IT seems that the day of oblivion for the sundial is not yet. Under its modern name of "sol horometer"—a name chosen, we imagine, to confound the poets—it is still counting the sunny hours. But as a concession to a world which is less inclined to take trouble than formerly, its mechanism has been adjusted to show the standard time to within the fraction of a minute without any mental deductions and allowances for position. A sector under the bowl of the instrument indicates the correct angle for any latitude, and the instrument is tilted accordingly. To enable the time to be read with precision, a box-shaped screen, somewhat resembling the eye-piece of the radiologist's fluoroscope, extends pivoted across the engraved surface. The purpose of this screen is to reduce the radiation of the light to a minimum, and thus secure a sharp image, which, after the slight adjustment of the dial for the date, duly passes the time of day. The instrument, which is described and illustrated in a pamphlet by Messrs. Pilkington and Gibbs, Limited, of Preston, is clock, calendar, and compass in one, and its appearance on an appropriate pedestal and with the inevitable motto around it, combines old-world dignity with chronological exactitude. The only disturbing element in this method of time-keeping is due to the erratic absences of the sun itself.

THE foundation stone of the new Helena Building at the Royal Free Hospital, Gray's Inn Road, was laid on May 19th by Princess Christian of Schleswig-Holstein, who was received on her arrival by the Earl of Sandwich (Chairman of the Hospital Committee), the Archdeacon of London, Dr. Harrington Sainsbury, Mr. James Berry, Miss R. Cox-Davies, matron of the hospital, and several members of the Board of Management. The Earl of Sandwich, who welcomed the Princess on behalf of all associated with the work of the hospital, said that it had long been the desire of the Committee of Management to provide improved accommodation for out-patients attending the hospital in a building that would meet all modern requirements for their efficient treatment. In this new building provision was being arranged for the reception of accidents and urgent cases, for the medical staff, throat and eye specialists, massage, and dental and electrical departments. A complete maternity department would be provided on the second floor, whilst accommodation was also being set apart for the medical students, in place of their present quarters in the old building. The Royal Free Hospital, continued the speaker, was the only one in London through which women could enter the medical profession. An ever-widening sphere of usefulness was opening out for medical women at home and abroad, particularly in India and the Eastern dominions, and therefore an increasing importance was attached to the work of the hospital and the need for extension was now more urgent than at any other previous time. The Earl of Sandwich then presented the architect (Mr. Ashley) and the contractor (Mr. Downs) to the Princess Christian; and the hymn "Thou to whom the sick and dying" having been sung, the foundation stone was laid, and the benediction given by the Archdeacon of London. The ceremony concluded with the presentation of a number of purses containing subscriptions towards the expenses of the new building. The total collection amounted to £1,632, the cost of the building having been estimated at between £40,000 and £50,000, of which over £11,000 has already been subscribed.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 423, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National):—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2630, Gerrard, BRITISH MEDICAL ASSOCIATION.

2634, Gerrard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

SOFT WATER AND IRON PIPES.

DR. E. H. O. SANKEY (Boschurch, Salop), who has a supply of very pure soft water, finds that it cuts away iron hot water pipes very fast and is always red and rusty. He asks what can be used to line pipes and boiler and so protect them.

INCOME TAX.

G. A. W. asks on what basis the income tax return for the present year should be made in a case in which the effect of the Insurance Act has been to increase income.

. The profits of the practice should be returned on the average of the past three years notwithstanding the increase. Neither an increase nor a falling off of the profits in a particular year is taken into consideration in arriving at the income-tax liability, except in so far as it affects the average profits.

F. J. W. inquires under what schedule of the income tax he should return his grant for vaccination.

. As the grant does not arise in connexion with an appointment for which "F. J. W." is assessed to income-tax under Schedule E, the grant should be regarded as part of the receipts of the general practice and included in the profits to be returned for assessment in following years on the average of three years.

DOUBLE TAX.—The Board of Inland Revenue offers no objection to the inclusion in a general practitioner's return (Schedule D) of fees received in respect of public appointments, and, in view of the indubitable injustice that would otherwise arise, we apprehend that the Commissioners will acquiesce in the assessment of insurance fees under Schedule D as profits of the general practice. We advise our correspondent to prepare his return on this basis, and if necessary urge his views on the surveyor of taxes.

ANSWERS.

T. H. M.—Carwardine's saccharometer does not differ in principle from a burette and porcelain capsule, and it is not clear why our correspondent should fail to get a complete reduction of the cupric oxide; after the test tube has stood for a while the bluish tinge, however complete the reduction, will return, as the cuprous oxide takes up oxygen from the air. This may be the source of the difficulty.

PARALYSIS AGITANS.

T. writes, in reply to "G. F. P." (May 10th, p. 1036), as to the treatment of ptialism in a patient afflicted with paralysis agitans, to recommend ten-drop doses of tinct. belladonnae three times a day or pilocarpine nitrate gr. $\frac{1}{3}$.

PAIN IN THE BACK.

IN reply to "Omega," Mr. Paul B. Roth, F.R.C.S., writes: Provided the abdominal and pelvic organs are healthy, and can be excluded, "pain in the back on rising and throughout the day," may be the only subjective symptom of (1) "weak relaxed back," (2) scoliosis, (3) subluxation of the sacro-iliac joint, (4) Pott's disease.

1. In this condition the natural antero-posterior curves of the spine are either exaggerated or diminished, and the patient may be unable to maintain the erect position for more than a few seconds without pain.

2. In scoliosis a hip or shoulder-blade may be prominent, and on flexion of the patient's trunk there may be seen a projection posteriorly on one side more than the other of the ribs, or of the erector spinae in the lumbar region.

The treatment of both these is by "posture and exercise."
3. This condition occasionally occurs: In addition to the pain in the back, a tender spot is found over one or other sacro-iliac joint when palpated behind. It is entirely relieved by encircling the pelvis firmly for some weeks with a strip of broad strapping.

4. Radiograms may be of use here, and an important sign is muscular rigidity; the treatment is, of course, immobilization.

LETTERS, NOTES, ETC.

CONFECTIONER'S PARONYCHIA.

A MEMBER of the British Medical Association resident in Australia informs us that on the same day that there reached him a copy of the JOURNAL for March 15th, containing an account of that comparatively little recognized disorder, confectioner's paronychia, there reached him also a copy of the *Sydney Daily Telegraph*, which contained an unintentional comment thereon. This was in the shape of an account of an action for damages in respect of an illness brought about, it was alleged, by the plaintiff finding in her mouth a human nail which had been embedded in a chocolate drop just eaten by her.

COUNTERCHECK FOR A PUSHFUL TRADESMAN.

WE are all considered fair game for touts of all kinds. Most of us are content to bear the nuisance with what philosophy we can muster, as we seldom have the chance of appropriately punishing the importunity. It is pleasing, therefore, to read of the countercheck administered by a Strassburg doctor to an enterprising tradesman who sent him a box of cigars which had not been ordered, together with a bill for 15 marks. The accompanying letter stated: "I have ventured to send these on my own initiative, being convinced that you will appreciate their exquisite flavour." To this the doctor replied: "You have not asked me for a consultation, but I venture to send you three prescriptions, being convinced that you will be quite as satisfied with them as I am with your cigars. As my charge for a prescription is 5 marks, this makes us quits."

RHEUMATOID ARTHRITIS.

DR. WM. HARDMAN (Bispham, near Blackpool) writes: As I entered the medical profession in 1864 and have been more or less actively engaged in practice until a year ago, you will believe me when I say that I have seen several cases of rheumatoid arthritis. That any single person has seen "thousands" of cases I have difficulty in crediting, as the disease is not common, though it seems commoner than it is, as each case usually lasts many years and passes under the care of several medical men. I have also seen several cases of chronic arthritis which I did not doubt were caused by micro-organisms such as the gonococcus, streptococcus, or pneumococcus. I have thought the rheumatic affections of this latter class usually easily distinguishable from rheumatoid arthritis, and in the arthritis of this kind the most valuable drug I have discovered is creasotol (creasote carbonate), the effects of which are very similar to those of guaiacol carbonate. From potassium iodide alone I have never seen any benefit. I do not believe in the least that exposure to cold and wet are ever essential factors in the causation, for the disease ought to be enormously more common if it were capable of being brought into existence by this, and should be particularly frequently met with in sailors, which, in my experience, it is not. I have noticed no especial connexion between rheumatoid arthritis and poverty; on the contrary, almost all the cases I have seen have been in people well-to-do or comfortably off. The only treatment I have found really effective in true rheumatoid arthritis is antistreptococcus vaccine, the killed cocci hypodermically injected weekly in increasing doses for long periods.

SHALL WE DRINK?

DR. WM. BRAMWELL (Liverpool) writes: Dr. Haddon's reiterations about the elimination of fluid from dietary are interesting in the extreme, but I would like to remind him that it is more than just possible that such advice, acted upon for any great length of time, might lead to disaster. I have had under my own observation more than one case in which I have reason to believe that the patient's continued dislike to fluid has resulted in operation for stone in the kidney. One patient that I have particularly in mind would rarely drink more than half a cup of tea at breakfast, and would frequently go the whole day without taking anything else to drink. His life became a perfect misery to him, even after he had undergone an operation for stone in the kidney; nor was health finally attained until he was advised as to his diet in which a normal amount of fluids was insisted on. And this, it seems superfluous to say, is necessary for the continuous flushing-out of the kidneys.

Since Dr. Haddon has quoted the habits of animals to illustrate his point, I would like also to remind him that farmers seem to think an abundance of water essential for their cattle, or they would not go to the expense and trouble of supplying tubs of water in fields which do not contain a pool or border upon a stream; and judging by the number of times animals are seen to drink at these, one would be led to believe that the elimination of fluids from dietary is against Nature, and particularly so since we know that so large a percentage of the animal body consists of water, a percentage which cannot possibly be kept up by no more than that amount of water which goes to make up the constituents of solid food. How often has a canary been found dead in its cage with an abundance of seed but no water! It is true that there is water in the seed, but yet far from enough to support life. The fact that horses do not drink when at grass seems to me sufficiently explained by their taking in sufficient water when the grass is saturated with morning dew or the rain, but I

cannot see any physiological reason for doubting that they get—must get in fact—considerably more water than is actually present in the grass itself.

In advising patients to limit the amount of fluid they drink where a continued low blood pressure has been essential, I have always felt some trepidation lest I should do some harm to the kidneys by favouring the development of stone, and it is this danger particularly that I wish to point out to Dr. Haddon, to say nothing of the possibilities of producing chronic constipation, extreme nervous depression, and all the miseries, nervous and otherwise, consequent upon an inspissated blood, which must of necessity lead to a uric acid diathesis with its thousand and one symptoms.

HERPES AND VARICELLA.

DR. GEORGE BRUCE (Melbourne, near Derby) writes: *Apropos* the note of Dr. B. Jones and his reference to the annotation in the EPITOME of January 11th regarding chicken-pox following shingles in different members of the same family, I write to say that on April 18th I was called to see a lady over whose right temple and eye a profuse crop of shingles was developing. She was nursed by her sister, who was with her almost without intermission. This sister complained on May 4th of feeling poorly, and during the next day or two numerous spots, which were without doubt those of varicella, began to appear over her face and body. These spots have been going through all the phases characteristic of that complaint.

AN IMPROVED NEVILLE'S AXIS TRACTION FORCEPS.

DR. F. WM. INMAN (Wallasey) writes: In your issue of January 11th, p. 79, Dr. Stack describes an improved Neville's axis traction forceps, the principal feature being an enlargement of the axis traction rod, so that the traction is in the line of a tangent to a semicircle in the axis of the pelvis. So far back as 1900, whilst obstetrical assistant to the Liverpool Lying-in Hospital, I had a pair of forceps made of similar design, and have used them since, finding them of great advantage, and certainly an improvement on the ordinary Neville's. The idea that these forceps might be improved occurred to me whilst a student at the Coombe, Dublin, in 1898, where I saw an unfortunate woman rather badly torn owing, in my opinion, to the insufficient amount of bend in the traction rod; in the efforts to pull in the axis of the pelvis the handles were dragged against the perineum, causing a laceration before the head reached the pelvic floor. Many will say, "Why not use Milne Murray's?" If you are content to apply the forceps, and to then pull until the head is torn, there does not appear to be much advantage; but if you are in the habit of frequently pulling with the left hand, and examining the advance of the head meanwhile, with the right in the vagina, then there is an advantage in not having so much metal in the passage. The great benefit of the simpler instrument lies in the greater ease of application and removal. To take an instance—suppose that you are called to a patient worn out by a long first stage, the waters having ruptured early on, leaving the cervix almost fully dilated, but owing to the failure of the head to descend, hanging loose in the vagina; having waited as long as possible, you apply forceps, and by gentle traction draw the head through the brim, you now find the cervix caught up and dangerously stretched. After gently pulling with the left hand, feeling the cervix meanwhile with the right, you remove the forceps, and either let the patient come out of the anaesthetic, or at any rate wait a short time, and then reapply. If the cervix still appears to threaten to tear you again remove, and wait for more pains. Having thus safely passed the cervix you bring the head down on the perineum; supposing the patient to be a primipara, you find this to be dangerously stretched, and you remove the forceps and wait for a few pains; progress being slow, you again apply, and gently cause the head to dilate the perineum; having got it well down, you again remove the instrument, and by traction on the back of the occiput, with the fingers of the right hand to draw the occiput down and to prevent early extension, combined with pressure on the chin behind the anus, you cause the head to pass the perineum with the smallest possible sub-occipite-bregmatic diameter distending it. In occipito-posterior cases it is very important to be able to remove the forceps easily, and to reapply after manual rectification.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|----------------------|-----|-----|--------|
| Eightlines and under | ... | ... | 0 4 0 |
| Each additional line | ... | ... | 0 0 6 |
| A whole column | ... | ... | 2 13 4 |
| A PAGE | ... | ... | 8 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

The Annual Oration

ON

THE TREND OF THOUGHT IN RECENT PHARMACOLOGICAL RESEARCH.

DELIVERED BEFORE THE MEDICAL SOCIETY OF LONDON.

BY

SIR WILLIAM WHITLA, M.A., M.D., LL.D.,

SENIOR PHYSICIAN, ROYAL VICTORIA HOSPITAL, AND PROFESSOR OF
MATERIA MEDICA AND THERAPEUTICS, QUEEN'S UNIVERSITY,
BELFAST; VICE-PRESIDENT OF THE BRITISH MEDICAL
ASSOCIATION.

PRESIDENT AND GENTLEMEN,—My first duty is to express my thanks for the high honour conferred upon me by the Medical Society of London appointing me Orator for 1913. I feel quite overwhelmed when I reflect that with hosts of metropolitans of world-wide fame, all far better fitted to fill this exalted position, you have honoured the outpost of civilization to which I belong by selecting an obscure provincial to address you to-night.

My colleagues and professional brethren across the Channel cling to the belief that though separated by this turbulent streak of melancholy ocean they are as proud of the traditions of English medicine as if a bountiful Providence had cast their lot in the heart of your mighty metropolis on the banks of the Thames instead of on the quiet shores of the Lagan. Therefore, though it may not be permitted of me to refer in these degenerate days to loyalty of a different kind, I nevertheless rejoice in assuring you that our pulses throb in unison with your own in every aspiration for the advance of British medicine.

In casting my eye over the wide domains of the science and practice of our art in search of a subject to claim your attention for a brief hour to-night the present condition of the field of therapeutics suggested itself. In no other department of medicine at the moment is such laborious research manifest or have there ever been more earnest attempts made to utilize every discovery in other branches of science for the prevention of suffering and for the relief and cure of disease. The triumphs of physics and the advances of synthetic chemistry are being daily pressed into the service of therapeutics, and each addition to our knowledge in pathology, etiology, and diagnosis is valued by the standard of how far it shall be found useful in leading up to a more successful treatment of human maladies. The result of this ceaseless activity has been an advance in the art of healing during the last three or four decades, which is perhaps as great as the progress registered in any corresponding number of centuries.

Whilst the militant army of chemists, bacteriologists, and pathologists was successfully wresting from Nature her treasured secrets when the majority of my present auditors were entering upon their professional studies, the therapeutic battalion seemed to be merely marking time. These were the days when the pessimist and the sceptic, strengthened by the startling revelations of microscopic changes in diseased tissues, and emboldened by the failures of empirics or the visionary seekers after specifics, scoffed loudest at the bare possibility of such results as have been since achieved. This condition of affairs was not without its depressing and retarding effect upon therapeutic progress, so that even the facts accumulated throughout many years of patient clinical observation on the old and well-tried remedies were frequently denied or altogether ignored, because a scientific explanation of their action was not immediately forthcoming.

In the present age of pharmacological activity and discovery, when the air is still ringing with the marvellous results achieved by such agents as thyroid extract, diphtheritic antitoxin, and salvarsan, we have to guard ourselves against the allurements of the opposite evil of credulity. We can, however, always rejoice in the existence amongst us of the honest doubter—one of the best assets of British medicine—for only through honest doubt can we hope to reach the final goal of sure belief—the essential factor in successful therapy.

The present seems to me, therefore, a suitable opportunity for pausing and investigating the truth of the more important theories which, like beacon lights, have been guiding pharmacologists in their successful search after new remedial agents. Obviously, the brilliant triumphs achieved by operative surgery and Listerism cannot come under our immediate consideration, owing to the shortness of the time at my disposal; neither, indeed, is it necessary to speak of them, since they have been ably dealt with by more than one of your recent annual orators.

On the threshold of such an inquiry we are reminded that very often the advances made in one era are to be traced backwards to their origin in a rational or accidental discovery made at a much earlier date, and sometimes to a research the importance of which was overlooked at the time. Should such a retrospect in the domain of therapeutics prove successful in elucidating a scientific starting point to which our present advances can be reasonably attributed, the subject becomes of more than a mere historical or academical interest, since we can confidently hope for further progress so long as research is conducted upon the lines originally laid down, or lines directly or indirectly communicating with the main track.

Such a starting point, I believe, may be found in the epoch-making researches on the action of methylstrychnine, conducted by Crum Brown and Fraser in 1868. It was well known that ammonia and its derivatives, when administered to animals, caused stimulation of the spinal cord and medulla, which ended in convulsions; it was also recognized that the chemical constitution of the vegetable alkaloids corresponded to the type of an ammonia derivative. These experimentalists made the discovery that by linking the organic alkyl radical, methyl (CH_3), to the nitrogen of the complex molecule of strychnine, the resulting comparatively slight change in chemical structure altered in a remarkable manner the physiological or pharmacological action of the alkaloid. The alteration was manifested by a change from the convulsant effect on the cells of the cord to a paralytic one on the terminals of the motor nerves, such as is witnessed in the well-known symptoms of poisoning by curare. This change of physiological action being manifestly due to the transformation of the original tertiary base into a quaternary ammonium compound, it was not to be wondered at that almost identical results were obtained by altering in the same way the chemical constitution or structure of a number of the other alkaloids exercising widely different actions on the human body.

Similar change in physiological action is also obtainable by linking other alkyl radicals, as C_2H_5 , instead of CH_3 , the radicals being, in each case, previously combined with iodine or bromine. That this change in action is not a mere coincidence or accident, is demonstrable in a remarkable manner by the methylation of curare itself—the drug which, in its natural state, affords the most typical example of a paralytic effect upon the motor nerve endings. This substance contains two ammonia bases—the active curarine and the comparatively inert curine. Now, if the latter base be altered by the before-mentioned manipulation with methyl, the transformation in its chemical constitution causes it to become about 230 times more poisonous than before, and the resulting new compound is found to be identical with curarine, the active principle of the drug.

Sir Lauder Brunton, to whom British therapy owes so much, speaking in 1886 of Crum Brown and Fraser's discovery as directing pharmacological advance along a new path, prophesied that another twenty years would not only add greatly to our stock of remedial agents, but to a better knowledge of our patient's condition, ushering in the era when we should be able to ensure the drug action we desired without feeling that our patients often died for lack of knowledge, not on our part but on that of our art. We all feel painfully that such a millennium is still far off, but, nevertheless, we are steadily, if slowly, approaching it. If we interpret Brunton's forecast concerning "our better knowledge of the patient's condition" as implying a clearer conception of the incessant changes taking place in the protoplasm of the body cells, it must be conceded that enormous strides have been made in our progress in this direction, since, during the last quarter

of a century, a chemical basis has been industriously constructed, upon which the science of pathology now securely rests—a fact not sufficiently recognized, even by pharmacologists.

Therefore in a re-survey of our therapeutic position any examination of the value of the theory concerning the relationship between pharmacological action and chemical constitution must proceed hand in hand with a consideration of the advances made in chemical pathology and physiological chemistry. The truth of the axiom that pathology must constitute the basis of every rational system of therapeutics is more obvious to-day than it was fifty years ago, at which time the study of diseased processes was mainly conducted on morphological lines. If the science of pharmacology is to rest upon the arch of pathology, whose keystone is physiological chemistry, it obviously follows that this foundation must be sufficiently strong and wide to support the growing fabric of all scientific therapy.

The subject of the relationship between physiological action and chemical structure is a most complex and tedious one for treatment in a solitary address, especially as the high pressure and whirl of professional activities permit few practitioners to cultivate the habit of thinking in chemical language. The nature of our work almost compels us to think out our clinical problems from the physical or vitalistic point of view, hence in my attempt to review the accumulating evidence in favour of accepting the doctrine of a close connexion between the action of a drug and its chemical structure I shall try to avoid as far as possible references to complicated graphic formulae and the highly technical phraseology of the student of organic chemistry.

It was expected by pharmacologists that Brown and Fraser's discovery would immediately revolutionize the science of therapeutics, but in this they had to realize soon a keen disappointment. The application of a few swiftly constructed generalizations to the solution of intricate therapeutic problems at first only led to failure and chaos, and, as always happens, a revolt against the new doctrine soon appeared. Even at the present hour some pharmacologists may be seen labouring under the old incubus of trying to explain the action of drugs on the theory of some purely physical or mechanical property in their atoms or molecules, whilst others are falling back hopelessly upon the ancient vitalistic conception. Hence arises the importance of a scrutiny of our present position, since the problem is not one to be decided only in the laboratory, but to be finally tested by the practitioner at the bedside.

It is hardly necessary to remind my auditors that in the examination of the theory of the relationship between pharmacological action and chemical constitution we must put aside the question of the mere chemical composition of a drug. It is not the number or nature of the atoms in a compound which we have to think of, but the plan of structure by which these are built up and linked to each other in the drug. In other words, it is not a consideration of the number or nature of the individual bricks or building stones employed, but the manner in which these are grouped together in the molecules of the compound radicals determining the final chemical construction or constitution of the compound. This vital distinction between the structure and composition of a chemical compound is seen in the empiric formula $C_6H_{12}O_6$, which is the label attached to no fewer than sixty-six compounds—all totally different substances. It is true that a simple change in the mere composition of a salt may change or vary greatly its action, but this will generally be found to be due to some alteration in its solubility which causes retardation of its absorption or acceleration of its elimination. Thus the victim of the malarial parasite can be often speedily rescued from his perilous toxæmia by a moderate dose of the hydrochloride of quinine when he would perish with an enormously larger amount of the insoluble alkaloid or its sulphate lying unabsorbed in his gastric cavity.

After the demonstration of the results of methylating the strychnine molecule came the valuable generalization of Braddon and Cash on the actions of the carbon compounds. These observers pointed out that the two great fundamental groups met with in organic chemistry differed very materially in their pharmacological actions. The

substances built up on the open-chain plan, the type of which is marsh gas (CH_4) and chloroform ($CHCl_3$), all paralyse the nerve centres and tend to exert an anaesthetic action, whilst the close chain or ring series, represented by the benzene nucleus, produce convulsions or spasms before paralyzing. Liebreich, seizing the truth of this common paralytic action of the open chain or fatty series of the carbon compounds, started out in search of a new hypnotic, which ended in the discovery of chloral, as Schmiedeberg likewise gave to therapy the invaluable hypnotic—paraldehyde.

When one of the hydrogen atoms in the closed benzene ring is replaced by the radical hydroxyl (HO) phenol is formed, and as each of the other hydrogen atoms is substituted by a further hydroxyl addition, or by methyl, the antiseptic power of the resulting aromatic compound proportionally increases. It was found that by varying the position of hydroxyl in the ring valuable antipyretic qualities could be developed; thus was achieved a notable triumph in therapeutics by advancing from hydroquinone to the synthetical building up of kairin, thallin, and finally of antipyrine.

Since then innumerable examples have accumulated equally suggestive of this close relationship, a mere recital of which would occupy the entire time at our disposal, and by their multiplicity would obscure the issues under consideration. It is noteworthy that these examples tell in opposite directions. Not only is the synthetical chemist able, by altering the structure of the molecule, to intensify greatly the action of the compound; but he can, with equal ease, render the poisonous drug inert by introducing into the molecule such acidic groups as the sulphuric, sulphonic, and carboxylic. Thus the poisonous phenol is converted into the inert phenyl-sulphuric acid, and morphine-sulphuric acid can be swallowed with impunity in drachm doses. Notwithstanding, however, these accumulating instances of close relationship, it must be conceded that it is still impossible for the pharmacologist to foreshadow with absolute certainty the physiological or therapeutical action of a particular untried drug, so that rational must proceed in company with a certain degree of empirical therapy. But the shrewd guesses of a couple of decades ago are now being replaced by the stronger probabilities of later years, and by the almost certainties of 1913. It is often argued by the sceptic, with an apparent show of reason, that this relationship between chemical structure and pharmacological effect, if it be a definite law, should always afford the certainty of a mathematically correct prophecy. That it does not is due to the fact of our want of knowledge about the construction of the molecules of the highly complex carbon compounds, whose number almost suggests infinity, and of which but a very few comparatively have been studied structurally. Each discovery of the true nature of the graphic formula of these shows that Nature is gradually, if reluctantly, yielding up her secrets to the indefatigable analytical and synthetical chemist, who at once seizes upon the advance as a new stepping stone from which to approach the creation of an entirely new compound with the almost certainty of obtaining a specific action upon some particular type of body cell or tissue. It is true that unforeseen secondary actions of the newly created drug may vitiate the desired result and prove a barrier to its safe use as a therapeutic agent, but often a further study of its complex molecule suggests a new substitution process by which untoward effects can be eliminated after handing back the compound from the pharmacologist to the synthetical chemist. Another real difficulty in the acceptance of the relationship as a definite law is the operation of the incessant changes, chemical and physical, which are occurring in the blood and body cells, but this difficulty, as already mentioned, is steadily being lessened by the new flood of light thrown on metabolic processes by the physiological chemist.

The few pharmacologists who attempt to belittle the importance or deny the truth of the intimate relationship between drug action and chemical structure because of their adherence to a purely physical or mechanical theory of the *modus operandi* of remedial compounds, appear to have overlooked the obvious possibility of the physical character of the molecules being entirely due to the chemical structure of their constituent groups. Thus, it cannot be too clearly realized that should some startling

discovery prove the correctness of the old physical theory (though such an event is almost inconceivable), the importance of the relationship as a factor in therapeutic advance would in no way be lessened, especially as it is abundantly recognised that the operation of purely physical laws plays an important part in at least either retarding or facilitating the entrance of the drug to the cells of the tissue upon which it acts.

Let us now, for a moment, suppose that sufficient instances are not yet forthcoming to justify us in regarding the connexion between chemical constitution and physiological action as a definite "law," but only as a working hypothesis, and let us glance at the results which have accrued to practical therapeutics from its application. No stronger proof could be produced for the demonstration of a truth in medicine or in any other science than the long list of new synthetic antiseptics, antipyretics, analgesics, local anaesthetics, and hypnotics, the discovery or creation of which has owed its origin not to empiricism, but to the inspiration of a rational therapy founded on the theory of this relationship. Truly men do not gather grapes of thorns or figs of thistles. If we even set aside the entire series of new remedial agents just mentioned, salvarsan would alone demonstrate the truth of the contention. Ehrlich in the introduction to *The Experimental Chemotherapy of the Spirochaetes* states that from the beginning of his medical studies he became possessed with the conviction that "if a connexion between the constitution and the physiological action were granted, this must be pushed further and the tissues must also participate in the distribution, and whereas formerly the substances were offered to the medical man by the chemist for testing purposes, the conditions could now be reversed and the chemiotherapist could give the chemist points which lead to the desired recovery of genuine curative substances."

To my mind the question of whether or not Ehrlich has discovered a genuine cure for syphilis sinks into insignificance when contrasted with the importance of the fact that his methods are based upon such a rock-bed of truth as must ultimately revolutionize the treatment of all parasitic diseases by chemical agents. That no single step in his laborious search for a remedy against the spirochaete was taken empirically or at haphazard is evident from his repeated assertion that from start to finish every advance was made in a most purposive manner and only after an exhaustive study of the molecular construction of each of his 606 tested compounds. How far Ehrlich pushed his conviction beyond the theory of mere relationship brings me to the consideration of the second great fundamental principle underlying the conception of a purely chemical basis for all therapy.

His term "chemiotherapy" implies a great deal more than the acceptance of an established dependence of action on chemical constitution. With this new word another working hypothesis leaps into view, and it is essentially different from the one which we have been considering. The mixing up of these two theories has already threatened a check to therapeutic advance. Stated in its most advanced form, this second theory attempts to explain the action of a drug as the result of a chemical combination of some of its groups with other constituent groups or radicals in the complex molecule of the living protoplasm of the cell or tissue upon which it acts. It must be at once conceded that such chemical reaction can only be proven in a few cases, and therefore cannot be said to rest, as a theory, on the solid basis which must be acknowledged as existing in the case of the established relationship between structure and drug action. Hence it is not surprising to find that some pharmacologists who regard the relationship theory as not incompatible with the older hypotheses of vital, physical, and catalytic actions, nevertheless deny the truth or probability of the newer doctrine.

It will repay us to put this working hypothesis of chemical reaction to the same severe test as we have applied to the outcome of Brown and Fraser's discovery in order to examine and determine what part it has played or is playing in therapeutic progress, so that we may judge of its truth by the fruit which it has brought forth. And here let me remind you that the molecular theory upon which the science of chemistry is based is still but a working hypothesis, and probably must remain as such

for all time. It has long been known that many drugs suffer a fundamental change between the periods of their absorption and final elimination from the body. The direction of this change, as put by May, is usually in the direction of a transformation of an active or poisonous substance into a less harmful compound, and though it cannot be accepted as proof that the effect of the original drug is due to a chemical reaction between its molecules and those of the living protoplasm on which it acts, it may nevertheless be incidentally mentioned that this knowledge has been put to practical account by suggesting to the synthetic chemist the planning of a new compound on the same type as the transformed eliminated product. In this way, from a study of the behaviour of aniline in the body, phenacetin and other valuable para-amino-phenol derivatives have been added to the therapeutic armamentarium.

The great difficulty of demonstrating the doctrine of a purely chemical basis for pharmacological action rests in our incomplete knowledge of the chemical construction of the living cell protoplasm and of the physico-chemical processes incessantly occurring therein. The puzzling and highly complex constitution of the proteid molecule is gradually being cleared up, and already about a score of its cleft off building stones have been examined and proved to be of definite chemical composition and constitution, containing strong basic and acid groups capable of combining with each other to form an infinite number of compounds. Though we are still a long way from a synthetical construction of a protein molecule, the building up of the polypeptides by Emil Fischer strongly encourages the hope that this giant achievement is a possibility in the not far distant future. How vast is the field for such research, and how numerous are the amino-acid groups all capable of combining with each other through their basic and acid radicals may be dimly appreciated by the estimation of the molecular weight of haemoglobin as 16,669.

On reflection it becomes obvious that the complexity of the construction of the molecule of the cell protoplasm and the almost infinity of its changing groups are in themselves arguments rather in favour of than against the theory of a true chemical reaction between the compound administered and some of the radical groups existing in the cytoplasm.

These considerations clear the way for a brief glance at Ehrlich's great side-chain hypothesis or working theory advanced in order to explain the phenomena of the action of the antitoxins of diphtheria and tetanus. It is based entirely upon the chemical conception, and at first view the remarkable fact is obvious that this purely chemical hypothesis was built up to explain the action of the most complex organic compounds known to science in order to elucidate the phenomena of immunization. It recognizes the fact that the toxin molecule contains a large number of complex organic groups or radicals bound together to a central chain or nucleus.

Some of these radical groupings possess a chemical affinity for other complex groups existing in the protoplasm of the cells susceptible to the poison. These chemical affinities constitute in the language of Ehrlich the side chains known as the anchoring group or haptophore, which combines with a receptor radical in the cell protoplasm, and thus fixes or anchors the toxin molecule to the protoplasmic molecule. The harmful radical in the toxin, being thus fastened in close relationship with a chemical group in the cell, combines with it through its toxophore radical, the chemical reaction accomplishing the injury or death of the cell.

According to this working hypothesis no result will follow the injection of a toxin unless the cells of the organism contain in their molecule a group or radical, known as the receptor, which possesses an affinity for the haptophore or anchoring radical in the toxin as well as a group capable of being injured by the toxophore side chain of the poison. The phenomenon of natural insusceptibility is thus easily explained, since the immune animal contains in its cellular protoplasm no receptors for the fixation of the toxin molecule. Of much more practical importance to the therapist is the working out of this hypothesis when applied to the elucidation of acquired insusceptibility or immunization, and of still greater importance is it in solving the problem of the action of

antitoxins in the cure of disease. When doses of the toxin short of producing a fatal result are injected the chemical reactions just described are assumed to have occurred, but the smaller amounts, instead of destroying the cell, only serve to excite it to regenerate its receptors. The cell is also further stimulated to produce more of the chemical receptor substance than is required merely to replace that which has already combined with the toxin, the excess being showered into the blood constituting the antibodies found in the serum. These, therefore, are to be considered as free cell receptors with unsaturated chemical affinities which immediately combine with the haptophore radicals of the toxin, thus effectually preventing them from anchoring to the cell protoplasm, without which fixation a toxic effect cannot be produced.

At the risk of wearying my auditors I have ventured to give this brief description of the side-chain hypothesis, which is often put in such technical language as to obscure its purely chemical application; we shall now glance rapidly at the practical results of serum therapy. This has been during the last few years confused often with vaccine therapy to the retardation of therapeutic advance. I have used the term "toxin" only in its now scientifically restricted sense as the poisonous product of a true secretion of a bacillus. It is necessary to keep in mind that probably only four pathogenic bacilli really secrete a chemical poison. These are the microbes of diphtheria and tetanus, botulismus and pyocyanus bacilli. The toxins obtainable from castor and croton seeds do not come within our present scope, and the product of Shiga's bacillus is still of doubtful nature. All the other vegetable parasites contain their poisons as an intracellular chemical or endotoxin, which can only operate deleteriously on the tissues after the death and dissolution of the microbe. This fact constitutes the fundamental difference between serum and vaccine therapy. Only toxins lead to the formation of true antibodies in the serum.

Sir Almroth Wright, who never loses an opportunity for demolishing the untenable pretensions of those who apply serum therapy to the treatment of bacterial diseases other than those of diphtheria and tetanus, speaks of the action of the serums for these latter affections as a miracle of successful immunization—a miracle which gives in a few cubic centimetres a sufficient antitoxin to change the entire course of the patient's disease. When we remember that Behring was able to immunize an animal to such a degree that one thousandth part of a single drop of its serum was sufficient to neutralize a lethal dose of the chemical toxin, we become able to realize that there is nothing in the whole realm of therapy which rests upon a more secure foundation than the serum treatment of diphtheria and tetanus. The comparative failure of the antitoxin of the latter disease only strengthens the structure upon which the therapy is erected, since by the time the first symptoms of trismus have appeared a chemical combination between the groups of the toxin and the molecule of the cell protoplasm has already taken place. We are even justified in asserting that if we could know the exact moment at which the bacilli of these diseases enter the body, by an immediate resort to the serum a fatal issue would always be averted.

It is necessary to realize the truth of this in order to judge rightly of the value of Ehrlich's hypothesis, which explains, on a purely chemical basis, almost every problem met with in the marvellous processes of active and passive immunization, notwithstanding the theoretical qualifying views of Arrhenius and Madsen regarding dissociation, or the adsorption theory of Bordet and Biltz and the recent experiments of Abderhalden with the polariscope. But even if we assume that the side-chain hypothesis does not assist us in establishing proof that the action of the antitoxic serum is of the nature of a true chemical reaction, the following facts must be accepted as conclusive evidence that the result is due to the operation of laws which govern all other chemical reactions:

1. The neutralization or saturation of the toxin by the antitoxin occurs in the test tube as well as in the animal body.

2. It is more rapidly effected by mixing together strong solutions than weak ones.

3. It occurs more quickly under warmth and is proportionally retarded by cold.

4. A very marked elevation of temperature always accompanies the reaction *in vitro*, the degree of heat having been accurately measured by Arrhenius and Madsen, who found it to correspond to about half the elevation which follows the neutralization of a strong acid by an active alkali.

5. It has been proved experimentally that the toxin and antitoxin do not perish, or are not destroyed by the chemical combination; though the former is deprived of its injurious property for the time, it can afterwards be recovered from the solution.

6. The neutralization of the toxin has been demonstrated to proceed in obedience to the law of constant proportion; that is to say, a given amount of the chemical poison, or multiples of this amount, are always saturated by corresponding multiples of antitoxin—a fact which alone would establish the purely chemical basis of the reaction.

7. If the tetanus toxin be mixed with an emulsion of the brain of a healthy guinea-pig it becomes innocuous, chemical combination being thus brought about between it and the nerve protoplasm, probably in the exact manner in which this takes place in the living animal after injection of the poison.

These indisputable facts, if they cannot be accepted as proof that all other drug action is the result of a chemical combination between the drug and a compound radical with unsaturated affinities in the protoplasmic molecule of the selective cells, nevertheless must be accepted as going a long way in this direction. That proof is so conclusive in this instance of serum-therapy where the chemical structure is so very highly complex is not without significance. (I may incidentally mention that if the result of the action of strychnine be due to a chemical combination between the alkaloid and the cell protoplasm in the spinal cord, this hypothesis should be proven if previous trituration with nerve matter rendered the poison innocuous, as in the tetanus experiment. I regret to state that a long series of experiments, inaugurated by me some years ago, failed to establish this result, the failure being probably due to the alkaloid being prevented in gaining an access to the cellular protoplasm, owing to the cessation of some preliminary physical or chemical process in abeyance in the dead protoplasm.)

The purpose, however, with which I have set out in these remarks is not so much to heap up examples in support of a purely chemical theory of the action of drugs as to point to the influence of the hypothesis on the most recent trend of therapeutic progress. If we find that by following this conception as a working hypothesis pharmacologists have been able to achieve a notable triumph over disease, we may then safely accept its truth after the manner in which the chemical explorer accepts the molecular theory.

In this consideration a study of the evolutionary steps in the side-chain hypothesis affords a considerable degree of interest. It started in Ehrlich's mind on observing the effects of various staining agents on different parts of the animal cell. After studying the chemical structure of the dye molecule he was led by the laws of reasoning to apply his inferences to the explanation of the phenomena of immunization, and it is a most noteworthy fact that he at first denied the possibility of any similarity between the action of a chemical substance of known composition and of an antitoxin. He was, however, inexorably led by his research work to the conviction that the protoplasmic molecule possessed chemio-receptors which united with the haptophore or anchoring groups in the drug.

Dixon argues with a brilliant *naïveté* that since these hypothetical receptors are obviously distinct from food receptors it is difficult to regard them teleologically as pegs specially designed for the physician on which to hang his drugs. From a consideration of the results achieved it must be conceded that they are pegs strong enough to support the heavy superstructure of chemotherapy, the coping stone of which at present is neosalvarsan.

Led first by the truth of the generalization arising from the research of Crum Brown and Fraser, Ehrlich proceeded on his path of exploration by applying at each step his side-chain hypothesis to the elucidation of the complex reactions occurring in the human body after the

injection of various dyo stuffs and a host of arsenical compounds, with the result that he was enabled to discover an agent possessing the maximum parasite-destroying power with the minimum of organotropic action. But this was not all; the blending of the solution of two problems which confronted him is to be seen when we examine his final achievement. He had not only to solve the problem of killing the parasite without injuring the patient, but he had to cure the disease, which was liable to be aggravated seriously by the rapid disintegration of the slain spirochaetes. In his method we find chemo- and sero-therapy working side by side, the one aiding the other. A dose of salvarsan injected into the veins of a syphilitic mother effects the dissolution of the parasites, whose liberated toxin at once leads to the formation of antibodies in the parental blood, these on being conveyed to the infant in the mammary secretion destroy its myriad spirochaetes or render their propagation impossible, as in the diphtheritic disease, even when no trace of the salvarsan molecule can be detected in the mother's milk.

In establishing chemotherapy, Ehrlich's aim was to effect a complete sterilization of the body by a single full dose of the antiparasitic drug without injuring the tissues, a result which he designates the *therapia sterilisans magna*. It is a very remarkable fact that in both this result and in the chemical combination theory which led to its achievement, he was forestalled by Binz of Bonn in a most important research made in 1867, the year previous to Brown and Fraser's discovery.

Binz, when experimenting on the action of various drugs on the infusorial organisms met with in ordinary hay infusions, discovered that active paramoecia were readily destroyed by a 1 in 10,000 solution of quinine, though they withstood the action of enormously stronger solutions of strychnine and other poisons of vegetable origin.

Three momentous conclusions were drawn from this simple experiment: First, that the cause of malaria, which was then unknown or dimly guessed at as a nervous manifestation, would probably be found to be of protozoan nature, since malarial disease was so readily cured by quinine. Secondly, that by administering 15 grains of the hydrochloride to an average man a solution of twice the strength in the blood necessary to kill amoebae was formed, thus fulfilling the ideal of *therapia sterilisans magna* of Ehrlich. Thirdly, at a later period the working hypothesis of true chemotherapy was applied, by which it was inferred that the quinine entered into chemical combination with the protoplasmic molecule of the parasite, whereby it was robbed of its power of absorbing oxygen, and died of asphyxia.

Though Binz's work was mainly empirical and not conducted upon the purposive lines of Ehrlich's researches, nevertheless it affords us evidence that he was but dealing with another glimpse of the seamless garment of an eternal truth which will be found ultimately to clothe all drug action as well as every mysterious metabolic process in the living body.

From a consideration of the chemical basis of serum-therapy one is naturally led to test the value of this working hypothesis as affording an explanation of the advances made in vaccine-therapy by Wright. We shall pass lightly over these brilliant achievements, not because they are of less importance, but because the progress made in this direction does not very obviously appear from Wright's published writings to have been started entirely by the impulse of a chemical theory, as was the case in the more apparently purposive scheme of Ehrlich's researches.

The recent Witwatersrand Report of Sir Almroth on "The Treatment of Pneumonia" gives no uncertain note about his views on this subject and forces us to believe that vaccine treatment owes its origin to the conception of a true chemical combination occurring between the remedial vaccine and the bacterial protoplasm. Thus, he states that there is within the human body a laboratory which can, within certain limits, furnish bacteriotropic substances which will enter into destructive chemical combination with any and every variety of bacterial protoplasm without poisoning the tissues or becoming inert in the blood. All immuno-therapy and, in particular, all vaccine-therapy has been built up, he says, "upon these

facts and upon the fact that the chemical machinery which elaborates bacteriotropic substances is set in motion whenever a chemical attack is made upon the tissues by dissolved bacterial protoplasm." He objects to the term "chemotherapy" being restricted in its application to specific treatment by drugs, since, in all cases, both in serum and vaccine treatment as well as in specific drug therapy, the attack upon the microbes is a *chemical* attack.

A host of workers has already been busy with the test tube and the chemical balance in this department of investigation, guided by the side-chain theory, so that the mysteries of vaccine action and its allied phenomena are being steadily cleared up. But the light let in upon the working of the process flows from the genius of Wright through the discovery of his own peculiar methods of demonstrating the possibility of measuring dosage and results by the opsonic index and other modifications of the phagocytic machinery.

The chemical reactions are much more complicated, and hence more difficult of demonstration than in the case of the simpler neutralization of a toxin by its antitoxin, because, as already stated, no true antibodies are produced during vaccine treatment. Nevertheless, the serum of an immunized animal will kill the corresponding bacteria when these are added to it *in vitro* though in a distinctly different manner from that by which the diphtheritic and tetanus antitoxin act.

Two substances are required for this destruction of the microbe; one of these, the so-called *immune body*, is produced during the injection treatment, the other, known as the *complement*, exists already in the normal serum, and is not elaborated in increased amount by the injections. The side-chain doctrine hypothesizes the immune body as possessing two receptors, one of which binds it to the bacterial endotoxin, whilst its second affinity satisfies itself by combining with the complement. The possession of this double affinity of the bacteriolytic is recognized in its name of amboceptor. It must be regarded as an intermediary body which (in the chemical language of Wells), on being added to the bacteria during the process of immunization, gives to them a chemical affinity for the complement existing already in the blood serum. It is therefore the complement and not the immune body which effects the destruction of the bacteria.

The sceptic may say that this explanation is pure fancy and that chemical laws have nothing to do with the result, but Hektoen has been able to isolate the complement and to prove that it is a definite chemical compound. He has rendered it inactive by causing it to combine with the ions of calcium, magnesia, and sulphuric acid, and Manwaring has succeeded in divorcing it from these ions by a simple chemical reaction. Other investigators have shown that it is a body which, though closely resembling an enzyme and very susceptible to heat, nevertheless combines with the amboceptor, in obedience to the law of definite or multiple proportions which prevails in every true chemical reaction.

The most inscrutable problem arising in serum therapy is the phenomenon of hypersensitiveness which appears on the reinjection of a serum, and causes death when all is apparently going well with the patient. Wolf-Eisner pointed out that the fatal result was due to the operation of a general biological law governing the action of a heterogeneous albumen, namely, that it causes the formation of reactive substances. It is a most noteworthy fact that, quite recently, this hitherto insoluble crux has been brought under the grasp of the chemical working hypothesis in a most unexpected way by Friedberger, who, by mixing quantitative proportions of antigens, antibodies, and complement obtained from healthy serum, was able to liberate the chemical compound which produces the tragic phenomenon of hypersensitiveness.

From these important discoveries which have established a true working theory for serum therapy, vaccination treatment, and hypersensitiveness, we derive faith that the long cherished hope of dealing effectually with all bacterial diseases will be soon realized, especially as it has been abundantly proven that the protoplasmic molecules of nearly all the pathogenic organisms possess receptors capable of combining chemically with various staining reagents.

Till quite recently it must be confessed that all the more

important advances in therapy left the greater problem of the treatment of the diseases caused by endotoxin microbes untouched. Neither did the triumph of salvarsan aid us directly, save by lifting therapeutics out of the old rut of empiricism by demonstrating what could be achieved by the application of rational methods based upon a sound chemical theory.

The fringe of the dark cloud which like a pall had overshadowed the therapeutics of the commoner bacterial affections has recently been lifted by the experimental researches of Morgenroth and his co-workers. Writing of these results, Wright states that "they are destined to stand out as a landmark in the history of pharmacotherapy, because they furnish the first demonstration of the possibility of preventing and curing a bacterial—as distinguished from a protozoal or spirochaetal infection by the administration of a drug." The experiments were made by injecting mice with the pneumococcus, which always proved fatal when untreated. By injecting ethylhydrocupreinhydrochlorate before the inoculation 90 per cent. of the rodents were saved, and in 50 per cent. death was prevented when the salt was injected after infection. These results place the action of Morgenroth's agent in a totally different category from that of any known chemical antiseptic. When tested in the treatment of pneumococcal infections in man, though the new drug was found disappointing and was proved to produce optic disturbances, it affords us every reasonable hope that by proceeding on Ehrlich's rational lines a substitution product will be discovered capable of giving equal or better results than the startling effects on mice suffering from the same microbial infection.

A grave obstacle to the acceptance of a purely chemical hypothesis of drug action has hitherto existed in what we may term the bogey of catalysis and cell enzymes. Even this, however, has now been removed by the scientific explorer. The most recent researches into the nature of the highly complex chemical structure of the enzymes afford no clue to the plan of their constitution, which remains still a profound secret. All we know about them is derived from a study of their effects. They are to be found in every living cell, and the old view which maintained that all the metabolic phenomena of life were due to the vital activity of the cell is now shifted to the action of enzymes. These, even when intracellular, have in many instances been separated from the living protoplasm though in a state of only comparative purity.

Every known enzyme is undoubtedly in the first instance the product of a living cell, but the same may be said of quinine and strychnine, and the part played by the parent enzyme cell may be conceived by the demonstration of Kobert, who procured chemically active trypsin from the body of a spider preserved for a century and a half in the Nuremberg Museum, as Sehart discovered active glycolytic ferment in the muscles of a mummy. The researches of Croft Hill and Oswald have proved that the action of enzymes is simply a chemical one, thus the mystery of their behaviour, which a few years ago was regarded as the bulwark of the vitalist argument, has now been demonstrated to be nothing but a series of chemical reactions which are occurring in every cell in the body. The enzyme merely increases the speed of the reaction, which, like other chemical reactions, is reversible, the change occurring from either side of the equation till equilibrium becomes established. In this way, as clearly pointed out by Wells, enzymes not only hasten the splitting up of organic compounds, but they quicken synthesis, though both processes would go on without their presence, only at a much slower rate of progress. He sums up the results of our recent knowledge in the following words: "All metabolism may be considered as a continuous attempt at establishment of equilibrium by enzymes perpetuated by prevention of attainment of actual equilibrium through destruction of some of the participating substances by oxidation, or other chemical process, or by the removal from the cell, or entrance into it, of materials which overbalance one side of the equation."

If we could clearly prove that the action of enzymes is to be explained on a purely chemical basis, as has been done in the case of the toxin and antitoxin, it must be conceded that the way to a clearer chemical conception of drug action is opened up. I believe that this has been done, for the following reasons:

Though enzymes do not act quantitatively, they are, nevertheless, practically identical, pharmacologically, with true toxins—that is, with those chemical compounds which are the free secretion of bacilli. If a full dose of a sterile enzyme be introduced into the circulation, a profound toxæmia, terminating in death, occurs. When a smaller amount is injected and repeated in increasing quantities, immunization results from the formation of antibodies, which impart an anti-enzymatic property to the blood serum. This serum, when removed from the vessels of the immunized animal, is found to possess the power of neutralizing fatal doses of the enzyme injected into another animal, and appears to behave, in every particular, in the same manner as the antitoxin of diphtheria does with its toxin. Moreover, the anti-enzymatic action of the serum is rigidly specific, combining only with its own enzyme, as pointed out by Lister.

It appears, therefore, impossible to escape the conclusion that the ferment contains a haptophore and toxophore group, which combine chemically with receptors in the molecule of the antiferment. This would probably apply also to the action of specific hormones, to which Dixon tentatively attributes the physiological activity of the tissues.

The importance of the acceptance of a chemical theory for the explanation of the action of enzymes affects the science of therapy much less than it does that of physiology and pathology. We realize this when we think of the modern biologist's view that the living cell must be regarded as a co-ordinated system of ferments, upon whose activities all the phenomena of life depend. Not only are they incessantly breaking down, but they are as continually building up or synthesizing new compounds and forming antibodies whose presence prevents the autodigestion of the different organs and tissues in the body.

To this broad conception of biological chemistry we might apply a modification of the old Greek's jest—The world is supported by Atlas, Atlas is supported by a tortoise, whilst *Chelonia graeca* itself is resting upon fair weather. E. J. Lewis has playfully suggested that the riddle of the world might be better figured by substituting the word "enzymes" for "fair weather," and I would venture to transform the burlesque into a scientific truth by suggesting that the enzymes are now resting finally upon the solid foundations of chemistry, whose laws govern—

"Air and ye elements, the eldest birth of Nature's womb, that in quaternion run, perpetual circle multiform; and mix and nourish all things."

Any survey of the potent factors in recent therapeutic advance would be very imperfect without a recognition of those purely physical forces whose fascinating influence is obviously manifesting itself on the mind of every explorer in each of the domains of natural science. I refer to those physical laws whose operations are seen in alterations of surface tension, osmosis, diffusion, dissociation, etc.

Our recently acquired knowledge of these forces sometimes proves a veritable *embarras de richesse* to the pharmacologist. Thus one of the latest arguments used for the support of the old physical view of drug action is derived from the study of the *modus operandi* of the hypnotics and narcotics by applying the theory of Hans Meyer and Overton. This postulates that the selective action of a narcotic depends upon its solubility in the brain lipoids, the more powerful members of the group being those least soluble in water and most soluble in fat. Traube's theory also runs on purely physical lines, since he attempts to explain the hypnotic action by assuming a difference of the surface tension, which alters the velocity and direction of the osmosis.

The applications of such theories may, with all respect to their supporters, be regarded as an illustration of the invisibility of the wood because of the presence of its trees. To the searcher after the truth of things such theories merely explain the entrance of the drug molecule to the cerebral cell protoplasm without affording us any help whatever regarding the way in which the narcotic effect is produced. To obtain this we must fall back on the chemical theory of Baglioni, which assumes that the temporary paralysis of the cerebral cell is due to the withdrawal of its life-giving oxygen, since the benzene-phenol compounds, in obedience to the law of relationship

between physiological activity and chemical constitution, exert their hypnotic action in inverse proportion to the amount of oxygen present in their lateral radicals. That such reduction explanation is almost certain to be true is proved experimentally by the fact that ether, chloroform, chloral, and alcohol reduce the oxidizing power of living cells. Moreover the physical theory of Overton and Meyer fails entirely to afford any explanation of the action of the most typical member of the group—alcohol.

The more closely we examine the physical and vitalistic conceptions of drug action the more certain does it appear that behind the operation of physical laws and vital activity, chemical reactions are continually taking place which are the real cause of the physical forces being themselves set in motion. Such a statement as this might at first sight appear to be bringing us perilously near to a futile discussion on the origin of life should we venture to define life itself simply as a form of chemical action as some have done. But it is quite another matter to recognize that the original fiat—"Let there be life"—effects its mysterious design through the operation of chemical laws aided by the physical forces which are to be seen in action everywhere around us.

As I draw these necessarily disjointed generalizations to a close, let me for a brief moment turn from the theories of drug action to a wider arena, where we may see in active operation all the forces which are probably also busily engaged in every pharmacological experiment. It will widen our horizon to realize what the application of a chemical hypothesis is doing for the science of pathology, upon which science only can we hope to build up a rational therapy. I will therefore ask you to glance at a subject which has engaged the attention of every pathological explorer since the advent of Virchow's conception of the cell being the structural unit of the living organism. I refer to the mechanism of inflammation. The most prominent and constant feature observable in the early stage of a local inflammatory process is the remarkable phenomenon of the invasion of the site of inflammation by hosts of leucocytes. Whence they come in such increased numbers into the circulating fluid we need not pause to consider; we are mainly concerned with the fact of their rapid swarming to the seat of injury. Why do they come? Can any explanation be given of their remarkable behaviour in penetrating the capillary walls and migrating far and near into the injured tissues? Whether we accept the earlier views of Metchnikoff and regard them as fighting cells or accept the later view of Baumgarten, which gives to them the position of grave diggers, we long for some light on the way in which they are seen to engulf foreign bodies such as bacteria or fragments of perished tissue.

Those who swallow the doctrine of vitalism have no difficulty in regarding each leucocyte as a sentient and discriminating gourmand who carefully selects and enjoys his food, who occasionally, disdaining the limits of his little reign, breaks bounds voluntarily, and may even seem in so doing to snatch a fearful joy. The scientist, however, explains easily the entire phenomenon in a perfectly rational manner by the application of the bio-chemical principle known as chemiotaxis.

It has been demonstrated that certain chemical substances powerfully attract the leucocytes, and these amoeboid organisms are seen to be drawn towards them when such compounds are brought anywhere near their zone. It appears to be absolutely certain that the immigration of the white cells into the site of an inflammatory action is determined by a chemical change in the protoplasm of the injured tissue or to the presence of a soluble chemical in its fluid constituents.

If any one doubts that the apparently volitional movements of a leucocyte cannot mostly be explained in this easy manner, he has only to resort to the simple experiment of manufacturing for himself an artificial amoeba and watching its extraordinary behaviour when various substances are brought into its presence. By placing a single drop of oil of cloves in a small dish partially filled with a mixture of alcohol and glycerine, the little bladder of oil floating on the surface will be found in structural and other peculiarities to conform to the type of an amoeba, and I have been able to form even vacuolated artificial amoebae by pouring chloroform into strong perchloride of iron solution.

Rhumbler's clove oil amoeba may be made to perform all the puzzling antics of a living leucocyte by gently injecting into the liquid in its immediate vicinity substances which alter the surface tension on one side of the sphere. In this manner it can be made to throw out pseudopodia like a living cell. A chloroform droplet in water can be repeatedly fed by various substances which it will take into its interior. If an insoluble solid, as a particle of quartz, coal, or glass, be coated over with a thin layer of shellac and presented to this artificial amoeba it is speedily swallowed, engulfed or surrounded, and after it has digested or dissolved its resinous envelope the droplet disgorges its indigestible prey. If the lac be offered in the form of a drawn out thin thread of sealing wax it will be seen to seize it by its middle and bend it, after which it throws out pseudopodia to the ends of the thread so as to pull the thread within itself by coiling it up in its interior till its solution, or we may say till its digestion, is completed.

The startling lifelike osmotic growths of Stéphane Leduc illustrate but another phase of the same phenomenon. These fantastic formations of dead sterilized chemical substances absorb food into their interior, break it up chemically, expel the waste products of the reaction, using only those necessary for their growth. They reject some chemical substances when offered to them and greedily absorb others; they grow up vigorously during their short-lived youth; remain stationary for a time, then die and suffer disintegration like living beings.

These phenomena of chemiotaxis and alterations in the surface tension so closely simulate life that many observers have ceased to hesitate to apply their action to the explanation of the behaviour of the leucocytes in the inflammatory area, though Jennings thinks that he sees a fundamental difference in the flow of the fluid contents. Each amoeboid leucocyte contains its own co-ordinated system of enzymes, the ceaseless activity of which is incessantly effecting changes of a chemical nature in the surrounding liquid medium by which the laws of surface tension and chemiotaxis are kept in constant action.

It is not only in the mechanism of the inflammatory process that chemiotaxis has been shown to play such a prominent part. From the biologist's point of view the crowning or supreme function of the living organism is seen in the phenomenon of reproduction. I need not remind you how Sir John Bland-Sutton, in the fascinating and original oration of last year, referred to the subject of genetic attraction, in which is witnessed the operation of some powerful and mysterious force by means of which the spermatozoon is drawn towards the passive yolk-laden ovum. Pfeffer experimentally demonstrated that malic acid strongly attracts the spermatozooids of various ferns when brought within their zone. Now, this substance has been found to be produced within the female sperm cell, and it can hardly be doubted that it is the agent which determines the actual contact of the male with the female elements of the cryptogam. It was to the discovery of this strange phenomenon that we owe the origin of the term "chemiotaxis"—a force which thus plays a leading part not only at the very inception of the life of the new individual, but all through his prolonged struggle against disease and final dissolution.

When we are thus enabled to realize the prominent part which chemical laws play in the phenomena of inflammation, and likewise also in the process of immunization, it cannot but aid us in accepting at least the high probability if not the actual proof of the force of such factors operating in all drug action. We then in renewed hope and strong faith can look forward to our arrival at the final goal of a rational therapy by travelling on the guiding lines which the genius of Ehrlich and of Wright has laid down for future research work.

THE late Dr. Alfred Chumbe Fletcher, Resident Medical Officer of Sutton's Hospital in the Charterhouse, left estate valued at £18,441.

THE Fourteenth International Antialcohol Congress will be held in Milan in September (22nd to 28th). The proceedings will be introduced by Professor Ettore Marchiafava, of Rome, with an address on the pathology of alcoholism. One day will be devoted to a discussion of the relations between the campaign against alcohol and the interests of viticulture.

FURTHER EXPERIENCE OF THE CARDIAC SIGN IN CANCER.

By WILLIAM GORDON, M.D.CAMB., F.R.C.P.LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

SOME nine years ago¹ I drew attention to a cardiac sign in cancer which seemed to possess some diagnostic value, and over four years ago² I published evidence that this value existed. I now desire to bring forward further evidence corroborating the former, and, from fuller experience, to define more closely the extent of the value and its limitations. May I remark that our means of diagnosing cancer, even in its later stages, are not always so perfect as to make any help superfluous?

The cardiac sign in cancer consists of a remarkable diminution of the cardiac dullness in the recumbent posture as determined by digital percussion. In that posture the dullness, in the normal adult, begins above about the third costal cartilage, reaches rightwards as nearly as possible to the mid-sternal line, and measures across about 3 to 3½ in. at the level of the fifth costal cartilage. On the other hand, in the cancer patient who presents the sign the cardiac dullness in recumbency begins above about the fourth or fifth costal cartilage, has its right margin ½ in. or 1 in. to the left of the mid-sternal line, and measures across less than 2 in. at the level of the fifth costal cartilage. Often it measures less than 1 in. across. Sometimes there is no cardiac dullness at all.

Digital percussion is a good deal dependent on personal factors. The measurements I am here quoting refer to my own observations. Others may find somewhat different limits. The percussion I use is moderately light.

The sign may be explained in three different ways:

1. In some cases of cancer the heart is small, and this reduction in size has been said to account for the reduction of the dullness. It may sometimes partly explain it; but by no means always; for often the dullness, though very small in the recumbent position, is normally or even abnormally broad in the erect.

2. If the loss of elasticity, so common in the skin in cases of cancer, affects the lung as well, it is conceivable that ordinary respiration may induce a sort of spurious emphysema and thus diminish the dullness. It is now known that a peculiar form of emphysema does often occur in cancer—Fenwick found it in 28 per cent. of his cases of gastric cancer³—and no doubt in many cases this helps to produce the sign.

3. The cardiac sign is often associated with a remarkably soft and toneless pulse, and with very feeble heart sounds. If we suppose that the first is due to a deficiency of blood—such as the anaemia so often present suggests—and that the second shows a flabbiness of the heart muscle comparable to the flabbiness of the skeletal muscles so often recognizable in such patients, it is not difficult to imagine a flabby and imperfectly filled heart dropping back from the anterior chest wall on recumbency more than a normal heart would do. And this is just what actually seems to occur. For the disparity between the heart dullness in the erect and recumbent positions in cancer is usually much greater than that observed either in health or in other diseases. I have found, for instance, a heart dullness in a case of cancer, measuring 5 in. across in the erect position, drop to 1½ in. across when the recumbent posture was assumed. Indeed, in cases where an enlarged heart prevents the appearance of the cardiac sign as I have defined it, I have thought that such an exceptional disparity in the erect and recumbent dullnesses, or an exceptional withdrawal leftwards of the rightward edge of dullness on assuming the recumbent position, had almost the same meaning as the cardiac sign itself. That, however, requires further investigation.

But it is necessary to bear in mind certain obvious limitations of the sign's significance. Thus, when any cause is present tending, like common emphysema, to reduce the heart's dullness, then a very small cardiac dullness has naturally no special meaning. Also where, in a case of suspected cancer, some well known cause of enlarged cardiac dullness is present, such as albuminuria, valvular heart disease or retraction of lung from phthisis or former pleurisy, then the absence of the cardiac sign is, of course, of no significance.

To these obvious limitations I would add two others, from experience, less obvious and yet easily understood. Where the heart is considerably displaced upwards by abdominal distension, I have found the sign unreliable. Here clearly the organ is pushed from a wider into a narrower space, where it cannot so easily drop away on recumbency from the anterior chest wall. Again, where a large oesophageal cancer has lain just behind the heart the sign has been absent, and I have thought that this might be explained by the growth pinning the organ forward against the sternum and rib cartilages.

TABLE I.—Thirty-six Cancer Cases in which all other Causes tending to Reduce the Cardiac Dullness were Absent.

| Seat of Disease. | Age. | Loss of Weight, etc. | Cardiac Dullness. | |
|------------------------------|------|---|-------------------|---------------|
| | | | Width. | Upper Level. |
| | | | Inches. Almo. | Rib. st nono. |
| Stomach ... | 46 | Late. 1 stone lost; trace of albumen | — | — |
| Stomach ... | 64 | Late. Died soon; 30 lb. lost | 2 | — |
| Stomach ... | 66 | Late. Died soon | 2 | — |
| Stomach ... | 60 | Late. Tumour | 7 | 5th |
| Stomach ... | 38 | Early. Operation; removed; microsc. | 1 | 5th |
| Caecum ... | 50 | Late. Emaciated; gland microsc. | 1 | — |
| Rectum ... | 55 | Late. Extremely thin; palpable | 1 | 4th |
| Prostate ... | 49 | Late. Ulcer into rectum | 1 | 5th |
| Stomach ... | 54 | Late. Operation; microscop. | 1½ | 4th |
| Stomach ... | 45 | Late. Tumour; 2 stone lost | 1½ | 4th |
| Stomach ... | 66 | Glycosuria. Died 8 months later of cancer of liver | 1½ | 5th |
| Pharynx ... | 54 | Large fixed glands in neck. Iodide useless | 1½ | 4th |
| Liver ... | 45 | Late. Trace of albumen | 1½ | 4th |
| Colon ... | 62 | Late. Died a month after leaving hospital | 1½ | 4th |
| Stomach ... | 47 | Late. Tumour | 1½ | 4th |
| Sigmoid ... | 42 | Late. Mass palpable; 2½ stone lost | 1½ | 4th |
| Cervix uteri ... | 50 | Not quite fixed | 1½ | 4th |
| Recurrent in brachial plexus | 64 | After removal of glands in axilla | 1½ | 5th |
| "Abdominal" ... | 48 | Late. Nodule microsc. | 1½ | 4th |
| Rectum ... | 62 | Early. Some loss of flesh; operation; removed | 1½ | 4th |
| Oesophagus ... | 56 | Late. P.M. | 1½ | 4th |
| Pancreas ... | 70 | Late. P.M. | 1½ | 4th |
| Stomach ... | 66 | Late. Died "evidently from cancer" | 1½ | 4th |
| Stomach ... | 64 | Late. Tumour | 1½ | — |
| Stomach ... | 70 | Late. Tumour | Under 2 | — |
| Caecum ... | 68 | Late. Died; tumour and large fixed glands | Under 2 | — |
| Oesophagus ... | 68 | Late. Died | Under 2 | — |
| "Abdominal" ... | 77 | Late. Died; doctor sure it was cancer | Under 2 | — |
| "Abdominal" ... | 70 | Late. Also cancer of breast | Under 2 | — |
| Skin of neck ... | 73 | Late. After removal of tongue | Under 2 | — |
| EXCEPTIONS. | | | | |
| Stomach ... | 44 | 7 months' duration. Lost 3½ stone; advised exploration; died 8 months later of perforation; operation | 3½ | 3rd |
| Ovary ... | 47 | 3 months' pain. No loss of flesh; healthy appearance; advised exploration; operation; removed | 3½ | 3rd |
| Rectum ... | 56 | Late. Fixed; considerable wasting | 3½ | 3rd |
| Transverse colon | 50 | 1 month symptoms. No loss of flesh; healthy appearance; diagnosed cancer; operation; too adherent to remove | 3 | 3rd |
| Stomach ... | 60 | Late. Tumours, apparently in stomach and liver; loss of flesh; no free HCl | 2 | 4th |
| Stomach ... | 56 | Late. Large tumour, apparently gastric; loss of flesh 1 stone | 2 | 4th |

Yet, allowing for all these limitations to its employment, there remains a very large number of cases in which its usefulness or uselessness can be tested. In the accompanying lists it should be understood that all sources of error from any of the causes I have mentioned have been carefully excluded.

What, then, is its precise value?

In 1908, from a study of 103 cases,² into all of which a suspicion of cancer had entered, I obtained the following figures: Of 38 cases in which a presumable cancer was naturally accessible to direct observation or was examined at operation or *post mortem*, 89 per cent. showed the cardiac sign. Of 19 cases which ended fatally in accordance with a diagnosis of cancer, nearly 90 per cent. showed it. Of 46 cases, on the other hand, which could not be supposed to have been cancerous, it was only found present in 24 per cent.

My further experience bears out this contrast. During the last four years I have collected 107 cases, either cancerous, simulating cancer, or accompanied by loss of flesh. They indicate that whereas in cancer the sign is present in an overwhelming majority, in non-cancerous cases it is even rarer than my former figures suggested.

Thus, of 36 cases which appear undoubtedly to have been cancerous, 83 per cent. showed the sign (Table I), whereas of 71 cases which cannot be supposed to have been cancerous, only 8 per cent. showed it (Tables II and III).

