant. Obstipation from obstruction of the transverse colon, or above it, may result in profound indicanuria, but this diminishes as the obstruction is lower down, and affections of the lower part of the bowel are rarely complicated by the condition. The most frequent cause appears to be a combination of improper diet with a run-down state and loss of nerve tone. The one symptom complained of in the largest number of patients was gas formation in the bowel, 96 being troubled in this way; and in addition the typical symptom-complex of the condition consists of vertigo, dull headache, languor, drowsiness, depression, lack of ambition, inability to concentrate the mind, insomnia, irritability, muscle pains and cramps, cold extremities, and fetid breath. While none of these symptoms are constant, nearly all cases exhibit some of them, very few having none at all. Treatment consists in measures to prevent the formation of toxins and the elimination of those formed, disorders of the gastro-intestinal tract receiving first attention. When direct treatment for the condition is needed, irrigations of salt, soda, argyrol, or ichthyol solutions are effective, ichthyol solutions often answering when others have failed. Diet aims at reducing the protein or any food favourable to the growth of the putrefactive bacteria, but butter milk and lactic acid bacilli treatment do not give the results that theoretically might be expected. Restoration of nerve tone, where overwork is a factor, is of the greatest importance.

277.

Tabetic Arthropathies.

LANDOLEI (Rif. Med., December 7th, 1912) in a synthetic review of recent work on the above subject reminds us how comparatively new the whole subject is. The joints most frequently attacked are those of the knee, hip, and shoulder, and the lower limbs give 75 per cent. of the cases; lately a good deal has been said about the tabetic foot. The lesions may be single or multiple, and may appear early or late in the disease, perhaps more often in the ataxic stage. Insensibility is a common feature—for example, in the knee-joint forced extension gives rise to little pain. The joint may become affected gradually or with great suddenness, there may be much effusion, or it may be comparatively dry, with much scrunching. The tabetic foot has received special attention of late years. Many explanations have been given of these arthropathies, and the theories may be broadly classified into two groups—the nervous and the non-nervous. Critical objection has been made as to most of them, and the question is still

unsolved. One of the most recent theories is that of Babinski and Barré, which traces the condition to vascular lesions of a syphilitic type in the articular arteries. According to these authors tabetic arthropathy is not an essential part of tabes, is not tabetic. Clinically it may appear as an arthropathy in tabetics or as an arthropathy of tabetic type occurring in syphilitics who have not got tabes. Landolfi attempts to co-ordinate the various theories as follows, starting with syphilis as the parent factor: On the one hand you have articular lesions and on the other the nervous lesions of tabes; of the articular lesions you have one group of arthropathies without tabes, a middle group of tabes plus non-tabetic arthropathies, modifiable with antisyphilitic treatment; and a third group of tabes plus tabetic arthropathies non-influenced by specific treatment. The joint lesions of syringomyelia differ from those of a tabetic type in more generally affecting the upper extremities, in being homolateral if multiple, and being often associated with suppuration or skin ulcers.

SURGERY.

278. The Surgical Treatment of Graves's Disease.

The surgical treatment of Graves's disease is a modern development, following on the general acceptance of Möbius's theory that the disease is due to a hyperfunction of the thyroid gland. Some surgeons have gone so far as to recommend operative measures in the earliest stages of all cases. A. Schlesinger gives an account of his experience of this surgical treatment of exophthalmic goitre in 20 cases, including severe, moderately severe, and mild cases, all of which were at least of six months' duration (*Berl. klin. Woch.*, January 13th, 1913). In all cases a medical form of treatment had been previously undertaken. In 3 cases the enlargement of the thyroid gland was only moderate, while the nervous symptoms were marked. In spite of having looked carefully for it, he has never been able to satisfy himself that the thymus gland had persisted in any case. He removed one lobe and part of the other in 2 cases; and in the remainder of the cases he removed one lateral-lobe and the middle lobe, save in 1 case, in which he merely excised the middle lobe. The operations were conducted with local anaesthesia ($\frac{2}{3}$ per cent. novocaine and suprarenin), but in a few cases the anaesthesia was not sufficient, and ether had to be given as well. The superior thyroid artery was always tied first of all, and later, before the posterior wall of the gland was freed, the inferior thyroid artery was also ligatured. In 1 case he experienced a severe haemorrhage on disengaging the lower end of the gland, which he was able to control with forceps. He also experienced secondary haemorrhage once, owing to the slipping of the ligature on the superior thyroid artery. Since then he applies a double ligature. Aphonia followed the operation once, but this disappeared spontaneously after a time. The recurrent laryngeal nerve was not damaged. Of the twenty patients three were followed up for about six months, when they were in good condition, with markedly diminished symptoms. The remaining seventeen patients were kept under observation until the time of writing. Of these three were cured completely, no symptoms having been seen for two years. Four were nearly cured, that is, subjectively and objectively almost without signs of the disease. He gives the details of two of these cases, showing the very remarkable disappearance of a severe psychosis, which he was forced to regard as being due to the disease. The other case was a typical one of secondary Graves's disease, goitre having been present from birth, and the symptoms having developed with an increase in size of the middle lobe. On the removal of this the symptoms practically disappeared. Seven further cases were considerably improved. In one of these cases the operation was followed by a diminution of the symptoms, but there was still severe cardiac asthma. When seen three years later the patient had developed well-marked myxoedema, she was practically demented (she had not been intelligent before), and there was distinct tetany. He had left a piece of the left lobe of the size of a man's fist, but no trace of this could then be felt. The asthma had disappeared. On giving her thyroid gland she improved considerably, but there were still traces of the myxoedema and the tetany. In two other cases recurrence of the symptoms were observed after two and three years respectively. These symptoms disappeared after medication with arsenic and electricity. The last of the seventeen patients also suffered from a recurrence. He discusses the question of persistent thymus and the risks

of sudden death after operation, and then passes on to consider the technique of the operations. He regards his results, in that there was not a single death or total failure, as good luck, since other operators have only obtained from 15 per cent. to 75 per cent. cures.

279. Fractures of the Superior Maxilla.

ALTHOUGH fracture of small portions of the superior maxilla is common, the involvement of the body of the bone is rare, as it is protected by the surrounding bony prominences and by the overlying pad of fat which is most marked in children. Yet R. Vogel (*Wien. klin. Woch.*, March 20th, 1913) has recently seen three cases of extensive fracture of the superior maxilla. A carter, aged 46, fell from a hay wagon while he was asleep and drunk. He struck the pavement with the left side of his body and head, but was able to get up at once and continue driving. Next day he was admitted to hospital, where he was found to be perfectly conscious in spite of extensive injuries to the head. The second, third, fourth, and fifth ribs on the left side were fractured, but there was sign of other internal injuries. On the left side the face was bruised and swollen, the cheek was cut over the malar bone, and the left eye showed traumatic exophthalmos, chemosis, conjunctival injection, and rupture of the sclera. The nose and the whole of the upper jaw moved as one piece on mastication. But this caused no pain. Although the upper jaw was altogether detached from the base of the skull and from its other bony attachments, the union between the right and left maxilla was maintained. The infraorbital margin on both sides moved with the upper jaw, the line of fracture running through the zygomatic process on the right side and along the outer angle of the orbit on the left side. On this side the processus coronoideus was also fractured. There was no lesion of the oral mucous membrane, but pressure on the pterygoid processes from within the mouth elicited characteristic pain. Suppuration and purulent thrombo-phlebitis of the cavernous sinus followed, and death occurred on the eighth day. Curious features of this case were the absence of cerebral symptoms, of paraesthesia and anaesthesia, of symptoms referred to the trigeminal nerve, and of marked discomfort. It was also strange that in spite of the complete detachment of the two bones from the base of the skull there was but little displacement, and the mucous membrane of the mouth was intact. A mason, aged 18, was rendered unconscious by a fall from a scaffolding. The right side of his face was swollen by oedema and haemorrhage, and the conjunctivae were also oedematous. There was crepitation over the root of the nose, the upper and lower incisors were loosened, and the mucous membranes in their neighbourhood were cut. The soft palate was divided in the middle line by a sagittal cut, which was separated by a small bridge of intact mucous membrane from a similar cut over the hard palate. This was divided in the median, sagittal plane by a 4 mm. wide furrow. The separation of the one maxilla from the other was easily demonstrated by crepitus. Excessive haemorrhage was arrested by the insertion of a tampon into the nose, and by the suture of the wound in the soft palate. The wound in the hard palate was left to heal by granulation, and the patient was discharged in three weeks. A man, aged 26, fell on his face, the whole of which became swollen. Crepitation could be elicited between the nasal bones, and between them and the frontal process. The mucous membrane covering the hard palate was divided in the median line by a sagittal wound which began just behind the teeth, and extended backwards for 5 cm. The wound extended to the hard palate, the two sides of which were separated by a 3 mm. wide cleft. The mucous membrane of the floor of the internal nares was, however, intact. The wound in the mouth was sutured, and an uninterrupted recovery was made. Discussing the diagnosis and treatment of fractures of the superior maxilla, the author points out that the nasal bones, the malar bones, and the pterygoid processes are the most common sites of pain and tenderness. Haemorrhage from the nose and mouth, and suffusion of the eyelids and orbits with blood, are common and serious conditions. The orbit may become enlarged owing to the downward displacement of its lower border. The lining of the mouth is seldom involved, and marked displacement of the bones is rare. These fractures are, therefore, often overlooked. It is easy to readjust the displaced fragments of bone, but the maintenance of such readjustment usually necessitates skilful dentistry. In the majority of cases, however, owing to the absence of marked displacement, the bones unite rapidly and without deformity, and treatment is limited to suture of surface wounds and the practice of oral antiseptics.

OBSTETRICS.

280. Phenolsulphonephthalein Test of Renal Function in Pregnancy.

SONDERN AND HARVEY, JUN. (*Bulletin Lying-in Hosp.*, New York, November, 1912), from observations in 21 cases, give a preliminary report upon the phenolsulphonephthalein test for estimating renal function in pregnancy, both as an aid in proving whether the diminished excretion of nitrogen is due to interference with function, and also as a guide to the degree of interference with renal function in toxæmia of pregnancy and threatened eclampsia. In order to insure free urinary secretion, 300 to 400 c.cm. of water are administered half an hour prior to the test, at the end of which time the bladder is completely emptied by catheter, and 1 c.cm. of phenolsulphonephthalein solution, containing 6 mg. of the drug, is given subcutaneously. Convenient ampoules are prepared for this purpose. The urine is then allowed to drain through the catheter into a test tube containing a drop of 25 per cent. sodium hydrate solution, and the time of the appearance of the first faint pink tinge noted. The catheter is then withdrawn, and all urine secreted during the next hour is voided into one receptacle, and all that secreted at the end of the second hour into another receptacle, and the amount of the drug excreted can be determined colorimetrically. Normally the drug appears in the urine in from five to eleven minutes, and in the first hour from 38 per cent. to 60 per cent., and in the second 22 per cent. to 25 per cent. is excreted, making a total for the two hours of from 60 to 85 per cent. The excretion of the drug does not correspond with the quantity of urine excreted, nor is there any constant relationship between its excretion and the amount of total solids or of any particular solid in the specimen. In severe cases of acute nephritis the permeability of the drug was decidedly decreased, and in cases of long-standing parenchymatous nephritis the time of the appearance of the drug was always delayed, and the amount excreted below normal. A similar delayed appearance and decreased output was noted in cases of chronic interstitial nephritis, and in a number of instances a marked decrease in, and even absence of, excretion with normal total solids and nitrogen excretion was soon followed by death from uræmia. The above observations show that the delayed appearance of the drug, and particularly the diminished excretion in the two-hour period of observation, are direct guides to the functional activity of the kidneys, and any functional derangement is more easily and accurately determined than by a diminution in the excretion of total solids or of nitrogen. Examinations made late in pregnancy in 18 clinically normal pregnancies showed a relatively diminished excretion, and consequently an interference with renal function, as compared with observations on normal non-pregnant cases, as shown in the following comparison:

| | Normal Cases. | Eighteen Normal Pregnancies. |
|-------------------------------------|---------------|------------------------------|
| Average time of appearance | 8 minutes | 12 minutes. |
| Average excreted first hour | 50 per cent. | 25 per cent. |
| Average excreted second hour | 24 per cent. | 19 per cent. |
| Average excreted two hours | 75 per cent. | 45 per cent. |

Although insufficient to justify definite conclusions, these data are suggestive of the depression in nitrogen secretion in late pregnancy being due to interference in renal function, and in the absence of actual renal lesions it may be fairly inferred that the cause is disturbed kidney circulation due to pressure of the gravid uterus.

THERAPEUTICS.

281. Cranial Nerve Disease after Salvarsan.

ALEX. ZALOZIECKI AND RICH. FRÜHWALD (*Wien. klin. Woch.*, Nos. 29 and 30, 1912) have made a careful study of cases of so-called salvarsan neuro-relapse. Lumbar puncture and examination of the cerebro-spinal fluid was undertaken in all cases, and was also undertaken, for purposes of comparison, in a series of cases of early syphilitic nerve disease and of early syphilis. The authors have taken the following characteristics as typical of normal cerebro-spinal fluid: A pressure which varies between wide limits, but does not rise above 15 to 18 cm.; no contained

cells, or at most up to 5 to 10 lymphocytes to the cubic millimetre; the amount of albumen very constant, from half to one-fifth per 1,000; (in a pathological increase of albumen the globulin constituent especially takes part, a circumstance upon which depends the value of the Nonne-Apelt reaction); a negative Wassermann reaction. The smallest deviation from the normal consists in an increase in the number of cells. Such an increase is very frequent in syphilitic, and by itself has little diagnostic meaning. A positive Nonne-Apelt, on the other hand, shows increase of albumen and is proof of an anatomical lesion of the central nervous system. Differences in degree of change in the cerebro-spinal fluid probably correspond to differences in extent and acuteness of the lesion. In acute meningitis marked cell increase may be absent, but increase in albumen is always present. The first six cases described are of neuro-relapse with diffuse disease and involvement of the cranial nerves. In the first four the relapse occurred at intervals of eight or, in one, of ten weeks after a salvarsan injection; in all severe headache was the first symptom and preceded by several weeks the occurrence of the paralysis which marked the definite onset. The fifth case was an especially important one; here the relapse occurred eight months after infection; the disease had been treated from the third month with mercury, but not with salvarsan. The cerebro-spinal fluid in all the six cases showed clearly the changes characteristic of meningeal disease; there was in all a speedy retrogression of the symptoms on the introduction of specific treatment. The sixth case is one of great significance, because in it the case was diagnosed as one of neuro-relapse by means of lumbar puncture when in the stage of severe headache before the onset of paralysis. The next six cases were instances of affections of isolated cranial nerves—most commonly the optic nerve—in which the changes typical of involvement of the meninges were found in the cerebro-spinal fluid on lumbar puncture. The first two were of salvarsan neuro-relapse with an acute onset, in which the process quickly localized itself to the optic nerve. With the retrogression of the acute symptoms the cerebro-spinal fluid changes also diminished—the number of cells became much smaller, and fibrinogen disappeared from the fluid. A distinction between such cases of salvarsan neuro-relapse and other cases of optic neuritis occurring in the secondary stage is important because of the more severe course often run by the former, and four cases of optic neuritis occurring in the second stage when no salvarsan had been given were therefore investigated. The first three of them had received no antisyphilitic treatment; the optic neuritis was double, and subjectively ran a course without symptoms. The cerebro-spinal fluid was essentially the same as in the preceding cases, and the conclusion to be drawn is that in these cases the syphilitic process involved further portions of the meninges, and may perhaps have extended to the optic nerve from the meninges. The fourth case was different. The patient had already been treated with mercury. Optic neuritis was severe and one-sided, and must have been in existence for some time. The only change in the cerebro-spinal fluid was a moderate increase in the number of cells, and the case must therefore be considered as being at the time of the examination narrowly localized to the optic nerve. In all these cases salvarsan treatment was given. The later course of the last case was of great interest. A relapse occurred about eight weeks after the last injection of salvarsan, and then affected another part of the eye; but that optic neuritis had been known to be present before salvarsan was given a salvarsan relapse would have been diagnosed; perhaps, indeed, the salvarsan did have an effect upon the later course of the case. In two of the cases salvarsan treatment did good, the third was resistant to salvarsan, but the symptoms yielded to a mercury inunction cure. Two cases of the development of optic neuritis are next described, one of which is only distinguished from the previous cases of diffuse meningitis with involvement of the cranial nerves by the absence of clinical symptoms typical of meningitis. Next comes a case of double optic neuritis occurring five months after infection and eight weeks after salvarsan treatment, in which the cerebro-spinal fluid was almost normal and the meninges not appreciably involved. Finally, two cases of affections of the auditory nerve are described, one which was characteristic of early syphilitic auditory disturbance, and occurred in an untreated case of syphilis, the other showing marked clinical symptoms of meningitis; positive cerebro-spinal fluid change was present in both. From the whole series of cases it is clear that in any given case it is impossible to say with certainty whether we are dealing with a salvarsan relapse or not.

Lumbar puncture may also fail to discover any differences between the relapse after the salvarsan treatment or without it. With regard to the possibility of the salvarsan injection itself causing an atypical change in the cerebro-spinal fluid, the authors' investigations, though they include only a comparatively small number of cases, make this appear improbable. Thirty cases of secondary syphilis without nerve affections were examined for purposes of comparison, forty lumbar punctures being made. The Nonne-Apelt reaction and amount of albumen were found to be normal in 23 cases, and showed slight changes in 5. In 2 cases only were considerable changes in the cerebro-spinal fluid present; these 2 must be considered as cases of latent syphilitic meningitis. The whole series of cases support the view that in the early secondary stage spirochaetes often settle in the central nervous system, and may there give rise to extensive changes not necessarily accompanied by obvious clinical symptoms.

282. Electrical Treatment of Commencing Muscular Atrophy.

MARQUÈS AND PECH (*Arch. d'electr. mèd.*, September 10th, 1912) describe the result of electrical treatment in a curious case of commencing muscular atrophy following upon traumatism. Severe contusions between the second lumbar and the left iliac crest, together with a deep wound at the right ischio-rectal fossa, had been produced as a consequence of a fall. Paralysis of the anal and vesical sphincters ensued, with anaesthesia of the genital organs and of the anal region. The sphincteric troubles amended to some extent in the course of a few days, but micturition and defaecation were not entirely under control, and the former at least gave rise to no sensation. In addition to these clinical phenomena of medullary origin—which still persist, although more than a year has elapsed since the accident—the patient presented other troubles of less certain causation, including the beginning of atrophy of the lower members, with pain along the tract of the left sciatic. Electrical examination showed that none of the muscles of the left leg reacted to the faradic current, and that with the galvanic current the contraction was only slow and dragging. In the right leg there was but a slight degree of hypo-excitability. Treatment of both members by galvanization (15 milliamperes for fifteen minutes) was instituted, with faradic excitation localized at the muscles of the right leg, and rhythmic galvanic excitation at the muscles of the left. The faradic brush was also applied to the zone of anaesthesia. Amelioration was rapidly produced, thus showing the peripheral origin of the motor troubles. The right leg returned to its normal condition after the first applications. The other leg also improved, and within a few weeks the patient was able to walk without the aid of a stick. Some months later he was found on examination to betray only a slight feebleness of the left leg, which was fatigued more quickly than the right.

283. Treatment of Typhoid Carriers.

DEHLER (*Münch. med. Woch.*, April 16th, 1912) has for some time past advocated operative treatment for the cure of the condition indicated by the name "typhoid carrier." The operations performed in 1906 and 1907—these cases have already been published—were successful. In one case, during the first six months after the operation, only 3 of 109 stools contained typhoid bacilli, and since then 187 stools have been examined with a negative result in each case. In the other, 2 of the first 17 stools contained bacilli, while none of the subsequent 80 stools contained any. In these two cases, cholecystotomy with prolonged drainage was performed. He considers, however, that the complete removal of the gall bladder with drainage of the hepatic duct would be a more rational operation. He now records two further operations. In the first, a female patient aged 64 years, without any known history of typhoid fever, was found to be a carrier in 1904. Up to 1907 she was examined forty-two times, and in thirty-six bacilli were found in the motions. On April 23rd, 1907, she was submitted to operation. The gall bladder was found to be perforated at the fundus. A large empyema was evacuated, some gall stones removed, and the gall bladder plugged and drained. She recovered. At first the bile did not flow well through the drain, and for a time the majority of the motions contained typhoid bacilli. Later this became rarer, until October 3rd, 1907. Since then no bacilli have been found in any of the 167 samples examined. The other patient was a nurse who contracted enteric fever from an unknown source. In September of 1909 she was again taken ill with

fever, jaundice, and tenderness in the region of the gall bladder. On October 10th typhoid bacilli were found in the motions. On May 5th, 1910, her gall bladder was removed. The walls were thickened and infiltrated with small abscesses; no stones were found, and the turbid bile contained typhoid bacilli in pure culture. The hepatic duct was drained, and sodium chololate given. The bile was deflected through the wound. Fifteen days after the operation the motions were free from bacilli, and the drainage of the duct was maintained for five weeks, until no further typhoid bacilli were found in the bile. Since biliary fistula has healed her motions have remained free from typhoid bacilli. He claims that this is the only proper treatment for typhoid carriers.

PATHOLOGY.

284. The Central Innervation of the Urinary Bladder.

R. LICHTENSTERN (*Wien. klin. Woch.*, xxv, 1912) has made a notable contribution to the physiology of the uterbrain and the central innervation of the bladder in a special part of that region. Karplus and Kreidl found in dogs and cats that electrical stimulation of the base of the diencephalon at a point between the optic tract and the third nerves, and behind the tract and on the outer side of the infundibulum, gave maximal pupillo dilatation, a widening of the palpebral fissure, a retraction of the third eyelid, with lacrymal and salivary secretion, and a profuse secretion of sweat in all four paws, together with a protracted contraction of the urinary bladder, both when empty and when full. Lichtenstern has studied the effects of stimulation of this hypothalamic region in cats; he performed laparotomy, opened the urethra, introduced a sound into the bladder, and detached the insertions of the abdominal muscles; he obtained a manometric rise of 5 to 6 cm. When the bladder contained but little fluid, it remained strongly contracted, and the contraction yielded only to affusion with warm water or vesical injection of warm water. He also made in animals serial sections of the conus medullaris, and found that section below the second sacral segment did not prevent the contraction of the bladder induced by hypothalamic stimulation, whereas injury of that segment did inhibit it. The work of Langley and Anderson, and also that of Elliott, showed that the nervi erigentes, which rise in the sacral cord, contract the bladder muscle, relax the sphincter vesicae, and have an antagonistic action on the hypogastric nerves which come from the lumbar cord. Lichtenstern found also that, after extirpation of one or both cerebral hemispheres, the effect of excitation of the sympathetic centre in question was twice as great from the manometric point of view as it was without such preliminary extirpation. He concludes that stimulation of the hypothalamus leads to bladder contraction, which is effected by way of the nervi erigentes rising in the spinal cord between the second and third sacral segments, and that this contraction is not prevented by extirpation of the cerebral hemisphere or hemispheres. He mentions that hypothalamic stimulation had no effect on the uterus or the spermatic cord.

285. The So-called Toxicity of Ascarides.

EGUERRINI (*Archiv di Biolog. Milan*, An. 64, f. iv) criticizes some of the evidence adduced in favour of the toxic power of ascarides, and gives the result of certain experiments on the frog's heart when the animal was injected with various extracts of ascarides. The coelomatic fluid of the parasite was first used, then an extract of the cuticular and muscular apparatus, next an extract of the intestines and genital organs, and, finally, an extract of the parasites *en masse*. In every case the result was negative, as far as any changes in the cardiogram could be detected. As the method (Engelman's) used by the author is very delicate, it does not appear that ascarides possess any toxic property. When authors affirm that certain phenomena are symptomatic of worms, or that certain symptoms are likely to occur in people who harbour these parasites, or, again, that certain symptoms have followed the experimental injection of extracts prepared from ascarides, the author replies by a direct negative, and says that if any of these things have occurred it is not a case of cause and effect, but either a coincidence or an error of observation. The particular ascaris experimented with by the author was the *A. megalocephala*.

AN EPTOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

286.

Periosteal Reflexes.

MYERSON (*Archives of Internal Medicine*, July 15th, 1912), in a preliminary paper on some unfamiliar and some new periosteal reflexes, considers the following: (1) Those obtained by tapping the ulnar styloid process when a contraction of the biceps, or of the posterior fibres of the deltoid, or of a combination of both results; and if the response is very active the reflex spreads to the supraspinati and infraspinati, rhomboids, trapezius, and biceps, comparable as an extensor response to the flexor response in the radial reflex. (2) A series of homolateral and contralateral responses from different bony points of the lower limb. With the patient lying in an easy, natural, relaxed attitude, the legs slightly abducted and rotated outwards, percussio in certain areas produces the following results: (a) From the internal condyle a homolateral adductor reflex, occasionally accompanied by (b) a less lively contralateral response; (c) from the anterior surface of the tibia a homolateral reflex, accompanied occasionally by (d), a weaker contralateral response; (e) from the external condyle a homolateral, frequently accompanied by (f), a more lively contralateral response; (g) from the sole of the foot a homolateral always accompanied by (h), a much livelier, and of more frequent occurrence, contralateral; (i) from the anterior superior spine a contralateral adductor response accompanied by a less lively homolateral. The homolaterals are livelier than the contralaterals down to the sole of the foot, where the relationship becomes reversed on passing from the internal to the external condyle. The activity of these reflexes is in direct relationship with that of the tendon reflexes, being active when the latter are active, and vice versa, and they are marked in diseases of the cortex, especially in uncomplicated general paresis, in cerebral arterio-sclerosis, in diseases of the pyramidal tract, and in preataxic tabes (though being absent in advanced tabes), in exophthalmic goitre, and in neurasthenia. Seeing that these reflexes are elicited from easily accessible surfaces, they should form part of every routine examination as affording additional information upon the patient's reflex irritability.

287. The Clinical Value of Electro-cardiograms.

H. E. HERING has attempted to ascertain the value of electro-cardiograms for clinical purposes in accordance with the present state of our knowledge and in the light of our present experience (*Deut. med. Woch.*, November 14th, 1912). He finds that the form of the electro-cardiogram in man reveals the function of indirect deviation, the position and the site of excitability of the heart. Of these three variables, only the first named is usually known, and for this reason the interpretation of electro-cardiograms must be associated with considerable uncertainty, and the clinical application of this form of examination suffers considerably in its possibilities. He proceeds to state that a normal electro-cardiogram does not exist; each cardiogram is individual. It is a highly delicate differential indicator, and reveals differences which other methods cannot register, but which may be physiological variations of function. The difficulty in determining whether each characteristic of the cardiogram is physiological or pathological further limits its use clinically. In regard to arrhythmia, the electro-cardiogram does reveal important information. Further advance can only be expected if full consideration be directed towards the deviation and the position of the heart. The external position of the body and the phase of respiration exercise a considerable influence on the curves.

288.

Chyluria.