Putting together this series and that of 1908, we obtain 33 cancerous cases showing the sign in nearly 87 per cent., and 117 non-cancerous cases showing it in only 14 per cent.; or, considering the results in another way, of

TABLE II.—Twenty-eight Cases of Pronounced Non-cancerous Wasting, in which Heart, Lungs, and Kidneys were Healthy.

| Disease. | Age. | Loss of Weight, etc. | Cardiac Dullness. | |
|-------------------------|------|---|--------------------|--------------|
| | | | Width. | Upper Level. |
| Addison's disease | 43 | 3 stone | Inches. Increased. | Rib. — |
| Leucocythaemia | 43 | 6 stone | 5½ | 3rd |
| Diabetes | 63 | " Much loss " | 4 | 3rd |
| Diabetes | 58 | " Much loss " | 4 | 3rd |
| Hysterical polyuria | 54 | Over 3 stone. Better 6 months later | 4 | 3rd |
| Gall stones | 49 | ½ stone. Well 2 years later | 4 | 3rd |
| Diabetes | 35 | 3 stone | 3½ | 3rd |
| Diabetes | 21 | 1 stone | 5½ | 3rd |
| Diabetes | 20 | 2 stone | 3½ | 3rd |
| Diabetes | 33 | 4 stone | 3½ | 3rd |
| Diabetes | 32 | " Emaciated " | 3½ | 3rd |
| Tuberculous glands | 34 | " Considerable loss." Operation; micros. | 3½ | 3rd |
| Gastritis | 62 | 3 stone. Well 6 months later | 3½ | 3rd |
| Psoas abscess | 53 | " Great loss " | 3½ | 3rd |
| Diabetes | 74 | " Great loss " | 5½ | 3rd |
| Addison's disease | 21 | " 2 or 3 stone." No question of cancer | 3½ | 3rd |
| Gastritis | 20 | Probably 1 stone | 3½ | 3rd |
| Gastritis | 34 | " Very much loss." Operation; no cancer | 3 | 3rd |
| Tuberculous peritonitis | 16 | " Much loss " | 3 | 3rd |
| Tuberculous peritonitis | 17 | " Much loss " | 3 | 3rd |
| Diabetes | 30 | " Considerable loss " | 3 | 3rd |
| Diabetes | 35 | 2 stone | 2½ | 3rd |
| Gastric ulcer | 37 | Emaciated; perforated; operation; no cancer | 2½ | 4th |
| Gastric ulcer | 27 | " Great loss " | 2½ | 3rd |
| Psoas abscess | 22 | 2½ stone | 2½ | 3rd |
| Febrile enteritis | 42 | Great loss. Recovered. | 2 | 4th |
| EXCEPTIONS. | | | | |
| Gastritis | 55 | 2 stone. Much better 6 months later | Under 2 | — |
| Gastritis | 69 | " Many pounds loss." Better 3 years later | Absent. | — |

TABLE III.—Forty-three Non-cancerous Cases, either with Wasting or with Suspicion of Cancer, in which Heart and Lungs were Healthy and Bright's Disease absent.

| Disease. | Age. | Loss of Weight, etc. | Cardiac Dullness. | |
|-----------------------|------|--|-------------------|--------------|
| | | | Width. | Upper Level. |
| Mucous colitis ... | 63 | Well 3 years later | Inches. 4 | Rib. — |
| Ovarian tumour... | 47 | Operation. No cancer | 4 | 3rd |
| Gall stones | 49 | Lost 20lb. Much better 2 years after | 4 | 3rd |
| Gastritis | 53 | Well 3½ years after | 4 | 3rd |
| Haematemesis ... | 56 | Well 1 year after | 4 | 3rd |
| Operation for piles | 37 | No cancer | 4 | 3rd |
| Abscess left kidney | 43 | Urine normal. Operation | 4 | 3rd |
| Gastritis | 26 | Lost a good deal of weight. Well 18 months after | 3½ | 3rd |
| Gastritis | 48 | His doctor suspected cancer. Well 1 year after | 3½ | 3rd |
| Gastritis | 29 | Lost a good deal of weight. No cancer | 3½ | 3rd |
| Tuberculous kidney | 28 | Urine normal after removal. Great wasting | 3½ | 3rd |
| Gastric ulcer | 41 | Much better 2 years after | 3½ | 3rd |
| Mucous colitis ... | 39 | Lost ½ stone. Well 5 months after | 3½ | 3rd |
| Gastritis | 62 | Lost 3 stone. Well 6 months after | 3½ | 3rd |
| Abscess of thigh... | 66 | Lost some pounds | 3½ | 3rd |
| Miscarriage | 25 | " Much thinner " | 3½ | 3rd |
| Hydronephrosis... | 65 | — | 3½ | 3rd |
| Splenomegaly ... | 43 | No suspicion of cancer. Improved | 3½ | 3rd |
| Gall stones | 55 | Operation. No cancer | 3 | 3rd |
| Appendicitis | 60 | Lost much weight. Operation; no cancer | 3 | 3rd |
| Neurasthenia | 55 | Lost much weight. Well 1 year after | 3 | 3rd |
| Gastritis | 37 | Had lost weight. Greatly improved | 3 | 3rd |
| Hysteria | 42 | Extremely thin. Greatly improved | 3 | 4th |
| Ovarian tumour ... | 30 | Loss of weight. Operation | 3 | 3rd |
| Gastritis | 37 | — | 3 | 3rd |
| Tuberculous bladder | 30 | Bright's disease absent | 3 | 3rd |
| Goitre | 43 | Had lost weight. No evidence of cancer | 3 | 3rd |
| Gastritis | 43 | Very thin. Well 1 year after | Normal | — |
| Abdominal adhesions | 65 | Operation. No cancer | Normal | — |
| Duodenal ulcer ... | 60 | Lost much weight. Operation; no cancer | Normal | — |
| Thyroid tumour ... | 56 | Hard, nodular, adherent. Well 3 years after | Broad | — |
| Abscess in pelvis ... | 53 | Question of sarcoma. None found | Normal | — |
| Gastritis | 63 | Family history of cancer. Well 3 years after | Normal | — |
| Gall stones | 60 | Well 1 year after | Normal | — |
| Neurasthenia | 47 | Well 1 year after | Normal | — |
| Dysphagia | 34 | Well 3 years after | Normal | — |
| Gastritis | 38 | Very thin. Well 4 years after | Normal | — |
| Gastritis | 56 | Losing weight. Well 2 years after | 2½ | 3rd |
| Gastritis | 31 | Stomach dilated. Well 4 years after | 2½ | — |
| EXCEPTIONS. | | | | |
| Gastritis | 52 | Advised exploration. Well 3½ years after | 1 | 4th |
| Dilated stomach | 47 | Better 2 years after | ¾ | 5th |
| Gastritis | 44 | Lost ½ st. in 2 months. Better 4 years after | ¾ | — |
| Dysphagia | 64 | Cause. Now has jaundice, but no proof of cancer | Absent | — |

98 cases showing the cardiac sign 82 per cent. were cancerous, and of 112 cases not showing this sign 88 per cent. were non-cancerous.

To be entirely fair, however, only such cases should be compared with the cancerous as themselves were open to a possibility of malignancy like those dealt with in 1908. Amongst those enumerated in Tables II and III, I think 37 cases may be so regarded, as may also the 6 exceptions.

Here, therefore, we have a series comparable to that which I published in 1908. They give a percentage of only 14 showing the cardiac sign. Adding the two series (of 1908 and 1912) together, we obtain 89 cases non-cancerous but more or less open to the suspicion of being cancerous, with only 19 per cent. showing the sign, a striking contrast to the actually cancerous cases: and of 88 cases which did not show the sign 85 per cent. were non-cancerous.

So that in a suspected case of cancer the presence of this sign adds considerably to the likelihood of the presence of cancer and its absence to the likelihood of the absence of cancer, except, I should add, in early cases.

But it has been objected by an able observer that the sign is only corroborative of considerable wasting. If this were correct, the sign would only be a curiosity. The following facts show that his suggestion is mistaken.

In non-cancerous wasting, even when extreme, it is rarely present (Table II).

In cancerous wasting, even when marked, it is occasionally absent (Table I).

In cases of cancer which have not wasted at all, it is sometimes present (Table I).

Indeed, it is not apparently even true that the diminution of the dullness in cancer is proportional to the wasting (see Table IV).

TABLE IV.—Cancer Cases in which the Amount of Wasting is indicated distinctly (in TABLE I).

| Amount of Wasting. | Cardiac Dullness. | | Amount of Wasting. | Cardiac Dullness. | |
|--------------------|-------------------|--------------|--------------------|-------------------|--------------|
| | Width. | Upper Level. | | Width. | Upper Level. |
| None | Inches. 3½ | Rib. 3rd | 2½ stone ... | Inches. 3 | Rib. — |
| None | 3 | 3rd | 2½ stone ... | 1½ | 4th |
| 1 stone... .. | Almost none | — | 3½ stone ... | 3½ | 3rd |
| 1 stone... .. | 2 | — | "Extremely thin" | 1 | 4th |
| 2 stone... .. | 1½ | 4th | "Emaciated" | 1 | — |

One very important question—the value of the sign in operable cases—I cannot settle because so few operable cases, satisfying the conditions I have laid down, have presented themselves. But it is worth mentioning that of 6 operable cases 4 gave the sign.

Another important question—how often the sign may lead one into error—can be reasonably answered. If ordinary care be taken and the frequency of its occurrence in cancer and of its non-occurrence in other cases be remembered it should rarely mislead. In the cancer cases which were operable it caused no mistake. In non-cancerous cases it has, perhaps, induced me to suggest exploration unduly often—a pardonable error—and in several to hazard an erroneous forecast. On the other hand, had I paid more heed to it, I should have saved myself more than once from mistake.

In sarcoma I have noticed that the sign seems less commonly present.

With regard to some of the earlier cases it is instructive to recall the opinions of others—all men well qualified to form a sound judgement, but without the advantage of experience of the sign.

Cicum.—Diagnosed five weeks before a distinguished surgeon would accept the opinion and operate. After operation the growth recurred.

Sigmoid.—A well-known surgeon declined to admit that a diagnosis was possible; it had been made, however, and on operation a cancer was found and removed. It has not recurred during five years.

Stomach.—An able surgeon declined to accept the diagnosis and to operate. He operated, however, several months later. Cancer was found (microscoped).

A friend of mine, who habitually looks for the sign, has had a similar experience to these. He sent an early uterine cancer to a well-known specialist. The specialist declined to operate, because he considered the case was not cancerous. In fact, I believe he treated my friend with some contumely. Later on, when the case was inoperable, he apologized.

In conclusion, I would sum up thus the results of my experience:

1. The sign is of practical value.
2. If present in a case where the presence of cancer is possible, the diagnosis of cancer should only be rejected after most careful consideration.
3. If absent in what may be an early case of cancer, little stress must be laid on its absence.
4. But if absent in what must be, if cancer at all, a late case of it, its absence strengthens considerably the likelihood of the absence of the disease.

LIPODYSTROPHIA PROGRESSIVA.*

BY

F. PARKES WEBER, M.D., F.R.C.P.,
SENIOR PHYSICIAN, GERMAN HOSPITAL, LONDON.

I WOULD define lipodystrophia progressiva (λίπος = fat, δυσ = bad, τροφή = nourishment), a term for which we are indebted to Dr. A. Simons¹ of Berlin, as a morbid condition, possibly confined to the female sex, and characterized by progressive disappearance of the subcutaneous fat from the face, upper extremities, and trunk, whereas the fat of the lower extremities and gluteal regions remains unaffected or is increased in amount. In some cases, perhaps, the condition is one of pathologically altered distribution of fat rather than of genuine wasting, or possibly merely of relative excess of fat in the lower extremities and buttocks of an otherwise rather thin subject. Although I have retained the adjective "progressiva" as suggested by Simons, it is by no means certain that the disorder is always a progressive one. In all probability all degrees of this abnormal fat distribution occur, progressive in some subjects, and arrested or stationary in others, whilst in yet other cases the condition may probably occur as only a temporary feature in the life-history of a patient or as little more than a slight exaggeration of a normal female sex character. In this connexion it must of course be remembered that the development of subcutaneous fat is greater in the thighs and gluteal regions of the average human female than of the average male. This local distribution of subcutaneous fat constitutes practically a secondary sex character, and the gluteal prominence is greatly exaggerated in some African races, constituting the racial peculiarity known as "steatopygia," which is illustrated by the pictures of the "Hottentot Venus."† In regard to the occasional exaggeration of this sex character in Europeans I would quote a remark made by Pierre Marie at the discussion of a case at the Société de Neurologie, at Paris, July 11th, 1912—namely, that it is not rare to meet with women the upper part of whose bodies is emaciated in comparison to the fatness of their lower limbs. A curious fact is that in some pathological conditions, notably in the case of a young woman shown by Dr. H. G. Turney at the Royal Society of Medicine on March 5th, 1913, as probably an example of "a pituitary and adrenal syndrome," this sexual predominance of subcutaneous fat about the thighs and gluteal regions is altogether wanting, though there may be an apparently excessive accumulation of subcutaneous fat in the face and trunk.

In June, 1911, I saw a young unmarried woman, aged 27, of Jewish parentage, who had lost almost all the subcutaneous fat from her body, but less from the parts below the iliac crests and groins—that is to say, from the buttocks, thighs, and legs—than from the trunk, face, and upper extremities; moreover, there was no extreme loss of fat from the orbits or mammae. I found no evidence of any visceral disease. There was a report of temporary glycosuria about one year previously,‡ which I

* A paper read at the Neurological Section of the Royal Society of Medicine on May 22nd, 1913.

† In regard to the racial distribution of "steatopygia," see S. G. Shattock, On Normal Tumour-like Formations of Fat in Man and the Lower Animals, Proceedings of the Royal Society of Medicine, Pathological Section, London, 1909, pp. 209-226.

‡ Transient glycosuria is, I believe, not rarely to be found in young persons with various disorders of general nutrition and development. I have noted it myself in an undeveloped girl of the "mitral infantilism" class, and in a young woman with a moderate degree of infantilism of the "atrophic" class. I showed both these cases at the Royal Society of Medicine in the first half of 1913.

regarded as of no importance. The clinical history was that the patient was a healthy girl up to the age of 16 years, when the menstrual periods commenced. Since then her general condition had been unsatisfactory. She had suffered from a certain amount of pain with the periods, and likewise complained of dyspnoea and of insomnia, for which she had taken various drugs. She was likewise discontented with life in her parents' home, and was desirous of obtaining some useful occupation, which would render her more independent. In January, 1913, I heard that her condition remained much the same. There was some neuropathic family history.

The condition had to be regarded as a peculiar variety of emaciation, probably in some way dependent on the nervous system, the distribution of the fat-atrophy being specially affected by the patient's sex, so that the lower extremities (normally very liberally supplied with subcutaneous fat in females) retained their fat.

At the time when I saw this patient in 1911 I already had seen one similar case:

A young woman, aged 21 years, was brought before the Clinical Society of London on March 22nd, 1907,² by Dr. Harry Campbell, who described the case as one of "disappearance, more or less complete, of the subcutaneous fat above the region of the lower extremities." The wasting of the fat was specially marked in the face, chest, and abdomen, including the region of the mons veneris, but there was no disappearance of fat from the mammary glands or the orbits, and there was an abundant deposit of subcutaneous fat in the buttocks and lower extremities generally. The patient, who was of Jewish parentage, was said to have been perfectly normal up to the age of 6 years, but from that time to the age of 14 years the fat gradually disappeared from the affected regions. The fat first disappeared from the face, and then the process of fat-absorption gradually spread downwards at the rate of about one inch every year. Six years later Dr. Campbell showed the case again, and said that the absorption of subcutaneous fat had spread about six inches downwards during the six years' interval. The orbital fat and the mammary fat still remained unaffected. Tests revealed no difference between the secretion of the sudoriferous glands in the affected and unaffected areas. He regarded the case as one of "trophic" changes of obscure origin.³

A very similar case was described and illustrated by Dr. Eugen Holländer, of Berlin,⁴ in 1910:

In a young woman aged 21 years the intraorbital fat appeared to some extent to have shared in the atrophic process, so that the patient had a peculiarly cadaverous expression. The cheeks were sunken and the orbits were hollowed out around the eyes. The mammae were round and hard, but apparently consisted of glandular tissue only. The superficial muscles of the neck, trunk, and upper extremities were mapped out, as in "anatomical manikins." Below the hips, on the contrary, all the parts were covered by subcutaneous fat in abundance, and, indeed, there was decided excess of fatty tissue in the outer parts of the thighs. Except for a rotatory nystagmus, apparently of congenital origin, nothing else abnormal could be discovered. All kinds of treatment had been tried, but had failed to fatten the patient—that is to say, to fatten the emaciated parts—but from the cosmetic point of view Holländer seems to have been more successful by injecting a sterilized mixture of human fat and mutton suet into the subcutaneous tissue of the face.

Sir William Osler has very kindly told me of a similar loss of subcutaneous fat, but occurring in a much younger girl.

The patient was only 10 years old in 1895, when she was first brought for treatment as a dispensary patient in America. The contrast between the extreme thinness of the face, trunk, and upper extremities and the plumpness of the part below the hips was very great. She had begun to get thin five years previously, the loss of flesh being first noticed on the face and back. She was very pale. Her mother and mother's mother were said to be "nervous."

Information obtained in February, 1913, showed that menstruation had commenced when the girl was 12 years old, and that her general condition improved afterwards. Her face had still little subcutaneous fat, though more than it had before, but no complete examination of the patient had been made during late years. Though she still looked thin and weak, she said that she felt well and was much stronger than most women. The tendon reflexes were excessive.

A case, evidently of the same class, was described by A. Pic and Ch. Gardère at the Society of the Medical Sciences of Lyon on December 23rd, 1908, as an example of "generalized atrophy of the face and parts of the body above the umbilicus with pseudo-hypertrophy of the pelvic region and lower extremities."⁵

The patient was a woman (age not stated) whose illness had commenced four years previously, with sudden loss of weight and strength, anorexia, digestive troubles, and pallor. There was no cough. She was unable to continue her work, as the

slightest effort gave rise to palpitation of the heart and feeling of oppression. She was also mentally depressed, and gave way to frequent attacks of crying without any reason. After a "rest and feeding cure" she commenced to regain strength, the lower extremities increased in size, and her pallor disappeared. At last, after an interruption of one and a half years, she was able to start work again. Nevertheless, her face, upper extremities and thorax remained emaciated, whilst her lower extremities progressively increased, chiefly in amount of subcutaneous tissue, so that their size came to be in striking contrast to the skeleton-like appearance of her face and the upper part of her body, in which, however, the mammae retained their normal size. The tendon reflexes in both lower and upper extremities were markedly exaggerated; in the lower extremities more than one jerk was sometimes obtained by a single tap ("clonic or trepidation type" of response); the plantar reflexes were of the normal flexor type; no disorder of sensation was present. Electrical examination of the muscles showed nothing abnormal. Her gait was natural, and there was no longer any special tendency to fatigue on exercise. Some physical signs in the chest pointed to the presence of slight pulmonary tuberculosis. Menstruation (which had commenced at the age of 15) was regular, and had always been so, excepting at the commencement of her illness four years previously, when she had amenorrhoea for six months.

The case of "segmentary adiposis of the lower limbs," recently published by Laignel-Lavastine and Viard,⁶ must probably be regarded as belonging to the group we are now considering, though the emaciation of the face and upper part of the body was less decided.

Their patient was an unmarried woman, aged 39, an embroiderer, who complained of great enlargement of the lower extremities. This commenced, according to the patient's account, at the age of 22 years, and first involved the legs, then the thighs, and lastly the buttocks. Various methods of treatment had been resorted to (thyroid extract and iodine, milk diet, etc.), but without satisfactory results. The great size of her lower extremities offered a striking contrast to her thin chest and the general slenderness of the upper part of her body. The left thigh was decidedly larger than the right thigh, but both thighs, both buttocks, and both legs shared in the enlargement. The mammae were very small. The thyroid gland was slightly enlarged. The menstrual periods, which had commenced at 14 years of age, lasted only two days each time. At the Salpêtrière the patient had been given thyroid and ovarian extracts, but as yet without any effect on the size of the lower extremities.

Laignel-Lavastine and Viard, besides the case of Pic and Gardère already described, quote a case published by L. Barraquer, at Barcelona, in 1906.

A young woman, aged 25 years, in her 15th year, after an attack of "influenza," had commenced to waste rapidly in her face and the upper part of the chest. These wasted parts contrasted strikingly with the plump condition of the rest of her body.

It seems, therefore, that "lipodystrophia progressiva" varies in degree in different cases. In some cases it is the excessive growth of subcutaneous fatty tissue in the lower extremities that attracts attention rather than any very decided emaciation in the face and upper parts of the body. In such cases the condition may be regarded as an exaggeration or caricature of the ordinary tendency to fat distribution which constitutes almost a "secondary female sex character." In other cases the wasting of the face and upper part of the trunk first attracts attention, the wasting usually commencing in the face, neck, and upper part of the thorax and spreading gradually downwards. In some of these latter cases the onset of the wasting may be fairly sudden, and the disease may, for a time at least, be associated with anorexia, neurasthenic symptoms, and excess of knee-jerks and Achilles-jerks. Such excess of tendon reflexes is often met with in persons of nervous temperament, and, I think, more frequently in persons of Jewish than in those of Anglo-Saxon or Teutonic descent. It may here likewise be noted that the first two patients whose cases I have above referred to were of Jewish descent, and it is possible that some of the other patients were also of that race.

The symptoms may commence in quite early life, at 10 or 13 years, or later on, up to between 20 and 30 years of age. The disease, though it seems (at all events in its most typical forms) to be confined to the female sex, does not appear to be connected with any obvious disease of the thyroid gland or ovaries. In a sense it might certainly be called a "trophic disease," but it is of uncertain origin, and no successful treatment has yet been discovered for it.

In regard to diagnosis, the distinctions from the cases of "trophoedema," as described by H. Meige and others,

seem to me too obvious for discussion, and the same may be said in regard to the conditions of muscular hypertrophy or pseudo-hypertrophy met with occasionally in various cases of primary muscular dystrophy, as well as in the typical pseudo-hypertrophic group. Other diseases, such as the various forms of chronic oedema and elephantiasis in the lower extremities connected with lymphatic obstruction, are still less likely to be confused. Just at the commencement, when the atrophy of subcutaneous fat is still almost limited to the face, the condition might possibly resemble that seen in cases of "bilateral atrophy of the face"; indeed, it is just conceivable that certain cases of bilateral atrophy of the face may have been mild examples of lipodystrophia progressiva, modified by the male sex of the patients, males not being so inclined as females to special deposit of subcutaneous fat in the lower extremities. At the Clinical Society of London, in 1905, H. Batty Shaw showed a boy, aged 10 years, who had commenced to show bilateral wasting of the subcutaneous tissues of the face when he was 2½ years old. The boy was brought to the hospital because the mother feared he might have tuberculosis. A. P. Hertz and W. Johnson,* at the Clinical Section of the Royal Society of Medicine, in January, 1913, showed a young man, aged 26 years, whose face had become progressively thinner during the last two years, so that his friends thought he must be consumptive. There was no weakness of the facial muscles, and otherwise he was well developed and strong. I instance these two cases of facial wasting in males to illustrate the kind of cases of "bilateral atrophy of the subcutaneous tissue of the face" to which I wish to draw attention in connexion with the diagnosis and pathological classification of "lipodystrophia progressiva."

I have given no photograph or drawing of the condition of lipodystrophia progressiva, but no such illustration is needed. For a typical case one need only imagine a grotesque figure the lower part of which seems to be modelled after an extraordinarily florid Venus of the ultra-Rubens style, whilst the face and upper part of the trunk might call up a picture of one of the forbidding Moerae, or their dreaded sisters, the Erinyes, or might bring to mind the popular idea of one of the witches in *Macbeth*.

THE estimated population of Jamaica in 1912 was 845,767, an increase of 6,520. The marriage-rate was 4.2 per 1,000 persons living, the birth-rate was 39.0 per 1,000, and the death-rate 22.1; the infantile death-rate per 1,000 births was 18.7 under 1 year old, and 27.4 under 5 years old. In 75.2 per cent. of the deaths registered during the year the causes of death were not medically certified. The principal causes of death were diarrhoea and enteritis, debility, phthisis, and enteric fever; 84 deaths were recorded as having been caused by "the vomiting sickness," 21 of these being medically certified. On April 1st, 1912, there were 127 names on the Jamaica Medical Register.

THE so-called sleeping sickness of Nyasaland, called by the natives kaodzera, differs in certain respects from the typical sleeping sickness, and the Royal Society's Commission finds that the trypanosome present in the disease, though it resembles *T. brucei* and *T. gambiense*, is a distinct species identical with *T. rhodesiense* (Stephens and Fantham). These observations were reported to the Royal Society, and have been published in the *Journal of the Royal Army Medical Corps* (May, 1913). The authors of the report are Sir David Bruce, Majors D. Harvey and E. A. Hamerton, R.A.M.C., Dr. J. B. Davey, Nyasaland Medical Staff, and Lady Bruce. The parasite resembles *T. brucei* more closely than *T. gambiense*. It is concluded that the human trypanosome disease of North-East Rhodesia and Nyasaland is not the disease known as sleeping sickness in Uganda and the West Coast of Africa, and it is suggested that the native name kaodzera might be used for this disease to distinguish it from the older-known sleeping sickness.

CHRONIC PNEUMOCOCCAL INFECTION OF
THE LUNGS IN CHILDREN.

BY

P. L. SUTHERLAND, B.Sc., M.B.,

BACTERIOLOGIST, WEST RIDING COUNTY COUNCIL;

AND

A. A. JUBB, B.Sc., M.D.,

ASSISTANT MEDICAL OFFICER OF HEALTH, WEST RIDING COUNTY
COUNCIL.

SINCE the beginning of the routine examination of elementary school children there has been much discussion on the prevalence of phthisis in children of school age, and while some medical inspectors consider that the disease is uncommon in school children, or at any rate not to be diagnosed always with assurance, others seem to believe that the cases are numerous and easily recognized. Indeed the amplitude of variation in figures given in the report of the Chief Medical Officer of the Board of Education compels the suggestion that the prevalence of phthisis in certain school areas may be not so much a matter of pathological fact as of clinical bias. For instance, the percentage of phthisis among the Staffordshire school children examined in 1910 was 0.151; the percentage in Worcestershire was 4.183; and yet the phthisis death-rate of these counties was the same, namely, 0.7.

It is, of course, the experience of all clinical observers to see children in whom the pulmonary signs suggest the presence of phthisis. These cases present the following features: (1) they are often the sequels, immediate or remote, of measles or whooping-cough; (2) cough, sputum, and emaciation are variable in amount or degree; (3) tubercle bacilli are not found in the sputum. It may be argued that these are cases of mild or chronic phthisis. We are of the opinion that phthisis is seldom mild or chronic in children; it is too often acute and progressive, and from observations made both clinically and pathologically we have come to the conclusion that many cases in school children diagnosed as, or suspected of being, phthisical, are not such, but are chronic infections due to some other cause.

In support of this we shall first compare the result of the examination of the sputum from (a) suspected cases of phthisis in adults, and (b) suspected cases of phthisis in children from the age of 5 up to and including the age of 15.

During the past eighteen months ending October, 1912, the sputum of 1,824 adults has been examined in this laboratory for the tubercle bacillus. Of these, 33.7 per cent. gave a positive result. During the same period the sputum of 230 school children has been examined for tubercle bacillus, and of these 9.1 per cent. were positive. In not a single negative case among the children was a positive result obtained by a subsequent antiformin examination.

To carry the matter to a more definite state the negative sputum was in the cases of 69 suspected children inoculated into guinea-pigs. Of the 69 guinea-pigs only 2 were found tuberculous when killed at the end of one month, 30 died in from one to nineteen days of peritonitis more or less acute, and 37 were normal when killed after one month. This gives a percentage of 2.9 tuberculous.

Negative sputum from adults was inoculated in only 18 instances. Of these, 2 guinea-pigs were found tuberculous, 7 died of peritonitis, and 9 were normal—a percentage of 11 tuberculous.

Results of Examination and Inoculation: Adults and
Children.

| | |
|---|--------------------|
| (a) Adults: | |
| Sputum examined and found positive | ... 33.7 per cent. |
| Guinea-pigs inoculated and found positive | 11.0 " |
| (b) Children: | |
| Sputum examined and found positive | ... 9.1 " |
| Guinea-pigs inoculated and found positive | 2.9 " |

There is a remarkably close resemblance in the proportion of the two sets of figures, the ratio in each case being nearly 3 to 1; and though the number of adult inoculations is small, the fact of the ratio between the microscopical and biological results being practically the same in adults and children may be accepted as far as it goes. That is to say, we may take the figures for the microscopic

examination of the sputa as being a fair approximation and index of the incidence of phthisis in adults and children. This is not to assume that the disease is over three times (33.9 to 9.1) more frequent in adults than in children, but we are entitled to say that tuberculosis of the lungs is less common in children than in adults, and less common, too, than is generally supposed.

In view of this conclusion, which is quite reasonable in the circumstances, the question is: What is the nature of these cases of suspected phthisis in children? The probable explanation is that they are chronic catarrhal conditions associated sometimes with varying degrees of bronchiectasis and are the chronic residue of pneumonic or bronchopneumonic inflammations which in turn have followed measles or whooping-cough, or indeed may have arisen alone. The cough, the types of breath sounds, the râles, and the sputum, can all be explained by such a condition, and where dullness is elicited it is no doubt due to pulmonary fibrosis. Dr. Theodore Fisher has already, in this JOURNAL, called attention to the existence of peribronchitis and bronchiectasis in children, and has emphasized the need of caution before diagnosing phthisis in such cases.

| Ages of 22 Positive Cases. | |
|----------------------------|---------------|
| Age 15 ... | ... 7 cases |
| " 14 ... | ... 3 " |
| " 13 ... | ... 2 " |
| " 12 ... | ... 4 " |
| Age 11 ... | ... 3 cases |
| " 10 ... | ... 2 " |
| " 9 ... | ... 1 " |
| " 8 (and under) ... | ... 0 " |
| Total ... | ... 22 cases. |

The fact that a positive result was obtained in only one case below the age of 10 and in twelve between that age and 15 suggests an increasing liability to phthisis as the age of childhood is left behind.

Out of 22 cases we have been able to trace 17. Of these in eighteen months 7 are dead, 6 are "worse" or "past relief," and 4 are indefinite, which supports our belief that phthisis in children is more apt to be acute and progressive than slow and benign. It must not be forgotten, however, that many of these suspected cases may give a tuberculin reaction through being infected with tubercle elsewhere, whence an invasion may take place later into the already damaged lungs, but this does not invalidate our contention that many cases of phthisis in children are falsely so called.

The next point to be considered is the fate of the inoculated guinea-pigs. The inoculation of the sputum from both adults and children resulted in a large percentage in peritonitis—namely, 38.8 per cent. from adults and 43.5 per cent. from children. In the negative sputa of children the pneumococcus was found in large numbers and was by far the most abundant organism present. The peritonitis in all the guinea-pigs inoculated with the children's sputa was, with one exception, pneumococcal. The organism was present in abundance, and was isolated from the peritoneal exudate.

The fact that from adults and from children about 40 per cent. of the inoculated animals died of a peritonitis which was pneumococcal in almost all the children's cases and in the majority of adults' cases—such a fact suggests that the pneumococcus has a special significance and virulence in the causation of these cases of suspected phthisis. Speaking with regard to children it seems to us that such a lesion—namely, a chronic infection by the pneumococcus—is the true explanation of many of those cases of suspected phthisis which live on from year to year, no doubt in a more or less debile condition, but able to go about and put in an irregular attendance at school.

CONCLUSIONS.

1. Phthisis is not so common in children as certain recent reports would appear to imply.
2. Many cases of "phthisis" or "suspected phthisis" in children are really chronic pneumococcal infections of the lungs inducing bronchial and peribronchial lesions.
3. These pneumococcal cases in children form a large percentage of the cases cured or improved in open-air schools.
4. It is extremely likely that such cases in children are treated at tuberculin dispensaries as phthisis in which the tubercle bacilli are not found in the sputum.
5. These pneumococcal infections tend to be chronic and non-fatal, though there is always the liability to tuberculous infection.

THE TREATMENT OF ADENOIDS AND ENLARGED TONSILS WITHOUT OPERATION.

By W. STEUART, M.R.C.S., M.I.E.E., ETC.

MEDICAL OFFICER, X-RAY DEPARTMENT, QUEEN'S HOSPITAL, BIRMINGHAM.

CONSIDERING the efficacy of x rays in reducing the size of chronically inflamed lymphatic glands it is surprising that hitherto there has been no attempt, as far as I am aware, to treat enlarged tonsils and adenoids by this method.

As the present surgical treatment is open to several objections, an investigation of the possibilities of the Roentgen rays was undertaken with a view to providing at least an alternative method which would be suitable in a large percentage of the cases now operated on. From inquiries made it would appear that the average number of hospital operations in London for this condition alone is not less than 500 a week.

Observations were at first confined to cases that had chronically inflamed lymphatic glands situated near the angle of the lower jaw and having enlarged tonsils at the same time. The treatment of the glands involved the radiation of the tonsils, so that there was no question of experimenting on patients until justification was obtained to proceed further.

All these cases showed a corresponding diminution in the size of both glands and tonsils. Patients were then selected in whom the condition of "tonsils and adenoids" was well advanced, and characteristic symptoms were marked—that is, mouth breathing, snoring, deafness, discharge from the ear, etc.

Each of the following examples is taken to show some special feature, with a view to the summation of the results to be obtained by radiation.

CASE I.

F. B., aged 10, had the typical adenoid type of face, mouth open, lower jaw dropped. Adenoids were made out by digital examination to be an exceptionally large mass, and the tonsils projected well beyond the pillars of the fauces. There was a discharge from the left ear. It was stated that the child suffered from colds and earache; that she could not hear properly, and that she snored at night.

As the result of the first dose it was reported that she could hear better and snored less, but the discharge from the ear continued.

After the second dose, discharge less and snoring less.

After the third, discharge from the ear stopped, snoring stopped, but child breathes heavily when asleep. Hearing much better. Mouth still open, but much less than at first.

Progressive changes were to be noted at each successive visit, the tonsils became smaller, but, though the adenoid tissue round the pharynx had shrunk sufficiently to give a good air passage, the change in actual size was not as much in this case as had been hoped for. This result was probably due to the prolonged neglect, the influence of which will be commented on in connexion with another patient.

The cases of two brothers are the subjects of the next examples, as their symptoms were much the same, differing only in degree.

CASE II.

James N., aged 11, had tonsils projecting beyond the pillars of the fauces, and adenoids could be felt as scattered masses. The father stated that the boy was constantly getting colds and was becoming increasingly deaf, so much so that arrangements had already been made to send the child to a school for deaf children, but the parents decided to seek further advice before giving their consent to this proposal. The boy snored when asleep and kept his mouth open.

Very little change was noted at first, but an improvement could be observed about a week after the second dose. A letter of inquiry to the schoolmaster elicited a reply to the effect that both boys had improved considerably lately, James, if anything, more than Joseph the other brother.

Six weeks after the initial treatment the boy showed marked improvement, though he was still snoring a little and breathing through his mouth.

After seven weeks the snoring had stopped and the mouth was kept shut. A further letter from the schoolmaster stated:

"Joseph—Improved. Can hear from the back of the class."

"James—Improved. Can only hear when sitting right in front of class."

Although the boy's hearing was far from perfect, as shown by the above report, his condition was immeasurably better than when it was considered advisable to send him to a school for the deaf.

On examination at this time the tonsils were found to be well within the pillars of the fauces, but they had not quite

regained their normal size. The adenoids could be made out, and the mass was smaller. How much so it was, however, difficult to determine.

CASE III.

Joseph N., aged 13. Tonsils and adenoids in apparently much the same state as the previous case, though his symptoms were not so marked. Snored at night, and breathed through his mouth. Hearing defective.

The boy showed progressive improvement throughout the course of the treatment. His snoring and mouth breathing ceased a week or so earlier than in his brother's case, and the schoolmaster reported as above at the end of seven weeks that the boy could hear when at the back of the class.

The tonsils became almost normal in size, and the whole aspect of the boy changed for the better, becoming brighter, and a dull, listless appearance that was evident when he first came for treatment quite disappeared.

CASE IV.

Alexander H., aged 8. Tonsils and adenoids causing mouth breathing, snoring, and defective hearing.

A fortnight after the first dose it was reported that the child did not snore so much. After the third dose the child kept his mouth shut when sleeping, but was still snoring. The child's teacher had remarked that his hearing had improved.

Seen a fortnight after the fourth dose, the mother stated that the boy then slept with his mouth shut and did not snore. On examination, the tonsils were normal in size and he could breathe freely through his nose.

As regards the diminution in the size of the tonsils this was the best case that was under observation, and the cure was brought about by only four applications of the rays.

In the following instance the enlargement was probably purely adenoid in nature, the amount of fibrosis being very limited:

CASE V.

Florence P., aged 22. Tonsils meet in the midline. Adenoids a large mass. The patient states she has had enlarged tonsils ever since she can remember. She cannot breathe through her nose, and when she wishes to clear her nose she can only do one nostril at a time, and even this with great difficulty. She is constantly getting sore throats and has had quinsy three times lately.

Five weeks after the first dose and two weeks after the second dose she stated she could breathe through her nose with her mouth shut for the first time and her throat did not feel sore. The tonsils, however, were still enormously enlarged, but not as big as they were when she first came.

Successive treatments though giving considerable relief to her symptoms did not cause much apparent effect as regards the size of the tonsils, although they looked much healthier and less inflamed.

In this case it is certain that the bulk of the hyperplasia of the tonsil was due to fibrous and not to adenoid tissue, so that it could hardly be expected that the x rays could exert much influence under such circumstances at once, but as soon as the septic state of the tonsil had been remedied the fibrous tissue would gradually become more compact, and the tonsil would shrink.

Such a case as this is altogether exceptional, but is used as a contrast with the next case—a child of 3.

CASE VI.

H. R., aged 3. Tonsils enlarged. Adenoids could be felt. The child had the adenoid expression, and kept her mouth open. She snored at night. Her mother had her examined because of constantly recurring colds and earache. The cervical glands were palpable on both sides. A third of a Sabouraud dose was given on each side, the irradiating area including the upper cervical glands, the mastoid process, and the nasal mucous membrane.

Six weeks after the mother wrote:—"I am glad to say that H. has been much better since she had the treatment: there have been no complaints of pain in the ear, and the glands seem quite normal. She has not snored so much at night, but it is still very bad. Do you think it would be better for her to have another dose of the rays?"

On examining the child the tonsils were found to be much smaller and the adenoids were less. The adenoid expression was scarcely perceptible. The glands in the neck could not be felt. The mother said that there had been no more colds since the treatment.

Another third Sabouraud was then given on each side, and about a fortnight later the mother stated that there was no further snoring.

The next example has been selected because, although both tonsils were equally swollen when the child was first seen, one tonsil rapidly regained a normal size, and the other yielded very gradually and incompletely to treatment.

CASE VII.

C. O., aged 8, was sent to the hospital for x -ray treatment of a unilateral mass of tuberculous cervical glands extending from

the mastoid process to half the length of the sterno-mastoid. Beyond noting that both tonsils were enlarged, no observation of adenoid symptoms was made when the boy first came. As treatment proceeded the tonsil on the side of the tuberculous glands yielded very gradually to the treatment, whereas the other disappeared after some four or five radiations.

This boy's history of glands in the neck extended back for over two years, so that probably the refractory tonsil had been infected with tubercle for some considerable time, and the fibrosis had interfered with the rapid reaction which characterized the other tonsil.

Other cases of tonsils and adenoids have shown similar changes as the result of treatment. In no case was there any failure of reaction to the rays. Some required only two or three doses to give relief to their symptoms. The longer the condition had existed the longer the treatment required to be; from which the inference can be drawn that tonsils and adenoids of long standing are to a large extent composed of fibrous tissue formed by the prolonged inflammation.

CONCLUSIONS.

1. Roentgen rays have a stimulating effect on chronically inflamed adenoid tissue, and enable it to resume its healthy condition.

2. The tonsils do not entirely regain their normal size except in favourable cases, the diminution in size being dependent on the time the organ has been inflamed or on the amount of fibrous tissue that has been formed.

3. The decrease in size is sufficient to dissipate all obstructive symptoms.

4. Conditions dependent on the septic state of the tonsils and adenoids are relieved.

Regarding the merits and demerits of the surgical and radiological methods the following points may be raised:

It cannot be right to remove tissues that have a definite function, and though this procedure has been necessary in the past it is surely better to restore such tissues to a healthy condition rather than remove them. A small proportion of tonsils owe their enlargement to tubercle, and in these cases it is a matter of risk to resort to surgery on account of the possible dissemination of the disease.

The radiological method certainly takes longer, but against this there is no shock to the child and no convalescent period; and as for the sum total of inconvenience the advantage lies with the x rays. The parts affected by operation do not comprise the whole of the inflamed area, whereas by radiation all the pharyngeal lymphoid tissue can be subjected to the influence of the x rays. Recurrences are not at all uncommon after the use of the guillotine, necessitating another operation.

TECHNIQUE.

The same method was not adhered to during the investigation but in all cases a hard tube was used, the rays were filtered and not more than a half Sabouraud dose was allowed to pass through any given area of skin. The rays were applied laterally, the anticathode of the tube being above and behind the angle of the jaw, so that the rays encountered the minimum resistance in reaching the tonsil; the head was so placed that the rays swept in front of the vertebral column and the posterior pharyngeal wall. After a dose had been given on one side the head was turned and a similar treatment given on the other side.

All measurement was done with a pastille lying on the skin. With restless children it is useless to adopt Sabouraud's plan of having the pastille halfway between the anticathode and the irradiated area.

The tube was placed at a greater distance from the patient than is usual in order to obtain approximate equality of intensity of radiation throughout the pharynx.

The interval between the doses and the amount of the doses was varied, but under no circumstances was a larger dose than a half Sabouraud given.

THE effect of radium in the treatment of cancer is to be made the subject of a special investigation under the direction of Dr. William Duane, at the Harvard Medical School. As soon as possible a special building is to be constructed adjoining the medical school expressly for the purpose of the research, which is to be carried out under the supervision of the Cancer Commission of Harvard, of which Dr. E. E. Tyzzer is director.

THE CAUSE OF ENLARGED TONSILS AND ADENOIDS IN CHILDREN AND THEIR TREATMENT WITH LYMPHATIC GLAND EXTRACT.

(PRELIMINARY REPORT.)

By HUGH T. ASHBY, B.A., M.D. Cantab.,
M.R.C.P. Lond.,

PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL; ASSISTANT
PHYSICIAN TO THE SALFORD ROYAL HOSPITAL.

MANY theories have been put forward as to the cause of enlarged tonsils and adenoids, but I think it is possible to rule all of them out conclusively. For this reason I am advancing a new theory, which may have some connexion with their enlargement.

By analysing some 3,000 cases in children suffering from enlarged tonsils and adenoids, it became apparent that by far the commonest ages for the children to suffer from enlarged tonsils and adenoids is from 2 to 5 years, but that many infants, even from birth, have enlarged adenoid growths in the naso-pharynx.

To find out at what age the adenoid tissue is developed I have obtained a number of fetuses of different ages and dissected away the posterior wall of their naso-pharynx, where the adenoids subsequently develop. The tissue thus obtained has been examined microscopically, and I have been able to find that adenoid tissue was present in every fetus after the age of 6 months. This being so, I think we can say that every child is born with adenoid tissue at the back of the naso-pharynx, but that it grows for some reason in some children more than in others.

The mere presence of adenoids does not constitute a disease, and they only become pathological when they hypertrophy and cause trouble. In infancy and childhood the lymphatic structures are at their maximum exactly at the time when enlarged tonsils and adenoids are commonest, and it is one of the functions of the lymphatic tissue to form the lymphocytes. Now it is a peculiar fact that children with enlarged tonsils and adenoids rather have a diminution of lymphocytes in the blood, and there is also an increase in the total number of leucocytes. For this reason it looks as though the enlargement of the tonsils and adenoids were an attempt on the part of Nature to supply the deficiency in the other lymphoid tissue of the body. At the age when enlarged tonsils and adenoids are commonest (2 to 5 years) the lymphocytes are normally beginning to decrease from the high percentage found in infants to the adult standard, and again, the thymus is also decreasing in size. I think these two facts support the view that the adenoids and tonsils are an attempt to augment the lymphoid tissue of the body. It is also a common fact that when the enlarged tonsils and adenoids are removed carefully by a competent surgeon before the age of about 5 years they are very liable to recur, so that Nature, as it were, makes a second attempt to raise the amount of lymphoid tissue, or at least supply the body with some secretion from the lymphoid tissue, which it needs at this age.

If we could supply these children with lymphoid tissue artificially, there would be no need for the enlarged tonsils and adenoids, and in consequence they would go down, and it is on these lines that I have been working. Messrs. Burroughs and Wellcome have made me some lymphatic gland extract, exactly on the same lines as they make thyroid extract. Up to the present I have treated about 30 cases of enlarged tonsils and adenoids with this lymphatic gland extract, gr. v, three times a day. No bad effects have been observed, and nearly all the children have improved in a very satisfactory way: the snoring and noises in breathing have disappeared, and the tonsils have diminished in size.

This being so, I think it is well worth while pursuing the treatment in a larger number of cases. In many instances of enlargement of the thyroid gland at puberty in girls, if thyroid extract be given the thyroid gland diminishes in size, showing that the gland enlarged to make up for some deficiency in its secretion, and that when the deficiency was made up artificially the gland went back to its normal size.

IODINE AS AN ANTISEPTIC IN TROPICAL COUNTRIES.

By J. C. RIDGWAY, B.A., M.D. DUBL.,

MEDICAL OFFICER, NIMULE, NILE PROVINCE, UGANDA.

In an article on strangulated epigastric hernia published in the BRITISH MEDICAL JOURNAL in December, 1910, I mentioned the beneficial use of a 2 per cent. solution of the tincture of iodine in skin preparation, as a preliminary to operation.

The following may be of interest, showing as it does the excellent results obtained by its use where preparatory antiseptic measures could not be adopted, and where the existing conditions were by no means favourable from an aseptic point of view.

Reclus, in *La presse médicale*, mentions the excellent results he obtained by its application in compound fractures, and quotes cases to substantiate his statement.

1. Early one morning a Bunyoro native came to my hut at Nimule to be treated for a crocodile bite. He had been down to the Nile close by to cut grass for his employer, an Arab trader. In stooping to do so, at the water's edge his right forearm was seized by a crocodile, but fortunately he was able to catch hold of a small tree with his left hand, and thus save himself from being immediately dragged under water. His call for help brought another native to his assistance, and he, by repeatedly belabouring the animal with a stout stick, succeeded in making the crocodile let go, and retire under water.

It was seen that he had sustained a compound fracture of both bones of the forearm in their middle third. The upper ends were protruding through the wound on the flexor side, the superficial muscles being extensively torn, but on the extensor side, beyond the skin and fascia being lacerated by teeth marks, the muscles escaped practically untouched. Embedded in the wound were small pieces of grass. From the nature of the wound I gathered that the forearm was seized by the front teeth of the crocodile, the hand, wrist, and lower third of the forearm being at the time inside the animal's mouth.

The wound and adjacent skin was thoroughly syringed, and washed with a 2 per cent. solution of iodine for about fifteen minutes. I then reduced the fracture and stitched up the wound, dressing it with plain sterilized lint and applying splints. The arm was bandaged to the side, and the forearm fixed across the chest, as it was impossible to get him to remain in a recumbent position. The wound was again dressed with the iodine solution in four days' time, and was to my satisfaction a healthy one, the same procedure of bandaging being carried out. The limb was left in this position until the twelfth day, when the stitches were removed. On examination of the forearm it was then found that union had taken place between the approximated ends. The same procedure as before was adopted in fixing the limb.

On the eighteenth day I again dressed him, and gave instructions to come to me again in five days.

On the twenty-fifth day, as he had not put in an appearance, my native servants were sent to look for him, and later brought him to me. He had removed the splints, but had applied the bandages over the lint covering the wound, which was then quite healed.

I again saw him on the thirty-seventh day. The radius and ulna had then completely united, he could grip firmly with his right hand, and was able to extend, pronate, and supinate the injured forearm, but had a limited degree of flexion.

Three months later he came to me complaining of symptoms resembling sleeping sickness, which unfortunately proved to be true.

2. On a punitive expedition which I accompanied as medical officer into the hinterland of the Nile against some hostile tribes, I was called upon to treat over a hundred cases, comprising gunshot, spear, arrow wounds, and cuts, incurred on both sides. In almost every case I treated them with a 2 per cent. solution of tincture of iodine, and was surprised at the excellent results obtained. The various injuries healed in a remarkably short space of time, and I am of opinion that the beneficial results obtained from the use of this drug compare most favourably with any of the other antiseptics now in use, and,

moreover, I venture to state that on active service of such a nature in tropical countries, it is to be preferred to other germicidal preparations.

THE BIONOMICS OF THE RAT-FLEA.

BY

C. STRICKLAND, M.A., B.C.,

TRAVELLING MEDICAL ENTOMOLOGIST IN THE FEDERATED
MALAY STATES.

(From the Office of the P.M.O., Kuala Lumpur.)

HAVING been in the "backwoods" for some time past, I have only lately had my attention drawn to a paper by Nicoll in the BRITISH MEDICAL JOURNAL for October 26th on the life-history of the rat-flea (*Ceratophyllus fasciatus*, Bosc).

The work which Nicoll describes and the facts which he has elucidated are essentially similar to my own in 1910-11, which are the object of a report to the Local Government Board now in course of publication. But I disagree with certain of Nicoll's hypotheses put forward to substantiate these facts, and I would like here to give the reasons for my disagreement.

The facts are these. Fleas are found to live in a certain medium of rubbish for apparently a great length of time without food—Nicoll found for fourteen months, while mine were alive after eighteen months, when they were accidentally thrown away. This fact is of great practical importance, of course, in itself, particularly if the fleas are able to remain disease-infective for the same length of time, and the explanation of the fact may be equally important to the fact itself. Nicoll's hypothesis is that the rubbish contains a large number of larvae, which do not all undergo metamorphosis at once. Some of them pupate and imagnate after one month, some after ten months, and so on, remaining in a resting state meanwhile. In this way a constant succession of new adults is produced which take the place of the old ones, which die off in about a month's time if kept without food, the net result being that the original fleas apparently live for a great length of time.

Now, I disagree with this hypothesis for the following reasons:

1. I have taken specimens of the rubbish from time to time and looked carefully in it for larvae, or pupa-cases which should contain either resting larvae or pupae, and I have never succeeded in finding a single one. Active larvae certainly could not escape detection. Pupa-cases are more difficult to find, but not so difficult that they cannot be seen on a careful search. I have therefore concluded that the rubbish does not contain either active larvae or any resting stages of the metamorphosis. (I admit, however, that for the first month or two resting larvae could probably be found.)

2. I have carefully taken away from a quantity of rubbish all the adult fleas present (a live bait is an efficient mode of procedure for this purpose), and I have then watched the material carefully from day to day for three to four months to see if more adult fleas would appear, but with negative result. Now, if resting stages of the larvae were living in the rubbish and constantly producing a batch of new imagines, it is difficult to see why during the time observed adult fleas did not appear.

3. It is postulated that metamorphosis is most active in summer, yet our actual experience was that the adult fleas to be found in the rubbish greatly decreased during the hot months. This is hard to explain, if the resting larvae imagnate more quickly than in winter.

The conclusion which my experiments led me to was that it was the adult fleas, and not any stages in the metamorphosis, which survived for such a great length of time as eighteen months. I imagined this was possible to the adult flea, because the rubbish in which it lived was hygroscopic and non-conductive to heat, so that heat and dryness inimical to the flea's life was escaped from in its depths.

The facts which I elucidated could only (on Nicoll's hypothesis) be explained on the assumption (1) that the pupa cases which I searched for and failed to find were actually there; (2) that although for some reason or other the resting stages failed to imagnate after three to four months, they might have done so later on; (3) that the resting stages are more prolonged in summer than in winter—a conjunction of events improbable enough to make me believe that the adult flea really survives for great lengths of time without food.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF DERMATITIS ARTEFACTA.

IN December, 1911, the patient, a domestic servant, aged 42, was admitted to a cottage hospital for convalescence from some skin trouble. The lesions on admission were merely several reddened patches fast clearing up.

In July, 1912, she returned for treatment in the initial stages of an attack. The lesions, which were distributed fairly generally all over the body, would start with painful erythematous patches followed shortly afterwards by the formation of little blebs. On several occasions there was vomiting and distaste for food, so that I wondered whether an intestinal toxin was the causal factor. This attack lasted one month.

In January, 1913, I received a letter from the patient, saying the trouble had recurred and asking to be readmitted. The lesions then were much larger and coarser, chiefly on the right side of the neck near the angle of the jaw and on the right upper arm (flexor surface). The patch on the neck was some four to five square inches in extent. Furthermore, reddened patches would occur, which were not always followed by blebs. I very soon doubted my original diagnosis, but there was nothing obviously artefact about the shape of the lesions. One day I remarked to her that it was curious how on this occasion all the patches occurred on the right side. Two days later a patch occurred on the left elbow with bleb formation. At the end of a month the lesions were healed, leaving a little pigmentation, and the patient looked out for and obtained a situation. As it was near London, I advised her to see Dr. Sequeira at the London Hospital if there should be any return of the trouble.

A fortnight later I had a letter from Dr. Sequeira saying that the patient had been to see him, and that "the eruption as then seen was undoubtedly artefact." One spot had such a curious shape that he felt at once it was self-produced. "Its boundaries were all straight lines and sharp angles." There was a faintly acid reaction to litmus. The patient then wrote to me that she had been compelled to give up her situation owing to recurrence of the trouble, and asked me to sign a sick-pay certificate. I refused to sign without seeing her, and she returned to the cottage hospital. A glance at the lesions was sufficient to make me confident that the patches were artefact. I tested one of them with litmus and got a faintly acid reaction, but when, as a control, I tested normal skin I got a much more acid reaction. This proved absence of caustic as an agent, and probably acid too. I accused the patient point-blank of practising deception. She was obviously taken aback, but soon met the suggestion with repeated denials and later with tears. In the pocket of her other dress a screw of paper containing yellow powder was found, but as I had told the searcher to look out for some fluid no notice had been taken of it and no sample obtained.

Next day I asked the patient privately to turn out her pockets, telling her that she had every right to refuse. She was then wearing the dress in the pocket of which the screw of paper with the yellow powder was found. She had no objection, and the pockets contained a few postage stamps and an empty purse. I rather expected this; it did not enable me to know what the powder was, but I felt tolerably certain that it was mustard. She told me most emphatically that there had been nothing in the pocket the previous day which was not in it at the moment of turning it out, and this confirmed me in the belief that I was on the right track. Even when I confronted her with the finder of the yellow powder she still denied it. I called her attention to the penalty under Section 69 of the Insurance Act, and she eventually confessed to having used mustard. In three days the skin trouble had cleared up.

The cottage hospital is partly supported by a small fee charged to the patients (5s. to 10s.). The patient was entitled to sick pay.

The case bears out the persistence of such patients. I was fortunate in being able to get her into an institution where her belongings could be easily searched. At home or in service to have found mustard in the house would have availed little.

I could find no anaesthetic areas so common in dermatitis artefacta associated with hysteria—that is, palate, glove, or stocking anaesthesia. For a moment the acid reaction of the normal skin nonplussed me, but, as events turned out, it strengthened my hand.

I am inclined to think the last attack in July, 1912, was not artefact.

The case shows the imperative need of medical referees under the Insurance Act, who will safeguard both the doctors' interests and the friendly societies' funds.

In conclusion, I would like to thank Dr. Sequeira for his valuable help in bringing the case to a successful conclusion.

Newick.

J. CHARLESY MACKWOOD.

A CASE OF GASTRIC ULCER ASSOCIATED WITH TETANY.

SOME features of the following case seem of sufficient interest to make it worth recording.

The patient was a married woman aged 37, who for twelve years had had constant symptoms of chronic gastric ulcer. In addition, during the later five years she had had, at intervals of about six months, attacks of acute left-sided abdominal pain accompanied by vomiting, which completely prostrated her for the time being. Four years ago she had been in a hospital for five weeks, her treatment there consisting in the administration of peptonized milk in measured quantities.

I was called to see her on December 5th, 1912, during one of her attacks of pain, and strongly recommended that she should undergo an operation as soon as the attack had subsided. Consequently she entered hospital, where on December 9th a small ulcer at the cardiac end of the stomach was excised. She left hospital at the end of December feeling somewhat relieved, but the symptoms soon recurred, and in the middle of February she had another of her old attacks of acute pain, vomiting, and prostration.

She remained in the same condition until March 20th last, when I was sent for in a hurry. She had suddenly collapsed in the street, and had been carried home. When I saw her she was in a condition of extreme shock, was unable to speak, but could understand questions addressed to her. The abdomen was extremely tender and rigid, especially on the left side. The lower border of cardiac dullness was $1\frac{1}{2}$ in. higher than normal, and in the left flank there was marked dullness. Both hands were in a condition of extreme tetany. Although she appeared to suffer from abdominal pain she indicated her shoulders, especially the left, as being the seat of most pain. I diagnosed gastric perforation at the cardiac end, and advised immediate operation. Mr. Basil Hughes, whom I called, took the same view, and as her condition was too grave for removal to a hospital we decided to operate in her own home.

Accordingly an incision was made one inch to the left of the middle line, and the peritoneal cavity opened. A large quantity of material resembling gruel poured out, and on examining the stomach a large indurated ulcer, about the size of a five-shilling piece, was found at the cardiac end. In its floor were two ragged openings through which the gastric contents were escaping. The gastric wall around the ulcer was soft and very oedematous. These openings were sewn up and the ulcer buried with Lembert sutures, much difficulty being experienced owing to the friability of the oedematous tissues. The procedure was then completed by posterior gastro-enterostomy. Her convalescence was rapid and uninterrupted, and the tetany, which disappeared under the anaesthetic, has never returned. She can now eat anything she fancies without the slightest inconvenience, and has quite altered in appearance, having become quite plump, with a good colour, and having lost that drawn, anxious expression of chronic pain, which formerly was hardly ever absent from her face.

The case is of further interest from the presence of the tetany described. In no other of the great number of perforated gastric ulcers seen by me has this symptom been present. In all these the perforation has been at or near the pyloric end of the stomach, and I have reason to believe that perforation at the cardiac end has been said to be associated with tetany. But whether the tetany in this particular case was of toxic or reflex origin, I am not at present prepared to say. The pain in the left shoulder is also of interest, because I have frequently noticed that in cases of perforation at the pyloric end (that is, to the right of the hepatic ligament) the pain is referred to the right shoulder.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

SOMERSET HOSPITAL, CAPETOWN.

TWO CASES OF FRACTURED PELVIS.

(By HOWARD W. REYNOLDS, M.B., B.Sc.Lond., Radiographer to the Hospital.)

THE two following cases present certain points of interest, among them being the absence of grave symptoms despite the extent of injury revealed by radiography.

The first case is that of a patient sent in as the subject probably of fractured pelvis. The injury was caused by a horse falling on him about a month previously and was thus due to direct violence. He was able to walk and had not much pain.

A radiograph was taken of which Fig. 1 is a pen and ink picture copied from the 12×10 negative; B is the posterior portion of the left ilium which had been torn off, but was still in articulation with the sacrum. The rest of the innominate bone is displaced upwards, the displacement at the pubic symphysis being very marked. One would have thought that the membranous urethra must have been damaged, but the patient has had no urinary symptoms, and indeed, except for a little lameness, is quite well, no reduction having been attempted.

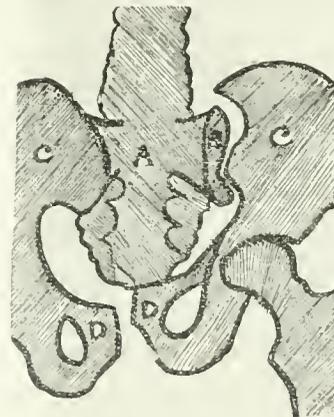

Fig. 1.—A, Sacrum. B, Torn piece of ilium. C, Rest of ilium. D, Pubis.

The second case was sent in as one of dislocation at the hip-joint, but the surgeon in charge of the case thought otherwise, though he could not make out what the actual condition was.

The injury was caused by a fall from a trolley on the railway, the tibia and fibula being fractured at the same time. A radiograph was taken, and of this Fig. 2 is a sketch.

The iliac portion appears to have been split by a wedge-shaped portion of the lower fragment, so that the inner portion of the ilium and the ischio-pubic portion are

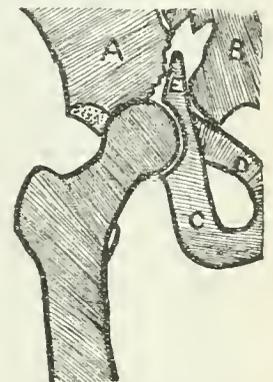

Fig. 2.—A, Outer fragment of ilium. B, Inner fragment of ilium. C, Ischium. D, Pubis. E, Wedge.

displaced inwards, carrying the femur with them. The head of the bone has left the upper part of the acetabulum, but still articulates with the lower part. Thus the original diagnosis was in part correct, though the fracture was overlooked. The patient was able to walk on crutches.

My thanks are due to the surgeons in charge of the patients for permission to publish these notes.

Reports of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

At a meeting on May 21st, Mr. J. M. COTTERILL, President, in the chair, the following were among the exhibits: Dr. DAWSON TURNER, two cases illustrating *Radium treatment*, one of a recurrent cancer in a woman (after surgical removal of a medullary cancer in the axilla), which disappeared after six weeks' treatment; the other a port-wine stain and keloid, which also disappeared under treatment, carbonic acid snow and nitric acid having been previously tried without much benefit. Dr. MELVILLE DUNLOP: *Syphilitic synovitis* of both knees in a boy aged 8, who showed no signs of congenital syphilis until a development of interstitial keratitis a year ago; under salvarsan the condition was showing gradual improvement. Dr. R. A. FLEMING: (1) *Spastic paraplegia* of two years' duration in a woman, aged 26, who had had rachitic deformity of the pelvis and legs since childhood. (2) A sailor, aged 24, with *Congenital heart disease*, and marked clubbing of fingers and toes, associated with acquired bronchiectases of nine years' duration. Dr. J. EASON: Two cases of *Pancreatic infantilism*, characterized by frequent large unformed motions containing a high percentage of fat: the first case, a boy aged 15 years, had shown remarkable improvement after a month's treatment with a pancreatic preparation; the second case, a lad aged 20 years, was of longer duration, and showed a more marked retardation of development. Professor CAIRD: (1) A case of *Intestinal obstruction*, first dealt with by colostomy, and later by resection of a carcinoma of the pelvic colon. A further operation was required to close the artificial anus. Nearly two years later a ventral hernia developed at its site, and it was treated by operation. (2) A case of *Pyloric carcinoma* fixed under cover of the liver, and not palpable even under anaesthesia. The symptoms, of three and a half months' duration, were pain, vomiting, and rapid emaciation. On operation the tumour was found to be mobile and removable by pyloro-gastrectomy. Mr. C. W. CATHCART: A case of *Epithelioma of the cheek in a miner*, occurring on the site of an injury by a fragment of stone seven weeks before. An ulcer formed here a week after, and had enlarged steadily. Mr. DAVID WALLACE: (1) A case of partial *Oesophagectomy*, in a woman aged 47, for an *Epithelioma* of the upper end of the oesophagus; the symptoms of sore throat and dysphagia had lasted a year. (2) A case of *Ileo-caecal stricture* in a man aged 43, who had suffered from pain and constipation for six weeks. A hard palpable mobile tumour was found in this region, and on operation a tumour of the caecum, with hard nodules in the mesocolon and ileum and hard enlarged glands, was found. The provisional diagnosis was carcinoma, and a lateral anastomosis of the ileum to the transverse colon was performed. Microscopical examination of a nodule showed the condition to be typical tuberculosis. (3) A case of plating of the humerus for ununited fracture of three months' duration. Mr. MILLS: (1) *Gummatous meningitis* in the region of the pons in a man aged 40. His symptoms were those of cerebral tumour, headache, vomiting, blindness of the right eye and defective vision in the left, nerve deafness, and facial paralysis on the right side. The Wassermann reaction was positive. Under potassium iodide and mercury headache and vomiting had ceased, but there had been no improvement in vision. (2) A man, aged 53, eleven months after *Occipital decompression* for tumour of the cerebello-pontine angle. His symptoms before operation had been unsteady gait, severe occipital headache, impairment of vision, deafness of right ear and defective hearing in the left, defective sensation to touch, etc. The tumour was irremovable, but since the

decompression operation there had been great improvement. Headache and vomiting had gone, and the patient could walk out daily and could read the paper. Mr. W. J. STUART: Three children after operation for *Tuberculosis of the vertebrae*. The object was to cause immobilization by ankylosing diseased vertebrae to one another and to healthy vertebrae above and below, and consisted in splitting the spinous processes and laminae subperiosteally and bending them down in contact with the adjacent bones. It was claimed that the children could walk without support in three to four months. Mr. FRASER showed several cases illustrative of the *Elastic ligature treatment of umbilical hernia* in children, a method which he regarded as being both shorter and more effective than the treatment by pad and pressure. Mr. SCOT SKIRVING: A case of very acute infective *Synovitis in the knee-joint* in a youth, aged 16½ years, resulting in a mobile joint after operation and subsequent massage.

EDINBURGH OBSTETRICAL SOCIETY.

At a meeting on May 14th, Dr. HAIG FERGUSON, President, in the chair, Professor ROBERT JARDINE (Glasgow) showed a uterus from a woman, who died during labour, in which there was a large *Retraction ring* that had obstructed the head. The lower uterine segment had ruptured during an attempt at version, and the woman died shortly after admission to hospital. Such obstructing rings might be in front of or behind the presenting part. Of the former condition he described two cases. In the first, a woman whose true conjugate was 3½ in., there had been four dead children before; only the last was at full time. She was admitted to hospital to allow of induction being performed if necessary. As the head could be forced into the pelvis right up to the time when the birth was expected, no interference was necessary. After labour had been in progress for some time and the cervix was fully dilated, with the membranes bulging into the vagina, the head still remained mobile above the brim. In front of it was a distinct ledge running round about one-half of the cavity. This was the retraction ring, and obviously prevented descent. Four hours after a full dose of morphine there was no relaxation of the ring, so Caesarean section was performed. Mother and child did well. In the second case, under Professor M. Cameron's care, the membranes were ruptured, the os was fully open, but the head was held back by the ring. Caesarean section was again performed with success. In cases of the kind under consideration attempts at manual dilatation were futile, incision of the ring from below was certain to be followed by an extending rupture of the uterus, and full doses of morphine never produced any benefit. Hence he would always advise Caesarean section. Where the retraction ring caused obstruction behind the presenting part, it formed after rupture of the membranes before there was much dilatation, or even before labour was begun. Of this condition he recorded two cases. In the first, a multipara with a roomy pelvis, the previous labours had been easy. The membranes ruptured at the onset of labour, dilatation increased; but many hours afterwards there was no progress. The head was high up in the first position, and apparently in no way obstructed. Milne-Murray forceps were applied, but they slipped, and on introducing the hand the attendant recognized the retraction ring tightly grasping the child's neck. The speaker, on examining the patient in consultation, found the ring almost complete, and as manual dilatation was impossible and the child was dead, and as the forceps slipped on being again applied, the head was perforated to give a grip to the combined extraction instrument. Delivery was then obtained. The placenta, however, being held back by the ring, had to be delivered manually. The second case was a uniparous woman with a roomy pelvis. The membranes ruptured early in labour, but as no progress was made after many hours, the forceps were applied and the head drawn down as far as the vulva. It was now evident that the body was obstructed, and the hand passed into the pelvis recognized that the neck was grasped all round by the retraction ring. Manual dilatation was impossible. As the child was dead the right clavicle was torn through with the crotchet and the right arm removed. Even then no impression was made on the body till the other clavicle was broken. The

author stated that no explanation could yet be given of these cases. As regards treatment, opiates were of no benefit. Manual dilatation was impossible, so with a living child forceps should be tried. If this failed Caesarean section was indicated.

The Lower Uterine Segment.

Dr. A. H. FREELAND BARBOUR outlined the position which this subject occupies at the present day. Schroeder first showed that the retraction ring develops at a higher level than the os internum, and that it was present in normal labour. This was confirmed by the specimen described by the author and Professor Webster (1890). In Bumm and Blumreich's section (1907) there is a retraction ring at the os internum, but this specimen was abnormal in that the cervix was extremely thinned out posteriorly. The author's conclusions were as follows: (1) A retraction ring is not present in every specimen; (2) when present it does not always develop at the same point. Sometimes it is as low as the os internum, but more frequently it is above this level. Dr. BERRY HART, in discussing the papers, referred to a case seen by him, in which the labour was obstructed by a retraction ring firmly grasping the fetal neck. As regards remedies, amyl nitrite was said to be useful. Dr. OLIPHANT NICHOLSON thought "contraction ring" a better term than "retraction ring." The PRESIDENT said that the danger associated with amyl nitrite was uterine atony. He had seen the retraction ring cause obstructed labour in a breech case.

MEDICAL SOCIETY OF LONDON.

At a meeting on May 19th, Sir W. WATSON CHEYNE, President, in the chair, Mr. JOHN HOWELL (Cheltenham), in introducing a discussion on the *Functions of the peritonium*, said that the chief of them was that of a "pericenteric trap" for the reception and annihilation of micro-organisms, which constantly and normally—that is, without producing symptoms—permeated the intestinal wall. It was part of the duty of certain organs intimately connected with the peritoneal cavity, of which the liver, stomach, and intestines were the chief, to excrete the toxic products formed therein, including, in times of stress, the bacteria themselves, with the minimum risk of contamination to the remainder and more important parts of the body. In illustration of his theory he dealt with the evolution of the coelomic cavity, and the part which it probably played in certain of the lower animals. He brought forward in support of his view many clinical observations. In his opinion, the symptoms of peritonitis, intestinal obstruction, and many other conditions were best explained by it. Dr. A. E. RUSSELL expressed the opinion that if organisms did constantly and normally permeate the intestinal wall, such process should be susceptible of demonstration in histological preparations. He briefly adverted to other functions of the peritonium, and to the importance of general toxæmia in peritoneal injections. Valuable as the peritonium was for the purpose of allowing free contractions and movements of the intestinal coils, the presence of a large surface with innumerable nooks and crannies carried with it grave disadvantage in the presence of any bacterial invasion. He was of opinion that Mr. Howell's views required substantiation by bacteriological evidence. Mr. PETER DANIEL said that he regarded the mucous membrane as the first line of defence against invasion by organisms from the intestinal tract. The peritonium, however, was capable of affording protection, even when no mucosa was present, as was shown by two cases he quoted. He believed that the portal vein was being constantly infected, and that most liver disease was due to this infection. He regarded no disease as a purely local condition. The peritonium did not protect the whole body, but only dealt with its own infections. If the bowel became damaged, it was easy to demonstrate its permeation by organisms. Mr. PERCY SARGENT said that the peritoneal cavity was a potential cavity rather than an actual one. There was no proof that a large number of leucocytes were present there in conditions of health. Dr. Dudgeon and he, in the course of their investigations, had never found organisms in a normal peritoneal cavity, and he asked whether

anyone else had. Many of the organisms concerned were non-motile, and could only be carried by external physical or mechanical agencies. They could not enter the peritoneal cavity by their own efforts. He thought that the fluid of an ovarian cyst was infected from the blood stream. It must be remembered that organisms reached the peritoneal cavity by other ways than through the bowel wall, the blood stream being an important channel. Mr. HOWELL replied.

UNITED SERVICES MEDICAL SOCIETY.

At a meeting on May 21st, Fleet Surgeon BASSETT-SMITH, President, in the chair, Major E. B. WAGGETT, R.A.M.C.T.F., in a paper on the *Medical problem of the mobilized Territorial Force*, laid stress on the lack of experience of the average Territorial medical officer in dealing with the sanitary problems of armies in the field. A fortnight in camp afforded no index of the success or otherwise of the sanitary measures taken, as it was unusual for epidemic disease to make its appearance for at least six weeks after mobilization. In regard to the safety or danger of billets as accommodation for large bodies of troops, England was a terra incognita, no large bodies of troops having remained in billets, or indeed under canvas, in this country for any length of time. If the experiment were made it would fall to the lot of the Territorial Force to make it, and the responsibility resting on the authorities to provide the force with an efficient sanitary service was very great. Salisbury Plain was sacred, in regard to disturbing the surface of the ground, so the sanitary authorities of the troops were deprived of opportunities of carrying out in peace the duties that would fall to them in war. Small-pox would be very likely to give trouble in the absence of efficient revaccination, and enteric fever would be rife under the conditions ensuing on mobilization of the Territorial Force. Excellent as were the sanitary companies they were insufficiently numerous to cope with the vast problems involved. Matters would be improved somewhat if Territorial medical officers were permitted to attend army manoeuvres as supernumeraries, thus obtaining an insight into the methods of dealing with large bodies of troops under service conditions, and if there were brought into existence a special class of officer who, on qualifying, would be attached for one year to the regulars, and thus bring to their service with the Territorials the knowledge derived from intimate association for a considerable time with regular troops, both in barracks and on manoeuvres.

A MEETING of an organization committee appointed by the Clinical Congress of Surgeons of North America was held at Washington on May 5th, with Dr. Edward Martin of Philadelphia in the chair, to discuss the formation of an American College of Surgeons. The object aimed at is the standardization of surgery in the United States. Five hundred representative surgeons from all parts of the North American Continent had agreed to become founders of the college, and of this number fully 300 were present at the meeting in Washington. They were unanimously in favour of the project. The proposal is that a minimum standard of requirement should be set up for any legally qualified doctor who wishes independently to undertake operations in general surgery or any of its special branches. An endeavour will be made to obtain the legalization, under national, colonial, State, or provincial laws, of a distinct surgical degree that will entitle those possessing the required qualifications to operate. The medical colleges are to be urged to confer the degree of surgeon on such graduates as have, in addition to the medical course, gone through the necessary apprenticeship in surgical hospitals, operative laboratories, and actual operative surgery. It is further urged that men who have gained the title of "Surgeon" in this way should be authorized to use it in medical directories and elsewhere by appending the initials F.A.C.S. to their names. The following officers were elected: President, Dr. J. M. T. Finney, Baltimore, Md.; Vice-President, Dr. Rudolph Matas, New Orleans, La.; General Secretary, Dr. Franklin H. Martin, Chicago, Ill.; Treasurer, Dr. A. J. Ochsner, Chicago, Ill. The headquarters of the college will be in Chicago, where the first meeting will be held in November. It is expected that the President of the Royal College of Surgeons of England will be the guest of honour on the occasion.

Rebifus.

ANOTHER YEAR'S EXPERIENCE OF TUBERCULIN TREATMENT.

TWELVE months ago we had the satisfaction of commending a new work on *Tuberculin Treatment*¹ to the notice of the profession. A second edition of that work, by Dr. CLIVE RIVIERE and Dr. EGBERT MORLAND, is now before us to testify that it has met with the appreciation that it deserved as a trustworthy guide in practice. In preparing it the writers have had the advantage of another year's experience and the opportunity of learning how the method has succeeded in other hands than their own. Already a great extension may be noted in the number of institutions in which tuberculin is used, and the reports hitherto have not disclosed any reasons for apprehension on the score of general safety. Caution, however, is as necessary at the present time as at any period of recent history, and it is equally needful that a general knowledge of tuberculin, its mode of preparation and administration, its action and results under different conditions, should be acquired before any one attempts to make use of it.

The two main lines followed by different schools may be expressed as the production of immunity (a) by means of large doses pushed until tolerance is established, and (b) by means of small doses extending over long periods and not pushed to the extent of producing tolerance.

Each of these methods would appear to have produced undeniable results in so far as present benefit is concerned. Even if full allowance be made for the influence of simple faith in a mysterious remedy, there can be little doubt that, for a time at any rate, the influence of the tuberculous process is checked, and the individual regains and maintains strength to a degree not attained by treatment on general hygienic lines alone.

The writers, from close observation of results, express considerable doubt as to the wisdom of producing focal reaction in cases of pulmonary tuberculosis, and it may be presumed that they have good grounds for recommending caution. In every case of pulmonary tubercle the use of inoculation is practically a leap in the dark. It is not possible to be sure of the extent or of the present condition of the focus of disease, and, although experience may enable the specialist to form a more or less accurate judgement, there must of necessity be certain cases in which the focal reaction produces far more systemic disturbance than had been anticipated. Although in the long run such vigorous reaction may lead to no serious harm, it is nevertheless advisable to avoid it if possible.

The treatment of mixed infections does not appear to have made much headway. Vaccines prepared from the actual organisms taken from the case to be treated appear to be greatly preferable to stock preparations, which are seldom of much use. It is only in cases of open tuberculosis where surgical measures are possible that septic infections can be dealt with effectively.

With the prospective addition of many tuberculous dispensaries throughout the country, the question of the success or failure of ambulant treatment becomes a burning one. The methods adopted at the Phipps Tuberculosis Dispensary, attached to the Johns Hopkins Hospital at Baltimore, have been generally recognized as a type worthy of adoption, and the experience gained in treatment at the Municipal Dispensary at Portsmouth affords some idea of the amount of practical success that may be looked for at the present stage of the movement. Already the number of cases treated without daily supervision has reached many thousands, and thus far no catastrophe has been reported. It cannot be forgotten, however, that many cases are lost sight of, and it may well be that some of these have deliberately abstained from further treatment, lest a worse thing should befall them. The advantages offered by ambulant treatment

are obvious from the patient's point of view, but there are many drawbacks from the scientific aspect.

As in their original edition, the writers refrain from the publication of their own or other workers' statistics. General experience points to the fact that closed tuberculous foci, uncomplicated by secondary infection, can be rendered quiescent or inert by the use of tuberculin, and that this desired result is obtained far more readily by such means than by simple hygienic or therapeutic measures. In cases of open tuberculosis, already the seat of mixed infection, tuberculin used with caution is a valuable adjunct to general hygienic and other means. Many patients are unquestionably better with it than without it, but in such cases it cannot be regarded as a specific in the same sense as would apply to the uncomplicated conditions.

Attention has recently been prominently called to the fact that tubercle in susceptible animals has never been shown to have been cured by tuberculin, and clinical experience does not warrant any larger assumption than that a neutralizing effect is produced upon the focus of disease, rendering it inert and for a time incapable of reinfecting the body. But this effect would seem to be temporary, and only the maintenance of sound health hereafter will serve to maintain permanent quiescence.

TREATMENT AFTER OPERATION.

MR. WILLIAM TURNER and Mr. E. ROCK CARLING have written a useful book on *Treatment after Operation*² containing a great deal that is of sound practical value, and readable throughout. A commencement is made with a chapter on the sick room, giving general nursing instructions, and drawing attention to such risks as burns from hot water bottles. There follows a consideration of general after-treatment, including that of vomiting, shock, restlessness, and so on. This chapter might have been enlarged with advantage by a more detailed analysis of the causes of the most important general complications. The advice for treatment is practical and to the point, but such a condition as shock requires more than two pages for such an exhaustive discussion as one is entitled to expect in a volume on after-treatment. The management of aseptic and septic wounds and of hæmorrhage is laid down on recognized lines; the necessity for great caution during convalescence from post-operative thrombosis is properly emphasized. There follow short chapters on operations involving different tissues and organs—the skin, nerves, bones, face, tongue, and so on. Very wisely the authors are definite in their instructions. Of course practice varies; for example, some surgeons eschew the use of protective silver leaf, etc., to cover skin grafts and find that grafts covering a clean granulating surface require no dressing other than sterile gauze. Other divergencies of practice might be noticed, but it must be acknowledged that a short handbook is no place for the discussion at length of alternative methods.

It is in the later chapters on abdominal and genito-urinary surgery that the authors fulfil their task most satisfactorily. The increasing practice of getting patients up within the first fortnight after aseptic abdominal operations is not supported; the authors are on the side of caution. The management of drained wounds of the peritoneal cavity is admirably dealt with. In acute dilatation of the stomach attention should have been directed to the value of the prone position. Mr. Cargill, who writes the chapter on treatment after eye operations, has been liberally dealt with in the matter of pages; he has therefore had an opportunity of writing a really detailed guide to the management of these cases, and has made good use of it. The illustration of this last chapter is full, of the rest of the book adequate. The practitioner or house-surgeon will find much in the volume (which is one of the series of medical books issued by the London University Press) that will help him in difficulties, and the instructions may be trusted as being throughout on sound recognized lines.

Lond., M.D. Berné, Visiting Physician to the English Sarsorium, Arosa, Switzerland. Second edition. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton. 1913. (Post 8vo, pp. 262. 6s. net.)

² *Treatment after Operation*. By William Turner, M.S., F.R.C.S., and E. Rock Carling, B.S., F.R.C.S., with a Chapter on the Eye by L. V. Cargill, F.R.C.S., London Medical Publications. London: University Press. 1912. (Demy 8vo, pp. 255; illustrations 55. 10s. 6d. net.)

REFRACTION.

PROFESSOR HIRSCHBERG of Berlin has published a short treatise on *The Treatment of Short-sight*,³ which has been translated into English by G. LINDSAY JOHNSON. The essay is founded on a lecture delivered in 1911. Professor Hirschberg first goes into the question of the history of myopia and its causes. In the matter of treatment he is most emphatic: he strongly deprecates the use of high concave glasses, and thinks that they should be used only with the utmost caution. In grades between 0.75 and 3 D. he allows a full correction to be used continually. In medium degrees from 3.5 to 6 D. full correction is to be used for distance only, while for near work weak glasses should be used or none at all. In the higher grades of 6 D. and upwards two separate pairs should invariably be ordered, and the reading pair should be half the strength, or a little more, of those ordered for distance. He disapproves of full correction for anything but momentary use in high myopia, and states that "nobody can endure wearing -16, -18, or -20 continuously." He prefers an opera glass for occasional use at a distance to the full correction. He refers to his own good results obtained by operating for senile cataract upon myopes, and shows that these results are very much better than the published results of those who have had a large experience in removing clear lenses for myopia. He goes fully into the various pathological changes known to complicate and be induced by high myopia. The use of the Heurteloup artificial leech he condemns, and considers that these cases require tonic treatment rather than the reverse, while rest from all near work is essential. Many cases are quoted illustrating the results of treatment, including that for detachment of the retina. He is by no means an advocate for the operation of the removal of the clear lens, and considers that detachment of the retina is very liable to follow it, but he has done it in specially selected and suitable cases with good results. Finally, he devotes several pages to the subject of the prevention of myopia. The book is original, and the facts are clearly stated, but the teaching will be found to differ considerably from many of the generally accepted theories on this important subject. The translator has done his work well.

DR. JAMES THORINGTON, of Philadelphia, has brought out the sixth edition of his very useful and practical book on *Retinoscopy*.⁴ It is quite a small volume but with 61 illustrations. It is particularly to be recommended because it is so well arranged, and because, in spite of its small size, it contains all that a beginner can learn, by reading, of the art of retinoscopy. All the rest has to come from practice. The author describes in detail the special method he uses in the arrangement of the light. He also advocates the self-illuminating retinoscope. There are various little devices to facilitate the working out of a refraction case which have for a long time been associated with the name of the author; these are all useful and practical, and are clearly described. The schematic eye for the practice of retinoscopy is figured, and altogether any one who wished to learn the principles of the method could not do better than study this book. We hope that the new edition, which has been revised, will be as popular with students and practitioners as those which have preceded it.

THOMSON'S "HEREDITY."

A WARM welcome for the second edition of THOMSON'S *Heredity*⁵ was ensured by the admirable qualities of the first. It was a model of comprehensiveness and impartiality. The author stated the facts fully and clearly, together with the deductions they had been held to justify, but he never hesitated to advise suspension of judgement. He played the part not of the schoolmaster who would compel acceptance of his formula by the threat of the ferrule, but that of the sweetly reasonable guide and companion who carefully and exactly told all that was known and said

and then suggested with a humorous smile that it is never wise to believe all that one is told. We have been led here into stating by implication one of the secrets of the success of Professor Thomson's book; it is stuffed full of facts, but its pages never long lack the lambent lights of humour and practical wisdom. As a text for the chapter on the history of theories of heredity and inheritance, he quotes from Pope's *Iliad* the apposite lines:

Like leaves on trees the race of man is found,
Now green in youth, now withering on the ground,
Another race the following spring supplies,
They fall successive and successive rise,

and adds this commentary: "The same may be said of the succession of theories of heredity, but, in both cases, there is a persistent living tree, to whose growth all the leaves contribute."

In consequence of the attitude of mind in which the author approached his task, he has had to make in his second edition very few changes in the matter of the first, and, so far as we have observed, the difference between the two lies chiefly in the records of new facts and theoretical developments which have arisen in the interval. This seems to be the case even in the discussion of Mendelism, a subject of much observation and still more speculation during the last five years.

The problems with which the book deals can never be long absent from the mind of any practitioner of medicine who thinks for himself. They insistently force themselves on his attention, but their complexity as they present themselves to him in man is so great that he must often put them away as insoluble. The biologist who has the whole of living nature for his field is more fortunate since he can begin with the simplest cases. The medical student of the subject must turn to the biologist for guidance, and in this book he will find what he needs. It cannot be too strongly recommended as a book to be read through, and then kept on a convenient shelf for reference. It is so well and logically arranged that anything that is wanted can quickly be found even without the aid of the excellent index. It should be added that Professor Thomson has compiled a bibliography which, though he describes it as "simply representative, not in any way exhaustive," yet fills sixty pages. Its value is greatly enhanced by the notes added to many of the entries, indicating the general scope and purpose of the work mentioned. There is also a list of the "best books to begin with," nearly all of them published in this century, but already numbering over thirty. There is, therefore, all the greater debt of gratitude due to Professor Thomson for giving us in one volume a comprehensive "best book to begin with," which will carry the student safely to a state of mind and knowledge enabling him to go on at once to any special line of investigation that may appeal to him. Many writers on heredity are afflicted by cocksurety. From this defect Professor Thomson is free, and we may apply to him the praise he gives to Professor Tower—his "general conception of the attributes of the organism appears to us to have a wholesome breadth and elasticity such as the present state of knowledge demands."

BREAD-AND-BUTTER WISDOM.

THE gratitude of our transatlantic brethren is due to Dr. T. F. REILLY, who, being Professor of Applied Therapeutics at Fordham University, New York, has not disdained to instruct his juniors in the art of making a success of life. Nor is the interest of his book⁶ confined to his compatriots; the conditions determining financial success or failure appear to be substantially the same in the New World and the Old. When one has become accustomed to some trifling differences of nomenclature—to hearing general practitioners spoken of as "physicians," their consulting rooms called "offices," and so forth—one finds one's self in the main upon familiar ground. We have, indeed, been surprised to find how generally applicable the author's advice appears to be. The book makes quite good reading, for Dr. Reilly has a gift of sly humour and a certain genial cynicism, as well as a wide knowledge of professional economics. In a chapter dealing with post-graduate study the young practitioner is advised to take out a course in

³ *The Treatment of Short-sight*. By Professor Dr. J. Hirschberg of Berlin. Translated by G. Lindsay Johnson, M.D., F.R.C.S. London: Reiman Limited, 1912. (Demy 8vo, pp. 123; figs. 12. 5s. net.)

⁴ *Retinoscopy*. By James Thorington, A.M., M.D. Sixth edition, revised and enlarged. London: Reiman Limited, 1912. (Demy 8vo, pp. 87; 61 illustrations. 4s. 6d. net.)

⁵ *Heredity*. By J. A. Thomson, M.A. Second edition. The Progressive Science Series. London: J. Murray, 1912. (Demy 8vo, pp. 643; figs. 47. 9s. net.)

⁶ *Building a Profitable Practice*. By Thomas F. Reilly, M.S., M.D. Philadelphia and London: J. B. Lippincott Co., 1912. (Demy 8vo, pp. 304; illustrations 16. 10s. 6d. net.)

any speciality to which he feels himself drawn, and preferably after five or six years of general practice. By that time his tastes will have matured, and he will have acquired a knowledge of his real aptitudes and limitations. Moreover, if he goes to Europe, the hygienic benefit will be a consideration. The facilities for post-graduate study in London are deservedly commended. It is interesting to note that what we call here club practice, and our American cousins lodge practice, does not appeal to the author any more than it has hitherto appealed to us.

As a matter of fact (says Dr. Reilly) few men get much out of this line of work. The man who does succeed would succeed just as well without it. The people do not think they are getting satisfactory treatment, no matter how careful and conscientious the doctor may be, and, once they have that notion, nothing will change their value of your services. They know you are cheap, and they will not trust their children to you. From the obstetric standpoint, their wives will have the same feeling.

As to family contracts, the author condemns them unreservedly.

Do not under any circumstances take up this work; rather retire from the profession and go behind a dry goods counter than touch it.

From the chapter on medical finance we gather that the average fee ranges higher in the United States than in Great Britain. Probably, where we should charge from 2s. 6d. to 5s. for a visit, an American practitioner of similar standing would expect from one to two dollars; and in obstetric cases a fee of ten dollars would seem to correspond to our guinea fee. A good example of the author's dry humour is a remark he makes apropos of the courtesy call. He advises the beginner to utilize the occasion of this visit to ascertain "the fee table in vogue in that particular location." But he is careful to add that "unless you are dealing with a particularly high class of practitioners, you will find the fee table idealistic, and that a third to one-half less is gratefully received." Similarly, while deploring the insistence of the laity upon an early and often impossibly definite diagnosis, he indicates a plan by which this weakness can be indulged without undue risk of humiliation. "It is better," he says, "to make a double diagnosis when in doubt, and at a later period drop one of the diseases if necessary." There are many other aphorisms which we are tempted to quote, but we will conclude with this suggestion as to the method of eliciting a cash payment:

At your first call, after having finished your work, stand up in the middle of the floor and slowly look about, twirling your hat as though you were waiting for some one to come, at the same time not saying anything for a few minutes. This will cause most people to make some suggestion as to payment.

OLD COOKERY BOOKS.

ALTHOUGH Englishwomen have never enjoyed much repute as first class cooks, they have always been regarded as notable housewives, and even the great ladies of the past did not disdain to take an active interest in all that concerned the health and comfort of their families and dependants. The position of mistress of a large household was no sinecure in the good old days, when the chatelaine, besides superintending and taking part in the housework, was usually her own baker, brewer, laundress, and dressmaker, and not infrequently was called upon to act as doctor and chemist as well. Nearly every family possessed a number of homely remedies, many of which had been handed down from mother to daughter for generations, and the relation between good health and good food was fully recognized by every good housekeeper. It is not surprising, therefore, to find that many ancient cookery books include, besides the usual receipts, full directions for making up different medicines and the treatment of a variety of diseases. Dr. ARNOLD WHITAKER OXFORD, whose book on *English Cookery Books to the Year 1850*⁷ contains a most interesting collection of title pages of these antique volumes, has found in them a wealth of curious detail relating to the medicine of the past. The majority of the remedies quoted by Dr. Oxford sound more strange

than efficacious to modern ears, and many are frankly disgusting. To "apply a live puppy to the naked belly," as advised by *The Family Magazine* published in 1741, sounds a remarkable way of treating acute abdominal trouble, whilst the lady mentioned in *The Complete English Cook* (1762) who was cured of "a Cancer in her Breast, a Consumption, a Sciatica, and Rheumatism, which she had near twenty years" simply by taking a cold bath, would have made an excellent advertisement for any spa or holy well. Dr. Oxford is to be congratulated on his careful arrangement of this mass of material. He gives, besides the title page of each volume, a short synopsis of its contents, beginning with the *Boke of Cokery* published in 1500 and ending with *Common Sense for Housemaids*, which appeared exactly three hundred and fifty years later. His occasional extracts from these dead and gone authorities on domestic economy have much the same effect on his readers as the workhouse gruel on *Oliver Twist*, inasmuch as they make them long for more. The book forms an interesting sequel to the *Notes from a Collector's Catalogue*, published some time back by the same author.

NOTES ON BOOKS.

IN the second edition of *A Manual for Women's Voluntary Aid Detachments*,⁸ by Lieutenant-Colonel P. C. GABBETT, are included chapters on the clearing of hospitals, the equipment of those intended for temporary use, the need for training, the preparation of rooms, instruments, and dressings for operations; the administration of medicines, and the choice and preparation of diets; on first aid to the injured, on field drills and the equipment required for the training of squads, and on the kind of outfit required by a nurse when going into camp. Since the volume devoted to these subjects numbers only 112 very small pages, it is natural to find that as a whole it hardly represents what might be expected from its title. Nevertheless, there are doubtless a good many beginners who will be able to derive from it much useful information, while to those already versed in the various subjects it may possibly supply some new idea.

Dr. LESLIE THORNE THORNE has brought out a new edition of his book relating to *The Nauheim Treatment of Diseases of the Heart and Circulation*.⁹ Intended to facilitate the use of this system in English-speaking countries, it describes the action and administration of the baths and the selection of cases for treatment, as also the exercises employed, the latter being very clearly illustrated. Finally come some detailed records of cases which have been under the author's observation for years. The book from the first supplied an excellent exposition of the subject, and this fourth edition, amplified as it is by the inclusion of electro-cardiograms and sphygmographic records, is decidedly attractive.

A psychological clinic, such as exists in connexion with the University of Pennsylvania, and is described by Dr. HOLMES in *The Conservation of the Child*,¹⁰ is an institution typically modern in the best sense of that word. Staffed by a trained psychologist, a medical examiner, one or two voluntary social workers, and a stenographer, its main function is to serve as a clearing house for abnormal, and in particular mentally defective, children. By a series of careful and systematic observations, often extending over a considerable period, the subjects brought by parents and guardians are ultimately classified in accordance with the degree and nature of their departure from the normal standard of their respective ages. Great pains are taken to provide for their future welfare by directing their parents as to home training or by placing them out in one or another of the various institutions available. The voluntary workers are required to keep in touch with the patients of the clinic, to follow up and supervise their progress, and to report thereupon. In the book before us a full and clear account is given of all these activities and an excellent case made out for the social utility of such

⁷*English Cookery Books to the Year 1850*. By Arnold Whitaker Oxford, M.A., M.D. Henry Frowde: Oxford University Press; London, Edinburgh, New York, Toronto, Melbourne, and Bombay. 1913. (Pp. 192. 5s. net.)

⁸*A Manual for Women's Voluntary Aid Detachments*. By Lieutenant-Colonel P. C. Gabbett, I.M.S. (retired). Second edition, revised, and enlarged. Bristol: John Wright and Sons, London: Simpkin Marshall, 1913. (Double post 32mo, pp. 115. 1s. net.)

⁹*The Nauheim Treatment of Diseases of the Heart and Circulation*. By Leslie Thorne Thorne, M.D., B.S. Durh. Fourth edition. London: Baillière, Tindall, and Cox. 1913. (Cr. 8vo, pp. 112; figs. 55. 3s. 6d. net.)

¹⁰*The Conservation of the Child*. By Arthur Holmes, Ph.D. Philadelphia and London: J. B. Lippincott Co. 1912. (Post 8vo, pp. 345. 4s. 6d. net.)

work. We cordially commend the study of Dr. Holmes's book to all who are interested theoretically or officially in the important subject with which it so admirably deals.

In reviewing the first edition of Mr. YULE'S *Introduction to the Theory of Statistics*¹¹ we expressed the opinion that it was decidedly the best work on the subject available. The appearance of a second edition within twelve months of publication is a practical confirmation of our judgement. Some errors have been corrected, the wording of certain paragraphs has been changed, and a few additions have been made, the most important being a section on the correlation ratio. Readers of current statistical literature will be aware that some of the methods of measuring association which are advocated by Mr. Yule have been vehemently impugned. Whatever may be the judgement finally pronounced by qualified persons upon the points at issue, we have little doubt that Mr. Yule's work is, and will long remain, the best introduction to statistics in our language.

The abolition of the army and navy and the blessings of universal peace form the subject of Dr. WINSLOW HALL'S allegorical play, *The Peacemaker*,¹² in which the identity of the four great nations who play the principal parts is but thinly concealed under the names of private individuals. Dame Britt, Uncle Sam, Fritz, and Jeannette have hitherto lived side by side in armed neutrality, until the first named, urged by her youngest son Layburr, dismisses her guards, demolishes her defences, and finally prevails upon her quarrelsome neighbours to follow her example and live together in brotherly love and tranquillity. Dr. Winslow Hall has evidently great faith in the humanizing effects of universal disarmament, and satirizes severely those politicians who believe that the surest way to preserve peace is to be strong enough to enforce it. His play, which is in blank verse, has been written with the object of turning men's thoughts away from the contemplation of wars and rumours of wars, and to hasten the advent of that happy time

When shall all men's good
Be each man's rule, and universal Peaceo
Lie like a shaft of light across the land,
And like a lane of beams athwart the sea.

The love story of Dermot Fitzgerald and Nora Townsend, as told by the author of *The Surgeon's Log* in his novel *The Night Nurse*,¹³ goes far to prove the truth of the saying that the course of true love never did run smooth, for his hero and heroine have even more than the usual amount of trials and misunderstandings before they are united in the last chapter. Mr. ABRAHAM has depicted the daily life of residents and nurses in a Dublin hospital with much vivacity and skill, though he has perhaps given undue prominence to what is, after all, only one side of the picture; and he has succeeded in treating the hackneyed theme of two women in love with the same man in a novel and interesting fashion. The author is at his best, however, when the scene of his story shifts to a little town in the wilds of Mayo, where an outbreak of typhus has caused the principal characters to congregate. It is then that his writing develops a depth and force that are lacking in the early part of the book; whilst his description of the squalid workhouse, transformed for the occasion into a fever hospital, and the heroic efforts of the overworked doctors and nurses to do their duty in the face of overwhelming difficulties, is tragic in its grim realism. The novel is considerably above the average both in style and in plot, and has, moreover, the supreme merit of being written by one who knows from personal experience the lights and shades of hospital service, and the strange mixture of tragedy and comedy that makes up the daily life of the little world enclosed within the walls of a public hospital.

¹¹ *An Introduction to the Theory of Statistics*. By C. Udny Yule. Second edition, revised. London: C. Griffin and Co. 1912. (Post 8vo, pp. 396; figs. 53. Price 10s. 6d. net.)

¹² *The Peacemaker: A Retrospective Forecast*. By W. Winslow Hall. M. D. London: A. C. Fifield 1913. (Pp. 63. 1s. net.)

¹³ *The Night Nurse*. By the author of *The Surgeon's Log*. London: Chapman and Hall, Ltd. 1913. (Post 8vo, pp. 316. 6s. net.)

A BELGIAN Association of Social Medicine was founded at Brussels on March 29th on the initiative of Dr. Stassen. The new association is to devote itself to the study of questions of hygiene, labour, insurance, and so forth. The provisional committee consists of Drs. Gilbert, Inspector of the Ministry of Labour; René Sand, agrégé of the University of Brussels; and Stassen, Physician to the Dispensaire de l'Espérance at Montegnée, Liège.

MEDICAL AND SURGICAL APPLIANCES.

An Operating Screen.

DR. C. A. STIDSTON, of Wolverhampton has recently had made to his design by Messrs. Allen and Hanbury an appliance by which both patient and operator can easily be screened from the anaesthetist when desired. It consists of an upright of plated brass tubing, carrying an horizontal arm of the same construction and material on which towelling can be hung. The upright is attached to the operating table wherever desired by an iron screw clamp, and both the upright and the arm are freely extensible to heights and lengths within wide limits, and movable in any direction. The screws bringing about these movements are so placed as to be under the control of the anaesthetist. The appliance has been found especially useful in connexion with operations about the neck.

A Sanitary Closet Seat.

In these days when frequent absence from home necessitates the use of public sanitary conveniences, it is important that the dangers incident to many appliances in public places should be reduced to a minimum. At large railway stations it is the usual custom for an attendant to cleanse the seat of a public water-closet after use with cloth which may be indifferently clean, while in some public latrines in parks and elsewhere a rail is substituted for the seat, though in military camps even the rail has been abandoned and the straddling position over a trench is enforced. For those closets provided with a seat this part of the apparatus can now be obtained made in two halves from before backwards, a space of a few inches being left at the front and the back of the divided seat. There is thus much less chance of the seat being soiled than where the ordinary type is in use. The seats can be fixed to any closet pan, and are obtainable from Messrs. Murray, Morgan and Co., Limited, 1, Norwich Street, Farnival Street, Holborn.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).

SECTION OF RHINOLOGY AND LARYNGOLOGY.

THE President of this Section is Sir St. Clair Thomson, and the Acting Secretary, Mr. Douglas Hamer, 45, Weymouth Street, W.

As in other sections the mornings will be devoted to discussions. The following subjects have been selected:

Discussions.

On Thursday, August 7th, Professor Killian and Professor Jackson will report on endoscopic methods as applied to the larynx, trachea, bronchi, oesophagus, and stomach.

On Saturday, August 9th, there will be a discussion on indications for and relative values of tonsillectomy and tonsillectomy. To be opened by Professor Burger and Dr. Goodale.

On Tuesday, August 12th, Professor J. Ferreri, Dr. H. Marschik, and Dr. E. Lombard will open a discussion on the pathology and treatment of malignant growths of the nose and naso-pharynx (fibroma to be excluded).

The remaining two mornings—namely, Friday and Monday (August 8th and 11th) will be devoted to a joint meeting with the Section of Otolaryngology. On the former day Professor Gerber and Dr. André Castex will introduce a discussion on the methods and results of treatment of diseases of the throat, nose, and ear by salvarsan and other arsenical compounds, and on Monday Dr. Victor Delsaux and Dr. E. W. Goodall will report on the special treatment of the throat, nose, and ear during the active stages of certain infectious fevers.

The afternoon sessions will be devoted to papers offered by members of the Section.

When the arrangements for the Congress were first considered, the question arose whether laryngology and otology should continue to be divided, or should be united in one section. The former plan was adopted, but it was arranged that the *Transactions* of both sections should be supplied to members of either, that they should have joint meetings, and should be in close contiguity. They will both meet in the Central Technical College in adjoining rooms.

Museum.

In connexion with the Section of Laryngology, a department has been arranged in the General Pathological Museum to illustrate the following three groups of diseases: (1) Neoplasms of the nose, accessory sinuses, and naso-pharynx (excluding mucous polypus); (2) the rarer forms of laryngeal tumours, including post-cricoid

carcinoma; (3) diseases of the trachea and bronchi. There will be an exhibition of instruments to illustrate recent improvements in broncho-oesophagoscopy.

The committee is prepared to arrange for a limited number of short demonstrations in the museum at stated hours. Members who desire to lend material for exhibition are requested to communicate with Dr. Dan McKenzie, 62, Brook Street, London, W.

SECTION OF OTOLOGY.

The President of the Section is Mr. Arthur Cheatle, and the Acting Secretary Mr. Sydney Scott, 130, Harley Street, W. Messrs. J. S. Fraser, G. J. Jenkins, and Patrick Dempsey are also secretaries. It has been stated that this section is closely connected with Section XV (Rhinology and Laryngology), and that a subscriber to either receives the *Transactions* of each. Joint discussions on (a) the methods and results of treatment of diseases of the throat, nose, and ear by salvarsan and other arsenical compounds; and (b) special treatment of the throat, nose, and ear during the infectious fevers, will, as there mentioned, be held. The other mornings will be given up to discussions on: (a) The pathology of deaf-mutism, on which Professors Alfred Denker and Holger Mygind will report, and Professor Siebermann will give a demonstration; (b) non-suppurative diseases of the labyrinth (reporters, Professors G. Alexander and Karl von Eicken); and (c) climatic and occupational influences in diseases of the ear, introduced by Dr. Clarence Blake and Professor Gradengo. In addition, an extra discussion has been arranged for surgical anatomy of the mastoid region. This will be held on Wednesday afternoon, August 6th, and will be opened by Professor Mouret. The afternoon sessions will be given up to independent papers.

There will be a museum connected with this section, which will be devoted to illustrating by specimens, transparencies, and other exhibits, the anatomy, physiology, pathology, and surgery of the labyrinth. Members who desire to lend material for exhibition are requested to communicate with W. M. Mollison (Secretary), 48, Brook Street, Grosvenor Square, London, W.

Entertainments.

The dinner of the combined Sections of Rhinology and Laryngology and Otology, to which all foreign members who register their names will be invited, will be held at the Hotel Cecil on Tuesday, August 12th, at 7.30 p.m. Tickets can be obtained from the Treasurer, Mr. Mark Hovell, 105, Harley Street, London, W., at the price of 2 guineas. An excursion to Oxford on Sunday, August 10th, will also be arranged. Visitors will be asked to pay their own expenses, amounting to about 10s. 6d. each, and it is possible that the numbers may have to be limited. Gentlemen wishing to give private entertainments of any kind during the Congress, and visitors who require hotel accommodation, are asked to notify the Secretary of the Entertainments Committee, Mr. Cecil Graham, 17, Upper Wimpole Street, London, W.

We are informed that, though a large number of the children when received into Dr. Barnardo's Homes are in an emaciated condition and physically afflicted in various ways, the death-rate last year was only 5.15 per 1,000; 17,191 children in all were dealt with during the year, and nearly 9,000 are always in residence.

At the annual meeting of the Medical Association of the Greater City of New York, the recent official request of the New York Board of Health that all practitioners should report promptly to them all cases of syphilis, gonorrhoeal infection, and chancreoid, together with the source of infection, if obtainable, was discussed. On the proposal of Dr. William S. Gottheil it was resolved that such notification would be an undesirable and useless invasion of the most confidential relationship between physician and patient. The mere compilation of statistics in venereal diseases, it was suggested, had no value, and the attempt to make it in this manner was a direct incentive to falsification and disobedience of the law. The measure was described as of value only as a step towards the relegation of these cases to the Board of Health, and it was urged that its ultimate effect would be to promote self-medication and quackery. It was further resolved that a committee should be appointed to decide what action should be taken in the matter.

THE REPORT OF THE ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

By ERNEST H. STARLING, M.D., F.R.C.P., F.R.S.,
JODRELL PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE.

II.—THE MATRICULATION QUESTION.

THE University of London has for so long been a mere sorting and labelling machine that we in London often find it difficult to conceive of a University from any other point of view. One of the main causes of dissatisfaction with the University has been the impossibility of obtaining a label, in the shape of a degree, for the majority of London medical students. Though the inability to obtain a degree may represent a real disability to London students, and may have had an injurious action on the entries to our medical schools, it is not a matter which directly affects either the community or the science of medicine, nor could it serve as a pretext for State interference with the present University or for the grant of funds from the State for the foundation of a new University. So far as labels and examinations go, the State protects itself by prescribing a certain minimum of knowledge which must be obtained by its licensed practitioners, and has entrusted a body—the General Medical Council—with the office of guarding this standard. It is, however, of importance to the community that as many practitioners as possible should have received an education considerably transcending the prescribed minimum, and it is therefore in its interests that the general standard of medical education should be as high as possible, and that London, with its rich store of clinical material and its attraction for the greatest intellects in the profession, should be equipped and organized for the utilization of material and men and thus play its due part in the education of the profession and in the advance of medicine.

Entrance to the University.

From this standpoint the State is justified on behalf of the community in remodelling the University and employing public funds in the foundation of a great school of medicine, and endeavouring to attract to this school as large a proportion as possible of its future practitioners of medicine. The continuance of the present impediments to the entry upon a University course in London would effectively bar the new University from taking its proper share in the medical education of the country. At first sight it is not easy to make out how the measures proposed by the Commissioners will accomplish this object—that is, an increased accessibility of the University course to the London medical students. Indeed, the report evidently contemplates that at first its constituent colleges or colleges of medicine will be confined to the students of London, Oxford, and Cambridge Universities; and it is significant in this connexion that the report estimates that more than half of these students will have received their preliminary and early training at Oxford and Cambridge, and thus will not be in the strict sense of the term London University students at all. A more careful consideration of the report shows, however, that this will apply only for a short time immediately after the inception of the University.

In order to see how this condition of things will be remedied, it is necessary to read the parts of the report dealing with the question of entrance to the University and school-leaving examinations, together with the report of the Consultative Committee of the Board of Education.¹ In the preface to the latter report the Board of Education indicates that it is engaged in formulating a definite scheme of action in accord with the main principles laid down by the Consultative Committee in respect to school-leaving examinations, and such examinations as give entrance to universities. This report appeared in 1911, and it seems probable that by the time the new University of London comes into existence, which we may hope will not be more than three years from the present date, the Board of Education will have devised some common scheme of school examination which will apply to the whole country, and which will determine the admission

¹Board of Education. Report of Consultative Committee on Examinations in Secondary Schools. H.M. Stationery Office, 1911. Price 2s. 6d.

to all the universities, and, perhaps, to all the learned professions. It may be interesting to anticipate, in the light of the recommendations contained in these two reports, the manner in which the Board of Education may be able to co-ordinate the multifarious school examinations, local examinations, and university entrance examinations, which at present are the terror of the schoolmaster and the stumbling-block of the students.

Most London teachers would agree that the majority of the London medical students are capable, or might be made capable, of profiting by university education of the highest type. A minority, which is probably not greater than 10 per cent., who have been crammed through some inadequate preliminary examination, ought never to have entered the profession at all. Some of these fail to qualify; others sink in after many years through some of the back doors to the profession which still exist in various parts of the country. The majority, however, fail to commence a University career simply because they have not passed the matriculation examination. It cannot be pretended that this examination is too difficult. It is, however, only suited to a certain number of schools. Boys coming from other schools would have to undergo a special preparation for this examination. At the present time the majority of the boys and girls in the secondary schools who are expecting to proceed to a University or to any profession pass some examination or other while they are at school. Of these school examinations there is an enormous number: Oxford and Cambridge both hold three examinations in addition to the Joint Schools Examinations. The students entering St. Bartholomew's Hospital in one year had passed the following examinations as entitling them to begin the study of medicine: London Matriculation, College of Preceptors, Cambridge Previous Examination, Oxford Responsions, Cambridge Senior Local, Oxford Senior Local, Oxford and Cambridge Schools Examination Board, Educational Institute of Scotland, B.A. Cape of Good Hope, Matriculation Royal University of Ireland, Central Welsh Board, Sandhurst Entrance Examination. Until a few years ago none of these examinations, except the London Matriculation itself, would have allowed a student to matriculate as an undergraduate of the London University, and even now, when a few of them are allowed as alternatives to the Matriculation, the subjects have to be taken in exactly the same combination as is prescribed for the London Matriculation, irrespective of the nature of the curriculum of the school at which the boy has been educated. The function of a University is to educate, to make the best of the students presented to it by the secondary schools, and it is neglecting its duties if it refuses to accept three-fourths of those who would enter its portals because the ideals of the school where they have been educated do not fit in to a certain Procrustean bed devised by the University.

There can be no doubt that a new University, guided by an Academic Council which regards education as the main function of a University, will at once get rid of the disabilities at present attaching to boys educated in two-thirds of the schools of the country, and will accept any school-leaving examination or local examination which affords evidence of a secondary education sufficient to enable a boy to profit by the education offered him by the University. The whole present system of school examinations is, however, temporary. University education must be hampered and kept back while secondary education is in its present inchoate and unorganized condition. Reform of secondary education will mean improved quality of the students coming to the University and greater power in the hands of the University, and this reform must be carried out by the schools themselves, and cannot be enforced on them by a system of matriculation regulations.

Let us consider what preliminary education the student needs who is to commence the study of medicine. In the first place he must have a sound knowledge of his own language, English, so that he not only apprehends what he reads or hears, but has also acquired the power of expression and of orderly thought. The development of reasoning power cannot be dissociated from the use of language, and it is one of the defects of our school education as compared with that of France that children are rarely taught to use language as an instrument.

"English" generally means English literature or English grammar, whereas every lesson in geography, in history, in chemistry or physics, should be at the same time a lesson in the use of English—that is, in the art of expression and of reasoning.¹ Since the student is to devote his time to some of the most difficult branches of biological science, he should also be acquainted with the principles of the nature and reaction of things—that is, he should have an elementary knowledge of physics and chemistry. For this purpose he will need to add to his knowledge of English a knowledge of the language of quantity and exact measurement—namely, mathematics.

Moreover, since science is international in character, he ought to have at least a reading acquaintance with one or two modern languages other than his own, and there is very little difficulty in teaching children during their school years both to read and speak sufficiently well for practical purposes two modern languages. Thus the training which a student should have received to qualify him to pass through the gateway of a medical faculty of a University should include English, mathematics, elementary physics and chemistry, and one or two foreign languages.

A medical man, however, is a member not only of a learned profession, but also of a community including individuals engaged in many other forms of activity. Social intercourse among these individuals involves a certain common fund of knowledge and interests, and for this purpose it is important that every child, whatever its future destination in life, should pass through a certain common education—an education which should give them some idea of the history and political conditions of their country, its relation to other countries, its literary possessions, and the foundations of its laws, customs, and ideals. As a result of this education, the child will acquire a fund of culture to which he may add in one direction or another according to his tastes later on in life, and it is evident that in the hands of different schoolmasters one or other side of this discipline will tend to undergo hypertrophy at the expense of the others. If, however, the education is such as to arouse the child's interest, to create mental alertness, and to impart habits of discipline, the education may be considered as having succeeded in its object.

The Scottish School-leaving Certificate.

Considerations such as these seem to have influenced the Commissioners as well as the Consultative Committee of the Board of Education in their respective reports, and to have actuated those responsible for the system which is actually in work in Scotland. In Scotland practically all the secondary schools are under the control, either in respect of grants or by their voluntary action, of the Scottish Education Department. This Department has a staff of inspectors and examiners, so that it is able to exercise a very considerable control over the curriculums in the various schools. It does not attempt to achieve uniformity among the different schools, but rather to encourage educational experiments. The work is, however, so arranged that, whereas during the early years of the pupil he is studying subjects of general culture, during the last two or three years he is specializing more in the direction of the subjects which will be of value to him in his future career. Two sets of examinations are held at the schools. The first examination is held at the end of a course, called the Intermediate Curriculum, which extends over not less than three years. This curriculum, in order to be approved by the Board, must provide for instruction in at least five subjects, embracing English (with English history and geography), a language other than English, mathematics, experimental science, and drawing. The general standard which is looked for as a condition of the award of the Intermediate Certificate is the degree of all-round proficiency which a well-taught pupil of average ability might reasonably be expected to attain at the age of 15 or 16. After gaining the Intermediate Certificate the pupil must take a post-intermediate course at the school of at least two years' duration. During this time he must study not less than four subjects taken from a fairly extensive list, and at the end he is examined, and, if successful,

¹This point has been extremely clearly brought out by Mr. P. J. Hartog (Academic Registrar of the University of London) in his small book, *The Writing of English*.

granted a Leaving Certificate. In this examination, as in the examination for the Intermediate Certificate, comparative excellence in one branch may be held as compensating for some degree of deficiency in another. This leaving certificate in Scotland is the usual avenue to the universities. The object of the whole scheme is to free the schools and give them the determination of the direction in which the education of the pupil should develop. It has not, however, done away with university preliminary examinations, which are still regarded as necessary for candidates from India, the Colonies, etc.

School Examination for England.

It is a weak point in the Scottish system that although the Leaving Certificate is necessary for the University, a relaxation of this rule is made in the case of medicine, admission to which faculty is made on the strength of the Intermediate Certificate. The report of the Royal Commission agrees with that of the Consultative Committee in recommending the institution of two such examinations in the secondary schools of England and Wales also. The first examination, to be passed at the average age of 16, would include the subjects of general culture which form the main basis of the curriculum of the school in question. In this curriculum it is evident that the chief emphasis might be laid either on classics or on science or on modern subjects, according to the traditions of the school or the ultimate destination of the majority of its pupils.

The second examination would be held two years later—that is, at the average age of 18—and in the case of future students of medicine, engineering, or science, would probably include English, mathematics, physics and chemistry, and possibly a modern language, and in some cases biology. It is evident that many schools would not be in a position to give this further specialized education in science, which should be the leaving examination for all students intending to take up the study of any science at the University. At first, therefore, it would be necessary to admit students to the University on the results of the junior examination, and the elementary instruction in science such as that given for the Intermediate Scientific or for the Preliminary Scientific Examination would have to continue to be given at the University. Under the fostering influence of grants, however, from the Board of Education it may be possible to group the schools in different districts and to provide first-class scientific instruction in one school in each group, together with bursaries or travelling allowances for the students, so that in this school a first-rate instruction in elementary science could be given. In the same way other schools might specialize in classics. It is doubtful whether the Board of Education will be able to effect so complete a unification as is carried out under the Scottish Education Board. It must be remembered, however, that it has considerable control over the majority of the schools in the country and of the universities by virtue of the grants which it makes every year. It seems possible that, instead of forcibly abolishing all the agencies of school examination which at present exist, it may make use of them and their organizations to conduct the type of examinations which in Scotland are in the hands of the Education Board itself. It could limit a school to that form of intermediate and school-leaving examination which is most suitable to the requirements of the majority of its pupils. By its inspectors it can satisfy itself of the sufficiency of the education imparted at each school, and it will then be in a position to insist on an equivalence of all the school-leaving examinations as entrance examinations to the Universities or to those departments of the University which are in receipt of its grants.

The Place of Teachers in the New University.

The main point, however, of the report of the Royal Commission is that in academic matters the guidance of the new University will be in the hands of the teachers. The aim of the University will be teaching and not labelling, and it is difficult to conceive that it will not, either in co-operation with the Board of Education or of its own initiative, endeavour to gather into its net all those who are in need of higher education and are in a position to profit by its instruction.

A CRITICISM OF PROFESSOR STARLING'S FIRST ARTICLE.

To the Editor of the BRITISH MEDICAL JOURNAL.

SIR,—Professor Starling has contributed to your issue of May 17th a very interesting dissertation on the Final Report of the Royal Commission on University Education in London. He naturally receives the report with approbation; indeed, he may feel some pride of paternity in it, for the Commissioners have done him the honour of largely reproducing his own individual views. In their most important recommendation, that is, as to the government of the new University, the Commissioners have followed "Report A" of the Academic Council. "Report A" can be demonstrated to be chiefly, if not wholly, of Professor Starling's drafting.

With your permission I shall comment upon the recommendations of the Commission, chiefly as presented by Professor Starling.

The Preliminary and Intermediate Teaching.

Professor Starling is obviously disappointed that the Commissioners have not—ostensibly—revived his pet scheme of concentration of the preliminary and intermediate teaching in three centres. Their astuter advisers no doubt cautioned them that it would not really do to run directly counter to the Report of Lord Macnaghten's Committee of the Senate, which had condemned this scheme, root and branch, only a few months previously to the appointment of the Commission. But Professor Starling may be, and no doubt is, completely reassured; for the Commissioners really concede the substance of his aspiration; they give back with one hand what they only seem to have taken away with the other. The Concentration Scheme, it will be remembered, contemplated the provision of three centres for the teaching of the preliminary and intermediate medical studies—that is, of chemistry, biology, physics and anatomy, physiology and pharmacology. Of these three centres, University and King's Colleges, the only ones actually in being—and the only ones, some of us think, ever really contemplated—were to be two. In spite of the most energetic canvassing, no subscriptions were received in response to the appeal for support of this scheme (Senate Minutes, 1907-1908, No. 543).

To understand the present position aright it must be carefully borne in mind that University and King's Colleges are by recent Acts of Parliament protected in the permanent retention of the teaching of these subjects; wherever else they may or may not be taught, they must be retained at these colleges.

Now we are told by the Royal Commission that the preliminary subjects will, it is hoped, in future be taught at the secondary schools of the country. But, as Professor Starling admits, there is no general provision, and cannot be general provision, of such teaching for many years, if, indeed, general provision ever becomes possible. "Meantime," we are told, "the teaching of those candidates who have been unable to obtain the necessary instruction at school should be provided for, either in the Science Laboratories of the University itself, or institutions recognized for the purpose by the University." For "Science Laboratories of the University" we must read the "Laboratories at University and King's Colleges," which are the only undergraduate laboratories at its disposal. The inference is fairly obvious that the preliminary teaching will be the monopoly of King's College and University College for many years to come, if not for ever.

The suggestion that chemistry, biology, and physics should be taught at the secondary schools and cease to be university subjects seems to me, if seriously intended, the most retrograde of measures. At a time when the civilized world is ringing with the discoveries in chemical therapeutics associated with Ehrlich and his school, it seems, indeed, singularly inopportune to withdraw chemistry, for example, from the University curriculum. The teaching of these subjects at the medical schools, as at present conducted, is said by the Commissioners to be "inadequate." Is it conceivable that the secondary schools, scattered throughout the country and with necessarily small classes in these special subjects, will attract abler teachers than those now employed by the medical schools? The insistence upon a high proficiency

in the preliminary scientific subjects has always honourably distinguished the London degrees, and this recommendation must inevitably reduce the standard of their teaching.

Intermediate Studies.

We are told that King's College is to be removed to the vicinity of University College in Bloomsbury, and it is hoped to found a University quarter in London round these two favoured seats of learning. As the medical faculty is one of the largest in the University and will certainly be the largest body of residential students, it is reasonable to suppose that the new medical colleges to be established will also be in that area. The supposition becomes stronger when we are told that intermediate teaching will be conducted "in close proximity" to the new colleges—Professor Starling says by the same institutions. Keeping in mind the privileges secured by King's and University Colleges, it is obvious that two of the three new centres must include these colleges. The old scheme of concentration of preliminary and intermediate studies is thus revived in all its nakedness, with the addition that that panacea is to be applied to the clinical teaching as well. I doubt whether the addition will make the scheme any more palatable to the schools left outside than it proved in 1906-7, and the arguments which weighed with Lord Macnaghten's Committee are stronger now even than then. That committee found:

That apart from the money difficulty (that is, the absence of adequate financial support) which, in the opinion of the Committee, is of itself fatal, the scheme has also become impracticable for other reasons. The Medical Faculty, which formerly reported in favour of the scheme, has now reported against it. Several of the medical schools have changed their opinions in the same sense, and some of them had made arrangements involving considerable outlay for providing more efficient instruction in preliminary and intermediate medical studies.—Senate Minute, 1907-1908, No. 553.

Final Studies.

Professor Starling describes the Commissioners as "men whose life business it has been to act or to devise policies after taking the opinion of experts on the different problems involved." How have they done so in the recommendations as to the final studies? They consulted a very large number of representatives from the medical schools, from the Royal Colleges, and from the various educational bodies. They ignored these real experts, and have produced practically in its entirety the fantastic scheme of one, or at most two, witnesses, both with no personal experience of medical education in London; one, the chief and perhaps "the only begetter," Mr. Abraham Flexner, is an American layman who exhibited the most ludicrous ignorance of our English system; the other is a physician who had spent all his active professional life in America. The "Flexner scheme," as it may very properly be called, was indeed condemned most emphatically and specifically by witnesses with actual experience and knowledge of the questions at issue, who really can claim to be experts. Professor Starling attempts to counter this serious opposition by a mere flippancy. "Mediocrity," he says, "is certain to be up in arms at the institution of any system which promises to pick out and place in a superior position the talented, the enthusiast, and the man of genius."

When it is seen by perusing the evidence that men such as Sir A. Gould, Sir H. Morris, Sir B. Dawson, Sir A. Bowlby, Sir Thomas Barlow, Drs. Herringham, Sharkey, Frederick Taylor, Norman Moore, Campbell Thomson, Norton, Fisher, Garrod, and others specifically opposed the Flexner scheme, I think Professor Starling is sufficiently answered.

Let us, however, examine these suggestions more closely. "The most important innovation in the scheme," says Professor Starling, "and the one which promises most for the advancement of medicine in this country, is the recommendation that university professors shall be appointed to deal with the clinical subjects." The clinical demonstration on the German model is, it appears, to be the means of salvation; but the professor and his assistant are also to continue the bedside teaching which is traditional in the English schools, and which is wholly absent from the German model:

No German student (says Dr. Head) has ever handled an individual patient until he has qualified. No student enters

the wards except very occasionally in the company of his professor or his assistants. Each patient he has seen has been brought out for examination to an auditorium. (Fifth Report, p. 141.)

The change in our present system is considered necessary because our teachers are said to be unable to give the time required for the elaborate staging and accessories of the German theatrical demonstration. How, it may be asked in turn, are the professor and assistants to find time for the much more exacting bedside teaching, absorbed as they will be by the glorified public demonstrations, and the researches which are their *raison d'être*. We are told that the professor will be limited in his private practice, and so will devote more time than it is presumed the present clinical teacher does. It is obvious that it will be about as possible to limit the professor's private practice as it would be to limit his hours of sleep or the amount which he eats at his meals. I have personal acquaintance with several German professors. They have one and all been men with large practices, a circumstance which, indeed, was rendered inevitable by the prestige and reputation conferred by their appointment. An entirely erroneous opinion, which has been demonstrated by many witnesses to be erroneous, seems to be held by the Commission, that present day teachers give the briefest possible time to their duties. I had the good fortune to be clinical clerk for nine months to that incomparable teacher, the late Dr. Howship Dickinson, who used to spend from three to four hours every day of the week in his wards.

Professor Starling says:

The complete lack in London of teaching of university rank in the professional subjects of the medical curriculum was brought clearly before the Commission by Flexner.

Most persons will accord more authority to the opinion of the great universities of Oxford and Cambridge as to what constitutes teaching of university rank even than to the opinion of the omniscient Flexner; and these universities have been willing for many years to give the imprimatur of their degrees to men whose tuition in these subjects has been wholly given in the London schools of medicine.

We are told by Mr. Flexner, who gets his usual echo from the Commission, that the professor is to use his hospital ward as the chemist uses his laboratory. Those who are familiar with German hospital methods have sometimes been shocked at what appears to the English-trained man as callous handling of the sick. This new notion of the function of the hospital patient as a sort of experimental reagent is not likely to be favourably received either by the charitable public or by the hospital patient himself.

The Faculty of Medicine.

The worst feature of the scheme is that it creates two kinds of medical school: the privileged college and the school not so privileged. The teachers at the colleges are to form the new Faculty of Medicine on which the schools will be unrepresented. Professor Starling makes as much as he can out of the new "Board of Studies," which is to satisfy the outside schools, but omits to mention that whereas the college teachers, constituting the Faculty, report directly to the Senate, the Board of Studies reports to the Faculty—that is, to a body of rival teachers directly and personally interested in the ultimate extinction of the outside schools. It is said that no compulsion will be exercised on the pupils of the schools to go to the colleges, but when we consider that at the latter institutions the pupils are to be examined by their own teachers, whereas the students at the schools will have to submit themselves, with no guidance from a syllabus as to the scope of the examination, to the collegiate teachers, and will have to compete with collegiate students whose degrees, we are told, will be given rather as certificates of good behaviour during pupilage than upon examination tests; when we further consider that the privileged colleges are to be subventioned from public funds by at least £12,000 per annum for each college in addition to students' fees and Board of Education grants; when we recall that these grants are, as Dr. Headlam, late Principal of King's College, has pointed out, almost certain to be manipulated so as to enforce the findings of the Royal Commission, the conviction is forced

upon us that the survival of the schools against such unfair competition cannot be long maintained, and is not expected to be maintained.

Professor Starling closes his dissertation with this clause, which is no doubt intended to discourage expression of dissent from his own opinion:

Those who oppose these changes (he writes) will have to show that their opposition is really based on a consideration for the welfare of medicine and the medical sciences, and is not directed by a regard for the private interests of themselves or their school.

It is equally pertinent to inquire to what degree the advocacy of those who advocate these changes "is directed by a regard for the private interests of themselves or their school." By both these canons Professor Starling stands condemned as himself the least interested of critics, a fact which cannot but detract from the respect which might otherwise be accorded to any avowal of his views.—I am, etc..

London, W., May 26th.

E. GRAHAM LITTLE.

NoVA et VETERA.

THE FIRST GERMAN BOOK ON SURGERY.

IS an address delivered before the St. Louis Medical History Club, and reprinted in the March number of *Janus*, Dr. Frank J. Lutz gives an interesting account of an old German book on surgery. It is entitled *Das Buch der Buednth-Erztnei* (the book of bandaging).

The author, Heinrich von Pfolzsprundt, flourished about the middle of the fifteenth century. At that time, in Germany as elsewhere, the treatment of all external diseases was in the hands of barber surgeons, who were united in a guild. They learnt their art from a master, and were accepted as apprentices on condition that they were of German parentage and were considered worthy by the freemen of the city. The admission of a pupil was a function accompanied by prescribed ceremonies, which took place before the assembled council of the burghers, and in the presence of the Master. After the apprentice had served his time, and had shown himself "learned in the art," he was made a journeyman. To become a master he had to present his indenture and pass an examination. In proof of his skill he was obliged to produce a "masterpiece." This, according to the regulations for the barber surgeons of Hamburg from 1468 to 1519, consisted in a demonstration of methods of reducing dislocations. Pfolzsprundt was a practitioner of this class; he learnt the elements of minor surgery in the barber's shop, and enlarged his knowledge by study under masters of renown in various parts of Germany and Italy.

His book is said to be the first surgical treatise written in German. It was composed in 1460, being thus older by thirty-seven years than that of Hieronymus Brunschwig. The manuscript of the work was found in 1858 among the effects of a doctor in Silesia, and probably had belonged to the library of the University of Erfurt. Since this was published in 1868 by Haeser and Middeldorf another copy has been found by Haeser in the Royal Library, Dresden, which differs in many particulars from the first manuscript.

Had the book been published at the time it was written, Pfolzsprundt would have been recognized as the first to describe the operation of rhinoplasty, to which the name of Tagliacozzi, who described it 126 years later, has ever since been attached. Pfolzsprundt seems also to have been the first who made special mention of gunshot wounds. His teaching as to some points in abdominal surgery shows that mediæval practitioners were more advanced than we at this time of day are apt to believe. In the thirteenth century the Four Masters had recommended that in transverse wounds of the intestine, especially the large one, the trachea of an animal should be inserted into the lumen of the gut, which was first drawn out with a thread. The intestine was then stitched together over the trachea and brought to the wound in the abdominal wall. It was thought that in time the trachea would be disintegrated and discharged. Pfolzsprundt recommended in such cases freshening the wound by complete division of the intestine and inserting a silver tube, large

enough to allow faecal matter to pass through. Over this tube the cut ends of the bowel were to be tied with green silk thread. Here we have a kind of forerunner of Murphy's button, but we are not told what became of it, or how the vitality of the gut was maintained, after the constriction of its ends by the threads tied over the tube. He says, however, that a patient so treated might survive from forty to fifty years.

Pfolzsprundt seems to have belonged to a noble family which dwelt in the little town of Pfolzpoint, which is still in existence near Eichstaedt in middle Franconia, Bavaria. He was a member of the German Order, and gained considerable surgical experience in the wars against Poland. His book was written for the instruction of barber surgeons. He was an uneducated man and had no knowledge of anatomy, not even of the bones, although he had a large practice in the treatment of fractures and dislocations. He does not quote a single author. But within his sphere he was a sensible, experienced practitioner, and frequently reminds the reader how necessary it is to use common sense in adapting the treatment to the special needs of the patient. He set up a high standard of professional morality, insisting that before the surgeon attended a patient he should hear Mass unless the case were too urgent, when he should recite five Paternosters, five Aves, and the Creed. He warns the surgeon against drunkenness, and urges that he should not eat onions because of the danger to the wound from his contaminated breath, nor indulge in unclean cohabitation before handling a patient. His bandages should be clean, and he should wash his hands before dressing a wound.

The barber surgeon collected and prepared his own plants, keeping his methods of doing so secret. Pfolzsprundt knew how to put "a person to sleep whom you wished to cut or one who is suffering from insomnia" by narcotic inhalations. Opium, hyoseyamus niger, atropa, mandragora, unripe mulberries, hemlock, etc., were dissolved and sponges saturated with the solution. These were afterwards dried in closed vessels in the sun or indoors. Before such a sponge was used it was placed in warm water for an hour and then held before the patient's nose until he fell asleep. After use the sponge was dried for future service. The patient was aroused from this sleep by holding before his nose a wad of charpie containing vinegar, fennel seed, and olive oil.

SCIENCE NOTES.

SOME account has already been given here of certain physiological observations at high altitudes made during the expedition to Pike's Peak under the leadership of Dr. J. S. Haldane of Oxford during the summer of 1911. Miss Mabel P. Fitzgerald has recently reported to the Royal Society observations made during the same expedition on changes in the breathing and blood in persons residing in towns, mining camps, etc., at various altitudes from 5,000 to 14,000 ft. in the Colorado portion of the Rocky Mountains. It was found that the volume of air breathed per unit mass of CO_2 produced by the body was always increased in persons acclimatized at high altitudes. The mean increase of breathing was such as to produce a fall of about 4.2 mm. (or roughly 10 per cent. of the normal for sea level) in the partial pressure of CO_2 in the air normally present in the lung alveoli for every 100 mm. of fall in the barometric pressure. Both men and women showed this fall, after allowance had been made for the normal difference in the alveolar CO_2 pressure of men and women. The percentage of haemoglobin in the blood of acclimatized persons was likewise increased, the mean increase being about 10 per cent. of the normal at sea level in men for every 100 mm. of diminution in the barometric pressure. Both men and women showed this fall. It might take some weeks for the changes to establish themselves fully in persons passing to a high altitude or to disappear in persons passing to sea level. The increased breathing and percentage of haemoglobin seem to be adaptations to the shortage of oxygen consequent on the diminished atmospheric pressure.

In his Bakerian Lecture last week before the Royal Society on positive rays of electricity, Professor Sir J. J. Thomson returned to a subject with which he dealt

earlier in the year, as noted in this column last March (p. 514). The positive rays were observed first by Goldstein in 1886, who named them *canal strahlen* (canal rays), because they are expelled backwards from the kathode through channels cut in the plate. They are deflected by strongly magnetic and electric fields. Sir J. J. Thomson used positive rays emitted through a minute tube, and studied the effect of these deflections by taking photographs of the tracks. The particles in the canal rays consist of charged ions, whose mass and velocity depend on the nature of the gas in the tube, and the main general interest of the Bakerian Lecture lay in the contention, the truth of which seems to be generally admitted, that the use of the positive rays in the manner indicated affords a new method of analysis which, in the skilled hands of its discoverer and his disciples, will render it possible to solve certain chemical problems, or at least to enable them to be attacked from a new direction. Sir J. J. Thomson adheres to the opinion that X_2 , described in the previous note on this subject, is a new element with atomic weight 3, though he discussed certain other possible explanations, one of them being that there was a hitherto unrecognized element with atomic weight 2, and that X_2 was a stable compound of this with hydrogen. He, however, preferred to regard it as a monatomic element of atomic weight 3 comparable with the inert gases, and pointed out that Mendeléef had predicted an element with that atomic weight, although he expected it to possess the properties of a superfluorine, which were very different from those of X_2 . The method of positive rays had also afforded evidence of the existence of another new element of atomic weight 22 occurring in association with neon in the proportion of 5 to 10 per cent.

LITERARY NOTES.

THE June number of the *English Review* will contain an article entitled "Spontaneous Generation" by Dr. H. Charlton Bastian.

Mr. E. V. Lucas, in his book entitled *A Wanderer in London*, when speaking of St. Saviour's, Southwark, says that among the epitaphs is one upon Lockyer, "the Cockle and Holloway, Beecham and Carter of his time—the middle of the seventeenth century":

His Virtues and his Pith are so well known
That Envy can't confine them under Stone.
But they'll survive his dust and not expire
Till all things else at th' Universal Fire.

Yet where, asks Mr. Lucas, are the pills of Lockyer? "Where are the galleons of Spain?" We suggest that not improbably their virtues and their pith are embodied in some newer pill. It were a curious speculation that might have engaged the attention of Sir Thomas Browne to conjecture the metempsychoses which these things undergo.

We have received a copy of the *Irish Book Lover*, a monthly review of Irish literature and bibliography, edited by Dr. John Smith Cronc, of Kensal Green. It contains an account of Mr. James Stephens, described by the *Saturday Review* as "a new power among the writers of Ireland." There is also a note on Dr. Edmund Bailey O'Callaghan, who, after a few years' practice in Quebec, went to Montreal and became editor of a newspaper. He was elected a member of the Legislature, but owing to a disturbance of the political atmosphere he removed to the United States, where he settled in Albany and again for a short time practised medicine. He was appointed custodian of the historical manuscripts in the Secretary of State's Office. That position he held till 1870, when he moved to New York. He died in 1880. He was the author of a number of monographs on historical and bibliographical subjects. We commend the *Irish Book Lover* to the favourable notice of all lovers of books and antiquarian lore. In a small compass it contains a goodly amount of interesting reading.

In Mr. John Fyvie's *Story of the Borgias* (Eveleigh Nash, 1912) there is an amusing account of a doctor of Ferrara in the seventeenth century, and a copy of a diploma given him in 1642 for his skill in medicine. It should be premised that Ferrara, like Padua and Bologna, was cele-

brated for its school of medicine, but some notion of the knowledge required of its graduates may be gathered from the diploma. The document is said to have been discovered by the historian Citadella in the archives of Ferrara, and was seen by Mr. William Gilbert (father of Sir W. S. Gilbert and author of a biography of Lucrezia Borgia which appeared in 1869) engraved on parchment in the library of that city. A certain Generoso Marini, wishing to practise as a legally qualified physician, applied to the judges for a diploma, and duly presented himself for examination. The following is the text of the diploma, which bears the signatures of "Joannes Cajetanus Modoni, Judex sapientum civitatis Ferrari," and "Franciscus Ultramari, Cancellarius."

Having publicly examined and approved the science and knowledge of medicine of Signor Generoso Marini, and his possession of the wonderful secret called *orvietano*, which he exhibited on the stage built in the centre of the Piazza of this our city of Ferrara, in presence of its entire population (so remarkable for their civilization and learning) and in presence of many foreigners and other classes of people, we hereby certify that, in our presence also as well as that of the city authorities, he took several living toads, not those of his own providing, which might have given suspicion of deception on his part, but from a great number of toads, which had been caught in fields of the locality by persons who were strangers to him, and which were handed to him at the moment of making the experiment. An officer of the court then selected from the number of toads collected five of the largest, which the said Generoso Marini placed on a bench before him, and, in presence of all the assembled spectators, he cut all the said toads in half with a large knife. Then, taking a drinking cup, he took in each hand one half of a dead toad and squeezed from it all the fluids and juices it contained into the cup; and the same he did with the remainder. After mixing the contents together he swallowed the whole; and then, placing the cup on the bench, he advanced to the edge of the stage, where for some minutes he remained stationary. Then he became pale as death, and his limbs trembled, and his body began to swell in a frightful manner, and all the spectators began to believe that he would never recover from the poison he had swallowed, and that his death was certain. Suddenly, taking from a jar by his side some of his celebrated *orvietano*, he placed a portion of it in his mouth and swallowed it. Instantly the effect of this wonderful medicine was to make him vomit the poison he had taken; and he stood before the spectators in the full enjoyment of his health. The populace applauded him highly for the indisputable proof he had given of his great talent. And he then invited many of the most learned of those present to accompany him to his house, and he there showed them his dispensary, as well as his collection of many antidotes, and among them a powder made from little vipers, a powerful remedy in curing every sort of fever, as he proved by different experiments he made on people of quality and virtue, all of whom he cured of the fevers under which they were suffering. He also exhibited a wonderful balsam he had invented, which cured with great rapidity all bruises and wounds, as well as burns and scalds of every description. The said Generoso Marini has also great skill in drawing teeth, in which he exhibited an extraordinary dexterity. But that which most distinguished him was his wonderful power in restoring many persons to health who were suffering from divers incurable diseases. In consequence of the rare talent exhibited by Signor Generoso Marini, and as a proof of our love and respect for his wisdom, we have resolved by the authority placed in our hands publicly to reward him with our diploma, so that he may be universally recognized, applauded, and respected. In witness whereof we here set our hands and the public seal of the municipality of Ferrara.

Well might Molière's quick say: *O grande puissance de l'orvietan!*

The *Journal of the American Medical Association* has recently taken occasion to call attention to a misunderstanding of the word "cure" as used by German, Italian, and, we may add, by the older physicians who wrote in Latin. The trap lies in the word *kur* or *cura*, which does not mean restoration to health, but care or treatment. An Italian writer is quoted as having said that he had cured ten typhoid patients within a given period and six of them died. What he meant to say, of course, was that he had treated ten cases. In the same way, when we read that some distinguished person has gone to Ems or Marienbad for a *Kur*, what is intended to be conveyed is that he has gone to the health resort to go through a course of treatment there. When Hahnemann enunciated his famous, but by no means original, principle, *Similia similibus curentur*, he meant that like things should be treated by like. The aphorism was for a long time almost universally cited *Similia similibus curantur*, and translated Like is cured by like—a very different thing.

THE NEW BUILDINGS OF GUY'S HOSPITAL MEDICAL SCHOOL.

As a preliminary to the formal opening by Mr. A. J. Balfour next week of the new buildings of Guy's Hospital Medical School, a number of representatives of the medical and lay press were shown over the buildings on May 27th. The opportunity was taken of indicating the important part played by medical schools attached to hospitals in the advancement of research and every department of medical science, and the hope was expressed that wealthy benefactors would come to the aid of medical schools in London—and that attached to Guy's in particular—in the way that is frequently the case in the big towns of the country.

After ten years' uninterrupted labour the work of rebuilding the medical school of Guy's Hospital has been completed at a cost of over £100,000. Of this sum no less than £77,000 had been found by the generosity of the governors and other friends of the school, while the members of the staff, in order that the ever-increasing cost of maintenance may be met, have voluntarily resigned

a great part of the income formerly paid to them from students' fees. What is needed is that the outstanding debt of £23,000 upon the building should be paid, and that an endowment of £200,000 should be raised for the establishment of lectureships and research fellowships.

The new buildings are divided into three main blocks. In addition, the old Department of Anatomy has been rebuilt and an extension added for the teaching of operative surgery. The old biological laboratory has been refitted throughout. In the main block there is to the left of the spacious entrance hall, containing busts of famous men associated with Guy's, a students' laboratory for physiological chemistry, and a large lecture theatre with accommodation for 400. To the right are the research laboratories of the demonstrators, and in the basement numerous store-rooms and class-rooms, and a room fitted with x-ray apparatus.

On the ground floor is the Wills Library, and a small museum of Guy's antiquities. The Gordon Museum is beyond this, and is of considerable extent, being divided into four bays or apartments by a central staircase. The shelves afford accommodation for nearly 10,000 specimens, and here are housed also the famous collection of wax models made by the late Mr. Towne. Adjoining the museum are a large lecture theatre, fitted with an epidiascope, the curator's room, and other small rooms and laboratories.