LAFFORGUE (*Journ. des praticiens*, March 1st, 1913) relates the case of a man who suffered from repeated attacks of this kind. Latterly they were complicated by haematuria. The onset generally began with violent pains in the testicles accompanied by fever and rigors. Haematuria then supervened, and after about forty-eight hours was replaced by the chyluria which persisted until the patient was died. His general condition was excellent. The matter is interesting from several points of

view: (a) The character of the urine. This is milky with red deposits. On standing there is no appreciable sediment. There is a creamy pellicle on the surface consisting of fatty matter. A chemical examination shows that the urine clears completely with Adami's fluid and glycerine, and partially by boiling with alcohol. The matters in suspension are insoluble in ether, chloroform, xylol, and acetone. Heated with potassium the urine clears up almost completely. The results of experiments would seem to show that the trouble is chiefly due to neutral fats. The complete insolubility in xylol excludes lecithins. The fatty matter and suspension takes up the colour from osmic acid slowly and indifferently. (b) The parallel between the appearances of the chyluria, and its immediate disappearance on a milk diet. It returns on the ingestion of haricots, pastry, fondants, chocolate. Wine and champagne have a particularly bad effect, while Strauss has further proved that if 150 grams of butter be added to the ordinary milk diet, the chyluria returns within twenty-four hours. (c) The origin of the chyluria. The author has found no evidence to support the view that in this case the condition was due to the bilharzia or filaria. In his opinion there are two types of chyluria: the one definitely due to a parasite; the other being the "fatty diabetes" of Gubler. These must be distinguished from one another. The chemical analyses of the urine should help this differentiation. Further information is needed however.

289. Spontaneous Perirenal Haemorrhage.

ABETRI (*Riv. Med.*, December 21st, 1912) reports in detail the case of a woman, aged 49, who, after a fall, developed a tumour in one loin and intermittent haematuria. The accident happened on December 20th, and on March 5th the swelling was incised and found to be a cystic haematoma; the kidney was removed, and the final result was excellent. The cause of the haemorrhage appeared to be an arterio-sclerotic condition of some of the cortical arteries. The author has been able to collect 24 similar cases, 11 occurring in males and 13 in females. The age of the patients varied from 16 to 76 years. Both sides were equally liable. The size of the haematomas varied from that of a hen's egg to that of a man's head. The exact pathogenesis of these haemorrhages is uncertain, but their ultimate origin is always renal, and usually there is evidence of arterio-sclerosis, either in association with chronic interstitial nephritis or more rarely with parenchymatous nephritis and periarteritis. In the acute cases the symptoms are violent and sudden pain in one loin, signs of internal haemorrhage, and the appearance of a lumbar tumour; later on ecchymosis of the loin or the scrotum may develop; haematuria may or may not be present, and may be intermittent. The chronic cases are more difficult. The appearances of the cyst when opened are such as one might expect in any haematoma, and, just as in any other haematoma, secondary septic changes may occur. The treatment is purely surgical. Mere incision with removal of the clot is not satisfactory, and is often followed by severe and fatal haemorrhage. The proper treatment is to remove the kidney, unless this is contraindicated by serious disease in the other kidney. As far as present figures go, nephrectomy gives a cure of 83.5 per cent., whilst mere incision is only 62.5 per cent. These deal merely with spontaneous haemorrhages, and do not include traumatism or haemorrhage secondary to tuberculous ulceration, new growths, haemophilia, etc.

290. Quantitative Estimation of Uric Acid.

VATTUONE (*Gazz. degli Osped.*, October 3rd, 1912) has carried out a series of contract experiments with the Ruheman method of estimating uric acid in the urine as compared with the Hopkins method. The difference in the two results were so very slight as to be practically negligible, and, since the Ruheman method is much simpler, it is worth knowing. Into a simple graduation tube known as the "micrometer" 18 to 20 minims of carbon sulphide are dropped, and on this an alcoholic solution of iodine (containing 0.015 gram of pure iodine). To this is added as much urine as corresponds to the scale, indicating 2 grams per 1,000. More urine is added until the brown colour of the iodine becomes more like straw; the whole is then vigorously shaken and the carbon sulphide becomes violet. Urine is then added drop by drop until

the carbon sulphide becomes nearly colourless; as a rule very little urine is required. The index is then read off on the scale and the amount of uric acid readily and quickly ascertained. If the amount of uric acid is above or below the scale figures, it is only necessary to divide the urine or the iodine as may be necessary and divide or multiply as the case may require. Bile pigments, glucose, and albumen (unless in large quantities) do not interfere with the test.

SURGERY.

231.

Post-operative Parotitis.

B. VALENTIN (*Berl. klin. Woch.*, March 16th, 1913) has collected the observations made on post-operative parotitis in the period 1904 to 1912. The condition had been observed about twenty-five years earlier as a sequel to ovariectomy, but it was misinterpreted as a result of an obscure relation between the reproductive organs and the parotid gland. It is now known that the condition may follow operations other than those on the reproductive organs. Indeed, post-operative parotitis is now recognized as a more common sequel to operations on the gastro-intestinal tract than on the ovaries, and it may also follow operations on the breast. The author observed two cases, in one of which appendectomy had been performed on a patient aged 33. The appendix had caused symptoms for the first time fourteen hours before the operation, at which it was found to be injected and covered with a recent layer of fibrin. The patient was afebrile till the fourth day, when the temperature rose suddenly, and the left parotid became swollen. The abdominal wound healed by first intention, but the parotid suppurated, pus being evacuated by an incision, and the patient ultimately recovering. In the second case the patient was a woman, aged 38, who was operated on for an incarcerated hernia with a faecal fistula. The paralytic swelling of the parotid which followed ended fatally. The complication usually occurs five to six days after the operation, and is almost invariably accompanied by general discomfort, high fever, and pain. Two to four days later it is common for the second parotid to become involved, the patient presenting an appearance typical of mumps. In Germany the condition apparently ends most often in suppuration, and, owing to the firmness of the fascia covering the gland, pus tends to track into the ear, the skull, the neck of the thorax, with fatal results. In France a more optimistic prognosis is given, and, as suppuration is considered to be the exception and not the rule, conservative treatment is advised. This consists of massage of the gland and Stenson's duct two or three times a day. The author recommends the application of wet compresses or Bier's hyperaemia at first. Later, if the fever, pain, swelling, and discomfort persist or increase, the gland should be incised, even if no fluctuation is demonstrable. The condition may be caused in one of three ways: By pressure exercised by the anaesthetist's hand while the jaw is fixed in a certain position; by infection from the blood stream in the same manner as a sore throat is supposed to infect the appendix; and by infection from the mouth. The two first views are but briefly discussed by the author, who devoted most of his space to the third view, the evidence in favour of which is considerable. Pawlow showed that the secretion of the submaxillary glands is much reduced when the abdominal cavity is opened and the intestines are drawn forward. He also showed that the inhibition of secretion from the glands is proportional to the duration of the laparotomy. Under these circumstances it is natural to suppose that germs in the mouth, which otherwise would have been washed away by the flow of saliva, gain access to the glands. Pawlow's observations and the author's deductions therefrom are, however, confined to parotitis following abdominal operations; and another explanation is necessary for parotitis following operations on the breast and haemorrhoidal vessels. According to Berth, chloroform alone is able to reduce the secretion of saliva; and after ether anaesthesia, patients are exhausted and breathe with open mouths without swallowing, and thus the escape of germs into the submaxillary glands may again be facilitated. But parotitis may follow an operation performed under local anaesthesia, and Baehrach has reported such a case. Gastrostomy was performed, and the patient fed through the fistula. Nine days later parotitis occurred. This was probably due to the enforced idleness of the parotids during the artificial feeding by the fistula. Parotitis following the use of morphine may also be due to lack of secretion and increased facilities for germs to spread up Stenson's duct. Leguen has induced

parotitis in dogs by implanting germs in their mouths after the administration of atropin. He obtained the same results by reducing the fluid in the body by venesection. The view that germs reach the glands by their ducts from the mouth is further confirmed by Orth and Hanau, who showed that the ducts were first infected, and that the central portions of the gland were infected before the outlying portions. The author concludes that post-operative parotitis is the outcome of a concatenation of circumstances.

292.

Botryomycosis.

ETIENNE (*Proc. mèd.*, March 15th, 1913) relates the case of a patient who for about seven months had had a small tumour of a vivid red colour about the size of the head of a large pin on the ulnar side of the terminal phalanx of the middle finger. The patient did not remember having received a blow of any kind. The tumour slowly increased in size, and latterly became ulcerated and bled readily. It was cut off and the pedicle cauterized with AgNO_3 , but after an interval reappeared. The nail remained normal, and movement of the terminal phalanx was unimpaired. The patient's general condition was good. Ultimately the growth was freely removed. From the surface of a section of the tumour a culture was made on Sabouraud's medium, the result being a growth resembling *Staphylococcus aureus*. In making the culture every precaution was taken to avoid any contamination. A section of the growth examined with the naked eye showed a whitish pedicle prolonged into the subjacent tissue and dividing into branches in the interior of the tumour itself. The intervening tissue was of a reddish colour. Microscopically the tumour appeared to be formed of fibrous tissue for the most part, branching in all directions, and small, dilated vessels filled with red cells, and surrounded by numerous cells of two types—a few with large nuclei, the others being embryonic cells. The latter more particularly surround the vessels, giving the growth the appearance of a granuloma. The epithelium is abnormal, and there is considerable hypertrophy of the corneal layer. Bacteriologically the cells described by Letulle and those of Labbé were not found. The author details the very conflicting opinions offered on the identity of these growths. Poncelet and Dor, at the commencement of their researches, proposed the terms "inflammatory papilloma" or "infective granuloma." It has been suggested by some authorities that the condition is identical with botryomycosis, which attacks the spermatic cord of the horse after castration, and is caused by a parasite allied to actinomycosis. In this the botryococcus and staphylococcus play the principal rôle in the formation of the lesion. As already mentioned, there has been some discussion as to the identity of these infective agents. Morphologically they are alike, but culturally they show decided differences. In the author's case the staphylococcus only—or a coccus indistinguishable from it—was found. The identity of the lesion in the horse and in man is still in dispute. Certainly there is no evidence of contagion from the horse to man at present. The author concludes by stating that in his view the growth in question was an inflammatory fibro-papilloma. The causative agent, it must be admitted, is still in doubt. In the tumour found in the human being it has not been isolated—as has been done in the case of the horse—nor has it reproduced the original lesion after inoculation.

293.

Acute Peritonitis ending in Cure.

CURTILLET AND LOMBARD (*Rev. franç. de mèd. et de chir.*, 1912, No. 15) describe the following cases: (1) Peritonitis following acute appendicitis in a boy of 12, followed a month afterwards by a subphrenic abscess. (2) Intestinal perforation during the course of typhoid fever, operated upon twelve hours afterwards. The cellular tissue, contaminated by the peritoneal liquid, sloughed. (3) Acute appendicitis and peritonitis at the commencement of typhoid fever. (4) Traumatic perforation of the intestine with peritonitis and sloughing of the abdominal wall. The perforation was due to a fall from a horse.

OBSTETRICS.

294. Abderhalden's Dialysis Reaction for Pregnancy.

ABDERHALDEN (*Deut. med. Woch.*, 1912, p. 2161) and Petri (*Zentrbl. f. Gynaek.*, 1913, No. 7) deal with the technique of this reaction. Founding himself on the parenteral entrance of fetal albumen by deportation of synechium, Abderhalden showed that the serum in pregnancy had

a special power of breaking up fetal albumen, and that this could be demonstrated by a polarisation method and by a dialysis method. With special apparatus and experience the former is specially suitable for qualitative work, but the dialysis method can be made available in any moderately equipped clinical laboratory. A set of dialysis capsules (Diffusionshülle, Schleicher u. Schüll, Düren) must be procured. From these must be selected by experiment a series which are impermeable for albumen but all permeable by peptone at nearly equal rate. For this they are laid in water and then carefully washed, and their permeability successively tested with serum and with peptone solution. The biuret reaction may be used as test, but preference is given to the reaction with triketohydrindenhydrat (ninhydrin, Lucius u. Brüning, Hoechst). After dialysis from sixteen to twenty-four hours, to 10 c.cm. of the dialysate add 0.2 c.cm. of a 1 per cent. watery solution of ninhydrin, and boil for a minute. A positive reaction gives a violet-blue colour, a negative no change or slight yellow colour. The capsules are serviceable for many experiments, and are kept in sterile water to which a little chloroform or toluol is added. The test is carried out as follows: Placenta is washed blood-free and coagulated by boiling. Successive boilings are made till the water shows no substances reacting with ninhydrin. Four boilings or more may be needed. Of the coagulated tissue 1 gram, in lentil-sized pieces, is placed in the dialysis capsule, and to it is added 1.5 c.cm. of the serum to be tested, absolutely haemoglobin-free. The capsule is then held closed with two fingers, and thoroughly washed with water. A layer of toluol is added, and the capsule is then placed in 20 c.cm. of distilled water in a dialysis flask. The surface of the water must be higher than that of the serum in the capsule. The water also is covered with a layer of toluol. The flask is now placed in the incubator for about sixteen hours. Thereafter 10 c.cm. of the dialysate, free from toluol, is removed with a pipette, and tested with ninhydrin as described.

GYNAECOLOGY.

295. Hypertonus in Women.

G. SCHIEKELL (*Wien. med. Klin.*, No. 31, 1912) discusses the significance of some of the rarer forms of hypertonus. Some of the cases are gynaecological and are diagnosed as cases of endometritis because of the presence of profuse menstruation occurring regularly or irregularly. The patients suffer from symptoms such as excitability, headaches, heat waves, sweating, palpitations, and disinclination and disability for work. Depression or a sense of inadequacy may also be present; the face is often flushed, though redness and pallor may alternate; there is sometimes a slight tremor and dermatography. The pulse-rate is usually increased to 110 or 120 per second, but not often to any greater degree; the heart appears to be normal, though a slight systolic murmur is occasionally heard. The kidneys appear to be normal. The blood pressure is increased to from 150 to 180 mm.; lymphocytosis and raised eosinophilia may be present. The patients are, as a rule, no longer young, the youngest of the author's patients being 29 years old, and many within the preclimacteric period. The author gives notes of 4 cases illustrative of the condition. The first 2 were of patients not yet in the preclimacteric period. Improvement in the first case followed the administration of thyroid extract. Curetting was carried out in the second case, but without improvement of the symptoms, while histologically the endometrium was found to be normal. In this case the condition improved almost immediately after a change of diet and administration of corpus luteum extract. The other two patients were older, one, 48, the other 50 years of age. In the first case curetting was followed by diminution of menstrual loss, but not by any general improvement in the symptoms. In the second menstruation had become scanty and irregular, and psychical depression was a marked feature of the case. Here, again, corpus luteum extract, although it did not lead to any lowering of the blood pressure, caused definite improvement in the general condition; the patient felt better, and was able to work better. Earlier researches have shown that the internal secretion of the ovaries acts in the direction of causing lowering of the blood pressure; the increased blood pressure of the menopause follows the withdrawal of this action. There is, apparently, a heightening of the sympathetic tonus. A similar condition may also occur before the ovaries have become altogether without function—that is, in the preclimacteric period. The first two

cases—those of women of a younger age—fall into line with the other two, if we accept that in the former the disturbance of function of the ovaries was a primary condition. The irregular bleedings would then be one of the numerous symptoms of this condition, and would have no connexion with an anatomical change in the uterus or uterine mucous membrane. This theory is supported by the favourable effect seen in such cases from the administration of ovarian or corpus luteum extract. The case cited above, in which thyroid extract proved beneficial, tends to show that the secretions of the internal secretory glands must have many substances in common. Further investigations are needed, but the author's cases are convincing as to the fact that abnormal haemorrhages from the uterus have origin in different causes in different groups of cases, and such different groups call for recognition and for different forms of treatment directed to the particular cause in each group.

THERAPEUTICS.

296. Treatment of Arthritic Rheumatism.

P. JUNGHANS is of opinion that the treatment of rheumatic affections with antipyretics has been disappointing (*Dent. med. Woch.*, November 7th, 1912). He finds that salicylic acid is not a specific remedy, and that the most it can do is to reduce fever, relieve pain, and diminish the joint swelling. Menzer has found that better results can be obtained without salicylates by local and general application of warmth. The author has therefore treated a number of rheumatic cases without salicylates. He placed the affected joint at rest, usually by means of a splint. The joint was painted with ichthyol and well packed with many layers of wool. In 21 out of 45 cases this alone effected a complete cure. In those cases in which this more or less expectative procedure did not suffice he applied either local heat or Bier's hyperaemia. In 24 cases he found that an active method of treatment was required. The high price of Menzer's antistreptococcal serum formed a bar to its general use. He therefore turned his attention to collargol in those cases in which salicylates proved useless. He preferred giving intravenous injections to applying the collargol per rectum, partly because the action is more rapid, and partly because it is easier both for the practitioner and for the patient. The dose employed was 2 c.cm. of a 5 per cent. solution. Rectal application, however, yielded excellent results. He was able to observe a rapid and permanent cure in the majority of his cases; severe recurrences were scarcely met with, and the heart remained free from gross lesions. In those cases in which a cardiac affection was already present the condition of the heart tended to improve, or at all events not to get worse. He recommends this form of treatment for all cases of rheumatism.

297. Treatment of Nervous Gastric Crises.

FIESSINGER (*Journ. des praticiens*, 1912, lvi) considers the treatment as follows:—Medical external measures: Rest in bed is necessary; cataplasms or warm applications to the epigastrium, ethyl chloride to the vertebral column, and galvanization one electrode on the dorso-lumbar region and one, the positive, on the epigastrium, with a current of 20 milliamperes. Régime: Iced water by the mouth, and lavement of physiological serum, 250 grams for each lavement with 20 drops of Sydenham's laudanum, or cutaneous injections of sodium chloride or glyceose (500 c.cm. to 1 pint); iced milk (one-third Vichy-Célestin water), or laudanum in milk (5 drops per cup), or iced champagne or coffee may be given if iced water is not retained. Drugs: (1) Applications to the abdomen. Laudanum (20 to 40 drops or a cataplasin or warm compress), or a liniment of chloroform, 10 grams, liquid extract of opium, belladonna, and henbane, aa 2 grams, balsam 30 grams. (2) Lavements or suppositories: Lavements containing opium, or suppositories of opium and belladonna or antipyrin, exalgine, or dionin by lavements if absorption by the mouth is not possible. (3) Draughts or solutions: Chloroform water (saturated) 80 c.cm., syrup of ether 10 c.cm., syrup of codeina 30 c.cm., hydrochlorate of cocaine 0.10 gram, or dionin 0.20 gram, aqua laurocerasi 10 grams; 6 to 8 drops for a dose. Morphine hypodermically should only be given as a last resource. Santonine 0.10 gram three daily, oxalate of cerium 0.05 gram to 0.15 gram three daily in pills, inhalation of amyl nitrite, sodium nitrite subcutaneously and daily, have all been employed with success. Robin recommends sodium bicarbonate 1.50 gram, magnesium hydrate 1 gram, carbonate of precipitated chalk 1 gram, powdered sugar 1 gram, bismuth

subnitrate 0.50 gram; codeine 0.005 gram every three hours during the day. Koenig injects into the muscles of the back, between the sixth and tenth dorsal vertebrae, 100 c.cm. of a solution of novocain 0.53 gram per 100. Lumbar puncture has given good results, and the injection of cocaine, stovaine, or novocain into the subarachnoid space has also had good effect. Marinisco has had better results with the following injection into the same place: Magnesium sulphate 25 per cent. solution, 1 c.cm. for 25 lb. weight of the patient. Surgical:—Foerster's operation: Open the dural sac after laminectomy, and resect the fifth, sixth, seventh, eighth, ninth, and tenth posterior roots of the cord. Franke's operation: Stretching of the sixth, seventh, eighth, ninth, and tenth intercostal nerves each side of the spinal column. The results of Foerster's operation are as follows: Death 15 per cent., return of the crises 17 per cent., complete cure 14 per cent., improvement 55 per cent.; and those of Franke, 7 out of 10 successful, 2 relapses, 1 death. These operations should only be performed as a last resort.

293. The Therapeutic Action of Tryamine.

HOYT (*Amer. Journ. Med. Sciences*, July, 1912) studied the pressor effects due to p-hydroxyphenylethylamin (tryamine) in twenty instances. There is considerable evidence to show that the above amine is formed in the human intestine from tyrosin, and that it is the most active pressor substance in extracts of putrid meat and in the watery extract of ergot. Dale and Dixon found that intravenous injection of tryamine caused a marked abrupt rise in blood pressure resembling that of epinephrin, except that the latent period is greater and the rise of pressure more prolonged, and that it is active either when administered hypodermically or by the mouth. From observations upon the twenty cases selected by the author as being those in which the blood pressure was likely to remain constant, and therefore such that any distinct changes following administration of the drug would be most probably due to that drug, the effect of hypodermic doses up to 20 mg. was found to be very slight. The drug is freely soluble in water, produces no gastro-intestinal irritation, and when given by the mouth it is uncertain and slow in action. In doses from 20 mg. to 40 mg. it produce a marked, abrupt, but extremely fugacious rise, sometimes associated with slowing of the pulse-rate and irregular cardiac action. The writer is in agreement with Clark, who, working independently, arrived at the same conclusions. In the treatment of marked vasomotor depression tryamine should be of value, but it cannot be relied upon for any prolonged action.

299. Treatment of Dysphagia in Tuberculous Laryngitis.

J. LAWRENCE (*Journ. des praticiens*, 1912, xxvii) recommends that dysphagia in tuberculous laryngitis should be treated by injections of alcohol into the superior laryngeal nerve. Technique: A solid platinum needle, 4 cm. in length, should be made to fit an ordinary syringe containing 2 c.cm. Two solutions are necessary, (a) an anaesthetic liquid such as physiological serum 100 grams; novocain, 0.50 gram; adrenalin, 1 per cent., 25 drops. (b) Alcohol at 0.85. One c.cm. of the first solution should first be injected and the syringe then withdrawn (the needle still being in position) and 1 c.cm. of alcohol drawn into it; the syringe is then attached to the needle and the alcohol injected. Some minutes after the injection the patients feel a sensation of numbness, accompanied by difficulty in swallowing. At the end of 10 to 20 minutes the pains reappear, which may last some hours to a day and then disappear it may be for 10, 20, 40, or 60 days.

300. Rectal Administration of Salvarsan.

RAJAT (*Ann. des mal. vén.*, November, 1912), while not wishing to defend salvarsan nor to advocate its employment instead of mercury, draws attention to the administration of the drug per rectum, a method which he considers of equal value to other methods. The patient is prepared by an enema of a litre of water. The dose of salvarsan is dissolved in 120 c.cm. of artificial serum in the proportion of 5 per 1,000, with the addition of soda, if necessary, to obtain complete solution. It is administered by means of a rubber injector, and retained for thirty-six to forty-eight hours. The author maintains that the effects obtained are absolutely similar to those after intravenous injection, and that rectal administration is free from many of the dangers of other methods. He has tried it in 125 cases.

PATHOLOGY.

301. Phenolsulphophthalein as a Renal Test.

ROWNTREE AND GERAGHTY have recently described a new means of testing the condition of the kidney before the removal of one organ. The substance employed in this test is phenolsulphophthalein. Injected subcutaneously, intramuscularly or intravenously, this substance is quite harmless in doses of 6 mg. J. Vogel (*Berl. klin. Woch.*, November 11th, 1912) has used the method, and is of opinion that it is of high value, although there are a few points on which he does not agree with the American investigators. The quantity to be injected is dissolved in 1 c.cm. of water and injected, preferably intramuscularly. It is then necessary to collect the urine from each kidney separately, and according to Vogel to continue this collection until the whole of the injected substance is excreted. The urine is stained a vivid bluish red, when rendered alkaline with sodium hydrate. The quantitative analysis is best performed by means of Königsberger and Autenrieth's colorimetric apparatus. Rowntree and Geraghty stated that in from 65 to 80 per cent. of the cases, the whole of the 6 mg. is excreted within two hours, but Vogel finds that this is not so. He comes, however, to the conclusion that the rate of excretion is of less importance than the relative quantity excreted by each kidney and the fact whether the whole is excreted by each kidney and the fact whether the whole is excreted. He describes the method which he adopted for collecting the urine from each kidney by means of ureteral catheterization. At first he compares the results obtained with those obtained with phloridzin, indigo-carmin and cryoscopy, but he has since learnt that phenolsulphophthalein can be trusted without control, and at most he uses a cryoscopic examination of the blood. The test has not failed him, when he has proceeded to remove a non-functionating kidney, but it may give rise to the impression that the kidney which it is proposed to preserve is not sufficiently active to support life, when this is not the case. The author learnt this in a desperate case, in which he underlook the risk of removing a kidney which was completely converted into an abscess cavity, when the function of the other organ appeared doubtful by the test. The patient was going down hill, and after the operation, he was delighted to find that remaining renal tissue sufficed for the maintenance of life. In dealing with the technical details, he mentions that urinary pigment and blood may obscure the colour results. The former may be overcome by precipitating the pigments with acetate of lead, while the admixture of blood from an accidental injury during the passage of the catheter rarely lasts long.

302. Teratoma of the Thyroid in a Fetus.

A. W. RUSSELL AND MILLS KENNEDY (*Journ. of Obst. and Gyn. of the Brit. Empire*, February, 1913) report a case of this very rare condition. The mother was a 3-gravida, and when labour commenced a diagnosis of brow presentation with hydramnios was made. Fourteen pints of fluid were drawn off, and she was subsequently delivered by forceps of a fully developed dead female child. A tumour about the size of a large Jaffa orange, which had obstructed labour by preventing flexion, occupied the neck from the symphysis menti to the sternal notch, about two-thirds of it being situated on the right of the middle of the neck. The tumour lay beneath the deep cervical fascia, had a distinct fibrous covering, and was trilobular. It displaced but did not occlude the oesophagus and trachea, but it formed a distinct mechanical obstruction to the entrance to the larynx. On section it was seen to be irregularly cystic, the cysts tending to be multilocular. Histologically very little thyroid tissue was found to be present. There was an adenomatous tissue the epithelium of which was much richer than that of ordinary thyroid tissue, but the greater bulk of the tumour was made up of heterogeneous tissue elements in which structures representing all three layers of the embryo were present, showing that the tumour was undoubtedly a teratoma. The following elements could all be seen in one microscopic section: (a) Epiblastic: stratified squamous epithelium, hair follicles, sweat glands, gliomatous tissue, pigmented columnar epithelium (retina). (b) Mesoblastic: hyaline cartilage, bone. (c) Hypoblastic: columnar epithelium of tracheo-bronchial and gastro-intestinal characters. According to current theory the growth originated from some fetal inclusion of "blastomeres" or "totipotent cells," and the inclusion being recognizable as a large tumour at birth, it is evident that the included cells must have undergone development practically *pari passu* with the host.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

303. Congenital Megacolon (Hirschsprung's Disease).

FAGO (*Gazz. degli Osped.*, March 9th, 1913) in a study of this condition points out that although Hirschsprung drew attention to this anomaly, the condition had been described earlier (in 1846) by Favalli. Incidentally he draws attention to the disadvantage of naming diseases after their discoverer instead of after some leading feature. Following Conetti he divides the disease into (1) macrocolia and (2) megacolia. Macrocolia is the more benign condition and consists in a lengthening of the colon especially in the descending and in the sigmoid part—for example, in one case the total length of the colon was 102 cm. as against 72 cm. which is the average. This increased length means greater inflexion so as to get it all packed away in the abdomen. In megacolia there is an enlargement of the colon in its entirety both in its diameter and in the thickness of its walls. The colon may also be enlarged unequally and associated with localized dilatation and hypertrophies. Various histological changes may occur in the different coats of the intestinal wall and the enlargement of the colon involves displacements of the abdominal organs, especially the liver. In newborn babies the first symptom is usually a delay in the expulsion of the meconium and early constipation, suggesting the possibility of imperforate anus; the abdomen soon becomes tympanitic. In older children obstinate constipation, meteorism, pressure symptoms are the leading symptoms. Peristalsis can be observed. Vomiting is rare until the later stages. Congenital megacolon almost always terminates fatally, either through autointoxication, colitis, and exhaustion. Nevertheless, it is compatible with a fairly long life, the chief trouble being the constipation. In rare cases death may occur from perforative peritonitis, or from intestinal obstruction. Of the 111 cases collated by the author, death occurred in 64. In the cases operated upon the deaths were 38.8 per cent.; in the unoperated, 75.8 per cent. The male sex is more often affected (84 males, 20 females, 7 sex not recorded). As regards age, 21 were under 1 year, 27 between 1 and 10 years, 15 between 10 and 20, 12 between 20 and 40, and 14 over 40 years. The etiology remains unknown. The differential diagnosis consists chiefly in excluding all the commoner possibilities of meteorism, and the author goes rather fully into this question. In treatment oil purgatives are seldom efficacious, or soon lose their efficacy; salines often cause severe vomiting. Large injections into the colon are more useful. Massage, electricity, exercise, and strychnine are also useful. Various surgical procedures have been tried, from simple intestinal puncture up to colectomy. Colostomy has for the most part proved disastrous. The latest suggestion is to sew up the colon upon itself, the serous and muscular coat of the bowel being the only parts touched. Some success has followed this operation, which is less severe than the previous procedures.