On the first floor are the students' histological laboratory, the research laboratories of the lecturer in physiology, the offices of the medical school, and the committee-room of the staff. The second floor accommodates the department of physics, and comprises a large students' laboratory, a dark room for the study of optics, class-rooms, private laboratories, and a large lecture theatre. The third floor

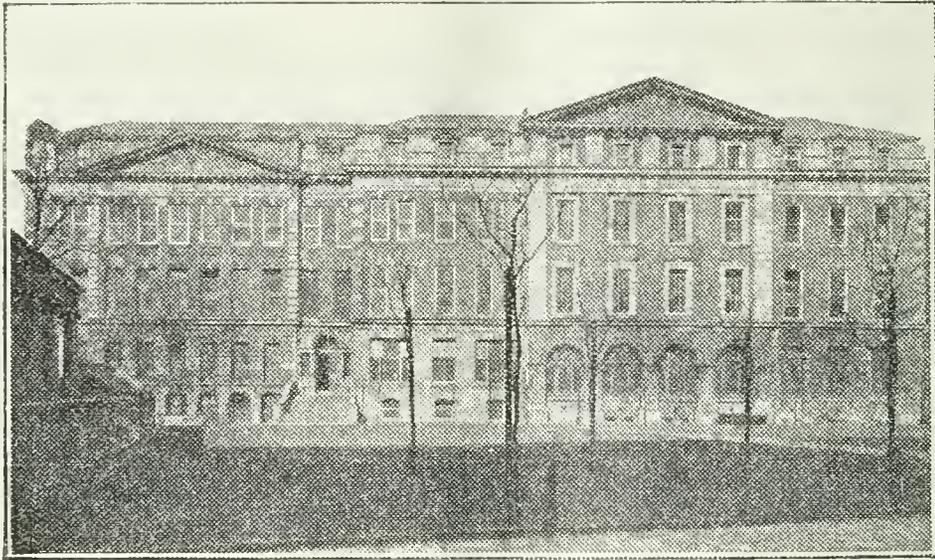

contains the students' chemical laboratory, with a balance-room and a research laboratory for the demonstrators. There is a smaller laboratory for chemical work of the department of public health.

The new Dental Block occupies buildings three stories high surrounding a central courtyard. Waiting rooms, offices, and a laboratory for probationary work occupy the ground floor. On the first floor are the students' and pupils' mechanical laboratories; the latter has accommodation for a hundred pupils. The metallurgical laboratory, in which the appliances are operated by electric power, are also on this floor. The conservation room extends over the whole of the second floor, and contains eighty pump chairs of the most modern type.

The third of the new blocks provides accommodation for the department of pathology in a building five stories high. Here are lecture theatres, laboratories for the teaching of morbid histology and bacteriology, pharmacological laboratories, private research laboratories, and accommodation for experimental work in pathology. No part of this building is used for the routine pathological work of the hospital, but the whole is devoted to teaching and research, the routine work being carried on by other

workers in separate laboratories at the expense of the hospital. A sum of £2,000 has been devoted to the equipment of this department, which was erected at the expense of an anonymous donor, and presented to the school this year, free of charge.

A comprehensive view of

The Main Block of New Medical School Buildings.

this great building scheme, obtained from the roof of one of the new blocks, gave some insight into the courage of the staff of the Medical School in embarking upon and bringing to completion so large a scheme for the advancement of medical education. It is to be hoped that their efforts will meet with the support and encouragement they deserve.

DR. WILSON, who perished with Captain Scott on the return journey from the South Pole, left estate valued at £965.

PROFESSOR RINA MONTI has been appointed, by a unanimous vote of the teaching staff, director of the School of Pharmacy in connexion with the University of Sassari.

THE Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India, No. 57, 58, and 59, deal with the anatomy of the mouth parts of biting flies, and with the flagellate parasites of different genera found in insects. Captain Patton's paper on the latter subject is entitled "Studies on the Flagellates of the Genera *Herpetomonas*, *Critidia*, and *Rhynchomonas*." Captain Cragg contributes the papers on the mouth parts of the biting flies. His first paper (No. 58) deals with studies on the mouth parts and sucking apparatus of the blood-sucking diptera (*Orthorhapha*). His second (No. 59) is on *Lyperosia minuta* (Bezzi). These papers are very interesting but, of course, somewhat technical. Those interested in the subjects can consult the originals in the library of the British Medical Association.

British Medical Journal.

SATURDAY, MAY 31st, 1913.

RECENT PHARMACOLOGICAL RESEARCH.

THE Annual Oration delivered before the Medical Society of London by Sir William Whitla, and dealing with the trend of thought in recent pharmacological research, is printed in full upon another page. It summarizes the present position and future prospects of pharmacology with all the charm and skill that we have learnt to expect from that able orator its author. To a pharmacologist the Oration is delightful, because it proves a willingness on the part of an eminent physician to go at least half-way to meet him. Eminent physicians there are in plenty who hold and act upon the negative and chilly view that only a few drugs, and those mostly old favourites, are worth using, and who are apt to exhibit sodium bicarbonate in small doses when called upon to prescribe for the majority of the ills they have to treat. To a chemist, also, the Oration is not less delightful, for in it he finds the science of chemistry, organic and synthetic, once more exalted to the position to which he fondly believes it entitled, while due credit is given to the pioneers who have led the way in this most complex of sciences, and the sympathy they deserve is measured out to their errors.

As Sir William Whitla points out, it is to the synthetic chemists on the one hand, and to the investigators of vaccine-therapy and opo-therapy on the other, that pharmacology owes its rapid progress during recent years. It may be said, perhaps, that these two groups of workers attack its problems from their opposite ends. It is the function of the opo-therapist to find out what is the effect of any given animal extract upon the body, and to prepare it in a state of the greatest purity. It is the business of the organic chemist to analyse this purified extract, to learn its structural formula by breaking it down into simpler organic compounds of known composition, and then to prove the correctness of his work by the synthesis of the active principle of the extract he set out to investigate. The first of these organic syntheses to be performed, one that is familiar to every medical student who takes up the study of organic chemistry, was made by Wöhler in 1828, when he formed urea synthetically by warming a solution of ammonium cyanate in water. As a single quite recent example of the progress in pharmacology that has been made possible by the co-operation of the opo-therapist and the organic chemist, may be quoted adrenalin. Its physiological and pharmacological properties have been long known to us, and it is a drug that is in daily use. As the result of elaborate researches, the organic chemist has been able to show that its structural formula is—

corresponding to its chemical name, pyrocatechin-ethanolmethylamino. As the result of an immense

amount of experimental work on its congeners and derivatives, it is now possible to refer its physiological activity to certain of the atomic groups that it contains, and to their relation to other of its atomic groups. The greater part of its activity is due to the presence of an amino group (—NH_2 , or rather —NHCH_3) separated from a benzene nucleus by another group ($\text{—CHOH.CH}_2\text{—}$); this activity is increased by the two hydroxyl groups (—OH) in the ortho-position to one another in the benzene nucleus, and is still further increased by the third hydroxyl group in the chain connecting together the benzene ring and the amino group.

Complex formulae and statements such as those just given must seem highly speculative or frankly incredible to many, particularly to those who are unfamiliar with the steady progress in experimental pharmacology and the vast amount of work that has been done in it during the last twenty years, or, to put back the date to the starting-point mentioned by Sir William Whitla, since the researches of Crum Brown and Fraser on methyl-strychnine were published in 1868. But it is impossible for any one who is acquainted with the data furnished by the organic chemist and the experimental pharmacologist, and who is in a position to trace the development of the ideas or theories that underlie their work, to doubt either that such formulae and inferences are true or that the work is being carried out along the correct lines. New drugs with properties foreseen and calculated are being put on the market daily; and if the calculations do not always come true—it would be idle to pretend that they do—if unforeseen secondary actions of the new drug may vitiate the required result, the fact merely illustrates the limits of chemical knowledge, and has often proved to be of service in the long run by stimulating further research.

Sir William Whitla, as we have said, has earned the gratitude of organic chemists and pharmacologists by showing how much the world owes to their tested synthetic drugs. In the latter part of his Oration he expounds the influence that Ehrlich's side-chain theory has exercised in the development of our views on the constitution of living matter and its *modus vivendi*, and he discusses the bogey, as he calls it, of catalysis and cell enzymes. Here we find ourselves face to face with questions as complex as any one can be called upon to answer; as Sir William shows, they must be left in suspension until the time when our knowledge is far more complete than it is at present. He draws particular attention to the all-pervading influence of the force known as chemiotaxis in the mechanical operations of the living cell, and points out how closely living nature can be imitated by solids and liquids of carefully adjusted surface tensions left to the influence of the osmotic forces that play between their surfaces. As to the future of therapeutics, that may safely be left to the future itself, so long as the science continues to follow the guiding lines upon which it now travels.

THE NEW DIPHTHERIA ANTITOXIN.

MUCH interest has been created in Germany recently by Professor von Behring's announcements with regard to the bacterial emulsion which he has devised with the object of producing immunity to diphtheria lasting for several months. More than one injection is necessary, and the active protecting bodies are produced in from three to five weeks after inoculation. Von Behring has himself published recently the results of some new investigations

relative to the toxicity and immunizing power of this prophylactic vaccine.¹ As has already been stated, the product is an emulsion of virulent diphtheria toxin with antitoxin in such proportions that the mixture is innocuous to the guinea-pig.

It had always been supposed—for toxin-antitoxin combinations are no new departure—that if the guinea-pig could withstand the injection of a mixture in a fixed proportion, other animals, including man, would likewise prove resistant. This, however, proves not to be the case. Behring has found that mixtures non-toxic for guinea-pigs may, in the monkey and the ass, produce marked febrile reaction with the formation of antitoxin in large quantities. The reaction in man is less violent, but varies considerably with age. In children between 4 and 5 it is far more marked than in newborn infants. Of great practical importance also is the fact that so-called "carriers" and individuals whose blood reaction, as expressed in units of antitoxin, proves them to have been carriers of bacilli at some period of their lives, have been found to be hypersensitive to the mixture and very readily produce large quantities of antitoxin after injection. One such case is reported from Marburg, in which $\frac{1}{16}$ c.cm. of the injection produced 600,000 antitoxin units, where 250 units would have sufficed to ensure immunity. The case is very noteworthy, for a second child was for the first time passively immunized from it—that is to say, it was immunized with an anthropogeneous or homogeneous, as opposed to a heterogeneous serum, and it was found that the immunity thus obtained was of far longer duration than can be obtained with the horse serum antitoxin now in common use. The great importance of such a discovery scarcely needs emphasis, for not only has the immune period been prolonged, but the well-known side-effects of heterogenetic serums have been eliminated.

Behring states that he is ready to place his antitoxin in the hands of clinicians for the purposes of research to ascertain the ideal dosage—that is, one in which there is a minimal local and febrile reaction with a maximum of antitoxin production. The experimenters must also undertake to place on record the antitoxin content of the blood both before and after inoculation, and are requested to employ it especially in persons exposed to infection, and for the inmates of asylums, orphanages, and prisons who remain under observation for considerable periods of time, and among whom the disease is often endemic. He recommends inoculation (1) among diphtheria-carriers to determine the destruction of nasopharyngeal bacilli as rapidly as possible; (2) to produce a prolonged immunity; and (3) for the manufacture from highly immunized subjects of an anthropogeneous serum, both for passive immunization purposes, and for the cure of the actual disease.

Professor Schreiber, who controls the Magdeburg Krankenhaus, published his own results, which supported this pronouncement, in the following number of the same journal. He states that the remedy is absolutely harmless and fully capable of producing immunity.

The time has been too short as yet to establish definitely that subjects inoculated do not take the disease, but a communication from the surgical side of his institution has reached Behring to the effect that no inoculated children had been infected to date, or could be proved to be carriers, although an epidemic of the disease was raging in the wards at the time.

In the last number of the *Wochenschrift* further observations are chronicled. Professor Zange-meister, Obstetric Physician at the Magdeburg Hospital, states that according to Prussian statistics the total infantile mortality from diphtheria is 0.58 per cent., so that it is important to establish immunity as rapidly as possible after birth. For this reason newly-born infants have been inoculated with the antitoxin—in some cases the pregnant mothers only, with a view to minimizing possible ill effects at a critical age. Blood determinations were not made in these cases for obvious reasons, but it will be interesting to follow the history of these protected children in ensuing years. We may rest assured, however, that inoculation of infants is not only possible but advisable, because, as already stated, the reactions in them are less violent than at later ages, and are constant.

Behring's assistant, Dr. Viereck, in the same journal, describes a method for the practical determination of the antitoxin content of the blood, and maintains that if a prolonged period of immunity be desired a comparatively energetic reaction to inoculation should be aimed at in order that a large amount of antitoxin may be produced. By this he means a pronounced local infiltration at the site of injection, which may, but need not, be accompanied by fever. Without such a local reaction, he states, there is probably an inadequate production of antitoxin. Behring is convinced that, just as the dose for guinea-pigs can be accurately gauged, that for the higher animals and man is also constant, provided that the special factors above indicated do not exist in the individual to be inoculated. The adult is about 100 times more susceptible than the infant, and Behring is of opinion that this hypersusceptibility rests solely on a preceding infection in the case of the former, an infection which but few escape, and which may have run its course without producing any of the classical symptoms of the disease.

TEMPORARY ABSENTEES.

THE Memorandums issued by the Insurance Commissioners in England with regard to the provision of medical benefit to temporary residents have caused a great deal of dissatisfaction and not a little perplexity.

As to the perplexity, its first source is that the Commissioners should have issued Memorandum 161 on Thursday and Memorandum 159 on Friday, for 159 is only 161 printed in different type on larger paper with some additional paragraphs, yet, if the numbering means anything, the longer memorandum in larger type must have been in existence before the shorter was extracted from it. It looks rather like waste of insurance funds; but the more important matter is that, after reading 161 and 159, or 159 and 161, according as the student prefers the chronological or the numerical order, he is still left in some perplexity, some doubt as to what after all the Commissioners in fact mean.

The calculations are based on the sum of 9s. a year available for medical attendance and drugs (medical attendance, 6s. 6d.; tuberculosis, 6d.; drugs, 1s. 6d.; drug suspense fund, 6d.) in respect of every insured person, and on the assumption that one-third of the insured persons fall ill during the course of a year. In that case the average rate of remuneration for each person attended will be 9s. multiplied by 3, or 27s. for both medical attendance and drugs. This sum of 27s. is called the "case

¹ *Deut. med. Woch.*, *Mar.* 8th. See also the issues of May 15th and 22nd.

value." It is a quite hypothetical value, and the Scottish Commissioners estimate it at one-third less, 18s., and it may very well turn out that even this is too high. But, taking the English Commissioners' 27s. a head a year as the "case value," we are then told that "the proposal is therefore to look to the cases of 'temporary residents' who actually require treatment, and to the circumstances of the Committee areas whence they respectively come, and to transfer from each Committee's funds to the Central Fund in respect of each temporary resident receiving treatment a sum calculated on the principle illustrated above by reference to the actual degree of sickness in the area of his usual residence. In this way no Committee will suffer a reduction of their funds by way of transfer at a higher rate than the actual rate of remuneration in their area."

These involved sentences have given rise to many difficulties of interpretation, and the failure to state the position clearly has caused the suspicion to arise in some quarters that the paragraph was deliberately intended to be obscure. We are far from accepting this suspicion, and believe that even without Sam Weller's pair o' patent double million magnifyin' gas microscopes of hextra power it can be perceived to be capable of only one meaning, and that it is the same as that expressed in the clear and precise paragraphs of the Scottish Commissioners, who have also issued a Memorandum 159/L.C. The draftsman of the Scottish Memorandum not only had a command of the English language denied to his southron colleague, but was endowed with sufficient imagination to foresee the difficulties of the reader and the frankness to forestall them. As already noted, the Scottish Commissioners base their calculations on the assumption that the number of cases of illness per annum will be "equal to half the total number of insured persons," so that "the average rate of remuneration in respect of each case of illness will be 9s. multiplied by two, or 18s., and this will be the 'case value' rate for that area." What the Scottish draftsman says is this: "The proposal is, therefore, to look to the cases of illness among 'temporary residents' which actually require treatment, and to the circumstances of the Committee areas from which the temporary residents respectively come, and to transfer from each Committee's funds to the Central Fund in respect of each case of illness of a temporary resident so receiving treatment a sum calculated in the manner indicated above by reference to the 'case value' rate in the area of his usual residence. Thus the contribution by an Insurance Committee whose 'case value' is 18s., and which has 20 insured persons treated outside its own area, will be £18."

The Scottish Commissioners again show their political wisdom by frankly admitting that for the current year the scheme "can only be adopted in so far as the doctors and chemists under the Act give their consent. The scheme is not included in the agreements signed by the doctors and chemists." The English Commissioners did not state this fact. They left the doctors to find it out for themselves. It was, of course, very soon found out, but the want of frankness in failing to state it has contributed to increase the irritation which the proposed deduction from the minimum remuneration promised has produced.

The plan would work out in practice as follows: If an insured person proposed to go away for three or four weeks for a holiday or to convalesce, he would apply to the Insurance Committee of the area in which his home is for a green voucher.

If he got through his three or four weeks at the seaside or health resort without needing medical attendance the matter would end there; he would tear up his green voucher and return rejoicing to his home. If, on the other hand, he found himself in need of medical treatment when at, say, a seaside resort, he would hand his green voucher to the doctor of his choice, who would retain it and enter upon it particulars of the services rendered. When the temporary resident returned home the seaside doctor would send the voucher to the Insurance Committee of his own district. The voucher would be examined by the Local Medical Committee. When this and all similar vouchers had passed that ordeal the Insurance Committee of the seaside district would notify the Insurance Commissioners the total amount of the local claim on the Central Fund, the claims being assessed according to the tariff appended to the Memorandums.¹

The Insurance Commissioners would then have two duties—first, to fill the pool (the Central Fund), and, secondly, to empty it. To fill the pool they would ascertain the case value of each insurance district which had during the year supplied temporary residents to other districts. This sum multiplied by the number of temporary absentees would yield an amount with which the Local Insurance Committee of the inland town would be debited. The total of all these sums so debited would form the central fund or pool. This total would be compared with the total amount of the several claims upon it from all the districts which had received green vouchers. If the two sums should exactly correspond, the local seaside insurance committees would be credited with the full amount of their claims, and the doctors would be paid in full according to the tariff. If the total amount in the pool fell short of the total claims upon it the Commissioners would declare a dividend; for instance, if the total claims on the green vouchers amounted to £10,000 and the total payments into the pool in respect of the case values amounted to £9,000, the seaside doctors would receive nine-tenths of the amount of their claims according to the tariff. If, on the other hand, the total of the claims remaining the same, the central pool amounted to £11,000, the seaside doctors would receive eleven-tenths of their claims. The scheme, it will be seen, does not attempt to deal with the insured persons as individuals, but in the bulk, nor does it attempt to deal with each area separately, but again in the bulk, deficiencies in one district being set against excess in others, on a principle well recognized in all insurance business.

Under the English scheme, if a temporary resident in a seaside resort continued ill after a period of three months from the beginning of his temporary residence, he would then be transferred to the Insurance Committee of the seaside town as a permanent resident, and the coast doctor from that time would be paid not by fees for attendance, but at the ordinary capitation rate (7s. per annum). In Scotland the period is six weeks, not three months, but it counts not from the beginning of temporary residence, but from the beginning of medical attendance whilst at the seaside town.

The term "seaside town" is used for convenience, but, of course, the doctors in every insurance area, seaside or inland, rural or urban, would be paid on the same attendance basis for any temporary residents within their bounds, so that there might, or perhaps would, be in most cases both income and

¹ SUPPLEMENT TO BRITISH MEDICAL JOURNAL, April 19th, p. 335.

outgo, the balance no doubt being in favour of the seaside and rural areas.

The Scottish Commissioners state that "the new system is put forward by the Commissioners because it is equitable as between town doctors and chemists on the one hand, and doctors and chemists in holiday and health resorts on the other," but there are, in fact, two questions of equity involved. The first is whether it is equitable to make any deduction, and the second, granting that a deduction should be made, whether the amount and method of deduction and the method proposed for the distribution of the fund so formed are equitable. With regard to the second point, we are disposed to agree with those members of the Association who have expressed the opinion that if the justice of making any deduction be acknowledged, the method proposed for forming and distributing the central fund is worthy of trial upon the understanding that should experience show it to operate inequitably it will be amended.

The equity of making any deduction at all from local insurance funds for this purpose is another matter. The doctors who have accepted service under the Insurance Act have undertaken to give medical attendance and treatment throughout the year or the whole period for which their contracts run; they are bound to give personal service or to provide a sufficient substitute; they never know when they may be called upon; and their establishment charges must be based upon a full year. Moreover, there is the distinct undertaking on the other side—that is, on the part of the Government—that the rate of 7s. for each insured person on the list would not be diminished. The central fund for temporary absentees is to be formed by making deductions from this minimum amount, or, rather, from the minimum 9s. including drugs and appliances. It is no answer to say, as is said, that the doctor is relieved of the responsibility for giving medical attention to the temporary absentee during the period of his absence. The doctor has entered into a contract to give his attention and must make his arrangements accordingly. If by a voluntary act one party absents himself for a certain period to suit his own convenience, the voluntary absentee may equitably be called upon to take the consequences, and the State Sickness Insurance Committee has, therefore, expressed the opinion that the Regulations should be so amended as to provide that medical benefit shall not be understood to include medical attendance and treatment on insured persons who temporarily change their residence for holiday or health purposes.

DR. ROBERTS THOMSON.

LAST week Dr. Roberts Thomson, who is well known to members of the British Medical Association by the great services he rendered to it when President in 1891 and Chairman of its Council from 1899 to 1902, was presented with the honorary freedom of Bournemouth. The honour was the greater, inasmuch as there had previously been chosen only four honorary freemen, of whom the first was Earl Roberts. The resolution of the town council conferring the freedom stated that it was given as the highest mark of esteem within its disposal in recognition of the eminent services rendered by Dr. Roberts Thomson to the borough, and of the splendid example of self-sacrificing citizenship which he had displayed during the whole period of his residence in Bournemouth. The resolution continued as follows: "The council acknowledge with gratitude the prominent and leading part he has taken in the founding, promotion, support, and administration of

the local hospitals, whose beneficent mission has been largely helped by his munificent contributions, personal service, and judicious counsel; his services in connexion with various phases of educational work, and particularly as the chairman of the governors of Bournemouth School; his able and impartial conduct as a justice of the peace for the county borough of Bournemouth and for the county of Southampton; his successive services as county councillor and county alderman; and the loyalty, patriotism, and military enthusiasm which he displayed as an officer of Volunteers, rising by successive steps to the command of the 4th Volunteer Battalion, and now honorary colonel of the 7th Battalion of the Hampshire Regiment. Such a record of citizenship, supplemented as it has been by private munificence of catholic and unstinted character, constitutes a unique and honourable record which entitles him to the sincere and lasting respect of every burgess, and justifies the highest form of official recognition." In speaking to this resolution, Alderman Mate referred in particular to Dr. Roberts Thomson's services to the cause of education in Bournemouth, Alderman Beale to his work in connexion with hospitals, and Alderman Robson to his military services. The presentation, made by the Mayor, consisted of the text of the resolution enclosed in a massive silver casket adorned with an enamelled miniature of the recipient, with the arms of the town, a trophy of the King's colours, and the regimental colours of the 7th Hants, and with views of the Victoria Hospital and the Bournemouth School. Dr. Roberts Thomson, in acknowledging the presentation and election, said that during his life at Bournemouth, extending now to nearly forty-seven years, he had seen enormous progress and had from the first recognized that the responsibility of the medical profession was serious in amount and would be far-reaching in its results. In his work for education he had been inspired by the thought that the community was engaged in a warfare against waste—waste in physical life through sickness and disease and waste in mental life, for of all causes of waste ignorance was the most prolific. After mentioning the growth of the Bournemouth School, he referred to the approaching opening of the Municipal College, and expressed his belief that the wisdom of this development of art and technical work would be fully justified. In conclusion, he thanked the Council for associating Mrs. Thomson's name with his own.

ENDEMIC FEBRILE OUTBREAKS IN INDUSTRIAL SCHOOLS.

A REPORT by Dr. McGowan and Dr. McNeil issued recently by the Scottish office deals with a problem which has perplexed the authorities in charge of industrial and reformatory schools for a good many years. In certain of these institutions mysterious outbreaks of febrile illness have occurred from time to time. An alarming and malignant character has been given to these outbreaks by the occurrence of fatal cases in which death took place within a few hours of the onset of symptoms; and in not a few instances boys going to bed in apparently perfect health have been found dead in bed in the morning. These fatal cases, however, form only a small proportion of the total cases of illnesses which, though differing in severity, belong, it seems fairly certain, to the same group. The new report is not by any means the first published account of these institutional illnesses. From 1836 onwards, descriptions of these outbreaks have appeared from time to time in medical journals, and in 1897 a Blue Book was published giving the results of Dr. Sidney Coupland's investigations into similar cases at two Lancashire schools. Drs. McGowan and McNeil now trace in full the history of an industrial school at Traicent, near Edinburgh, which has been marked by particularly virulent and extended outbreaks of this character; and at the same time they have been at pains to collect all the

available records from other schools of this kind. From this point of view alone the report is of value, as it collects and brings under review all known data and facts concerning these illnesses. The authors divide the illnesses into three clinical groups: Cases of acutely fatal illness, of pneumonia, and of febricula, a term used by Complaind in his report. From the *post-mortem* and clinical evidence obtained, the definite conclusion is drawn that all the cases are examples of pneumonia, but of pneumonia in a "distorted" form. Two groups are formed: the first of fulminant, and the second of irregular, pneumonia. The cases in the second group are examples of latent or abortive pneumonia. Like previous observers, they find no evidence of contagion; and they also record the striking fact that these illnesses are confined to the boys, the resident staff being completely exempt. They make the further hypothesis that these forms of atypical pneumonia, endemic in certain industrial schools, owe their irregular character to the pre-existence in the boys of a morbid diathesis, which in the fatal cases resembles that of status lymphaticus. This hypothesis is founded on the record of enlargement of the thymus and hyperplasia of other lymphoid tissues in a significant number of the necropsies made at Tranent. The report gives a full account of the sanitary and general environment of the boys, and the conclusions are controlled by similar observations at a neighbouring industrial school which is free from illnesses of this character. The authors show great reserve in expressing any opinion as to unhealthy conditions that might explain the prevalence of this peculiar form of pneumonia. The school at Tranent actually shows a superior record as regards zymotic and tuberculous disease over the control school: and no gross departure from the usual hygienic and sanitary standards could be discovered. But in some respects the environment was found unsatisfactory—in the inadequate clothing of the boys and the insufficient heating of the dormitories in winter, and in insufficient allowance of air space in the dormitories and recreation rooms. The hypothesis as to status lymphaticus is interesting, but further observations will be required before it can be regarded as established. If it should prove correct, it may very well lead to some extension of knowledge of this obscure condition. If it is to be held as accounting for the severity of outbreaks of this nature in industrial schools, it would seem that it must be present there in endemic form, and predispose to the occurrence of peculiar types of pneumonia, some of them fulminant and rapidly fatal.

THE LONDON INSURANCE COMMITTEE AND ITS FUNDS.

It will be noted at the last meeting of the London Insurance Committee it was proposed that the money due to the medical profession in respect of the 400,000 insured persons in London who have not chosen a doctor should be distributed among the doctors on the panel, and a discussion took place as to the most equitable method of distribution. The Chairman of the Committee moved a resolution in favour of the money (£34,000) being distributed in proportion to the number of accepted persons on each doctor's list, but Mr. Rockliff took exception to the legality of this, and on the Chairman justifying it by Circular 10 I.C. of February 18th, Mr. Rockliff expressed the opinion that the distribution could not be allowed to take place on the strength merely of a circular of the Commissioners. On this the Chairman withdrew the motion, and the whole matter is to be considered by a special meeting, doubtless after consultation with the Commissioners. The legal aspect of the case would appear to be that, according to Section 15 (2) (d) of the Act, every Insurance Committee must adopt a system which will secure that the insured persons who, after due notice, have failed to make any selection,

or who have been refused by the practitioner whom they have selected, shall be distributed amongst the several practitioners whose names are on the list. That is to say that all insured persons in the area, and therefore all the money payable on their account, must be distributed amongst the doctors on the list. Many Insurance Committees have already distributed or arranged to distribute the money in hand in respect of persons who have not selected a doctor, instead of acting in strict accordance with the provisions of the Act and distributing the patients in respect of whom the money has accumulated. It seems so obvious that no method of distribution of patients by any Committee can be as satisfactory as the selection of doctors by the patients themselves that we should have thought that any method which would delay the distribution of insured persons amongst the doctors, and would give them further time to make their selection, would be welcomed by representatives of such persons on Insurance Committees. There can be no doubt that the money belongs to the doctors already on the panel. The only way in which any capitation fee can be made to pay doctors for contract medical work is by the fees from all the insured persons being paid to them, and not merely those from the persons who, because they were ill, or because they thought they were likely to be ill, took the precaution of choosing a doctor. This seems so elementary that we trust there will be no undue delay in distributing this money.

THE DECLINING BIRTH-RATE.

BAGEHOT tells the story of an indifferent public speaker who, when at a loss what to say next, was accustomed to begin, "Mr. Gladstone, gentlemen"—whereupon his voice was drowned in cheers, and he had time to collect his thoughts. It is possible that some proportion of the pamphlets, speeches, and books dealing with the declining birth-rate and "race suicide" owe their origin to similar considerations, and it is at least certain that they are of very unequal merit. In the production of this literature Germany takes a leading place; three treatises of some size by Drs. Wolf, Borntraeger, and Marcuse¹ have recently appeared, and we have lately received a pamphlet by Dr. Hermann Rohleder of Leipzig on the same topic.² Dr. Rohleder is of opinion that a declining birth-rate is a necessary consequence of increasing civilization, and that those who are of a different opinion are merely displaying their incomplete scientific culture. He energetically combats Wolf's theory that the birth-rate tends to vary with the prevalence of certain religious beliefs, and pours scorn upon the measures suggested by Borntraeger—some of which do indeed appear to argue a degree of confidence in the powers of a bureaucracy which could hardly exist outside of Germany—to arrest the decline. Rohleder contends with some show of truth that race suicide is not a pressing question so long as a population even with a declining birth-rate continues to increase; but he is on more doubtful ground when he argues that declining fertility necessarily must imply superior quality of the offspring, since the larger the family the less adequate the provision which can be made by the parents for their children. This is, indeed, the crux of the problem. Given a fixed income anywhere near the poverty line, it is obvious that a parent can provide better housing, nourishment, and education for two children than for five. Do the environmental advantages which thus accrue to the diminished numbers of the offspring outweigh the disadvantages of a slackening of the intensity of natural selection operating upon a large number of children, some of whom must be

¹ Wolf, J., *Der Geburtenrückgang—Die Rationalisierung des Sexuallebens in unserer Zeit*, Jena, 1912. Borntraeger, J., *Der Geburtenrückgang in Deutschland, seine Beurteilung und Bekämpfung*, Berlin, 1912. Marcuse, J., *Die Beschränkung der Geburtenzahl ein Kulturproblem*, München, 1913.

² Rohleder, H., *Der Geburtenrückgang—eine Kulturfrage* (from the *Berliner Klinik*, March, 1913), pp. 35.

"weeded out"? Again, are the effects upon the health and morals of a nation of the employment of artificial methods of restricting fertility so prejudicial as to counterbalance the individual advantages? Neither of these questions can be answered offhand, and many persons who have given a good deal of attention to the subject differ fundamentally with respect to them. We believe that the medical profession as a whole is by no means agreed upon the matter, and it would be very undesirable for us to propound in these columns a solution of the problem which must, in the present state of knowledge, be tentative and subject to revision. We do, however, think it fitting to remark that various writers on this topic—Dr. Rolleder is by no means an exception—have expressed themselves with a confidence that the knowledge at command by no means warrants. The attainment of definite knowledge will doubtless require the co-operation of scientific workers in different fields, and at present writers on the subject might advantageously adopt as a motto the words of Helmholtz: "The confession of actual doubt is better than the delusion of dogmatic certainty." As usually happens, this caution will be least regarded where it is most required—namely, on the platform and in the popular press.

A PRINCELY PRACTITIONER.

THERE have been sovereigns who found a pleasure in practising surgery on the bodies of their lieges. James IV of Scotland had a passion for surgery, especially for the extraction of teeth. Henry VIII is said by Froude to have been the best physician of his realm, and he is credited with an ointment for the cure of ulcers of the legs. Peter the Great was fond of operating, but little seems to be known as to the fate of his patients. Edward VII was an Honorary Fellow of both Royal Colleges, but as far as we are aware he fulfilled the hope expressed by Lord Rosebery—himself an Honorary Fellow of the College of Surgeons and the descendant of a surgeon—that he would not practise the art of healing. It has often been stated that the ex-Queen of Portugal is a fully qualified doctor, but this is a mistake; her Majesty takes a great interest in medicine, but has never been formally admitted *in nostro docto corpore*. In the House of Wittelsbach, however, there is what may be called a medical tradition. Several princes of the blood royal of Bavaria have gone through the whole course and graduated doctors of medicine. The late Duke Karl Theodor was well known as an ophthalmologist, and practised at Munich and at Meran. Prince Ludwig Ferdinand, who also is a real not an ornamental doctor, spends his time in the practice of his chosen profession. He not only treats his patients without fee, but also supplies medicines gratuitously, while to the very poor he gives help in money. It is stated that his practice has grown to such an extent that the vast rooms of his palace are inadequate to accommodate the patients who wait their turn to consult the princely oracle. The Prince, therefore, has had to seek a larger stage for his activity. He first looked for a house which could be transformed into a clinic, and not having found any that was hygienically satisfactory in the older parts of Munich, he asked the Minister of Instruction to place at his disposal some rooms in the university buildings. The Minister hastened to set aside for him various rooms of a clinic that was not in use, and thither the Prince transferred his outpatient department. This concession roused the profession of Munich, which had already begun to look on the work of their august colleague with jealousy, to a vigorous and unanimous protest. The medical faculty, making itself the interpreter of the general feeling, addressed a remonstrance to the Minister, urging that this act was illegal, as the Prince is not a university teacher. The Minister replied that although the Prince is only a private practitioner, his

work is so beneficial to the people that it well deserves such modest aid from the Government as the assigning to his use of a few rooms in a public building. The medical faculty is not satisfied, and continues to protest, but the Minister refuses to withdraw from the position he has taken up. Meanwhile the Prince keeps himself apart awaiting the issue of the controversy. There the matter rests at present. We confess that, while admiring the self-sacrifice and humanitarian zeal of the Prince, our sympathies are entirely with the doctors. Philanthropy is an excellent thing, but the virtue should not be exercised to the detriment of a particular class of the community, especially when that class is one that more than any other devotes itself, regardless of its own selfish interests, to the public welfare. The conception of a rich man ministering to the sick out of pure benevolence is grand, no doubt, and has found a beautiful embodiment in Balzac's *Médecin de Campagne*. But princes and millionaires who undertake the drudgery of medical practice purely from the love of the work are few indeed, and the profession at large will always have to shape its life in accordance with the principle of the French *émigré*, who was met by a noble friend when trundling a costermonger's barrow, *Faut vivre*.

A NURSING HOME FOR PATIENTS OF LIMITED MEANS.

THE experiment which is being made in Edinburgh in the establishing of a new nursing home for patients of limited means (to which attention is directed in another part of this JOURNAL, *vide p. 1185*) has evoked considerable local interest, and it will probably excite discussion much more widely now that the home has actually been opened. The principle upon which the home has been founded is that the existing hospital and nursing-home system fails to provide suitable accommodation for people of limited means who are on the one hand not able to pay the large fees asked by the ordinary nursing homes and who on the other hand do not wish to receive for nothing services for which they are able to pay a small fee. Physicians and surgeons have always been ready to reduce their fees or indeed in many cases to forego them altogether in such cases; but there remained the difficulty of the home charges. To many in Edinburgh it seemed that if the initial cost of the home and its furnishing and equipment could be met by public subscription, it would be found possible to carry it on as a self-supporting institution and yet not charge fees which would be outside the resources of people of limited means. Dr. Chalmers Watson deserved to the full the encomium which Lord Balfour of Burleigh passed upon his organizing and constructive work at the opening ceremony last week, for, since the inception of the scheme in 1910, he has been the heart and soul of the undertaking; and it is largely to his energy and skill that the result is due. Lord Duncedin, too, who presided at the opening of the home, is entitled to feel some sense of reward for the time and labour he must have given to the cause which he has so ably championed. It remains to be seen how it will all work out; but the success of the smaller home which has been in existence for some years in Edinburgh (Rutland Square) is a good augury for the new and larger institution, more especially as the services of Miss Shaw, the matron, are being retained. The crux of the experiment will be whether the fees received will be sufficient to meet the working expenses and the necessary repairs and possible new developments to satisfy the ever advancing requirements of modern medicine and surgery. This will greatly depend on the extent to which the twelve private bedrooms at three guineas a week each are occupied; for, doubtless, the management is relying upon them to help to defray the cost of the cheaper beds at one and two guineas. It will be necessary for the home to be fairly well filled constantly to make it a success; but those who have studied the local circumstances

closely do not dread this part of the test. The physicians and surgeons who send patients into the home and its doors are open to the patients of any medical man who wishes to give them treatment himself or to obtain the assistance of a specialist for that purpose—will probably be able to obtain a certain rate of remuneration for their work which will not be oppressive to their clients and will yet reward them to some extent for their time and skill. It is more than likely that, as Lord Balfour of Burleigh said, the institution will have many imitators elsewhere; at any rate, the experiment will be closely watched in many large towns where the need which has brought it into being in Edinburgh is equally pressing.

A SHORT WAY WITH LEPERS.

THE mediæval methods of dealing with leprosy were extremely drastic. Lepers, and it is to be feared, many persons suffering from syphilis, lupus or other unsightly skin diseases, or who, like Falstaff, had lost their voice through hallooing and singing of anthems, were dragged into the net and swept into lazar houses, where they were cut off from the fellowship of their kind. Philip the Fair of France, if he is not belied, had a still more effectual way of stamping out leprosy in his realm, for he is said to have burnt some 11,000 supposed sufferers from the disease. It is true that a large proportion of the pestilent persons thus purified by fire were Jews, and it may perhaps be conjectured that the King owed many of them money or coveted their wealth. If we are to believe Dr. J. J. Matignon, for many years physician to the French Legation at Peking, Young China, whose professed aim is to bring the Flowery Land within the pale of modern civilization, has adopted Philip's hygienic methods in dealing with the leper question, though as yet on a much smaller scale. In the *Chronique Médicale* of May 15th he says that in the neighbourhood of the town of Nan Ning, the capital of Kouang Si, there lived a small colony of lepers. No notice was taken of them by the authorities or anybody else, except some French missionaries who helped them as far as they were able. It was proposed to build a refuge for them, and many of the well-to-do inhabitants promised their support. The governor of the province was understood to approve of the scheme. But Young China resented the interference of foreigners in a matter of social hygiene, and did its utmost to stir up public opinion against the lepers, who were described as outcasts rejected by Heaven whom it would be impious to help. A general massacre in the interest of the public health was openly spoken of. The rest of the story is told in a long letter, the authenticity of which is guaranteed by Dr. Matignon, which is published in the *Bulletin du Comité de l'Asie Française* for March, 1913. It is there stated that on December 14th, 1912, the leper village was at daybreak surrounded by more than a hundred soldiers. Like a flock of sheep driven to the slaughter-house the lepers were forced towards a pit from two to three metres deep that had been carefully prepared in the manœuvring ground. At the bottom of this pit was a thick pile of wood, and a ladder was placed at the side. One by one the lepers, the women with their children in their arms, went down the fatal ladder and sat at the bottom. Then the word of command, *Cha* (kill), was given, and the soldiers fired almost point blank at the victims. Petrol was then poured into the pit, and a flame of fire announced this triumph of the new hygiene. A few lepers who had escaped were pursued and shot. The governor declares himself particularly satisfied with this sanitary achievement. In a proclamation he says: "I Tan Hao Ming, wish to bring this to the knowledge of the people. The lepers commit abominable excesses and are feared by everybody. They take advantage of their disease to molest the inhabitants of the village, to ravish their women, and to extort money

from them. The recital of these crimes makes the hair stand on end. I have referred the matter to the president of the province, who, by a secret order, commanded me to seize and kill all the lepers of the town of Nan Ning. At once, therefore, I had a large pit dug and had all the lepers arrested and exterminated. Thus shall we be delivered for ever from contagion. I am assured of universal approval." This is certainly a more drastic method of dealing with lepers than segregation. The complacency of the governor is that of a man who thinks he has deserved well of the commonwealth. If Young China continues to follow this path in its progress towards hygienic reform there will, in no long time, be no contagious diseases—and no citizens—left in the new republic.

THE GASTRIC JUICE IN DISEASES OF THE STOMACH AND DUODENUM.

THE *Quarterly Journal of Medicine* has acquired an honourable position by according the hospitality of its columns to lengthy papers for which there has been no place since the death of the *British and Foreign Medical-Chirurgical Review*. This service should gain for it the support of all who desire to see the work done by physicians in this country put upon an equal footing with that performed abroad, and it is satisfactory to know that the *Quarterly Journal* has not only gained a scientific position, but is successful as a commercial venture. Its current issue contains an account of a laborious investigation carried out by Drs. Schryver and Singer in the Research Institute of the Cancer Hospital on 125 cases of malignant and non-malignant disease of the stomach and duodenum, to determine the diagnostic value of chemical methods of examining the gastric contents. The points inquired into were the phenolphthalein acidity, the dimethyl acidity, Guenzburg's test, the peptic index, the total chloride, the secreted chloride, the nitrogen, and the nitrogen factor. The labour involved in such a research must have been immense, and we are sorry the results are disproportionate to the time and work devoted to them. However, this has for some time been anticipated by the experience of clinicians, who have come to regard the chemical examination of the stomach contents as rather interesting than important, and frequently to be safely dispensed with in private practice where a practical conclusion is all that is desired. The writers conclude that all available methods of estimating the chloride-secreting activity of the stomach "contain sources of error beyond experimental limits," and must be checked by determining the "nitrogen factor," arrived at by subtracting the estimated hydrochloric acid acidity from the total acidity and dividing this by the number of cubic centimetres of decinormal sulphuric acid required to neutralize the ammonia formed by a Kjeldahl examination of 10 c.cm. of the filtered gastric juice, the result being multiplied by 10. They believe the gastric efficiency as regards hydrochloric acid is best determined by the "secreted chloride" (that is, the total chloride less inorganic chloride), and they dispute the delicacy of Guenzburg's reaction for showing the presence or absence of free hydrochloric acid. Yet the estimation of the "secreted chloride" is essentially a laboratory process, and they speak of it as "comparatively cumbersome" and "involving certain sources of experimental error." Their methods have not enabled them to distinguish pyloric from duodenal ulcer, in both of which the "secreted chloride" is high, but in the case of ulcers in the body of the stomach the results vary. Similar results were seen in carcinoma in accordance with its position, hyperchlorhydria or euclorhydria being common in cancer of the pylorus, while the presence of this disease has "no specific effect on the composition of the gastric juice."

Again. "hyperchlorhydria, hypochlorhydria, and achylia are encountered independently of coarse gastric lesions." This is in contradiction to the positive assertion of some surgeons, which have never been generally admitted by physicians, although "the coincidence of a definite hyperchlorhydria with a greatly raised 'peptic index' (80 or over) is practically diagnostic of pyloric and duodenal ulcer among gastric diseases"; but these "must be carefully distinguished from certain cases of chronic appendicitis." By "peptic index" the authors mean the numerical expression of the peptic activity determined by the Fuld-Levison method. They also find that a "nitrogen factor" over 2.8 is "almost diagnostic" of delayed emptying of the stomach—a point obviously better determined by direct examination. A more interesting statement is that chronic gastritis "probably causes dissociation of chloride and pepsin secretion," by which they mean excess of hydrochloric acid and diminished pepsin. It should not be forgotten that the diagnostic rules formulated by Ewald were empirical, but that further experience has justified most of his conclusions. It is, however, unwise to rely in diagnosis on any single method, and stomach chemistry becomes a dangerous snare if depended upon to the exclusion of other means. It can hardly be maintained that the complicated and elaborate investigations carried out by these workers afford such trustworthy information as to induce clinical workers to devote to them the time and labour they need.

TROPICAL ULCER.

DURING the past few years many observers have studied the peculiar condition known as tropical or sloughing ulcer, and its etiological agent is now usually admitted to be a spirochaete, which Prowazek, who discovered it, named *Spirochaeta schaudinni*. Garin,¹ who has worked on the subject in Lourenço Marques, states that the disease is very frequent there in all its forms, from the mildest, small ulcerations, only one-fifth of an inch in diameter, to serious and even phagedaenic types which cover the whole leg, destroying tendons and muscles and attacking the bones. Within the last two years he has studied more than 400 cases, all, with two exceptions, in natives. He agrees that the spirochaete is the cause, though apparently it has to be associated with fusiform bacilli, which have some relationship with the *B. fusiformis* of Vincent. He points out, however, that the species of these organisms is not yet fixed, and that many points in this alleged fuso-spirillar association are still very obscure. It has been suggested that the parasite may be transmitted by leeches, but this seems not to have been established, and it must be admitted that, frequent though the disease be in certain places, the mode of infection is unknown.

LISTER MEMORIAL.

THE President of the Royal Society has received from the Portuguese Legation subscriptions amounting to £21 5s., forwarded by the Society of Medical Science of Lisbon as a donation to the Lister Memorial Fund. A sum of 867 dollars has been collected by Dr. W. W. Keen, F.R.C.S., of Philadelphia. Further donations intimated from foreign countries include: The University of Paris, 500 francs; *Munchener medizinische Wochenschrift*, 200 marks; the University of Lyons, 100 francs; the Société de Chirurgie de Lyons, 100 francs; the Faculty of Medicine of the University of Munich, 100 marks; the Faculty of Medicine of the University of Breslau, 110 marks; Stockholm Medico-Chirurgical Society, £5; and Naturhistorisch-medizinischer Verein, Heidelberg, 50 marks. A donation of £10 has been received from the University of Calcutta.

THE PHILADELPHIA COLLEGE OF PHYSICIANS.

WE have received a reprint from *International Clinics* of an account of the Philadelphia College of Physicians by its president, Dr. G. E. de Schweinitz. It is not definitely known to whose initiative the foundation of the college is due. As early as 1767 John Morgan made proposals to Thomas Penn for the erection of a college, but a charter was refused. It was not actually instituted till September, 1786, and the first meeting took place on January 2nd, 1787. That day, therefore, is regarded as the official birthday of the college. Its objects, as set forth in the original constitution, are: "To advance the Science of Medicine and thereby to lessen Human Misery by investigating the diseases and remedies which are peculiar to our Country by observing the effects of different seasons, climates and situations upon the Human body, by recording the changes that are produced in diseases by the progress of agriculture, Arts, Culture, and Manners, by searching for Medicines in our Woods, Waters, and the bowels of the Earth, by enlarging our avenues to knowledge from the discoveries and publications of foreign countries; by appointing stated times for Literary intercourse and communications, and by cultivating order and uniformity in the practice of Physick." Two years after its foundation the college was incorporated by charter. The college has nothing to do with licensing practitioners, but is a scientific body which holds monthly meetings (except during July, August, and September), at which papers on medical, surgical, and allied subjects are read and discussed. These communications are published in the *Transactions*, the first volume of which appeared in July, 1793. In addition to its purely scientific work the college almost from the beginning has taken an active interest in matters concerning the health and welfare of the community, and it has been consulted on such questions by the State and municipal authorities. The first standing committee, that on meteorology and epidemics, was appointed in 1787 and presented a yearly report until it was abolished in 1882, a period of ninety-five years. In 1787 another committee was appointed to submit plans of hot and cold baths and a botanical garden for the city. It held consultations with the State Legislature in 1789 as to the spread of infectious diseases. In 1794 it considered the regulation of the practice of physic within the State and the establishment of quarantine and a hospital for contagious diseases. It worked in conjunction with the Philadelphia Board of Health in the management of an epidemic of cholera in 1788; it memorialized the State Legislature in 1787, and the Congress of the United States in 1790, on the deleterious effect of alcohol on the human system and the need of laws regulating its consumption. In each decennial revision of the *Pharmacopoeia* of the United States, the College has taken an active part. In regard to animal experimentation, especially since 1885, when it first addressed a protest to the Legislature against a bill to prevent such experiments, it has played the part of a research defence society. The college is now, as it has been in the past, always ready to give advice in matters pertaining to the welfare of the community. As an example may be mentioned the careful investigation made by a committee at the request of the Commissioner of Health of Pennsylvania as to the expediency of the free distribution of the various county societies of antitetanic serum. Of the library not much need be said, as a full account of it was given by Professor W. W. Keen in an illustrated article which appeared in the *BRITISH MEDICAL JOURNAL* of October 16th, 1909, p. 1161. The nucleus of the library was a donation of twenty-four volumes by Dr. John Morgan in 1788. The total number of volumes in the collection is 95,896, besides which there are 8,917 unbound theses and dissertations, and nearly 90,000 unbound pamphlets. Two years ago the college instituted a series of lectures on great doctors

¹ *Transvaal Medical Journal*, December, 1912.

and achievements in medical research; these are intended for the education of the public in the aims and progress of scientific medicine.

THE FRIEDMANN CURE FOR TUBERCULOSIS.

The first official opinion of the board appointed by the American Government to investigate and report as to the value of Dr. Friedmann's treatment of tuberculosis was embodied in a statement read before the National Association for the Study and Prevention of Tuberculosis at its annual meeting held at Washington on May 9th, by Dr. John F. Anderson, of the United States Public Health Service, Chairman of the Board. The report, according to the *Medical Record* of New York of May 17th, was to the effect that the board, without presenting in detail the condition of patients under observation, was in a position to state that the effects thus far observed did not justify the confidence in the remedy which had been inspired by widespread publicity. The report proceeds: "In our opinion harm may have been done by this undue publicity in so far as it has lessened the confidence of tuberculous persons in well recognized methods of treatment or interrupted their use, and we are constrained to advise against any lessening of these well-known measures which not only have effected cures, but which have reduced the incidence of the disease." After the reading of the report the association passed the following resolution: "That there is no information before the National Association for the Study and Prevention of Tuberculosis to justify the belief that any specific cure for tuberculosis has been discovered which deserves the confidences of the medical profession or the people, and that it is the duty of the public to continue unabated all the present well-tried agencies for the treatment and prevention of tuberculosis."

At the anniversary meeting of the Royal Geographical Society, on May 26th, the patron's medal, which had been assigned to the late Dr. Adrian Wilson, chief of the scientific staff of Captain Scott's expedition, was handed to his widow. Lord Curzon, in the course of his presidential address, said that Mrs. Wilson had offered to present to the society some of the water-colour sketches of her late husband, which apart from their special interest were works of art of high merit. They would be placed in the museum, which would form a conspicuous feature in the new and spacious quarters of the society in Kensington.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Prospects for the Session.

THE House of Commons reassembled on Tuesday, May 27th, and it was quite evident from the events in the House and from the general state of business that the prospect of getting through the bills already projected by an early date in August is by no means favourable.

Tuesday and Wednesday, May 27th and 28th, were to be devoted to an Address to the Crown that an additional judge should be appointed to the King's Bench Division, to the second reading of the Appellate Jurisdiction Bill already passed by the House of Lords, and to the second reading of the Mental Deficiency Bill, Elementary Education (Defective and Epileptic Children) Bill, Milk and Dairies Bill, and of the Bee Disease Bill, if time permitted.

Considerable opposition was offered by a small number of members to the Judicature Bills, so that the whole sitting of Tuesday, May 27th, was occupied in the adoption of the Address to the Crown, and in the commencement of the discussion on the second reading of the Appellate Jurisdiction Bill. Further, out of the time available for Government business, an hour and a half was

occupied in opposition to a bill promoted by the London County Council. In view of the opposition to the Appellate Jurisdiction and Mental Deficiency Bills, it is certain that the other measures on the list cannot be proceeded with further this week.

The second reading of the latter bill was moved on Wednesday by the Home Secretary, who in a short speech directed attention chiefly to the points in which the bill of this year differs from that of last year. The differences and the general scope of the bill were fully discussed in an article published in the *BRITISH MEDICAL JOURNAL* of April 5th, p. 730. A motion to reject the bill was made by Mr. Handel Booth, who received a good deal of support from other members sitting on the ministerial benches, including Mr. Wedgwood and Mr. Athlerley Jones. The debate had not concluded when it was adjourned under the rules of the House at 11 p.m.

As the period of the session becomes more advanced, the prospects of the passage of the Mental Deficiency and Milk Bills become much less favourable, unless the House is to sit throughout August, or have another autumn session. In view, however, of the strong opposition of members to sitting through August, it is very likely that some of the bills above mentioned will be abandoned.

The other business of the session will be the passage of the Finance and Revenue Bills, and the second reading debates and other stages of the Home Rule, Welsh Disestablishment, and Scottish Temperance Bills, which are to be passed a second time under the Parliament Act; the remaining days that must be devoted to the discussion in Supply must also be taken into account, and in addition the Plural Voting Bill, although a very short measure, is to be taken in Committee of the whole House. A resolute opposition to it is to be anticipated both on the Committee and Report stages, and the order paper already shows a large number of ingenious amendments. There will also probably be a debate on the report of the Marconi Committee.

Finally, in view of the statement of the Prime Minister, it is certain that the Government proposes to introduce and pass a measure directed to the amendment of the National Insurance Act in various respects.

In connexion with the last-named measure, the reports current in the Lobby are of the most diverse and fanciful character. The rumours which have been spread as to alterations in its compulsory character may certainly be dismissed as baseless, since any one acquainted with the financial arrangements which have been made by the societies and the Commissioners will recognize that such a fundamental alteration is quite outside the field of practical politics. No doubt an effort will be made to keep the amending bill as non-controversial as possible, although it can easily be imagined that in financial, administrative, and other matters there may be various adjustments to be made, as a number of points have arisen during the debates and in questions to which the Government has promised to give consideration.

So far as professional matters are concerned, we have heard of nothing which would induce us to depart from the forecast which was given in a recent issue.

THE Croonian Lecture before the Royal Society will be delivered by Dr. Robert Broom, Keeper of Vertebrate Palaeontology in the South African Museum, on Thursday next, at 4.30 p.m. The subject is the origin of mammals.

THE course of three Chadwick Lectures, to be delivered by Dr. F. W. Mott, F.R.S., at the Royal Society of Arts, John Street, Adelphi, W.C., at 5 p.m., on June 6th, 13th, and 20th, will deal with nature and nurture in mental development. Sir James Crichton-Browne will preside at the first lecture; Mr. Henry C. Stephens, Chadwick trustee, at the second; and Sir William J. Collins, chairman of the trust, at the third. The lectures will be illustrated by lantern slides, and will be free to the public.

THE Medical Society of London, at its meeting on May 19th, appointed Sir David Ferrier, F.R.S., president, in succession to Sir Watson Cheyne, and Dr. J. Mitchell Bruce, treasurer, in succession to Sir John Tweedy. Other officers appointed were Dr. R. A. Young and Mr. G. E. Gask, honorary secretaries, and Dr. F. Parkes Weber, honorary secretary for foreign correspondence. Dr. F. M. Sandwith was chosen to deliver the Lettsonian lectures and Mr. Robert Jones, of Liverpool, the annual oration. A council of twenty was also appointed.

WALES.

RESEARCH IN MENTAL DISEASE.

LAST week the Home Secretary, at the invitation of the Lord Mayor of Cardiff, who is also Chairman of the Committee of the Cardiff Mental Hospital, visited that institution, and, after making a tour of the buildings, was received in the new pathological research laboratory by Dr. Goodall, the medical superintendent, who pointed out that the pathological problem of mental disease was now viewed more and more from the standpoint of general pathology. The problem was mainly of a biochemical nature, and for its solution the services of the general pathologist and bacteriologist, the chemist and the physiologist were needed. A properly equipped department or institute for pathological research in mental disease should provide facilities for workers in these branches of science, and, of course, for ordinary clinical pathology, such as would be conducted by the physicians at the mental hospital with which the department was connected. Correlation of the work of these experts was necessary, as each could throw light on the difficulties of the other. The immediate requirements of the research department were a worker in physiology and funds for the formation of a library, and eventually for the remuneration of a scientific director to devote his whole time to the work. Subsequently the Home Secretary was shown round the general laboratories by Dr. H. A. Scholberg, and over the chemical laboratory by Dr. Stanford, Research Chemist.

It will be remembered that some time ago the Lunacy Commissioners received a deputation representing some fifty-three asylums, which pointed out the need for the establishment of hospitals for mental disorders with adequate laboratory provision for research in contiguity with every complete school of medicine. The Lunacy Commissioners have made representations to the Home Secretary suggesting the propriety of making a State grant for research in mental diseases, and at a luncheon held at the City Hall after the visit the Lord Mayor of Cardiff said that it was hoped that the Home Secretary would shortly make a new departure by instituting Government grants to local authorities progressive enough to establish departments of research into the cause and cure of mental diseases. In the research work so successfully carried out by Dr. Goodall and his staff of expert assistants, the Committee of the Mental Hospital had been heartily supported by the corporation as a whole, but local burdens were already very heavy, and it was time to ask Parliament to set aside a certain sum to be administered by the Lunacy Commissioners by way of grants in aid of mental research laboratories.

Mr. McKenna, in his reply, after declaring Cardiff *de facto* the capital of Wales, said that he was much impressed by the representations which had been made to him and by what he had actually seen at Cardiff, and would impress upon the Treasury the necessity for the extension of the work, not only at Cardiff, but in other great centres, such as London, the West Riding, and Lancashire, where attempts of a similar character were being made to effect a larger proportion of cures of mental disorders than had been possible in the past.

MANCHESTER AND DISTRICT.

THE PHYSIQUE OF THE MODERN BOY.

IN a paper recently communicated to the Statistical Society of Manchester,¹ Dr. A. A. Mumford brings together a considerable mass of statistical data relating to the physique of children of school age. In the first part rather scanty data collected by the Factory Inquiry Commission, giving the heights and weights of factory and non-factory children in 1833, are compared with the measure-

ments of city children recorded by the Anthropometric Committee of the British Association in 1883, and the conclusion drawn that, so far as growth in height and weight are concerned, no progressive decay is observable. In the second part a similar comparison is instituted between the boys in the Manchester Grammar School during 1881-6 and 1905-10. These figures show, if anything, an improvement in the later period. From a study of the records of their athletic sports it would also appear that the physical attainments of middle class boys have not deteriorated, but evidence of this kind is of somewhat limited application. Very useful tables give the heights, weights, and girths of deaf and normal children at the same ages, and seem to show that "in spite of the very superior care in feeding, in physical training, and in bodily care they [the deaf] receive at the Royal Schools for the Deaf, Old Trafford, they never catch up to the normal members of their own class." This statement applies to the boys rather than to the girls. Lastly, the "free place" boys in the Manchester Grammar School are compared with their fellows, the differences found being apparently of little moment. It must, of course, be remembered that the "free places" are all picked boys and presumably above the average of their class.

GUARDIANS' VISITS OF ASYLUM PATIENTS.

Several weeks ago the South Manchester Guardians proposed to stop paying visits to patients they had sent to asylums, the idea being that no good ever came from such visits. In a letter dated May 8th, the medical superintendent of the Lancashire County Lunatic Asylum gave it as his opinion that visits of guardians did no harm and might even be beneficial to some patients, providing the number of the deputation were limited to, say, three or four, with, in addition, the clerk and the medical officer. The South Manchester Guardians have now received a letter from the Lunacy Commissioners which very strongly expresses the views of the Commissioners "that the visitation by guardians of patients from their unions is of the first importance to the comfort and contentment of the patients, who, cut off and separated from their friends and homes, and suffering frequently from a sense of injustice at their confinement at all, regard with much pleasure the visits of the outside local authorities who bring them into some sort of relation with their own homes."

LIVERPOOL.

MEMORIAL TO DR. WATERS.

ON Sunday, May 25th, at St. Luke's Church, in the course of the morning service, Archdeacon Madden unveiled a handsome brass mural tablet which has been placed in the church by Mrs. Waters in memory of her husband, the late Dr. A. T. H. Waters of Liverpool. The unveiling was preceded by a few appropriate words, addressed to the congregation, and by a short dedicatory prayer. The inscription is as follows:

To the glory of God and to the dear memory of Alderman Thomas Houghton Waters, M.D., F.R.C.P., born 5th June, 1826, died 8th June, 1912, who for 32 years within these walls found strength for the service of his Master. Associated with the medical charities of this city for nearly 60 years, and always active in the relief of human suffering, he shared in every effort to increase knowledge or to ennoble life, till having served his generation he was called to his rest.

THE INSURANCE ACT.

The Liverpool tramway employees have obtained a certificate exempting them from all contributions under the Act, on the ground that the persons concerned have a scheme which provides medical benefits, superannuation, etc., on even better terms than the Act could offer. Unfortunately their estimates are based on a rate of remuneration to their medical officers which is considerably less than the standard secured by the Act. It is hoped that the doctors concerned will not consent to an arrangement which would negative much of the work of the Association during the last two years. They naturally ask an assurance that if they insist on the higher rate they will not be undercut by their neighbours. The matter is one which will no doubt receive the early attention of the local Division.

¹ *The Physique of the Modern Boy*. By Dr. A. A. Mumford. Reprint of a paper read before the Manchester Statistical Society, December 11th, 1912. Manchester: John Heywood, Limited.

CHANGES IN HOSPITAL STAFF.

Owing to transfer of Dr. Warrington to the Royal Infirmary, a medical vacancy has arisen at the Northern Hospital. There will also be vacancies for an assistant physician and an assistant surgeon at the Children's Hospital, and for an assistant surgeon at the Women's Hospital, Shaw Street.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

EDINBURGH PARISH COUNCIL AND THE ROYAL INFIRMARY.

At the meeting of the Parish Council on May 19th (Mr. Huie, Vice-Chairman, presiding) a letter was read from the Clerk of the Royal Infirmary with reference to the application of the Council for representation on the board of managers of the infirmary. The managers pointed out that election to the board was regulated by the Infirmary Act of 1870 and by the charter of the institution, and they regretted that they were not in a position to grant the request of the Parish Council. A discussion followed, in which some feeling was expressed regarding the reply of the infirmary board; but finally, on a vote being taken, 12 voted for no further action being taken, and 10 for the matter being remitted to the Chairman's committee. The subject was therefore allowed to drop.

THE LORD HIGH COMMISSIONER AND MEDICAL INSTITUTIONS IN EDINBURGH.

During the ten days or so once a year in which royalty is represented in the Scottish capital, and in which the halls of Holyrood Palace re-echo once more to the tread of many feet, the Lord High Commissioner has always some minutes to spare to visit the many medical institutions with which Edinburgh abounds. This year has been no exception to the well-established custom, and during the past fortnight the Lord High Commissioner, with Lady Glenconner, and in some cases Lady Glenconner alone, have visited the Hospital for Diseases of Women, the Royal Victoria Hospital for Consumption, the Royal Institution for the Education of Deaf and Dumb, the Royal Blind Asylum, the Deaconess Hospital, the Hospice, the Royal Maternity Hospital, the Cripple Children's Home, the Royal Infirmary, the Royal Sick Children's Hospital, and Donaldson's Hospital (for deaf and dumb children). The Royal Colleges of Physicians and Surgeons have also been officially present at the levees in Holyrood, and representative medical men have had the honour of dining with His Grace.

OPENING OF NEW NURSING HOME, EDINBURGH.

On May 21st Lord Balfour of Burleigh, in the presence of a large and distinguished company, declared the new nursing home open. The home is the outcome of a movement to provide for persons of limited means a hospital where they will be able to obtain medical and surgical treatment as in-patients by paying moderate fees: it is, therefore, intermediate between the hospitals where accommodation and treatment are received as charity and the expensive nursing homes, which, by reason of the fees charged, are beyond the reach of a large section of the middle class. A beginning was made in 1910, when some preliminary subscriptions were obtained, chiefly from the medical profession itself, which has responded handsomely all through; then in 1911 a public meeting was held in Edinburgh, under the chairmanship of Sir Robert Usher, Bart., when an influential committee was formed, with Lord Dunedin as chairman, Professor Lodge as chairman of executive, and Dr. Chalmers Watson as honorary secretary; an appeal then made for funds was so well responded to by the public that now £13,000 out of the £13,500 asked for has been received. Public sympathy was excited in a remarkable manner when it was made clear that, provided the initial expense of buildings and furnishings was met, the home could be made self-supporting, the patients paying from 1 to 3 guineas a week, according to the accommodation supplied. Public sympathy was aided to make itself practically effective by means of a band of voluntary lady collectors, 250 strong, who in all parts of

Scotland brought the scheme intelligently before the notice of the charitable. As a result over 10,000 subscribers gave sums varying from £250 to 3d. Meantime a pioneer home managed on the principles above described was being successfully carried on in Rutland Square; but it was on a much smaller scale than that now available, and it has been merged in the latter. Still, it has served to open the way and make the public more fully aware of the possibilities of such an institution. The home, formally opened by Lord Balfour of Burleigh on May 21st, is situated in what may be called the hospital quarter of Edinburgh; it is within a stone's throw of the Chalmers Hospital, an institution with somewhat similar aims, although not intended for quite the same class of patients, and of the Royal Maternity Hospital, and it is within sight of the Royal Infirmary. It is thus, so to say, within the sphere of the daily work of the various physicians and surgeons who are attached to these institutions, and who will doubtless be amongst the medical men who will give operative and other treatment in the new home. The home came into being through the adaptation of three continuous villa residences in Chalmers Street, and Mr. T. Duncan Rhind, A.R.I.B.A., deserves great praise for the skilful manner in which he has carried through the necessary changes and extensions. There are beds both for male and female patients: two of the wards have each 8 beds, five of them have 3 beds each, and there are twelve private rooms with 1 bed in each. There are two operating theatres, with a sterilizing room between, and there is an anaesthetic room with wide folding doors; there is an electric lift big enough to take a bed with patient in it, and a nurse, and there is another for food. In place of bells there is a silent system of electric signalling, and there are rooms for x-ray treatment, for hydrotherapeutic treatment, for massage, etc., as well as a dark room for photographic work. In addition to all these things there is accommodation for the matron and nurses, for the maids, for the doctor, for convalescent patients, and a bright room with four cots for children. At each end of the building there is a fire-escape iron stair which leads to the back green, and is connected with each floor.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

NURSING CONGRESS IN DUBLIN.

The National Council of Trained Nurses of Great Britain and Ireland will hold a nursing conference and exhibition in Dublin on June 4th, 5th, and 6th, in the house of the Royal College of Physicians. Various papers will be read and discussed on the Wednesday and Thursday. A very attractive programme, arranged by the Irish Nurses' Association, will commence by a reception at the Royal College of Surgeons on June 3rd at 8.30 p.m., when a pageant illustrating the history of nursing will take place. On Wednesday the Master and Lady Superintendent of the Rotunda Hospital will be at home to the members, and in the evening, in the Abbey Theatre, a series of tableaux descriptive of the history of nursing will be shown. On Thursday there will be a garden party at the Zoological Gardens, and in the evening a banquet in the Manston House. On Friday there will be an excursion to Glendalough, returning by Newcastle, where the governors of the Consumptive Hospital will entertain the party to tea. Shorter excursions to Howth and Killinay will be made on the same day.

TYPHUS FEVER IN CONNEMARA.

At the last meeting of the Oughterard Board of Guardians, the Chairman of the District Council handed in a notice of motion calling on the Congested Districts Board to sink wells and place pumps in the fever-stricken districts of Connemara. Sir Acheson MacCullagh, medical inspector to the Local Government Board, said that the majority of the patients came from Rosmuck—13 cases had occurred there; but he was glad to be able to state that at present there were only 3 cases of fever, 2 of which were practically convalescent and the other was improving. It was stated that some of the patients had to remain lying on the floor of their cabins, as it was impossible to transport them thirty miles to the fever hospital. All the cases were

miles away from the tracks of the tourist visitors, and it seemed that many of the statements which appeared in the public press were largely exaggerated. Typhus fever is endemic in the islands off the coast of Connemara, and since last September 40 cases have been notified in a dispensary population of 10,000 persons; as there have been only 5 deaths, the epidemic cannot be considered very serious. The standard of living in these islands is very low, and the people are housed in miserable hovels and draw their drinking water from stagnant pools. The local authority is too poor to undertake the necessary reforms, and it therefore rests with the Congested Districts Board to take steps to see that the urgent needs of these poor districts are supplied. This outbreak has shown the necessity for a temporary hospital on the mainland near the islands to which the patients could easily be brought, and to this purpose, perhaps, the funds which are being raised by public subscription could best be devoted.

At a meeting convened by the Lord Mayor in the Mansion House, Dublin, last week, to consider the condition of Western Connemara, the following resolution was passed:

That a subscription list be now opened to ameliorate the conditions of life existing in the western parts of Connemara, and this meeting calls upon the responsible authorities to take immediate steps in discharge of their obligations for the purpose of securing decent conditions of life for the inhabitants of that district.

Correspondence.

MALARIA PREVENTION IN GREECE.

SIR.—Students of malaria may remember that seven years ago I published (*Journal of Tropical Medicine*, November 15th, 1906, ix, 22, page 341) an account of a visit to Greece, especially to the Copaic Plain, for the purpose of advising upon the reduction of malaria there. They may now like to have a short account of a second visit which I have just paid there, after an expedition to Cyprus on behalf of the Colonial Office for a similar purpose.

It will be remembered that the British employees of the Lake Copais Company suffered much from malaria in the old days, and that I advised the houses to be protected by wire gauze, and the neighbouring collections of water to be kept free of weeds and periodically oiled. I am glad to say that these measures have had an excellent result, and that I was informed during my recent visit that no indigenous cases have occurred amongst the British employees in the neighbourhood of Moulki for some years past. The houses are excellently protected, and the waterways kept periodically cleaned.

Some distance from these houses there is the Greek village of Moulki, which is, of course, under the sanitary rule of the Greek Government. Here much quinine has been given to the villagers, especially to the children; and the company has been good enough to oil the stagnant waters round the village as much as possible, though this duty does not lie upon its shoulders. The result has been that whereas in May to June, 1906, I found splenomegaly in 35 out of 62 children, or 56 per cent., now, early in May, 1913, I find it only in 14 out of 50 children examined. But this is not a quite fair measure of the reduction which has been effected, because I have been much more particular on this occasion to take into account the very smallest enlargements of the spleen. I should say, therefore, that the reduction has been greater than 50 per cent. Moreover, the village children and the villagers in general looked in every way much healthier than they did previously, and the priest, the innkeepers, the schoolmaster, and the head man of the village all testified to the improvement which had taken place, and praised the company for the work that it had been doing.