304. The Excretion of Sodium Chloride by the Kidney.

BORCHARDT examines the data connected with the excretion of sodium chloride by the healthy and diseased kidney, and discusses the facts critically (*Deut. med. Woch.*, September 12th, 1912). He comes to the conclusion that, in contrast to the majority of urinary substances, sodium chloride is excreted by means of filtration through the glomeruli, and is concentrated by absorption of water in the tubules. Frey has shown that, apart from this, a small portion of the common salt is reabsorbed in the place of secreted material. Marked retrograde absorption of sodium chlorides takes place when the tubules of the kidney are damaged. In this case, instead of the vital reabsorption of water, retrograde absorption of the glomerular filtrate—that is, the provisional urine—takes place, so that a concentration of sodium chloride cannot take place. A retention of chlorides also takes place in defective glomeruli during the acute stage, which can be explained by the assumption of a lessened filtration of provisional urine in the glomeruli. As a rule, however, this retention passes off rapidly. In mild or chronic glomerular disease the sodium chloride excretion, if not interfered with, and any salt which has previously been retained,

can be washed out in the urine. A normal excretion of sodium chloride always indicates that the renal epithelium is not markedly damaged. Retention of chloride is one factor in the production of nephritis oedema.

305. Hypophysial Nanism.

BRUNIER has described a new hypophysial syndrome characterized by arrested growth and a persistence of infantile type. A translation of his paper by Frederiek appears in the *Annals of Ophthalmology* for April, 1912. Marie, Fröhlich, and Bariels have described other symptom complexes caused by lesions of the pituitary body, and it is to-day universally admitted that acromegaly is due to overaction of the anterior lobe of the hypophysis, while diminished function of the posterior lobe leads to an adiposo-genital degeneration. It is also well known that in giants lesions of the hypophysis are not rare, and Brissaud and Meige believe that gigantism and acromegaly are one and the same pituitary disease; gigantism is acromegaly during the period of growth, and acromegaly is gigantism when body growth has ceased. There are, however, some little-known troubles during the period of growth of persons afflicted with pituitary lesions, which manifest themselves as arrested development of the skeleton. Brunier draws attention to this "hypophysial nanism," which is apparently due to a decreased functioning of the anterior lobe commencing in infancy. This fact has been proved by experiments. Aschner, Gemelli, and Fischera showed that removing the pituitary body in young animals gave rise to a certain amount of nanism and infantilism. Brunier's case, although 26 years old, looked like a child, and was the size of an ordinary child of 8 years old. One optic disc was completely atrophic and the eye quite blind. An examination of the other eye showed that the field was hemianopic in character. There was complete impotence and double cryptorchidism. Skiagraphs showed that the sella turcica was enlarged and the epiphyses ununited. Similar cases have been described.

306. Uncontrollable Haemorrhage in Infants.

K. BLÜHDORN calls attention to the conditions spoken of as uncontrollable haemorrhage in infants, and gives his experience of the treatment of the same by means of serum and calcium salts (*Berl. klin. Woch.*, January 6th, 1913). He was called upon to treat a case of severe melaena neonatorum, one of Henoch's purpura abdominalis, and a third case of severe bleeding from the umbilicus in a 10 days old infant, who was suffering from sepsis with pernicious jaundice. In all these cases the condition of the infants was extremely grave, and experience showed him that death would in ordinary circumstances take place. In the first instance he gave the patient, a 3 days' old child, an injection of 2.5 c.cm. of diphtheria antitoxin for the serum action, and 0.5 gram of calcium acetate every two hours. In all the infant took 3 grams of calcium acetate. In the second case 3.8 c.cm. of diphtheria serum were injected twice; the patient was 6 months old. In addition he gave 2 grams of calcium chloride each day. In the third case the serum was injected subcutaneously around the umbilicus, and a tampon soaked in normal human blood and serum was applied to the navel. This child also received calcium chloride. All the three patients made rapid and complete recoveries. Experimentally he demonstrated that in the third case the coagulability of the blood was diminished. Normal blood was found to clot in two minutes; the blood from the umbilicus did not coagulate until seven minutes, the same blood with an equal part of serum clotted in two minutes, and the patient's blood mixed with clotted normal blood coagulated within fifty seconds. The manner in which the bleeding ceased in all three cases justifies him in his opinion in regarding the improvement as a direct result of the action of the serum. He gave diphtheria antitoxin instead of normal horse serum, because he had it ready, while time would have elapsed if he had waited for the latter. He is of opinion that fresh serum, if obtainable, is preferable to older serum, but in ordinary general practice it is not easy to procure fresh human serum. In regard to the calcium salts he prefers the soluble chloride or acetate to the insoluble lactate and citrate. The dosage must be large. He gave them in solution with saccharine and anise, by mouth.

SURGERY.

307.

Cancer of the Stomach.

S. WEIL (*Berl. klin. Woch.*, March 3rd, 1913) gives an account of the results of the treatment of gastric carcinoma in Küttner's surgical clinic in Breslau. He states that 15,000 persons die of gastric carcinoma every year in the German Empire, and if his 2 to 3 per cent. of complete cures had general application this would mean the saving of from 300 to 450 lives each year. During the past five years resection had been performed in the clinic 149 times. In 14 of these cases the tumour proved to be benign, but the author points out that there is no means of determining with absolute certainty, before the tumour is placed under the microscope, the benignity of certain lesions of the stomach; he maintains that it is only fair to the patient that the only chance of recovery is given, should the disease turn out to be cancer. Pain was present as an early symptom only in 10 per cent. of the cases, vomiting in 20 per cent., while loss of flesh was seen in every case. In 80 per cent. of his cases a tumour could be detected by palpation, but this does not mean that the tumour cannot be properly resected. He points out that success depends, *inter alia*, on an ideal co-operation of the surgeon with his assistants, and, for this reason, he considers it advisable to adhere to one technique, in which all who assist may become proficient. In Küttner's clinic the operation usually carried out was Billroth's second method. He gives many highly interesting details in regard to the disease found at the operation and the methods adopted for dealing with special cases. The operation mortality (limited to the carcinoma patients) was 22 per cent. In 18 out of the 31 patients who died in this manner purulent affections of the peritoneum set in. At times this was due to the giving way of the sutures; in others the peritoneal cavity was already infected before the operation, while in a third category it was found to be impossible in the extremely difficult operations to avoid contamination. He gives a most important table of the ultimate results of the operations. One hundred and four patients were able to leave the clinic, the majority in a comfortable condition. Of those who were operated before 1907 not one is now living. Of those who were operated on in 1908 4 are now alive and well; while of those operated on in 1909, 1910, 1911, and 1912, 5, 5, 13, and 13 respectively are still living. Eight patients have been freed from their disease and have not had a recurrence for three years or more, which he regards as cure. In 16 per cent. of the patients operated on life was prolonged for more than three years. The complete recovery of from 2 to 3 per cent. applies to all carcinoma of the stomach patients admitted in 1907, 1908, and 1909. He calls attention to the fact that the condition of the patients after resection is far more comfortable than after gastro-enterostomy, and that the improvement lasts longer. In comparing his cases with those published previously from the same clinic he finds that the operation mortality has decreased, but that the percentage of permanent cures has remained about the same. He pleads for an earlier operation in order that more lives can be saved.

308. Non-specific Infections of Submaxillary Gland.

POTEL AND VERHAEGHE (*Echo méd. du Nord.*, 1913, xvii, Nos. 5 and 6) describe the non-specific infections of the submaxillary gland. Anything which modifies or decreases the secretions of the gland favours the invasion by microbes, hence contraction of the duct, or a foreign body or calculus play a part, so also cachexia, organic diseases, as diabetes, Bright's disease, etc. The disease may also spread from carious teeth, thrush, and phthisis, and the like. Inflammation of the gland and swelling of the cells and oedematous infiltration of the intestinal tissue represent the first stage, and this passes on to suppuration. The epithelium of the duct loses its striation, the lumen is full of lymphocytes, and the epithelial cells desquamate. Some of the affected parts of the glands desquamate, others become atrophied. The capillaries rupture and small haemorrhages result. If the disease becomes chronic sclerosis occurs. The acute form may be primary or secondary, and be of the catarrhal or suppurative variety. The former is chiefly met with in old people. The temperature rises and the gland enlarges, becomes red, hot, and painful. The disease is short if suppuration does not occur. In some cases the inflammation is due to a calculus, and colicky pains occur in the gland, and are known under the name of salivary colic. Pains in the throat and towards the ear are frequent, and difficulty in swallowing is

always present. When the gland suppurates the dullness and pain are more marked and the redness more excessive. Here again the cause may be a calculus, or as a result of other and neighbouring infections. In chronic cases the gland becomes sclerosed and hard, and a nodule movable under the skin can be felt. Prognosis: This should always be reserved. The catarrhal form becomes cured in a few days; that due to calculus is more serious, and may last for some time without any symptoms, but usually presents exacerbations and remissions. The suppurative forms, as a result of infection elsewhere, generally usher in a fatal termination. In the acute forms the diagnosis is usually easy. The symptoms described sufficiently indicate the nature of the diagnosis. In the suppurative forms pus may frequently be pressed from the canal of Wirsung. Regarding treatment the authors say that in children sweets should be forbidden and disinfection of the mouth undertaken. In cases of calculus removal of the same should be undertaken, and warm compresses and disinfection of the mouth indicated. When suppuraton occurs incision of the gland is imperative. In the chronic forms, if the condition is troublesome, extirpation of the gland is the only remedy.

309.

Scopolamine as an Anaesthetic.

AMONG local anaesthesia, one of the best known combinations is scopolamine and morphine. Physiologically these two drugs are antagonists, and it has been stated that the mixture could not be regarded as a safe one. H. Offergeld (*Deut. med. Woch.*, No. 50, 1912) now suggests the combination of scopolamine and omnipon, and reports the results which he has obtained with these drugs in support of his contention that the mixture is safe, reliable, and efficacious. His experiments are divided into three groups, according to the doses given. In all cases he injected 0.04 gram of omnipon, and he varied the dose of scopolamine from 0.0004 to 0.0006 and 0.0007 gram. The effect of the smallest dose was a quieting one but sleep was not produced. This, however, was obtained with quite small quantities of ether or chloroform, and in each case was satisfactory. The medium doses effected a drowsy state, with complete amnesia. In one patient, however, no sleepiness was obtained at all. The full doses were given for major and prolonged surgical procedures, and were usually associated with the inhalation of an anaesthetic. The quantity of the latter, however, was extremely small, and in a few cases the sleep was maintained past the stage of diminishing doses of chloroform but also without any at all. He gave the mixture to patients with various organic diseases; even lung and heart cases tolerated the narcosis well in the majority of cases. A few cases of respiratory disturbances were met with in these cases, and the same took place in persons with normal organs. Myocarditis appeared to be the most dangerous complication. Two of his patients died, one five days after the operation of acute heart failure, and the other after a septic abortion. The operation conducted under scopolamine and omnipon brought some temporary improvement, but the symptoms returned with a rigor, and after death septic thrombi and complicating myocarditis were found. In summing up his experiences, Offergeld states that if care be exercised in the dosage the mixture is calculated to rob inhalation anaesthesia of much of its dangers.

OBSTETRICS.

310.

Nervous Affections in Pregnancy.

A. SAENGER (*Muench. med. Woch.*, October 8th, 1912) discusses a few nervous affections which occur during pregnancy and which stand in direct relationship with the same. First he tells of cases of polyneuritis. In one case, all the extremities as well as the muscles of deglutition and of the rectum were paralysed; in a second case, there was also a general distribution of the paralysis. Both cases ended in complete recovery. Möbius has recorded a case of neuritis affecting the ulnar and median nerves following a severe parturition. Other cases are also mentioned. Saenger also records a case of retrobulbar optic neuritis in the puerperium. There was total blindness of both eyes. Partial recovery followed in a few months. In all these cases the author regards that the cause existed during the pregnancy. Autointoxications occur during pregnancy, as is shown both by albuminuria and by the vomiting of pregnancy. The causes of hyperemesis gravidarum are supposed to be either hysteria or the marked passive movements in the

uterns, affecting the intestines, or the disproportion between the uterus and the growing contents of the same, or the direct reflex action on the part of the increasing uterine wall. Saenger recognizes that hysteria may play a part in some cases, but it certainly does not account for all the cases. His own opinion is that the most common origin of hyperemesis is of a toxic nature, and supports this view by calling attention to the frequency with which it is associated with polyneuritis. Next, he turns his attention to epilepsy in pregnancy. He shows that at times the attacks can be controlled by the exhibition of cerebrin and bromides. In some cases a previously-existing epilepsy may be favourably influenced by pregnancy, while in others the reverse may be the case. He cites cases in which a latent epilepsy became active again during pregnancy and in which the patients lost their lives in status epilepticus. Some difficulty may be experienced when epilepsy is associated with eclampsia. As a rule, the differential diagnosis is not difficult. Lastly, he deals with puerperal insanity. He cites cases in support of the view that when a previous attack has been experienced and recovery has followed, the question of the induction of abortion should be considered, should a fresh pregnancy occur. His cases show that this procedure may lead to very satisfactory results. He is of opinion that many a woman can be saved from permanent insanity if an abortion is induced in good time.

GYNAECOLOGY.

311. Radio-therapeutic Treatment of Uterine Myomata.

ALBEES-SCHÖNBERG (*Arch. d'électr. méd.*, April 10th and 25th, 1913) describes his technique in the deep radio-therapy of uterine myomata. The *x* rays are indicated in all myomata except the following, in which operative treatment is preferable or incumbent, namely, pedunculated myomata of the neck of the uterus; myomata combined with a carcinoma of the mucosa; rapidly increasing myomata with abundant haemorrhage and metrorrhagia, raising a suspicion of sarcomatous degeneration, gangrenous myomata, and, finally, myomata which have caused acute retention by compression of the bladder. Women over the age of 40 years are the most amenable to *x* ray treatment, and the action of the rays is more rapid and certain the nearer that the subject approaches the natural menopause. For younger women the dose must be considerably increased, and even then all possibility of relapse is not evaded. Generally speaking, the diminution of the myoma is very slow, the first improvement being announced by the patients themselves, who experience less heaviness in the abdomen. In a number of cases a considerable increase of haemorrhage has been observed after the first sittings, diminishing after subsequent sittings. In certain cases also an alteration of the menstrual blood has been noticed, the blood presenting no longer a clotted and coagulated appearance, while the menstruations have been less painful. In one case he observed an augmentation of the haemoglobin content of the blood from 30 per cent. to 90 per cent., but in other cases, chiefly those of women of poor condition who could not exercise the necessary care during treatment, while there has been a diminution of the myoma and a complete disappearance of the haemorrhage, the haemoglobin content has remained comparatively low. In no case that he has treated has he found any severe burning. A passing redness, some degree of erythema, a distension of the pilous follicles have been the only phenomena observed. Lesions of the skin may be altogether avoided by a prudent technique. At first he used filters of tin and leather, but he thinks now that aluminium filters, 2 mm. in thickness, are an additional safeguard so far as the security of the skin is concerned. Two methods of dosage are in vogue, that of the Hamburg school, in which exactly the necessary dose is applied and no regard is paid to the duration of treatment, and that of the Freiburg school, in which strong doses are applied within as short a time as possible. He favours the former method, which has given him 78 per cent. of cures among the cases treated. His dosage has ranged between 60 X and 100 X on the Kienböck quantitative scale. At first he irradiated at a single point of entrance, applying a bundle of rays sufficiently great to fall perpendicularly on the abdominal wall, and thus reaching at once all the genital organs. Subsequently he irradiated at two points of entrance, projecting the rays obliquely and laterally, the patient being in lateral or dorsal decubitus. But, in view of the uncertainty of reaching the ovaries and the

myomata by this second method, he has returned to his former practice of irradiating at a single point of entrance, and in order to accelerate the treatment he employs two tubes, working at the same time, one of them being placed below, and the other above the patient. Each series of irradiations is limited to four sittings of eight minutes each.

THERAPEUTICS.

312. Serum Treatment of Erysipelas.

DURING the past two years, Welz (*Therap. Monats.*, April, 1913) has used the polyvalent Meyer-Ruppel serum in 23 cases of erysipelas. All the patients were seriously ill and febrile, and the dose was usually 100 c.cm. injected into a vein. Twelve other patients were given the serum by the mouth, but this method was abandoned, as it appeared to be futile. The serum's action in each case was first tested by injecting 10 c.cm. subcutaneously, and, when this was well tolerated, a large dose was slowly injected into the same patient's cubital vein. During or immediately after this injection rigors and collapse sometimes occurred, but in only one case did they necessitate the use of cardiac and cutaneous stimulants. In most cases the injections caused no reaction. Two patients exhibited a typical serum rash eight days after the injection, and complications of erysipelas, such as transitory cardiac and renal disturbances, were not evaded by the use of serum. The injections were given on the second to the fourteenth day of the illness, and were supplemented by the application of a cooling lotion to the inflamed parts. Two of the patients died. About half of the remainder showed a uniform reaction, the temperature being taken ever other hour in the axilla. First there was a slight rise immediately after the injection, accompanied by a sense of discomfort, chilliness, and vomiting in some cases. On the evening of the same day, and during the following night, the temperature fell, to rise again next day, but to a lower level than before. On and after the third day it was normal. This fall of temperature was accompanied by general and local improvement. This type of temperature curve corresponds with that commonly observed in cases of septic infection treated with antistreptococcal serum. Of the remaining patients, 4 showed a fall of temperature by lysis after the injection, and 5 showed no immediate improvement, although they ultimately recovered. No change in the number of the leucocytes was observed in the two cases in which the blood was examined. Summing up his observations, the author considers that the serum was responsible for the fall of temperature in half his cases, that the serum's failure to influence the temperature in some cases was due to its being a stock serum without a specific action on every strain of germ causing erysipelas, and that in the successful cases the serum reduced the temperature irrespective of the stage at which the disease existed when the injection was given. Thus, in one case, a girl aged 19 had been ill for eleven days without improvement when the serum was injected, and a rapid recovery was effected; but it is doubtful whether the serum reduces the frequency of relapses, two of which occurred in the author's series. The objections to the general use of this serum are its cost (30 marks for 100 c.cm.) and the risk of collapse. This may, indeed, be lessened by injecting the serum cautiously and very slowly, but it cannot be altogether eliminated. The serum should not, therefore, be given in slight cases, nor in cases in which disturbances of the circulation are the most prominent features of the illness.

313. Nervous Symptoms after Salvarsan.

RAYAULT (*Ann. de derm. et syph.*, March, 1913) cites a case in which the patient, a man aged 31, contracted a chancre in January, 1911, for which he received nine mercurial injections and a course of mercury by the mouth. In July of the same year there were hypertrophic, oral, and palatal plaques, but no symptoms drawing attention to the nervous system. The Wassermann reaction was positive. Four intravenous injections of salvarsan—0.3, 0.4, 0.5, 0.6 gram at intervals of a few days—were given in the latter part of July and beginning of August, and in September fifteen intravenous injections of cyanide of mercury—0.01 gram—were administered. The mucous plaques healed after the first salvarsan injection, and none of these had any more serious sequel than persistent headache, of which the patient was still complaining in January, 1912, and for which mercury and iodide were freely prescribed. In May the patient again presented himself for further treatment of the same symptoms, which had continued in spite of all measures. In November he returned,

complaining of very sharp pain in his left flank with nocturnal exacerbations. The physical examination pointed to a diagnosis of intercostal neuritis in the last dorsal nerve roots. The history of the case then suggested the possibility of a specific etiology—possibly meningial—and lumbar puncture was proposed and accepted. The cerebro-spinal fluid was under considerable pressure, and contained a large excess of lymphocytes, some polymorphs, and a few cells resembling plasma cells. There was a good deal of albumen, and the Wassermann reaction of the cerebro-spinal fluid was positive. The withdrawal of the fluid had a marked therapeutic effect, for his pain subsided, and the headaches markedly diminished. Enesol was then injected intravenously every day (3 c.cm.), and under its influence there was still further amelioration of symptoms. In January, 1913, the patient's symptoms had completely subsided; the Wassermann reaction of the blood was negative, but that of the cerebro-spinal fluid still positive. The patient wrote that towards the end of that month the pain had returned, with weakness of the right leg, and a patch of anaesthesia on the outer side of the left thigh. The chronic syphilitic meningitis had recurred, as it is wont, in spite of the most energetic and radical treatment. The author emphasizes the importance of an examination of the cerebro-spinal fluid in all cases of syphilitic neural manifestations, especially where there is any chance of the presence of a latent meningial endarteritis syphilitica. He goes so far as to say that it is dangerous to base one's antisymphilitic treatment on the results of the Wassermann reaction of the blood alone, for it is always possible, as in this case, that active cerebro-spinal syphilis may be progressing, with a negative reaction to Wassermann's test in the peripheral circulation.

314. A New Morphine Substitute.

E. P. NOGUERA (*Revista de Medicina y Cirugía Practicas*, October 21st, 1912) summarizes the considerations and evidence which have been advanced in favour of "narcophina" as a succedaneum for morphine. He points out that a mixture of all the alkaloids of opium has a narcotic effect not only greater than the morphine in it will account for, but considerably greater than a summation of the effects of the different alkaloids would lead us to anticipate. Most of the alkaloids other than morphine are present in very small amount, and some of them have an action which is antagonistic to that of morphine. It is to Straub (Director of the Institute of Pharmacology in Freiburg) that we are indebted for the first attempt to explain this discrepancy—the physiological action of morphine and the total alkaloids of opium. According to Straub, the increased effect of morphine when united with the other alkaloids of opium is due to the presence of one of them only—narcotina, which is present in very small quantity, and is by itself almost inactive. It is a case in which the two alkaloids added ($a + b$) have a physiological effect nearer to their product ($a \times b$). On cats narcotina has no particular effect, nor does morphine produce narcosis in cats. A quantity of morphine sufficient to narcotize any other animal of equal weight produces in the cat a state of violent excitement. If, however, a mixture of equal parts of morphine and narcotina be administered to a cat, no excitement follows; the animal becomes dull, indifferent to its surroundings, and soon sleeps. It appears also from Straub's experiments on other animals that the paralyzing action of morphine on the respiratory centre is very much lessened—in some cases abolished by the addition to the morphine of an equal quantity of narcotina. In the case of mice the toxicity of morphine, with narcotina added, is so small as to be scarcely measurable. Straub has experimented with different proportions of the two alkaloids, and has found that the maximum increase in the narcotic effect of the morphine and decrease in its toxicity is obtained when they are mixed in equal quantities. Opium contains only 0.02 per cent. of narcotina as against 10 per cent. of morphine. Straub has prepared a double salt, the two alkaloids in equal proportions—a meconate of morphine and narcotina—which he calls narcophina. Clinical trials of this drug in the University of Breslau and in the Gynaecological Clinic of Freiburg, by Zehle, Hans Selhimpert, etc., in most of the conditions in which morphine is usually given, and in many (diseases of the organs of respiration, etc.) in which it is (alone) contraindicated, seem to substantiate these conclusions. Narcophina is given in doses of 2 or 3 cg. as a simple hypnotic. Sleep generally supervenes in from a half to one hour and lasts six to eight hours. As is usual in the case of new hypnotics or morphine substitutes, it is claimed that all the undesirable after-effects are absent.

PATHOLOGY.

315. Bacteriological Investigation of Bile.

PETRY and BOLDYREFF have described a method of obtaining bile in the stomach by means of an oil test breakfast. It was found that a large quantity of oil caused a regurgitation of pancreatic juice and bile mixed. This finding led G. Királyfi to undertake a methodical investigation of the bacteriology of the bile in varying conditions (*Bert. klin. Woch.*, October 14th, 1912). Working with aseptic oil and instruments, he succeeded in obtaining results on which he claims that reliance can be placed. He found that under normal conditions the upper part of the duodenum is sterile (39 times out of 69). In cholecystitis, the bile obtained by means of the oil test meal revealed *B. coli* in the majority of cases, while streptococci, staphylococci, and other pathological micro-organisms were found at times. In cholelithiasis, bacteria were only found exceptionally in the bile. He explains this by assuming that in some cases the flow of bile is hindered mechanically and the bacteria are kept back in the same way, and in a certain number of cases, as has been shown by Aschoff, Riedel, and others, gall stones are sterile. The examination yielded bacteria in cases of gastrointestinal affections, but in these cases, the bacterial flora of the stomach and intestines often obscure the bacteria of the bile. When there is an acidity or hyperacidity, a positive result can be obtained. This form of investigation may be of the utmost importance in enteric fever. In the early stages before Widal's test is positive, and before the bacteriological examination of the faeces or blood reveals the nature of the illness, the examination of the bile may yield a pure culture of *B. typhosus*. When bacteria are found in the bile without any signs or symptoms pointing to a disturbance in the bile ducts or in the gastro-intestinal tract, two possibilities are possible: either there is a very insidious affection of the gall bladder, a cholecystitis without symptoms, or the infection is secondary, which is the more likely with staphylococci than with other organisms. He has further ascertained that there is a distinct connexion between infections of the bile and the albumen content of the fluid. A strong reaction with sulpho-salicylic acid is only met with when the bile contains bacteria. This reaction, when marked, and the find of bacteria indicate cholecystitis. A less marked reaction possesses no diagnostic significance. The albumen test of bile may reveal a symptomless cholecystitis. The content of albumen is found to be independent of any collection of pus cell and the only conclusion which can be drawn from the detection of a large number of these cells under the microscope is that somewhere in the bile ducts there is an inflammatory affection. Otherwise, he does not regard the microscopic appearance of diagnostic value.