Nevertheless, in spite of all the trouble that has been taken at Moulki village, a spleen-rate of something like 28 per cent. remains; and the old stagnant pools of water remain also, even though they are kept oiled. This only confirms me in the belief which I have long held that quinine, oiling, and even wire gauze protection are seldom sufficient by themselves to eradicate malaria completely so long as the breeding pools remain undiminished in

extent. In this connexion I would specially invite attention to the Indian experiences, well summarized by the Director-General of the Indian Medical Service, Surgeon-General Sir Pardey Lukis, in his presidential address at the third meeting of the General Malaria Committee held at Madras on November 18th, 1912. I doubt much whether, after all, the radical measure is not in the end the cheapest and the best, even for such semi-waterlogged places as the Copaic Plain.

It will also be remembered that, after my first visit to Greece, the Liverpool School of Tropical Medicine raised a subscription, which reached several hundreds of pounds, for the Greek Anti-Malarial League. The work of this league has been fully and ably set forth by my friend, Dr. Savas, Professor of Hygiene and Bacteriology at Athens, in his contribution to my book on *The Prevention of Malaria* (Murray, 1911, page 432). The league persuaded the Greek Government to make quinine a State monopoly in order to avoid the expense and frequent adulteration which used to occur in Greece. It also frequently sends experts to the villages in order to teach the people how to act against the mosquitos; but its funds are low, and I understand the Greek Government gives it only 5,000 drachmae (francs) a year. On the other hand, the Greek Government appears to be making quite a nice profit out of the sale of the quinine, amounting to 46,000 drachmae in 1908-9, 61,000 in 1910, and 83,000 in 1911. It seems to me to be scarcely a part of the function of Government to make a profit from sanitary measures; and Professor Savas and I therefore sought and obtained an interview with Mr. Venezelos, the distinguished Greek Minister, and urged that the money should be utilized for malaria prevention, and that the Greek Government should do more for draining the villages; and I am sure that our representations will have every consideration from him.

The fact is that the same defect holds almost everywhere throughout the world. The unfortunate villager produces the food of the world and pays his taxes, but almost nothing is done for him in the sanitary line by any of the Governments under which he toils. They give him peace and a certain amount of justice and education (at his expense); but scarcely ever spend even a few shillings to keep his village in a wholesome condition, or even his roads in proper repair. Thus, I learnt that at Moulki no money had been spent on the village for this purpose for years past. One reason why I have always so strongly urged mosquito reduction in malarious countries is because this sanitary measure means in fact a sanitary charter for the immense rural population of such areas; and if we can only persuade Governments to adopt it generally, a new epoch will be created in rural life in warm countries.—I am, etc.,

London, W., May 23rd.

RONALD ROSS.

THE FORM AND POSITION OF THE STOMACH.

SIR.—I must apologize for writing again on this subject; but Mr. Gray accuses me of "throwing dust in the eyes of the reader and confusing the issue." If he will re-read my letter of May 3rd, he will see that in the last paragraph on p. 970 I state that I often find a pause in the onward progress of the food "just below the air shadow"—that is, just below the cardiac orifice—and also "at the lowest point before turning to the right along the pyloric canal," the normal stomach being approximately J-shaped. In the next paragraph I speak of the food being held up (1) "just below the cardiac orifice," (2) "at the lowest part of the organ," and (3) of spasmodic contractions being most often noted in the "middle of the body of the stomach." (If Mr. Gray will look up Figs. 10, 11, and any of Figs. 19 to 23 in my articles in the *Medical Chronicle* of January and February, he will see diagrams that should make these points quite clear.) And yet again in the next paragraph I wrote that apparently Mr. Gray claims a middle sphincter "just below the cardiac orifice, in the middle of the body of the stomach as well as at the lowest point." And yet, in spite of these very definite descriptions, Mr. Gray writes—in inverted commas, as if quoting from my letter of May 3rd—that I described these sites as "half-way down the stomach," "the lowest part of the organ," and "the middle of the body." I have re-read my letter most

carefully and cannot find these descriptions, and yet it is on this that Mr. Gray accuses me of throwing dust in the eyes of the readers, and says that I am "particularly unfortunate in choice of terms and descriptive powers."

The reason I took no notice of Mr. Gray's query as to the position of the pylorus is obvious; the question seemed to be raised with the object of discrediting radiographic findings, and the question in point was "the middle sphincter." Incidentally I notice that in the case Dr. Jordan describes and figures, and Mr. Gray quotes so frequently, the patient was "admitted for nausea and vomiting with hæmatemesis." It does not sound like a normal healthy subject, even if the surgeon did fail to discover anything abnormal in the stomach. Also, Dr. Jordan does not state that the pylorus is opposite the fourth lumbar vertebra, but that the pylorus is "behind the umbilicus," and I am sure Mr. Gray knows that this surface marking is not necessarily a fixed point in relation to the vertebrae.

If Mr. Gray will again look up the *Medical Chronicle* of January he will find on pages 208 and 215 an explanation of the discrepancies between the x-ray and operative appearances. Has he by any chance reopened an abdomen and found at the second examination a much larger or smaller stomach than when he first saw it? Or has he seen in the *post-mortem* room some of his own cases and found that what he had thought was a normal stomach had become a large flaccid sac or vice versa? Or, if he ever examines patients with the fluorescent screen, has he by any chance seen one who turned faint or became suddenly frightened, and noted how the lower border of the stomach dropped, or has he seen how the organ may contract right up under the diaphragm in the act of vomiting?

The changes that may be brought about by anaesthesia or death are infinitely more profound than those that might possibly be induced by mixing a little bismuth or barium into ordinary food. But why will Mr. Gray always seek to discredit radiographic findings, and confuse the issue by seeking out discrepancies which he could easily verify or disprove by undertaking for himself the systematic examination of a considerable number of healthy persons, and investigating the subject for himself? If he has not efficient apparatus at his disposal my offer is still open, and I trust that he will accept it.

With regard to the explanation of his clinical phenomena, I offer no suggestions, and admit that Mr. Gray's theory would be a satisfactory explanation but for the fact that no "middle sphincter" can be found, and that the stomach, with certain reservations already stated, is one undivided cavity.—I am, etc.,

Manchester, May 20th.

A. E. BARCLAY.

RHEUMATOID ARTHRITIS.

SIR,—In the first place I wish to make a correction in my last letter. In the thirteenth line from the end the word *soluble* should be *insoluble*. This is a distinction with a difference.

Opinions such as those expressed by Dr. J. Tertius Clarke, of Perak, in the Federated Malay States, make one despair of the medical profession ever becoming a scientific one; in fact, it is only a medical journal that would print such rubbish. What does he mean by "the absence of proof that a particular cause produces a particular effect is not a very strong proof that it may not do so"? To help in the solution of this riddle I suppose we may say that the absence of proof that *two* and *two* make *five* is no very strong proof that they may not do so. His talk about a theory and a theorem is not very relevant to his further remarks. A theorem should be true though the truth is not self-evident, but when I have finished with his conjectures—I will not call them a theory—I shall leave your readers to form their own opinion as to how far distant his conjectures are from a theorem, or even from anything bearing the semblance of truth.

"I have pointed out that there is no such thing as rheumatic fever in the Malay Peninsula, and Major Buchanan agrees with me that there is none in tropical India." What a peculiarly constructed sentence! The man in tropical India agrees with the man in the Malay Peninsula, not that there is no rheumatic fever in the Malay Peninsula, but that there is none in tropical India.

Now, I suppose Dr. Clarke will agree with Major Buchanan that there is no rheumatic fever in the Malay Peninsula. As they are agreed about something which it appears they do not see, perhaps they will also agree, say, about some feature of the moon which they really can see from their respective spheres. Dr. Clarke again says, "I may now add that in eighteen years' experience in the tropics I have never seen a case of rheumatoid arthritis," and yet he thinks he knows all about it.

The experience of these gentlemen reminds me of the story of an English officer who, after expatiating on his prowess in shooting lions and tigers in India, took part in a conversation about missionaries, and boldly stated that there were no missionaries in India, as he had been there for a quarter of a century and had never seen one; a missionary who happened to be present said that from a similar paucity of reasoning he could assert that there were no lions and tigers in India, as he had been there for thirty years or more and had never seen one.

Regarding rheumatism, let us see what Dr. August Hirsch says:¹

In *India*, according to nearly all observers, rheumatism is not only more frequent than in many countries of the temperate zone, but in fact it holds, after the malarial fevers, one of the first places in the statistics of sickness. We have details of it from nearly all parts of the country; including Lower Bengal, Tirhoot, Chota Nagpore, the Himalayan slope, and other regions of the Bengal Presidency; the Upper Godavery in Central India; many parts of the Madras Presidency; Cochin, Goa, and other places on the Malabar Coast; Balmang, Poona, Aurangabad and Satara, Gujerat, Cutch, and Sind in the Bombay Presidency; Meerut, Futtegar, and other parts of the Upper Provinces.

Similar accounts of rheumatism being endemic come from various parts of *Lower India* (Prome, Rangoon, Malacca, Singapore), from *Cochin China*, and the *Malay Archipelago* (particularly Samarang in Java, the coasts of Borneo and Sumatra, and the Riouw-Lingga group); also from a number of places on the coast of *China* (Chusan, Shanghai, Canton, Hong Kong, Ningpo, and Hangkow); from *Japan*; from many of the *Polyneesian* groups (Hawaii, Tahiti and Eimeo, Fiji, the Marquesas, Samoa, and New Caledonia); and from *Tasmania* and *New Zealand*.

In *Cochin China* rheumatic fever complicated with heart affection is often seen among the native Anamese. It occurs also in the *Malay Archipelago*, particularly among the men of the Dutch navy, and there have been cases in China among the British troops.

From 1859 to 1883 the annual number of cases of rheumatism among the British troops at home and abroad per 1,000 men were: Nova Scotia and New Brunswick 26, Bermuda 29.1, Mauritius 30.4, Cyprus 32.2, New Zealand 34.2, Canada 35.8, Ceylon 36.2, West Indies (English regiments) 38.4, Cape and St. Helena 41.2, Great Britain and Ireland 43.1, Gibraltar 43.8, Madras Presidency 44.9, Bombay 46, Malta 46.3, Australia 49.5, Bengal 55.2, West Indies (black troops) 62.5, West Coast of Africa (black troops) 74.2.

So much for rheumatic affections in general, but regarding rheumatic fever he says:

While tropical and subtropical countries have no absolute immunity from it, and some of them, indeed, such as Central Arabia, India, the Cape, the Abyssinian plateau, and Peru, are much subject to it; yet the maximum of frequency falls quite decidedly within the higher latitudes.

I may say that Dr. Hirsch was the first to look upon rheumatic fever as a specific infective disease.

Some years ago I had a letter from a surgeon-major in the Madras Presidency in which he stated that there was plenty of malaria there, but there were no mosquitos. When I mentioned the matter to Sir Ronald Ross he said there are some men who cannot see anything so small as a mosquito. Last year I saw an extremely bad case of rheumatoid arthritis in a lady aged 36, who was born in India and lived there the greater part of her life; she was in this country from the age of 10 to 17 for her education; contracted the disease in India at the age of 18 years, and only returned last year to see what could be done for her helpless condition.

Dr. Clarke's last paragraph is such an extraordinary piece of reasoning that I will not trouble to tear it to shreds, but just content myself with quoting the following sentence: "I do not mean that rheumatic fever is the cause of rheumatoid arthritis, but suggest that the cause of rheumatic fever is a necessary constant in the production of rheumatoid arthritis." His conjectures imply that he thinks or believes that rheumatic fever is due to an organism which he has never seen and about which he

¹ *Handbook of Geographical and Historical Pathology*, vol. iii, pp. 749, 750, 751, 757, 758, 759, and 763.

knows nothing; that because he has never seen rheumatic fever or rheumatoid arthritis in the Malay Peninsula, that therefore they do not exist there, and that because they don't exist there then they are causally connected; that the organism which gives rise to rheumatic fever may be, or rather is, "a necessary constant in the production of rheumatoid arthritis," even without any intermediary stage of rheumatic fever. In the same way he asserts that "nephritis may manifest itself as a sequel of scarlet fever or of quartan malarial fever without any history of the occurrence of one of these diseases previously." Surely a disease which was not present cannot have a sequel. Again, he supposes that the organism is "unable to exist extracorporeally at a mean temperature of 80° F.," and yet it is supposed to thrive in the human body at 105° F. or more, and to survive in Lapland at much below freezing point.

I have taken a pleasure in exposing the kind of stuff that is purveyed in a *soi-disant* scientific journal. Surely it is about time that you insisted on your contributors exhibiting some slight knowledge of the subject about which they write.—I am, etc.,

Liverpool, May 24th.

JAMES BARR.

SIR.—Sir James Barr expresses his regret at seeing me "parting with the substance for the shadow" and goes on to add that it will be time enough for me to clench my view "that the disease is a toxic arthritis of bacterial origin" when I have discovered either the bacterium or its toxin. I can make no satisfactory reply to the first part of the above, as I really do not understand his reference to the substance and the shadow; with regard to his second point, I do not think Sir James Barr has quite grasped my position.

I pointed out that a close study of rheumatoid arthritis has led me to accept the bacterial origin of the disease as the view most consistent with available clinical and pathological data.

I did not enter into the consideration of facts personally observed in my investigation of many cases, which led me to accept this view. I contented myself with pointing out the strong support given to it in Sir James Barr's instructive address. I pointed out—and to this there has been, and can be, no denial—that the four fundamental principles of treatment so admirably laid down by Sir James Barr implied the probable existence of a bacterial origin of the disease. It might further be added that if the bacteriological basis for Sir James Barr's principles of successful treatment be removed, there is little or no substance left for any other theory of origin of the disease.

In the purely practical side of the question with regard to treatment, I am glad to find myself in complete agreement with him. In his letter published on May 24th, Sir James Barr rightly emphasizes the personal equation in treatment—in other words, the individual variations in the power of resistance to infection determined by conditions of the "soil," inherited or acquired. The bacterial element in any chronic infection is only a half, and sometimes a small half, of its etiology. It is to be hoped that Sir James Barr's stimulating address, which has served as the basis for an instructive correspondence, will lead to a wider recognition of the soundness of the principles of successful treatment of this disease, so admirably outlined by its author.—I am, etc.,

Edinburgh, May 24th.

CHALMERS WATSON.

SIR.—In his letter in the *JOURNAL* of May 17th Sir James Barr says I jumbled joint diseases together. He has himself made a great point of the evidence of skiagrams in support of the decalcifying theory, but of my experience in this direction he writes, "I cannot attach much importance to his skiagrams, seeing that he does not clearly differentiate between the different affections of the joints." If Sir James will read my letter again he will see that I especially took his own definition and differentiation of the disease, and merely recorded my experience as to the use of skiagrams for diagnosing rheumatoid arthritis, which is evidently similar to that of Dr. C. Fred. Bailey, namely, that increased translucency is not peculiar to this disease.

I do not understand why Sir James Barr should take exception to my presuming that he cures his cases with lime salts. If he does not claim that lime is the all-

important factor, by its absence through the "mild chronic acidosis," in causing the disease and by its presence as a curative agent, then it is not clear what his views, as expressed in his address, really are. He told us in that address that by using decalcifying agents we run the risk, from which he himself has escaped, of producing rheumatoid arthritis, and under the head of treatment he speaks of the importance of lime salts and of the various ways in which they may be administered. Sir James Barr has tried decalcifying agents upon himself, and has produced some of the symptoms of rheumatoid arthritis, but he has "succeeded in establishing a calcium equilibrium," and yet he objects to my suggesting that he cures his cases with lime salts.

Sir James also takes exception to my statement that according to his views rheumatoid arthritis begins in the larger joints, saying: "I have not laid down any hard-and-fast rules as to which joints are first affected." But in his address (*BRITISH MEDICAL JOURNAL*, p. 753) he says: "In my experience the large joints, especially the knees and shoulders and ankles, are first involved."

I entirely agree with Sir James Barr that the joint affections are only part of the disease, and his general rules and directions with regard to treatment, apart from the calcium theory, are full of sound common sense.

For the rest, as Dr. Chalmers Watson points out, the toxic and bacterial origin of the disease is far more present in Sir James Barr's mind than he seems aware.—I am, etc.,

Bath, May 19th.

PRESTON KING, M.D.

SIR.—I have never at any time either attempted to differentiate the different forms of rheumatoid arthritis or any other kind of joint affection, or signified my acceptance of any existing classification, so that when Sir James Barr writes: "The whole series of chronic joint affections were then as inextricably mixed, as they are to-day by Dr. Craig," his remark can only be regarded as another example of his peculiar style of reasoning. Sir James Barr associates the thermopentrating current with barley water. There is no doubt that any one who knew nothing of the action and methods of using the diathermic current would find barley water not only more efficacious but much safer. At a meeting of the Balneological and Climatological Section of the Royal Society of Medicine in April of this year, where the gentlemen present consisted of physicians to whom, if there be any truth in the statement that "an ounce of practice is worth a ton of theory," we must look for guidance in the treatment of this disease, one of the speakers, in advising copious water drinking for rheumatoid arthritis, stated that "the presence or absence of some lime is of no importance whatever," confirming Sir Robert Christison's wise statement made forty years ago. None of the experts present cavilled at the remark, although, of course, they all knew of the deleterious influence lime has on the body, especially on the circulatory system, when the amount given exceeds the requisite amount—10 grains daily for the adult.

In reply to Dr. Bailey's advice to give ionization a more prolonged trial, I may say I have seen cases that have undergone this treatment for many months, with about the same improvement as occurred in other cases, when the electrodes were moistened either with warm water or salt water, the same number of milliampères being used in each patient; in each of the three divisions the improvement was very marked.

What does Sir James Barr mean when he writes: "That the finely stencilled lines of absorption occurred at the edges of the bones where the blood supply comes from the periosteum?" I advise Sir James Barr to continue to diligently study Burns, and if he must prescribe lime, to abandon the somewhat dangerous calcium salts, and give his adherence to the products of the Linden tree.—I am, etc.,

Llandudno, May 24th.

JAMES CRAIG.

VACCINE TREATMENT OF ACUTE LOBAR PNEUMONIA.

SIR.—It appears to me that something very much more in detail than the records given by Dr. Lyons (*BRITISH MEDICAL JOURNAL*, May 10th, 1913, page 992) is

required if it is sought to establish that improvement and recovery in his four cases of pneumonia not only followed but were the result of vaccine therapy.

In pneumonia, as in acute infectious generally, everything depends on the virulence of the infection. Some cases are mildly toxic, and run a short course without at any time causing grave anxiety. Other cases show from the start serious symptoms, and signs of heart embarrassment are present in the earliest days of the attack. For the records of cases to be really convincing, some idea should be given of the degree of toxæmia present prior to the administration of the vaccine, particularly the condition of the heart and circulation. Especially valuable would be details of cases of asthenic pneumonia which had improved and recovered after the use of vaccines.

On May 5th I removed an undescended testicle from a boy aged 10 years. He promptly developed typical right apical pneumonia with a temperature which kept at about 103° until May 11th, when it came down to 100°. It went up again in the evening to 102°, but on May 12th it was normal. The boy's appearance did not cause any anxiety throughout; he had no vaccine, yet the course of his attack was very similar to, say, Dr. Lyons's third case (as regards the pneumonia).

Another case operated on the same day points to the possibility of fallacy even in cases where there is marked toxæmia. A gangrenous appendix was removed from a girl aged 8 years. Within twelve hours there was increasing abdominal distension, no passage of flatus, a pulse of 140, respirations 38, and a marked toxic appearance. I asked Dr. Enrich to prepare an autogenous vaccine. By the time the vaccine was ready the clinical picture had entirely changed—temperature 99°, pulse 112, bowels well moved, restlessness gone and some hours of normal sleep. The vaccine was consequently not given, but had it been possible to inject it whilst the patient was critically ill I should most assuredly have given it the credit for the remarkably rapid improvement in the symptoms.

I am a convinced believer in the efficacy of vaccine therapy and have seen not only symptoms abated, but lives—as I believe—saved by its use. But I think distinct disservice is done to the cause of vaccine therapy when cases are published in such an incomplete fashion that while the virtues of vaccines are asserted it is impossible to deduce them from the meagre details given.—I am, etc.,
Bradford, May 12th. JAMES PHILLIPS.

TUBERCULOSIS OFFICERS.

SIR,—While quite appreciating the good intentions of Drs. Graham and Lissant Cox as to the inclusion of tuberculosis officers in the Medical Officers of Health Superannuation Bill, I am sure I am voicing the opinion of many of us when I say that we do not quite fall in with the view that we are "a junior branch of the public health service" (Dr. Graham), that we "look forward to entering the main branch of the public health service," or that "the ranks of medical officers of health will be recruited from . . . tuberculosis officers" (Dr. Cox).

We are a new and distinct service created by the necessities of the Insurance Act, working in close harmony with medical officers of health, but whose training has been of necessity absolutely different, and whose experience, if to be of any value, has been gained not in the public health laboratory and in the working out of administrative and mathematical problems, not in studying the various Acts of Parliament so essential to the post of a medical officer of health, but in the wards and out-patient departments of chest hospitals, sanatoriums, and tuberculosis dispensaries. Our goal is not the position of a medical officer of health, who from the outset of his choice of a career works in quite a different channel, but rather that of promotion in the special service we have chosen, posts in sanatoriums, or in our later lives the career of consultants for diseases of the chest.

To class the tuberculosis officers as a junior branch of the public health service, and suggest that it is a stepping stone to the post of medical officer of health, is an error, and creates the idea of a hybrid service into which no man would put his best energies; nor is it in keeping with the spirit of the recommendations of the Local Government Board and Departmental Committee.—I am, etc.,

HORACE WILSON, M.D., B.S. Lond.

Merthyr Tydfil, May 10th.

TRADE UNIONISM AND MEDICINE.

SIR,—It has come to my knowledge that members of the profession in certain areas resent the suggestion contained in my letter published in the *JOURNAL* of May 10th, p. 1030, that we should aim at the abolition of the panel system in the future.

May I explain that to my mind the ideal panel list is the *Medical Register*, and I look forward to the substitution of this for the publication of lists of panel doctors in post offices? Then any doctor who chooses to take patients at 7s. per head per annum can do so and will be paid in full for them, while any patient who desires to go on paying his fees can also do so. Such people should be allowed to contract out of the capitation system of payment, and be allowed at the end of each year to receive 7s. against any medical bills for that year that they may be in a position to present. I suggest that under such a system the medical profession retains its freedom, the community retains a large portion of its freedom, and better work will be done than by bringing the bulk of the community under a capitation system. Capitation is a bad system in its essence, although undoubtedly necessary for the poorer classes of the community. It should be restricted to these classes.—I am, etc.,

London, W., May 27th.

CHARLES BUTTAR.

FAT IN INFANTS' FOODS.

SIR,—Complaint having been made to me by Messrs. Allen and Hanbury that the proportion of fat in their infant foods given in the last edition of my book on *Food and Dietetics* is too low, I have had a fresh analysis of these preparations made, and find that the percentage of fat in their No. 1 and 2 foods should be 18.5 and 17.6 instead of 14.0 and 12.3 respectively as stated.

I am glad to have the opportunity of correcting this mistake and of pointing out that the proportion of fat in the No. 1 food when mixed ready for use is thus made practically the same as that in human milk. (See *Food and Dietetics*, third edition, page 470.)—I am, etc.,

London, W., May 22nd.

ROBT. HUTCHISON.

Medico-Legal.

MEDICAL INCOMES DERIVED FROM INSURANCE FUNDS.

AT the Lambeth County Court on May 20th a question arose as to whether fees due to panel medical officers could be garnished—that is to say, whether they are liable to be ordered by a court to be paid, not to the medical man concerned but to some creditor of his in part or full payment of a debt proved before and ordered to be paid by a court of law. His Honour Judge Parry delivered judgement to the effect that a garnishee order must be issued, but that as the court was entitled to temper the wind to the shorn lamb, the order would only affect about one-third of the arrested sum; the balance would be paid to the defendant.

ALLEGED NEGLIGENCE AT AN ISOLATION HOSPITAL.

IN the King's Bench Division, on May 23rd, damages in respect of alleged negligence in the treatment of a patient at its isolation hospital were claimed from the Hendon Rural District Council. According to reports in the *Morning Post* and *Daily Telegraph*, the patient, a boy suffering from scarlet fever, was admitted as a paying patient, and remained for sixteen days. Towards the end of his stay he developed rheumatism in the arm, and on removal to a nursing home symptoms of heart trouble supervened. He was ill for several months, and was now regarded as unfit to enter the navy. His rheumatism and heart trouble were ascribed to the way in which baths had been administered at the hospital. They were given in a verandah; the verandah was enclosed, but it was alleged that it faced north-east, and that the bath was within a few feet of the entrance door of the hospital, and that at the opposite end there was a hole in the wall owing to building operations being in progress. It was also alleged that there was negligence in other respects, there being a deficiency of egg-cups and glasses in the wards.

For the defence it was stated that when the boy first had his bath he was carried to and from it wrapped in a blanket by a nurse, that the partition separating the verandah from the open air had been rendered airtight by a special arrangement, that the doors and windows had been properly closed and the temperature was kept at one approximating to that of the wards. Medical evidence was also given to the effect that there was nothing inconsistent with the possible results of scarlet fever in the boy's condition subsequent to leaving the isolation hospital.

Rheumatism and endocarditis, such as that from which the boy suffered, might result from scarlatinal infection and ensue despite the most skilful treatment.

After prolonged consideration the jury returned a verdict to the effect that the defendants had taken all reasonable care in providing a competent staff, and that though a verandah did not seem to the jury a desirable place for the administration of baths to fever patients, the plaintiff had not suffered from any negligence on the part of the defendants.

The Services.

ROYAL NAVY.

ROYAL NAVY MEDICAL CLUB.

THE annual dinner of the Royal Navy Medical Club was held at Prince's Restaurant, Piccadilly, on May 23rd. The President on this occasion was Surgeon-General Arthur W. May, C.B., Medical Director-General, and the guests of the club included Sir Thomas Barlow, Bart., K.C.V.O., F.R.S., President, Royal College of Physicians; Sir Rickman J. Godlee, Bart., President, Royal College of Surgeons; Sir Archibald Geikie, K.C.B., F.R.S., President, Royal Society; and Surgeon Ed. L. Atkinson, who has recently returned from the Antarctic. Professor Harvey Littlejohn, Dean of the Faculty of Medicine, Edinburgh University, and Mr. W. Girling Bell, F.R.C.S., were also present as guests.

There was a large attendance of members and the meeting was in every way successful. The toast of "The King" was followed by that of "Our Guests," proposed by the President and responded to by Sir Thomas Barlow, Surgeon-General Sir James Porter, late Medical Director-General, then proposed the toast of "The President of the Dinner," and in his reply Surgeon-General May gave expression, on behalf of the Service, to the universal esteem held for Sir James Porter and the regret at his retirement.

Among the members of the club present were the following:

Surgeon-Generals.—J. J. Dennis, Charles James, A. J. J. Johnston, Christopher Pearson, K.H.P.

Deputy Surgeon-Generals.—R. Gavin Brown, W. M. Craig, F. J. Lilly, Lawrence Smith, M.V.O., G. Welch.

Inspector-Generals.—Henry Macdonnell, C.B., Belgrave Ninnis, C.V.O.

Deputy Inspector-Generals.—F. A. Jeans, J. McC. Martin, D.S.O.

Fleet Surgeons.—W. G. Axford, A. S. G. Bell, P. W. Bassett-Smith, C.B., F. W. A. Clayton, J. Chambers, W. R. Center, Sydney Croneen, E. C. Cridland, R. A. Fitch, A. Gaskell, A. F. Harper, Robert Hill, C.V.O., D. W. Hewitt, J. A. Keogh, Antony Kidd, M. H. Knapp, D. J. P. McNabb, W. L. Martin, P. M. May, R. C. Munday, C. J. Mansfield, M.V.O., J. A. Moon, J. Moore, E. S. Miller, C. L. Strickland, J. W. O. Underhill, A. E. Weightman, E. C. Ward, G. W. P. Waters.

Staff Surgeons.—P. Bolster, A. A. Forrester, H. Hunt, L. Lindop, J. McCutcheon, F. G. McKenna, C. A. G. Phipps, P. D. Ramsay, T. B. Shaw, E. G. Swan.

Surgeons.—A. F. Fleming, A. B. Marsh, J. H. B. Martin, N. C. Ridley, Campbell Ross, G. T. Verry.

Obituary.

WE regret to record the death of Dr. CECIL FERMIN LILLIE after an illness which commenced in December in South Africa and terminated in London on April 17th within a week of his arrival. Dr. Lillie, who had just completed his 40th year, was a son of the late Rev. William Lillie, rector of Newchurch, Kent, and commenced his medical education at Cambridge, where he took a Second Class in the Natural Science Tripos, 1894. He joined St. Bartholomew's Hospital as a university student, and within the next few years became M.R.C.S., L.R.C.P., and in addition to completing his medical degree examinations at Cambridge received the diploma in public health of that University in 1897. Meantime he had filled a number of appointments at his hospital and its school, including those of house-surgeon, clinical assistant in the nose and throat department, and assistant demonstrator of pathology. He was one of those who went out to South Africa as a civil surgeon during the war; on his return he proceeded to M.A., and then began to divide his time between a winter practice at San Remo and summer work in England. In 1907, however, he went out to Grahams-town, where he remained working at the Albany General Hospital for some two years. He then went up country to take temporary charge of a practice at Salisbury, and

on the return of its owner was invited to become a partner. Eventually, however, he decided to start a practice on his own account in Rhodesia, and on doing so met with the success to be expected of a man of his amiable personal qualities and wide experience in all branches of his profession. But at the end of last year misfortune overtook him; an attack of pneumonia was followed by pleurisy and pericarditis, and finally ended as already stated, Dr. Lillie, who was a member of the British Medical Association, contributed to our columns in 1902 a paper on the treatment of dysentery based on some of his experiences during the war, and in 1906 dealt with the incubation period of morbilli in the *Journal of St. Bartholomew's Hospital*. Dr. Lillie, who married in 1899 Caroline, youngest daughter of the late Rev. G. P. Percy-Ayscough, Vicar of Braybourne, Kent, and the Hon. Mrs. Percy-Ayscough, is survived by his wife and by three children, the eldest of whom is a chorister at Westminster Abbey.

DR. ACHILLES BARUFFALDI died at Milan on April 11th of pyaemia, contracted in operating on a puerperal woman. He had a high reputation as a gynaecologist, and was a prominent figure in the local world of sport. He was only 31 years of age.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degrees have been conferred:

M.D.—W. E. Hume, G. H. Harper-Smith, G. L. Webb.
M.B.—T. N. Wood.

Scholarship.

The electors to the Michael Foster Research Studentship in Physiology have given notice that an appointment thereto will be made this year. The regulations concerning the scholarship will be found in the *University Reporter* for February 6th, 1912.

THE VICTORIA UNIVERSITY OF MANCHESTER.

Professor of Clinical Medicine.

DR. ERNEST S. REYNOLDS has been appointed Professor of Clinical Medicine. Dr. Reynolds, who received his education at Owens College, is physician to the Manchester Royal Infirmary; he was at one time pathologist at the West Riding Asylum, Wakefield, and in addition to many contributions to medical literature dealing especially with neurology, he is well known as the physician who drew attention to the epidemic occurrence of peripheral neuritis due to the presence of traces of arsenic in beer. He is a Member of the Council of the British Medical Association, and was Secretary of the Section of Psychological Medicine at the annual meeting of the Association in Manchester in 1902.

CONVOCATION.

Parliamentary Representation.

At a special meeting of Convocation of the Manchester University on May 23rd, a resolution of a previous meeting came under review, which expressed the opinion that the right to parliamentary representation at present confined to certain universities should be extended to the universities now unrepresented. A motion was proposed to the effect that, having asked for parliamentary representation, the university principle of equal privilege for all its graduates should be maintained by the inclusion of women in the exercise of the proposed privilege. It appears, however, that the opponents of any parliamentary representation of any universities are fairly numerous, though most of them hold that all the universities should be treated alike. At the same time, under the charter of the Manchester University, women are eligible for every office in the university, and it was felt that it would be wrong if the first distinction were allowed to be set up in respect of parliamentary representation. Considerable discussion took place as to the most suitable form of words to meet the situation, and eventually the following resolution was adopted without opposition:

If the principle of parliamentary representation is to be extended to this university, Convocation wishes to affirm its desire that the university principle of equal privilege for all its graduates should be maintained by the inclusion of women in the exercise of this proposed privilege.

Diploma in Ophthalmology.

For some time past a movement has been on foot to induce the Manchester University authorities to institute a special diploma in ophthalmology. This has met with considerable opposition, and a motion by Dr. Goodfellow, "That, in the opinion of Convocation, the institution of a diploma in ophthalmology is not to be desired," was carried by 16 votes to 2.

UNIVERSITY OF EDINBURGH.

THE following bursaries have been awarded in the faculty of medicine: The *Mackenzie Bursaries* in Anatomy to A. J. Caird, F. R. Cripps, W. Goldie, and E. F. Griffin; the senior *John Aitken Carlyle* in practical anatomy and physiology to J. L. Owen; the junior *John Aitken Bursary* in anatomy and chemistry to J. S. Bow; the *Crichton Bursaries* to D. H. Cameron, J. Learmont, and W. G. Robson; the *Grierson Bursary* to G. J. Alexander. The *Van Danksop* Scholarship has been divided between A. Peffers and T. Skene.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following candidates have been approved at the examination indicated:

FIRST FELLOWSHIP.—A. C. Ainsley, A. Anderson, C. W. Archer, E. B. Barnes, H. E. Batten, C. F. Beyers, A. L. Blunt, J. F. C. Braine, C. M. Burrell, P. F. Chapman, F. B. Chavasse, G. H. Chisnall, W. A. Curry, R. G. Dainty, H. McW. Daniel, J. Davidson, T. B. Davies, M. Donaldson, J. D. Dyberg, H. H. Dummer, H. Evers, J. F. Fairley, E. Forrester-Paton, H. E. Gibson, D. W. Hume, J. G. Jones, T. H. Just, R. D. Lawrence, R. S. Lawson, G. L. Lillies, W. S. Lindsay, G. Lynden-Bell, D. A. McCombie, T. P. McMurray, J. T. Morrison, C. E. Petley, L. G. Phillips, K. N. Pankis, N. L. M. Reader, F. D. Sauer, A. Seddon, H. N. Shuttlebotham, R. F. Standage, T. C. Summers, R. E. T. Fatlow, D. C. Thomas, G. H. Wickens, C. M. Williams, C. R. Wright.

Medical News.

THE late Dr. Philip Frank, F.R.C.P., formerly of Cannes, left estate valued at £70,428.

A COURSE of five lectures and demonstrations on the psychoses and neuroses of children will be given by Dr. Francis Warner at the London Hospital Medical College, Mile End, E., on Thursdays at 2 p.m., beginning on June 5th.

UNDER the will of the late Mr. Abraham Haigh Crowther of Rochdale the infirmary in that town receives a bequest of £5,000 for the maintenance of five beds. Under the same will £5,000 is left to the Queen Victoria Memorial Nurses' Home in Rochdale for endowment purposes.

THE General Infirmary at Burton-on-Trent has received an intimation that the sons of the late Mr. Robert Ratcliff, a director of Messrs. Bass, Ratcliff, and Gretton, intend to present to the institution £20,000, a bequest of that amount having been included in a will which had not been signed when their father's death occurred.

THE Ingleby Lecture of the University of Birmingham will be delivered in the Medical Lecture Theatre by Professor J. T. J. Morrison, Surgeon to Queen's Hospital, at 4 p.m. on Thursday, June 5th. The subject of the lecture is spinal anaesthesia by tropacocaine, with a review of 1,000 cases.

THE *Annals of Tropical Medicine and Parasitology* (vol. vii, No. 1), issued by the Liverpool School of Tropical Medicine, contain several important papers on trypanosomiasis and malaria, including a description of a mosquito-proof and storm-proof house for the tropics, by T. F. G. Mayer, and a paper on Sanitation in the Panama Canal Zone, Trinidad, and British Guiana, by David Thomson.

THE attention of Fellows of the Royal College of Surgeons of England who desire to offer themselves as candidates at the coming election of members of council on July 3rd should be turned to the notice received from the secretary of the college, announcing that nomination papers may be obtained from him on application, and must be received by him in return not later than next Friday, June 6th. Our usual analysis of the present council appeared in the JOURNAL of May 24th.

THE election of officers for the Obstetrical and Gynaecological Section of the Royal Society of Medicine resulted in the appointment of Dr. W. S. A. Griffith as president, of Drs. T. Watts Eden and C. Hubert Roberts as honorary secretaries, of Dr. C. Cuthbert Lockyer as representative on the library committee, and of Dr. John Phillips as representative on the editorial committee. Nine vice-presidents and eighteen other members of council were also appointed.

DR. W. HORTON DATE, who recently left Cumnestock in Devonshire to devote himself entirely to public health work, was the recipient of a testimonial on May 19th from his former friends and patients. The gifts took the form of an oak sectional bookcase, a Chesterfield satin cabinet, a mirror, and a piece of silver, together with a book containing the names of the many subscribers, and a statement that the gifts were made as a token of sincere regard and gratitude. A corresponding presentation was also made to Mrs. Horton Date.

THE following have been elected officers of the Brighton and Sussex Medico-Chirurgical Society for the current year: *President*, Dr. W. Broadbent; *Vice-Presidents*, Drs. E. Hobhouse and F. Hinds; *Honorary Treasurer*, Mr. R. F. Jowers; *Honorary Librarian*, Dr. R. J. Ryle; *Honorary Literary Secretary*, Dr. S. B. Figgis; *Honorary Financial Secretary*, Mr. A. J. Martineau. A council consisting of nine members has also been elected. In this society the vice-presidents are chosen from among the ex-presidents, while those elected to the council must be members of at least three years' standing.

A SPECIAL post-graduate course is to commence at the North-East London Post-Graduate College on Monday, June 9th, and terminate on the 20th of the same month. The time has been very carefully mapped out, the first week being mainly devoted to practical instruction in the diagnosis and treatment of affections of the digestive system. The authorities, however, appear ready to arrange other classes in any subjects which may be desired. The fee for the whole fortnight is three guineas. The names of those wishing to attend should be sent to the dean at the hospital not later than June 6th.

THE annual report of the Royal Sanitary Institute recently issued shows satisfactory progress and development in the institute's work, both in England and other parts of the Empire. A new branch has been established in New Zealand, and the total number of members and associates on the roll is 4,257. An epitome of the three years' work since the institute was established in its new premises in Buckingham Palace Road is appended to the report; the attendance at the lectures of members, students, and the general public, indicates that the present situation of the institute is convenient. The institute has paid for the new buildings out of its accumulated fund, and the growth in the income has more than overtaken the increased expenses involved by the larger buildings.

ON May 10th the new building of the Henry Phipps Tuberculosis Institute at Philadelphia, which is under the direction of the University of Pennsylvania, was formally opened. On the occasion the honorary degree of LL.D. was conferred on Mr. Phipps, who has given £200,000 for the establishment of the institute and an endowment of £10,000 a year for its maintenance, and on Dr. Edward L. Trudeau, founder of the famous Adirondack Sanatorium. Addresses were delivered by Dr. Herman B. Biggs, of New York; Dr. W. H. Welch, of Johns Hopkins; Dr. Theobald Smith, of Harvard; Dr. A. Stenzel, of the University of Pennsylvania, and Dr. Weir Mitchell. The building is not primarily intended for a hospital, though it can accommodate twenty-four patients. Besides dispensary and hospital treatment of patients, the work of the staff will be sociological, educational, and preventive. The sociological work now in progress is the investigation of the relationship of tuberculosis to garment-making trades.

THE Surrey County Council has decided to provide medical treatment as a corollary of school medical inspection. The number of children whom it is believed will be inspected during the current year is 27,500, and it is estimated that 5,500 of these children will be found defective and to require treatment of some kind or other. It seems to be intended that this shall be furnished partly by whole-time medical officers and partly by private practitioners, and that there shall be 21 treatment centres, ultimately to be increased to 24. Operative treatment for diseases of the nose and throat is to be carried out at fixed fees by local medical practitioners, either at cottage hospitals, when available, or at school clinics, or failing either at the patient's home if the consent of the Board of Education can be obtained. Defective vision will usually be treated by the whole-time medical officers, but in certain districts local medical practitioners who specialize in this subject will be employed and will receive fixed fees. Subject to the consent of the Board of Education, x-ray treatment of ringworm will be undertaken by medical practitioners at a fixed fee either at hospitals or in local surgeries possessing the necessary equipment. The Surrey Education Committee formulated this scheme after several conferences with representatives of Surrey medical practitioners, and submitted it in outline to the Board of Education in January. The latter promised to contribute not less than 50 per cent. of the net cost, but stipulated that the local authority must retain full control over all arrangements for treatment. The Board would not approve the use of local surgeries except in special classes of treatment, such as x-ray work, and would hesitate to make any grant if the scheme included the payment of subsidies to medical committees or voluntary agencies.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Autology, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National).—
2631, Gerard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerard, BRITISH MEDICAL ASSOCIATION.
2634, Gerard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

DERMA asks for advice in the treatment of superfluous hair on the chin in a lady who objects to electrolysis. He asks whether avulsion, shaving, depilatories, or bleaching with hydrogen peroxide would be the best.

McW. asks whether there is any evidence that the sense of smell is stronger in man than woman.

. There is no evidence of any certainty that the sense of smell differs in acuity in the two sexes. Reference may be made to the following papers: Nichols and Bewley, *Nature*, 35, 74, 1887; Ottolenghi, *Riv. d. Psicol. Psichiatr. e. Neurol.*, 2, 1393; Toulouse et Vaschide, *C. R. Soc. Biologic*, 1899.

OXALURIA.

Z. asks for a reference to a discussion of the oxalic acid diathesis.

. We are indebted to Dr. Saundby for the information that, in his opinion, the best statement on oxaluria is contained in von Noorden's *Metabolism and Practical Medicine*, translated and edited by Walker Hall, vol. iii, p. 1046. The following dietary has been based by Dr. Saundby on Klemperer's principles; some salt of magnesia—for example, the chloride—should be given daily:

Breakfast.—Weak coffee and cream, sugar if desired; any fish or bacon; dry toast; butter; no milk or eggs.

Lunch.—Meat or fish of any kind, except liver, sweetbreads, and kidneys; toast or rusk; potatoes, lentils, peas, asparagus, turnips, lettuce, cucumbers, mushrooms, onions, salads; stewed apples; boiled rice or hominy; Vichy, Contrexéville, Salutaris, or distilled water; a little whisky if desired.

Tea.—Weak coffee with cream, as at breakfast; toast, teacake, or cake; butter.

Dinner. Soup; any fish; any meat, as at lunch; potatoes, rice, lentils, peas, turnips, onions, leeks, salads; mushrooms; stewed apples, pears, peaches, or apricots; no jellies or rich pastry; beverages as at lunch; apples, nuts; coffee.

LETTERS, NOTES, ETC.

HERPES AND VARICELLA.

DR. GEO. CHAS. WALKER (Southport) writes: On January 30th I was consulted by a nurse suffering from shingles of the left side of the body. In about fourteen days two of the children developed chicken-pox, and subsequently four others, going through all the phases characteristic of that complaint. I was at a loss to trace the source of infection in this instance.

SUPRARENAL ACTIVITY.

DR. J. BARCROFT ANDERSON (East London, S.A.) writes: On page 708 of the JOURNAL of April 5th I read: "The suprarenal is divided into two parts, the cortex and the medulla. . . . Now the changes that seem to indicate excessive activity of the suprarenals occur in the cortex." My experience with human *post-mortem* examinations is that in those cases where there has been a great call upon the suprarenal secretion before death the medulla is hyperæmic, enlarged, and in extreme cases broken down. In some cases, as in bubonic plague, one notices a hyperæmia of the cortex as well. Accordingly I presume that the remark in the JOURNAL is intended to apply to chronic activity.

MALINGERING.

SIR JOHN COLLIE (London, W.) writes: In a recent address on "Malingering, Valedudinarianism, and their Prevention," delivered before the Pathological Society of Manchester, and published in the BRITISH MEDICAL JOURNAL of April 19th,

1913, Dr. Byrom Bramwell referred to some misleading statements, which he said had been made at the last meeting of the British Medical Association in the course of discussion on medical training for the detection of malingering, with regard to the reaction of degeneration and the electrical testing generally of muscles. In the course of his remarks he said: "In a recently published book on malingering, equally erroneous statements as to the effect of electricity in cases of paralysis, and of the value of electrical testing in the diagnosis of malingering are made." I have been in communication with Dr. Byrom Bramwell, and I have his authority for stating that his criticisms did not refer to my book on malingering, but to an entirely different work.

SCARCITY OF SHIP SURGEONS.

LATE SHIP SURGEON writes: At present the many steamship companies are experiencing the greatest difficulty in obtaining surgeons. A large number of the companies have increased the pay from £10 to £12, £15, and £20 per month. Also, to obtain the best class of doctors, the companies have agreed to sanction the charging of medical fees for services to first and second class passengers. No fees can be charged to the crew nor to emigrants.

Many doctors complain bitterly of the action of those doctors who, going out to stay in Australia or New Zealand, sign on for a shilling a month, and of the doctors who, wishing for a cheap sail, sign on for a similar wage. Any sensible person must see that the action of these two classes of doctors tends seriously to lessen the social and professional standing of doctors generally. There is no reason why each doctor cannot obtain a minimum of £15 monthly.

Another thing which the ship doctor is now asked to do is to examine medically the crew before these sign the articles for the voyage. Many of the ship doctors are not paid one penny for this work; and, as the shore doctors are paid a fee of from £2 to £3, it is easily seen how the ship doctors are practically doing other doctors out of just fees.

My idea is that no doctor should accept any ship surgeoncy except through a medical agency, and that the deans of the various medical schools should so inform all the doctors, and that the British Medical Association similarly instruct them. In the better-class liners it is no exaggeration when one says that a month's salary is swallowed up in providing for the two suits of uniform now insisted upon.

THE TYPHOID CARRIER.

SURGEON-GENERAL VON SCHJERNING, Chief of the Sanitary Corps of the German Army, Professor Ehrlich, Professor Gaffky, Professor Kraus, Director of the Second Medical Clinic of the Charité of Berlin, Professor Uhlenhuth, Director of the Hygienic Institute of Strassburg, and Professor Hoffmann, of the Ministry of War, have issued a circular calling attention to the offer by an anonymous donor of a prize of Mk. 10,000 (£500) for the discovery of a remedy which shall free typhoid carriers from the bacilli which make them a danger to the people among whom they live. It must be shown that the intestinal excreta and the urine of the typhoid carrier have after treatment remained free for at least half a year from the typhoid bacillus. The researches must be described in detail and preparations must be sent at the competitor's expense to the committee for purposes of control. The period of control will extend to June 1st, 1915. If an entirely satisfactory solution of the problem is not reached, a portion of the prize may be awarded. Papers, which must be written in German, should reach the President of the Prize Committee, Professor von Schjerning, Wilhelmstrasse 86/87, Berlin, W., at latest by October 1st, 1914.

WARNINGS.

THE Oxford University Press desires to give notice to the profession that a man named John Williams is reported to have called upon doctors in North Wales, Lancashire and Cheshire districts, soliciting orders for the Oxford Medical Publications, and giving receipts in their name. The Oxford University Press can accept no responsibility for orders placed with him. Messrs. J. and A. Churchill also desire to state that the man calling himself John Williams is not in their employment, nor authorized to represent them.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restante* letters addressed either in initials or numbers.

A CLINICAL STUDY OF PNEUMONIA:

WITH NOTES OF

ONE HUNDRED CONSECUTIVE CASES OCCURRING
IN HOSPITAL PRACTICE.*

BY

JAMES ALEXANDER LINDSAY, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY OF BELFAST.

PNEUMONIA constitutes one of the most formidable problems which confront the physician. The disease is upon the increase; nothing is known as regards its prevention; it involves a very heavy mortality; the treatment is a matter of much difficulty and anxiety. On all these grounds it calls for the best thought and study which we can devote to it.

The series of 100 consecutive cases here recorded were treated in my wards of the Royal Victoria Hospital, Belfast, in the years 1899-1913. They are recorded as they arose, without any selection. The deaths include 2 cases which were moribund on admission. Hospital mortality is everywhere somewhat high, inasmuch as, speaking generally, only cases of considerable severity seek admission; patients are in some cases only admitted when the disease has run its course for several days; and the number of children admitted to general hospitals is relatively small. All these factors have a bearing upon the mortality.

I. Age.

| Age. | Cases. | Deaths. | Mortality. |
|-----------------------|--------|---------|------------|
| | | | Per Cent. |
| Under 10 years | 5 | 0 | 0 |
| 10-20 | 17 | 0 | 0 |
| 20-30 | 27 | 5 | 18.5 |
| 30-40* | 18 | 3 | 16.5 |
| 40-50 | 14 | 5 | 35.7 |
| 50-60 | 13 | 3 | 23 |
| 60-70 | 5 | 3 | 60 |
| Over 70 | 1 | 1 | 100 |

* Under 40 years—67 cases 8 deaths; average mortality 11.94 per cent.

This table brings out clearly the dominating influence of age. Under 20 years there were 22 cases and no deaths. Under 40 there were 67 cases, with 8 deaths—average mortality, 11.94 per cent. After 40 the mortality rose rapidly. The fact that the mortality was higher in the ages 40 to 50 than in the ages 50 to 60 was probably a casual fluctuation. The general influence of advancing years is clear.

II. Sex.

| Sex. | Cases. | Deaths. | Mortality. |
|----------------|--------|---------|------------|
| | | | Per Cent. |
| Males | 75 | 15 | 20 |
| Females | 25 | 5 | 20 |

The higher attack-rate in the male sex is in accord with general experience. The mortality was identical in the two sexes.

III. Occupation.

| | Cases. | Deaths. | Mortality. |
|--------------------------|--------|---------|------------|
| | | | Per Cent. |
| "Indoor" occupations ... | 55 | 10 | 18.18 |
| "Outdoor" occupations.. | 45 | 10 | 22.2 |

So far as these figures go, the influence of occupation upon the attack-rate and the mortality is not noteworthy.

Though Belfast is a great port, it is remarkable that only one sailor appears in the series, and he was a Hindu.

* Read at a meeting of the Ulster Branch in Londonderry.

HISTORY OF PATIENTS PRIOR TO THE ATTACK.

Alcoholism.

There was a definite history of alcoholic excess in 17 cases all males—of whom 4 died, 3 of these being over 40 years of age. This is a lower mortality in the alcoholic than might have been anticipated, especially in the light of the age law. Unacknowledged alcoholism was, no doubt, a factor in other cases—it is impossible to say how many.

Previous Attacks of Pneumonia.

In 18 cases there was a history of previous attacks, varying in time from thirty years to three months before admission. Of these only 2 died. One patient who had had two previous attacks recovered.

These statistics support the view that the prospects of a patient who has passed successfully through a previous attack of the disease are above the average.

Wetting and Exposure.

Only 6 patients attributed their attack to a wetting. Exposure is so common in patients of the hospital class that its influence as a causal factor cannot be determined with any accuracy. It has probably considerable influence.

Pulmonary Tuberculosis.

Twelve patients had a definite history of tubercle, and of these only one died. This tends to support the view that the prospects of phthisical patients in pneumonia are, on the whole, good. My experience in private practice confirms this view.

Abnormal Histories.

- 1 case followed immersion in the docks and proved fatal.
- 1 " " gas poisoning and also proved fatal.
- 1 " " ether administration—recovered.
- 2 cases were moribund on admission.
- 3 occurred during attacks of bronchitis.
- 2 " had previously had acute rheumatism—1 died.

The absence of a history of influenza is noteworthy.

Mode of Onset.

- 47 cases gave a history of one severe prolonged rigor.
- 1 case had two rigors.
- 1 " had three rigors.
- 1 " had several rigors.
- 1 " had "shivered for six hours."
- 1 " had "shivered for three days!"
- 48 cases gave no history of rigor.

Early prostration was marked in nearly every case. Only 2 cases remained at work after the initial rigor.

SYMPTOMS.

Most cases presented the typical pneumonic syndrome, but—

- (a) 5 cases were admitted as "abdominals"—namely, 3 as "colic"; 1 as enteric fever; 1 as subphrenic abscess. All these patients recovered.
- (b) 13 cases had persistent vomiting; all recovered.
- (c) 17 cases had albuminuria in considerable amount; of these 6 died—mortality, 35.3 per cent.
- (d) 7 cases had valvular disease of the heart; of these only 1 died—mortality, 14.3 per cent.
- (e) 3 cases had marked delirium; all died.
- (f) 1 case had practically no symptoms. In elderly patients the onset of pneumonia may be quite insidious.
- (g) A tinge of yellow in the conjunctiva was common, but marked jaundice hardly occurred.

Relation of Temperature to Mortality.

| Maximum Temperature. | Cases. | Deaths. | Mortality. |
|-------------------------|--------|---------|------------|
| | | | Per Cent. |
| Exceeded 105° F. | 1 | 1 | 100.0 |
| 104°-105° F. | 10 | 3 | 30.0 |
| 103°-104° F. | 39 | 7 | 18.0 |
| 102°-103° F. | 27 | 5 | 18.5 |
| 101°-102° F. | 7 | 4 | 57.1 |
| Under 101° F. | 16 | 1 | 6.25 |

The most noteworthy feature of this table is the high mortality in cases where the maximum temperature ranged from 101° to 102° F. A low temperature in pneumonia may indicate imperfect reaction, and is common in

the elderly and in the alcoholic. It may also indicate a mild attack. A smart pyrexia is not unfavourable.

Lung Involvement.

| | Cases. | Deaths. | Mortality. |
|---------------------------|--------|---------|----------------|
| (a) Double pneumonia ... | 13 | 7 | Per Cent. 54.0 |
| (b) Right base | 40 | 8 | 20.0 |
| (c) Left base | 31 | 2 | 6.4 |
| (d) Right apex | 5 | 1 | 20.0 |
| (e) Left apex | 3 | 0 | 0.0 |
| (f) All right lung | 4 | 1 | 25.0 |
| (g) All left lung | 4 | 1 | 25.0 |

These figures emphasize the deadliness of double pneumonia. They show a heavier mortality in right than in left pneumonias. They run counter to the view which has sometimes been maintained, that apical is more serious than basal pneumonia. In my cases, upon the whole, the contrary was the case. The moderate mortality in cases where an entire lung was involved is worthy of note.

Complications.

The complications recorded as having been present were as follows:

| | |
|---------------------------|----------|
| Pleurisy | 8 cases. |
| Empyema | 3 " |
| Pulmonary fibrosis | 4 " |
| Pharyngeal abscess | 1 case. |
| Gangrene of lung | 1 " |
| Pharyngeal abscess | 1 " |
| Unilateral spasm | 1 " |

No case of abscess of the lung was recorded. One patient developed aortic reflux during the attack. No clear case of malignant endocarditis occurred in the series, though its presence was more than once suspected. No patient, not previously tuberculous, developed phthisis as the result of his illness. Pleurisy was only noted as a complication where it was a prominent feature. No case of meningitis occurred. The small proportion of cases of empyema is noteworthy.

Course of the Disease.

Definite crisis, 52 cases—namely:

| | |
|-----------------------|---------|
| On the 3rd day | 8 cases |
| " 5th " | 19 " |
| " 7th " | 19 " |
| " 9th " | 3 " |
| " 11th " | 3 " |

It is curious how this table supports the old medical tradition that the crisis usually occurs upon the uneven numbers. A termination by lysis was recorded in 34 per cent. of cases.

Average duration of patients' stay in hospital: Uncomplicated cases, 23 days.

PATHOLOGY.

The pneumococcus was found to be practically constant in the sputum.

Seasonal Influence.

The attack-rate, as is shown in the following table, was

Influence of Season upon Attack-rate and Mortality.

| Month. | Cases. | Deaths. | Mortality. |
|------------------|--------|---------|----------------|
| January | 11 | 3 | Per Cent. 27.2 |
| February | 16 | 3 | 18.7 |
| March | 9 | 1 | 11.1 |
| April | 14 | 3 | 21.4 |
| May | 12 | 2 | 16.7 |
| June | 8 | 1 | 12.5 |
| July | 3 | 0 | 0 |
| August | 4 | 0 | 0 |
| September | 5 | 2 | 40 |
| October | 4 | 1 | 25 |
| November | 7 | 2 | 28.5 |
| December | 7 | 2 | 28.5 |

much higher in the months November to May than in the months May to November. The mortality shows some curious fluctuations in the monthly averages, but is, upon the whole, higher in the months of greater prevalence of the disease.

Comparative Virulence of the Disease in Different Years.

There is evidence that the disease varies much in intensity in different years. The following table is instructive from this point of view:

| Year. | Cases. | Deaths. | Mortality. |
|-------------|--------|---------|-------------|
| 1899 | 3 | 0 | Per Cent. 0 |
| 1900 | 2 | 0 | 0 |
| 1901 | 1 | 1 | 100 |
| 1902 | 4 | 0 | 0 |
| 1903 | 12 | 1 | 8.3 |
| 1904 | 3 | 1 | 33.3 |
| 1905 | 3 | 1 | 33.3 |
| 1906 | 9 | 3 | 33.3 |
| 1907 | - | 3 | 33.3 |
| 1908 | 8 | 0 | 0 |
| 1909 | 10 | 2 | 20 |
| 1910 | 8 | 0 | 0 |
| 1911 | 14 | 5 | 35.7 |
| 1912 | 7 | 0 | 0 |
| 1913 | 7 | 3 | 43 |

Thus in six years out of fifteen the mortality was nil, while in seven years it was over 30 per cent. This can hardly have been a matter of chance. We must assume variations in the intensity of the virus of the disease. I cannot trace any connexion between varying rates of mortality and the meteorological characteristics of the different years. None of the years in the record were specifically "influenza years."

MORTALITY.

The general mortality was 20 per cent., or, omitting, as we may fairly do, two cases which were moribund on admission, 18 per cent. This is roughly the average mortality of the disease in general practice, including all ages and every degree of severity, but hospital statistics, which are usually less favourable, often show a much higher figure. Osler's mortality in his clinic at the Johns Hopkins Hospital was 30.4 per cent., or, excluding some cases of terminal pneumonia, 26.4 per cent. Goodhart had 25 deaths in 120 cases. At the Presbyterian Hospital, Philadelphia, the mortality was 28.7 per cent.; at the Montreal General Hospital, 20.4 per cent.; at the Boston City Hospital, 29.1 per cent. On the other hand, Fraenkel at the Hamburg Hospital had a mortality of 19.2 per cent., and Powell at the Middlesex Hospital a mortality of 17 per cent.

PROGNOSIS.

The prognosis is determined mainly by the following factors, namely:

- (a) The patient's age; this dominates the outlook.
- (b) The amount of lung involved. Double pneumonia is very deadly.
- (c) The general character of the symptoms. Marked cerebral involvement is very serious. Very high temperatures are grave, while abnormally low temperatures may indicate either a mild attack or deficient reaction. The latter is common in the aged and alcoholic. Slight febrile albuminuria has little weight, but signs of marked renal congestion are serious.
- (d) The nature of the complications. Gangrene and abscess of the lung are very serious. Pericarditis, of which curiously there is no record in any of my series of 100 cases, but which is not extremely rare, is a grave complication, and malignant endocarditis carries with it an almost certainly fatal issue. Meningitis is another rare complication which usually involves death. The good

record of my cases with endocarditis—7 cases with 1 death—is somewhat surprising.

DIAGNOSIS.

The diagnosis of pneumonia is usually obvious, yet mistakes are common, and not always due to carelessness on the part of the practitioner. In a small minority of cases the diagnosis is really difficult. Mistakes arise in the following ways:

1. Because the physical signs may be entirely latent for one, two, three, or more days. It is not very rare for a patient to have a typical seizure and to present all the typical symptoms while the most careful exploration of the chest fails to yield any definite signs. The sudden onset, the initial rigor, the sharp pyrexia, the urgent dyspnoea, and the rapid prostration should suffice to put us on our guard in such cases.

2. Because the early symptoms may be mainly cerebral—namely, intense headache, convulsions, delirium, excitement, or coma. The unwary practitioner is apt to diagnose these cases as meningitis or acute mania, but movements of the alae nasi, the temperature, the burning skin, and the signs in the chest make a correct diagnosis easy.

3. Because abdominal symptoms may be prominent at the outset, especially abdominal pain. Five instances of this unfortunate error are recorded in my series, three cases being mistaken for "colic," one for enteric fever, and one for subphrenic abscess. But this by no means exhausts the category of abdominal conditions which have been confused with pneumonia. Perforation of the stomach or bowel, appendicitis, peritonitis, and even acute pancreatitis have been wrongly diagnosed and laparotomies needlessly performed. These mistakes are easily avoided by attention to the history, the mode of onset, the temperature, the dyspnoea, and the physical signs in the chest.

4. Because certain of the specific fevers have occasionally a pneumonic onset. I have seen several cases of enteric fever which began with pneumonic symptoms and signs and where the diagnosis at first was difficult. But if we are on our guard we need not fall into error. Some of the characteristic signs of enteric will soon appear. An enlarged spleen, a suspicious spot or two, a significant course of the temperature, or Widal's reaction, may give us the necessary hint. In some countries, in the presence of an untypical pneumonia, our thoughts should turn to plague.

I will not occupy your time by a discussion of the differentiation of pneumonia from pleurisy, bronchopneumonia, or pneumonic phthisis. Every textbook on medicine does full justice to such matters.

TREATMENT.

It remains to speak of treatment. I shall first indicate my own methods and then deal with two or three controversial points.

I treat pneumonia as an acute general infection, with special impact upon the lungs, inducing a very intense type of toxæmia, and involving special danger from the side of the heart. Everything that tends to conserve the patient's strength and remove sources of irritation receives attention. Our system of ventilation at the Royal Victoria Hospital, which changes the air seven times in each hour, secures an abundant supply of pure air. Only milk is allowed—three pints in the twenty four hours—any excess of nourishment being regarded as likely to remain unabsorbed, and to distend the stomach, and embarrass the heart. A light warm poultice, frequently renewed, is applied to the chest, care being taken not to embarrass the respiratory movements, and after the third or fourth day this is replaced by a jacket of cotton-wool. In the hope of diminishing the toxæmia the skin, bowels, and kidneys are gently stimulated, all remedies which might tend to depress the heart being avoided. If the patient is in great pain or very restless a hypodermic of morphine or a few grains of Dover's powder are administered.

In the presence of any signs of circulatory weakness strychnine is given hypodermically, and ammonia and digitalis, and sometimes caffeine, by the mouth. Alcohol is used sparingly, and only in the more serious cases and in moderate or small quantity. Of the 100 cases in my series, only 39 received any alcohol. Brandy was the usual stimulant, and the amount seldom exceeded three or

four ounces. In the presence of unusual dyspnoea or cyanosis oxygen is administered, the gas being passed through alcohol. Tepid sponging is vigorously practised in every case, and cold sponging when the indications seem to point to its use. Antipyretics or expectorant drugs are not administered.

Bleeding was not employed in any of this series of cases, though I have had some small experience of that procedure elsewhere. For the relief of persistent insomnia paraldehyde, bromides, and morphine are sparingly used. The various complications, when they arise, are treated upon the usual lines. After the crisis all special medication is suspended, the patient is allowed a liberal diet, and some tonic is administered. Alcohol is always stopped at this stage, unless there are serious complications.

The above represents a comparatively simple therapy, and I am persuaded that fussy and meddling treatment in pneumonia does more harm than good.

In conclusion, let me deal briefly with some controversial points. I have never used icebags or ice poultices to the chest in pneumonia, and I can furnish no evidence as to their value. This method of treatment does not appear to be gaining favour. There seems to be some danger that it might depress the heart. As elots are found *post mortem* in the right heart in many fatal cases of pneumonia, I tried the administration of citrates and citric acid in a few cases some years ago, but I could not satisfy myself that this line of treatment presented any advantage. I have made a limited trial of serum treatment, but have not felt encouraged to persevere with this method. On theoretical grounds pneumonia seems a particularly unpromising field for vaccine therapy. We may yet get an efficient serum, but up to the present no such remedy appears to be available.

I have seen bleeding employed in a few cases, and there is no doubt that the removal of a few ounces of blood tends to relieve the labouring right heart, and to mitigate the dyspnoea. But I have no wish to see this long-discarded method reintroduced into general favour. If applied without great discrimination, it is quite capable of turning the frail balance against a patient at the critical juncture. We should need some definite statistics to prove the efficacy of venesection before adopting it as a common expedient. Textbooks give the practice a sort of qualified benediction, but cautious practitioners are shy of it at the bedside.

The value of alcohol in pneumonia is a vexed question. I incline to its use in moderate quantity in severe cases, and in the presence of circulatory weakness, especially in patients who are no longer young and who have been accustomed to it in health. In mild attacks, in most young patients, and where the pulse is good, it is better withheld. It should certainly not be given in any routine fashion or in the excessive quantities which were at one time in vogue. If we may often be in doubt as to the wisdom of prescribing alcohol, we can generally toll without much difficulty whether, when given, it is proving of service. The effect upon the pulse, the nervous system, the skin, the urine, and upon sleep are the chief points which should guide us in this matter.

Among the errors to be avoided in the treatment of pneumonia we might signalize the following: Neglect of thorough ventilation; forgetfulness of the fact that any local applications which impede the free movements of the chest are likely to do harm; the use of expectorants which are probably inert; the excessive employment of strychnine and cardiac tonics in the absence of signs of circulatory weakness; too much timidity in the use of sedatives in the early days of the disease; too much nourishment; too free exhibition of alcohol.

In the treatment of unresolved pneumonias every case must be dealt with according to its special indications. Counter-irritation is usually employed, and fibrolysin and the x rays are recommended. Our main reliance, however, will probably be upon general tonic and hygienic measures and change of air. Mountain air is often useful.

To sum up, we should treat pneumonia on the lines of the acute general infections, remembering the intensity of the toxæmia, its self-limitation and relatively brief duration, its tendency to depress the heart and cause circulatory failure, the increase of the fibrin elements in the

blood, the importance of a fortifying line of treatment and of avoiding all depressing measures.

The problem of specific treatment still awaits solution.

(I have to acknowledge the valuable assistance of my house-physician, Dr. Turkington, in preparing the data for this paper.)

A Lecture ON RADIUM IN THE TREATMENT OF MALIGNANT DISEASE.

DELIVERED AT THE CANCER HOSPITAL, BROMPTON.

By ROBERT KNOX, M.D.,

DIRECTOR OF THE ELECTRO-THERAPEUTIC DEPARTMENT OF THE
HOSPITAL; AND HONORARY RADIOGRAPHER TO
KING'S COLLEGE HOSPITAL.

The action of radium on human tissues was accidentally discovered by Bécquerel in 1901. He carried a quantity of unprotected radium in one of his pockets for a time. A fortnight later a burn appeared on the skin. This accident quickly led to a number of experimental exposures, first on animals and later on human subjects. Wickham of Paris experimented largely with the new agent, and there is no doubt that the medical profession is greatly indebted to this pioneer in radium-therapy, both for the valuable work he has carried out himself, and for having stimulated others to work on the subject.

Remarkable success followed the use of radium on superficial lesions of the skin; naevi, keloid, lupus, rodent ulcer, and, later, epithelioma, have yielded to its curative power.

METHODS OF APPLICATION.

The emanation may be used for inhalation alone or mixed with oxygen, by injection, or, after its deposition upon metals, in glass tubes or on agar pads.

Inhalation has had up to the present no practical value in the treatment of malignant disease. The emanation may be injected into tissues in a saline solution. The solution takes up a very small percentage of the active gas, and is therefore hardly applicable for the type of case we are usually called upon to treat.

The deposition of the active principles upon metals, etc., opens up a large field of usefulness, and it is possible that in the future we may be able to make good use of this method in selected cases.

Experiments are being carried on by Mr. Phillips, the honorary physicist to the hospital, on the absorption power of petroleum, and we hope to get a fairly large percentage of the emanation taken up by petroleum, giving us a very active preparation which may be useful both for internal administration and for injection into the tissues; by the former method it is hoped that we shall be able to introduce into the system a large quantity of radio-active matter. We cannot expect to influence cancer and similar disease, but Dr. Bellingham Smith has shown that radium emanation in whatever form it is used is rapidly eliminated by the respiratory organs, so that a future field of usefulness for radium may lie in the treatment of respiratory diseases (phthisis, asthma, chronic bronchitis, etc.).

The deposit of emanation upon flat surfaces (pads of agar-agar) and their application to the surface of a growth and ionization of the particles into the deeper structures by the aid of a galvanic current may prove to be a useful method.

Flat applicators containing the radium in a varnish are useful in the treatment of rodent ulcer, superficial epithelioma, recurrent nodules of cancer, etc. It is chiefly the beta rays which are employed by this method.

Radium contained in metal tubes which act as filters, of the necessary thickness, may be used for particular purposes, and several tubes may be arranged around a growth.

Tubes may be inserted into the various cavities of the body (mouth, oesophagus, etc.). In treating a stricture of the oesophagus, a preliminary x-ray examination is necessary to locate the stricture and to give some idea of the

extent of the malignant growth. A bismuth cachet is swallowed by the patient, and when screened may be seen passing down the oesophagus. Should there be obstruction, the cachet will be found in the stricture. The exact situation of the obstruction can be determined before the radium tube is passed into it. Later, a radiograph will help us to ascertain if the tube occupies the correct position necessary to influence the growth.

Radium tubes may be buried in the substance of a tumour for a time determined beforehand. It is important that the tubes shall be well surrounded by the growth in order to get the maximum effect of the radiations upon the new growth: the tubes should be placed at equal distances from one another to ensure an equal distribution of the radiations.

ACTION OF RADIUM UPON TUMOUR CELLS.

The action of radium on tumour cells is not purely caustic, though caustic effects can readily be produced if the exposure is too prolonged or the filtration is insufficient. In some growths we deliberately make use of the caustic action to produce necrosis of the mass, in the hope that when the slough separates the normal tissues will fill in the resulting ulcer.

Occasionally enlarged glands are reduced in size with hardly any skin reaction; nothing more than a slight erythema may be produced even after repeated exposures to the same area of skin, yet the enlarged glands situated at a much deeper level slowly diminish in size.

Malignant indurated ulcers will rapidly break down and heal under the action of radium.

The degree of action induced is dependent upon the method of application. The various degrees of tissue change depend upon the filtration employed and the length of the exposure. Thus, if necrosis of the growth is necessary, a thin filter would be used and a long exposure given. Here we are making use of the beta ray almost entirely. Should it be necessary to act on a deeper structure and at the same time protect the skin from such action, a thick filter of platinum or lead is used. Two millimetres of platinum or four of lead are sufficient to cut off all but the hardest of the beta rays, while the gamma ray is unaltered. The filters containing the radium are enclosed in a rubber tube to prevent the secondary radiation induced in the platinum by the radium rays from damaging the superficial structures. If the exposure be long, further protection can be secured by using an inch or more of lint or gauze tissue.