316. Pathogeny of Albuminuric Retinitis.

CHAUFFARD (*Journ. des praticiens*, January 18th, 1913) refers to the numerous theories advanced on this subject, and points out that the modern one of azotaemia only partially explains the lesions. The author has noted particular properties of the blood serum in those cases. Certain of the lesions as described by Widal and Gaucher are probably due to retention of chlorides, and have disappeared under dechloridization. But in addition to these the observations of Chauffard have proved another factor in the case in a great number of instances—that is, a state of hypercholesteraemia. He quotes a case of albuminuria with double neuro-papillitis in which an analysis of the blood serum showed an almost normal urea content; but considerable augmentation of cholesterolin—about six times the normal amount. Lumbar puncture was practised in this case, and 30 c.cm. of fluid withdrawn in a state of hypertension. This was followed by considerable relief of all the symptoms, including the headache and ocular symptoms. The researches of the author have shown that azotaemia and cholesteraemia follow an inverse evolution. The latter is constantly present in chronic nephritis, but not during the acute period. It appears to have been proved that the white retinal plaques are not composed of fat, but of a lipid substance. The author suggests that it is the excess of cholesterolin in the blood serum which is deposited in the retina as the pearly spots characteristic of albuminuric retinitis. There is some evidence that these processes have a suprarenal origin. In such cases the author recommends lumbar puncture to diminish tension, and a dietary consisting of skimmed milk, green vegetables, and a little roast meat prepared without butter or salt.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

317.

Chylocele.

E. LEVIN (*Med. Klin.*, April 6th, 1913) defines chylocele as an encapsuled collection of sterile bile in the peritoneal cavity, and he reports two cases illustrating this condition, which has not, he says, hitherto been described. It has lately been shown that bile may escape into the peritoneum by transudation without any gross lesion of the biliary system, such bile being either already infected, or becoming so after its escape into the peritoneum. The author claims that bile may escape from the gall bladder, the extra- or intra-hepatic biliary passages into the peritoneal cavity, and become encapsuled therein without being infected; and that the capsule formed about the bile may be developed after its effusion, or it may have already been partially formed by adhesions, between which the chylocele forms in the same manner as a retrofronterine haematocoele. A chylocele may form either as a sequel to rupture of the biliary passages, or to transudation of bile, as the following cases show: A married woman, aged 50, had suffered for about eight weeks from pain about the right costal margin. She had also suffered for a year from abdominal pain after eating, from nausea, and occasional vomiting. She was cachectic and somewhat jaundiced. The abdomen was distended but nowhere rigid or tender. No free fluid in the abdominal cavity was demonstrable. The liver dullness was increased, and along the right costal margin several painless nodules could easily be felt. The temperature was raised, and the pulse, though strong, was rapid. Cancer of the liver was at first diagnosed, and, later, cancer of the stomach. After six weeks in hospital the patient suddenly died. The necropsy showed a large carcinoma of the pylorus compressing the common bile duct. The gall bladder, extra- and intra-hepatic biliary passages were much dilated, and a chylocele containing about two litres of pure bile was found below and behind the right lobe of the liver, and bounded behind by the diaphragm. Its walls were fibrous, smooth, and green. Two smooth-walled ducts, thicker than a lead pencil, passed from the lower part of the chylocele into the substance of the right lobe of the liver, the whole of whose under surface was covered by the chylocele. Evidently two of the biliary passages in the right lobe of the liver had given way, and bile had escaped into the peritoneal sac, becoming immediately encapsuled, or escaping between adhesions which had previously formed in the neighbourhood of the liver. The nodules felt over the liver during life yielded on incision a milk-like fluid. A married woman, aged 71, had suffered from abdominal pain and violent vomiting for about four weeks. Two weeks earlier there had been transitory jaundice. The abdomen was distended, and there was a dull area extending from the liver dullness on the right to three fingerbreadths below the umbilicus on the left, and, when traced upwards, merging into the cardiac dullness. Cholecystitis and cholelithiasis were diagnosed, and laparotomy was performed in the middle line above the umbilicus. Division of the anterior layer of the peritoneum and omentum revealed a smooth-walled cavity containing about $1\frac{1}{2}$ litres of bile. This was withdrawn and a tampon inserted. The patient died a month later. At the necropsy the anterior surface of the liver was found firmly adherent to the abdominal wall. The drainage tube which had been inserted after the operation passed into a cavity of the size of an apple, with thick fibrous walls, and containing pus and bile-like matter. A second cavity of similar formation was filled with pure bile, and was situated between the spleen, the tail of the pancreas, and the diaphragm. A third such cavity, also containing pure bile and of the size of an apple, was found in front of the foramen of Winslow, extending as far as to the ligamentum gastro-colicum. The gall bladder was much shrunken and packed with small stones. The extra-hepatic biliary passages were much dilated, and also contained stones. At no point, inside or outside the liver, could a perforation of the biliary passages be found. The author concludes, therefore, that the gall stones caused biliary obstruction, and that bile consequently transuded into the peritoneum, in which it became encapsuled in three separate compartments.

318.

Bismuth Poisoning.

WAREFIELD (*Amer. Journ. of Med. Sciences*, November, 1912) records a case of bismuth poisoning following the injection of 2 oz. of bismuth subnitrate paste into an ilio-psoas abscess, and he incidentally remarks the absence of adequate description of such intoxication in modern textbooks. Previous observers had noted the toxicity of bismuth when administered to animals, a characteristic brownish-violet stomatitis being present. The patient, a girl, aged 9, had been treated a year previously for tuberculosis of the spine with an ilio-psoas abscess, which pointed in front of the leg opposite the lesser trochanter. After two incisions, one above and one below Poupart's ligament, 2 oz. of bismuth subnitrate paste (Beck's) were injected into the sinus, after which the sinus closed, and no paste was ever extruded. Within a fortnight a black line appeared at the gum margins, and this persisted until, nine months later, a sore started in the right cheek opposite the second molar tooth, with, later, a violet-black discoloration of the right side of the tongue, in the centre of which discoloration was a white opaque scruated membrane adherent to the underlying tissues. On the buccal surface of the right cheek were two discoloured plaques of the same appearance as the ulcer on the tongue. An x-ray of the right lumbar region showed an irregular shadow of the bismuth paste, which did not appear to be much encapsuled. From this and other reported cases three stages of the condition may be recognized as typical of bismuth poisoning, and differing from the poisoning of lead and mercury: (1) Benign, where the violet-black line is the only manifestation; (2) moderately severe, in which there is a stomatitis characterized by discoloration of the gum margins and tattooing of the mucosa, which extends to the buccal cavity; and (3) a severe form, in which ulceration and secondary infections supervene, with general constitutional symptoms. The violet black line on the gums is usually the first sign of the poisoning. Since there is a definite danger of poisoning following the injection of bismuth subnitrate into sinuses, care should be taken that the paste is extruded and not left *in situ* too long, and in x-ray work in the intestines it is best to withhold the drug in inflammatory cases, or where the patients are debilitated. Bismuth carbonate and oxide of iron are recommended, and are being used, as substitutes to avoid the danger of poisoning.

319.

The Origin of Nephritic Oedema.

FARINI (*Gazz. degli Osped.*, February 23rd, 1913), in a synthetic review of this subject, starts by pointing out some of the well-known differences between nephritic oedema and other forms of oedema, and shows how the former are localized independent of the laws of gravity, and are often wandering and fugacious. Some of the older cardio-vascular theories (for example, Bright's) are to-day given up, as it was found in opposition to the hydraemic theory that the oedema might precede the albuminuria, whilst in other cases with a marked dilution of the blood there was no oedema. Again, it is possible to have anuria without dropsy, so that hydraemic plethora by itself will not account for oedema. Theories based on differences of osmotic pressure are not entirely satisfactory, as cryoscopic research shows, the changes in the molecular concentration of the blood serum, in electrical conductivity, and in filtration power, stand in no constant relation to the presence of oedema. The retention of sodium chloride is not sufficient to explain all cases, but clinically there are a few cases where a diet free from salt has a marked beneficial effect on reducing the oedema. The probable explanation of these cases seems somewhat as follows. Perhaps the most effective cause of oedema is the presence of certain substances—for example, nephrolysin, nephroblastin, etc., whose property it is to stimulate the vasa endothelium; if these substances are present in small quantities, they may not set up oedema, except in the presence of a good deal of retained sodium chloride, so that by reducing the intake of salt the additional stimulus which this gives is removed and the nephrolysin left are not sufficient to keep up the oedema; hence the improvement which follows in certain cases by limiting the intake of salt. Where this treatment fails it is probable that there is a large amount of nephrolysin upon which the salt has, of course, no influence. This theory does not

explain the curious distribution of nephritic oedema, but it suggests why in some cases a salt-free diet succeeds and fails in others.

SURGERY.

320. Tuberculosis of the Prostate.

IN 18 cases of tuberculosis of the testicle, E. Löwenstein (*Deut. med. Woch.*, March 13th, 1913) found tubercle bacilli in the urine. Even after the removal of diseased testicles and seminal vesicles tubercle bacilli were sometimes found in the urine. In 2 cases in which unilateral castration had been performed a year earlier the urine withdrawn from both ureters was found to be sterile, while the urine withdrawn from the bladder teemed with bacilli. Also in the remaining 16 cases there was no sign of renal tuberculosis. There were also no signs of irritation of the bladder, and the urinary sediment was not indicative of disease of the bladder. Digital exploration of the seminal vesicles did not once reveal any definite sign of disease; and though such negative evidence is not altogether convincing, it is probable that the seminal vesicles in most, if not all, of these cases were intact. The source of the tubercle bacilli was therefore narrowed down to the prostate. But there was no other sign of prostatic disease. The gland exhibited no swelling, hardening, softening, or pain on defecation or micturition. There was also no tenesmus, and secretion pressed out of the prostate was apparently normal. It has, however, been emphasized by Frisch that tuberculous foci in the lateral lobes of the prostate usually cause no symptoms at first, and that they may cause no discomfort for a long time. It has hitherto been generally held that tuberculosis of the prostate is rare. But the author agrees with G. Koch in regarding tuberculosis of the testicle without involvement of the rest of the genital tract as rare, and isolated tuberculosis of the prostate as exceedingly common. Koch has collected the statistics of seven surgeons whose 243 cases of genital tuberculosis are thus classified: Isolated tuberculosis of the prostate, 78 cases; isolated tuberculosis of the testicle and epididymis, 47 cases; combined tuberculosis of the prostate, testicle, and epididymis, 118 cases. Koch himself found tuberculosis of the prostate in 86 out of 87 cases of genital tuberculosis. Probably the prostate is infected by the blood stream. It is also highly probable that tuberculosis conveyed to the prostate by the blood stream may extend thence to the vas, the epididymis, and testicle by their ducts; for Oppenheimer and Low have shown that germs may pass to these organs by their ducts when antiperistaltic movements occur.

321. Lupus Erythematosus.

GAUCHER (*Journ. des praticiens*, February 15th, 1913) points out that, although primarily this condition is generally to be regarded as distinct from tuberculous lupus, it has sometimes changed into the latter condition, and occurs in tuberculous families. Further, the serum of patients suffering from lupus erythematosus agglutinates the bacillus of tubercle. Clinically the diagnosis may be made by the fact that lupus erythematosus attacks adults, more especially females, while tuberculous lupus commences in childhood or youth. The condition may be confused with papular syphilides, but the latter are characterized by the squamous periphery known as the collar of Biedl. Further, they are indolent in type. Possible confusion may also arise with some cases of herpes circinata. In these cases a microscopic examination may be necessary. More difficult sometimes is the differential diagnosis from seborrhoeic eczema and psoriasis. The edge of the former is not so hard as lupus, while the regional disposition of psoriasis assists in settling the diagnosis. The diagnosis of generalized lupus erythematosus is as a rule not difficult. The constitutional treatment is that of tuberculosis. The local treatment is directed to produce counter-irritation. Equal parts of iodoine and acetic acid may be used, or, according to Hardy, a solution of metallic iodine and potassium iodide. In the intervals some inert paste or powder may be used. If the former application is too irritating a solution of resorcin may be tried, and in the intervals 2 to 5 per cent. pomade of salicylic acid. Resorcin may be similarly employed as a paste. On the more limited plaques a plaster of black soap after the formula of Hebra may be applied for a period lasting from half an hour to three hours. In the older and more rebellious types of the disease linear scarification is recommended, associated with the local application of potassium permanganate; and in the most inveterate cases galvano-puncture.

322. A Late Secondary Syphilide.

BALZER AND BELLOIR (*Bull. de Soc. Franc. de Derm. et Syph.*, January, 1913) relate a case of late secondary syphilis. The interest of this case lies, according to them, in the fact that the patient must have had syphilis for at least five years before the outbreak of the present lesions, since a palmar specific eruption had been present all that time untreated. In all probability the disease was contracted before 1892, when she had a miscarriage, following closely on her marriage in 1890 to an admittedly infected second husband. The authors describe the present eruption as a recurrent peribucaal erythematopapular syphilide. It is situated concentrically with the lips, and appears to radiate from the left labial commissure. The elements of it are nodular and infiltrated, irregular in shape, and of the rosy colour of raw ham. The margins are sharply demarcated from the healthy skin. On the mucous surfaces of the labial commissures are definite mucous patches. The tongue has a corrugated appearance, and presents, on its borders only, some small leucoplastic patches. The pharynx and palate are free; nothing else of a specific character can be discovered on the body, and the patient's general condition is good. In 1910 she had an identical irruption, similarly localized, which disappeared quite rapidly under mercury and potassium iodide. This treatment has been repeated, and the lesions have almost disappeared. This type of case—namely, a recurrent papular peribucaal syphilide *in eodem loco*—was first described and recognized as a clinical entity by M. Pournier, who gave it the name of "syphilide papuleuse péribuccale récidivante," pointing out that the disease can maintain its secondary characters for a considerable time, reappearing in a form analogous and similarly situated to the lesions present originally in the secondary period.

323. Sporotrichosis from the Surgical Standpoint.

GORSE (*Arch. de méd. et de pharm. militaires*, March, 1913) gives a summary of all the clinical manifestations hitherto attributed by laboratory tests to this newly-discovered fungus (Bhurmann, 1903). After referring to the appearances and differential diagnosis of the various types met with on the skin, he passes to a consideration of those osseous and arthritic types most likely to be referred to the surgeon. Usually such a case will be absolutely indistinguishable clinically from a chronic osteomyelitis due to other causes (especially tubercle), and it is only the growth of cultures in the laboratory on Sabouraud's medium that can definitely settle the question. The importance from the patient's point of view—when possibly an amputation may be under consideration—of definitely excluding this fungus as a cause of the existing condition can hardly be overestimated, for every case, so far, has been permanently cured by the administration of from 30 to 120 grains of potassium iodide per diem. The pathological histology of bony lesions due to the sporothrix does not differ in any important particular from that of ordinary hyperplastic or rarefying osteomyelitis, but the dictum *noli me tangere* applies in the treatment of this disease perhaps more than in any under surgical control. In a cavity containing pus this may be aspirated and washed out with iodine solution, but any sort of radical interference is contraindicated. Sporotrichosis, besides its special affinity for the skin, the bones, and the joints, has been met with in all the organs, and has given rise to the most complex and diverse clinical signs. Whilst most commonly a chronic affection resembling tubercle or syphilis in its local manifestations, cases of acute abscess and even of septicaemia have been described, and as the treatment is specific the possibility of its presence ought not to be lost sight of in any case where the local signs are a little unusual, and especially in such cases when serious radical measures are about to be undertaken.

OBSTETRICS.

324. Physometra from Fetal Putrefaction.

BONNET-LABORDERIE (*Bull. de la Soc. d'Obstét. et de Gynéc. de Paris*, etc., March, 1913) reports three instances of distension of the gravid uterus with gases produced by the decomposition of a dead fetus. In the first case premature rupture of the membranes occurred, and two days later sudden tetanus of the uterus set in without any previous pains, and Bossi's dilator was applied. Basiotripsy was found necessary, and the child was delivered. During these manœuvres quantities of fetid gas kept escaping, with considerable noise, and also putrid reddish

fluid. The cervix was lacerated laterally, and parametric deposit developed, with high temperature, but the patient recovered. In the second case a dead fetus was retained in the cavity of a fibromatous uterus, and the placenta presented. The periods had been absent for eleven months. Febrile attacks set in; the patient for a while rejected all advice, but at length a hysterectomy was performed. The uterus was full of putrid gas. The patient died thirty-six hours after operation. The third patient, a multipara aged 24, sought medical advice on October 25th, 1912. The last periods were seen on November 23rd, 1911, and the last coitus on December 5th. No pains had been felt until October 15th, 1912; then a quantity of fluid came away. On the 22nd some pains, not very strong, set in: the head lay above the pelvis, but the pelvis was quite roomy. After exploration the pains became strong. The fetal head, very bulky, filled the pelvic cavity, and the forceps could not be made to grasp it. Much fetid fluid escaped from the vagina, and the patient, it appeared, had recently felt rigors. The pains ceased, the uterus was found greatly distended, and its upper portion was tympanitic on percussion. At length, after another examination, it was found that the fetus was hydrocephalic. Foul gas escaped with a distinct sound during the explorations, and after craniotomy and extraction the perineum, deeply lacerated during the delivery of the shoulders, was repaired. The fetus was very big, independently of its deformed head, and quite macerated. A large area of the perineum and adjacent vulva sloughed, yet the patient recovered rapidly, and was able to leave hospital at the end of a fortnight. The space of time between the last coitus and the first pains was 322 days, nearly eight weeks over the average in normal pregnancy, and implied retention of the dead fetus.

GYNAECOLOGY.

325. Large Retro-cervical Fibromyoma in Girl.

ROSENSTEIN (*Monats. f. Geb. u. Gyn.*, February, 1913), in reporting a series of operations for fibroid disease of the uterus before a meeting of the Gynaecological Society at Breslau, described one instance of retro-cervical fibromyoma developed at an unusually early age. The patient's periods began at the age of 13, and were always free. Seven years later she suffered for several months from hypogastric and sacral pains, followed by dysuria and ultimately incontinence of urine. The thoracic viscera were sound. A large hard tumour could be felt above the symphysis, and it extended downwards below the portio. Rosenstein operated, endeavouring to save the uterus on account of the patient's youth. He enucleated the tumour—a typical fibromyoma—but found that he had opened the cervical canal, and was compelled to remove the uterus as well. The left ovary was of the size of a child's fist, owing to a cyst which was filled with blood; it was removed, whilst the opposite ovary was saved. The patient recovered. The measurements and weight of the tumour are not given in the report.

THERAPEUTICS.

326. Spinal Anaesthesia with Stovaine.

BEDESCHI (*Gazz. degli Osped.*, February 25th, 1913) analyses the results of 924 cases of spinal anaesthesia observed during the last three years at the hospital in Ravenna. The amount injected varied from 4 to 7½ cc., and the usual precautions were observed. The mean duration of anaesthesia was forty to forty-five minutes. In 4 cases where the patient was put into the Trendelenburg position the anaesthesia reached above the umbilical zone, and in one case even reached the head. If a patient has once been anaesthetized in this way, the same dose, especially if given at a comparatively short interval of time, will not suffice. In the few cases where this was attempted it was found necessary to have recourse to a general anaesthetic. In the few cases where anaesthesia seemed to fail at the first attempt, the failure was probably more apparent than real, and usually occurred in very neurotic subjects, who translated a mere tactile into a painful sensation. The age of the patients varied from 16 to 60 years. Amongst the immediate accidents resulting from the injection were pallor, cold sweats, slowing of the respiration and pulse, nausea, and vomiting. These usually occurred on placing the patient horizontally or in the Trendelenburg position,

and could for the most part be overcome by the injection of cardiac stimulants. Rectal incontinence was noted in 30 per cent. of the cases. Serious collapse only occurred in two cases. Amongst the later results the following were noted: Headache, retention of urine (10 per cent.), and rather persistent paralysis of the sphincters. Although these accidents are not very numerous nor very serious they are sufficient in the author's opinion to detract considerably from the general use of spinal anaesthesia which the earlier statistics seemed to suggest, and he now prefers to confine its use to those cases in which a very small amount of the anaesthetic is all that is necessary.

327. The Action of the Alkaloids of Opium.

In 1909 Sahli introduced a preparation under the name "pantopon," in which all the alkaloids of opium were contained, which was soluble in water, and could be injected subcutaneously without producing any symptoms of local irritation. E. S. Faust raises the question whether all the alkaloids are required to bring about the full therapeutic effect of opium (*Munch. med. Woch.*, November 12th, 1912). It has been shown on the one hand that the action of opium is actually the action of morphine, and on the other that the action of two alkaloids given together is not the sum of each when given alone, but the one may be enormously increased by the second. In view of the many aspects which still need illumination, the author has conducted a direct investigation. He prepared mixtures of various opium alkaloids, and not only made pharmaceutical observations with these, but also requested clinicians to employ them in practice and report on the action. As a result of his studies he maintains that all the alkaloids are not necessary to produce a full opium effect. The only essential alkaloid is morphine. He therefore considers that both pantopon and also opium contain unnecessary ballast. A combination of morphine with some of the more important of the opium alkaloids does not diminish its paralyzing action on the sensory apparatus, but rather tends to increase it. On the other hand, the paralyzing action of morphine on the respiratory centre can be diminished and even neutralized in certain cases by judicious combination with thebain and certain other alkaloids. He is inclined to believe that morphine excites the so-called vomiting centre, and that this action may be checked to some extent by some of the alkaloids. He is convinced that neither narcotin, nor narcein, nor papaverin, nor any combination of them, has any influence on the preservation of the tone of the stomach or on its power of emptying itself. For practical purposes he advises the two following mixtures of opium alkaloids, for which he suggests the name of laudanum I and II. Morphine 0.010 gram, narcotin 0.006 gram, codein 0.001 gram, thebain 0.0005 gram, papaverin 0.002 gram, and narcein 0.0005 gram in the first; and morphine 0.01 gram, narcotin 0.002 gram, codein 0.001 gram, papaverin 0.0001 gram, thebain 0.0005 gram, and narcein 0.0001 gram in the second.

328. Ringworm Treatment in Country Districts.

CERESOLE of Venice (*Arch. d'electr. mèd.*, January 25th, 1913) describes the first experiment in what he calls the ambulatory system of treating ringworm by x rays in a country village. Some time ago it was found by the sanitary inspector of the Venice prefecture that in a scattered village of the province large numbers of children were suffering from ringworm of the scalp. The disease had existed more or less for years, and the village authorities had never dreamed of taking any measures, therapeutic or prophylactic. On an exact list being drawn up after a house-to-house visitation, the number of ringworm cases, most of them very severe, was returned at nearly 150, and these were ordered to be conveyed for treatment to the hospital at Venice. The authorities of the village, however, declared that it was impossible for them to spend the sum necessary to give effect to this measure, and the parents also were indisposed to send the children to the city hospital; therefore Mahomet had to come to the mountain, and it was decided to obtain an x-ray installation, the current being furnished by a dynamo actuated by a benzine motor. This was lodged in the village, and a radiologist—the author—was sent three days a week to make the applications. After the usual preparatory treatment the small patients were x-rayed in turn, each case occupying about an hour and a half. The head was divided into five regions, and the epilation dose was obtained for each region in about a quarter of an hour. The parents were instructed to wash the children's heads with soap and water each morning, and when the fall of hair commenced they were told to effect the epilation with the hand. After

this the scalp was treated every day alternately with tincture of iodine and with sulpho-salicylic pomade for a week, and then the latter emollient alone was given until the regrowth of the hair. By this method the author treated 137 cases, with 94 per cent. of cures and without any trace of radio-dermatitis. The hair invariably fell within fifteen or eighteen days, and grew again as regularly as could be expected in view of the atrophy of the scalp owing to the long duration of the disease. One x-ray tube sufficed for the whole two hundred hours of working, and the extemporized village infirmary still possesses a perfect installation. Such a method of treatment presents difficulties owing to the straggling character of the population and the repugnance of the peasants to submit their children, but the result has been most encouraging, and represents a considerable economy as against detention in hospital.

329. Dioradin (Radio-active Menthol Iodine) in Tuberculosis.

The action of dioradin on tuberculosis has been tested by J. Kalm (*Zeit. für Tuberkulose*, vol. xix, Part 5, 1913), whose verdict is distinctly unfavourable. It was claimed by Scandetty that the drug completely immunizes guinea-pigs against tuberculosis. The author experimented with twenty-four guinea-pigs, all of which were infected with tuberculosis, fifteen being treated with dioradin, and nine being used as controls. Full details of the technique and dosage of the injections are given by the author, who argues that the conditions were as favourable to the drug as possible. Yet the results were negative, both groups of guinea-pigs developing tuberculosis. As a rule, the control guinea-pigs lived somewhat longer than those treated with dioradin, the injection of which probably lowered the animal's vitality. Four patients in an advanced stage of pulmonary tuberculosis were also given injections of dioradin, as it was asserted by Bernheim and Dienpart that the drug effects marked improvement, even in the advanced stages of the disease. In the first case haemoptysis followed the first injection. After forty injections there was transitory improvement, subjective and objective. But this soon ceased, and the last state of the patient was worse than the first. In the second case haemoptysis occurred after the seventh injection. For this reason, and because the temperature had been raised during the injections, the treatment was abandoned. It was also an utter failure in the remaining two cases, and in only one was the treatment unaccompanied by haemoptysis. The author does not venture to condemn the treatment dogmatically on the strength of these four cases, but he argues that in the face of his experiments on guinea-pigs the extravagant claims made for dioradin by its advocates are untenable.

330. Combined Scarification and Radiotherapy in Lupus.

SOME excellent results in the treatment of lupus vulgaris by a combined method of scarification and radiotherapy are brought forward by Marqués (*Arch. d'électr. méd.*, February 10th, 1913). The author has adopted the plan of making linear scarifications in squares across the whole lupous surface, and immediately afterwards irradiating the region with a small dose of x rays—less than an erythema dose—without a filter. This combined procedure is repeated fifteen or twenty days afterwards, the dose being slightly smaller, and is repeated again after a similar period until the region is completely cicatrized. One of the observations relates to a boy of 12 years, who had a six years' history of lupus on the face, resulting in the disappearance of the whole of the antero-inferior part of the nose and the invasion of the neighbouring regions. Six sittings were given at intervals of three weeks, and the result was complete cicatrization, and a more aesthetic appearance than would have resulted with either method taken alone. The author states that, encouraged by the results of this method of treating lupus of the orifices, he has tried the same plan in the case of hypertrophic lupus, vegetating and ulcerous, of the limbs. A girl aged 19 years was treated in this manner for lupus of the dorsal region of the foot. It was a bad case, with crusts and ulcerations on a congested, oedematous and painful surface. Three times the scarifications were carried out, followed immediately by irradiation, and the patient was cured, as in the other cases, dating back for more than a year. When the ulcer occupies a very large surface, it is divided into zones, each zone being treated separately and each receiving the same quantity of x rays.

PATHOLOGY.