In this way we can control the exposure so that we get nearly the pure gamma-ray effect. This enables us to get an action upon the deep seated parts.

It has been claimed that radium possesses a "selective action" on cancer cells. While admitting that it undoubtedly appears to act on such cells, the word "selective" is badly used. Radium exercises an action on all living cells in a varying degree according to the resistance of the particular cell in question. Thus, young actively growing cells are more readily influenced than mature cells. The cells of a new growth approximate in structure and power of resistance to the actively growing cells of a tissue. In this way it is conceivable that the cancer cell is influenced should it at the time of exposure be attacked comparatively early in its life-cycle. Should the cancer cells be of a stronger or more vigorous type, it is conceivable that the action of the radium may be stimulating, and instead of a decrease in vigour of a particular cell we may find an increase in activity, and a consequent increase in the size of a tumour. It is a fact that some cases of cancer increase in size at a quicker rate after radium has been applied. Some types of cancer are more amenable to radium treatment than others.

In addition to the action upon the cancer cell itself, radium acts upon all the tissues composing the growth and surrounding structures unequally. There is a general stimulation of the healthy tissues as a result of radium treatment so long as the exposure is not excessive. If it should be excessive the action is apt to produce a caustic and ulcerative effect, which leads to local death of the tumour and a portion of the tissues around it. This may sometimes be desirable.

When the effect upon the healthy tissues is confined to stimulation, we expect to find an increase of fibrous tissue formation which shuts off the cancer tissue from its blood

supply and causes the atrophy of such cells. The reparative power of the normal tissues is strengthened, enabling them to cope with the invading cells and lead to their destruction. These changes can be seen in sections removed from cases undergoing treatment.

The changes induced in malignant growths by the action of radium and similar agents are, so far as we can see, indistinguishable from the degenerative changes seen in cases of growth which have received no treatment; but this important point must be insisted upon: that the percentage of cases in which we see these changes is much larger in the group of cases treated by radiations than in the group which has received no treatment.

It must be admitted that occasionally we see a case of untreated cancer diminish in size and, in a very small percentage, ultimately disappear. During the treatment of cancer by radiations it is by no means uncommon in a fairly large percentage of our cases to see a marked diminution in size produced. In a smaller percentage we do see the growth disappear—at all events for a time.

The local disappearance of a growth is not a cure. The disease may have, and in the majority of cases undoubtedly has, extended to other parts of the body. Consequently no case can be said to have been cured until we have given the deeper ramifications of the growth sufficient time to develop and manifest their presence. It is therefore important that before we treat the local condition a search be made for secondary deposits. From the point of view of prognosis, this is a most important matter.

Of the means we possess of ascertaining the secondary spread of cancer the first important point is to remember the distribution of the lymphatics draining the area in which the growth shows itself. Recent improvements in radiographic technique enable us to examine the thorax and other parts for secondary deposits in the mediastinum, pleura, or lungs.

A man, aged 24, came for the treatment of a growth of the lower jaw, in itself a serious condition to deal with, because at that age the progress of a new growth is rapid and exceedingly difficult to check. An examination of the thorax revealed a large secondary growth in the right lung. One has to treat such a case, but the result can easily be foretold.

In another case a parotid tumour had been operated upon on several occasions, and latterly the condition had practically disappeared under radium. The patient appeared to be in good health, but had lost a great deal of weight in a few months and complained of occasional attacks of dyspnoea of short duration. A radiograph showed that both lungs were riddled with secondary growths.

A woman, aged 55, had her left breast removed. She came for prophylactic x-ray treatment. The scar was free from secondary deposits, but she complained of a deep-seated pain at the upper end of the sternum, and secondary deposits were discovered in the anterior mediastinum.

One more case may be quoted. A patient, who had the left breast removed about a year earlier, came for the treatment of recurrent growth in the scar, axilla and supraclavicular region on the left side. For several months she had complained of a severe pain on the right side of the sternum, deep seated and gnawing. Several screen examinations and radiographs failed to reveal the presence of definite recurrence on the right side. She was carefully watched, and another radiograph revealed the cause of her pain. A well marked secondary nodule could be plainly seen, and in addition, on the left side, a supraclavicular gland.

This case is most instructive. It illustrates a point I am anxious to emphasise, namely, that regular examinations at intervals should be carried out on all patients undergoing treatment, either curative, palliative, or prophylactic.

SELECTION OF CASES FOR RADIUM TREATMENT.

The class of case which offers the best results in radium treatment also holds out the best promise of success by operation. The earlier we can treat a case of malignant disease the surer can we be of the result. At the very outset we must decide between the two, and in the present state of knowledge of radium and its effects upon new

growth the choice must be given to early operation. We cannot tell when a case is going to do well under radium. Two cases of the same disease, and to all appearances precisely similar, may react quite differently to radium. Further, should the growth not promptly yield to the treatment, it may happen that the stimulation of the tissues composing the growth leads to a rapid extension of the disease: secondary nodules appear at the periphery of the tumour and grow rapidly, or metastases may appear quickly in deeper parts. Even when, to all appearances, the growth has disappeared, sooner or later recurrences may follow, and this after what at the time seemed adequate prophylactic treatment.

Rodent ulcers, when treated early, are particularly amenable to radium. They remain healed for considerable intervals, yet in the end a small recurrence appears at the periphery of the ulcer, and if not promptly dealt with may spread. Repeated recurrences have frequently to be dealt with in the same patient.

Admitting that in every early case of malignant disease operative measures should come first, there are some conditions when radium should be our second choice:

1. The patient may refuse operation, and thorough treatment by radium in early cases may lead to a disappearance of the growth.

2. Or the patient may not be in a suitable condition for operation, and again radium may be found useful.

3. Or it may be that the operation must be so radical that the risk to life is great. Radium should here be given careful consideration as a remedial agent.

4. Inoperable cases of malignant disease are generally handed over for radium treatment. Many of these are hopeless from a curative point of view. Here radium will relieve pain, diminish discharges, check haemorrhages, and frequently heal up ulcers of considerable size.

For comparison of results, it is well to subdivide the group of inoperable cases into the following classes:

- (a) Advanced cases of malignant disease, in which it is obviously impossible to hope to do anything beyond relieving the pain and other distressing symptoms. This relief is sometimes a marked feature in radium treatment. Discharges may be lessened, and where haemorrhage is a feature in the case, especially if it be a general oozing from the growth and surrounding tissues, a sufficient exposure to the action of radium will lead to a cessation of the bleeding. Failing the prospect of achieving either of these results, such advanced cases should be left severely alone, as their treatment by radium can only bring discredit upon it.

- (b) Less advanced cases, in which there may be a prospect of inducing degenerative changes in the tumour mass which will lead to a diminution in size. Some cases may thus be brought within the range of operative treatment. The method of treatment adopted must be thorough: full exposures given at regular intervals and the patient kept under observation. The treatment may be external, or, in selected cases, tubes of radium may be buried in the substance of the growth. Inoperable tumours of the breast come under this heading.

Surgical methods may profitably be combined with the use of radium, and partial operations are a great help to the radium therapist, as it is quite rational to remove as much of the tumour as is possible in order to facilitate the use of radium. A large fungating necrotic tumour of the breast is not likely to yield to radium treatment alone, but if the surgeon removes as much of the growth as possible, then radium may be employed on the portions of the tumour left. Secondary deposits in the glands and areas drained by the lymphatics may be vigorously treated by radium, and if a diminution in size is brought about these may be removed at a subsequent operation. Life may be rendered more tolerable, and undoubtedly prolonged by such measures. Several such cases treated by radium and x-rays have shown marked improvement; enlarged malignant glands have been successfully removed after reduction in size following upon radiation treatment.

While admitting the claims of operative measures in dealing with early cases of malignant disease, and with no intention of pushing the claims of radium, I should like to quote two or three cases which were in my own, and in the opinions of several surgeons, operable, but the patients refused operation and were treated by radium.

A case of endothelioma of the soft palate with a secondary gland in the neck was operated upon for the removal of the gland; a portion of the growth in the palate removed for microscopic examination showed it to be a slowly-growing endothelioma. The palate growth was of considerable size; under radium treatment it slowly subsided and practically disappeared. The case was treated nearly three years ago; to-day the patient is in hospital for a recurrence of the growth in the posterior aspect of the soft palate. She has been quite comfortable during the time that has elapsed since she was first treated. I have no doubt she will derive benefit from further treatment by radium.

A gentleman about 60 years of age was referred to me for treatment of a growth in the right tonsil involving the soft palate and uvula. He was seen by several surgeons, but refused to have an operation performed. A section removed for examination showed the growth to be an epithelioma. A gland removed from the left side of the neck was inflammatory; a number of enlarged glands were present on both sides of the neck. Under radium treatment the growth slowly diminished in size; a portion removed later still contained malignant cells, but they were changed in character and surrounded by inflammatory products. The glands in the neck slowly subsided. To-day the patient is perfectly well and free from recurrence.

Rodent Ulcer.

Early cases are readily influenced by treatment. They quickly heal, but prophylactic doses should be given after the ulcer has healed. If the condition is quite superficial the filtration need not be great. The beta rays appear to exercise a profound change in these cases. After healing has taken place filtered doses should be used to reach the deeper parts. Even after thorough prophylactic treatment recurrences are apt to follow at longer or shorter intervals, but frequently respond to further treatment. All cases treated should be kept under observation for a considerable time in order that an early stage of the recurrence may be observed and promptly treated.

When the ulcer is large and involves bone and cartilage the prospect of a cure is not so good. Most complete and powerful dosage may fail to check the progress of the disease. These cases may be even stimulated by radium treatment and increase rapidly in size. In such cases it is better to combine surgical measures, such as scraping or excision, with radium treatment. Several cases so treated have healed and remained well.

Epithelioma.

Growths in the skin are sometimes successfully treated by radium. Here again the excision of the growth and after-treatment by radium commends itself as a rational method of cure.

When the mucous membrane is involved greater difficulty is experienced in influencing the growth favourably. Some growths of the mucous membrane of the mouth and pharynx are hardly influenced by radium.

Epitheliomata which have healed may break down later and grow rapidly. Secondary involvement of glands must be treated as well as the primary growth.

Sarcoma.

The round-celled variety seems to be the type of growth most readily influenced by radium. Large tumours may gradually diminish in size, smaller growths disappear, while secondary glands also clear up. The spindle-celled variety is not so readily dealt with, possibly because it is a more active type of growth. When the mediastinum is involved, exposures may be made over the sternum and ribs in the hope that the disease may be checked.

Cancer of the Breast.

This class of cases forms a large percentage of those sent for radium treatment.

Secondary deposits may be met with in the glands of the axillary and supraclavicular regions. These may be treated at the same time as the primary growth. Secondary deposits in the cartilage of the ribs or sternum may also require treatment. Prolonged exposures to large quantities of well-filtered radium have in several instances led to a diminution in the size of the growth.

Cancer of the Oesophagus.

This condition has been treated with a beneficial result for a time; a number of patients have gained weight and retained the use of the oesophagus up to the time they died of secondary growth in the mediastinum.

Cancer of the Rectum.

Symptoms may be relieved for a time. The radium must be passed into the stricture, otherwise it may act as an irritant to the healthy mucous membrane, and increase the distressing symptoms so common in this situation.

Cancer of the Cervix Uteri.

Radium treatment may also benefit this condition; haemorrhage and discharge are lessened, and great relief of pain is a frequent result of treatment.

Cancer of the Bladder.

If a tube can be introduced into the bladder and brought in contact with the growth, relief may be obtained.

FACTORS INFLUENCING THE RESULT OF TREATMENT.

In routine treatment by radium, the following factors should always be kept in mind, as a full consideration of all in each case will help us to foretell the degree of action and the result likely to follow from treatment:

- (a) Type of growth and condition of patient.
- (b) Situation of the tumour, size, etc.
- (c) The quantity of radium used.
- (d) The filtration employed.
- (e) The duration of the exposure.

An improvement in the results at present obtainable by radium in the treatment of malignant disease may be obtained:

(a) Larger quantities of radium may be used. Up to the present the largest quantity used has been about 1 gram of pure radium salt. Far-reaching effects may be produced by such treatment, especially if the filtration is great and the exposure prolonged; yet, even with such a dose, the result in one or two cases has been temporary benefit only. The type of case so treated has been a deep-seated growth which could only be acted on by the very penetrating rays. For surface lesions the increased dosage may have a speedier effect, which should help to prevent the spread of the growth to deeper structures if it can be efficiently checked.

(b) A more thorough knowledge of the physical properties of radium may enable us to select for particular cases the quality of radiations likely to influence the cell metabolism.

(c) Improvements in the technique.

It must be admitted that the technique has hitherto been more or less faulty. A knowledge of the influence of the various thicknesses of filters may help us to get speedier results. It may be that the use of the beta rays in some cases would lead to better results. Similarly the alpha rays, which up to the present have been little used, may in the future be found to exercise an inhibitory effect upon morbid processes when they are brought into contact with the cells of a growth. The difficulty has been to apply them at all. The radio-active waters at present in use do not appear to have any influence on cancer cells when administered by the mouth.

It may be possible to deposit the active principles of the radium emanations in such a way that we can utilize them either by direct application or by ionization with the aid of a galvanic current, or a combination of radiations may be helpful. In several cases radium and α rays appear to have hastened reparative processes. It is possible that some of the effects noticed may be due to secondary radiations, produced in the structures composing the growth, which exercise a physiological action. Some such general action appears to take place, because it is quite a common occurrence for patients so treated to improve in general health.

The employment of radiations in any form leads to a constitutional disturbance which we designate as reaction. This varies in time of onset according to the dosage. After a time a period of depression sets in, most probably due to a change set up in the growth which leads to the liberation of toxins into the circulation. If they are excessive, the condition of the patient may be rendered serious. This form of toxæmia is met with when large rectal growths are treated. It is possible to make the condition of the patient much worse if care is not taken to regulate the dose.

Up to the present the treatment of malignant disease by radium and other radio-active bodies has been purely local. Consequently it cannot be regarded as a specific

method of treatment. The conditions under which it may become so are being investigated. The endeavour must be to procure a substance, radio-active or not, which, when introduced into the general circulation, will influence morbid processes in the tissues. It may be possible to use a substance which when treated locally by radium, x rays, or other agents capable of exciting the secondary radiations of such substances, will benefit the tissues.

The best we have yet been able to do has been by local stimulation to produce secondary radiations from the tissues, blood, and lymph in the deposits of cancer. When the secondary radiation value of these tissues is better known, and when we know which particular radiation acting upon them will give us their maximum value, then we may hope to improve our results.

CONCLUSIONS.

1. In all cases of early cancer the operative method is undoubtedly the best; it is quicker, safer, and offers the best prospect of cure.

2. Radium is a useful adjunct to the treatment of all cases, first as a prophylactic after operation, and, failing operation, the next best method we possess. It must, however, be stated that x rays are in selected cases quite as useful as radium.

3. In patients who refuse operation, or are for other reasons not suitable for operation, radium is a useful remedy.

4. In inoperable cases radium may help to render the case operable; and, failing that, is undoubtedly useful as a palliative measure.

DIACHYLON OR DUTY: A CALL TO ACTION.

By SIR THOMAS OLIVER, M.D., LL.D., D.Sc.,
F.R.C.P.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE,
UNIVERSITY OF DURHAM COLLEGE OF MEDICINE,
NEWCASTLE-UPON-TYNE.

It is now several years since I drew attention to the fact that not only is the female white lead worker more predisposed than the male to plumbism, and to the worst types of it, but that lead probably exerts its baneful influence upon her through the medium of the reproductive organs. A female lead worker, if pregnant, frequently miscarries, so that expected maternity in many instances can only be realized by women when *enccinte* keeping away from the lead works altogether. In pressing the Home Office, through the White Lead Committee, of which I was a member, to abolish female labour in the dangerous processes of lead manufacture or where lead compounds are manipulated, I based the recommendations upon the idiosyncrasy of the female sex generally, upon the disastrous effects of lead upon offspring born either prematurely or at term, and also upon the fact that most of the children born of women who work in lead die from convulsions a few hours or several days after birth. Experience has shown that by the abolition of female labour in the dangerous processes of lead manufacture, both in this country and abroad, not only has much suffering been spared and loss of expectant life to the race been averted, but that actual benefits have been conferred upon the industry itself. Public opinion is less hostile to the trade than it was, and there has been less sickness among the employed, while the manufacturers have saved considerable sums of money, owing to fewer claims than they otherwise would have had under the Workmen's Compensation Act.

Since such admitted benefits have followed the prohibition of female labour in the dangerous processes of lead-making a comparatively new problem of plumbism in female life must now be faced. Medical men in the potteries and elsewhere have repeatedly drawn attention to the fact that, for the purpose of procuring abortion, pills made from diachylon plaster are frequently taken, so that it is unfair to regard all the cases of plumbism occurring in female workers in the potteries as arising from occupation. This announcement has not been acceptable to a section of the reforming public, who, while admitting

that such a practice probably exists, can only regard it as of limited extent, and as a statement put forward by interested persons to prevent further legislation for the protection of females working in lead processes in the manufacture of pottery. The self-administration of diachylon pills by pregnant women for the purpose of procuring abortion is a practice more widely indulged in and with more serious consequences than at first sight appears. The time has come when something must be done, and that at once, to put an end to a practice in some instances followed by death, though the cause is not always recognized, and in more instances by acute suffering and by protracted illness.

Several medical men have written upon the subject, of whom from memory I may allude to Dr. Handford of Nottingham, Drs. Prendergast, Shufflebotham, and Ward of Staffordshire.

During the last two years I have seen seven or eight cases of acute plumbism in married women who had taken diachylon. Two of them just escaped dying, while two others will probably never be the healthy women they were previously to their illness.

CASE I.

A woman, aged 40, pregnant, mother of eleven children, ten of whom are alive, was admitted into the Royal Victoria Infirmary under my care on June 9th, 1911, suffering from severe pains in the abdomen and great weakness of the limbs. Three months before this, believing herself to be pregnant, she took in all 40 diachylon pills. After taking two pills night and morning for ten days she became seriously ill. She had acute abdominal pain and repeated vomiting; she felt listless and was so weak that she could hardly stand. On her admission the menses had not been re-established; there was a marked blue line on the gums, absence of sulpho-cyanide in the saliva, and complaint of pains in the arms and legs. On two occasions albumen was present in the urine. A large tender mass could be felt in the lower part of the abdomen in the middle line corresponding to an enlarged uterus in the fifth month of pregnancy. On examining the blood the red corpuscles numbered 2,400,000 and the white cells 11,000 per c.mm. No lead was found in the urine by Professor Bedson. Under the administration of $\frac{1}{4}$ grain of sodium monosulphite with tincture of cardamoms in water thrice daily, and an occasional opiate when the pain was severe, the patient made a good recovery, left the infirmary on July 7th, and in due course was delivered of a healthy child at term.

CASE II.

A married woman, aged 29, with four children, was admitted into the infirmary under my care on July 13th, 1911, suffering from severe pains in the abdomen and back. She was in a highly strung and nervous condition. Believing herself to be pregnant, she had taken "black stick"—a mixture of diachylon and aloes—in the form of pills, sold to her by a chemist. She took six pills night and morning for the first week, and half that number for the second week. Severe abdominal pain developed, and she miscarried on July 14th, about seventeen days after taking the first pills. For five days previously to miscarriage she had fairly free but interrupted uterine haemorrhage.

She vomited several times daily, and continued to do so for a few days after entering the infirmary on July 13th. There was neither diarrhoea nor constipation, but severe pain during defaecation. She had lost considerably in weight. Her legs were so weak that she could hardly stand. There were tremors of the lower half of the face, and also of the hands. There was not only a dark blue line on the gums, but a patch of deeply pigmented buccal mucous membrane opposite the lower teeth. The abdomen was extremely tender, especially over the left ovarian region. The knee-jerks and the plantar reflex were lost. On microscopical examination of the blood, which was repeated on several occasions, only once were four basophile corpuscles found over the whole field. The urine was free from albumen on admission. A few days after treatment had been commenced the urine contained a trace of albumen, but this disappeared, and was never again found. On one occasion only was lead found in the urine by Professor Bedson, and that was after the commencement of the administration of sodium monosulphite, which formed the regular treatment throughout, and under which she made a good recovery, leaving the infirmary on August 23th. This woman had taken 144 pills, each of which contained 1 grain of oleate and stearate of lead.

In one woman whom I saw with Dr. Nesham at the Maternity Hospital, and who had taken a pennyworth of diachylon and a pennyworth of aloes, the abortion, was incomplete, and enneting had to be resorted to. In another whom I saw with Dr. Tiplady the symptoms were those of abdominal pain and intractable vomiting, to which the patient all but succumbed. She too had aborted, and presented temporary albuminuria.

I will only mention one other case, and that with the permission of my colleague, Professor Thomas Beattie, in

whose ward I have had the opportunity of frequently seeing and examining the patient.

CASE III.

A married woman, aged 24, the mother of two children born within the period of one year and two weeks, had taken "black stick" with the object of inducing abortion. Seven days after taking the drug she aborted. Two weeks afterwards she was seized with severe headache and vomiting. There was neither colic nor constipation. A month after taking the pills the right hand, and shortly afterwards the left, became paralysed, and then both legs. The muscles of hands and legs rapidly atrophied. There was a blue line on the gums, and marked naso-labial tremor. The urine was free from albumen. Professor Belson found a trace of lead in the urine. Blood films were stained and carefully examined, but on no occasion was one basophile corpuscle found. It is now five months since this patient took ill, and although her legs have partly recovered their power, there is still almost complete double wrist-drop, so that she lies in bed in a comparatively helpless condition. It will be months before she is better, and even then it is a question as to the completeness of her recovery.

There is not the least doubt that lead is a powerful and a dangerous ecbole. It probably acts upon the unstriated muscle fibre of the uterus, setting up strong muscular contractions followed by expulsion of the fetus. I am disposed to take this view rather than that lead destroys the fetus first. Pregnant rabbits to whom I administered lead miscarried, and in one instance so severe were the muscular contractions that the uterus ruptured.

The dangers following the self-administration of diachylon are not only that the woman may have a long and painful illness, accompanied or not by paralysis of hands and limbs, but that she may die in the attack of acute plumbism, either from intractable vomiting, acute inflammatory affections of the pelvis consequent upon incomplete abortion, or from convulsions. To my knowledge young females, married and unmarried, have been admitted into hospitals or been treated by medical men outside, and have died in convulsions or from recurrent vomiting, and at the *post-mortem* examination nothing has been found to explain either the symptoms or the death. In a few of these it was afterwards ascertained that diachylon had been taken.

What, then, is the duty of women, the Government, and the medical profession in regard to this important question? Disciples of Malthus would probably maintain that there is something to commend in the action, not the means, by which when patient Case 1, in her twelfth pregnancy, with ten children alive, the eldest only 18 years of age, and her husband earning 30s. a week, finding herself pregnant, sought to relieve herself of a prospective burden by a remedy so easily obtained as diachylon. It would have been a greater and more disastrous calamity to the husband and to the family had this woman died and left ten children to be brought up, the eldest daughter being only 18 years of age. Where the means to procure abortion are attended by such risks to life and health it is the wiser plan for women not to take anything. It is the light-hearted manner in which unmarried and young married women, in their eagerness to avoid responsibilities and the assumption of tasks which interfere with their pleasure, resort to the use of diachylon that calls for condemnation.

Seeing that for two pence abortion can be procured, and that women in the guise of nurses are secretly preaching the advisability and encouraging the practice of it among the poorer working classes, also that in the full glare of daylight druggists are selling the material, surely the time has come when we might well ask the question how long the Government is going to allow this state of things to continue? It can no longer be said that the Government is ignorant of the practice nor of the extent to which it prevails. The responsibility rests with it to put a stop to a practice which is discreditable to the age in which we live, a source of danger to adult female life, and a cause of antenatal death. The sale of diachylon should be prohibited. Soap plaster can be made, and just as effectively, without lead as with it. By the prohibition two years ago of white phosphorus in the manufacture of lucifer matches, and which was also resorted to as an abortifacient, death has been averted and much suffering has been prevented. This, too, would be the case if the sale of diachylon or of lead pills, unless the latter under medical prescription, was made a criminal offence.

Notification of industrial lead poisoning is compulsory; why should lead poisoning by diachylon be made the occasion of its evasion?

The attitude of the medical profession has in this matter been consistent. Its duty is simple: it is to discourage by all means the use of such a drug; to point out to women, wherever possible, the grave danger to life and health attendant upon its administration, also to comply with the wish of the Government, should such be expressed, to notify, on the same terms as those concerning industrial plumbism, the occurrence of lead poisoning by diachylon or by any other medicament.

THE USE OF CELLULOID IN THE TREATMENT OF TUBERCULOUS DISEASE OF THE SPINE.*

[WITH SPECIAL PLATE.]

BY H. J. GAUVAIN, M.A., B.C.CANTAB.,
M.R.C.S.ENG., L.R.C.P.LOND.,

MEDICAL SUPERINTENDENT, LORD MAYOR TRELGAR CRIPPLES' HOSPITAL, ALTON, HANTS.

CELLULOID was first introduced into orthopaedic surgery by Phelps and Lorenz, both of whom used it for splint manufacture in the form of sheets softened in hot water. Later, Landerer and Kirch in Germany and Duroquet and Calot in France rendered its employment more practical by conceiving the idea of dissolving the celluloid in acetone and applying the solution to woven tissues. In France its use is now very general. At Alton it has been adopted to the almost entire exclusion of other removable spinal supports, and the interest which these jackets has created is my apology for this paper.

For my acquaintance with celluloid for orthopaedic purposes I am indebted to my friend Dr. Jacques Calvé, of Bercé, who first instructed me in its use and has devised a particularly ingenious and useful jacket, which is described in his paper referred to below.[†]

CHEMISTRY OF CELLULOID.

Celluloid is made by gelatinizing nitro-cellulose of low nitration with an alcoholic solution of camphor. The alcohol is nearly all driven off during the subsequent process of manufacture, leaving an intimate mixture of nitro-cellulose and camphor. It is uncertain to whom its original discovery can be certainly attributed. Parkes, in Wales, early in the fifties, patented a process for preparing a substance, which he afterwards called "Parkesine," prepared from pyroxylin. In 1869 the Hyatt Brothers, in America, made xyloloid, which was essentially celluloid, and in 1877 the business of Daniel Spill, who was Parkes's successor, was taken over by the British Xylonite Company, Ltd. In 1876 the Hyatt Brothers founded the first celluloid factory in France.

Transparent celluloid is a hard, tough, somewhat elastic substance of horny appearance. Its chemical composition is not constant but may vary within considerable limits according to the method of its manufacture. Its density is about 1.37. It is softened by heat, but if kept too long at a temperature of 130–140° C. slowly decomposes; at a temperature of 198° C. it decomposes instantly. It is highly inflammable. It is soluble in various substances, of which acetone alone concerns us here. It may be decomposed by concentrated sulphuric, nitric, and hydrochloric acids.†

THE ADVANTAGE OF CELLULOID SPINAL JACKETS.

Jackets made of this material are light, elegant, rigid but slightly elastic, strong, are not acted upon by the heat and moisture of the body, maintain their shape indefinitely, are comparatively easy to make. Their greatest value lies in the fact that they may be made to accurately fit a cast of the patient and maintain the shape of this cast indefinitely.

The great objection to the use of celluloid is its inflammability. Impregnated, however, in woven tissues there is very little danger in its use. Both in France and in

* A paper read before the Medical Society of London.

† For kindly confirming the accuracy of this paragraph I am indebted to Mr. T. R. Brooke, of the British Xylonite Company.

England Calvé and I have made many hundreds of celluloid splints, and have never witnessed a case where its use has been harmful on this ground to patients. Neither have we been able to find any record of disaster following its use in the practice of others. Actual contact with flame is necessary before the jacket will burn, and even when it is well alight the flame can be readily extinguished. It is, however, not generally known that even this slight danger from fire can be easily avoided. Celluloid splints may be easily rendered non-inflammable. Two methods may be employed: (1) By covering the celluloid splint with non-inflammable material; (2) by making the celluloid itself non-inflammable.

As an example of the first method, the splint when made may be covered by a tissue which has been impregnated with sodium tungstate. Such a tissue is non-inflammable. The tissue may be protected by a light covering of leather, and the resulting splint at least equals in appearance one made of leather, and is more serviceable.

The celluloid splint may be covered by one of the numerous non-inflammable paints now procurable, and it has even been suggested that a light coating of potassium silicate may be used. Such expedients, however, are clumsy and not of great value, and a far better method is to render the celluloid itself non-inflammable. This may be very easily done by mixing with the celluloid in solution in acetone various substances of which the following are examples—iron perchloride, calcium chloride, magnesium chloride, salts of aluminium, the acetate or oleate of zinc, etc. Of these, after numerous painstaking and exhaustive experiments, for which I am indebted to Miss Butler, our late plaster sister, the substance which at Alton has been found of the greatest practical value is calcium chloride. Miss Butler discovered that if a supersaturated solution of calcium chloride in very hot water is added to the celluloid dissolved in acetone, the resulting mixture when dry is absolutely non-inflammable.* It retains its non-inflammability when made into a splint, and such a splint cannot be made to burn even when held in a fire. This discovery, therefore, disposes of the greatest, and indeed the only, objection which can be raised to the employment of celluloid in the manufacture of orthopaedic appliances.

Celluloid made into splints in the manner to be described, either alone or combined with metal, forms one of the most useful materials for orthopaedic appliances.

To mention but a few of the conditions in which I have used it with success, I may cite almost all forms of tuberculous joint disease, infantile paralysis, various forms of talipes, genu varum, genu valgum, Charcot's disease of the knee-joint, scoliosis, after fractures and osteotomies, etc. In some of these and in other conditions it is likely to surpass other materials hitherto employed, as, for example, in the convalescent stages of joint disease, the ambulatory treatment of fractures, and in infantile paralysis.² I would also suggest its value in the manufacture of artificial limbs, though, with the conservative measures adopted at Alton, such aids are rarely necessary, and I have not had an opportunity of using it for this purpose.

In this paper I propose to confine myself simply to outlining its use in tuberculous disease of the spine, and will describe the manufacture of such a spinal jacket as might be used in an ordinary case of dorso-lumbar caries. In such a lesion, when complete immobilization is required, there is no doubt that celluloid should not be employed. No form of mechanical support hitherto devised can compare with an efficiently applied plaster jacket,³ but when the time comes when this extreme immobilization is no longer required, and when, indeed, if unduly prolonged, it might be harmful, there is no doubt that a properly made celluloid splint is the best mechanical support which can be used. Too prolonged immobilization in plaster may increase the muscular atrophy produced by the disease, and this is especially seen in cases of hip or knee disease, but it is also apparent in tuberculous disease of the spine. Prolonged immobilization in plaster does not of necessity result in fixation of the joints—indeed, tuberculous joints long properly immobilized are much more likely to recover

good movement than joints inefficiently immobilized, but there is undoubtedly a period when such complete immobilization as effected by a perfectly fitting plaster jacket is neither essential nor, indeed, desirable. Such a period in the natural history of the disease is reached when it may be inferred that the lesion has consolidated and become well shut off from the rest of the body, and that the disease is apparently arrested. Limited movement, either active or passive, is now of value; and, indeed, the aid of gentle massage and electrical treatment may be invoked to further restore muscles long inactive. Now a removable jacket is indicated. The function of such a jacket should be only regarded as one of support and reasonable protection to the area affected, but not of complete immobilization, though very efficient immobilization is obtained. It, indeed, may be so designed that it will still further assist in correcting deformity which might have persisted, but the manufacture of, and indications for, a celluloid jacket adapted to such a purpose will not be considered here.

The advantage at this stage of an efficient jacket which may be removed is manifold. It affords protection in the interval between the period when complete support or protection is no longer required, but entire absence of both might be harmful. It should be worn by the patient at such times as its absence might be a source of danger—in other words, when the patient is lying in bed or resting it is not required, but when he is walking about and might presumably be exposed to extraneous injury or strain, then it is of the most extreme value. Numerous materials have been employed from time to time for this purpose, each having its own advocates, but after extensive use of every mechanical support which I have been able to try, none presents, to my mind, so many advantages as celluloid. Moreover, celluloid has this extreme value—the jacket itself can be made by the surgeon who is treating the case or made under his immediate supervision, and this is an undoubted advantage. It is not realized how much crippling results from the indefensible practice of leaving all details of mechanical support to the instrument maker. In the treatment of bone and joint tubercle skill in the application of properly designed mechanical supports is of far greater importance than mere surgical dexterity, and the surgeon-mechanic will obtain results which neither the surgeon nor the instrument-maker, working singly, can approach. To such a worker celluloid affords the most valuable assistance in the exercise of his skill. The jacket, to fulfil the necessary requirements of a spinal support, should be made on a very accurate cast of the patient, and the first step in its manufacture consists in the taking of such a cast. This, indeed, should be done with almost every form of spinal support, though unhappily it is comparatively rarely attempted, largely because of the prevailing ignorance of plaster technique.

METHOD.

There are various ways in which a suitable cast may be taken; but I shall confine myself to describing one simple and practical method.

The patient is suspended from a suitable gallows by a bridle applied to the chin and occiput so that the spine occupies the desired position. This position varies within considerable limits but in the majority of cases should be one of slight hyperextension. Suspended from the gallows in the selected manner, he is thoroughly anointed with warm olive oil and a plaster bandage is applied around and on to the trunk from below upwards, commencing below the right iliac crest encircling the trunk at the level of the pubis and gradually rising until the shoulders are reached. The thickness of two or three turns of the plaster bandage is all that is required. The shoulders are taken in by turns of bandage being passed from chest to back and vice versa and fixed by a further turn around the trunk, and just before the cast is setting the crests of the ilia, the pubis, and the sacrum are very carefully moulded. The counterpoints of application in such a simple jacket as this would be the two clavicles, which are moulded also with the greatest care, and behind the negative must be accurately applied to the whole length of the spine and to the two scapulae. A point to be ever borne in mind in making any jacket for dorsal caries which can have any pretence to efficiency is that

* Three ounces of calcium chloride should be added to 2 oz. of boiling water. The resulting mixture, added to 150 oz. of celluloid of low nitration, dissolved in acetone, will render the celluloid non-inflammable.

possibility of flexion of the spine by the patient must be prevented. Hence the importance of careful moulding about the pubis and its counterpoint the clavicles, or in a high jacket the mastoid processes and occiput. In other words, the distance between the *points of application* should be constant. Very rarely is it insisted that a jacket should take proper purchase from the pubis, and this is obviously essential if the jacket is to be efficient. In applying the plaster the greatest care must be taken to pleat each turn of the bandage so that the resulting negative shall occupy the greatest bulk of the trunk and not cause any compression of the thorax or abdomen.

As soon as set, the jacket is cut up laterally in the way shown and gently removed from the patient. The jacket should be removed just as its set is completed, and it will be noted that at this moment every movement of respiration is accompanied by slight sucking noise as the skin recedes from the now firm negative. When the jacket has been slipped off the patient it is allowed to thoroughly dry, and the cut edges are accurately apposed and fixed together by another plaster bandage which encircles the negative. The holes for the arms and the base of the jacket are covered over likewise with a plaster bandage. This being done, the inside of the jacket is carefully oiled again, and the negative thus produced is allowed to thoroughly dry, which at an ordinary room temperature takes three to four hours.

Making the Positive.

Into the oiled negative fluid plaster of Paris is poured, which plaster is prepared by adding five parts of water to three of dry plaster. Cheap plaster of Paris is sufficiently good for this purpose. The negative may be placed in a box full of sand or sawdust which will support it all round and the open neck end alone left exposed, or, if preferred and sufficiently strong, filled without such support. Before the plaster sets a substantial piece of wood is thrust down the centre and forms a convenient projection for subsequent manipulation. As soon as the plaster has set the negative is removed and the positive is left ready for further treatment. This treatment consists in carefully modelling above the pelvic brim and accentuating its outline so that the grip on the pelvis may be secured with certainty and precision. This carving of the cast is of great importance and requires care and skill. The plaster to be removed is cut away with a strong long-bladed knife. The subclavicular fossae are also sculptured. The whole of the cast is then covered with an additional thin layer of plaster which will increase its bulk slightly in all directions, and thus ensure the jacket which is to be made on it being of comfortable though perfect fit. On to the positive thus formed the splint has now to be made.

Making of the Celluloid Splint.

The fluid celluloid, which has already been referred to, has the power of thoroughly impregnating any loose texture to which it is applied, as, for example, vesting or gauze. When applied the acetone evaporates, and leaves the celluloid deposited as a solid. The most effective way of making a splint is to place over the cast a vest of cotton which is slightly smaller than the cast, and which can be very accurately applied to it. Frequently parts of the vest have to be stitched to secure accurate approximation. This vest may be pinned to the bottom of the cast and on to the neck and the armholes with ordinary drawing pins. It may be accurately applied to depressions in the cast, such as those about the iliac crests, by means of either tape or cotton drawn tightly over these depressions and fixed at appropriate intervals with drawing pins. This being done, it will be found that the vest now is correctly adapted to the shape of the cast made, and on to this vest is painted with an ordinary stiff brush a coating of the celluloid solution. It is very desirable that this solution should be thoroughly worked into the vest. It will be found that when the acetone has evaporated and the celluloid is left deposited on the vest, there are probably numerous places which have not received a sufficient quantity of celluloid, and therefore two, three, or more coats should be painted in turn on the vest. When a sufficient quantity of celluloid has been incorporated, a layer of thin muslin—ordinary book-muslin stiffened—is applied to the cast in two pieces, one to occupy the front and the other the back, the two parts overlapping at the sides, and the

celluloid is then worked into this. This process is repeated until it is estimated that the jacket has attained sufficient strength, each layer being allowed to dry before the next is applied. It will be found that the number of layers of muslin with incorporated celluloid will vary usually from ten to twenty. For small children the former will be sufficient, but for adults the latter will be required. It should be noted that those parts which will have a special strain placed upon them—as, for example, round the points of application of the jacket to the pelvis—a greater thickness may be required, and this can easily be obtained by placing a small additional piece of gauze in the appropriate situations and impregnating these with celluloid at different stages of the manufacture of the splint.

When the last layer of muslin has been applied, and that has thoroughly dried on to the splint, two or three more coats of celluloid should be painted on to ensure that the splint should have that smooth and elegant appearance suggestive of a highly polished surface, which adds so much to the attractive appearance of the finished celluloid.

It will be found that between each layer of muslin which is applied, and which is coated with celluloid, an interval of from five to ten hours should elapse to allow the acetone to evaporate and the splint to dry. Great care should be taken in the manufacture of the splint that no air bubbles are allowed to remain between the different layers, and that each layer is in the most accurate apposition to the layer subjacent. Otherwise the strength of the splint will be diminished and the layers of celluloid may tend to separate in laminae.

The application of the celluloid having been concluded the splint must now be removed from the cast and this may be done in various ways, according to the inclinations of the surgeon. For a simple spinal jacket as is here described, the easiest way is to cut through the splint in the middle line anteriorly from top to bottom. The edges around the armholes and neck and bottom of the pelvis are carefully trimmed, and the splint can now be removed from the positive. It is now very desirable that the splint at this stage should be tried on the patient and the patient resuspended for this purpose. The splint having been put on the suspended patient it is a wise plan to tie it on the patient round the middle of the trunk by a piece of bandage, and on to the jacket thus applied lines are marked with a suitable pencil to indicate those parts which need not be retained. The first essential is to see that the splint thoroughly fits the pelvic brim and is accurately in apposition with the pubis, both iliac crests, and the sacrum. Above it must accurately fit the clavicles, and behind it should lie in close apposition to the spine.

A large ventral window should now be marked, and this cutting out of a ventral window is very important in securing a perfect fit, for it will be seen that the dimensions of the patient's trunk varies according to the amount of air inspired or expired from the lungs, and to the distension or retraction of the abdomen. The ventral window allows these alterations in the bulk of the patient to take place without in any way impairing the fit of the jacket or interfering with the support and protection it will give; while, if such a window is not cut out, it will be at once seen that the jacket will either be too tight or too loose for it to be of really complete value. It is to be regretted that spinal jackets made in this country rarely have effected this very simple expedient for their accurate fit. The lower part of the jacket should be cut somewhat in the manner shown in the figure, so that, while securing accurate apposition to the pelvic brim, there shall be ample allowance made for any movement of the thigh.

In front the lower border of the splint corresponds with the upper border of the pubis, at the sides to a point about the middle of Poupart's ligament and just over both great trochanters. Behind, its lowest limit should be the uppermost portions of the natal cleft. Above, it should be cut well away around the arms, so that free movement of the arms is obtainable. The moulding around the clavicles will ensure that the shoulders are kept pressed backwards. The moulding around the pubis will prevent forward flexion of the spine, and the spine will be maintained in an extended position consistent with comfort. It may not be out of place here to enter protest against the too frequent use of

axillary crutches, which are employed with the mistaken idea that they give the spine some support. The use of these crutches has been well deprecated by Vignard and Monod,⁴ whose observations on them may well be repeated here: "They constitute one of the gravest faults in the old-fashioned spinal jackets. Their object is, as has been already said, without doubt to support the spine by the aid of the shoulders, but raise the shoulders and you will appreciate their inefficiency. Movement of the shoulders in the vertical direction which this action causes the axillae to undergo shows that it is only when having pressed up the shoulders to the extreme limit of their possible excursion that the axillary crutches can have any effect. These movements of ascent are partly limited by the serratus magnus muscle which, attached to the scapula, acts on the ribs and not on the spine. Only the lower slips of the trapezius muscle can furnish the means of useful action, and this action on the spine is really only an apparent one. The raising of the axillae is accompanied by a swinging movement of the scapula in its lower angle. The muscles which resist this swinging movement are the rhomboidei which are attached to the lower cervical and upper dorsal vertebrae, which vertebrae are thus drawn from above downwards. The exaggerated raising of the shoulders by the axillary crutches produces a compression of the spine and not stretching, which stretching is, on the contrary, only possible when the shoulders occupy the lower position.

"Untenable from anatomical considerations, on physiological grounds still stronger objections may be made to the use of axillary crutches. Even light, long-applied axillary pressure causes a strain which is uncomfortable, and may, indeed, be painful. The action on the respiratory movements is still more important. The raising of the shoulders has an enormous influence on the respiration. It corresponds to forced inspiration. The shoulders remaining high, it is impossible for the patient to accomplish complete expiration. Indeed, it is as bad to keep the thorax in a position of inspiration as it is to impede thoracic movements by compression. For these reasons, then, the use of axillary crutches should be abandoned, and the shoulders should be allowed to remain free, but pressed backwards and somewhat downwards."

The Completion of the Celluloid Jacket.

The splint having been cut out in the manner indicated, the edges may be bound and stitched with leather and suitable hooks, eyelets and buckles inserted into the celluloid. The splint is then to all intents and purposes completed. Nothing more is really essential, but it may be found advantageous to strengthen it with light steel as figured, though this is not by any means essential. From hygienic reasons it is desirable to punch numerous holes in the jacket to allow sufficient ventilation of the subjacent skin.

Such a jacket will be found of the greatest value to patients being treated in the convalescent stages of spinal caries. Its weight is negligible, it affords no obstruction to respiration or digestion, the support and protection it affords is ample, and the comfort and security it confers upon the patient renders it of unequalled value in mechanical treatment at this stage of tuberculous disease of the spine.

A CASE OF COMPLETE AURICULO-VENTRICULAR HEART-BLOCK.

WITH A REPORT OF THE PATHOLOGICAL CONDITION OF THE HEART.

BY

T. WARDROP GRIFFITH, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE, UNIVERSITY OF LEEDS; HONORARY PHYSICIAN, LEEDS GENERAL INFIRMARY;

AND

ALEX. MILLS KENNEDY, M.D.,

ASSISTANT TO THE ST. MUNGO (NORMAN) PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW; SENIOR ASSISTANT PATHOLOGIST TO THE GLASGOW ROYAL INFIRMARY; PATHOLOGIST TO THE GLASGOW MATERNITY AND WOMEN'S HOSPITAL.

[WITH SPECIAL PLATE.]

In the Schorstein Lecture which was delivered by one of us (T. W. (G.)) at the London Hospital last October, and published in the *BRITISH MEDICAL JOURNAL* on

October 12th, mention was made of a case of complete auriculo-ventricular heart-block which presented some points of special interest. The patient died of pneumonia, and the examination of the heart was undertaken by one of us (A. M. K.). A preliminary note of the condition found was given in the lecture. The examination has now been extended and completed, and it is believed that the record will prove of greater interest if the paragraphs and figures in the lecture dealing with

the ease are reproduced. These were as follows:

The tracing Fig. 38 [p. 1204] is from the case of a member of our own profession, and was taken when the patient was 81 years of age. The ventricles were beating at 40 and with great regularity, as all the pulse periods are seven and a half fifths of a second, except the few which are marked otherwise. The auricular beats are rather less than double the number of those of the ventricles; they have no constant relationship to the ventricular beats, and we have here the additional evidence of the block being complete, in the fact that the auricular rhythm is markedly irregular, but that there is no reflection of this irregularity in the pulse.

There is another peculiarity in the tracing to which I desire to call attention. When a premature contraction of the auricle occurs it is followed by an interval which is seldom longer than those which separate the systoles of the auricle which occur about the same time. Now it is possible that this may represent nothing more than a sinus arrhythmia; but as it is clear that there is a profound interference with the conducting functions of the heart, I venture to suggest the possibility of another explanation, which I admit is highly problematical, and which I advance purely in the hope that others may meet with cases to confirm or to confute it. We have already seen that in complete auriculo-ventricular heart-block premature contractions of the ventricle are not followed by any compensatory pause. Let us apply the explanation of this to the possibility of a sino-auricular block, as suggested by the lower outline in the diagram I have already used (Fig. 32). When

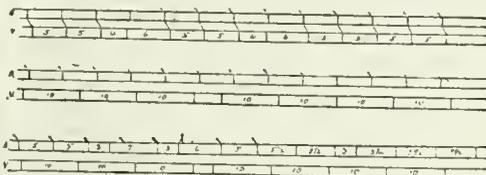

Fig. 32.

the sinus rhythm is dominant, we have seen that a premature contraction of the auricle is followed by a pause which is more or less complete according as the stimulus does not or does pass back to disturb the rhythm of the sinus. If, as the latter part of the diagram shows, the auricle may be supposed, in

* In the report of the lecture an unfortunate slip occurred, the word *half* appearing instead of *double*.

consequence of a block, to be emancipated from the influence of the sinus, a premature beat on its part would be followed by an interval of the usual interauricular length.

The patient was a man of active habits, and up to the time of his death, which occurred two years afterwards, was in the

muscles show some degree of fibrosis. There is fibrosis of the endocardium of the left ventricle just below the attachment of the mitral valve, and this fibrosis is distinctly evident over the situation of the auriculo-ventricular bundle—

namely, below and behind the pars membranacea septi. In this situation the fibrosis is seen to be continuous with the atheromatous thickening of the anterior mitral cusp along its attached margin bordering the anterior edge of the pars membranacea septi.

There are no other valvular lesions.

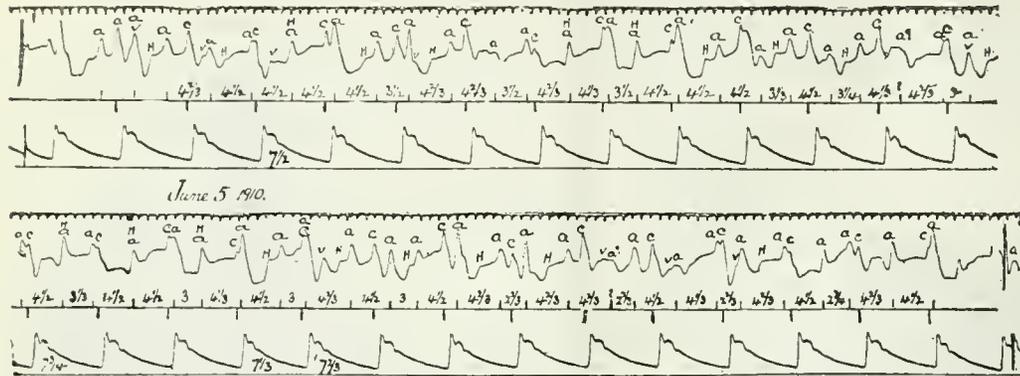

Fig. 38.

habit of walking some five miles a day. His daughter told me that as long ago as the early seventies she remembers her father being subject to peculiar attacks. Sometimes when making up medicine in his surgery he would suddenly, after apologizing to those who were present, lie down on the floor for a few minutes as if overcome by a feeling of faintness, and then resume his work as if nothing had happened. Of these attacks the patient had no recollection during all the time, some two years or more, that he was under my immediate observation. I saw him about eighteen years ago, when he had influenza, and my notes show that during the moderate fever which prevailed his pulse varied from 104 to 112. What the pulse-rate was in the interval I cannot tell. He had often had attacks of giddiness, but of late years these had got much less frequent, and for some time they had ceased. There was some tendency to cyanosis; the arteries were very atheromatous; the systolic blood pressure was as high as 260, and about the end of May of this year, though he was still rather a wonderful man for his age, and continued his active habits, he appeared to me to be failing. I was asked to see him early in June by his medical attendant. He was clearly suffering from pneumonia of a low type, and he died at the end of the sixth day. A tracing of the radial pulse on the third day of his illness (Fig. 39

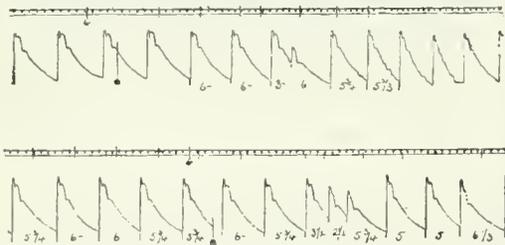

Fig. 39.

shows that the pulse-rate had risen to about 50, and it never rose above 60. The upper tracing shows a premature systole, and the lower two in succession, without in either case a compensatory pause.

The pathological examination of the heart shows that there is a generalized hypertrophy of the cardiac musculature, and dilatation of both auricles and of right ventricle; the left ventricle is contracted in systole, and there is an excessive deposition of fat on the surface of the heart. There is some superficial atheroma of the aorta, and, about 1½ in. above its valves, there is a large thick atheromatous patch which is softened in its centre; the coronary arteries are slightly fibrosed.

The mitral orifice is normal in width but the tricuspid is slightly dilated. The anterior mitral cusp on its ventricular aspect shows a uniform atheromatous thickening of its basal half, and extending outwards in strands to some of the chordae tendineae, and at its left-most edge, where it meets the posterior mitral cusp, there is a small area of calcification about the size of a lentil. This atheromatous area on the anterior mitral cusp extends inwards and spreads on to and involves the adjacent half of the pars membranacea septi, so that it must at least pass over the auriculo-ventricular bundle. Some of the chordae tendineae are thickened—a chronic atheromatous thickening—and the tips of the papillary

A block of tissue was removed from the cardiac septum, which contained the pars membranacea septi, the adjacent portions of the auricular and ventricular muscular septa, the central fibrous body, and the attachments of the anterior cusp of the mitral valve and the septal cusp of the tricuspid valve. The block extended sufficiently far back to include the mouth of the coronary sinus, and it was cut out in such a manner that its long antero-posterior diameter was at right angles to the long axis of the heart. Such a block includes the whole of the auriculo-ventricular node and main stem of the auriculo-ventricular bundle and a portion of its two principal branches. It was cut in serial sections from above downwards in the horizontal plane, and a series at intervals of five were mounted and stained with haemalum and van Gieson's stain.

Examination of the sections shows enormous dense fibrosis at the base of the mitral valve, extending outwards as a thickened atheromatous plaque on the ventricular aspect of the anterior mitral cusp and inwards to the auriculo-ventricular node. The fibrosis extends downwards into the ventricular septum as a very thick and very dense layer; this layer extends from the endocardium of the left ventricle inwards to the auriculo-ventricular bundle, forming a thick mass along its left side, and extending underneath it, and appearing also along its right side, though here it is less abundant. The thick fibrous layer on the left side of the bundle can be easily followed from the mitral valve to the aortic valve, at the base of which it again increases in bulk. The normal space between the bundle and cardiac tissue proper is almost completely obliterated, and, particularly from the left side, strands of fibrosis can be seen extending into the bundle about its middle from the greatly thickened sheath, and so breaking the continuity of the main stem.* The left side of the node and the whole length of the main stem of the bundle are thus enclosed in a dense thick sheath, the thickening of which underneath the bundle raises the latter up, so that on leaving the node it takes a curved course upwards and then downwards to enter the ventricle; this gives the convexity towards the auricle, which has been described as normal, but which in this case is exaggerated and certainly abnormal.

In the dense fibrosis at the base of the mitral valve, along the left side of the bundle, and at the base of the aortic valve, there are areas of calcification. In the auricular tissue above the node there is probably some excess of fat, and a short distance below the node there is some fatty infiltration in the bundle visible as numerous large globules. The small arterioles in the node and bundle and cardiac tissue generally show well marked thickening and considerable periarterial fibrosis. The principal vein from the node and its tributaries show recent thrombus within them—a terminal formation, but the main trunk is not completely occluded.

* The preliminary note in the report of the lecture is not quite accurate; the continuity is completely interrupted.

There is fibrosis and slight calcareous infiltration in the ventricle, particularly on the left side.

A block of tissue, to include the sino-auricular node, was next removed from the junctional region of the right auricle and superior vena cava, and cut in serial sections, which were mounted and stained as above described.

Examination of the sections shows that the excessive deposit of fat, already noted on the surface of the heart, infiltrates into the right auricle in the sino-auricular nodal region, causing considerable alteration. The nerve endings in this region are all conspicuous, and a considerable number of the ganglion cells are visible, but there is apparently a scarcity of the true "nodal tissue" fibres and

abundant fatty infiltration instead; there is also periarterial fibrosis.

The main bundle of the auriculo-ventricular junctional system being the path by which the auricular contractions are transmitted to the ventricles, it may be inferred from the pathological findings alone in this case that a condition of complete auriculo-ventricular heart-block was present during life. Regarding the pathological changes in the sino-auricular region, it does not seem justifiable in the present state of our knowledge to make a definite statement as to what their effects on the cardiac rhythm would be. One must simply record the facts, clinical and pathological together, and await further confirmation.

THE POSITION AND FORM OF THE NORMAL HUMAN STOMACH.

By A. MELVILLE PATERSON, M.D. EDIN.,
F.R.C.S. ENG.,

PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LIVERPOOL.

It may be generally admitted that the normal human stomach exhibits many variations of form, dependent on temporary physiological or permanent anatomical causes.

From personal observations I am of opinion that the normal stomach is, in the majority of cases, a four-

cardia and pyloric antrum may form a definite tubular canal (Fig. 5), or it may be a deep V-shaped notch in the greater curvature (Figs. 3, 6, and 9), producing often a typical hour-glass contraction. There is usually a considerable thickening of the muscular wall of the organ in relation to the pyloric vestibule and the pyloric canal. Out of twenty stomachs taken consecutively from subjects in my dissecting-room the majority showed this form (Figs. 1, 2, 3, 4). All these subjects were preserved by the same method—an injection of a mixture of equal parts of pure carbolic acid, pure glycerine, and water.

The variations from this type are due to repression of

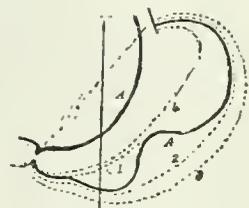

Fig. 12.

chambered organ (Figs. 1-12) composed of the following parts:

1. Cardia and fundus (Fig. 1, c).
2. Pyloric vestibule (P. V.).
3. Pyloric antrum (P. A.).
4. Pyloric canal (P. C.).

The constriction forming the pyloric vestibule between

one or more of the parts referred to or to confluence of one with another of certain parts of the organ.

The commonest variation is due to repression of the pyloric antrum, so that the pyloric vestibule and pyloric canal form one continuous tubular passage (Fig. 7). Less common is the form in which the pyloric vestibule is absent and the cardia and pyloric antrum are confluent (Fig. 8).

In the series are two examples of extreme conditions. In one case (Fig. 10) the stomach is contracted into a narrow thick-walled tube extending from oesophagus to pylorus, with a small thin-walled fundus to the left of the oesophageal opening. In the other case the stomach is wholly distended, with only a slight constriction near the pylorus (Fig. 11).

In any consideration of the form of the stomach, its position and connexions must always be regarded as of fundamental importance in determining its shape.

The chief alterations of form occur in the pyloric half and along the greater curvature.

Two main causes, in my opinion, are responsible for the form of the stomach and its variations. The less important factor is the relation of the organ to the vertebral column and the structures which lie in front of it—diaphragm, aorta, etc. The projection forwards of these structures may have an influence in producing lateral dumb-bell-like dilatations, with the pyloric vestibule as an isthmus between them.

The more important factor is to be found in the mechanical supports of the stomach. The organ is slung from two main attachments—on the one hand by the diaphragmatic connexions of the oesophagus; on the other hand by the connexion with the liver of the pylorus and the first part of the duodenum. It is obvious that these two points are only relatively fixed. Both undergo changes in position along with the movements of the diaphragm, and the position of the second point is influenced by the position and size of the liver. An oblique line (shown as a dotted line in the figures) may be drawn between these two points. This line may be regarded as fairly constant in position. It is obvious that any change in its obliquity will affect not only the position but also the shape of the stomach. Along this line the stomach sags. There are few alterations of importance in the form of the concave lesser curvature, whereas alterations, dilatations and constrictions, commonly occur along the more mobile and plastic greater curvature.

An hour-glass contraction of the stomach is not necessarily pathological. Indeed, it is the form most commonly found in the dissecting room.

Fig. 12 shows the outline of the normal stomach in a black line (A A), with the several varieties in dotted lines (1, 2, 3, 4).

A NOTE ON THE SHAPE OF THE NORMAL EMPTY STOMACH.

By J. S. B. STOPFORD, M.B., CH.B.,

SENIOR DEMONSTRATOR OF ANATOMY, UNIVERSITY OF MANCHESTER.

[WITH SPECIAL PLATE.]

WHILST performing an autopsy on an elderly woman who had died from malignant disease of the ovary only a few hours previously, I had the good fortune to find the excellent example of an empty stomach figured in the plate facing page 1203, which conforms precisely to what the radiographers tell us is the real shape of the stomach in the living, but is so rarely seen in this characteristic form in the dead body.

The viscus was tubular, except for one dilatation, and its outline corresponded exactly with the J shape described by Barclay¹ and Hertz.² This dilatation, which was roughly cone-shaped, was situated at the summit of the vertical cardiac portion and obviously represented the fundus. The vertical portion of the organ *in situ* corresponded with the description of Hertz,² but I should like to draw particular attention to the direction of rather more than the terminal inch of the pyloric portion, not only because it cannot possibly be understood or appreciated from a photograph, but also because certain writers have expressed their inability to understand the relationship of the stomach to the liver if the radiographers are correct. The alteration in direction of this part of the "horizontal" limb was very marked as it passed backwards, upwards, and to the right to come into relation with the visceral surface of the liver. Great difficulty has been experienced in understanding how the recurved portion of the J reached the gastric area of the liver; and in order to believe and realize the shape and position of the stomach as seen by the radiographers, it has to be more or less presumed that

the terminal portion of the "horizontal" limb must be directed backwards, upwards, and to the right to reach the liver when the stomach is empty. On this account it is interesting and instructing to find that this was found in a case illustrating what the radiographers have shown to be the empty stomach.

The photograph shows clearly the very oblique oesophageal entrance and the incisura cardiaca between the oesophagus and the fundus.

The recent advances in radiography have revolutionized our ideas of the anatomy of the stomach, and attention is no longer paid to the "sac-like" and distorted specimens seen in the dissecting-room, as it has been repeatedly proved that they are untrustworthy and unreliable; but I consider this specimen worthy of attention, because it illustrates so well the outline of the normal empty stomach as demonstrated by the Roentgen rays.

The normal stomach is subject to the greatest variation, as is evidenced by the numerous descriptions published by anatomists; and it is only since the advent of radiography that correct differences in shape have been realized between the empty, the partially full, and the full stomach.

It is generally admitted now that a correct knowledge of the anatomy of the normal stomach can be acquired only by supplementing what is learnt in the dissecting-room by what is seen in x-ray examinations; but for reasons which have been explained many times of late it is rare to be able actually to handle a normal empty stomach that conforms to the radiographer's ideal.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

TETANUS SUCCESSFULLY TREATED BY ANTITETANIC SERUM.

W. T., aged 30, was admitted into the Epping Workhouse Infirmary on the evening of April 22nd, suffering from tetanus. His body was absolutely rigid, the head immovable, the hands tightly clenched, the forearms pressing the chest, and the legs straight; the mouth could be opened about $\frac{1}{2}$ in.

He had a recent wound on the head, and a foul wound of old standing on the left shin. The history was that he had felt his jaws stiff for several days, and when walking suddenly fell down, and was unable to move. The police found him on the ground. His only complaints were of great and constant thirst, and the painful rigidity of his limbs. He could swallow liquids easily.

He was given 100 c.cm. antitetanic serum on April 23rd; this appeared to relieve his jaws somewhat. After another 100 c.cm. on April 25th he could open his mouth to half an inch, and the fingers and forearms became movable. After a third injection of 100 c.cm. on April 27th he could move his head, open his mouth with ease, move his arms, and bend his knees, the latter with difficulty; the rigidity of the back remained as before. He now developed an erythematous rash all over the abdomen, and when this disappeared on May 4th I gave him 60 c.cm., and within twenty-four hours he could move his legs comfortably and turn in his bed without assistance. All through he had no opisthotonos and very few spasms. The temperature never exceeded 99°. His further progress was uneventful. The injections were made in the anterior abdominal walls, 50 c.cm. on each side.

C. E. DENNING,

Medical Officer, Epping Workhouse Infirmary.

THE VALUE OF EMETINE IN LIVER ABSCESS.

The patient in the following case, a woman aged 40, with a history of alcoholism, had a severe attack of dysentery about a year ago, and this had continued off and on in the form of diarrhoea up to the time I saw her. There was a clear history of excessive drink. About four months ago she had started getting high fever with rigors, and later on this fever abated a little and was unattended with

rigors. About the end of this period she was seen by Dr. A., who on three occasions aspirated her liver and removed large quantities of pus mixed with blood (30 oz., 29 oz., and 21 oz.). But the pus continued to collect, and the patient was getting weaker, so it was suggested that the abscess should be opened up, but the patient being unwilling to submit to such an operation I was consulted on March 13th this year. I found her extremely weak, anaemic, and emaciated, with enlargement of the liver extending almost to the umbilicus in the median line and about 6 in. below the right costal arch in the right mammary line. The swelling due to enlargement of the liver was quite distinct and visible. She had severe throbbing pain in the region of the liver, and was unable to lie on that side. She was having five liquid yellow motions daily without any gripping pain, and the fever ranged between 99.8° in the morning and 103° in the evening. It was distinctly of hectic type, and she had hectic flush on the malar bones. She was not even able to sit or move in bed. She had nausea, and was unable to take her food. I prescribed $\frac{1}{4}$ grain of emetine dissolved in distilled water to be taken thrice a day.

Within a week the temperature came to normal and remained normal; the diarrhoea stopped, and the pain in the hepatic region diminished. The swelling gradually began to diminish, and in a month the liver returned to its normal dimension; pain completely ceased, she was able to walk and had an appetite; anaemia disappeared, and she began to gain weight. She had altogether 21 grains of emetine.

During the treatment I noticed two things: First she had oedema of the face and feet, most probably due to excessive work being thrown upon the kidneys as a result of absorption of pus; it was relieved by diuretic and digitalis. Secondly, anaemia increased, most probably owing to the haemolytic effect of the pus absorbed. This was treated by haematogen.

My object in publishing the case is, first, to impress upon medical men that emetine is efficacious even when suppuration has already taken place, and second, that it is equally efficacious when given by the mouth.

S. MALLANAH, M.D., D.P.H.,

Bacteriologist to H.H. the Nizam's Government,
Hyderabad, Deccan.

TREATMENT OF PUERPERAL ECLAMPSIA.

I AM much interested in the article on page 70 of the *Epitome of Current Medical Literature* (JOURNAL, May 3rd, 1913) on the condition of the kidneys in eclampsia. Zinsser states that the convulsions are regarded as the signs of oedema of the brain. It would thus appear to be more rational to aim at the treatment of the oedema than of the defect of the kidney. Such a theory is in accordance with what physiologists teach us, namely, that our nerve cells are being drowned by the failure of the elimination of fluid from the system, and I had the opportunity of seeing a case treated on that theory, which recovered, as the consultant said she "had no right to do." The treatment by very small frequent doses of potassium bitartrate caused increased diuresis, and the patient improved. That drug was stopped and the symptoms again increased. Slight jaundice being noticed, the urine was found to contain leucine and tyrosin, and on the theory that acute yellow atrophy of the liver was present, a very grave prognosis was given. The treatment by potassium bitartrate was resumed, diuresis again occurred to a remarkable extent, and the symptoms of eclampsia simultaneously subsided. The patient made an excellent recovery, and is still alive. Such a case seems to support Zinsser's rational treatment.

Hawick.

JOHN HADDON, M.D.

PAROXYSMAL HAEMOGLOBINURIA.

Dr. E. W. SQUIRE informs us that a case which was recorded at page 768 of our issue for April 12th as one of paroxysmal haemoglobinuria has turned out to be a case of haematuria, but that the cause of the condition has not yet been discovered.

THE late Sir H. R. Swanzy, M.D., of Dublin, left personal estate in the United Kingdom valued at £12,487.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

LONDON HOSPITAL.

CASE OF PERFORATING WOUND OF OESOPHAGUS AND AORTA
BY FISH BONE.

(By CHARLES JOSEPH TAYLOR, M.A., B.M., B.Ch. Oxon.,
M.R.C.S., L.R.C.P.)

[Under the care of Dr. WARNER.]

A YOUNG woman, aged 22, by trade a box maker, presented herself in the receiving-room at 3 p.m. on February 14th, 1913.

History.

She stated that on February 9th she was eating some fish, when something seemed to stick in her throat. She tried to vomit, but could not. She then felt an uncomfortable sensation as of something sticking in her stomach; this persisted from that time onward up to her coming to hospital. She had been unable to swallow anything but slops since February 9th. On the evening of February 13th the feeling of discomfort gave way to a heavy choking sensation, accompanied by a strong desire to vomit with inability to do so. The stifling feeling prevented her from lying down; she could not sleep, and there was great discomfort in breathing, as she felt as if there was a weight on her chest. Inquiry into her previous health elicited the fact that on and off for four years she had suffered from "indigestion"—vague discomfort after meals with flatulence and a desire to vomit, though she never actually vomited.

Progress.

Whilst waiting in the receiving-room she suddenly vomited about two pints of bright red arterial blood. Her pulse became thready, and its rate rose to 160 per minute. She was somewhat blanched and very frightened. She was at once admitted to Dr. Warner's wards. By the time she had been put to bed her condition was much improved. The pulse was rapid, 116, but the volume and tension were fairly good. She was quite comfortable, and said she felt better than she had done all the week. Her colour had returned, and she was lying quite quietly. Examination showed her to be a well-developed and well-nourished young woman, with no physical signs of disease either in the abdomen, heart, or lungs.

Her condition remained the same till 4.30 a.m. on February 15th, when she again vomited about one and a half pints of bright red blood. She was given a hypodermic injection of morphine sulphate $\frac{1}{4}$ grain, and went to sleep. When seen about 11 a.m. the pulse was 116 and the temperature 100° F. She was cheerful, and made no complaint of pain or discomfort. At 12.20 p.m. she had another copious bright-red haematemesis—about two pints—which was followed in a quarter of an hour by another, after which she rapidly became collapsed. An attempt was made to transfuse saline solution intravenously, but death ensued within ten minutes.

Autopsy.

For the following notes of the autopsy I am indebted to Dr. Turnbull, Director of the Pathological Institute.

On *post-mortem* examination, forty-eight hours after death, it was found that a portion of a fish bone 2 cm. long and in shape resembling an arrow-head was projecting into the oesophagus through a ragged wound in the anterior wall immediately below the level of the bifurcation of the trachea. The perforation measured 0.5 cm. in diameter. There was a ragged, shallow wound in the descending thoracic aorta at the site of the obliterated ductus arteriosus. There was an abscess cavity containing brown purulent fluid in the areolar tissue between the perforations in the oesophagus and the aorta. Some red blood clot was found in the stomach, the lining membrane of which was in a state of mucous catarrh. There was melanæna throughout the small and large intestines.

Remarks.

Apart from the rarity of the condition, the most interesting point in connexion with the case is the long latent

period intervening between the swallowing of the bone and the actual perforation of the aorta. It seems fair to conjecture that the haemorrhage actually commenced on the evening before her admission, and that at first there was a slow leak into her stomach, which had just about filled up as she arrived in the receiving-room. The bone itself may well have perforated the artery earlier and plugged the wound in the aorta until the surrounding area of ulceration had spread too widely to make this longer possible. Needless to say, the correct diagnosis was not even suspected. Had it been, and oesophagoscopy performed, one shudders to think of the haemorrhage which would have followed the extraction of the offending foreign body.

My thanks are due to Dr. Warner for kindly allowing me to publish these notes.