331. Haemoglobinuria.

J. W. MILLER (*Berl. klin. Woch.*, October 7th, 1912) analyses the varieties of haemoglobinuria and their modes of origin. To commence with, he deals with serum haemoglobinuria. Every case of haemoglobinuria presupposes the presence of blood pigment free in the blood. This haemoglobinaemia may be artificially produced by the action of specific haemolysins. Free haemoglobin in the blood stream, however, is dealt with to a very large extent by the liver, which possesses the capability of transforming it into bile pigment or haematoidin. Small quantities of the pigment can be transformed by the spleen, bone marrow, and cortex of the kidney into haemosiderin. Should these organs fail to perform their functions, the haemoglobin will pass unchanged into the bile and urine, to be recognized as haemoglobinocholia and haemoglobinuria. The author discusses the significance of jaundice in haemoglobinuria, and after showing that in arsenuretted hydrogen poisoning, for example, the bile is so inspissated that the gall bladder and ducts are filled with a stagnant, gelatinous fluid, which can only pass into the intestine slowly, he emphasizes the doctrine that a true haematogenous jaundice cannot exist. On turning to the types of haemoglobinuria, he first speaks of that following burns. Helsted has shown that extensive lethal burns are always associated with haemoglobinuria, that comparatively extensive burns with marked implication of the general condition yield some blood pigment in the urine; that after severe burns without serious constitutional symptoms, but little, if any, haemoglobinuria is met with, and that the symptoms are seen after small burns with a fatal termination. Haemoglobinuria due to the effect of cold is also discussed. Next he describes those curious cases in which this symptom has been noted after strenuous marching. He points out that other forms of over-exertion do not lead to the same result. Toxic haemoglobinuria follows the inhalation of arsenuretted, antimonuretted, and sulphuretted hydrogen; carbolic, hydrochloric, sulphuric, oxalic, chromic, and other acids; glycerine, chloroform, sulphonal, bile salts, saponin, strychnine, tannin, the poison of truffles, ricin, abrin, robin, croton, phallin, and other alkaloids, and the toxins of toads, spiders, snakes, etc. Methaemoglobinuria follows potassium chlorate, phenylhydrazin, naphthol, turpentine, iodine, bromine, ether, carbon, disulphide, etc. These various forms are briefly discussed. Next he mentions the haemoglobinuria of pregnancy, "water" haemoglobinuria, post-haemorrhagic haemoglobinuria, and the haemoglobinuria of the domestic animals. It is thus manifest that haemoglobinuria may develop from noxae acting on the respiratory and digestive tract, from the skin, uterus, blood vessels, and from wounds.

332. The Toxicity of Methyl Alcohol.

A. LANGGAARD has experimented on rabbits in order to ascertain some facts in regard to the toxicology of methyl alcohol (*Berl. klin. Woch.*, September 2nd, 1912). A comparison with ethyl alcohol was made in each case. Giving doses of 3 c.cm. pro kilo body weight diluted in equal parts of water, 19 and 21 doses were required to produce death, while 23 doses of ethyl alcohol were required to produce the same result. With 5 c.cm. pro kilo doses, 10 killed in the case of methyl and 12 in the case of ethyl alcohol. Five doses of 6 c.cm. pro kilo body weight of methyl alcohol produced death, but 9 similar doses of ethyl alcohol were required. When the dose was increased up to 8 c.cm. pro kilo body weight, 3 doses of each of the alcohols killed. In regard to a single lethal dose he found that 10 c.cm. of ethyl alcohol killed all six rabbits, while the same dose of methyl alcohol only killed one out of six. The minimum lethal dose of methyl alcohol appears to be 14 c.cm. pro kilo of body weight for rabbits. It thus may be stated that methyl alcohol is more poisonous than ethyl alcohol when given in daily repeated doses, while in large single doses the reverse is the case. Rühle (*Berl. klin. Woch.*, November 4th, 1912) objects to the deduction drawn by Langgaard on the ground that herbivora are unsuitable test animals. On testing the toxicity of methyl alcohol as against ethyl alcohol in dogs, he found that the former was considerably more toxic. The reason he gives for the diminished reaction to single doses of methyl alcohol in rabbits is that the presence of formic acid, which is a toxic product of disintegration of methyl alcohol, in the blood of normal rabbits protects these animals to a certain extent.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

333. An Epidemic of Gastro-Intestinal Disease.

In the course of the past year several cases of poisoning have occurred which, according to A. Eisenheimer (*Med. Klin.*, February 16th, 1913), have been attributed to the presence in food of vanilla used as a flavouring agent. The symptoms were those of acute gastro-enteritis or cholera, and the part played by vanilla was in certain cases obscure. The following epidemic is described by the author, whose diagnosis of poisoning by vanilla proved mistaken. A household consisting of ten persons developed signs of severe gastro-enteritis one evening. They had previously eaten meat-soup, veal, pork, beans and cucumbers, as well as groats flavoured with vanilla. One of the patients had eaten no soup, two had eaten neither beans nor cucumbers, and those who had eaten veal had not eaten pork. By a process of exclusion, therefore, the dish containing vanilla was suspected. This had been prepared from groats, sugar, and eggs in an enamelled iron vessel, which was found to be in good condition. Vanilla had been added both before and after cooking, and the pudding had been kept for one day before it was served. The symptoms which occurred five hours after it had been eaten consisted of pains in the head, limbs, and abdomen, vomiting of bile-stained fluid, tenesmus, severe diarrhoea, and, in many cases, high fever and rapid pulse. In some cases the condition was most alarming, and the patients were unable to resume their work for a fortnight. No typhoid or paratyphoid bacilli were demonstrable in the blood, urine, or faeces; and chemical, bacteriological, and inoculation investigations of the vanilla used by the cook were completely negative. No milk had been added to the pudding, and the groats and sugar used must also be considered blameless, for they have never been convicted of provoking severe gastro-enteritis. There remains, therefore, only the egg albumen, which may not have been fresh when added to the pudding, and which may have yielded a large amount of microbes and toxin during the interval between the preparation and the eating of the dish. At all events, egg albumen is a favourable medium for the growth of microbes; and the symptoms observed in the author's epidemic correspond closely to those of other epidemics which have been traced to infected albumen.

334. Diverticulitis.

STANTON (*Boston Med. and Surg. Journ.*, vol. clxviii, No. 10) relates the history of five cases of diverticulitis. He points out that Meckel's diverticulum is a true congenital diverticulum in that it embraces all the coats of the intestinal wall. It is usually attached to the ileum, rarely more than 3 ft. from the caecum. The symptoms resemble those of appendicitis; the pain, however, is nearer the umbilicus. Alarming complications may arise by its adhesion to the wall of the bowel or to the abdominal wall. Acquired diverticula, on the other hand, are not true diverticula; they may be likened rather to herniac of the mucous membrane protruding through the muscular layer. They are most commonly formed along the mesenteric border of the large intestine, particularly on the sigmoid. They hardly ever occur above the splenic flexure. In other words, in that section of the bowel developed from the embryonic hind gut they are to be found most usually. These diverticula occur in fleshy individuals about middle life, and increased abdominal pressure due to any cause, such as constipation, seems to be a factor in their causation. They may be single or multiple. Their occurrence during the so-called cancer age is of importance, in view of the fact that in about one-fourth of the cases which come to operation malignant changes are taking place. Magrath and Wilson have called attention to the possible origin of cancer in the isolated groups of cells found in cases of diverticulitis. Sometimes a condition known as peridiverticulitis is produced, resulting in the formation of a tumour about the size of a hen's egg. This, on clinical examination, may easily be mistaken for malignant disease. The symptoms of an attack have been described as those of a left-sided appendicitis. The initial epigastric pain is not so common, however, as in appendicitis. The differential diagnosis from carcinoma is often difficult. The recurrence of attacks is

in favour of diverticulitis. The presence of blood in the stools, on the other hand, favours cancer. The inflammation may subside or abscess formation may occur, with rupture into the bladder or one of the neighbouring viscera. If rupture occurs extraperitoneally, it is likely to be followed by a persistent faecal fistula. If the patient is old, and the attack is slight, it is better to leave it alone. Colotomy may be necessary, however, or even resection of part of the gut. The author's conclusions are as follows: (1) Diverticulitis is not a rare disease; (2) recessional attacks of left-sided abdominal pain, with tenderness and tumour formation is, in the absence of any active urinary disturbance, usually due to an inflamed diverticulum; (3) as a focus of chronic irritation it may be the starting-point of cancer of the sigmoid.

335. Intoxication by Carbon Monoxide.

CHAUFFARD (*Journ. des praticiens*, March 15th, 1913) draws attention to some interesting points in a case of this kind. The case was one of attempted suicide, and on arrival at hospital the patient was almost comatose. The face had the characteristic rosy flush of CO poisoning, and there were slight contractions. A marked feature was an extreme exaggeration of the olcranon reflex. In the lower limbs this was not so marked, although Babinski's sign was positive on both sides. There was rectal incontinence and retention of urine. On the following day signs of meningeal irritation appeared—notably Kernig's sign—and the respiration took on the Cheyne Stokes rhythm. A lumbar puncture was done, but with negative results. The next day the patient remained in a state of coma vigil, and there was paresis of the upper limbs. The urine contained neither albumen or sugar—the latter a fact to be noted. The author goes on to say that poisoning by CO ought to be regarded from the point of view of the blood corpuscles only. The effects on the nervous system have also to be studied. There was no azotaemia in this case, but, on the other hand, the amount of cholesterol was above the normal. An excess of urobilin was also present. These signs indicate that the hepatic cells have been affected. Although there was no evidence in the cerebro-spinal fluid of the fact, experimentation by Bard and Hirtz has proved the existence of intense congestion of the pia mater and haemorrhages in cases of intoxication by CO. There is, the author concludes, a toxic encephalitis in these cases. In the case under review it appears rather to have been a toxic myelopathy. The absence of any cytological reaction might be accounted for by the limitation of the lesions. The question of prognosis goes beyond the immediate effects of the intoxication. The secondary nervous lesions resulting from toxæmia have to be considered. The ultimate prognosis therefore has to be guarded. Sometimes a slow neuritis like that following arsenical poisoning occurs. The treatment consists of bleed-letting to the extent of 300 grams, inhalations of oxygen, and subcutaneous injections of sterilized oxygen, following the method of Ramond. This cannot displace the CO fixed in the red cells, but assists in their more rapid regeneration. Cardiac stimulants, such as strychnine, are also useful. Complete rest for the central nervous system is also enjoined.

336. Acute Gout of the Larynx.

BUSS (*Med. Klin.*, April 6th, 1913), commenting on the growing interest taken in gouty conditions of the larynx, records the case of an officer, aged 60, who had long suffered from gout, and who complained of violent dysphagia and difficulty in speaking. The pharynx showed nothing abnormal apart from a moderate degree of redness. But the epiglottis was very red and swollen; it was erect, and apparently fixed in this position. On its free border were two to three greyish-yellow spots surrounded by intensely red mucous membrane. The rest of the larynx, including the vocal cords, was apparently healthy. The appearance of the epiglottis was suggestive of a burn or cauterization; but the history of the case pointed to a gouty condition, and the spots were diagnosed as deposits of uric acid. A 5 per cent. solution of cocaine was prescribed as a spray, and the general treatment for gout was adopted. The patient, who had previously found the acute attacks respond satisfactorily to large doses of aspirin, took it on this occasion also. Next day the symptoms had abated, but at the same time

the right knee became swollen in a manner already familiar to the patient. A few days later the dysphagia had disappeared, and the difficulties of speech had ceased completely. The epiglottis had regained its normal mobility, and was no longer swollen and red, and the spots previously seen were now only just visible. The rapidity with which the laryngeal condition yielded to the general treatment of gout is the best proof of its gouty nature.

SURGERY.

337. Treatment of Spastic Contractures.

STOFFEL (*Amer. Journ. of Orthopaedic Surgery*, May, 1913), remarking the unsatisfactory results of tendon operations for spastic contractures, devised an operation upon the nerves giving better results and suitable for the majority of cases. In order to exclude the predominance of the spastic muscle, and so reduce its tension as to render antagonistic co-operation possible, he does not regard the individual muscles as units, either from an anatomical or physiological aspect, but separates each into several sections and subdivisions, designating a muscle unit as the aggregate of muscle fibres innervated by the ramification of one nerve fibre, the nerve of the motor ganglion cell. Many such units go to form a muscle division, and several divisions make up a muscle complex, while several muscle complexes compose the whole muscle. The nerve is built up in perfect analogy to the muscle, the nerve unit being the nerve fibre, the nerve of the motor ganglion cell, several fibres forming a funiculus, and several funiculi collecting into a branch, the nerve of a muscle representing the sum of branches. Each one of the funiculi of a nerve supplies motor fibres to a definite portion of muscle, and severance of one of these funiculi, or destruction of its motor ganglion cells in the anterior horn, produces a paralysis isolated to the muscle group of those portions of the muscle which are supplied with motor fibres by the respective funiculi. Having demonstrated the cable structure of a nerve, the interior topography of the nerve followed, and the topography of the muscle cross-section for the large extremity nerves has been accurately defined in a previous work. Operations on the peripheral nerves are governed by the two facts that the extremity nerve represents a cable, and that every motor and sensory tract has its definite position in the cable. The operation aims at injuring the spastic muscle only to such an extent that it can no longer disturb the muscle equilibrium, while its function is preserved and it is possible to so regulate the severance of motor nerve tracts that the desired degree of energy in the muscle can be obtained. Exact anatomical knowledge of the topography of the nerve cross-section is essential, and in nearly a hundred operations performed lesion of a nerve tract other than those intended has not occurred. All spastic contractures localized in definite muscles or muscle groups are suitable for such operations, but familiarity with technique and the cross-section relationship of nerves is essential for success. Notes and details of cases and operations are given showing the advantage gained, such operations on the nervous system affording a distinct advance upon tendon operations for similar conditions.

338. Pseudo-calculus of the Kidney.

MARIO PONZIO, of Turin (*Arch. d'electr. mèd.*, March 25th, 1913) has compiled a long list of conditions which in a radiograph may simulate renal calculus. These include phleboliths of the renal vein, small calcifications of serous purses in the muscular masses of the lumbar region, myositis ossificans of the psoas and quadratus lumborum muscles, exostoses of the surface of the iliac bone, calcifications of the cartilaginous extremity of the lower and false ribs, and abnormal calcifications of the extremity of the transverse apophyses of the lower dorsal and first lumbar vertebrae. Of a different order are the intestinal calculi, which may be mistaken for renal. Even when the calculous shadow is seen superposed on the shadow of the kidney it may not signify nephrolithiasis, for the colon, which traverses this region, may itself contain a small calculus. Enteroliths in the colon, too, as well as pathological lesions of organs adjacent to the kidney, may give rise to error. In one instance a carcinoma of the head of the pancreas with calcifications was mistaken for renal calculus, and the same danger applies in the case of calculi of the gall bladder, especially when these are rich in salts of lime. The biliary calculi, however, can usually be differentiated, because of their situation exterior to the

renal shadow, and their true position may be revealed by a second radiograph, made with the patient lying on his abdomen. More difficult is the differential diagnosis when there are pathological calcifications of the epiploic appendages or the prevertebral lymphatic or mesenteric glands. The difficulties of diagnosis are further aggravated by the fact that in the renal region itself there may exist pathological lesions, such as incrustations of the efferent vessels localized thickening of the renal parenchyma, as well as cicatrices, which may readily simulate the existence of a calculus. The radiological differentiation between these forms and that of the true calculus poor in salts of lime or magnesia is excessively difficult and frequently impossible. To all these sources of error the author adds one from his own experience. The radiograph in this case revealed an ovoid body the size of a hazel nut, situated in the renal territory. This, combined with the clinical symptoms, pain and haematuria, made it appear probable that the case was one of calculus of the renal pelvis. An operation was performed, but no trace of such calculus was discoverable, though the kidney was found enlarged at the lower extremity by reason of a cystic dilatation. The renal cavity was then explored and at its inner wall there was found a hard body, corresponding in form and dimensions to the one observed in the radiograph. When extirpated its smooth and hard surface proved to be constituted by a shell of calcareous matter intermingled with osseous substance, and this enclosed a blood clot perfectly conserved. On a histological examination of the coating the characteristic structure of a large vein was observed, though it was not possible to state exactly whether this belonged to the renal investment proper or to the retroperitoneal tissues. The case had its pathological interest, because, in spite of the well advanced and complex lesion of the wall of the vessel, this continued to be permeable by the circulation.

339. Phrenicotomy in Pulmonary Disease.

DURING the past two years the division of one phrenic nerve in order partially to immobilize one side of the diaphragm and thus limit the movements of the lung on the same side, has been discussed by several writers, and F. Sauerbruch (*Muench. med. Woch.*, March 25th, 1913) has now performed the operation five times. After division of the nerve, the diaphragm rises to the position it normally occupies in extreme expiration, and scarcely moves on respiration. The slight movements it now makes are of the paradoxical type, the diaphragm sinking on expiration and rising on inspiration. The normal respiratory changes in the volume of the lung are lessened, particularly in the lower lobe which is partially compressed by the diaphragm. It has been experimentally shown that phrenicotomy favours the growth of fibrous tissue in the lung, just as a pneumothorax or ligation of the pulmonary arteries or veins. It is therefore claimed for phrenicotomy that it immobilizes, compresses, and induces fibrosis in the lung; and these are the factors on which the success of plastic operations on the chest depend. But phrenicotomy is a much simpler undertaking than the resection of several ribs. The operation is easy, and causes little discomfort to the patient, who is able to leave his bed in two or three days. It is performed on the patient in a semi-recumbent position with the head turned away from the operator so as to stretch the muscles of the neck on the side to be operated on. A 10 cm. long incision is made over the posterior border of the sterno-mastoid muscle, extending down to the clavicle. After separation of the overlying muscles, the scalenus anticus is exposed, the sterno-mastoid meanwhile being drawn to the middle line, and the omo-hyoid being displaced downwards. The phrenic nerve will now be found passing over the scalenus anticus from above downwards. It is divided after isolation, during which the patient complains of dull pain in the lung. One patient suffered from severe pulmonary tuberculosis on the right side, and a moderate amount of disease on the left side. The cough, which had previously been troublesome, ceased at once. In 2 cases phrenicotomy was performed for bronchiectasis; and in 1 of these the sputum speedily fell from 300 to 150 to 200 c.cm. In 2 cases the operation was performed for tuberculosis of the left upper lobe as a preliminary to resection of ribs. In both cases the division of the phrenic nerve was followed by diminution of cough and expectoration. The value of the operation cannot, according to the author, yet be accurately gauged.

340. Syphilis and Cancer.

GOUGEROT (*Journ. des praticiens*, 1912, lvi) finds that syphilis and cancer are frequently associated. According to his statistics, amongst 157 cases of syphilis of the

tongue, 102 showed cancerous growth at some time or other. When the two diseases are associated the author finds as follows: If the patient bears signs of old syphilis but no active lesion is present, the treatment should be that for cancer. If both lesions are active both diseases should be treated. Iodides are contraindicated, but arsenic or mercury may be employed.

OBSTETRICS.

341. Infant Mortality and the Accoucheur.

CHAMBRELENT (*Journ. de méd. de Bordeaux*, No. 17) emphasizes the importance of the infantile death-rate in the question of depopulation. The proportion of stillbirths to live-births in the principal towns of France is about 8 per cent.; abortions are not included in this figure, but only cases at the period of viability. The chief causes of stillbirth are albuminuria of pregnancy and mal-presentations, and the author estimates that half the still-born children might be saved if their mothers were properly examined during pregnancy. At his consultation for pregnant women, one found in 1910 that 135 cases out of 642 presented complications or anomalies requiring special care, and as the result of such care the birth-mortality was reduced to 2.85 per cent., or a saving of nearly two-thirds as compared with the official figure. Since the institution of consultations for pregnant women there has been a tendency for the proportion of stillbirths to diminish, but the consultations are not used to the extent they should be, and not till women understand that it is to their own and their children's interest that they be examined during pregnancy will the consultations bear their full fruit. As well as his part in the prevention of stillbirths, the accoucheur has an important duty in the instruction of mothers on the care of their children, particularly during the first year. The proportion of children who die during the first year is 15 per cent. to the births, or a yearly loss of 120,000 units to the population of France. This proportion could be greatly reduced by the supervision of children during the first year of life, as is proved by the fact that, whereas the death-rate in Bordeaux during three years from infantile diarrhoea was 38.29 per 1,000 of the births, the proportion of deaths among children attending the consultations was only 9.69 per 1,000. Further, at the Pouponnière at Porchfontaine, where the newly-born receive meticulous care, the infantile death-rate is only 3 per cent., as against 15 per cent. for the whole of France. Such good results can hardly be hoped for in private practice, but the mortality can be reduced by more than half by careful supervision during the first year, particularly in the matter of feeding. Good results are especially to be obtained by insisting on maternal suckling. It is extremely rare for a mother to have insufficient milk to feed her child at the outset, and after the first few weeks there is no objection to supplementing her milk with cow's milk, provided the latter is of good quality and properly administered. Only in very exceptional cases should the employment of a wet nurse be advised, for by this means another child is robbed of its mother's milk, and is exposed to all the risks of a stranger's care.

GYNAECOLOGY.

342. Artificial Vagina.

BALFOUR MARSHALL (*Journ. of Obstet. and Gyn.*, April, 1913) says that it is important to recognize that there are two distinct types of atresia vaginae, since for the cases belonging to the first class, in which a functioning uterus is present, operation is imperative, owing to the formation of a haematoma from retained menses; whereas in the second class, in which the uterus is absent or very rudimentary, the justification of making an artificial vagina is a matter of opinion. In the first class hysterectomy as an operation of selection should, if possible, be avoided, and the formation of an artificial vagina be attempted, not only to permit of the escape of the menstrual flow, but to give the afflicted woman the chance of becoming a mother. Should pregnancy ensue, delivery should be by Caesarean section, since parturition destroys the artificial vagina. The most recent improvement in plastic operations is Pfannenstiel's, which consists in freeing the cervix by laparotomy after partially opening the recto-vesical septum from below, then completing the opening of the septum from above, and, after closing the abdomen,

attaching the cervix to the skin edge of the vulvar orifice or mucosa of a vaginal rudiment. In the second class the writer very much doubts the justifiability of performing an operation which, while giving the patient a coitional vagina, cannot give her a uterus. He would, however, be willing to operate by Baldwin's method (transplantation of a resected segment of ileum), if specially requested by both husband and wife, and provided both parties clearly understand what the operation means. Apart from ethics, the surgeon must not lose sight of the fact that he may be condemning the husband to the life-long companionship of a pseudo-hermaphrodite with cryptorchidism. It is quite unjustifiable to make an artificial vagina in an unmarried girl simply because she wishes to get married. The after-results of operations where the vagina is formed by transplanted bowel have been most successful, as the canal does not show the same tendency to excessive contraction, but it secretes mucus more or less freely. So far as is known, fifteen cases of ileum transplantation have been done with no deaths from the operation. Nevertheless, it cannot be said that an operation involving resection of the bowel is absolutely safe, and the justifiability of performing it must be left to the personal view of the operating gynaecologist.

THERAPEUTICS.

343. Mercurial Preparations in Spirochaetosis.

J. ABELIN (*Deut. med. Woch.*, September 26th, 1912) has investigated the pharmacological action of a large number of mercurial preparations, more especially in relation to spirochaete infections. Pharmacologists have endeavoured to prepare a combination of mercury which, while exercising the same action as the ordinary mercury compounds, does not produce such toxic or irritating effects. The modern endeavours in this direction chiefly concern the aromatic mercurial compounds. Imitative of the composition of atoxyl, Dimroth was able to show that the salicylate of mercury contains a firmly bound Hg group, which does not give the reactions of free mercury ions. The possibilities of aromatic compounds are found to consist in the attachment of the Hg atom direct to one of the carbon atoms of the benzol ring, with a side chain tacked on to the mercury, or the mercury may be attached to two benzol rings, with or without some organic radical arising from one of the carbon groups. For example, the oxy-mercuric benzoate of sodium has the former constitution. The disinfecting power of this body can be raised by the introduction of a chlorine or iodine atom, or a methyl or methoxy group in the ortho position of the ring, while a hydroxyl, an amido, or a sulpho group diminishes this power. The second type proves to be little toxic in many instances, such as the dinitro-mercuric, diphenyl-dicarbonate of sodium. While the lethal dose of this compound is high its disinfecting power is low. A further instance of the Hg atom being so firmly bound to the carbon atom of the benzol ring that the metal has practically no chance of acting toxically is given in the case of mercuric dibenzoate of sodium. It has been found that this compound is largely excreted unaltered in the urine. Mercuric dipropionate of sodium is one of the least toxic of the mercuric compounds. Another means of attaining slight toxicity is the introduction of a group like the sulpho group as an agent which lowers the poisonous effect of the metal. In this case the Hg atom is not fixed in the ring but takes part in a side chain. Such a compound is met with in dimethyl-phenyl-pyrazolon-sulph-amino mercury. Abelin enters into a detailed discussion of the pharmacological and toxicological action of a number of mercury compounds, and concludes that the toxicity of the compounds stands in some relation to the chemical constitution. The toxicity may be reduced in the two manners already mentioned, and conversely the most toxic compounds are those in which the Hg can be ionized most readily. He further points out that mercury is stored up in the liver, and in hepatic exudations after the injection of the various mercury compounds; and, finally, he finds that the aromatic compounds have distinct therapeutic advantages over other organic and inorganic compounds of this metal.

344. Nitro-glycerine in Seasickness.

O. BURWINKEL (*Wien. medicin. Klinik*, No. 29, 1912) suggests the use of nitro-glycerine as a remedy for seasickness. Its use appeared to him to be hopeful on the theory, recently again brought forward by Peters, that in seasickness we have to do with a cramp of the vessels and anaemia of the central nervous system. He tried it

himself on a voyage, taking at need a teaspoonful of the following solution: Solut. alcohol nitro-glycerin (1 per cent.) m. xx, aq. dest. 150.0. As a result, the symptoms of seasickness were quickly and strikingly alleviated. The result was temporary only, and the dose had to be frequently repeated, which can be done with perfect safety. He suggests that the inhalation of amyl nitrite might prove to be even more efficacious.

345. Diathermy in the Treatment of Blennorrhagia.

CARLOS SANTOS FILS, of Lisbon, has worked out a method of treating blennorrhagia by means of diathermy (*Arch. d'electr. méd.*, March 25th, 1913), for which purpose he has constructed a special electrode. This "thermo-electrode" consists of a mercury thermometer surrounded, by means of galvanoplasty, with a layer of copper. It can be used for the mobile or fixed part of the anterior urethra, according as to whether it is introduced up to the root of the penis or to the bulb. A modified form is employed for posterior urethritis. The indifferent electrode, when the mobile part of the urethra is acted on, is constituted by a conducting cylinder surrounding the penis, contact being made by means of wadding saturated in saline water, so that the active thermo-electrode is placed in the axis of the cylinder formed by the indifferent electrode. When, on the other hand, the treatment is applied to the fixed part of the anterior urethra, two indifferent electrodes are placed on the anterior surface of the thighs and pelvis. By experiments *in vitro* the author has found that the gonococci of greatest resistance are killed off with a temperature of 112° F. in forty-five minutes, and of 121° in five minutes. The lower of these temperatures can be reached gradually in the human organism without producing damage. The author brings forward some clinical cases in which mean temperatures of 110 to 112° F. have been employed for forty-five minutes or an hour or more in the treatment both of the mobile and of the fixed part of the urethra, and he holds that the results in these preliminary cases justify the hopes entertained with regard to this particular diathermic application.