Reports of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

At a meeting on May 16th, Dr. H. C. DRURY in the chair, Dr. NESBITT gave an account of four *Tests for liver function*, which he stated were in general use at some Continental clinics, and which, he considered from his own experience, would be found of service. Two of them depended on the fact that laevulose and galactose were excreted in the urine in considerable quantity after their administration by the mouth when disturbance of liver function existed. In the laevulose test 100 grams of this sugar were given in the morning, and any trace in the urine indicated liver disorder, but not its nature. The size of the dose was objectionable, and the further fact that about 10 per cent. of normal cases show some sugar in the urine rendered the test unreliable. The use of galactose in 40-gram dose formed a much better test. Normal cases excreted sugar for one, or at most two, hours subsequently. Cases with general cell, as apart from local lesions in the liver eliminated sugar for five, six, or more hours in considerable quantity. The test was therefore positive in cirrhosis of all varieties, toxic forms of icterus, and parenchymatous degeneration, but negative in local lesions, such as tumours, and in two more or less general conditions—namely, chronic passive congestion and amyloid disease. This test was easily applied and reliable. A further test, depending on quite a different function of the liver, was the use of amino-acids. Ten grams of glycocoll are given, and the amino-acid in the urine estimated by a modification of Henrique's method. No increase over the usual small traces was found when the liver was healthy, but disease of this organ caused the appearance of substantial amounts, even up to 5 grams. The test was rather more troublesome to carry out, but in practice had been found extremely accurate. The most novel and reliable of these tests was, however, the "aldehyde reaction." Two drops of Ehrlich's aldehyde solution (a 2 per cent. solution of dimethyl-para-amino-benzene-aldehyde in 50 per cent. HCl) were added to 5 c.cm. of urine. A deep rose-red colour indicated excess of urobilinogen, and therefore insufficiency of the liver, which was allowing urobilinogen (formed in the intestines from bilirubin) to pass through into the systemic circulation. Normal cases showed only the faintest trace of pink, which constituted a negative reaction. This test had been found very reliable, and was given by any condition of the liver which would derange even a small number of cells, but was most strongly positive in such conditions as chronic congestion, cirrhosis, tumours, degenerations of various forms, syphilis, and amyloid disease. Further, the reaction would be obtained frequently before physical signs of any kind had appeared. Its advantages in cases of this kind would readily suggest themselves.

SECTION OF SURGERY.

At a meeting on May 9th, Sir JOHN LENTAGNE in the chair, Mr. W. I. DE COURCY WHEELER, in a paper on the various abdominal angulations and kinks associated with the term *Intestinal stasis*, based his conclusions on a study of 20 recent abdominal cases. Stress was laid on the

association of various intra-abdominal lesions, and the speaker condemned the practice of performing the operation of appendicectomy with great rapidity. If an appendix lent itself to rapid removal by its anatomical position of gross pathological changes, either the operation was not justified, or, more likely, the symptoms were equally due to such conditions as Lane's ileal kink or Jackson's membrane. The speaker had been able to trace Jackson's membrane in direct and unbroken communication with the right margin of the omentum, and he accepted the theory of Gray and Anderson that it was nothing more than the lateral margin of the great omentum pulled out during the descent of the caecum. The congenital theory as to the formation of this and other bands and membranes forming kinks was satisfactory and comprehensible. Dilatation of the duodenum was often overlooked, and was due to developmental adhesions at the duodeno-jejunal juncture or to a band stretching across the duodenum to the right of the superior mesenteric artery. Jackson's membrane, so far from helping to fix the caecum, often caused a marked kink at the hepatic flexure, with prolapse and dilatation of the caecum. Cases with slight or marked visceroptosis, with splashing caecum and diffuse right-sided discomfort or pain, almost invariably had a well-developed Jackson's membrane. The membrane should be divided if causing exaggerated angulation of the hepatic flexure. The cases with a little experience could be diagnosed before operation. Left-sided pain was often due to an exaggerated kink of the pelvic colon, rendered worse in females by the implication of the left ovary in the line of fusion between visceral (mesocolic) and parietal peritoneum which caused the kink. A plastic operation on the mesocolon relieved the kink, and often cured constipation in the most intractable cases. In enteroptosis cases the conditions described were most marked. Gastro-enterostomy, like appendicectomy, was often performed without having regard to developmental adhesions and obstructions of a congenital kind below the duodenum. It was a simple and rapid operation to perform, but was seldom indicated beyond cases of pyloric obstruction. Until recently, gastro-enterostomy was too frequently performed, and the after-results were not as favourable as was generally supposed. The whole subject matter required riddling and discussion, but certain points were definitely settled, one of the most important being the definite presence of abnormal angulations and rotations of the gut, which, when relieved by operation, caused the disappearance of symptoms in a number of obscure abdominal cases. The relief of constipation by a plastic operation on a developmental kink was worthy of attention. Dr. MAURICE HAYES, in a paper on the *Intestinal tract*, stated that in all cases the data furnished by the x-ray examination should be carefully analysed in conjunction with the previous history and the subjective and objective symptoms of the patient. Radiography should be employed as an aid to, and not as a substitute for, the ordinary methods of diagnosis. To interpret accurately the different shadows cast by the intestines required much practice and experience. The shadow of a loop of the bowel, when viewed obliquely, gave the idea of an existing kink; in reality this curve might be the arc of a circle quite insufficient to delay the passage of the intestinal contents. In spasmodic strictures of the oesophagus the bismuth food might be seen to enter the stomach with a sudden rush when the spasm relaxed. In cicatricial stenosis the food passed in a thin stream, and peristaltic movements were violent. In malignant strictures the peristaltic movements in the neighbourhood of the growth were feeble. Reversed peristalsis was often present, and enlarged glands could be observed near the gullet in the posterior mediastinum. As the position of the umbilicus varied, a transverse line between the summits of the iliac crests would be the most accurate landmark. In the erect position the greater curvature of what might be termed the "normal" stomach reached this line. Radiography was of doubtful value in determining the presence or absence of gastric ulcers. A point of maximum tenderness to pressure over a particular part of the stomach or duodenum was not strong presumptive evidence of an existing ulcer. Adhesions which fixed the terminal part of the ileum to the right pelvic brim could be detected by x-ray examination, and the latter was the most valuable method of accurately determining the

position of the large intestine. The duodenum was often seen to be much dilated—especially when there was obstruction to the free passage of food into the jejunum, or when there was delay in entering the caecum. Dr. FARNHAM said he had gone into the literature, and was not satisfied that the clinical symptoms attributed to these kinks were really due to them. It was well known that rest in bed improved the condition. He was not satisfied that the performing of plastic operations and the removal of them would improve the condition, nor would the removal of the adhesions improve it. The Chairman (Sir JOHN LESTRAIGNÉ) said his opinion largely coincided with Dr. Farnham's. There were two main schools of mechanical theory of this affection—the English school, led by Lane, and the Danish; and there was a third, namely, the French. All the schools acknowledged that there were cases in which symptoms similar to those complained of in these instances were present without evidence of stasis, and that there might be some other cause. The Continental school said that most of the trouble was due to putrefactive changes in the intestine and that the condition was due to intestinal toxæmia; that there was a good deal of truth in this there was not the slightest doubt.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

At a meeting on May 27th, 1913, Dr. FREDERICK TAYLOR, President, in the chair, Dr. H. A. LEDIARD (Carlisle), in a paper on *Chyliform effusion*, described a case which commenced in 1903 with abdominal pain, resembling that of peritonitis; a month later there was a second attack, and the recovery from it was associated with emaciation. All who examined the patient agreed that he had tuberculous disease of the abdomen. The face was expressive of prolonged physical depression, and his appetite was vicarious. The anterior abdominal wall showed distended veins, and, when he coughed, fluid passed down the left inguinal canal into the scrotum. There was dullness on percussion over a limited area above the umbilicus. Diarrhoea was a prominent symptom, probably on account of the unusual things the boy ate. The urine was free of albumen and sugar. Tuberculous peritonitis was diagnosed, and drainage recommended. The fluid withdrawn was reported upon as milky looking, alkaline in reaction, specific gravity 1005, 6 parts per 1,000 albumen, and less than 0.2 per cent. of fat. No distinct cellular elements could be found, nor was there either blood or pus. There was some improvement following the operation, but afterwards the patient fell away, and disturbance of the mentality suggested tuberculous meningitis; there was, however, no convulsion or fit. The abdominal swelling persisted, the tongue became dry, he was emaciated, and he died, obviously of brain symptoms. At the *post-mortem* examination chylous fluid escaped from the abdomen, and was found to be free in the abdominal cavity, more on the right side than on the left. It was not shut up in loculi; 65 oz. was removed. There was distension of the coils of the intestine, resulting in the heart having been pushed upwards. There were no adhesions between the coils of the intestines, nor between the latter and the abdominal wall. The omentum showed minute tubercle granulations, and the mesentery was much thickened; the mesenteric glands were much enlarged but not caseated. Near the pancreas was a mass of glands $2\frac{1}{2}$ in. in diameter; the mesenteric vein was much obstructed. The thoracic duct in the thorax showed no abnormality. The glands presented numerous tuberculous foci, and in most of these the centre was caseated, with cellular proliferation, and giant cells. The lymphatic channels contained numerous mononuclear cells. The liver was not enlarged, but the spleen was large and doubled on itself; there was tubercle of the kidney also. There were no cavities in the lungs, but the air cells were filled with an exudate, and there were some tubercle bacilli found. The origin of the condition seemed to be that tuberculous disease affected the glands, and caused pressure on the receptaculum chyli. Death ensued owing to tuberculous involvement of the membrane of the brain, after a long period during which the disease was only abdominal.

There was no means, short of tapping, by which the presence of a chyliform fluid could be determined. It had occurred to him that pressure could have been relieved by tapping the scrotum, though the chance of keeping that part aseptic was not great. In one of the cases on which the paper was based 31 oz. per day of fluid was drawn off. Dr. MACKENZIE WALLIS discussed the chemistry of these effusions, following upon analyses of the fluid obtained from 6 cases; 3 of these had been published in the *Quarterly Journal of Medicine*, and in that paper reference was made to the cases which could be found in the literature, 174 in all. The triple classification by Quinke was based upon the presence of fat in various quantities; but he believed that criterion was an erroneous one. He suggested the cases should be divided into two groups—the chylous and the pseudo-chylous. By chylous he meant the fluids which resulted from trauma or disease of the chyle vessels, with the escape of chyle from the lacteals of the pancreatic cyst. The pseudo-chylous were those fluids in the serous cavities in which the opalescence was only partially due to fat, other substances also being present. The commonest associated diseases with milky fluid were malignant disease, tuberculous infections, cirrhosis of the liver, and nephritis. Out of 172 cases, 42 had simultaneously pleural effusion which was milky and pseudo-chylous in character. In 18 the effusion was bilateral, in 24 it was unilateral. There were two examples of milky pericardial fluid, and four of milky peritoneal fluid associated with hydropericardium. In the chylous variety, the fluid reaccumulated much more quickly than in the pseudo-chylous, and the latter was a pure white, as against the yellowish-white of the other form; it also diminished in quantity after successive tapplings. In one case, in which the disease was a septic hip-joint, the peritoneal fluid withdrawn was first milky, and later became serous. Odour was a great help in differentiation, for the pseudo-chylous was odourless, while the other smelt of ingested food, owing to the fat present in such food. Dr. RYFFEL described two cases in which milky-looking effusions were encountered. The first was one of chronic nephritis, in the later stages of which the fluid accumulated at a great rate. Its character corresponded with that described by Dr. Wallis as pseudo-chylous ascites. The second case, in which the fluid was found in the thorax, was a more difficult one, and the *post-mortem* examination did not enable the origin to be definitely stated. The liquid contained globules of fat, but they did not fully account for the opalescence.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

At a meeting on May 24th, Professor E. W. HOPE, President, in the chair, Dr. C. O. STALLYBRASS, in a paper on the *Declining incidence of typhoid fever*, pointed out that this decline affected almost every civilized country; the statistics for Great Britain might be divided into two periods of decline, separated by a period lasting from 1890 to 1900, when the rates were stationary and there was an actual rise in some towns, notably London, Edinburgh, Birmingham, and Glasgow. Though one of the principal factors in the reduction of typhoid fever of late years had been the change from the conservancy to the water-carriage system of excrement disposal, yet in Liverpool the substitution of water-closets for privies was being actively enforced during the years 1880-93, and it was in those years that there was an increase of the disease in that city. Whatever influence was at work and operating to increase the prevalence of typhoid fever, it was sufficient to counterbalance the effect of the removal of the privy-middens which formerly existed. The speaker did not consider that the decline of the disease could be altogether attributed to an improved water supply, for this was excellent before the decline set in, nor did he think it was due to a diminished consumption of shellfish. It was more likely to be due to the increasing number of removals to hospitals, and most likely to the important sanitary work that had been effected in Liverpool in the last fifteen or twenty years, more especially as regards the rehousing schemes that had been carried out. These had involved the destruction of many insanitary courts, which at one time were a striking feature of the central and older parts of the city. They were provided with trough closets, common to several

families, which, in spite of the greatest care on the part of the sanitary staff, were often in a state of unspeakable filthiness. As a result there was an excessive incidence of typhoid fever in the central parts of the town compared with the outskirts. Since 1896 the number of these courts had been reduced from 1,540 to 500, and the annual number of cases of typhoid fever from 1,300 to 125; in other words, for every court destroyed there was one case of typhoid fever per annum less. Professor HORE referred to the danger of fly contamination, and said that the public should be urged to obtain their food supplies only from those shops in which precautions against the contamination of food from the filth of flies were carried out. He was certain that more energetic control of the shellfish industry would benefit both those engaged in it and the public generally. Dr. VAENER was not convinced that immunity from typhoid fever was obtained by a previous attack. Dr. SYDNEY MARSDEN agreed as to the important association of privy-middens with outbreaks of typhoid fever, and stated that in Birkenhead the disease had practically become extinct with the adoption of water carriage. The Lord Mayor of Liverpool entertained the members of the society to luncheon, and in the afternoon motor excursions to the Liverpool Garden City and elsewhere were made, and about seventy members were taken for a cruise on the river.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

At the quarterly meeting, held on May 27th, Dr. J. GREIG SORTER, President, in the chair, there was a unanimous acceptance of the resolution of a special committee that representations be made to the Home Secretary to the effect that it was most undesirable that criminal lunatics be sent to county or borough asylums. The Lunacy Commission had expressed its support of this attitude. The meeting was also unanimous in urging that Ireland should be included in the Mental Deficiency Bill now under discussion in the House, and it was shown that Ireland was in special need of such an enactment, even more so than the parts of the kingdom catered for in the measure. Dr. R. G. ROWS read a paper by himself and Dr. DAVID ORR on the spread of infection by the ascending lymph stream of nerves (ascending neuritis) from the peripheral inflammatory foci to the central nervous system. He said that it had been shown that toxins and organisms could travel by the lymph streams of peripheral nerves into the central nervous system; but while they could prove that degeneration of the myelin sheaths of fibres in their intramedullary course might thus be produced, they did not find unequivocal evidence of actual myelitis. In the present series of experiments the capsule containing the organism was placed much nearer the spinal cord than in the previous series, the cord being exposed at the level of the lumbo-sacral enlargement, and a capsule containing *Staphylococcus pyogenes aureus* was sutured against the dura mater. In some other experiments the capsule was placed close against an intervertebral foramen. All the experiments gave positive results, though in some instances the change was more acute than in others, owing to the capsule having burst and the nervous system being invaded by the organism. Generally it could be said that the nervous and meningeal tissues nearest the focus of irritation suffered most, and the phenomena became less marked from without inwards, with a minimum near the central canal of the cord. Only rarely were organisms found to have passed the barrier of the dura mater. Yet in both the white and the grey matter of the cord the vessels exhibited marked pathological changes. The resemblance between the experimental phenomena produced by the authors and the pathological phenomena found in acute poliomyelitis was very close indeed, and there could be little doubt that poliomyelitis was essentially a lymphogenous infection.

UNDER the will of the late Miss Margaret Jane Ashley, of Rowan House, Dorchester, Dorset, County Hospital receives a bequest of £1,000 and Weymouth Eye Infirmary one of £500.

Reviews.

THE BRITANNICA YEAR BOOK.

ENCYCLOPÆDIAS are, of course, invaluable as works of reference, but their utility is greatly lessened by a serious drawback. Even when all the volumes appear at once, as in the last edition of the *Encyclopædia Britannica*, not a few of the articles are necessarily out of date before the mechanical difficulties of publication can be overcome. No encyclopædia, therefore, is absolutely trustworthy at every time at a given time. This is true of all branches of knowledge, but it is especially so in the case of science, which is subject to changes often amounting to revolutions every few years. It was Sir Michael Foster, we think, who estimated the average life of a physiological theory at ten years, and surgery is liable to changes almost as rapid. A considerable time must necessarily elapse between the editions of an encyclopædia, and in the meantime knowledge continues to grow at a pace with which no publication covering the whole field of human activity can keep pace. It was a happy inspiration, therefore, which led the publishers of the *Encyclopædia Britannica* to issue a year book which is at once a supplement to the *Encyclopædia*, bridging over the gap between 1910 and the present time, and an independent work of reference.¹ The *Year Book* is a companion and in many points a corrective of the great work published in 1910-11. In the words of Mr. CHISHOLM, the editor, "it comes in direct series, though in a different form, with the eleventh edition of the *Encyclopædia Britannica*, and carries on under the same auspices, with the same ideals, and with the same corpus of contributors—selected and enlarged for adaptation to the circumstances, the same attempt to give accurate and disinterested expression to the best judgement of the civilized world." The *Year Book* is designed on the plan of an annual survey, but the arrangement of the matter is on the same lines as in the *Encyclopædia*, which as it were hands on the torch to those responsible for its production. It begins with a diary of events from January, 1911, onwards, which, as far as we can judge, is remarkable for its completeness and accuracy, and it contains, packed into a wonderfully small space, information not only about the present state of knowledge in various departments, but about the events which have led up to the political and social situation and to discoveries in diverse fields. *Quidquid agunt homines* would have been an appropriate motto for the book. Turning to the articles likely to be most interesting to our readers, Mr. Stephen Paget gives a concise but lucid summary of the advances made in medical science within the last two years, and Professor Edward Cameron Kirk, of the University of Pennsylvania, reviews the progress of dentistry. We are somewhat surprised in a publication such as the *Britannica Year Book* to find an article on osteopathy. The editor seems to feel that some kind of explanation of the intrusion of such a diatribe in the domain of science is necessary, for he prefixes a note in which he says: "The distinctive school and system of medicine to which this name has been given has become so prominent in recent years that an authoritative statement of its principles and claims appears desirable." Such an "authoritative statement" is accordingly supplied by G. W. RILEY, Ph.B., D.O., who is described as "a leading American osteopathist." We need not discuss the article further than to compare the statement of the author that "the curricula of the osteopathic colleges embrace all the subjects taught in the other medical schools except materia medica" with what is said about these schools by Mr. Abraham Flexner,² who states "with all possible emphasis" that not one of these schools is in a position to give such training as osteopathy itself demands. "In so simple and fundamental a matter as anatomy—assuredly the cornerstone of a science that relies wholly on local manipulation—they are fatally defective." The equipment of the schools is of the

¹ The *Britannica Year Book, 1913*. A Survey of the World's Progress since the completion in 1910 of the *Encyclopædia Britannica*. Eleventh edition. Edited by Hugh Chisholm, M.A. Oxon., Editor of the *Encyclopædia Britannica*. London and New York: The Encyclopædia Britannica Company, Limited, 1913.

² *Medical Education in the United States and Canada*. A Report to the Carnegie Foundation for the Advancement of Science. New York, 1910.

poorest; the laboratory work, where it exists, is a farce. To quote Mr. Flexner again, "the eight osteopathic schools fairly reek with commercialism. Their catalogues are a mass of hysterical exaggerations, aliko of the curving and of the curative power of osteopathy." We can only express regret that a book of such high aims and so thoroughly well executed should be disfigured by what we can only call a piece of rigmorole. But on the whole the *Year Book* is a marvellous piece of work, and it is to be hoped that its success will encourage the publishers to continue an enterprise that will, so to speak, keep the *Encyclopaedia Britannica* permanently alive and abreast of advancing knowledge. That there is a good prospect of this being accomplished may be gathered from a circular which we have received from the publishers in which, in apologizing for any delay experienced in obtaining copies of the book, they state that the filling of 10,000 orders already received has exhausted the first impression, and the second printing has not been obtainable from the press quickly enough for the delivery of further copies on demand. They add, however, that the second impression will now be shortly received from the binders. For a doctor who wishes to keep himself well posted without much trouble in the progress of human affairs we know of no better guide than the *Britannica Year Book*. For the period which it covers it is an admirable *Conversationslexicon*.

TUBERCULIN IN DIAGNOSIS AND TREATMENT.

PRACTICAL experience in the use of tuberculin is gradually affording a mass of evidence as to its therapeutic value, its indications, and its limits. An important contribution to the common stock of information is forthcoming from the chief workers at the Henry Phipps Institute in Philadelphia, where the treatment has been in use for the last five years.

DES. HAMMAN and WOLMAN have issued a substantial volume, *Tuberculin in Diagnosis and Treatment*,³ containing a very full account of the principles underlying the action of tuberculin, and of their experience of its uses. Nominally written as a guide to the uninitiated worker, it makes clear certain general lines of thought, but the reader will rapidly discover that the points upon which all observers are agreed are not very numerous. From much that is purely speculative certain considerations stand out definitely, and of these we may mention the opinion that reaction to tuberculin is an indication of infection, but not of necessity of the clinical disease. Another important fact with regard to immunity may be held to be established. Actual immunity is only a relative condition. It depends upon the size of the reinfecting dose. A small reinfection may lead to much local disturbance in the immune subject by which the virulence of the infecting bacilli is destroyed, but a large reinfection may be attended by general symptoms continuing for a long time, and indicative of a chronic rather than an acute progression of the disease. A very acute infection, on the other hand, may produce all the symptoms of intense intoxication leading to death, even in a person previously assumed to be immune. The relapses so commonly observed in the human subject, varying in intensity and duration, are doubtless often due to auto-infection reacting in proportion to the size of the dose of poison that may be at work.

Although reaction to tuberculin, experimentally introduced, is a fairly good test, it is open to several sources of error and hence it will not surprise the reader, who may have hitherto put all his faith in the textbook, to find that a great divergence of opinion is obvious amongst experimenters as to the actual nature of the tuberculin reaction. The phenomena of hypersensitiveness have been more fully studied in recent times, but much remains to be done before its full diagnostic significance can be established. Most observers are agreed that a vigorous response to the cutaneous test is a good indication of such hypersensitiveness in early life, but in later years the frequent exceptions prevent any positive deductions. It would appear that from 40 to 60 per cent. of healthy adults have been found

to react to the subcutaneous test, but the interpretation of this high average has been the subject of much contradictory discussion. The conjunctival reaction also has met with varied degrees of support and objection. It seems to have proved injurious in too large a number to admit of its unrestricted use, and the conclusion drawn from the large field of the authors' experience is not in favour of the routine use of any tuberculin test for diagnosis, but only when other means have proved inconclusive.

The later part of the work is devoted to the discussion of treatment, and full information is given as to the methods of preparation and technique employed. Like other special workers in the field of tuberculosis, the authors are fully alive to the danger of attributing recovery to any special means of treatment adopted. They maintain that three points must be regarded in estimating success or failure—namely, the duration of life after treatment, the ability to work, and the absence of bacilli from the sputum. The persistence or modification of physical signs are, they consider, of minor import, if the other conditions are favourable.

Although nominally intended as a practical guide, the work is in fact a compendium of former and latter observations and of the opinions founded upon them. The average reader without special knowledge may well be confused and enlightened in turn by the mass of conflicting evidence that is put before him. It need hardly be said that the ultimate verdict is in favour of tuberculin treatment, but there are so many side-issues to consider that the particular conditions of each individual case must still count for much before the decision that tuberculin should be used is reached.

EYE-STRAIN.

THIS useful little book⁴ consists of a collection of articles contributed to the *BRITISH MEDICAL JOURNAL*, the *Lancet*, the *Birmingham Medical Review*, the *Ophthalmoscope*, and the *Reports of the Society for the Study of Disease in Children*. They include the Middlemore Lecture, delivered in 1910 at the Birmingham and Midland Eye Hospital. It is obvious that there must be a great deal of repetition, but the subject is of such vast importance that many of its phases cannot be too often reiterated.

The first article is on eye-strain, or asthenopia and its detection in practice. The author defines eye-strain as a convenient modern expression which may be taken to mean that the eyes cannot be used as they should be in a state of health without entailing a strain upon the muscles, intrinsic or extrinsic, of the eye, which in its turn betrays itself by local or general discomfort. This strain is more likely to be manifested among the cultured classes, and is more common in women and children than in male adults. The "neuropathic temperament" is an important factor in determining the symptom complex of eye-strain. Chronic headache and neuralgia are the symptoms most frequently met with; some American authors would add a multitude of other functional disorders, including epilepsy and chorea, but the author gives cogent reasons for believing that this is to go too far. The detection of eye-strain is by no means easy, especially when no eye symptoms are present, such as pain, blepharitis, conjunctivitis, or chronic sties, all of which are associated with errors of refraction. Many of the patients have perfect vision, and the error of refraction may be very small. In a susceptible individual even one quarter of a dioptré of astigmatism may be responsible for all the symptoms, especially if the axis be oblique or against the rule. The author agrees with Weeks in urging the absolute necessity of using a mydriatic in such cases, and he rightly says that full cycloplegia with atropine may be necessary. This advice is the more welcome because many ophthalmologists treat these cases without cycloplegics; the result is often failure to cure the symptoms of asthenopia. Time must be devoted to the case, and it may be necessary in a bad case to see the patient several times.

The second chapter deals with ocular headaches. The causes of headaches are classified, and among them eye-strain occupies a prominent place. Errors of refraction and of muscle balance are fertile sources of headache. The

³ *Tuberculin in Diagnosis and Treatment*. By Louis Hamman and Samuel Wolman, of the Johns Hopkins University. New York and London: D. Appleton and Company. 1912. (Demy 8vo, pp. 395, figs. 30. 12s. 6d. net.)

⁴ *Eye-strain in Everyday Practice*. By Sydney Stenbenson, M.B., C.M. Edin., D.O. Oxon., F.R.C.S. Edin. London: *The Ophthalmoscope Press*. 1913. (Demy 8vo, pp. 139. 3s. 6d. net.)

author believes that migraine is often due to eye-strain: "I do not for one moment doubt that the essential factor in migraine is eye-strain." We are inclined from our own experience to agree with Flemming, who said that "he did not believe that the migraine would be cured merely by correcting errors of refraction, as there was a general condition to be considered in addition." Many cases of migraine have no errors of refraction or of muscle balance, and careful correction of such errors when present may fail to cure. Many cases may be greatly improved, but the prognosis should be most guarded or much disappointment may follow.

The third chapter, upon some unusual forms of migraine in children, is most valuable, coming as it does from the pen of one who has made the diseases of children his special branch of ophthalmology. Many of the headaches of children are migrainous in nature, and the migraine is apt to be atypical in infants. It is often bilateral, its periodicity is striking, tinnitus is frequently present, and hemianopsia and scintillating scotomata are rare. Stephenson discusses migraine associated with aphasia; migraine replaced by bouts of vomiting; and migraine associated with alterations of sensation or disturbances of mobility. Cases are cited in support of these types. Finally, the author believes that severe vertigo may be a manifestation of migraine.

The fourth chapter treats of habit spasm and eye-strain. The habits are jerking movements of the lids, often accompanied by a drawing up of the angle of the mouth; convulsive movements of the nose, the forehead, shoulders, arms, hands, or legs; and a tendency to make uncouth noises, such as "grunting," "clucking," "sniffing," or "hiccupping." A careful examination of the eyes is essential in all these cases, which may often be cured by suitable glasses.

"Pseudo-optic neuritis" is the subject of the fifth chapter, which is headed "A Common Appearance of the Optic Disc liable to be Mistaken for Optic Papillitis." The reviewer has found these cases exceedingly rare; although he has examined the disc of every child in a school clinic, he has so far not detected one among the last 250 cases; Stephenson finds 22.8 per cent. James Bordley describes the condition as "fairly rare," and Poltbeck gives the figures as 0.214 per cent. The cases to which references were made have all the characteristics of real papillitis, and can only be separated from it by a consideration of the whole circumstances of the case. The common mistake is to take pseudo-papillitis for real optic neuritis, but the reverse error has been made, even by Stephenson himself. The appearances of the disc vary so much that in slight cases it is difficult to decide whether a given example is within the physiological limits or whether there is an actual hyperæmia. The edges of the disc may be indistinct and yet the fundus may be normal. These facts may account for the frequency with which the author finds papillitis of the pseudo-hypermetropic type. The differences between the real condition and the "pseudo" type are discussed by the author. The final chapters deal with cases of eye-strain simulating grave organic disease of the central nervous system and the aftermath of eye-strain, the last being the Middlemore Lecture.

We have said enough to indicate the extreme interest and real value of the book, so we shall leave these last chapters to the reader. The subject of eye-strain as a cause of headache and an exciter of other manifestations of the neurotic habit is receiving much more attention from the general practitioner than formerly, but even to-day many persons suffer lifelong misery and often incapacity for work because no one tells them to consult an ophthalmic surgeon. The practitioner will never earn more gratitude from his patient who is a martyr to headaches than when he sends her to a careful and competent ophthalmologist. Too often such persons fall into the hands of the advertising "optologist." Every medical man would do well to buy, read, and digest Mr. Sydney Stephenson's book.

DISEASES OF THE HAIR.

The work of Sabouraud has added more than that of any other dermatologist to our knowledge of the hair and its diseases within the last few years, and although many problems still remain unsolved he has done much to evolve

order out of the chaos of vague ideas and empirical therapeutics which so long have prevailed in this department of dermatology. The *Treatise on Diseases of the Hair*,⁵ by JACKSON and McMURTRY, would deserve a welcome if for nothing else than that it presents the main results of Sabouraud's work on seborrhoea of the scalp and kindred subjects in a form easily to be understood of the English-speaking public, but it has the merit also of being written in a scientific manner, and of making use of modern bacteriological observations. The first great advance in our knowledge of diseases of the hair was made by Gruby, who discovered the fungus which is the cause of ringworm; then came the differentiation of ringworm from alopecia areata and the separation of the different varieties of ringworm from one another; lastly, Sabouraud has thrown considerable light on the problem of premature baldness, now perhaps commoner than ever. One great question still, however, remains as obscure as ever, the etiology of alopecia areata. This problem has exercised the minds of many dermatologists, but the only fact as yet established is that heredity plays a part in its causation. The present authors discuss at some length each of the current theories, the parasitic, the trophic, and the dystrophic theory of Jaquet, but they do not throw any fresh light on the subject. We are driven to take refuge in the blessed word "toxaemia." Although a book on diseases of the hair must necessarily concern itself chiefly with the scalp, due attention has been paid to the hair of other parts of the body, and such diverse conditions as sycosis, hairy moles and trichotillomania are all dealt with adequately. The subject of treatment is in most cases fully dealt with, and there are many interesting prescriptions given which will repay examination. We are pleased to note that the Kienbock-Adamson method of applying x rays to the scalp is recommended as the method of choice when the whole scalp is affected with ringworm, but Fig. 71, which illustrates the points to which the rays should be directed, is not quite accurate, as the lines of application are not drawn in each case perpendicular to the surface of the scalp. The book is well got up, the illustrations, many of them derived from Sabouraud, to whom in their preface the authors handsomely recognize their indebtedness, are excellent, and we can recommend it confidently.

THE HISTORY OF CHEMISTRY.

A PERUSAL of Dr. CAMPBELL BROWN'S *History of Chemistry*⁶ impresses the reader with the fact that the subject is practically coextensive with the history of all experimental science. The various branches into which science is now divided—chemistry, physics, botany, physiology, and all the departments of the science of medicine—all have a common origin, and in their earlier stages are scarcely distinguishable. As they have gradually diverged, chemistry has contributed to all of them, and in turn has been helped by each.

Dr. Campbell Brown commences his book with an account of the most ancient observations and speculations of which records have come down to us, and divides the history approximately into five periods, which partly overlap: (1) The Prehistoric, from prehistoric times to 1500 B.C.; (2) the Alchemical, from 1500 B.C. to 1650 A.D.; (3) the Iatro-chemical, from 1500 A.D. to 1700 A.D.; (4) the Phlogiston period, from 1650 to 1775; (5) the Quantitative period, from 1775 to 1900. In dealing with the first of these periods, ancient Chaldean and Egyptian records supply most of the material; the knowledge of metals, pigments, etc., in those remote times shows a practical acquaintance with some chemical processes which is by no means to be despised. The alchemical period was dominated, though perhaps to a less extent than is sometimes supposed, by the quest for the philosopher's stone and the power of transmuting baser metals into gold. In the iatro-chemical period, the association of chemistry with medicine, which has never since been dissolved, may

⁵ *A Treatise on Diseases of the Hair*. By G. T. Jackson, M.D., and C. W. McMurry, M.D. London: Henry Kimpton. Glasgow: A. Stenhouse. 1913. (Roy. 8vo, pp. 366; 109 engravings and 10 coloured plates 16s. net.)

⁶ *A History of Chemistry, from the Earliest Times till the Present Day*. By the late James Campbell Brown, D.Sc. Lond., LL.D. Aberd. Professor of Chemistry in the University of Liverpool. With a portrait and 106 illustrations. London: J. and A. Churchill. 1913 (Med. 8vo, pp. 568; 106 illustrations. 10s. 6d. net.)

be said to have definitely commenced, since the main object of the iatro-chemists was the production of substances of value as medicines for human ailments. The theory of phlogiston marks the beginning of the more definitely scientific aspect of chemistry, the phlogistonists and antiphlogistonists being more concerned with the discovery of the explanation of such general phenomena as combustion than with any directly utilitarian object. But as a large proportion of the notable chemists from that time to the present were either practising physicians or pharmacists, or began their careers in medicine or pharmacy, the association between chemical science and the art of medicine has continued to be close. The quantitative period may be said to have begun with Lavoisier, who employed the balance systematically in the study of chemical phenomena; Priestley, Cavendish, and others were working at the same time in a genuinely scientific spirit, and with the enunciation, soon after, of Dalton's atomic theory, the science of chemistry began that advance which has revolutionized the world.

Dr. Campbell Brown's book, published posthumously, and edited by Mr. H. H. Brown, is based on the lectures delivered by him as part of his chemical course in the University of Liverpool, and shows an amount of research which proves how deeply he felt the absorbing interest of his subject. Practically half the book is devoted to the development of chemistry in the nineteenth century, and as the present time is approached details are more fully given; the final chapter is devoted to that latest field of chemical study, the radio-active elements. It is of great interest to observe from the narrative how imperfect theories, like that of phlogiston, which had to be abandoned and fell into discredit, can nevertheless be seen in the light of fuller knowledge to have come so near to the truth that comparatively little alteration suffices to identify them with the views now held and established by experience; and another striking observation is that an erroneous theory has not infrequently been maintained to the last by the very men whose work was making it untenable.

The interest of the book is considerably enhanced by the numerous portraits of famous chemists, from Boyle onwards, whose work is dealt with; there are also many reproductions of illustrations from old manuscripts of the apparatus and the signs employed by alchemists.

NOTES ON BOOKS.

DR. NORMAN PORRITT has published, under the auspices of the Church of England Temperance Society, a useful pamphlet of warning with regard to the dangers of the drug habit.¹ As he points out, the secrecy with which such indulgence is invariably practised renders it difficult, or rather impossible, to estimate the extent of the evil, but there can be little doubt of its wide and growing prevalence. Nor can it be denied that its effects upon moral and physical health are even more disastrous than those of alcoholism. The pamphlet is well calculated to enforce the gravity of the evil with which it deals, and deserves wide circulation.

Popular handbooks on the part the mosquito plays in the spread of disease are required, and one² by ALVAH H. DOTY, formerly health officer of the Port of New York, may be recommended. It deals sufficiently with the identification, breeding places, food, and length of life of mosquitos, the distance they can travel, and with their hibernation. The extermination of the mosquito, and remedies and agents for the prevention and treatment of mosquito bites, are discussed. The book is well illustrated with diagrams of larvae, pupae, and adult insects, which greatly increase its value. It should prove useful to the laity generally.

A monograph by G. A. WETTERSTRAND,³ dealing with the many aspects of perforated gastric and duodenal ulcer, gives an analysis of 60 cases operated upon between 1900 and 1911 at the University Hospital in Helsingfors. Only in a few cases was it possible to distinguish ulcer of the

stomach from ulcer of the duodenum before operation. It is unfortunate that hitherto satisfactory information as to the ultimate results of operation has not apparently been forthcoming. Previous publications indicate vaguely that more than half of the patients operated on for perforation of a gastric or duodenal ulcer lived many years after in perfect health, and that troublesome symptoms seldom occurred after recovery. The author has found it difficult to follow up his patients, only 17 of whom he has succeeded in tracing. Of these, 13 were fit for work, and of these, again, 8 showed no symptoms of ulcer. The author concludes that the disease is as common in Finland as in other civilized countries, but that men are far more liable than women to contract the disease. In 75 to 80 per cent. there was a history of symptoms indicative of ulcer. In three-quarters of his cases the author found changes in the liver dullness due to the escape of air into the abdominal cavity, and comments on the scant recognition which this valuable sign has hitherto received. He finds that peritonitis following perforation is usually diffuse, and that the mortality from this source is 45 per cent., as compared with 39 per cent. in cases of diffuse peritonitis following appendicitis.

MEDICAL AND SURGICAL APPLIANCES.

A Milk and Butter Cooler.

MESSRS. BILTON AND Co., of Fenton, Stoke-on-Trent, have made a milk or butter cooler of a kind many house-keepers have been looking out for. The principle of its construction is scientifically sound and is well carried out. It consists of a large outer vessel of red porous earthenware and an inner of glazed white ware which rests on the rim of the larger and has a ventilated glazed cover. The outer vessel is filled with water which slowly filters through, so that if the vessel is kept clean and free from grease the outer surface is constantly moist, and the evaporation in warm weather keeps the temperature of the interior below that of the atmosphere. The outer vessel is of good design. The price varies, we are informed, from 4s. 6d. to 1s. 6d., according to size.

Tonsil Forceps.

Dr. JAMES DONELAN (London, W.) states that he has used the tonsil forceps shown in the drawing for a long time with great advantage in the removal of embedded tonsils or in those in which only a small amount of tonsillar tissue has been left by a previous operation, but which are liable to become

enlarged through recurrent infection of the remaining crypts. He has lately had the jaws of it modified so that it holds the gland without tearing it, as is so often the case with hooked instruments. It will be found especially useful in the removal of embedded tonsils by dissection, but is made without scissor handles in order to allow of the passage over it of a snare or guillotine.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

THE ADVERTISING OF "BEAUTY SPECIALITIES."

THE Committee of the House of Commons appointed to inquire into the sale and advertisement of proprietary medicines resumed its sittings on May 29th, when Mr. S. F. Ely, secretary and manager of Messrs. Dearborn, Limited, proprietary manufacturers in London, was called.

The Chairman (Sir Henry Norman) explained that the attention of the Committee had been directed to a series of advertisements in popular monthly magazines of medical preparations which were alluded to in the form of answers to correspondents appearing under the names of various ladies. The Committee desired to ask the witness certain questions about these advertisements—was he prepared to answer?

The Witness: I am afraid I am not. Mr. J. D. Daniels, who is the only director of the company and who writes the advertisements, is in America at present.

Questioned further, the witness said there was no one in this country at present who knew anything about the advertisements. Mr. Daniels was the sole proprietor of the company, whose authorized capital was £2,000.

Mr. Parkes, a solicitor, who accompanied the witness, offered to give evidence, and after the Committee had

¹ *The Drug D-nger: A Warning.* By Norman Porritt, M.R.C.S., L.R.C.P. London: Church of England Temperance Society. 1d.

² *The Mosquito, its Relation to Disease, and its Extermination.* By Alvah H. Doty, formerly Health Officer of the Port of New York. New York and London: D. Appleton and Co. 1912. (Fcap. 8vo, pp. 80, 10 figs. 5s. net.)

³ *Undran till Kännedomen om de perforerade Mag- och Duodenal-saren.* Helsingfors. By G. A. Wetterstrand. 1912. Aktiebolaget Lilius and Hertzberg. (Pp. 153.)

considered the situation in private, Mr. Parkes took his seat in the witness chair. He stated that the company was incorporated in January, 1912; there were two shareholders, Mr. Daniels and another; Mr. Daniels held 501 £1 shares and the other shareholder one share.

The Chairman: Under the agreement this director, Mr. Daniels, sold to himself his own knowledge and his own services?

The Witness: That is so in all these one-man companies.

It was also elicited that when the company was formed Mr. Daniels became a debenture holder for £500, but after two or three months' trading the debenture was paid off. The witness said that Mr. Daniels consulted him as to the form of the advertising of the firm; he felt it would be a breach of professional confidence to state what advice he gave, but he had no objection to stating that since the interview the advertisements had not appeared in the form of answers to correspondents.

Mr. Glyn-Jones: Do you think it is a legitimate form of advertising to publish, apparently as part of the editorial matter of a paper, advice to use certain articles by means of fictitious answers to non-existent correspondents?

The Witness: My own view would be against it. I am not speaking of the legality or morality of it.

Mr. S. F. Ely was then recalled and sworn. The Chairman read the names of various ladies which appeared in several magazines as conducting a page of "Beauty Hints." The names were Mlle. Florence Gauthier, Mlle. Agnès Déprés, Mlle. Marguerite Fournier, Mlle. Mildred St. Aubyn, and others. He then said to the witness: You are speaking now with very great responsibility and upon oath. Are we to take it you state you have no knowledge either as to the existence or non-existence of these ladies?

The Witness: I do not know if they exist or do not exist.

The Chairman: It would strike anybody as strange that anyone in the responsible position of secretary and manager should be ignorant on the point.

The witness replied that Mr. Daniels did not discuss the advertising with him at all. He also said he had never seen any letters from these ladies, nor were there any entries in the books with reference to payment for services rendered. He could point to no fact leading him to think these ladies had a real existence; he "had an idea" that "Mildred St. Aubyn" was a real person, but he could not give any specific reason for this impression. He declined to say he believed the names were used for advertising purposes only.

Many questions were put by the members of the Committee, and after appealing to his legal adviser, the witness consented to say that the company had declared a dividend; but, he added, "you must not ask me how much." He told Mr. Lawson that "reader advertisements" cost 50 per cent. more than display advertisements, and that the magazine charges amounted to £15 and more a page. Mr. Lawson asked what the turnover of the company was. "You cannot know that," replied the witness; "it is private information."

In reply to the Chairman, the witness said he thought there were letters at the office of the company from "Mildred St. Aubyn."

The Chairman: Then you can produce them?

The Witness: I should not do so.

The Chairman: I do not think you realize the powers of the Committee. We can call on you to produce any documents or papers you have.

The Witness: Tell me what you want and I will decide whether you shall have it. (Laughter.)

The Chairman: Mr. Ely, I want to warn you. I quite understand you are in a difficult position in being called upon to give evidence in the absence of your employer, but that must not lead you into disrespect for this Committee. We desire to know whether these ladies have a real existence or not, or who they only exist in imagination and for advertising purposes.

The examination concluded after the witness had stated, under pressure, the name of the firm of wholesale chemists manufacturing the company's preparations and had mentioned that the staff at the office consisted of himself (his duties being mainly those of an accountant), a typist, two bookkeepers, and two packers.

Nova et Vetera.

A MEDICAL PIONEER OF SOCIOLOGY.

It is noteworthy that among the pioneers of political economy medical men figure in the first rank. Sir William Petty, who may be said to have laid the foundations of the science in his *Political Arithmetic*, was professor of anatomy at Oxford and afterwards physician-in-chief to the army in Ireland. His *Political Arithmetic* was first published in 1691, after his death, but several writings of his on taxation and finance appeared in his lifetime. About the same time questions of currency and finance were much in the thoughts of John Locke, the philosopher, who was for some years a commissioner of the Board of Trade. Locke studied medicine and practised the profession at Oxford; although he was known among his friends as "Dr." Locke, it seems doubtful whether he ever took a degree. He gained the confidence of the first Lord Shaftesbury by his successful treatment of a chest complaint, and he became the confidential adviser as well as the physician of his patron. To this connexion he owed his introduction to the world of action, and he gave up medicine to devote himself to political and philosophical studies. Another pioneer of political economy—or perhaps it would be more accurate to say sociology—was also a member of the medical profession. This was François Quesnay, physician to Madame de Pompadour, the founder of the *physiocrates*. He was one of the most remarkable figures among the philosophers of the eighteenth century, and may even be held to rank among the great thinkers of all time.

Quesnay was born at Méré, near Montford-l'Amury, in 1694. He was of peasant stock, and his knowledge of the conditions of rural life largely determined the line of his intellectual development. The records of his early life are obscure and confused. His latest biographer, M. G. Schelle,¹ has taken great pains to get at the true facts. It appears that, after being apprenticed to a surgeon of Equevilly, he entered himself as a regular student at the Paris College of Surgeons and the Faculty of Medicine. Quesnay was a diligent student, never, it is said, missing a visit or a dressing at the Hôtel-Dieu, and finding time besides to complete his general education, which had been neglected. This he did to such good purpose that he obtained the degree of Master of Arts from the University of Paris. In 1718 he was admitted a Master by the College of Saint-Côme, and settled at Mantes as a surgeon, being at that time 24 years of age. He had a good practice at Mantes, and was held in special repute as a man-midwife.

Even at that early time he showed independence of thought and character. He was bold enough to break a lance with a Paris physician, Silva, who had advocated bleeding as a universal means of dispersing the humours localized in any part of the body. At this time the long quarrel between the physicians and surgeons of Paris had come to a head. It was a war of pamphlets and lawsuits, and the controversy between Quesnay and Silva was regarded as an incident in the campaign. On the initiative of La Peyronie, first surgeon to the King, an Academy of Surgery was formed. Quesnay gave valuable help in carrying the scheme into effect. La Peyronie formed a high opinion of his capacity, and it was probably by his advice that Quesnay resolved to settle in Paris. In 1734 the Duke de Retz appointed him medical attendant to his household, and in 1739, by one of those abuses common at the time, the Duke nominated him a commissioner for war. Quesnay drew the salary of his office till the time of his death. He accompanied his patron on his travels to Lyons, of which de Retz was governor, and to the army, but his chief domicile was the Duke's house in Paris. There he had time enough on his hands to devote himself to studies of his own choice. La Peyronie, on his part, in 1736 got Quesnay appointed sworn surgeon to the Prévôt de l'Hôtel, a post to some extent corresponding to that of police surgeon. In 1738 he was nominated "royal professor" of surgical medicaments. In that capacity he drew up reports on suppuration and the repair of tissues, and on resolvents, emollients, detensives, etc.

¹ *Le Docteur Quesnay, Chirurgien-Médecin de Madame de Pompadour et de Louis XV, Physiocrate*. Paris: Félix Alcan, Editeur, Librairies Félix Alcan et Guillaumin Réunies, 108, Boulevard Saint Germain, 108. 1907.

In 1740 he was appointed secretary to the Academy of Surgery, an office which he held till 1748. In 1743 the first volume of the *Mémoires* of that academy was issued under his supervision. It contained articles on suppuration, gangrene, wounds, ulcers, and tumours, from his pen. His advanced views on the surgical treatment of abscess and "fungus" of the brain brought upon him the wrath of John Bell. Quesnay also contributed a preface in which he urged that surgeons should not be satisfied with manual dexterity and mere observation, but should look upon a knowledge of anatomy and chemistry as essential. He insisted that to be a sound practitioner it was necessary to be a surgeon as well as a physician. Quesnay had a considerable share in the great history of surgery issued under the auspices of La Peyronie. That work was intended to prove that the College of Surgeons had always been independent. The public was generally on the side of the surgeons, and in the end the surgeons were victorious.

In 1744 Quesnay took his degree as Doctor of Medicine at the little university of Pont-à-Mousson while he was at Metz with the army in attendance on the Duke de Retz. His abandonment of surgery is said to have been due to an infirmity which crippled his hands. His graduation brought him into conflict with the Faculty of Paris, which put in force an old decision that the doctors of Paris should not consult with those of provincial universities. La Peyronie continued to be a powerful protector, and left him a considerable legacy. On his death Quesnay was talked of for the post of first surgeon to the King, and his candidature was supported by Diderot with his pen. La Martinière was, however, appointed.

It was in an essay on the quarrel between physicians and surgeons, published in 1748, that Quesnay first showed the bent of his mind towards social philosophy. The interesting feature of this essay is that Quesnay considers the whole question from the point of view of the public good rather than that of the doctors. There is in more than one place a note of scepticism, as when he hints that the first thing to be inquired into is whether these professions are useful rather than hurtful to society, and whether they should be maintained or done away with. He points out that among poor people treatment is very simple, consisting in bleeding, *tisanes*, some purges, and very little else in the way of medicine, and this, he adds, is "perhaps the best."

By 1750 we find Quesnay installed at Versailles. A year or two before he had been chosen by Madame de Pompadour as her doctor. He had rooms in the palace near the floor occupied by the favourite. Madame de Pompadour was an exacting patient. She often had headaches and kept her bed, and Quesnay could not leave his post day or night. When she went to Paris, however, he sometimes got permission to pay visits to the capital. He followed her wherever she went, and it is said that on two occasions he saved her life. She left him a pension by her will, and gave him many other marks of kindness. He was on a very confidential footing with her, and had naturally many opportunities of becoming acquainted with people of influence. Quesnay's position at Court steadily improved, and he was often admitted to the conversations of the King with Madame de Pompadour. In 1752 he had

charge of the Dauphin during an attack of small-pox, and the King's gratitude showed itself by the grant of a pension and letters of nobility. The King used to call him his thinker, and in allusion to this gave him three pansies on his arms ("pansies, that's for thoughts"). On one occasion when the King was taken so ill in the apartments of his mistress that he was thought to be dying, Quesnay was sent for and had the good fortune to cure him. This was rewarded by a gift from the King which made it possible for Quesnay to buy a considerable estate, where his son gave himself up to agriculture. He was also one of those who treated the King after the attempted assassination by Damiens. Although he visited his royal patient five or six times a day he made very light of the wound, saying if it was anybody else he could go to a dance.

Notwithstanding his position at Court, Quesnay led an independent life. He received persons of all parties in his rooms, and his friends knew that there they could talk with the greatest freedom and that nothing said there

would be repeated outside.

Among those who frequented his quarters were Diderot, d'Alambert, Helvetius, Buffon, Marmontel, the Marquis of Mirabeau (*L'Ami des Hommes*, father of the Mirabeau of the Revolution), and Condillac. Adam Smith knew him and formed a very high opinion of him. In Quesnay's rooms the Revolution was confidently foretold. Quesnay had neither taste nor talent for intrigue, and his rugged honesty was recognized by all. Though small and ugly, the brilliancy of his conversation made people forget his appearance. He knew men well and had the art of making them show themselves as they really were. In 1753 he published his last contribution to medical literature, a treatise on continued fevers, which he dedicated to Madame de Pompadour. His reputation was then well established. He was a Fellow of the Royal Society of London and of many other learned bodies.

Soon after Quesnay became attached to the Court the first volumes of the famous *Encyclopédie* appeared. The authors were his familiar friends. He took part in their work and con-

tributed an article on pure metaphysics under the caption "Evidence" to the sixth volume. To the other volumes he contributed articles on farming and husbandry, but when in 1759 the licence was withdrawn Quesnay ceased his collaboration, although he had prepared articles on the functions of the soul, taxes, and interest on money. Although Quesnay took religion as the fundamental basis of his system, respected it in all his writings, and died quietly in the arms of the Church, he had a horror of fanaticism and dreaded the advent to power of the Dauphin, whom he believed to be under clerical influence. It may not be rash to conjecture that his orthodoxy was, at any rate to some extent, dictated by caution.

Where did Quesnay get his knowledge of economics? He acknowledges a debt to Locke, but there was very little economic literature in the eighteenth century to read. He had observed and thought much for himself. The son of peasants of the Beauce, and having lived long within a short distance of Paris, he had seen the effects of the famines of the last years of Louis XIV and that of 1723. He had seen with what arbitrary violence the police made requisitions for the food supply of Paris. He knew

the wretchedness of the rural districts. On the other hand, at Versailles he witnessed the selfishness of the Court, and the enormous fortunes made by contractors. Attached to the service of a woman who, because she was beautiful, believed herself capable of controlling the destinies of France, living close to a king given over to idleness and pleasure, who was content to leave the conduct of affairs to men who were mere empirics in statecraft, Quesnay was led to believe that in applying to the science of government the methods which he had used in medical science he might be able to exercise a beneficial influence. Had he been ambitious he might have pushed himself forward to high place, but he thought mainly of getting solutions of the problems which he studied accepted. Thus we have the extraordinary spectacle of a man of 60 giving up the studies of his life and devoting himself to researches on subjects hardly explored by others.

The crime of Damians awakened Louis XV and even Madame de Pompadour for a moment to the importance of political economy. Taking advantage of this, Quesnay tried to get his views on taxation, agriculture, and commerce accepted by the Government. In his *Tableau Economique*, which was printed at Versailles under the eyes of Louis XV, he attempted to convey his ideas to the King and the favourite without their perceiving that they were being taught the principles of economics by their doctor. The manner in which he carried out this intention was as bold as it was ingenious. The King was beginning to feel the boredom of life, and at Quesnay's suggestion he sought diversion in mechanical work. A set of turner's tools was got for him, and he made wooden snuff-boxes for the whole Court. Quesnay next spoke about printing, and a press was set up in the private apartments of the King, of which the doctor was placed in charge. Quesnay induced him and Madame de Pompadour to print one of his own writings; it was arranged that it should be an unpublished work, which should remain secret, and should at the same time afford occasion for the display of all the resources of printing, with notes, italics, capital letters, and so forth. For this purpose Quesnay drew up his *Tableau*, following it up with a series of maxims which he fathered on Sally. He presented the little book to the King, saying, "Sire, you have seen when hunting a great deal of lands, farms, and labourers. You are going to print an account of how these people produce all your wealth." The King, who was more interested in printing than in turning, set up about half Quesnay's booklet, and revised the book several times. He was too indolent to give his mind seriously to the subject, but in setting up the type he noticed the daring opinions expressed. These led him to say: "It is a pity the doctor is not in the trade (government). He knows much more about it than any of them." The edition was magnificent, but only a few copies were printed, and it is believed that no public library has a copy to-day. The exact date of printing is not known, but it would seem to have been at the end of 1758 or the beginning of 1759.

The *Tableau* was considered very obscure by Quesnay's contemporaries. He appears to have wished to make the system which he opposed to the mercantile system visible, and with that intention drew up a scheme of the circulation of wealth evidently based on the mechanism of the circulation of the blood. The doctor was not forgotten in the economist. The maxims are the most suggestive part of the work. In them he showed himself a strong partisan of free trade, and insisted that rulers should remove all hindrances to the development of agricultural production. He advocated a single direct tax, susceptible of increase in critical times and always paid by the landlord. In this way he hoped that the farmers, freed from the arbitrary control of the tax collectors, would be able without fear to improve their cultivation. He also advocated limitation by law of the rate of interest on money, so that the State should not borrow at usurious rates which attracted capital to Paris and diverted it from agricultural use. He was strongly opposed to what he calls "pecuniary fortunes," understanding by that not capital employed in agricultural, commercial, or industrial enterprises or in the development of landed property, but fortunes consisting in interest got from money or employed in the acquisition of useless

offices, privileges, and so forth. These are, he said, fortunes which gnaw and oppress the nation; they know neither king nor country. It was dangerous at that time to criticize finance, and Mirabeau, who collaborated with Quesnay, was sent to the Bastille for having said in his work on the theory of taxation that there were no services without money, and that the King had no money to pay for services. Owing to the influence of Madame de Pompadour he was released after five days, but his work with Quesnay was interrupted. The work of the physiocrats was afterwards carried on in silence. Quesnay, who attacked the financiers in the booklet which he got the King to print, and touched up the work of Mirabeau in which the farmers-general were treated as vampires, must have felt that he was indirectly aimed at by the denunciation which sent his friend to the Bastille. This doubtless explains the disappearance of the copies of the *Tableau* which had not been distributed. They were seized and probably destroyed.

The death of Madame de Pompadour in 1764 deprived Quesnay of most of his influence. But when he was deserted by personal friends disciples gathered round him and the "physiocratic" school was founded. It seems probable that the word itself was invented by Quesnay. Its principles are set forth in a collection of Quesnay's writings, entitled *Physiocratie ou Constitution naturelle du Gouvernement le plus avantageux au genre humain*, which appeared in 1767. The essentials of the doctrine are embodied in the motto on the title-page—

Ex natura, jus ordo et leges;
Ex homine, arbitrium regimen et coercitio

—which implies that the government most beneficial to the human race originates not from the arbitrary regulation and control of men, but from right order and obedience to the laws of Nature.

Towards the end of his life Quesnay fell upon evil tongues and evil days. The physiocrats became unpopular because to their teaching was attributed the dearth of bread which followed a bad harvest in 1767. In 1770 Senac, first physician to the King, died, but Quesnay was not named in his place, and in the last illness of Louis XV in 1774 he took no part in the consultations. Louis XVI had not the same regard for Quesnay that had been shown by his grandfather.

Quesnay was a martyr to gout, the pain of which he bore with patience. His conversation was lively, and he kept at work till the very end. Among other things he applied himself to mathematics, which he had neglected, but he was led astray into fancying that he had squared the circle. He died at Versailles on December 16th, 1774.

In Quesnay the social philosopher was not separated from the economist. Coming from the plough and prepared for observation by his medical studies, he began by seeking for the causes of agricultural distress and the means of remedying it. He laid the foundation of the theory of free trade. Henry George dedicated his book, *Protection and Free Trade*, to the memory of Quesnay and his friends "who in the light of despotism have foreseen the splendours of the new era." Quesnay's position at Court made it difficult for him to write freely, and he had little literary faculty. Therefore he required disciples to help him. He made them work under his eyes and constantly stimulated them. His little apartment at Versailles was a sort of workshop where, as in the case of old painters, pupils worked under the direction of the master. It was not a little thing to do to influence Madame de Pompadour, and through her the King, to take an interest in economic questions. The physiocrats, however, never gained much influence with the public even in their own country. This was due to the dryness of their style. Some of their doctrines, too, were regarded as chimerical, and were ridiculed in contemporary literature, as by Voltaire, who laughed at the single tax in his *L'Homme aux Quarante Écus*. They were too absolute in their belief and too rigid in their doctrine, which they held to be universally and immediately applicable in practice. They did not take into sufficient account national diversities or different stages in social development, nor did they adequately estimate the impediments which ignorance, prejudice, and interested opposition presented to statesmen.

THE GENERAL MEDICAL COUNCIL AND THE PROPOSED ALTERATION IN THE STANDARD OF PRELIMINARY EXAMINATIONS.

BY

SIR HENRY MORRIS, BART., M.A., M.B.LOND., F.R.C.S.

WHEN in November, 1910, the General Medical Council, with the object of raising the standard of preliminary education, resolved on making certain changes which were to date from January 1st, 1914, it was felt by some competent critics that the time for doing so was inopportune because of the falling off in the number of students entering the profession.

It may be thought, however, from the statement recently made as to an increase of 165 students registered in 1912 over the number registered in 1911, and as to the total number registered in the year 1912 coinciding with the average yearly number of the five preceding five years, that this objection no longer exists.

But the increase is apparent, not real. It is due to the fact that a large number of students, owing to recently altered regulations, were enabled to register in 1912 instead of a year or so later; and when this number is discounted, the real increase for the year 1912 is only 80, and the total number of entrants is considerably below the average of the previous five years, although it exceeds the total for the year 1911.

What, however, is of greater importance than any question as to the "how" and "when" of raising the standard of existing examinations, is the urgent need of the several universities and examining bodies in the United Kingdom uniting to foster the establishment of a recognized school-leaving certificate; of a certificate which, without indicating a uniformity in kind of the education received, and without pretending to imply an exact identity of standard, will yet be a sufficient proof of a sound general education to admit the holders of it to any university or to the curriculum of study for any professional or scientific calling.

The entrance to a university or to a profession ought not to be barred by (in the words of Huxley) "any absolute and defined preliminary examination, the passing of which shall be an essential condition of admission to the University." The instruction of a university, or that required for any professional career, ought, to be accessible to every one who is fit to take advantage of it, although he may not have been prepared at school to pass a particular "absolute and defined preliminary examination."

It is the want of a universally recognized and accepted school-leaving certificate which handicaps students, and is so embarrassing to school masters. It is this want which has been and is the chief obstacle in the way of many an excellent and accomplished student taking a university degree which otherwise he was fully competent to do; or changing from a profession for which he finds himself unfitted, or to which he has taken a dislike, into one for which he has developed a liking and realizes an aptitude. It is the difference between the educational course they have pursued and the character of the particular entrance examination which they too late discover they have to pass, and not because their education and grounding are deficient or inferior, that under present circumstances keep the door shut against many students who are even more capable and better instructed than some of those who have been allowed to pass through the portal.

The General Medical Council could not exert its influence in a better cause than in reiterating its desire that the Board of Education and the Oxford and Cambridge School Examination Board should co-operate in getting established such a certificate; in soliciting the universities, the State, and the local authorities to take steps to standardize the different inspections by making the inspection a joint matter between them; in trying to induce the head masters of all the secondary schools of the country to have their schools officially inspected; and in urging the various universities and licensing bodies to accept such a school-leaving certificate, without requiring anything else.

Pending the establishment of such a certificate the Council, voicing as it does the whole profession, would go a long way towards bringing about compulsory inspection of secondary schools if they could induce the universities

and examining bodies of England to admit as candidates for their examinations (except, perhaps, in certain special cases) these only who have been educated at inspected schools.

But were such a desirable goal reached at home, it would still be advisable for the guidance of those Indian and Colonial examining bodies who already are recognized, or who in future desire to be recognized by the General Medical Council, that information should be given to them as to what should be the scope, character, and standard of their preliminary examination in general education.

The revision of the existing Recommendations of the Council whereby such information is at present conveyed alike to the examining bodies at home and in India and the Colonies has occupied much of the attention of the Education Committee since November, 1910. These Recommendations, which, on the joint advice of three educational experts, were adopted by the Council in 1900 and have ever since been in force, were, with "three important changes," reaffirmed in a report of the Education Committee in 1911. Two of these suggested "important changes" are (1) the increase of the percentage of marks required for the pass, and (2) the abolition of compensation between subjects. This report of the Education Committee was merely entered on the minutes of the Council.

Six months later—namely, in June, 1912—precisely the same proposals were again entered on the minutes of the Council. On neither of these occasions was the approval of the Council moved. On both occasions, on the contrary, a motion was proposed, though not carried, to refer the report back to the Committee.

In the reports of 1911 and 1912 the Sections I and II, which refer to "the character of the examination" and "the distribution of marks," are word for word the same as the Recommendations of the year 1900; whereas Section IV, as to "the Minimum Percentage of Pass," is entirely different, the pass marks then suggested being much higher than those recommended in 1900. Another important difference is that Recommendation IX of 1900 specially provides for granting compensation when the four subjects are taken at one examination "if the candidate reach the necessary percentage in the aggregate marks of his papers as a whole, provided that the required pass mark must be reached in the English paper"; whereas the reports of 1911 and 1912 suggest that "no pass should be granted in any subject when the percentage gained in the subject is less than that which is stated in Section IV of those reports."

Again, Section VII of the Recommendations of 1900, which allows of each of the four subjects of certain senior examinations being passed separately, is omitted from each of the reports of the Education Committee.

Since June, 1912, the Education Committee has been engaged in obtaining the opinions of the chief examining bodies, including those of India and the Colonies, on the proposals of the Committee; and now after nearly twelve months' interval the Committee has at the session just ended submitted a third report to the Council.

On comparing Sections I and II of this last report—which sections were adopted by the Council yesterday (May 30th)—with the corresponding sections of the Recommendations of 1900, several trifling alterations, chiefly, but not entirely, of a verbal nature, will be found. But the most important fact to mention, and, so to speak, what has cut the entire character of Hamlet out of the "Prince of Denmark," is the rejection by the Council of the whole of the section dealing with the raising of "the Minimum Percentage of Pass, in each subject."

Thus the various examining bodies—including the revised list of Indian and Colonial bodies conducting examinations recommended by the Committee to be accepted by the Council and mentioned in Division B of the report as having "intimated their readiness to adopt immediately the new standard proposed"—are left with no other standard of marking but that of 1900. And as the only allusion to "the abolition of compensation between the subjects" is in the first or historical section of Division A of the adopted report, the judicious and just No. IX of the Recommendations of 1900 obviously also remains *de facto* intact.

In a word, except for any indirect effect which the communications which have passed between the Education Committee and the various examining bodies may have upon those bodies, the decisions arrived at on May 30th by the Council, after two and a half years of deliberation by, and three reports from its Education Committee, give this result, namely, that in the words of the approved preamble, "the recommendations adopted by the Council to indicate the scope and character to be maintained in any preliminary examination in general education for which recognition is sought as qualifying for admission to the students' register" are substantially and essentially those which were adopted by the Council in 1900.

The consenting examining bodies are, therefore, now in the same quandary as children who have been encouraged to hope for a box of new toys, but who, finding the new toys have been withheld, are left with nothing but the empty box and the old toys to play with. Unless some change is agreed upon at the session of the Council in November next, the recommendations as to what should be the standard of the examinations on and after January 1st, 1914, will remain precisely the same as those of the last thirteen years.

May 31st, 1913.

ONE HUNDRED YEARS AGO.

MEDICAL REFORM IN 1813: AN ABORTIVE BILL.

In the half-yearly report of the progress of medicine from January to June, 1813, which is dated June 1st, 1813, and appeared in the July part of the *Medical and Physical Journal*, a considerable amount of space is given to the subject of medical reform. The previous half-yearly report had also concerned itself largely with the same question.

The matter in controversy was the position of the apothecaries, who included in their ranks, it must be remembered, not only persons practising pharmacy but also many of those who exercised the arts of physic, surgery, and obstetrics. There was need, urgent need, for some legislative enactments to systematize and safeguard and elevate the privileges, position, and status of the apothecaries, who were really the general medical practitioners of the time. But there were also the Colleges of Physicians and Surgeons of London with their Charters, and their well established and predominant influence; "they," said one of the reports referred to, "felt every attack on their privileges like a wound." Against the "mighty hosts" of the two Colleges the "little phalanx of Apothecaries," strictly so called (that is, including under that name solely persons practising pharmacy alone), would be helpless, unless it were "reinforced with the strong arm of the country practitioners." At the time to which we allude (June, 1813) some such reinforcement had taken place, and a committee of the "Community of Associated Apothecaries and Surgeon-Apothecaries" was preparing a bill for the House of Commons. Indeed, a bill, "immature, hurried, imperfect, and defective in detail, though incontestably sound in principle," had been presented, but fortunately it had been withdrawn before the second reading, to be "revised and improved."

The writer of the 1813 report was strongly of opinion that there was need for some measure which should substitute for the "heterogeneous mass assuming the title and functions of medical practitioners, persons properly educated, of ascertained qualifications, respectable by the class of society whence they were taken, and by having passed through the series of essential gradations." The expression "heterogeneous mass" is defined in a footnote, for which room must here be found for its graphic delineation of the practice of the day, if for no other reason:

The mass of the medical faculty of the British Empire is, indeed, an heterogeneous compound. Physicians, doctors of the English universities, fellows of the Royal College, versed in all human science, learn'd, honourable, and approximating to the "corinthian capital of society," are "pushed from their seats" by doctors of no universities, unlearned men and even women, without science, and without honor. The Abernethys, Coopers, and Brookes's have opposed to them self-created surgeons, raspers of shin-bones, advertising gonorrhoeal cures, and men whose chirographical knowledge has been acquired by carrying a box after the dresser at a hospital. The legitimate apothecary

is circumvented by the druggist who was yesterday a grocer; by the chemist who hardly knows a crucible from a cauliflower. To the educated physician, to the regular surgeon, to the instructed apothecary, this is personally, perhaps, unimportant; but what is it to the public? pain, mutilation, death. London, that common sewer, teems with this surreptitious multitude. From Tower-hill, a doctor advertises that "all persons afflicted with any complaint whatever, may have an easy, speedy, and certain cure, without confinement," by applying to the said doctor. Mrs. — cures the king's evil radically, and, what is more, safely too. Another benevolent female, at Battlebridge, continues, as usual, to cure consumptions; and still another, at Islington, cures cancer. Even at the college-gate of Edinburgh lived, very lately, a female "practitioner in medicine" from England; and the druggists of a Midland county at this moment are querulously complaining that a horrible attempt is making to take from them the privilege of prescribing for the sick.

Truly, if things were as bad as this, or half as bad as this, there was sore need for some Act of Parliament to protect society against these dangerous quacks, dangerous to the health of the community as well as to its pocket.

The apothecaries were, to begin with, simply persons who kept shops in which were sold spices, drugs, confits, preserves, and the like; but gradually some of these goods were dropped, and in 1617 the Apothecaries' Company of London was separated from the Grocers', and incorporated. Under this charter of the time of James I (and VI) the apothecaries of London practised their art for nearly two centuries, until, in point of fact, the year 1813, of which we are speaking. At first they simply prepared and sold drugs for medicinal purposes, the work which is now carried on by the druggist and pharmaceutical chemist; but from about the beginning of the eighteenth century they began to take a place as general medical practitioners. A correspondent to the *Medical and Physical Journal* (p. 48, July, 1813) traces the entrance of the apothecaries into medical practice back to the year 1666. "I find," he wrote, "that the apothecaries had very little employment as prescribers of medicine till the time of the great plague, when the physicians, taking the alarm, honestly and disinterestedly ran away, but the apothecaries kept their proper posts, and as far as they were able assisted the sufferings of their fellow creatures; after which they rose into estimation, and from that time to this have either legally or illegally practised."

At any rate, in 1813 they were so practising, not only in London, but all over England; indeed, those who practised pharmacy alone were few in number, compared with those who exercised all the branches of the profession. They were still, however, working, although in very different circumstances, under the old charter of 1617-18. Almost the only cognizance which the law had taken of the changed conditions was the exemption of apothecaries from serving on juries or other civil offices which came into force in 1712. The application to the Legislature in 1813 could not, therefore, be termed hasty; neither was it unnecessary or uncalled for. The three main objects in view were the improvement of the school education of the apothecary and surgeon-apothecary; his instruction in the elements of science; and the prevention of unqualified persons entering this department of the profession, by means of the barrier of a strict examination. These main aims were, unfortunately, weighted by and almost hidden under a great number of other matters, side issues, and conflicting interests; and, worst of all, the privileges and rights of the College of Physicians and of the Court of Assistants of the College of Surgeons were, or rather seemed to be, affected injuriously. The Colleges stood on the one side, and on the other was the London Committee of the Apothecaries, now (in 1813) strengthened by the inclusion of deputies or delegates from the county districts of the whole of England and Wales. Here we see the beginning of something of the nature of a national association of medical practitioners, a something which was to be followed in 1832 by the British Medical Association. The immediate result, however, of the enlargement of the Committee of the London Apothecaries, and its conversion into the Committee of the Community of Associated Apothecaries and Surgeon-Apothecaries was delay; for a joint meeting revealed such complexities and so great need for adjustment of rival claims and the like that the pressing of a bill through Parliament had to be postponed.