346. Premonitions of Intolerance to Salvarsan.

MILIAN (*Bull. de Soc. Franç. de Derm. et Syph.*, December, 1912) says the symptoms will sometimes develop coincidentally with the injection, and should put the practitioner on his guard. He discusses them under three heads: (1) Gustatory or olfactory; (2) glandular hypersecretion; (3) phenomena of vaso-dilatation. (1) The most common are those of the taste or smell of ether, salt, or garlic; sometimes the patient thinks he smells them in the room. It is not infrequent to find the pulse considerably slowed down in such cases, and it is worthy of note that tolerant individuals never present this phenomenon. (2) Hypersecretion of tears or saliva is a very common phenomenon in those who are intolerant, coming on during the injection itself, and persisting for several days afterwards. Occasionally the nasal symptom just precedes the onset of the severe toxic reaction, and an immediately induced "cold in the head" should always put the practitioner on his guard. Mucous membranes in general, especially those of the stomach and intestines, are portals of excretion, and the diarrhoea so frequently symptomatic of intolerance is doubtless an expression of hypersecretion from the glands of Lieberkühn. (3) Cardio-vascular signs occurred in Milian's cases 26 times in a series of 532 cases. They appeared during the injection, and consisted in cyanosis and congestion of the face, swelling of the lips and tongue, praecordial distress, and the usual concomitants of the syncopal state. Such cases especially call for the utmost caution in administration. When slowness of the pulse is not a symptom of a too rapid injection, it is probably an indication of bulbar susceptibility, and syncopal tendencies.

347. Neuronal.

MAX SEIGE (*Deut. med. Woch.*, September 26th, 1912) reports on neuronal, a drug which has been in use for some eight years, and which has yielded good results in the psychiatric clinic in Jena. The doses employed varied between 0.5 and 3 grams. In simple sleeplessness, especially in patients suffering from increased emotional susceptibilities, neurasthenia, or hysteria, from $\frac{1}{2}$ to $1\frac{1}{2}$ grams suffice to induce quiet sleep. In certain severe cases, it is true, neuronal does not act so well as paraldehyde. Seige had also obtained satisfactory results in the neuroses accompanying the climacterium, and also in dysmenorrhoea. While this drug alone was not satisfactory in epilepsy, he obtained good results by a combination of it with amyl hydrate. In maniacal patients, 2 grams of neuronal only sufficed to

quiet the patient for a very short time. On the other hand, regular medication with from $1\frac{1}{2}$ to 2 grams a day for five or six days produced a very quieting effect. Even when $\frac{1}{2}$ gram was given three times a day, it became possible to place the refractory patients into the permanent bath. The only disturbances which he has observed as a result of the drug were slight indistinctness of speech and slight unsteadiness of gait. The kidneys were never harmed, and the blood pressure was not lowered. He speaks favourably of a combination of neuronal and antifebrin (1 gram of neuronal with $\frac{1}{2}$ gram of antifebrin) as a sedative for pain. This combination was found especially useful for the intolerable headache in arterio-sclerosis and tumour of the brain. It also acted well in migraine.

348. Treatment of Taenia by Thymol.

ARTAULT (*Bull. de thérap.*, February 23rd, 1913), in all cases of taenia, gives crystallized thymol, 25 cg. in cachets daily, fasting. Generally the taenia is expelled on the third or fourth day, but it is advisable to continue the treatment for a week to ensure the complete expulsion of the parasite. The process is simple, the tolerance is perfect, and the ill effects are *nil*. The author has treated 23 cases with perfect results, and recommends the treatment as the method of choice. The only precaution to be observed is that the patient shall abstain from alcohol while taking the treatment.

PATHOLOGY.

349. Symptoms Due to Bacillus pyocyanus.

C. KLIENEBERGER (*Deut. med. Woch.*, December 26th, 1912) considers that the *Bacillus pyocyanus* is pathogenic to man, and that it not only causes local suppuration, but that it also invades the blood stream, and causes symptoms of generalized infection. He admits, however, that the virulence of this bacillus is still in dispute, and that some authors hold that it invades the body only after its vitality has been reduced by long suppuration, gastro-intestinal catarrh, or tuberculosis. This view he discredits, for he has found the bacillus in the blood of otherwise healthy persons who exhibited merely transient septic manifestations. He also argues that were the blood oftener examined in cases of obscure transient fever, the discovery of the bacillus would often be made. It usually enters the body through abrasions or ulcers of the integument and mucous membranes. The urinary tract may also be a portal, though this mode of infection has hitherto been scarcely mentioned, in spite of its being, according to the author, quite common. The diagnosis of a generalized infection is made by cultivating the bacillus from the circulating blood and by a positive agglutination test. This probably varies with the nature and duration of the infection, and the prognosis, contrary to the opinion of earlier writers, is not necessarily bad. A man, aged 47, who had suffered for many years from renal calculus, for which nephrotomy had been performed on the left side, developed cough, fever, and purulent expectoration four weeks before admission to hospital. He also suffered from anorexia and diarrhoea. The sputum teemed with pneumococci, but contained no tubercle bacilli. The cloudy urine contained traces of albumen and pus and numerous staphylococci. Great improvement was effected in hospital, and the temperature was normal when the patient began to get up. But this was suddenly followed by a rigor and a temperature of 104.4°. Headache and anorexia were complained of, but there were no objective signs to indicate the nature of the fever. The cultivation of 15 c.c.m. of blood on various media yielded, however, fifteen colonies of *Bacillus pyocyanus*. Next day the temperature rose to 105° and three more rigors occurred. On the following day there was one rigor, and the temperature fell to 102.2°. This soon became normal, and the headache and anorexia ceased. Nine days after the onset of the fever the patient was discharged in perfect health. Throughout the illness Widal's reaction was consistently negative to the typhoid bacillus, while it was positive to the *Bacillus pyocyanus*. This bacillus was also cultivated from the scrotum, which was eczematous, owing to incontinence of urine. A culture of the *Bacillus pyocyanus*, made from the patient's blood, was injected into the peritoneal cavity of a guinea-pig, which died twenty hours later. Its peritoneal cavity contained a watery exudate, and the lining of this cavity was covered by a gelatinous membrane, which also appeared on the surface of the diaphragm, liver, stomach, and colon. The bacillus was again recovered from the interior of the guinea-pig's heart. The author thinks that the bacillus reached the patient's blood through the kidneys.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

350. The Fate of Carbohydrates in the Body.

A. JOLLES points out that since carbohydrates form between two-thirds and three-quarters of the usual diet of man, their metabolism is of vast importance (*Bert. klin. Woch.*, September 23rd, 1912). The chief carbohydrates of human diet are the starches and the hexoses, while the pentoses only enter into the question to a slight extent. Some of the problems are yet unsolved: for instance, which ferments split up the polysaccharides into monosaccharides, whether maltose is reduced to dextrose in the interior of the intestine or in the intestinal wall. On the other hand, it is certain that starch is split up first to dextrin, next to maltose, and lastly to dextrose. What the fate of the resulting dextrose is forms a matter on which opinions differ. He finds that there are reasons for refusing to accept the view of a primary splitting up into carbonic acid and alcohol, and a subsequent oxidation of the alcohol to carbonic acid. Another view suggests that lactose is an intermediary product. Jolles investigated the chemical behaviour of the various sugars in the presence of very weak alkalis and when undergoing oxidation. Jolles makes the following deduction: The ingestion of carbohydrates raises the respiratory quotient considerably; it is the most prolific source of muscle power, and is a more economical source of heat than fat. Glucose, which is the type of carbohydrate met with in the blood, is acted upon by the mild alkalinity of the blood and by a variety of oxidizing agents (peroxydase, catalase, and other ferments), and is reduced to acids of almost the lowest molecular weight, principally in the form of formic acid, which in their turn are rapidly oxidized to carbonic acid and water. The formic acid cannot act toxically, firstly because it only exists as an intermediary product for a very short time, and secondly because, like many other metabolic products, it is rendered harmless by being combined with acid products, such as sulphuric acid, glycolic or glyconic acid. He suggests that lactic acid derived from muscle furthers the immediate dissociation of the carbohydrates, by means of a restricted supply of oxygen. Jolles shows that it is possible, under favourable conditions of oxidation, to obtain glyconic acid directly from dextrose. This fact is of great importance. In the first place it shows that glyconic acid may serve as the intermediary product in the splitting up of dextrose, and in the second that the source of glyconic acid in the body may be the carbohydrates. Whether glyconic acid can be substituted under certain conditions by sulphuric acid is an open question; but Jolles points out that when the organism loses the capability of oxidizing sugar to glyconic acid, an important means of getting rid of poisonous dissociation products is lost.

351. Raynaud's Disease with a Positive Wassermann Reaction.

GAUCHER, COUGEROT, and MEAUX SAINT-MARE (*Bull. de dermat. et syph.*, February, 1913) describe the typical syndrome in a stable boy, aged 21. The stages were well marked in his case, tending in the course of a month to develop from local syncope and local asphyxia towards gangrene of the finger tips, especially of the right hand. The crises were exceedingly painful, but were markedly benefited by the constant current (positive pole to the neck, negative in a basin of water covering affected extremity, 5 milliampères passed for ten to fifteen minutes daily), and the afflation of hot air at 60°. The Wassermann reaction was found to be strongly positive, in spite of the denials of the patient of ever having contracted the disease, and he was accordingly subjected to intensive mercurial treatment by injection, and potassium iodide per os, under the influence of which very distinct amelioration of his symptoms was noted. In their discussion of the etiology of this affection the authors emphasize their belief that most cases are the sequel of hereditary syphilis, or of acquired syphilis on a hereditary syphilitic basis; and they quote from the literature several cases in support of this view. As for the pathology, they regard (1) vascular spasm, caused either by a syphilitic peripheral neuritis or a central vasomotor disturbance, as the primary feature, and they consider that a secondary endarteritis

from prolonged vaso-constriction suffices to complete the clinical symptoms; or (2) alternatively and more probably, that the endarteritis is primary and remains latent symptomatically, until a spasm set up through the nerve channels determines the onset of local asphyxia and subsequent syncope and gangrene.

352. Alkaptonuria.

BALDWIN (*Amer. Journ. of Med. Sci.*, January, 1913) records a case of alkaptonuria in a widow, aged 31, suffering from vague rheumatoid pains in her back and neck, accompanied by a general feeling of weakness. Ten years previously she had been told that she had diabetes, to which there was a family tendency, but no history of other abnormality in the urine of any member of the family. When 1 year old it was noticed that the patient's diapers were stained by the urine, and as she grew older the clothing became stained a red brick or maroon colour. Tall, dark, and well nourished, the sclerotic coats of the eyes presented a greyish tint (ochronosis), and there was one small dark spot in the cartilage of the left ear. The urine gave the characteristic reactions of alkaptonuria due to the presence of homogentisic acid, a powerful reducing agent turning brown when oxidized. When freshly voided the urine was pale yellow, but it soon assumed a brownish tint, which slowly darkened until it became nearly black. The addition of an alkali caused the surface exposed to the air to become brown quickly, and the darkening of the entire specimen was hastened. Patients with this condition present no characteristic symptoms, and the only diagnostic alteration in their metabolism is the failure to normally burn tyrosin and phenylalanin, which become converted into homogentisic acid, and this is excreted unchanged in the urine. In the above case the principal symptoms were the constant presence in the urine of homogentisic acid, the darkening of the sclerotic coats of the eyes and slight darkening of the cartilage of the ear, and the local irritation of the strongly acid urine. In addition, there were noted a general weakness, neurotic disposition, tendency to rheumatoid pains, and an irritation of the bladder causing increased bladder cells and leucocytes in the urine. A rapid coagulation of the blood and low tolerance for sugar, with a family history of diabetes, were also noted. The patient was of German origin, and most of the cases have been reported by German physicians, and of those reported from other countries several have been German.

353. Etiology of Alopecia.

SABOURAUD (*Ann. de dermat. et de syph.*, February, 1913), after a short and admittedly incomplete survey of the alopecia associated or coincident with the cessation of the menstrual flow, reaches the following conclusions: Ten cases were post-climacteric, two during pregnancy, and two after a double ovariectomy. (1) There is an alopecia in women, which follows the menopause, or prolonged suppression of the menses. This type may be mild or severe, and obstinate to all forms of treatment, both local and opotherapeutic (with ovarian extract). (2) An alopecia may follow ovariectomy. Its prognosis is equally variable. (3) In a few rare cases the condition may occur during pregnancy, and in these the prognosis is relatively good. Sabouraud also mentions a case of a man 40 years old where a complete alopecia of the whole body coincided with a bilateral tuberculous orchitis, for which double castration had to be performed. The hair loss began on the chin during the course of the disease, had progressed slowly for fourteen years, and had nothing to do with the operation.

SURGERY.

354. Membranous Pericolitis (Jackson's Membrane).

IN 1908 Jabez N. Jackson described certain pathological changes found in the region of the ascending colon, to which he gave the descriptive name of "membranous colitis," or the "pericolic membrane." This membrane has since been known in this country as "Jackson's membrane," and various explanations of its pathology and etiology have been hazarded. In *Annals of Surgery*,

March, 1913. A further study of the subject is presented along with a summary of the whole matter from the beginning. The author discusses the various aetiological theories put forward—the congenital, the mechanical, the inflammatory. His personal observation of a considerable number of cases at operation inclines him to the belief that varied causes may be responsible for the production of this membrane. One case observed was clearly and unmistakably associated with antecedent acute appendicitis with abscess. Two cases suggested the correctness of the congenital theory, which regards the membrane as a lateral expansion of the omentum fixed to the posterior abdominal wall on the outer side of the ascending colon, while a few cases suffering from alternating constipation and diarrhoea have led him to suspect a coincident colitis. The symptomatology is sufficiently established to permit a diagnosis on clinical evidences only. The symptoms, briefly, are: Pain of moderate severity, of definite abrupt onset, more or less constant though marked by "acute spells"; tenderness, generally diffuse, with no rectus rigidity; marked constipation; gaseous distension of caecum, palpable and often visible; mucous diarrhoea; disturbances of digestion simulating gastric disease; loss of weight and tone; neurasthenia. The membrane is apparently only productive of these diagnostic signs when it has become a factor in the establishment of mechanical interference with intestinal peristalsis. The restriction of the pericolic membrane in about the upper two-thirds or thereabouts of the ascending colon results in long-continued distension of the caecum, and that again in dilatation of the caecum. The treatment of the condition may vary with the view of its etiology. If the symptoms are relatively slight with little or no mechanical interference with the peristaltic activity, non-surgical treatment may avail (massage, exercise, dietetic regulation, etc.). Surgical treatment is generally called for, because most cases are of long standing and already medical means have been tried. In discussing operative treatment two factors have to be kept in mind: first, the presence of the membrane; second, the resultant dilatation of caecum. Treatment of one of these alone must necessarily be inefficient. In Jackson's original operations effort was directed to removal of the constricting effect of the pericolic membrane; in about 75 per cent. the result was quite satisfactory, but in a few cases no benefit at all followed. On the ground that the caecal dilatation was possibly the cause of failure, the operation of caecal plication was performed as a supplementary proceeding. Plication is done by longitudinal reefing mattress sutures, usually one paralleling each longitudinal band, or by two or three series of transverse sutures, turning in each a fold of about $\frac{1}{4}$ in. depth. These sutures are of linen, and pick up both musculosa and serosa. The combined operation has been employed by the author for a year in ten cases, and so far with apparently perfect success. Regarding the operation on the membrane itself, the author holds that it ought to be removed entirely. The remaining covering of the supposed raw surface is really an epithelial lining of lymph space which will take the place of peritoneum. No one method is applicable in all cases; and it must not be forgotten that post-operative treatment must be rigorous by correction of diet, regulation of habits, muscular exercise, and abdominal massage.

355. X-ray Diagnosis in Dermatology.

THE use of the x-rays for the diagnosis of certain cutaneous affections has been advocated by Belot and Nahan before the Société de Radiologie Médicale de Paris (*Bull. et mém.*, March, 1913). They do not suggest that all dermatoses should be subjected to radiographic examination, but in certain cases the procedure is extremely useful. The method is advised when there are circumscribed deposits and calcareous material in the skin or subcutaneous tissues, such as the "stony tumours," or calcified lobules of adipose tissue in old people, true osteomas of the skin, subcutaneous varicose calcified veins, and that rare and curious condition known as subcutaneous calcareous granuloma. One typical case described is that of a small tumour on the chin, stone-like in character at its centre. The radiograph showed this centre as a deeper shadow and a curious one by reason of its osseous structure. Trabeculae were clearly distinguishable, suggesting the appearance of the spongy tissue of the epiphyses of the skeleton, and in this way the tumour was revealed, not as a simple calcified mass, such as is presented frequently by fibromas of the skin, but as a true osseous transformation. In another case, one of subcutaneous varicose calcified veins in arm and shoulder, the radiograph, by the contour of the soft parts, readily furnished an idea as to the state

of deformity of the diseased region. It also showed the distribution of the concretions in the subcutaneous tissues, which simulated the appearance of a discharge of grains of lead, save that they were of smaller opacity, and it demonstrated conclusively the soundness of the bone. In the case of the tumour-like nodules in subcutaneous calcareous granuloma the radiographs again furnished proof that the calcified points were much more numerous than there was reason to suppose from the clinical examination, and concretions were found widely disseminated in the subcutaneous cellular tissue. The radiographs also brought out the integrity of the bone and the absence of connexion between the bone and the concretions. In this particular instance it was the radiograph alone which permitted the diagnosis of the nature of these subcutaneous tumefactions to be made. The authors insist upon the value of radiography for elucidating the actual number and distribution of calcified points, and add that by this means they are able to detect fresh nodules at the beginning of their evolution when clinically they are not appreciable. This is of great importance in an affection so obscure as subcutaneous calcareous granuloma, and an affection in which the point of anatomical departure of the processes of calcification is in doubt. By revealing the differences in opacity of the elements which constitute the dermic productions, the rays furnish practically a means of chemical analysis, the transparency of bodies being in effect a function of their atomic weight.

356. Operative Treatment of Elephantiasis.

KONDOLLON (*Zentralbl. f. Chir.*, No. 30, 1912) points out that treatment of chronic oedema of elephantiasis type by posture, compression bandages, and massage fails, and surgical aid is required. Mikulicz, Lanz, and Sampson Handley have each suggested operative methods. The last-mentioned method is well known to English readers. The Lanz operation seeks to establish a collateral lymph circulation by introducing strips of fascia into holes in the bone (femur) and by cutting multiple openings in the fascia lata. Anatomical observations have led the author to another procedure, adopted in six cases. He noted that in addition to the well-known changes in the skin and subcutaneous tissue, the fascia was thickened up to 3 cm., densely infiltrated, immobile; the upper surface of the aponeurosis was irregular, of opaque appearance; the inner surface next the muscles was of normal glistening colour and consistence. The greater portion or the retained lymph came from the neighbourhood of the thickened aponeurosis. Microscopically the tissue was found to be dense fibrous structure, which in various parts showed a separation and softening of the bundles from oedema and small-celled infiltration. The underlying muscles, examined both macroscopically and microscopically, were found to be quite normal. These observations, the recollection of previous failures, and the fact that the lymph stasis in old-standing elephantiasis occurs chiefly in the fascia, seemed to indicate the establishment of a wide communication between the subcutaneous tissues and the musculature. From previous experiments he knew that the muscles will quickly absorb lymph. The technique as applied to the leg is as follows: Two long incisions, one on each side from knee to ankle (if necessary two also in the thigh), are made; removal of the subcutaneous fascia and its covering of fat; removal of a strip of aponeurosis as long as the incision and three or four fingers broad; haemostasis and suture of skin without drainage. He has operated in six cases, and is exceedingly well pleased with the results. Two of the cases, of thirty and twelve years' duration respectively, withstood other methods of treatment, but responded well to this operation. Healing occupied from one to two months, and the hard, dense, infiltrated tissues became soft and pliable.

OBSTETRICS.

357. Sudden Death from Attempted Abortion.

LANDE (*Journ. de méd. de Bordeaux*, No. 19) was called to see the dead body of a girl of 18. He found no trace of external violence, but noted that a No. 12 gum-elastic sound had been introduced into the vagina. There was a little blood on the inner aspect of the thighs, and the left thumb and index finger were blood-stained. The inferior lobes of the lungs were very slightly congested; the right ventricle contained a fibrinous clot; the liver and kidneys were congested; the other organs were normal. The sound which had been introduced into the vagina did not, at the time of examination, enter the uterus. The uterus

contained a complete ovum, but the placenta was separated, and there was a retroplacental effusion of blood, the condition being apparently due to abortive manœuvres. There was no organic lesion which could have accounted for the death, and Lande estimated that the girl must have died suddenly while abortion was being attempted, but whether by herself or by another it was impossible to say. As a rule, the introduction of an instrument into the cervix is painless, but occasionally women complain of sharp pain, faintness, vomiting, giddiness, etc. These symptoms may be followed by sudden death. Vibert reports the case of a young woman, four months pregnant, who went to a midwife to have an abortion procured. The midwife introduced a cannula into the os, but before she could make an injection the woman complained of feeling very ill, lost consciousness, and rapidly died. Grave or fatal inhibitory phenomena of genital origin may be observed, though rarely, apart from criminal practices. Thus a vaginal examination or injection have sometimes caused sudden death, and Vibert considers that inhibition must be attributed to physiological conditions which are transient and variable from one moment to another, rather than to the intensity of the traumatism or a special susceptibility of the nervous system. Brouardel thinks that the cessation of palpitations or intermittences in certain nervous women following cauterization of a small ulcer of the cervix is a proof of the intimate relation between the innervation of the genital organs and that of the heart. At all events the incidence of sudden death of genital origin ought not to be forgotten because of the question of medical responsibility which may arise.

GYNAECOLOGY.

358. Placental Cancer or Malignant Chorion-epithelioma of the Fallopian Tube.

BAZY (*Ann. de gynéc. et d'obstét.*, April, 1913) publishes a short but instructive monograph on chorion-epithelioma in association with tubal pregnancy. Eleven authentic cases of this condition have been reported, and Bazy adds a twelfth, which was observed in Ribemont-Dessaigne's practice. A young woman, aged 25, believed herself to be pregnant, but she fell ill in the seventh month, and uncontrollable vomiting set in. The right side of the abdomen alone was prominent; indeed, her left was flat. The uterus was enlarged, but the abdominal swelling corresponded to a tumour as big as an adult head entirely to its right. The fetal heart sounds were audible. As there was increasing anaemia, Bazy operated. The tumour was extremely vascular, so as to look like a sponge soaked to its full with blood. It broke up on handling, bleeding to an alarming extent, as it was full of big venous sinuses, but the operator found that the right utero-ovarian ligament ran on to it. The bleeding mass adhered closely to the uterus, which, in order to save time, was amputated with the tumour and right ovary. The left ovary being cystic, the left appendages were removed. Much peritonium was stripped off during the separation of the outer and lower part of the tumour from the adjacent parts, so as to necessitate gauze packing. The patient died thirty-six hours after the operation. Bazy describes minutely the microscopical appearances of the tissues of the tumour, which was a true cancerous degeneration of the placental tissues of a tubal gestation sac. Unfortunately no autopsy was allowed. Bazy reviews the other cases of malignant chorion-epithelioma of the gravid tube. Surgically the great vascularity and friability of the cancerous sac and its tendency to adhere to all adjacent tissues makes its removal far more difficult than the amputation of a tubal sac with its fetus and normal placenta. Out of 9 operations for the removal of a cancerous sac, it had to be removed piece by piece in no less than 5.

THERAPEUTICS.

359. Tuberculosis and the Salts of Copper.

LUTON (*Progr. méd.*, December 14th, 1912) points out that the value of the salts of copper in tuberculosis has been rather overshadowed by the general adoption of tuberculin as a means of treatment. All the various manifestations of tuberculosis are available for treatment by the salts of copper. Articular, osseous, glandular, and even testicular tuberculosis yield more or less rapidly to the treatment when begun early. Lupus also is successfully influenced by cupric medication. In the incipient stage of pulmonary

tuberculosis the results are very good, and the author quotes a case in the second stage which he treated by this method with marked success. He admits, however, that this is exceptional. If copper is given as an injection in a case of coxalgia, the affected articulation shows slight congestion for some days, and the tissues are painful. After three or four weeks, however, these symptoms gradually disappear. In the more advanced cases several injections may have to be given at intervals of a fortnight. The existence of fever is regarded as an obstacle to the treatment. For the purpose of injection the acetate and colloidal phosphate of copper are the salts most generally employed. Electro-cuprol, the chloride, and tartrate have also been used. Copper may be used internally in the form of a pill in cases in which the stomach is irritable or when the lesions are too advanced for hypodermic treatment. For tuberculous peritonitis and glandular conditions a paste of copper may be used in much the same way as mercurial inunctions, in a proportion of 1 in 100 or even 1 in 1,000 when there is an irritable surface lesion. When copper is administered internally it is as well to give a little milk or Vichy water, or a menthol pastille at the same time. The pill the author recommends is the acetate of copper—1 centigram for a dose. For hypodermic use the following formula is a good one:

| | |
|--------------------------|--------------|
| Sodium phosphatis | 5 gr. |
| Glycerini) | |
| Aquae) | āā to 60 gr. |
| and | |
| Cupri acetatis... .. | 1 gr. |
| Glycerini) | |
| Aquae) | āā to 40 gr. |

The two solutions are mixed without filtration. One gram of the mixture is equal to a centigram of the acetate of copper. In general the site of injection does not matter, but a deep injection into the buttock is on the whole the best procedure. If the resulting reaction is slight the injection may be repeated as discretion suggests. The duration of treatment varies, and the requirements of the case must be judged by results.

360. Injections of Alcohol into the Gasserian Ganglion.

W. ALEXANDER AND E. UNGER (*Berl. klin. Woch.*, January 27th, 1913) consider that peripheral and central resection of nerves for trigeminal neuralgia has become obsolete since the introduction of injections of alcohol into the branches of the trigeminal nerve. Hitherto relapses have followed both the resection of nerves and the injection of alcohol into their sheaths; and extirpation of the Gasserian ganglion has been undertaken as a last resort. But the difficulties of this operation are great, and its mortality, in spite of technical improvements, is still very high. The chief dangers are: Pressure on the brain during the operation, circulatory disturbances following ligation of the middle meningeal artery, venous haemorrhage, and neuro-paralytic keratitis. The authors claim that these dangers can be lessened if the ganglion is destroyed *in situ* by injections of alcohol. In one case they attempted to inject alcohol through the foramen ovale into the ganglion, using Hartel's technique. But they failed to find the foramen. They therefore exposed the ganglion by Krause's method without having to ligature the middle meningeal artery, or to use the large instruments necessary for extirpation of the ganglion. Only local anaesthesia was employed till the ganglion was exposed. Then ether was administered, for, had a solution of novocain been injected into the ganglion, the alcohol subsequently injected would have been diluted and its action lessened. A few minims of an 80 per cent. solution of alcohol were injected through a long needle into the intracranial portions of the second and third branches of the trigeminal nerve, as well as into that part of the ganglion from which these branches arise. As O. May has shown that regeneration of the ganglion may occur after a single injection of alcohol, care was taken to inject it in many places, so that many deposits of alcohol might become confluent and render the necrosis of the injected area complete. The patient thus treated had suffered since 1900 from toothache of the upper jaw on the right side. A year later the tongue and lower jaw were involved. In 1909 the infraorbital nerve was resected without any improvement. Injections of alcohol into the second and third branches of the trigeminal nerve gave only temporary relief, and the procedure described above was accordingly adopted in October, 1912. Headache and paraesthesia followed during the first few days. On the fifth day there were complete analgesia in the area supplied by the second and third branches of the trigeminal nerve, and slight lagophthalmos, owing to the division of

some branches of the facial nerve on the right side. The corneal reflex was, however, unaffected, and, though the lagophthalmos persisted, no disease of the cornea followed. No relapse had occurred two months after the operation, but the writers admit that the permanence of the results is not yet assured. Among the advantages of their procedure over extirpation of the ganglion is the accuracy with which its destruction may be limited. A part only of the ganglion may thus be treated, and, in the case described, that part of the ganglion was spared from which the first branch of the trigeminal nerve arises.

361. Rectal Injections of Salvarsan in Chorea.

WEILL, MOURRIQUAND, AND GOYET (*Annales de méd. et de chir. infant.*, December 1st, 1912) report a case of very grave chorea successfully treated by this method. A girl of 13, who had had a previous attack which had yielded to treatment by arsenic, came into hospital with a recurrence of a mild type. Instead of improving under ordinary treatment, she became worse; she grew pale and lost flesh, and the choreic movements became continual and generalized, so much so that she had to be fed, was unable to stand, and when in bed banged her arms and legs against the bedposts. It was decided to try salvarsan, but intravenous injection was out of the question on account of her condition, apart from the usual difficulty of finding the veins in children. She was accordingly given, by means of a long cannula, a rectal injection of 0.05 gram salvarsan, prepared as for intravenous injection, and diluted with 10 grams NaCl solution (5 per cent.), to which were added 5 drops of laudanum; the injection was retained scarcely an hour. In nine days an injection of 0.10 gram salvarsan was given, which was also retained an hour. In a week she showed slight improvement, and began to be able to feed herself; she was given 0.20 gram salvarsan, which she retained seven hours. After two days she showed marked improvement; she lay quietly in her bed, could answer questions, and could eat and drink without soiling the bed. She still retained some choreic movements, but they were not continuous. She became more happy and felt better; her appetite returned, and she began to gain weight rapidly. The treatment was admirably borne, and the writers are continuing in the hope of being able to report a complete cure in the near future.

362. Sulphur in Dermatological Practice.

THE application of sulphur in the treatment of skin affections offers some serious disadvantages. Vörner has therefore experimented with this subject, and offers two improved methods (*Munch. med. Woch.*, No. 35, 1912). The first he calls sulphuration. He prepares a concentrated solution of potassium sulphide in water; 50 grams are dissolved in 100 grams of water. This is a yellow fluid, and is to be painted on the skin, which must first be dried thoroughly and then freed from fat. After the fluid has dried on to the skin a second coat may be applied. The skin is then treated by blowing acetic vapour by means of a hand bellows, or, failing this, the surface may be dabbed with 5 to 10 per cent. acetic acid. When this is done the sulphur will be found adhering firmly and in a thick coat to every part of the skin on which the solution was painted. The second method is by ointment. He calls the ointment thiolan for convenience. It is prepared by dissolving 2 to 2.5 grams of sulphur in a kilogram of fat at from 50° to 100° C., then adding 45 to 50 grams of sulphurated oil, and lastly, the precipitate from 40 or 50 grams of calcium sulphurium, after it has been rendered anhydrous by washing on the filter paper with alcohol. He advises the application of heat with this ointment. He has obtained excellent results with both methods in those cases in which the therapeutic action of sulphur is desired.

PATHOLOGY.

363. A Serum Reaction in Psoriasis.

ACCORDING to A. Sommer (*Berl. klin. Woch.*, January 13th, 1913) the pupil of an isolated frog's eye dilates rapidly in normal serum, but it remains contracted if it is placed in serum taken from a patient suffering from psoriasis. He has tested this reaction in 21 cases, and has not once found it fail. It was also so definite that observers who did not know which of two specimens of serum were normal distinguished the one from the other merely by

the condition of the pupil. The serum employed for purposes of control was taken from healthy persons, and from the subjects of gonorrhoea, syphilis, soft sores, and lupus. None of them deviated from normal, and patients suffering from other skin diseases, such as dermatitis herpetiformis, lichen chronicus, lichen ruber planus, prurigo, and eczema, also exhibited no specific reaction when the frog's pupil was immersed in their serums. The reaction seems, therefore, to be confined to psoriasis, the extent of which varies directly with the strength of the reaction. Thus, when the disease involved a large area of the skin, the contraction of the pupil was very marked; while the contraction was less obvious, and was even followed by partial dilatation, when the psoriasis was limited to a few spots. The technique of the reaction is simple. The frog's vertebral column is divided, and its spinal cord is broken. Both eyes are enucleated and placed in physiological saline solution. From being widely dilated in the frog's head they at once become contracted in the saline solution. One eye is now placed in normal serum, the other in the serum of a patient suffering from psoriasis. In five to ten minutes the first eye is plainly dilated, while the second remains contracted. Only after half an hour, and when the psoriasis is not very extensive, does the second pupil begin to dilate. The reaction is also positive many years after psoriasis has disappeared, and this was the case with a patient who had suffered from psoriasis six years before, and who had subsequently exhibited slight transitory recurrences of the disease. The author considers that the reaction is due to conditions of the blood which cause the psoriasis, and that it is not a secondary manifestation dependent on the cutaneous eruption. Adrenalin, even in as dilute a solution as 1 in 20 million, acts on the pupil in the same manner as the serum in psoriasis. But in this disease the reaction is clearly not due to the presence of this substance, for if it be destroyed by oxidation before the test is carried out, the reaction is yet the same as before. The author therefore concludes that the reaction depends on bodies in the blood which resemble adrenalin, but which differ from this substance in not being readily destroyed by oxidation.

364. A Simplified Gram Technique.

STAINING by Gram's method is apt to be neglected, chiefly because the solution of gentian-violet in aniline oil rapidly deteriorates, and dirty specimens are the result of an attempt made with a partly-spoilt solution. Dr. Snyder, of Toledo, U.S.A., has devised a method (*Annals of Ophthalmology*, November, 1912) in which, instead of the gentian-violet stain, a stain made according to the following formula:

| Methyl-Violet Stain. | |
|-----------------------------------|------------|
| Melted carbolic acid crystals ... | 12.5 c.cm. |
| Absolute ethyl alcohol ... | 25.0 c.cm. |
| Methyl-violet 6 B (Gruebler) ... | 1.0 gram. |

Dissolve, keep in a warm place for twenty-four hours, and filter.

| Lugol's Solution. | |
|----------------------|------------|
| Iodine crystals ... | 1 part |
| Potassium iodine ... | 2 parts |
| Distilled water ... | 300 parts. |

The following method is recommended for staining smear preparations: A clean slide is taken, and the patient's number marked on it. A drop of formalin solution 1 in 1,000 in distilled water is placed upon the slide. Some of the secretion is evenly mixed with the drop of formalin solution. A drop of absolute alcohol is now placed upon the original drop to fix the slide. The author finds that alcohol fixation is superior to the flame method. When the alcohol evaporates, a thin smear is left upon the slide. Three or four drops of distilled water are placed upon the smear, and to the water is added one drop of the methyl-violet stain. This is left for twenty-five seconds, and then the slide is washed under the tap. Lugol's solution is now added, and after fifteen seconds the smear is decolorized with absolute alcohol. Now wash again under the tap and counterstain with a 5 per cent. watery solution of safranin or weak fuchsin for five seconds. Wash again, dry and examine, either with cedar oil alone or after a coverslip has been laid upon a drop of Canada balsam. It is best, however, not to use a cover-glass at all. The solutions keep indefinitely, and are always ready. The author describes a loop made of platinum-iridium wire for taking up secretion from the eye and from other situations. Those who work in hot countries where the aniline solution decomposes in a couple of days will, it is thought, appreciate the advantages of this stain.

AN EPILOGUE OF CURRENT MEDICAL LITERATURE.

MEDICINE.

365. Acute Fatal Tetany in a Day-old Child.

M. KRUGER-FRANKE (*Zentralbl. f. Gyn.*, January 11th, 1913) claims that the following case is in some respects unique. A primipara, aged 33, was confined with twins. After labour had lasted forty hours, the os was only 3 cm. wide, and the breech of the first child had not descended much. The pains also were weak. After labour had lasted sixty hours, a dead and macerated child was born. The liquor stank. Half an hour later the head of the second child presented at the os. The membranes were ruptured, and version was performed. The child was asphyxiated when born, and it was necessary to pass a catheter down the trachea to remove some stinking liquor which had been aspirated. Respiration was successfully started, but the child's cries were feeble throughout the day. Next day it was somnolent, and the cries were still feeble. The limbs were partially flexed at the elbows and knees, and did not yield to passive extension. Opisthotonos and cervical rigidity were also present, and all the muscles showed tonic contractions. The skin was like wet pulp, and stinking purulent matter was vomited. The stomach was repeatedly washed out with sterile saline solution; but no improvement followed, and the child refused nourishment. Death occurred on the second day. Streptococci were found in the intestine, which was opened under antiseptic precautions, and death was attributed to absorption of toxins from the intestines, and to sepsis. The author was unable to secure a necropsy on the brain, but he does not think that meningitis existed, for the period between infection and the onset of symptoms was too short for such a condition to be the cause of death. The earliest case of meningitis recorded is one in which the symptoms appeared five days after birth. This allows an incubation period of several days, whereas in the author's case the time between rupture of the membranes with consequent infection of the living child by the liquor of the dead child and the onset of symptoms was much shorter. The rarity of the condition described must be largely due to the present standard of cleanliness in midwifery; for a few decades earlier the mortality from sepsis among infants was as high as 30 per cent., according to Epstein, whose statistics are obtained from a maternity hospital in Prague.

366. Radiological Diagnosis of Pulmonary Granulation in Infants.

RIBADEAU-DUMAS and ALBERT WEIL, in a communication to the Société de Radiologie Médicale de Paris (*Bull. et mém.*, March, 1913) state that, while following up their work upon the radiological diagnosis of tuberculous in infancy, they have found it possible with suitable technique to obtain radiographic evidence of pulmonary granular processes in sucking children. In the cadaver very clear radiographs of pulmonary granulation are forthcoming, but in the case of the living it is necessary under ordinary conditions to have the thorax immobile and the exposure made in apnoea, and infants do not lend themselves to this form of examination. With instantaneous radiography, however, such images are obtainable, and the authors bring forward four cases, three being those of infants suffering from tuberculous meningitis, and the fourth that of an infant in a typhoid condition, and in each case small miliary spots studded over the pulmonary field were visible in the radiographs, the stereoscopic image making it plain that they occupied unequal depths. The comparison of the radiographs with necroscopic records of other cases confirmed the diagnosis.

367. Poisoning by Deodorized Gas.

E. THOMSON (*Petersburger med. Zeit.*, February 1st, 1913) gives an account of the poisoning by odourless gas of several persons in a house into which gas had escaped through the soil. The house was not supplied with gas, and the nearest gaspipe was underground several yards away. The house was one-storied and contained ten rooms. During the summer the drains were repaired and a new water supply and soil pipe were laid on and an old cesspool was closed. In the following winter, when the ground was frozen, a party was given. During the next night all the twelve persons

sleeping in the house suffered from intractable vomiting, violent headache, and lassitude. As none of the other guests who slept out was affected, and as three persons who slept in the basement of the house and who did not share in its festivities were included among the sufferers, the food and drink of the party were clearly not to blame. During the day the patients recovered, only to suffer from a more severe form of the illness on the following night. As soon as they slept elsewhere they recovered, while three volunteers who slept in the house developed their predecessors' symptoms. Poisoning by noxious fumes was suspected, but their source was not at first evident. The ground over the old cesspool was opened up, when odourless and inflammable gas was found to be escaping. This was clearly not sulphuretted hydrogen. The problem was solved when a leak was detected in a gaspipe as it passed over a water-pipe, several yards from the house. The gas had evidently escaped through the cesspool, up a ventilation shaft which opened under the house, and had thus invaded the whole house. The frozen condition of the ground may account for the direction in which the gas passed.

368. Blindness as a Result of Acute Anaemia after Loss of Blood.

BETREMIEUX (*Echo méd. du Nord.*, 1912. ix) narrates the case of a man who suffered from severe hæmatemesis, and two days after the last attack complained of feebleness of vision, which gradually increased until total blindness resulted. The ophthalmoscope revealed complete atrophy of the papillae. The author quotes other instances from the literature and draws attention to Terson's treatment—namely, an injection of 400 c.cm. of artificial serum—as worthy of consideration.

369. Cardiac Symptoms of Endemic Goitre.

J. BAUER (*Deut. med. Woch.*, October 17th, 1912) has analysed the various cardiac disturbances associated with endemic goitre and has compared these disturbances with those met with in Graves's disease. He finds that in endemic goitre a pathological condition of the heart can be recognized clinically, which is quite distinct from the condition spoken of as "Kropfherz" (goitre-heart). The condition which he describes is characterized by a systolic murmur, which is best heard over the pulmonary orifice by an accentuation of the second pulmonary sound and by an extension of the cardiac dullness to the left. The impulse at the apex is not increased, the pulse is not accelerated, and subjective cardiac symptoms are not complained of. He is of opinion that this form of cardiac disturbance is toxic in origin, the noxious agent being the thyroid gland. He suggests that the condition may be spoken of as a "torpid" type of a thyreo-toxic goitre heart, as contrasted with the "erethic" type, described by Krauss. He recognizes transitions from what he describes as the normal, dysgenital heart disturbances due to anaemia, pseudochlorosis, etc., to the torpid and to the erethic types of goitre heart disturbances.

370. Hydatid Cyst in Children.

VERDELET (*Gaz. hebdom. de la Soc. Méd. de Bordeaux*, 1913, No. 18) describes a case of paranephritic hydatid cyst in a child of 8, a hydatid cyst in a child of 10, both ending in recovery, and a case of multiple hydatid cysts of the abdomen in a child of 7 ending in death. The condition is rare in children. Of the author's 23 personal observations only 3 were in children. The dog is the animal which always propagates the disease. The treatment is always surgical.

SURGERY.

371. Removal of a Tuberculous Bladder.

L. CASPER (*Berl. klin. Woch.*, March 17th, 1913) claims that the following case establishes certain of his contentions which have hitherto been opposed: A man suffered from advanced tuberculous of the left kidney, which was removed. The vesical symptoms from which he had suffered before the operation abated, and the urine secreted by the remaining kidney was clear, and contained only a moderate number of leucocytes. At the end of the

next six years, during which the patient pursued his work as a locksmith, he again suffered from violent pain in the bladder, continuous tenesmus, and painful micturition, which was distressingly frequent. The urine was cloudy and purulent. The patient was extremely emaciated, and as no other treatment gave relief, the bladder was completely removed, and the right ureter was implanted into the skin in the lumbar region. The pain and tenesmus ceased at once, and the patient gained 12 lb. in weight during the following three months. At this stage he was shown to the Medical Society of Berlin, when the urine escaping by the ureter was clear, and contained only a few leucocytes and casts. During the discussion which followed three objections were raised to the author's action. It was urged that puncture of the bladder was preferable to extirpation. But the former increases instead of relieving pain and tenesmus, and the presence of a cannula or permanent catheter in a tuberculous bladder renders previously intermittent tenesmus continuous. A second objection raised was the difficulty of collecting the urine from a ureter transplanted to the skin. This objection is certainly valid, although the latest contrivances enable the patient to keep dry except under certain movements, when a few drops of urine elude the best fitting receptacle. A third objection to the author's procedure was based on the common supposition that a kidney whose ureter opens directly on the surface of the body must inevitably be destroyed, sooner or later, by an ascending infection. This objection, raised three months after the operation, could not forthwith be dismissed as invalid. But nearly a year and a half after the operation the urine was found to be perfectly clear and without a trace of albumen. It contained a few leucocytes, but no bacteria. The patient at this stage was free from his previous symptoms, could walk without much discomfort, and could pursue the occupation of a caretaker.

372. Early Recognition of Vesical Tumours.

CRUTE (*Boston Med. and Surg. Journ.*, February 27th, 1913) discusses the unsatisfactory character of the results of operation in these cases. He points out the great range of operative treatment from intravesical cauterization of papillomata to the removal of a part, or even the whole, of the bladder. But having realized the limit of operative possibilities, satisfactory results, he states, can only accrue when earlier recognition of these cases occurs than is at present the case. To this end the author refers to the significance of haematuria, which is seen quite early in these cases. As this occurs in many other conditions, and is often in any case unattended by pain, there is too often a dilatory method of dealing with it. Haematuria as a symptom should be regarded in much the same light as a tumour of the breast now is. It may be innocent and trivial, but this must be definitely demonstrated to be the case. The author states that he has not seen a tumour of the bladder which was not actually or potentially malignant. Even papillomata, although microscopically benign, may proliferate and finally break down, ulcerate, and become septic. The author emphasizes the difficulty at times of discovering the source of the bleeding. A cystoscopic diagnosis cannot be made in a single examination. Before operation it is essential to accurately localize the lesion, as in the open and collapsed bladder there is much difficulty in recognizing a small and non-infiltrated area. The author's conclusion is that the only satisfactory treatment of tumours of the bladder is early and complete removal by excision.

373. Amauroses and Amblyopias from Ischaemia after Haemorrhage.

DUBOT AND PIERRET (*Echo méd. du Nord*, 1913, No. 17) review, with four personal observations, amauroses occurring after haemorrhages from various organs. Haematocremia has been the preceding cause in about 35 per cent. of cases, metrorrhagia in 28 to 38 per cent., epistaxis in 7 to 8 per cent., haemoptysis and haematuria in 1 per cent. In some cases the blindness is fluctuating, in others acute, and in others delayed. The lesions are nearly always bilateral. The pupils are clouded, unequal, and dilated, light reflex is diminished, and accommodation enfeebled. Examination by the ophthalmoscope may be negative. In the majority of cases papillary discoloration occurs, the fundus of the eye being pale, the arteries frequently contracted, the veins slightly increased in size and filled with blood. In a second form papillary oedema occurs, the arteries are markedly contracted, and the veins tortuous and dilated. Retinal haemorrhages are frequent. The commonest termination is simple atrophy with slight excavation of the papilla. In cases of amblyopia the atrophy is only partial. The prognosis is always very

grave. In cases where there are no appreciable lesions of the fundus, *restitutio ad integrum* is the rule, but when the papilla is strongly affected cure or amelioration are rare. The essential cause is a retino-optic ischaemia. The treatment consists in arresting the haemorrhage, for which purpose gelatine, calcium chloride, and haemopoietic serums are useful. The head should be lowered and the patient placed in the horizontal position and the limbs elevated and bandaged. Amyl nitrite or trinitrine may be given with advantage. Subcutaneous or intravenous injections of physiological serum, transfusion of blood, and injections of ether and caffeine or spartein should be employed, and subconjunctival injections of sublimate (1 in 2,000) and chloride of gold (1 in 1,000) have been recommended, as well as iridectomy and sclerectomy.

374. Formalin Treatment of Echinococcus Cysts.

FELIX FRANKE (*Zentralbl. f. Chir.*, No. 29, 1912) recalls the formalin treatment of the echinococcus sac recommended by him eleven years ago. He still regards his method as superior to the methods of injection of iodoform and glycerine and of sublimate solution. A recent case is typical of all. The patient was a woman of 57 who had a very large echinococcus cyst in the right lobe of the liver, first properly differentiated after removal of a piece of rib for exploration. The cyst was emptied of innumerable daughter cysts of varying size. These formed a thick pulpy mass, requiring to be removed with a tablespoon and weighing 5½ lb. After thorough cleansing of the sac with spoon and gauze swabs, the cavity was filled with 50 grams of a 5 per cent. solution of formalin in glycerine and water, and thoroughly washed out. The sac was closed in two layers with catgut, and the large abdominal wound also was closed except for a small drain leading down to the sutures of the closed sac. Primary healing followed, and sixteen days after the operation the patient left the hospital. Examined two months later liver dullness was rather less than normal. The author regards the method as superior to drainage or attempts to extirpate the echinococcus sac. The technique of treatment by formalin will depend on the nature and condition of the echinococcus lesion. A simple cyst filled with fluid only may be punctured and emptied as completely as possible, filled again with 150 to 300 grams of a ½ to 1 per cent. watery solution of formalin; this is left in the cyst for five minutes, and is then permitted to flow out by the cannula; lastly, the puncture is closed by a purse-string suture. A small quantity of formalin remains in the cyst, and suffices to kill remaining daughter cells. If the contents of the cyst are not simply a thin fluid, instead of the watery solution a 5 per cent. solution of formalin in glycerine may be employed; its weight permits it to reach outlying corners of the cyst cavity. Should the contents of the cyst be a pulpy mass, as in the case narrated, the cyst must be opened wide, the contents thoroughly evacuated, its walls cleansed with gauze swabs, the cavity filled with formalin glycerine solution, and almost completely emptied again. The cyst may be diminished in size by doubling in sutures. Extirpation of the sac is unnecessary, and often, indeed, is dangerous, as the author found in a recent case.

375. Abnormal Mobility of Caecum.

DELBET (*Rev. de Thérap.*, 1913, No. 10) finds that abnormal mobility of the caecum and dilatation of that part of the intestine are capable of producing certain symptoms resembling appendicitis and thereby leading to an error in diagnosis. Fixation in the former and removal in the latter condition are frequently successful.

OBSTETRICS.

376. Treatment of Haemorrhagic Disease of the Newborn.

VINCENT (*Archives of Pediatrics*, December, 1912) gives notes of 15 cases of haemorrhagic disease of the newborn, and advocates the use of human blood or its derivatives in the treatment of the condition. Eleven of the cases, of which eight were cured, were treated by transfusion, the treatment effecting an immediate change from sickness to health. Four cases received injections under the skin of the back of whole human blood drawn from an adult, and, although these cases ended fatally, the issue cannot be attributed to ineffectiveness of the treatment, since three of them were moribund, and in the fourth the injection was not repeated as should have been the case. Since the trouble is probably due to a defect in the infant's blood,

which is apparently improved by either injections of serum or whole blood, or by transfusion, it would seem that the latter is more likely to be the ideal method, because it directly restores to the circulation all the elements needed for coagulation, besides correcting the anaemia by replacing the cellular elements lost through haemorrhage. Where bleeding is rapid and profuse, immediate transfusion is indicated, but where the initial haemorrhages are slight, blood or serum injections may be undertaken, a whole-blood injection being administered first to save delay, and sufficient blood being collected to furnish serum for further treatment. Transfusion is a more formidable procedure than serum or blood injection, but its results are immediate and permanent. The author transfuses with coated glass tubes 13 cm. long and 3 mm. in diameter, the end inserted into the infant's vein being 2.5 mm. in diameter. The danger of air embolism may be averted by filling the tubes with salt solution, which is held in the tube by a small plug of sterile cotton covered with vaseline. The radial artery of the donor is connected with the infant's external jugular vein, a flow of five minutes usually being sufficient, and care should be taken that the flow is not too rapid and is stopped when the infant's face regains its normal colour. With the exception of those cases where the bleeding is due to bacterial infection, syphilis, and ulceration of the stomach or duodenum, or where the location and not the extent of the haemorrhage is the vital factor, as in the brain adrenals, etc., experience shows that the use of human blood or its derivatives properly applied to suit each individual case is capable of curing a large percentage of these cases.

GYNAECOLOGY.

377. Radiotherapy of Uterine Fibroma.

JAULIN, in a communication to the Société de Radiologie Médicale de Paris (*Bull. et. mém.*, April, 1913), states that he has treated nine cases of uterine fibroma by means of x rays, the principal value of his observations lying in the fact that the six successful cases date back for a considerable period. Of the three others, two were still under treatment, and the third, a woman of 64 years in whom the tumour had taken a malignant aspect, was a failure both with x rays and with subsequent surgical treatment. The author's original practice was to use an aluminium filter 1 mm. in thickness, the equivalent spark being 10 to 12 cm., and the dose about 3 Holzkecht units (tint 0 on the Bordier chromoradiometer, or 6 X on the quantimeter of Kienböck) at the point of introduction. The rays were directed principally to the ovaries, the irradiation being made at the iliac fossae and in the flanks, while the median region occupied by the fibroma was little or non-irradiated. When patients complained of sharp pain at the region of the sacrum, irradiation was also made at the posterior part of the pelvis. Later he gave higher doses, using a filter of 2 mm. thickness, but he does not believe, after observing the reactions obtained on the skin of his patients, that it is prudent to go beyond the limits of tint 0 under the filter. He has waited three weeks or a month before returning to the irradiation of the same point. The definite results obtained in the six cases of functional cure were: (1) The suppression, not only of the haemorrhages, but also of the menses; (2) the suppression or diminution of the pain; and (3) the decrease in the size of the fibroma, though in no case did this disappear completely. Upon the disappearance of haemorrhage and pain, however, he classes the case as cured, for these are the symptoms to which the patients attach most importance. The age of the six patients cured varied from 36 to 47 years. In two instances the haemorrhages were augmented at the beginning of the treatment.

THERAPEUTICS.

378. Artificial Pneumothorax in Phthisis.

LEURET (*Arch. gén. de méd.*, March, 1913) considers that the only cases of pulmonary tuberculosis suitable for treatment by artificial pneumothorax are serious cases with unilateral lesions, not spontaneously curable, not associated with serious visceral lesions, and with a sound heart. Tuberculous laryngitis is a particular contraindication. The treatment is thus of very limited application, and in a large number of cases Leuret has found less than 4 per cent. suitable. The primordial indication is in acute cases, but the author thinks the method might usefully be employed in chronic cases with acute

exacerbations. With regard to results, the author has never experienced such accidents as sudden death, pleural epilepsy, etc., noted by other writers, but he has several times observed violent pain, with shallow respiration, small pulse, cyanosis, coldness of the extremities, cough and vomiting. Such symptoms have passed off rapidly, and were only seen in his earlier cases, when the injections were probably made too rapidly. Extreme slowness of penetration of the air into the pleural cavity is the most certain means of prevention of these ill effects. The immediate therapeutic results are often remarkable. The temperature falls, often to normal, after a twenty-four hours' exacerbation; the expectoration is rapidly diminished; the cough becomes infrequent; the general condition is improved, and the tuberculous process is arrested. Unfortunately the "cure" is only temporary, all Leuret's patients having relapsed after a variable interval; and he holds with Burnand that the method is not of universal application, but is an expedient to be proposed to patients who would be condemned to death without it.

379. Deaths after Salvarsan and Neo-Salvarsan.

BUMIER (*Ann. des mal. vén.*, February, 1913) has collected 23 cases of death after the administration of salvarsan and neo-salvarsan during six months. Analysis of these cases shows (1) that the subjects were mostly young, from 19 to 32 years of age; (2) that death nearly always occurred after the second injection in the case of salvarsan, and the third or fourth in the case of neo-salvarsan; (3) that the dose of salvarsan was not usually above 0.60 gram, and in some cases was only 0.30 or 0.40 gram, but in the case of neo-salvarsan high doses of 1.20 or 1.40 grams were often given; (4) that the injections were mostly intravenous, but in two cases death occurred after the second injection of 0.35 gram, and after an intramuscular injection of 0.30 gram in each buttock; (5) that the toxic effects are in most cases identical with those produced by experiment; almost immediately after injection appear fever, vomiting, diarrhoea, sometimes scarlatiniform eruptions, paralysis, delirium and convulsions, followed by coma and death on the third or fourth day after injection; (6) that at the autopsy there is generally found hyperaemia of the brain and meninges, haemorrhagic encephalitis and congestion of all the viscera. To explain these accidents faulty preparation, impurities in the distilled water, Herxheimer's reaction, etc., have been invoked. It appears more rational to attribute them to arsenical poisoning, since the accidents correspond to those observed in arsenical intoxication. Bumier concludes that as there is no criterion by which these accidents can be avoided, even in young subjects with no organic disease, nor any therapeutic means by which they can be got rid of when produced, such dangerous substances cannot be used with too great prudence.

380. Anogon.

E. KOCH (reprint from the *Med. Klin.*, Nos. 39-40, 1912) has investigated the pharmacological action of a compound known as "anogon," which is the di-iodoxy-(p) sulphobenzoate of mercury, having the formula $C_6H_4I_2O-11g-SO_3-Hg$. Anogon contains 48.95 per cent. of Hg and 31.78 per cent. of I, is insoluble in the usual solvents, and can well be used in oily suspension. It possesses a strong antiseptic action, which is due to the primary splitting off of iodine and the subsequent liberation of mercury ions. Rabbits tolerate doses of 0.1 gram without symptoms of toxic effect, while 0.54 gram was given in seven weeks without disturbance. The chemical changes were followed in mice. After injection, highly refractive, clear rhomboid crystals appear in the yellow anogon mass. Within a short time some crystals are seen free. A little later, minute black globules of about one-tenth of the size of a red blood corpuscle, with a distinct concentric outline, are seen. These have the appearance of a percussion cap. The next step in the dissociation is the liberation of iodine and the formation of the sodium or potassium salt of the compound. Koch states that the black droplets are mercury in colloidal condition. The reaction locally is not great, but the number of leucocytes which aggregate is large. At no time does the organism absorb a considerable quantity of mercury at one time. He is of opinion that the mercury ions are present in small quantities and in low concentration, but that they are continuously being liberated. He therefore conceives that anogon should prove itself a good reliable mercury-iodide preparation, which will not give rise to alarming toxic properties. He suggests that the utility in syphilis should be marked, in that the mercury would kill off the spirochaetes and the

iodine neutralize the endotoxins, and clear them out of the organism. He states that it has been tried with good results in Strassburg and Dorpat for syphilis.

381. Intravenous Injection of Salvarsan in the Chorea of Sydenham.

MARIE AND CHATELIN (*Bull. de l'Acad. de Méd.*, December, 1912) draw attention to the value of salvarsan and neo-salvarsan in this condition. Four injections in doses of 20 to 35 cg. were given at eight days' interval. They have had no accident of any kind, or, at the most, a transient malaise, and, in some cases, a scarlatiniform eruption. This method of treatment is more rapid in its results than any other treatment, the duration of the disease being shortened to about a month from the commencement of the treatment. A marked feature in all cases was the rapid improvement of the general condition, more especially of nutrition, and this was so even when the choreic movements disappeared comparatively slowly. A certain number of the patients who had suffered severely from vomiting and almost complete anorexia developed an appetite and gained weight. This eutrophic action was one of the remarkable features of the treatment. The ages of the patients varied from 8 to 19 years and in a good many of the cases the Wassermann test was done on the cerebro-spinal fluid with negative results. The author quotes Von Bokay and Haines as being the first to use salvarsan subcutaneously in classical cases of chorea. Recently Weill and others have used "606" per rectum in chorea, and claim to have obtained an appreciable amelioration of the symptoms. The authors do not believe that the beneficial effects which follow the use of salvarsan in chorea are in any way proof that the disease is syphilitic in origin. The arsenic may quite well be supposed to act by increasing the leucocytes and so adding to the resistance of the body to toxins.

382. Iodides in the Treatment of Tuberculosis.

NIEVELING finds that the physician is forced at times to resort to medicamentous treatment in phthisis, and has turned his attention to the effects of iodglidin, of which he states that better results are obtained than when creosote or guaiacol preparations are used (*Berl. klin. Woch.*, October 14th, 1912). He gives the details of a number of cases treated with iodglidin, and concludes by stating that in nearly every case the thick, sticky mucus is rendered more fluid and is more easily expectorated. In the majority of his cases the dyspnoea was markedly relieved by the iodide, the cardiac action became stronger, and in numerous cases the palpitations ceased. He is not in a position to say whether iodides can affect the fever of phthisis; in the febrile cases in which he employed iodglidin no benefit was derived. He is, however, of opinion that iodine influences the scarring and induration of pulmonary foci favourably, and at all events delays the disintegration of tuberculous tissue. He naturally does not suggest that iodides should be given in substitution of the general treatment, but as a supplementary measure.

383. Indications and Contraindications of Potassium Iodide in Syphilis.

GAUCHER (*Journ. des praticiens*, 1912, xxvi) finds that this drug is an adjuvant of mercury, and should be given at all stages of syphilis in serious cases. It is contra-indicated in laryngeal lesions, owing to its power of producing congestion of the membrane, and should be given with great caution in pulmonary tuberculosis, whether associated or not with syphilis. In gumma of the lung it acts, on the contrary, very well, and should be administered. In acute nephritis iodide should not be given; in secondary syphilitic nephritis it likewise should be avoided if the amount of urine is scarce, but if abundant with a normal amount of urea, it is an excellent remedy. In amyloid degeneration it is the remedy *par excellence*.

PATHOLOGY.

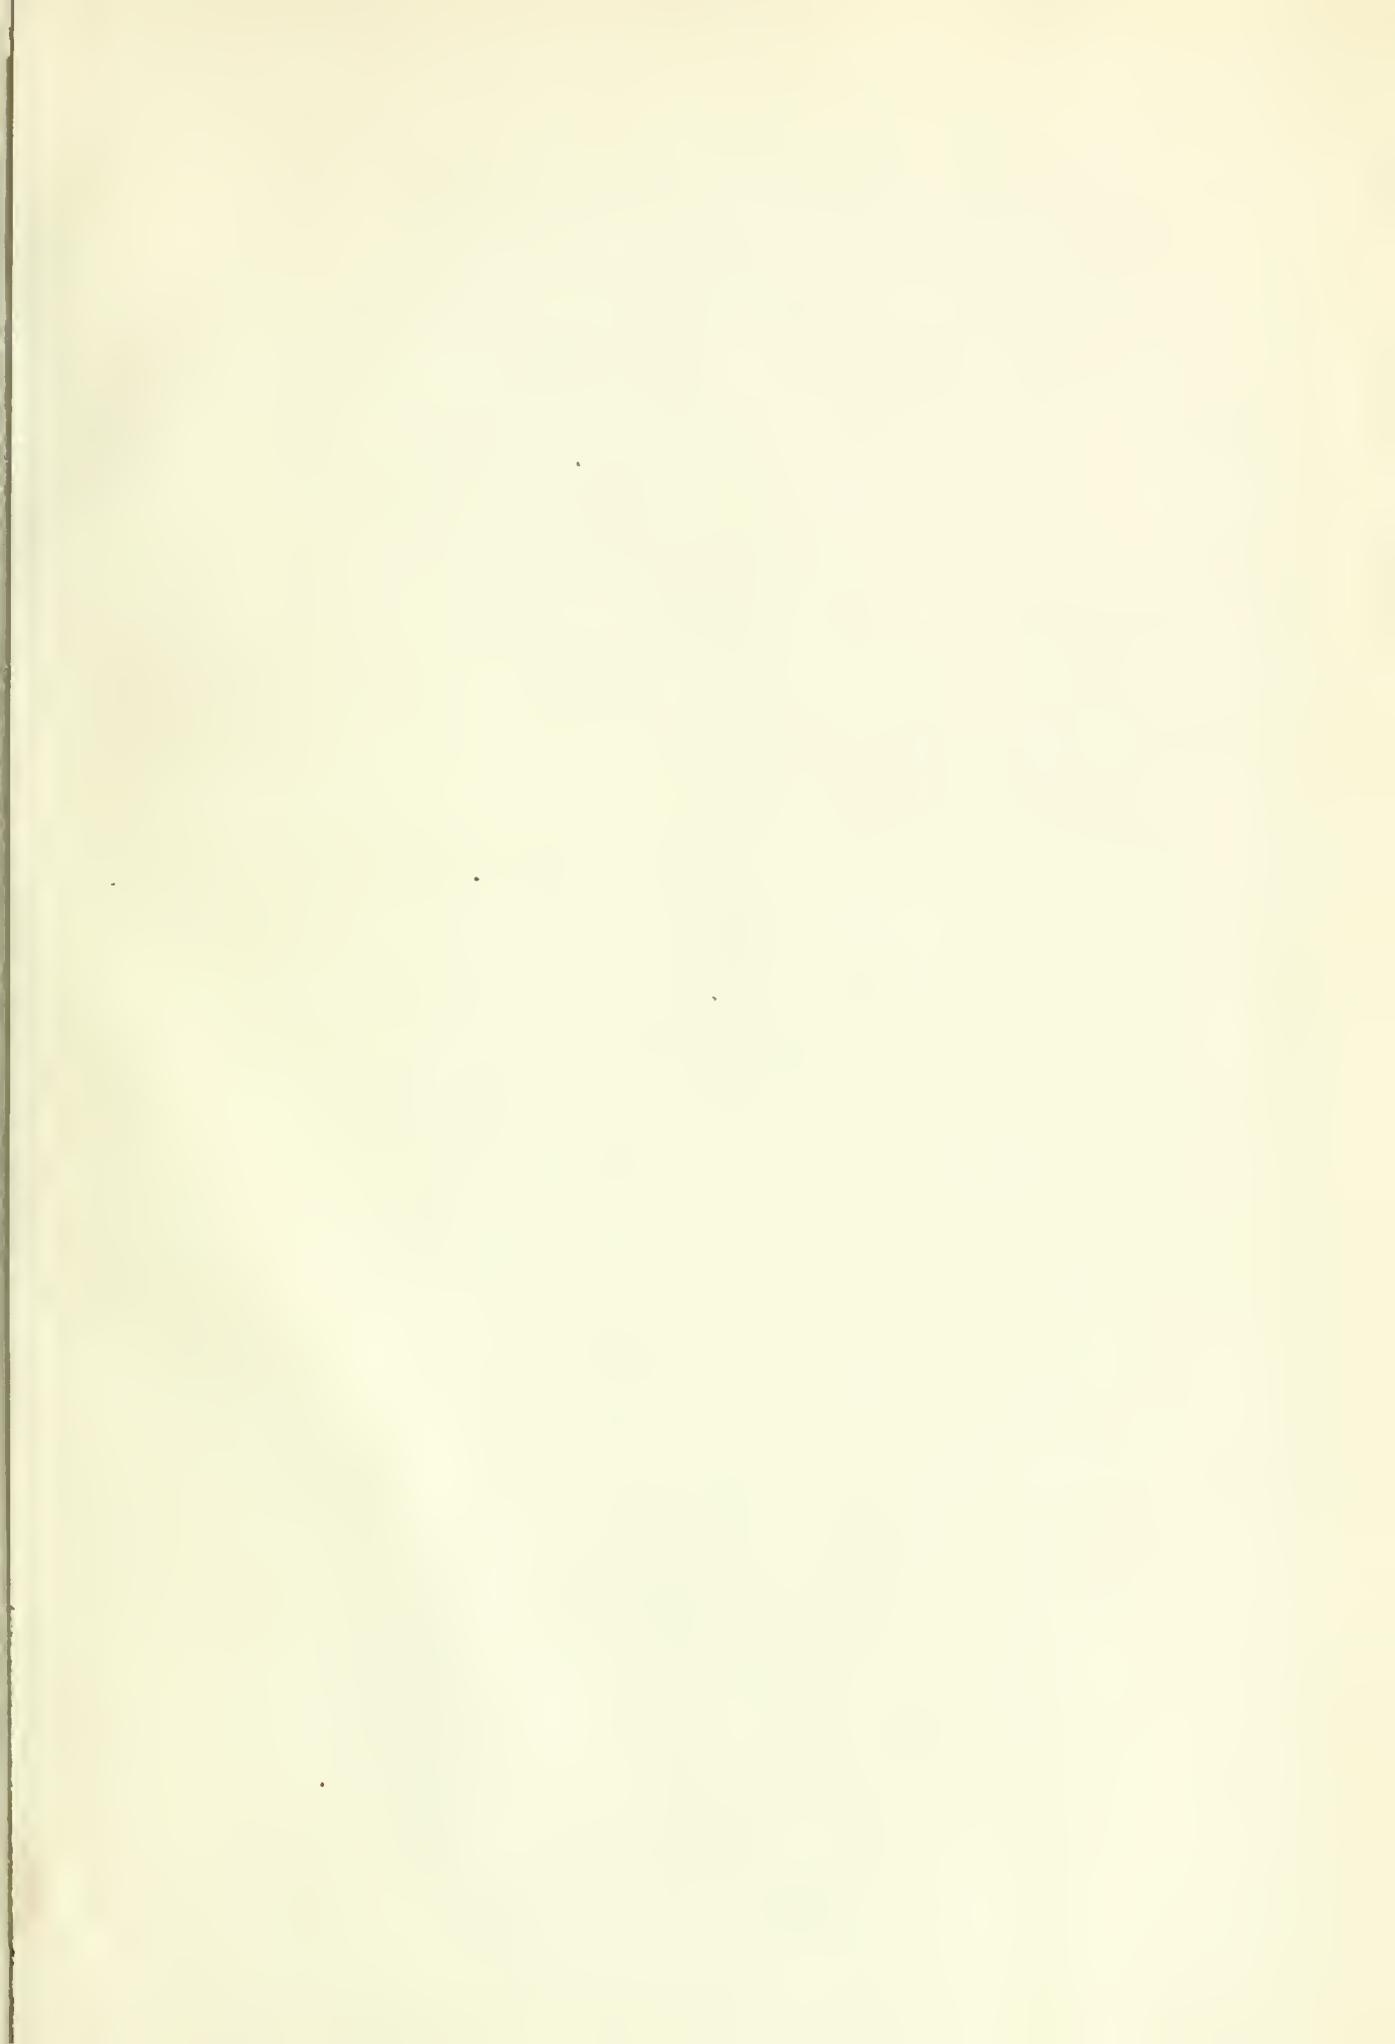

384. Antitoxic Content of the Blood of Diphtheria Patients.

IN theory the effect of injecting diphtheria antitoxin during a severe attack of acute diphtheria would be that a greater or less proportion of the antibody introduced would be bound by the diphtheria toxin and that the rest of the stock, so to speak, would be used up during the remainder of the illness. W. Beyer (*Deut. med. Woch.*, No. 50, 1912) has investigated this problem and finds that

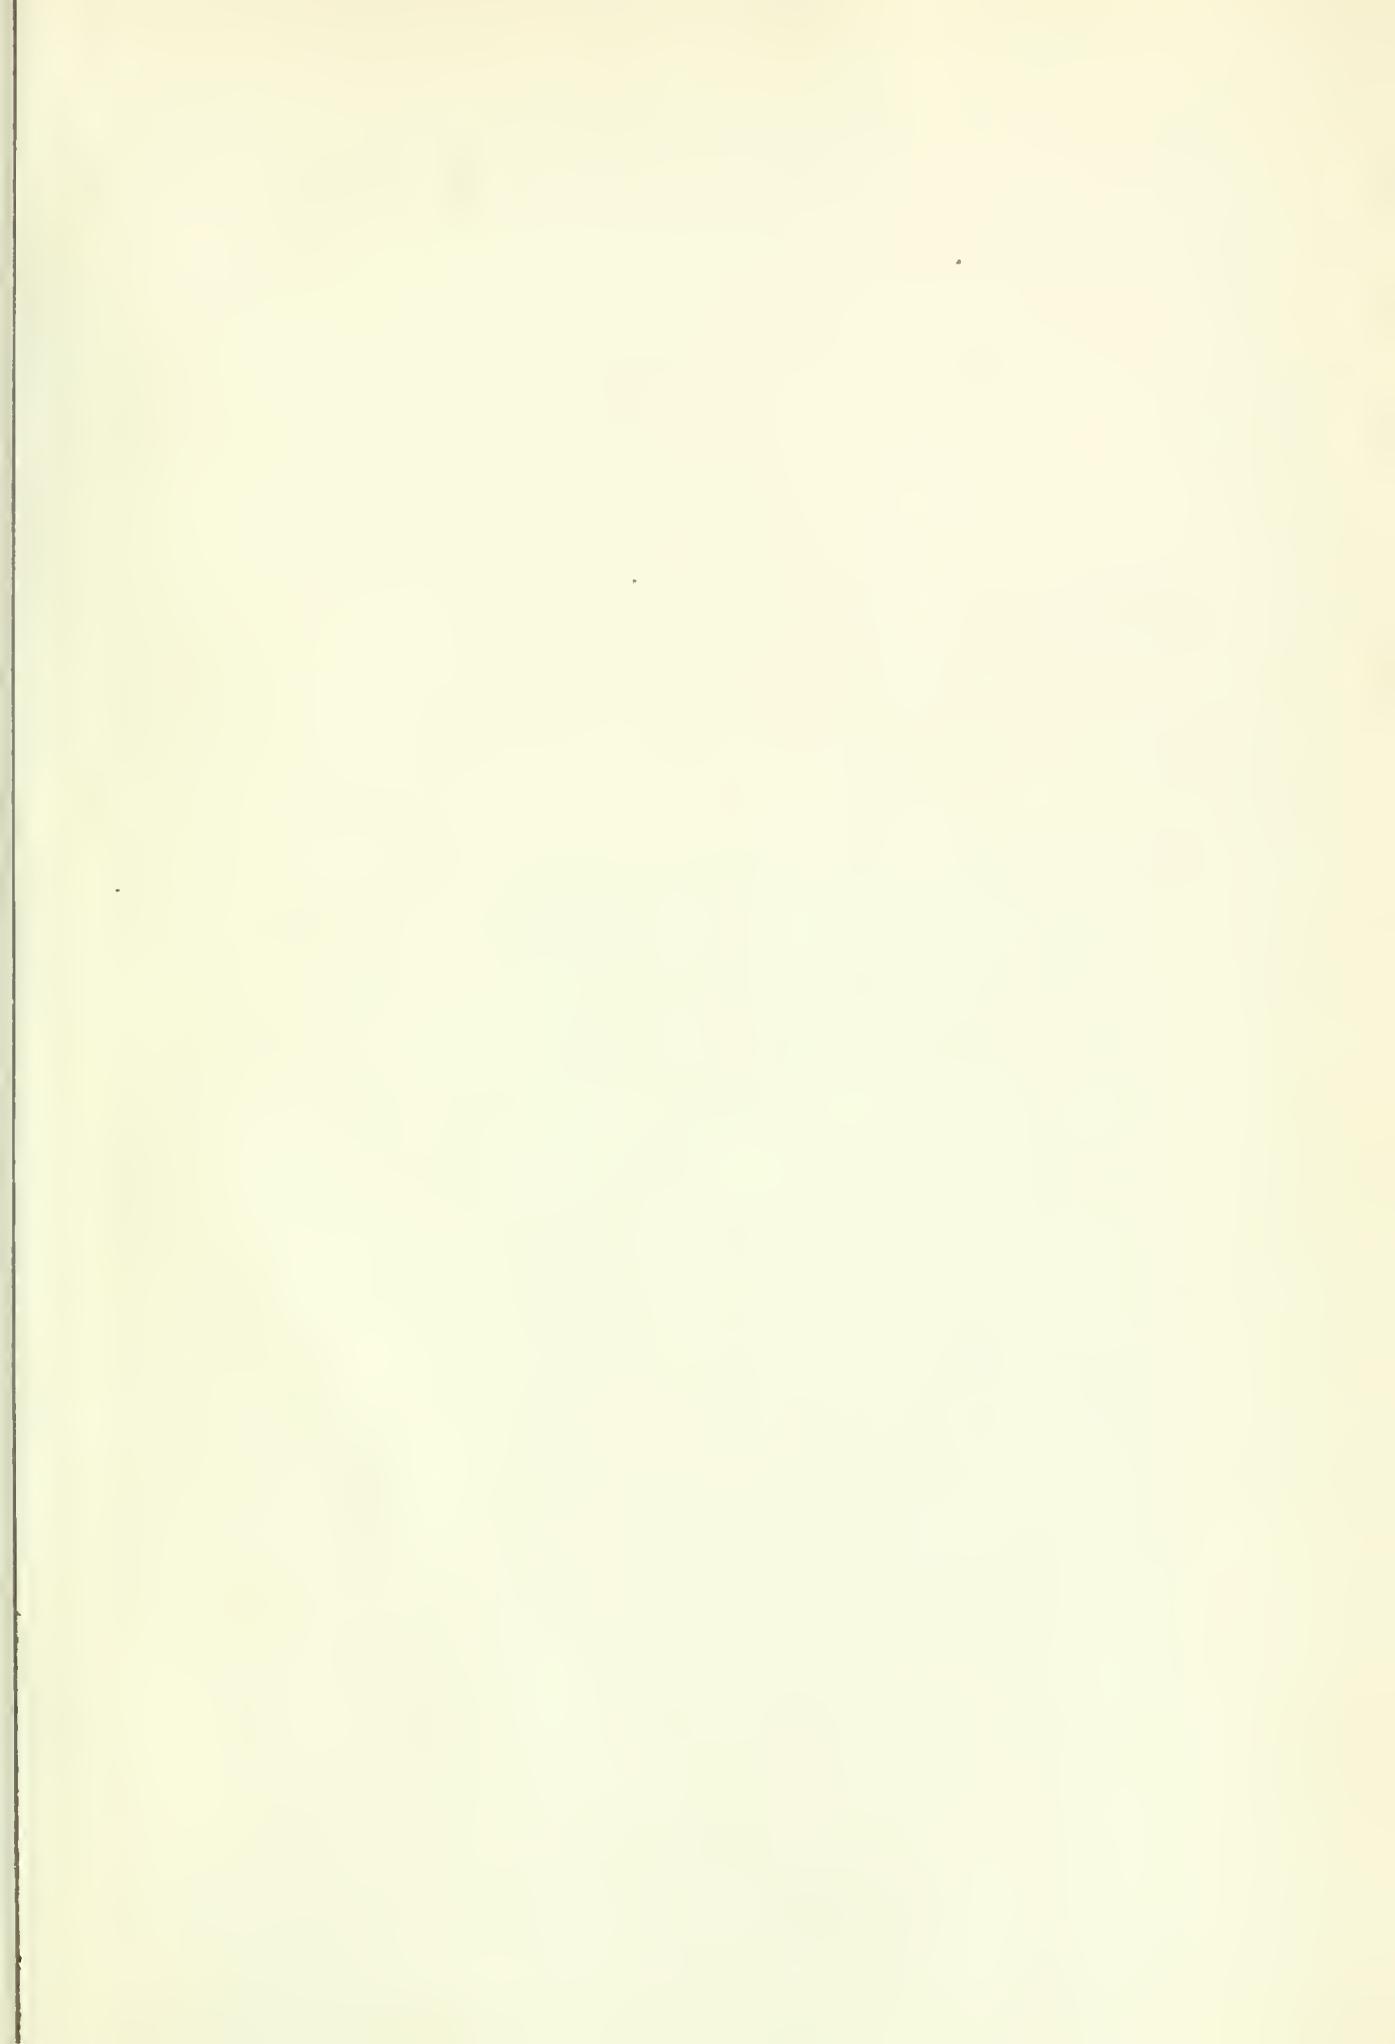

these theoretical expectations are not realized. He claims that his results bring fresh proof of the extreme activity of the antitoxic treatment of diphtheria. His method consisted in collecting the serum of patients who had received antitoxin, before and after the injection, diluting this serum and mixing it with measured quantities of diphtheria toxin and injecting the mixture into guinea-pigs. His results were as follows: In no early case before antitoxin was administered could he discover any antitoxin in the mixture at all. This held good up to the end of the febrile period. In a number of mild and severe cases which were treated by antitoxin, practically the whole of the antitoxin was accounted for in the blood shortly after the injection. This was arrived at by titrating the serum drawn off with the toxin, calculating the amount in antitoxin units in the sample used and calculating this content for the total quantity of blood. When the antitoxin was injected intravenously, nearly the whole was accounted for within a short time, but if the antitoxin was injected under the skin, the absorption was much slower. In one case only one-fifteenth of the injected quantity was found on the following day. The author draws from this the deduction that in acute cases it is far better to inject intravenously than subcutaneously. The quantity of antitoxin usually diminishes slowly, about one quarter to one half of the quantity being frequently found on the third or fourth days. On the sixth day he often found as much as one-third to one-fourth, while on the seventh day he found one-sixth. After two or three weeks the quantity still found was very small, and in some cases none was found. He continues to discuss the negative finds late in convalescence. It thus appears that no antitoxin is formed actively in the body of a patient who has been treated with antitoxin. He leaves it an open question whether the small quantities of toxin which are absorbed into the circulatory fluids are so completely neutralized by the large excess of antitoxin that no stimulation is present for the active formation of native antitoxin. In conclusion, he pleads for early intravenous injections rather than large doses.

385. Circumscribed Necrotic Fatty Tumours.

HERMANN KÜTTNER (*Berl. klin. Woch.*, January 6th, 1913) describes some unusual conditions which he considers may be of value in throwing light on the pathology of fatty tissue. In the first case, that of a 56-year old somewhat corpulent lady, abdominal attacks of considerable severity recurred within the course of three weeks, and on physical examination, a round, hard tumour of the size of a fetal head was found in the ileo-caecal region. He was inclined to regard the tumour as inflammatory. At the operation, on separating the coils of adherent intestines, some opaque fluid escaped. This fluid did not have any characters of pus, but rather looked like necrosed fat. A cavity was then found in which a large mass of particulate material was found. This was removed, and after it was ascertained that the appendix was quite intact, the wound was tamponed. Microscopically, the material proved to be necrotic fat, with a few round cells and some fat granular cells. No elements of a tumour were discovered, and the bacteriological examination proved negative. The second case was that of a stout man, aged 45 years, who was taken ill suddenly, with violent vomiting, rigors, and high fever. He complained of pain in the region of the stomach and liver, radiating to the right shoulder and arm. No flatus or stool was passed. A tumour was felt in the region of the gall bladder, and an operation was undertaken for its removal. Attached to the ascending colon at the level of the gall bladder a tumour was found in the omentum, having all the appearances of necrotic fat. It was removed. Nothing else pathological was found, and the patient made a good recovery. Microscopically, the tumour proved to consist of connective tissue septa, containing numerous leucocytes, large cells containing blood pigment and spindle connective tissue cells. Between the septa were fat lobules of necrotic fatty tissue. In a third case a mammary tumour was removed which likewise proved to consist of fatty tissue imbedded in connective tissue septa. In this case there was marked inflammatory infiltration of the septa, with numerous lymphocytes, and spindle-shaped cells. In the necrosed fatty portions some giant cells were seen in which bundles of needle-shaped crystals were placed. These stained pale yellow with Sudan stain, and dark blue with Fischler's fatty acids stain. The author considers that it is more probable that the chronic inflammation followed as a secondary process on the splitting up of the fat. He considers that these tumours deserve notice in view of the fact that they differ in several respects from the fat necrosis described by Lanz, Targett, Shattock, and others.