These joint meetings of Apothecaries and Surgeon-Apothecaries, "at the Crown and Anchor," must have

been very interesting events. Here is the brief report of one of them :

The London Committee having met the Deputies of the County Districts (who came from the most remote parts of the Kingdom) on Tuesday the 23rd inst. (April, 1813), at the Crown and Anchor; and, on Wednesday the 24th, a General Meeting of the London practitioners being convened at the same place; so many new views of the subject were developed, which promised so much improvement to the plan, that the Committee has thought it expedient to withdraw the Bill for the present session, with the avowed intention of submitting it to parliament next year, under circumstances of considerable melioration.

Dr. George Man Burrows, chairman of the Association of Surgeon-Apothecaries, presided over these meetings; he had himself been apprenticed to an apothecary at Rochester, had qualified at the College of Surgeons and Apothecaries' Hall, and was in general practice in London¹; he was therefore well fitted to preside, being able to sympathize with the various interests at stake.

Much of what was said in these meetings is now of no moment; but one fragment which has been preserved almost accidentally is of some interest. The question under discussion was whether the London Committee, even with its added honorary members, representing Colchester, Hampton, Putney, Hampstead, Plaistow, Richmond, Clapham, and Tunbridge Wells, could be said properly to represent the "mixed" practitioners of England and Wales. One member was stung to ask, using an expletive not often heard in debate, "can it be admitted that Liverpool, Birmingham, Manchester, Exeter, Gloucester, Newcastle, Bristol, Bath, the universities, will confide their interests to four or five villages in Middlesex and Essex; that Tunbridge Wells shall represent the numerous, powerful, and never-submitting men of Kent?"

As is usual during such controversies, the medical papers were full of letters. Here are extracts from two letters, one of them written in dread lest the apothecaries should get the upper hand altogether, the other penned with a measure of far-sight which seems to have been rather rare at the time. The first is from a letter signed "Salus publica";² "Let us all retain our proper places, and the medical profession will afford fame for many, and a fair reward for all; but, when the floodgates are removed, and the rushing torrent breaks down its banks, I confess I see nothing but desolation and ruin for the country round." The "rushing torrent" of this writer was the crowd of apothecaries, better educated, and with a licence, and able to make legal claims for fees. "Let them only be confined to their proper sphere—let them compound, dispense, and deliver"—that is "Salus publica's" safeguard. The other extract is from a letter to Dr. G. M. Burrows, signed "C. W. S.," and the writer, seeing right into the heart of the matter and correctly gauging the real needs of the profession, said: "I think the bill might with a great deal of propriety be termed that of the general practitioner in medicine, surgery, and midwifery, in which the apothecary would be considered as included."

To make a long story short, the Apothecaries did not get their Act in 1813, nor yet in 1814, but only in 1815 (55 Geo. III, c. 19); and it was not all they wished, having to be amended in 1825 (6 Geo. IV, c. 133). By it the London Apothecaries' Company had its practice regulated, and its authority extended over all England and Wales. No person, not already in practice, might for the future practise as an apothecary, or apothecary's assistant, without passing an examination as to his fitness, and obtaining a certificate of his qualification. Armed with his certificate he could recover charges in a court of law. The Act, however, left undefined what "practising as an apothecary" was, and it was not till many years afterwards that it was settled to be "dispensing, mixing medicine, giving medical advice, and attending the sick as medical adviser."

It was, however, a distinct and notable beginning in medical reform. It left much unsettled; and it had to be followed by the Medical Acts of 1858, 1859, 1860, 1876, and 1886; indeed, it was not till the Apothecaries Act, 1907, had passed that the Society of Apothecaries was entitled to grant to those passing its qualifying examination the diploma of Licentiate in Medicine and Surgery (L.M.S.S.A.); but it opened the way for much that was sorely needed in regard to the state and the status of the profession, that

"heterogeneous mass assuming the title and functions of medical practitioners." This too must be said for the Society of Apothecaries, that when the time came (in 1874) they were ready to admit women to the examinations required for certificates to practise as apothecaries, leading the way once more in another department of medical reform.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).

VOLUNTEER INTERPRETERS WANTED.

It is hoped that members of the Congress who speak foreign languages will be willing to wear a small badge denoting the language they can speak, as such an arrangement will be a great convenience to foreign visitors. If those who will consent to this will communicate with the General Secretary, 40, Wimpole Street, W., he will be very grateful.

SECTION OF RADIOLOGY.

This is the first time there has been a Section of Radiology included in the International Congress of Medicine. And every effort is being made to show that the advance in this branch of medical science fully justifies the formation of a separate section.

The section, of which Sir James Mackenzie Davidson is president, deals with x -ray work in all its branches and with radium therapy, but does not include electro-therapeutics. This subject is dealt with as before under the heading of Physiotherapy, a subsection of the Section of Therapeutics. Some little irritation is apparently felt on the Continent at the non-inclusion of electro-therapeutics. The formation of a separate Section of Radiology has, however, been entirely due to the energetic action of radiologists. There has been no special effort on the part of electro-therapists either to obtain a section for themselves, or to be included in the Section of Radiology, until too late, and therefore it behoves workers in this branch of medicine to see that they are more adequately represented at the next congress.

The morning meetings of the Section of Radiology are to be devoted to discussions of special interest and the afternoons to the reading of papers. The meetings will be held in a lecture theatre in the new School of Mines at South Kensington, which can be completely darkened, and will be provided with a lantern for the demonstration of lantern slides; provision will also be made for the illumination of original negatives where this is considered necessary. In the museum a room will be set aside for the exhibition of transparencies, and adjoining this room will be a continuation of the department of radiology, in which apparatus, skiagrams, and other daylight exhibits can be shown. Members wishing to exhibit should communicate with Mr. H. W. Armit, Honorary Secretary of the Museum Committee.

The following is the list of the discussions, together with the reporters selected for each:

The radiography of the stomach and intestines (Dr. Holzknicht and Dr. Leonard); That of the chest (Dr. Hugh Waleham and Professor Wenckebach); The radiotherapy of malignant disease (Dr. Abbé and Dr. Kienböck); Roentgen and radium therapy in gynaecology, a joint discussion with the Section of Obstetrics and Gynaecology (Dr. Albers-Schönberg, Dr. Foveau de Courmelles, and Professor Krönig); The radiography of bones and joints in its value in orthopaedic surgery, joint discussion with the Subsection of Orthopaedics (Dr. Fedor Haenisch, Dr. Nové-Josserand, Dr. P. Redard).

Many offers of papers have been received, but the final selection of these has not yet been made. Preference will be given to papers received before April 30th, and no paper can be considered unless the title has been received by the Secretary before July 1st. Any members wishing to read papers, and who have not yet made application, should communicate at once with Dr. G. Harrison Orton, Honorary Secretary, 67, Upper Berkeley Street, Portman Square, W.

A dinner will be held, probably on August 8th, to which members may bring their lady friends, and the Electro-therapeutic Section of the Royal Society of Medicine and the Roentgen Society are arranging jointly for an entertainment to take place after the dinner. A committee of ladies has been formed to look after the interests and make arrangements for the entertainment of foreign ladies, but the final arrangements are at present necessarily incomplete.

MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held this year in Exeter on May 29th, when the President, Dr. E. G. BARNES, was in the chair.

ANNUAL REPORT OF COUNCIL.

The annual report contained a general statement by the council itself, a report from the solicitor of the Union, a special note on indemnity insurance, and the report of the Finance Committee.

The general statement indicated that the work of the year had been carried out to the complete satisfaction of the council, and that there was reason to believe that this was fully shared by members. Applications from the latter for advice and assistance were so numerous that even in August, usually a slack month, the executive was fully occupied. Much of the extra work was due to the Insurance Act, a measure which the council regarded as certain to make the existence of the Defence Union more necessary than ever. In this connexion the council pointed out that medical men whose duties included insurance work were liable to have their conduct challenged now not only by their patients, as in the past, but also by the Insurance Committees, and that the risk in this connexion was all the greater because the final decision as to how many patients he should accept did not rest in his own hands. The council also recorded in detail sundry negotiations with the Insurance Commissioners, and the dictum obtained from the authorities at Buckingham Gate as to there being nothing in the Act itself or in the regulations drawn up under it, or the rules of any approved society, which would justify a society in declining to accept a medical certificate on the ground that it was not signed by a doctor on the local panel. The passages relating to this matter were no doubt drafted before the hearing of the appeal action on the same subject, the upshot of which was recently recorded in our columns (May 10th, p. 1033). In connexion with an account of the measures by which the council succeeded in getting erased from the *Medical Register* the name of an impostor last November, it was mentioned that the Union was investigating four other cases of apparently like character. The statement concluded with a long list of subjects on which the council had been consulted, a note on the desirability of members applying for assistance as soon as a cloud appeared upon their horizon, an expression of belief that the Union was growing in repute and prestige every year, and regret at the death of one of its vice-presidents, Dr. Herbert Manley.

The solicitor's report recorded that his advice had been sought in 175 matters; 47 related to libel or slander actions; 42 to the defence of members in action for mal-praxis brought or threatened; 11 concerned the suppression of unauthorized practice; 46 dealt with questions regarding the interpretation of deeds of partnership and claims arising under articles of appointments; and 29 with miscellaneous matters, such as the representation of practitioners at inquests and the adjustment of claims for giving evidence. Two of the cases involving legal action were settled by payments but all the others were successful. There was evidence during the year of a kind of epidemic of actions against medical men in the Liverpool and Manchester districts, but it is hoped that the people in that area have now learnt the Union's strength. Stress was laid in the report on the desirability of members who require the help of the Union in connexion with slanders obtaining at the earliest possible moment signed statements from persons who are in a position to speak personally of the fact of such slanders being current. The Union regards the obtaining of such statement as an essential preliminary to legal actions, even though members sometimes regard this precaution as somewhat of a grievance.

The note on indemnity insurance dealt with the conditions on which insurances were granted by the Yorkshire Company and made it quite clear that such additional insurances might be taken out or otherwise as the member wished, the Union itself being ready to pay, as always previously, the actual cost of the member in defence, apart from the costs of the other side in lost actions, and any damages which might be imposed by the court.

The financial statement included an interesting table showing the total amount which had been paid by each of some twenty-four members in the way of membership fees and the law cost incurred by the Union on their behalf during the concluded year. The balance-sheet showed liquid assets amounting to over £5,000, in addition to moneys due for the current year and arrears. The membership roll included 8,530 members.

PRESIDENT'S ADDRESS.
The Insurance Act.

THE PRESIDENT gave an address on the subject of the Insurance Act, in the course of which he said that he would not go into the vexed history of the past, but would deal with the subject from the point of view that the Insurance Act was the law of the land, that it was being more or less successfully worked throughout the United Kingdom, and that at the present time 14 millions of insured persons were receiving medical treatment at the hands of 18,600 doctors, an average of 750 insured persons to each doctor, for which service an average of £262 10s. per annum was paid exclusive of drugs. A change like this could not fail to have very decided consequences for good or for evil on the nation at large, on the insured persons in particular, on the friendly societies, on the hospitals, on the medical profession, and on the chemists.

The effect on the nation at large was that another step had been taken by modern legislation towards the increased taxation of the classes to ameliorate the condition of the masses—a step tending to the improvement of the conditions of labour, and especially of so-called manual labour, by placing medical benefits in sickness within the reach of all. They welcomed such a provision for the really poor, but they felt that it should be strictly guarded by a suitable income limit which should render it impossible for those who were in receipt of incomes in many instances larger than those of the medical men attending them to claim medical attendance as contract rates. The effect of the Act on the insured person was also complex; to many it was an undoubted boon, though hampered by red tapeism and vexatious delays, due mainly to the undue haste with which a vast scheme was brought into existence. To those insured who pay through the Post Office, the Act was a mockery, a delusion, and a snare, and it could not be too widely known that the only means of securing the real benefits of the Act was through an approved society. The Post Office contributor had only the sum paid for his individual insurance to his credit, and as an example he pointed out that with the Act only in existence a few months, that sum was so small, that, after payment of management expenses and the medical capitation fee, a claimant for maternity benefit found only 7s. or 8s. instead of 30s., and a claimant for sickness benefit found that it lasted but ten days or a fortnight. The effect on the old friendly societies was somewhat difficult to gauge; undoubtedly they had in some respects reason to think that after the pioneer work they had done for so many years the Act had not been too generous to them. It had exposed them to the keener competition of insurance companies, who, with their agents calling week by week to collect payments, and to pay sickness benefits without trouble to the insured persons, were building up a large increase of business. Another—and to them the most satisfactory—result had been that, owing to the free choice of doctor and the abolition of the club doctor, the friendly societies could no longer exercise the grinding pressure they had so often done in the past on the less fortunate members of their profession; indeed, in his opinion, that was one of the very few really satisfactory results of the National Insurance Act. The chemists, too, were directly affected by the Act—a large amount of dispensing hitherto done by doctors was placed in their hands, and to that many members of the profession strongly objected. On the other hand, there was little doubt that the tendency of the Act would be to check the large amount of counter-prescribing hitherto done by chemists.

As to the effect of the Act on the medical profession, he made bold to say that, whilst it was by no means a boon, it was not an unmixed evil. The conditions under which the profession worked were so varied that it was impossible to pronounce definite opinions, except as partial truths.

In London, and generally in large towns, they might recognize three distinct classes of practice, which were affected in different ways. They had, in the first place, a class of practitioners who were almost entirely unaffected by the Act, and whose practices would continue much as they were before it was introduced, such are hospital physicians and surgeons, specialists, and those general practitioners whose work laid mainly amongst the upper classes of society. The second class, whose work lies mainly with the middle classes, would be most affected. Many persons, such as clerks, shopmen, and domestic workers, who had hitherto paid their small accounts with regularity would become insured persons and be lost to private practice, and these practitioners had an anxious question to decide, whether they should join the panel or retain their full independence; and to such the act was an unquestionable evil. The third class—those who had had mainly working-class and club practices—would distinctly benefit under the Act; their rate of payment would be increased by more than 50 per cent., and taking into account the cost of drugs, would in many cases be doubled: the Insurance Committees with their medical members and members chosen by the county councils influencing, though not controlling, their proceedings would be better masters than the old club committees, composed exclusively of working men; and the free choice of doctor would give them more independence than under the old system. On the other hand, they would be more worried by book-keeping and red tape. One effect of the Act, which was much to be deprecated, would be the formation in towns of two distinct classes—panel and non-panel doctors. In the country places, however, the evils of the panel system would not be so great; the rural doctor had in some respects been the true general practitioner; he had attended all classes of patients from the peer to the pauper; he had had all classes of practice—obstetrics, medical cases, emergency operations, such as hernias and appendicitis, anaesthetics, accidents of all sorts—and his work trained him to all emergencies without the hospital and the hospital staff to fall back upon. The panel system would be no loss of caste to such a man; he would retain his better-class patients: he would diminish his bad debts and get a better average pay for the poor he must, in humanity, attend. The effect of the Act on hospitals could hardly be estimated. It might not improbably seriously affect their finances, as people who had to lick insurance stamps would correspondingly be less willing to subscribe to secure hospital treatment for their dependants. The in-patient departments would be as much wanted as ever, but it might, he hoped, be expected that the attendance at the out-patient rooms would be much diminished. The experience of the Medical Defence Union had made painfully apparent the enormous impulse given to that section of the profession who sought to attract patients by the advertising methods of the quack. If that were not speedily checked, the result must be a lowering of the profession in the eyes of all right-thinking men.

The defects of the Act which should be removed were numerous. The book-keeping difficulties which first existed (a cumbrous day-book and ill-designed carbon prescription books which would not be tolerated in a third-class restaurant) were fortunately giving way to simplified forms and a reasonable card system; but whilst book-keeping in any form seemed to be specially obnoxious to medical men, it must be remembered that the keeping of such returns as were now required were necessary in the interests of medical men. They were necessary because without them the profession would be unable to gauge the amount and character of the work done, and therefore unable to ascertain how far the present payments were adequate or inadequate. Dr. Barnes believed that if medical men generally had kept as close records of their club practice as of their private work, they would have been able long ago to have demonstrated in an incontrovertible manner the inadequacy of club pay, and would have had a far better chance of securing better terms under the old club system, and also have had a mighty weapon to deal with the Insurance Bill before it became an Act. Another pressing and difficult question was how to provide the medical attendance promised by the Act to itinerants—persons moving from one district to another to convalesce from illness, or to obtain

home nursing and comforts during illness. The scheme of the Commissioners, which took money from the panel doctors in the district from which they removed to pay for actual work done by the doctors of the district into which they went, was unsatisfactory, inasmuch as it involved a distinct breach of the agreement under which each practitioner was entitled to 7s. per annum for each person on his list. If an attempt was made to carry this out it would be incumbent on the Medical Defence Union to take the highest legal opinion, and if that opinion confirmed the statement that he had ventured to make, to carry a test case even to the Court of Appeal. There were only two ways in which this question could be dealt with in fairness to the profession. But one—namely, to leave these casual cases to be treated as private patients, as had been the case under the old club system—was prohibited by the lavish promises made to the insured by the authors of the Insurance Act; the other way was for the Government to redeem its promise to the insured by making a special grant for this purpose, and this it at present refused to give.

Another crying evil was the almost complete absence of payment for mileage in country districts. The Government had made an utterly inadequate grant for this purpose, and it behoved every Medical Committee to see that application was made to the Commissioners for participation in this grant, and to support this application by all the evidence obtainable. Though this meant much trouble for the hope of, at the best, an inadequate reward, yet it should not be neglected, for it was an important step that the justice of the claim had been admitted by any grant, however inadequate, being made. The principle having been admitted, there was hope that with clear demonstration of the facts a more adequate grant might some day result.

Another point of principle to which the energies of the medical profession should be directed was the absence of any provision for payment of fees to medical men necessarily called in to administer anaesthetics or to assist in emergency operations. This was not only unfair to the practitioner, but was distinctly contrary to the principle of the Act to provide adequate medical attendance to insured persons. Among other matters towards the removal of which in any amending Act the profession should devote itself whole-heartedly were the enforced duty of attending insured persons for diseases brought about by immorality and misconduct; the encouragement of illegitimate births by the payment of maternity benefits to unmarried women; and the inclusion of attendances on abortion and premature confinements in the capitation fee.

An important matter which could be dealt with without an amending Act was the multiplication of medical certificates which many approved societies were seeking to insist upon. It should be sufficient to give a simple certificate that John Smith was incapable of following his occupation through sickness or accident, without any mention of the nature of that illness, and thus avoid all danger of libel actions founded on certificates incautiously or inadvertently given to unauthorized messengers; a weekly certificate of continued inability to work, and a final certificate of ability to resume work should complete the series of compulsory certificates. All other certificates, either more amplified or duplicated, should be paid for by the person needing them. In the meanwhile, if medical men were compelled to state the nature of the illness on certificates, it was incumbent on them to insure themselves against possible danger by the help of the Medical Defence Union and of the Yorkshire Insurance Company.

Another grand defect of the Act was the encouragement given to malingering, of which ample evidence was already forthcoming. This could only be checked by the appointment of medical referees, on whom should lie the onus of refusing sickness benefit rather than on the attendant practitioner alone.

In conclusion he uttered a word of warning: "The friendly societies were much concerned with the conditions under which such old members who did not come under the Insurance Act could receive medical benefit, and plead old age, infirmity, and long membership as reasons why the 7s. of the Insurance Act should in their cases be reduced to 4s. or 5s., and also that women and children should be attended at inadequate rates. He feared that

from many causes, from a feeling of charity, from the competition of medical institutes, from unfair competition between members of our profession, those somewhat plausible though shallow arguments were being allowed to succeed—but surely, such a policy on the part of the profession was extremely short-sighted; the work was admittedly fully worth the 7s. exclusive of drugs, or the 9s. inclusive of drugs, fixed by the Insurance Act; and when, as they were promised, in a very short time the Act was extended to include women and children, some future Chancellor of the Exchequer would use with telling effect the argument that he was merely taking the profession at their own valuation, when he offered them and expected them to accept the inadequate rates of payment now being accepted by many. The experience of the past two years ought to show them the folly of undervaluing their own services as they had done in their dealings with friendly societies in the past. It was only fair to acknowledge that, with respect to medical institutes, the Commissioners by requiring, as to his personal knowledge they had required, that they should not interfere with the free choice of doctor by their members and that they should produce duly audited accounts and only be able to claim what they actually expended in providing medical benefit, showed that they were determined that the Harmsworth amendment should not be made a lever to defeat the true intent of the Act."

The usual statutory resolutions were passed, and one resolution added in respect of the payment to members of the council of out-of-pocket expenses should attendance at a council meeting necessitate their stay in London for the night.

Dr. Edgar Barnes, Dr. Gunton Alderton, and Mr. Larkin were re-elected members of the council.

A vote of thanks to the President and Council for the valuable work done for the members during the past year was carried with acclamation.

ROYAL MEDICAL BENEVOLENT FUND.

At the May meeting of the Committee thirty-six cases were considered, and grants amounting to £300 made to thirty of the applicants. Appended is an abstract of the cases relieved:

1. Wife, aged 48, of L.R.C.P., L.R.C.S.Edin. No income, and since her husband broke down mentally six years ago has endeavoured to support herself by taking boarders. Two sons, aged 20 and 17, who will, it is hoped, soon be able to give slight assistance. Relieved three times, £45. Voted £15.
2. Daughters, aged 54 and 47, of late M.D.Aberd. Each has an income of about £20 a year, but is unable to supplement it owing to permanent ill health. Voted £5 each.
3. Widow, aged 42, of M.R.C.S., L.R.C.P. Practically unprovided for at husband's recent death, but having many friends in the neighbourhood hopes to maintain herself by receiving boarders. Three children, aged 15½ to 2. Voted £10.
4. M.R.C.S., aged 73. Incapacitated by paralysis and practically destitute. No children. Voted £20.
5. Widow, aged 58, of M.R.C.S. Supported herself for some years by designing lace, but is now incapacitated by an incurable complaint. No children. Voted £10.
6. Widow, aged 62, of M.D.Aberd. Only certain income £12 a year. No children. Voted £12.
7. Daughter, aged 43, of late M.B.Lond. Was partially provided for, but lost her capital through unfortunate investments and is now without any means. Receives a home in return for services, but being in bad health is unable to obtain a salary. Voted £5.
8. Daughter, aged 36, of late M.R.C.S. Has been a clerk at a large draper's, but left through no fault of her own, and has quite exhausted her small savings. Voted £5, with leave to apply again if necessary.
9. Daughter, aged 85, of a surgeon in practice before 1815. Only income a pension of £13 a year. Voted £12.
10. Widow, aged 42, of L.R.C.P., L.R.C.S.Edin. No income; tries to support herself by nursing, but finds it impossible to obtain regular work. Two children, aged 18 and 9, the elder just self-supporting. Relieved seven times, £55. Voted £5.
11. Daughter, aged 58, of L.R.C.P.Edin. Exhausted small saving in the attempt to establish a small business, and now dependent on a weekly allowance from a friend, and small earnings by needlework. Relieved eight times, £64. Voted £10.
12. Widow, aged 79, of L.R.C.P.Edin. Only income an old age pension. Husband was an Epsom pensioner. Relieved once, £12. Voted £12.
13. Widow, aged 50, of L.R.C.P.Edin. No income; slight help from two sons who are sailors. Relieved nine times, £99. Voted £12.

14. Daughter, aged 74, of late M.R.C.S. No income, and entirely dependent on uncertain help from relations. Relieved once, £12. Voted £12.

15. Daughters, aged 66 and 63, of late M.R.C.S. Have a small income from a house, but at present it all has to be paid away for repairs which were necessary to secure a tenant. Relieved once, £12. Voted £10.

16. L.R.C.P., L.R.C.S.Edin., aged 53. Has been paralysed and nearly blind for the last five years, and is entirely dependent on his wife's earnings by letting lodgings. Five children, aged 18 to 13. Relieved five times, £90. Voted £18.

17. Daughter, aged 67, of late M.R.C.S. Income reduced to a few shillings a week through the failure of the family solicitor, and is now broken down in health. Relieved once, £5. Voted £5.

18. Daughter, aged 58, of L.F.P.S.Glasg. Only income £1 a month from a society, and physically incapable of earning a living. Relieved six times, £70. Voted £10.

19. Widow, aged 64, of L.S.A. Practically dependent on lodgers, and has had three rooms unoccupied for several months. Relieved eleven times, £120. Voted £10.

20. Daughter, aged 61, of late M.R.C.S. Only income a pension of £20 a year; health delicate and sight greatly impaired. Relieved once, £12. Voted £6.

21. Daughter, aged 57, of late L.R.C.P.Edin. Has been in bad health for several years, and requires help for unavoidable expenses consequent upon recent operation. Relieved eight times, £76. Voted £5.

22. Widow, aged 54, of L.R.C.S.Edin. No income, and requires help during convalescence after a severe operation. Relieved twice, £24. Voted £12.

23. Daughter, aged 64, of late L.S.A. Used to support herself by teaching, but lost her pupils during a long illness which preceded her mother's death. Only income a pension of £21 a year. Voted £10.

24. Daughter, aged 74, of late M.R.C.S. Maintained herself for many years as a housekeeper, but is now dependent on an old age pension. Voted £12.

25. Widow, aged 54, of L.F.P.S.Glasg. Slight help from children, and small earnings by letting rooms. A daughter, aged 18, had been seriously ill for the past twelve months. Relieved nine times, £94. Voted £12.

26. Wife, aged 45, of L.R.C.S.I. Husband was obliged to give up eighteen months ago owing to a complete break down in health, but is now sufficiently recovered to make a fresh start and hopes to build up a small practice. Three children, aged 18 to 11, for whose benefit some money is invested on trust. Relieved once, £12. Voted £6.

27. Widow, aged 52, of M.R.C.S. No income; small earnings from crochet and needlework and lives rent free in return for slight services. Two children, just self-supporting. Relieved twelve times, £115. Voted £9.

28. Widow, aged 42, of L.R.C.P.Edin. Has an income of about £1 a week, but having seven children, the youngest only 2½ years old, is unable to supplement it in any way. Relieved once, £12. Voted £12.

29. Widow, aged 56, of L.R.C.P.Edin. Endeavours to maintain herself by taking boarders, but finds great difficulty in obtaining them. No children. Relieved twice, £10. Voted £5.

30. Widow, aged 56, of M.R.C.S. Only income a pension of £26 per annum; children unable to help. Was assisted several times by this fund when a young widow, but has not applied for nineteen years. Voted £10.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole Street, London, W.

UNDER the will of the late Mr. Edward Beck of Heddon House, Isleworth, University College Hospital becomes entitled to the reversion of a sum of £8,000 left in trust for the testator's brother.

THE twenty-third Congress of Mental Specialists and Neurologists of France and French-speaking countries will be held this year at Le Puy from August 1st to the 6th, under the presidency of Dr. Arnaud. Among the subjects to be discussed are: Disturbances of movement in dementia praecox; anaesthesia in cerebral hemiplegia; the conditions of surgical intervention in insane persons from the therapeutic and medico-legal points of view. The general secretary is Dr. Sutel, 8, Boulevard Gambetta, Le Puy (Haute Loire), to whom all communications should be addressed.

THE fourth International Congress of Hygiene and Health of the Dwelling will be held at Antwerp from August 31st until September 7th. The President is Dr. Victor Desguin, President of the Royal Belgian Society for Public Medicine, and the General Secretary, Walthar Van Kuyck, engineer-architect, Antwerp. The congress will comprise four sections—the hygiene of emigrants, colonial hygiene, hygiene of ports and ships, the development of towns from the hygienic point of view. Expropriation on account of insalubrity will be considered as a special question by the congress, the study to be continued by the tenth International Congress on Cheap Dwellings which is to meet at The Hague on September 8th and following days.

OPENING OF THE NEW BUILDINGS OF GUY'S HOSPITAL MEDICAL SCHOOL.

MR. A. J. BALFOUR ON THE ENDOWMENT OF RESEARCH.
A distinguished company assembled at Guy's Hospital Medical School on June 3rd, when Mr. A. J. Balfour formally declared open the new buildings described in our last issue.

Lord GOSCHEN, Chairman of the Governors of the hospital, who was supported by the President, Mr. Cosmo Bonsor, presided at the meeting in the Physiological Theatre, and students of the medical school had seats in the gallery. Sir Arbuthnot Lane, whose baronetcy had just been announced, was received with great applause. Mr. Balfour had an enthusiastic reception. Among those present were the President of the Royal College of Physicians, the Regius Professor of Medicine in the University of Cambridge; the Vice-Chancellor, the Principal, the Chairman of Convocation, and the Member for the University of London; the Principal of King's College, the Provost of University College, the Head Master of Westminster School, the Curator of the Museum of the Royal College of Surgeons, the Commandant of the Royal Army Medical College, the Master of the Apothecaries' Company, the High Commissioner for South Africa, Lord Aldenham, Lord Revelstoke, and many members of the staff of Guy's Hospital.

Lord GOSCHEN, in opening the proceedings, said that Mr. Balfour was closely connected with Guy's as a governor and as a disciple of science who had enthusiastically supported the scheme that had resulted in the completion of the new buildings. In fact, a great deal of the success of the enterprise was due to the encouragement and inspiration which Mr. Balfour gave them when he delivered an address at a prizegiving at Guy's in 1898 on the subject of the endowment of research, and made an eloquent appeal in that cause. Lord Goschen also alluded to the interest the late King had displayed in the work of Guy's Hospital Medical School, and said he was glad to note that that interest had been handed down to his son, King George, who had that day given a proof of his feelings towards Guy's by the honour he had conferred upon Mr. Lane, to whom, in the name of all connected with the hospital, he offered hearty congratulations. Lord Goschen mentioned that, although the new buildings had been erected at considerable cost, not one penny had been provided out of the funds of the hospital, and the governors owed a deep debt of gratitude to the medical staff and the friends of the staff who had so generously assisted in the building scheme. The governors realized that a great heritage had been handed down to them by famous men connected with Guy's in the past, and that they had a great trust for the future to provide for the rising generation adequate means of obtaining knowledge fitting them to take their place in the great profession of medicine, which was always moving forward.

MR. BALFOUR'S SPEECH.

Mr. BALFOUR recalled that some fifteen years ago he had the pleasure and honour of speaking in that hall to the predecessors of the present students upon the claims which research had, and must have, upon all who desired to see this country maintain its place among the nations of the world in what was, after all, the greatest of the practical professions. In the fifteen years that had elapsed since then, this great block of buildings, which it would be his privilege to declare open, had been almost entirely constructed. A hundred thousand pounds had been spent upon them, and those responsible for the scheme might be disposed at first to say, "We can now look back upon the work which has been done, congratulate ourselves upon its success, and rest from our labours." That was not the spirit in which he intended to address them. The work had only just begun. The buildings, it was true, were finished, but a sum of money estimated at twice the amount that had been spent on the buildings was required before these could do all they were called upon to do in the interests of medicine, as the science was now, and to make medicine what it would be in the lifetime of many of those present. It was a great task, and one not unworthy of the energy and liberality of this

country. Some unacquainted with the movement of modern science might ask why it was that apparatus, buildings, expenditure of all kinds, infinitely in excess of what were necessary even fifty years ago, were necessary in 1913. It was not due merely to the growth of a great urban population; the necessity arose from the inherent progress of science. Looking back fifty years it was found that some of the branches of science, studied then as they were now by those who intended to devote their lives to medicine, had nevertheless an incomparably smaller connexion with medicine than they had now. As the connexion of chemistry, physiology, bacteriology, and other collateral sciences with the science and practice of medicine had become closer, so the apparatus required had greatly increased in cost, and the amount of knowledge required from the teachers, and the specialization of the teachers, had extended, until he sometimes wondered how it was possible for any physician in practice even to keep himself abreast of what was being done by researchers in his own country and in all other countries, which were now engaged in a happy rivalry for the furtherance of knowledge—a rivalry indeed far happier than the rivalry in armaments, but he sometimes thought hardly less expensive. (Laughter.)

To the public a hospital might simply be a place where those who were sick or injured came for healing and relief; that was a very small and narrow view to take of its functions, because, unless a hospital was in addition a place where the doctors of the future were to be trained, its functions would, as it were, die out with the existing generation, and no provision would be made for the carrying on of the great philanthropic duties which for the moment it might perform, but for which it would not train a new generation with increased knowledge and command over Nature to continue to carry them on in the future. It was at least as important that the great hospitals should be made training grounds for the surgeons and physicians of the future as that they should provide surgeons and physicians of the present day with scope for their beneficent enterprise. To carry out this work effectively required three separate kinds of gifts—qualities not necessarily or commonly associated in any single individual. The really successful professor of the healing art must have not merely a knowledge of all that the science of medicine could now teach, but that ready and happy intuition, that power of diagnosis and knowledge of human nature which made a physician a helper as well as a healer to those whom he attended. Next, if the hospital was to be a great school it must have men who could not only do, but men who could explain. Doing and explaining were very different things, and required very different qualities; they were not always associated in the same individual. Further, if the school was to be all it might be, it wanted also men who could investigate, who possessed that kind of originality which enabled them to see and to map out—not indeed the provinces of which they knew nothing; any fool could do that; it was quite easy to explain what it was the world did not know. It was not so easy to point out in what direction the next advance should be made, where progress might be expected, where Nature might be most easily compelled to yield up her secrets. They wanted men who could by the happy inspiration of genius suggest a solution of some long-standing difficulty which might throw a light upon a multitude of apparently separate phenomena and bring them all under one law, and suggest in reference to them one line of successful investigation. That was research. (Applause.) Genius was rare in any country and in any profession; the medical profession could not hope to have a larger share of it than others. All that organization could do was to give to these rarely endowed individuals an opportunity for effectively exercising for the common advantage the gifts God had given them. He was not sure that the present medical organization in this country did not need amendment in that respect. Men must live; they must have a profession; they could not be asked to give up the domestic life or the security of an assured income. Therefore, if the man of research was to devote to research hours which might be profitably given to the practice of his profession, there must be provided positions of security in which he could feel he was not sacrificing—not his own interests, but the interests of those nearest and dearest to him—in the pursuit and

advancing of our knowledge. The system here—like most things in this country—had grown up somewhat at haphazard. The result had been a great system. Nobody acquainted with the work the great hospitals had done, not merely in the day-by-day work of healing the sick and afflicted, but in the work that looked to the future—the work of education, of investigation, of research—would say that the hospitals had fallen short of the great duties they had taken voluntarily upon themselves and for which they had made great sacrifices. Yet so rapid was the movement of modern thought, so various were the qualities now required by the members of any great and scientific practical profession like medicine, so absolutely necessary was it to differentiate more than had been done in the work of teaching and research, that it was impossible now to ask that the whole of the teaching and research should be done by men engaged for more hours than was probably good for their health in the actual trying work of their profession.

I am certain (continued Mr. Balfour) that the public must assist these great hospitals by a form of endowment which will enable them, when they get a man gifted with a genius for research, to keep him and use him. I cannot forbear, though it may be somewhat outside my duties at the present moment, formally to make the appeal to which I have been leading up in the arguments I have laid before you. There are men who have got a quite unique talent for research who probably would not be very great clinical physicians, and who may have a very small power of expounding doctrines to large bodies of students. You must find a place for such men—when you can catch them; there are not many of them. If there is to be a true organization of medical research for the future you must find a place for these; it is to the liberality of the general public that I make the appeal.

The actual suffering of the moment touches all our hearts. Take the most indifferent man through the wards of a hospital, show him what is being done to diminish suffering and restore a man to a happy, fruitful, and effective life, and the most callous are moved, and the most indifferent open their purse-strings. The appeal I am making has no such immediate and natural advantages; I am appealing for the future, and not for the present; in favour of long, academic lives of research, of which the public know nothing, of which, if they knew anything, they could understand nothing, and yet upon which depend the real future of the healing art in this and other countries. Such an appeal is not easy to make; it is apt to fall on indifferent ears, it does not touch the immediate sense of the present, it looks forward through the mists of difficult scientific terms to some unknown future, but the future in this respect is as real as the present. Exercise your imagination but a little and you will see that it should touch you just as much as the immediate pain endured by a man who has broken his leg in the street and is being treated in the hospital here. If only those who have the means will exercise that small effort of imagination which I am endeavouring to elicit I am quite certain that those who are responsible for this great and important institution will find it as easy to collect the £200,000 that has yet to be gathered before what has been done can be continued to the best advantage, as it was to obtain from the public, and from the staff, the £75,000 which has been collected already for the buildings. It is my most agreeable duty to declare them open,

Vote of Thanks.

Dr. HALE WHITE proposed a vote of thanks to Mr. Balfour, whose mind, he said, was in tune with the advance of knowledge and in sympathy with the idea that led to the erection of the buildings. Dr. Hale White briefly traced the association of modern science with medicine and the recognition of this by those responsible in the past for the policy of Guy's Hospital Medical School. He urged that not only in this country but in the Dominions and in India the appeal for the endowment research at Guy's should find a generous response.

Sir ARBUTHNOT LANE, who seconded, remarked that in no country was research worse remunerated than in this; in the United States money was poured out for this purpose.

The resolution was carried with acclamation, and, Mr. BALFOUR having briefly replied, the visitors adjourned for

tea in the "Park," the delightful little open space in the midst of Guy's Hospital buildings. The new laboratories, lecture rooms, etc., were also visited, and demonstrations were given of some of the equipment.

SCIENCE NOTES.

Mr. G. E. BULLEN contributed to a recent meeting of the Zoological Society a short paper on cases of blindness in marine fishes. Hofer, de Drouin de Bouville, and others who have studied the pathology of fishes, appear to have directed their attention mainly to species of freshwater habitat. Mr. Bullen has found, in certain specific cases of blindness in marine fishes, pathological conditions similar to those described in several freshwater species and others presenting slight modifications. The examples dealt with in detail were traumatic corneal opacities in a conger eel and corneal opacities in a greater weaver and in a pollack, in the last instance accompanied by cataract.

The theory of the transmutation of elements has been carried a stage further by the paper read by Sir William Ramsay before the Chemical Society of Rome on June 2nd. He then stated that he had experimental evidence indicating that eight and four atoms of hydrogen respectively had been added to sulphur and selenium, with the result that argon and krypton made their appearance. A report of the portion of the lecture dealing with these points appeared in the *Morning Post* on Tuesday. As regards the experiment with sulphur, a control experiment, in which helium took the place of hydrogen, was made with negative results. Spontaneous changes which take place in radium and its products are attended by successive losses of helium atoms, and it is believed that the substance eventually remaining is lead. The recent suggestion of Ramsay, Collie, and Patterson is that the reverse process may also take place with the production of elements of higher atomic weight. The two observers last named maintained in their communication to the Chemical Society (noted in the *JOURNAL* last February) that on bombarding glass with cathode rays in the presence of hydrogen helium was produced, and that if oxygen was present neon appeared. All the chemists concerned make abundant reservations as to the necessity for the repetition of the experiments, but if the accuracy of Sir William Ramsay's experiments is accepted we have four similar reactions, two due to Collie and Patterson, and two due to Ramsay. In each of the four a single condition is altered, and the conclusion suggested is that transmutation has occurred. Sir William Ramsay believes that under the conditions of his experiment dry hydrogen is polymerised into helium, a change which may be expressed thus: 4 Hydrogen = Helium the atomic weight of which is 4. He would then go on with the following series: 4 Hydrogen + Oxygen (16) = Neon (20); 8 Hydrogen + Sulphur (32) = Argon (40); 4 Hydrogen + Selenium (79) = Krypton (83). The theory is made possible if not plausible by recent work on the constitution of the atom and on radio-active substances, and it certainly satisfies one of the conditions of a useful hypothesis, for it should suggest a fruitful line of research.

THE Royal Academy of Medicine of Turin has awarded the Riberi Prize of £800 to Professor Luigi Pagliani for his treatise on hygiene and public health. The thirteenth competition for the prize is now open, and will remain so to December 31st, 1916. For particulars application should be made to the Secretariat of the Academy, 18, Via Po, Turin.

THE French legislature has before it two bills regulating the sale of narcotics. M. Felix Chantemps, Deputy for the Haute-Savoie, proposes to forbid the sale, circulation, and smoking of opium in France and the French colonies, and also the sale, circulation, and use without a medical prescription of morphine, cocaine, and all analogous substances. A bill introduced by M. Charles Leboucq, Deputy for the Seine, provides for the prevention of the sale or keeping in stock or unauthorized transport of cocaine, opium, and its alkaloids, the dispensing of prescriptions except in cases of therapeutic necessity, and the establishment of places or the loan of rooms for the purposes of smoking opium.

Madeira Drive, Covered Walk.

The Annual Meeting of the British Medical Association Brighton, July 18th to 26th.

THE Association will hold its Eighty-first Annual Meeting at the popular seaside resort of Brighton, in Sussex. The annual conference has been held in this town on two previous occasions—for the first time in 1851, and for the second in 1886, twenty-seven years ago.

A few words of this meeting of over a quarter of a century past, and some comparison of names, facts, and figures with the present, will perhaps be of interest.

In 1851 the membership of the Association was only 1,700; in 1886 the members numbered 12,000; at the present time there are over 26,000 members. There was then, of course, no Brighton Division; now it is one of the most prosperous and flourishing of the whole Association.

Dr. W. Withers Moore, Senior Physician to the Sussex County Hospital, was President on the occasion of the Fifty-fourth Annual Meeting at Brighton (1886). On looking through the account of the meeting many items of interest are discovered. There were only eight Sections, compared with sixteen to-day. In the Surgical Section Mr. Willoughby Furner acted as Secretary; this year his name is found as Vice-President of the same Section. Mr. Jowers was a Vice-President; this year his son occupies the same position. In the Pathological Section Dr. Ulthoff acted as Secretary; at the present meeting he is Vice-President of the Pharmacology Section. Mr. A. Nicholson was Secretary of the Section of Ophthalmology; at this meeting he is a Vice-President of the same Section. So that only three officers of Sections of the 1886 meeting are in this year's list.

The titles of some of the addresses make interesting reading. Dr. Withers Moore selected as his subject The

Higher Education of Women, and the views he expressed excited a prolonged controversy in the public press. The Address in Medicine was delivered by Dr. John S. Billings of the United States Army, whose death we have had so recently to lament. His subject was Medicine in the United States and its Relation to Co-operative Investigation. The Address in Surgery, delivered by Mr. F. A. Humphry of the Sussex County Hospital, was on The Medical Aspect of Surgery. Many papers by men whose names are now historical were read—for example, Sir William Broadbent spoke on Remote Effects of Remedies, Sir John Eric Erichsen on The Tendency of Modern Surgery. Other papers were read by Sir Lauder Brunton, Sir Thomas Clouston, the late Professor Dreschfeld of Manchester, and many others who have since risen to the first eminence in our profession.

The Honorary Secretaries of the meeting in 1886 were Mr. T. Jenner Verrall, now Chairman of the Representative meeting, and Mr. Alfred Scott, still practising in the town.

The various functions held on that occasion were very similar to those to be held in the present year. The annual dinner was held in the Dome instead of the Hove Town Hall, not then built. A garden party was given by Sir Julian Goldsmid, M.P., in the grounds of St. Ann's Well, then his private property. The Mayor of Hove is this year giving a garden party on the same spot, now the property of the town. The Mayor of Brighton, as on the present occasion, gave a reception in the Pavilion, the local Branch also held an evening reception. Excursions were arranged to Eastbourne, Tunbridge Wells, Arundel, and other places, all of which are to be visited this summer.

From the published accounts the whole meeting was a great success, and there is every reason to believe that the annual meeting on the present occasion will be at least as profitable and enjoyable to those who determine to make Brighton their Mecca this July.

The town of Brighton is situated on the English Channel, fifty miles from London, on the coast of Sussex, facing almost directly south. The population, including Hove, is 173,000. The railway service is excellent, plenty of trains doing the journey from London either way in exactly the hour. There are also good connexions with other lines. The L.N.W.R. runs a through train daily from Liverpool, Manchester, Stockport, Birmingham, Crewe, Stafford, and Rugby, and vice versa, and there are also through trains to Salisbury, Exeter, etc., via the L.S.W.R.; to the East Kent Coast (Margate, Ramsgate, Dover, Folkestone, etc.) by the S.E. and C.R. There is a regular service of steamers from Newhaven, a few miles from Brighton, to Dieppe, which renders it easy for visitors from all parts of the Continent to make a stay in the town. Facilities are offered for amusements of every description. The municipal orchestra is a great attraction, and military bands constantly perform on the piers, two in number, both of which cater for the entertainment of the public by all varieties of performances, dramatic and otherwise. There are several good theatres, notably the Theatre Royal, with a weekly change of programme, and in addition flying matinées by first class London companies. Concerts, ballad and classical, are very frequently arranged at the various halls.

There are numerous opportunities for bathing, boating, steamer trips, motor boat trips, and coach, motor, and char-a-banc excursions to places of interest in the neighbourhood. Golf links are plentiful; tennis, croquet, football, and cricket are catered for in various parts of the town. On the Sussex County Cricket Ground in Hove the finest English teams hold their matches, and the Australians are frequent visitors. Archery, roller skating, racing, cinematograph theatres must all be mentioned; in fact, there is no end and no limit to the forms of amusement which the visitor to the town can procure.

Some of the principal municipal buildings must be mentioned. The celebrated Aquarium, opened forty years ago, was purchased by the Corporation in 1901. It contains the finest piscatorial collection in the world, as well as a large collection of marine shells. Organ recitals and concerts by the municipal orchestra are given frequently.

The electric lighting works at Southwick are very fine, and capable of supplying the whole town with electricity. The waterworks provide one of the purest and best waters in the world. The department owns 1,400 acres, eighteen

reservoirs, and six pumping stations. The water is entirely underground, never seeing daylight from the time of its absorption by the chalk to its exit at the tap.

The public parks are numerous and well kept, Preston Park, 66 acres in extent, being especially noticeable. Here are courts for lawn tennis and bowls. Polo matches are held, as well as cricket and football. Facilities are given for riding, one side of the park being set aside for equestrians, the riding track being continued right on to the South Downs.

North Entrance to Pavilion, showing Exhibition Building.

a mile in length, sheltered from the worst weather, and decorated with euonymus. The walk is divided from the roadway by shrubs and a lawn. Above is another promenade not covered in, and beyond that a fine broad road, the Marine Parade.

The Royal Pavilion, which will be occupied by the Association for its Annual Meeting, was built by George IV when Prince of Wales, and used by him and some of his successors as a seaside home. The decorations of the chief rooms have been renewed, and the building is now used for concerts, plays, and meetings. In the Pavilion an interesting collection of prints, etc., is

kept, illustrating Brighton in its many aspects. The Dome, which adjoins the Pavilion, formerly the royal riding school, is now used for large public gatherings. It is a fine building, capable of holding about 2,500 people.

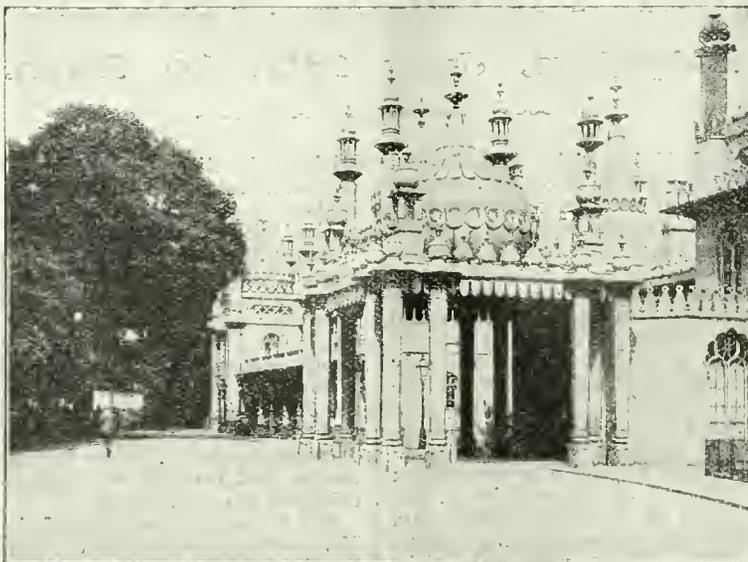

HISTORICAL.

Before the Norman conquest Brightelmstone, as the name was then spelt, came into possession of the family of Earl Godwin, and passed into the hands of his son Harold, who was defeated and slain by William the Conqueror at Hastings. The lordship of the manor was then presented by William I to William de War-

renne, afterwards Earl of Surrey. The rent paid, according to Domesday Book, was 4,000 herrings.

In the sixteenth century the town was burnt by the French, an interesting picture of which event is shown in the Public Library.

When Charles II escaped from this country after the battle of Worcester, he embarked at Shoreham, having spent the previous night at an inn (no longer in existence) in Middle Street. He was helped in his escape by Captain Tetersell, who was subsequently granted a pension of

The Pavilion. Reception Room: Mayor's Reception.

£100 a year, and was buried at his death in the church-yard of the old parish church of St. Nicholas.

It was at the beginning of the eighteenth century that Brighton commenced to rise to fame. Dr. Russell, who was born at Lewes in 1687, settled in practice in Brighton, and, after a long study of his subject, issued his celebrated

work, *On the Use of Sea Water in the Diseases of the Glands*. He recommended his patients to drink sea-water as well as bathe in it. A short account of his views, for which we are indebted to Dr. Gervis, an ex-mayor of Brighton, will be of interest. According to him the internal use of sea-water should precede its external application, for he says, "Many persons are apt to hurry into a course of bathing before the body is altered and sufficiently prepared by drinking sea-water or by a previous course of other remedies, which hurry is always detrimental to the

patient by protracting his cure." It would be quite erroneous to regard Russell as a mere crank, for in many ways he was in advance of his time. He recognized the value of open air in the treatment of consumption, and distinguished between those cases that required absolute rest and those which would be benefited by exercise. For the latter he recommended riding on the Downs. In the case of delicate children he insisted on the importance of keeping the nursery windows open, or not dressing the children too warmly, and on avoiding the use of opiates. In fact, his advice might be that of the most up-to-date county council health visitor.

It is possible that Dr. Russell's sage advice was even more efficacious than the pint of sea-water he made his patients drink daily; at any rate, his treatment had a tremendous vogue, and invalids deserted Bath and other inland health resorts and flocked to Brighton to be cured of all their ills by the novel method of bathing in the sea and drinking sea-water.

It is difficult nowadays, when the custom of spending holidays by the seaside is so widespread and everybody bathes in the sea as a matter of course, to realize how great a revolution Dr. Russell inaugurated. The tendency to regard sea-bathing as a medicinal process lasted long after Russell's time, even down to the middle of the nineteenth century. Dr. Russell, who did so much to raise Brighton to fame, died in 1759, aged 72, and the Rev.

Dr. Mannington, of Levington, enshrined his memory in the following epitaph:

Clara per omne aevum Russellii fama manebit
Dum selinet vires unda marina suas.

It was during the time of the Regency and of George IV that the zenith of Brighton's popularity was reached. As already mentioned he, as Prince of Wales, built the Pavilion as a royal marine residence, at an enormous cost, with riding schools and stables connected with the Pavilion by an underground passage. The orgies which occurred in this residence during his occupancy are historical, and no credit to him or his satellites. After his death it was used by William IV as a seaside house, and Queen Victoria resided there several times during her brief visits to the town.

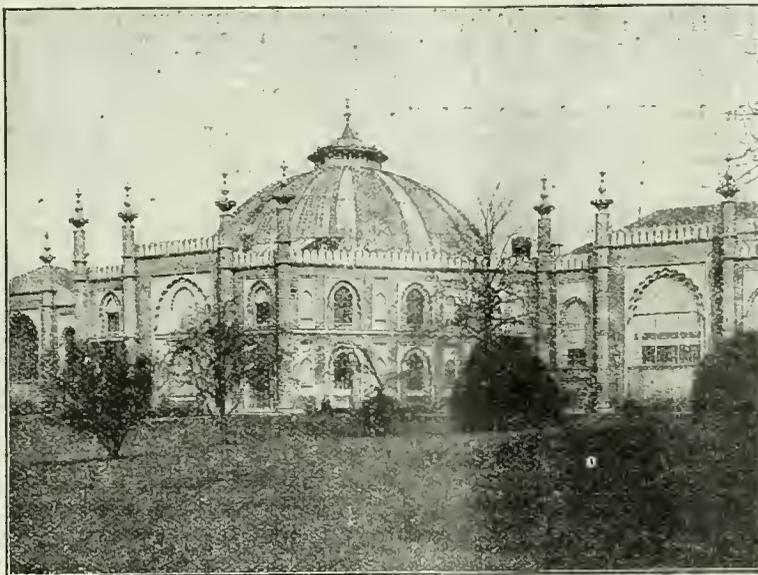

In 1850 the building was purchased by the town for £30,000. The old riding school is now the Corn Exchange—where the Annual Exhibition of the Association is to be held; the stables have been converted into the Dome, where Dr. Hollis will deliver his Presidential address. The Pavilion remains much in its original state, and is to be used for the purpose of the Annual Meeting, the reception, reading, writing, and other rooms being situated here.

In the Old Steyne is the house of Mrs. Fitzherbert, wife of George IV; her tomb is situated in the Catholic Church of St. John the Baptist in Bristol Road, where the Catholic service of the Association is to be held.

Some reference to the sister town of Hove must be made. This borough, though only separated from Brighton by a purely artificial boundary, has a corporation of its own, and manages its own affairs entirely.

The town has been well planned with wide, open streets, roads, and avenues. The sea wall, erected at a total cost of about £70,000, under the supervision of Sir John Cooke, is one of the finest in England, extending almost to Aldrington.

The most imposing building in the town is its Town Hall. It was erected in 1882 at a cost of £50,000. The central hall has a good organ, and is capable of holding about 2,000 people. The central tower has a fine carillon of twelve bells, which play throughout the day every three hours.

The Dome Assembly Hall. President's Address; Dr. Spitta's Lecture.

The Palace Pier.

Hove was a favourite resort of the late King Edward, who frequently stayed at the house of Mr. Reuben Sassoon at 8, Queen's Gardens. It was here he had an historic interview with the Prime Minister, Mr. Asquith, in reference to the steps to be taken to secure the passage of the Parliament Bill into law.

There are many parks and open spaces in Hove, the most beautiful of which is the rural St. Ann's Well. There is a chalybeate spring in the gardens, at one time much resorted to by visitors to Brighton, but it has now fallen into disuse.

Hove Park, situated in the old Shoreham Road, in the district known as Goldstone Bottom, takes its name from the Goldstone, an enormous grey wether, lying there for many years on the land of farmer Rigden. It was at one time supposed to be a Druidical altar or sacrificial stone, and it is said that it formerly lay in a stone circle. In the early portion of the nineteenth century it attracted the attention of archaeologists so frequently, that the owner, finding it a nuisance, dug a hole and buried it; and there it remained till 1902, when, after much searching, it was found and dug up, and remains in Hove Park, weighing 20 tons, and measuring 10 ft. by 14 ft. by 5 ft. at the thickest part.

This park, now the happy hunting ground of children and nursemaids, and one of the prettiest spots for the residents and visitors at Brighton to explore, was once the scene of a tragedy so terrible and sombre that it is difficult to imagine that it is only a little over one hundred years since it happened. A riot broke out in the Oxfordshire Regiment, and those who took part in it were tried by the authorities, who determined to make an example of the guilty ones. Various punishments were dealt out, and two of the unfortunate men were condemned to be shot. The following account of the execution of the sentence is taken, with slight alteration, from a contemporary newspaper:

On Friday, June 14th, 1795, at 11 o'clock at night, the Oxfordshire Regiment marched from Seaford in order to attend the execution of the two men who were condemned by a general court-martial for riotous and disorderly conduct. The hour of four was the time appointed to assemble. On the march the regiment halted, and twelve men who had taken part in the riot were called out, when the commanding officer ordered them to fix their flints and prepare to execute the sentence. This was done to demonstrate to the men that state of obedience in which the officers were determined to hold them, and by this measure they felt more pointedly the folly of their former conduct, when those persons, whom they had before made their leaders, were now to suffer death at their hands.

The regiment was then conducted to a spacious valley, now part of the New Park at Hove, and divided into two wings, which were stationed on each side of the place of execution. They were then followed by the whole line of encampment. On the rising ground above the valley three thousand cavalry were posted. They were followed by all the horse artillery. The guns were pointed and matches lighted. From the disposition of the ground and the arrangement of the troops a more magnificent and a more awful spectacle was never exhibited in this country.

After the corporal punishments had been inflicted on the prisoners of less note, Cooke and Parish, the two unfortunate men condemned to die, were brought forward with a very strong escort. They walked along the vale in slow and solemn procession, accompanied by the clergyman who had devoted his time so conscientiously to them from the moment the sentence was made known that they were fully prepared to meet their fate. They approached the fatal spot with resignation, and expressed much concern and penitence for the crime. They then kneeled down upon their coffins with cool and deliberate firmness, when the one who was to drop the signal said to his comrade, "Are you ready?" Upon the reply being made, he dropped a prayer book, and the party did their duty at about six yards distance. One of them, not appearing to be entirely dead, was instantly shot through the head, and the same ceremony was performed to the other. After this the whole line was ordered to march round the dead bodies.

This ghastly performance shows the callous brutality of the time—only a little over one hundred years ago. On the same day at Lewes two of the Oxford Militia were hung for stealing flour at Blatchington. They appeared very penitent, and desired the spectators to take warning by their untimely fate, and not to mix with any mob, as they themselves were insensible of the consequences at the time of committing the offence for which they suffered. The troops of the yeomanry cavalry raised in Sussex attended the execution.

The new parish church is a very fine building, or rather will be when completed by the erection of the tower. It is the largest parish church in Sussex.

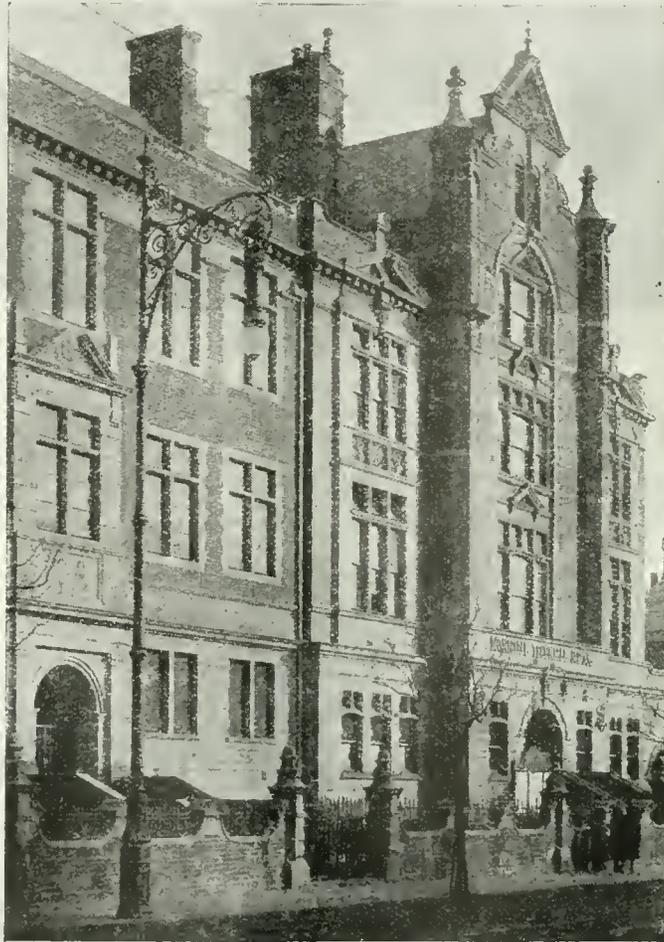

The origin of the name of the borough is not quite clear. In the Domesday Book it is recorded that the Earl of Godwin held the borough wick of Hove before the Conquest. In the thirteenth century the manor of Hove was held by the Pierpoint family, now extinct, but with the record of their name in Hurstpierpoint, a village a few miles out. At this time the sea had begun its inroads, which ended in the destruction of Aldrington.

An interesting event in the history of the town is the march of the men of Hove to the assistance of the men of Brighton. It was in 1545, when Francis I, King of France, invaded England and made his attack on the south coast. On July 18th Admiral Claude d'Annebant with 200 ships and 26 galleys of the French navy made his descent on the Sussex coast. An old print shows houses burning on the shore, with the town beacon alight, and the men of Aldrington and Hove marching to the assistance of their neighbour.

Hove only began to develop into importance at the time of the Regency, and since then has rapidly advanced to a fine attractive town.

THE ANNUAL REPRESENTATIVE MEETING.

The Annual Representative Meeting will be held on Friday, July 18th, and subsequent days in the Hove Town Hall, situated in Church Road, in the centre of the town of Hove, and easily reached by motor bus from Brighton. Ample accommodation is obtainable in the

Brighton Municipal Technical School and Day Training College: Sections.

Lent by Messrs. E. & J.]

Hove Town Hall: Annual Representative Meeting.

[Church Road, Hove.

building to accommodate comfortably all the Representatives. The Mayor of Hove (Alderman Barnett Marks) will, on the opening day, welcome the meeting to Hove. It has been arranged on this occasion to make a presentation to the Representative Meeting by the local Division of a set of minute glasses mounted in silver. The work has been executed by the Goldsmiths' Company, of Regent Street, and makes a very handsome ornament. It will be a welcome addition to the regalia of the Association. A refreshment room will be opened on the premises, where lunch and tea can be obtained at a reasonable price.

Although the controversy over the Insurance Act has become less acute, there are many important and debatable subjects (including such questions as increased subscription for membership, the advisability of the Association becoming a trade union, the payment of expenses of Representatives, and the reorganization of Branch and Divisional areas in the United Kingdom, the proposed decrease in the size of the JOURNAL, etc.) still to be discussed at the Representative Meeting—subjects which will tax the powers and patience of the able Chairman (Mr. T. Jenner Verrall), whose name is so well known in Brighton, with which he was so intimately connected in the past. The provisional agenda of the meeting was published in the SUPPLEMENT of the JOURNAL on May 10th.

THE PRESIDENTIAL ADDRESS.

The head quarters of the Association are at the Pavilion, and the reception-room will be open early on Monday, July 22nd, for the issue of members' tickets, *Daily Journal*, guide-books, catalogues, etc.

The annual address of the President will be delivered on Tuesday, July 22nd, by Dr. W. Ainslie Hollis, Consulting Physician to the Royal Sussex County Hospital, who has selected as his subject the medical history of Brighton. The oration will be delivered in the Dome. This function is always a picturesque one, and there is every reason to believe that this occasion will be no exception. Many distinguished visitors, both lay and medical, are expected, and as academic costume will be worn the display of colours of the gowns and hoods of the various universities, combined with the gay dresses of the ladies, will make a brilliant spectacle.

The Mayor of Brighton, Alderman Thomas Stanford, will open the proceedings by welcoming the Association to Brighton. The Mayor is intimately connected with the medical profession and it is an open secret that he only consented to the urgent wish of his colleagues to retain office for a third time on account of the visit of the British Medical Association to Brighton this year.

It has been decided on this occasion to present to the President, Dr. W. A. Hollis, a replica of the presidential badge of office, from the local Division, as a token of the esteem in which he is held by his colleagues in the town. To this ceremony the Mayors and Corporations of Brighton and Hove and many distinguished people are to be invited, so that a very large meeting is expected, but the seating accommodation at the Dome is very large and room will be found for all.

THE ADDRESSES IN MEDICINE AND SURGERY.

These addresses will be delivered in the Music Room of the Pavilion on Wednesday and Thursday at 12.30 p.m., that in Medicine by Professor George R. Murray, physician to the Royal Infirmary, Manchester; that in Surgery by Sir Berkeley Moynihan, Surgeon to Leeds General Infirmary.

THE SECTIONS.

The sections, sixteen in number, will all hold their meetings in two adjacent buildings, the Municipal Technical College and the Municipal Training School, kindly placed at the disposal of the Association by the Brighton Education Committee. These are easily reached from the Pavilion by tram in two minutes or by walking in five. Here there are plenty of large and well-arranged rooms, which will afford ample accommodation not only for the whole of the Sections but also for the Pathological Museum. The preliminary programme of the Sections was published in the SUPPLEMENT of May 17th, and reference need only be made here to a few of the discussions. Thus, in the Section of Climatology and Balneology, Dr. W. J. Tysou is to open a discussion on Sea Bathing, and Dr. Neville Wood will speak on The International Aspect of British Health Resorts. In the Ophthalmological Section an important discussion on School Clinics and the Prevention of Myopia will take place; and in the Section of Diseases of Children Professor Foerster of Breslau

will read a paper on Posterior Root section in the Treatment of Spastic Paralysis. In the Section of Laryngology, Rhinology, and Otology a discussion on a most important subject, the Care of Patients after Operations on the Nose and Naso-pharynx, will be held. In the Pharmacological Section Dr. Wilcox will open a discussion on the Use and Abuse of Hypnotics. In the Section of Medical Sociology, at which a large number of non-medical members are expected to attend, many important discussions which will appeal to the intelligent public have been arranged. A debate on Crime and Punishment, in which Dr. Charles Mercier, Sir Bryan Donkin, and Dr. James Scott will take part, is one of the items; the Consideration of Eugenics is another; and the subject of Hospitals in Relation to the State, the Public, and the Medical Profession is sure to provoke animated argument. In this latter discussion Mr. Masterman, Under Secretary to the Treasury, will join, and the Chancellor of the Exchequer, the Right. Hon. D. Lloyd George, has been asked to contribute his views; he has intimated that he is unable to make a definite engagement so far ahead, but the local profession sincerely hopes he may be able to be present.

It will be seen from the above brief reference that the scientific proceedings have been arranged to include many subjects of interest and importance to every member of the profession, no matter what particular branch he may be engaged in, and the names of the officers and of those who have promised to take part in the discussions or read papers should vouch for the excellence of the material to be supplied.

THE PATHOLOGICAL MUSEUM.

This is being well organized by Dr. Galt of the County Hospital and his colleagues. Specimens are being collected from all over the country to illustrate the subjects treated of in the papers and discussions of the various Sections. In addition special branches of pathology are being taken up and illustrated, especially those relating to any recent research work. It is hoped also to have on view, with demonstration, the most recent instruments relating to clinical diagnosis and pathological investigation, such as the epidiascope. A good collection of microscopic exhibits has also been arranged for in a special room adjoining that in which the Pathological Section meets.

CHURCH SERVICES.

It has been decided that a service shall be held at the parish church of St. Peter's, Brighton, on the afternoon of Wednesday, July 23rd. The members will assemble and robe at the Pavilion; they will then march in procession, preceded by the Corporations of Brighton and Hove and their officials, through the gardens to the church. Canon Hoskyns, the vicar, will conduct the service; it is hoped that the Bishop of Truro, whose brother Dr. Ryle is a well-known practitioner in Brighton, will preach the sermon, and a leading member of the Association will read the lesson. Arrangements for hiring the robes, on this and other occasions, have been made with various firms, so that no difficulty will be encountered in the wearing of academic costume.

On the morning of Wednesday, at 9 a.m., a Roman Catholic service (short mass) will be held at the church of St. John Baptist, Bristol Road, Brighton. This church is situated within a few minutes of the Pavilion by motor bus. Canon Monsignor Johnston, D.D., will conduct the service, and afterwards will be pleased to show visitors round the church, which contains, among other objects of interest, the tomb of Mrs. Fitzherbert, wife of George IV.

ANNUAL DINNER.

The annual dinner will be held at the Hove Town Hall on the night of Thursday the 24th. The number of tickets has, on account of seating accommodation, been limited to 400; and, as it is expected that there will be a great demand for these, early application should be made. Some very distinguished visitors are expected, and a successful function is with confidence anticipated. The after-dinner speeches will be few and short.

POPULAR LECTURE.

A popular lecture entitled *Some Wonders of Animal and Plant Life in Pond and Pool* will be delivered in the Dome on the evening of Friday, July 25th, by Dr Spitta,

and will be illustrated by a cinematograph; 2,500 tickets are to be issued, and they will be distributed mainly to working men, school teachers, and elder scholars, and the public generally. Dr. Spitta is so well known as a clever and capable lecturer, that there is sure to be a very large demand for admission. Captain Tryon, one of the borough members, will take the chair, and Mr. Percy Taylor will preside at the organ.

ANNUAL EXHIBITION.

The annual exhibition of foods, drugs, books, and instruments, has been arranged in the Corn Exchange, a spacious building adjoining the Dome. It is hoped, in spite of the competition of the International Medical Congress to be held in August in London, that this will prove as useful and attractive as it has in the last few years. A unique opportunity is here presented to the members of the profession actually to inspect the latest productions in elegant pharmacy, the most recently published medical works, and the most modern surgical instruments. It has been decided to keep this exhibition open during the Mayor's evening reception, to be held in the adjoining buildings, the Dome and Pavilion, on the night of Wednesday, July 23rd.

MAYORAL RECEPTION AND OTHER ENTERTAINMENTS.

Many evening functions have been arranged. The Mayor of Brighton is issuing invitations for a concert and ball to be held in the Pavilion and Dome on Wednesday evening. These buildings essentially lend themselves to an entertainment of this nature. The handsome suite of rooms with their quaint ornamentation are specially suitable for a state reception, and no more appropriate place could have been selected than the old dwelling place of George IV. The municipal orchestra which will perform on this evening, under the direction of Mr. Lyell-Taylor, is justly celebrated for its performances, and will be heard to advantage in the Dome.

On Thursday night, the evening of the annual dinner, an entertainment is being arranged for the ladies and those members who are unable to be present at the dinner. It is not quite settled what form this will take, but probably one of the theatres in the town will be reserved for them.

On Friday the local Division is giving a soiree in the Hove Town Hall, and this should be a great success. A large number of invitations will be issued to prominent residents in the two towns to meet the members of the Association.

On the afternoon of Thursday, July 24th, the Mayor of Hove, Alderman Barnett Marks, will entertain the Association at a garden party in the grounds of St. Ann's Well Gardens. This park is without exception the most beautiful in either town. The picturesque paths, winding up and down hill, in the well-wooded grounds, are perfect on a fine summer's day, and no more suitable spot could have been selected by His Worship to entertain his guests.

LADIES' ENTERTAINMENTS.

A ladies' committee, presided over by Mrs. W. Ainslie Hollis, wife of the President, has been formed to look after the interests of the lady visitors, and they are endeavouring to provide amusements for them during the time their husbands are engaged at the Sections. Croquet, tennis, golf, etc., are all being arranged, and it is proposed to have a ladies' golf competition, the local Division presenting a cup to the winner. Visits to various places easy of access will be made, motor rides round the district will be taken, and so on. Nothing is being left undone by the Committee to ensure the comfort of their lady guests. Some members will be in constant attendance at the ladies' room in the Pavilion to assist the visitors in every way, and to provide them with afternoon tea.

EXCURSIONS.

Plenty of excursions to places of interest in the neighbourhood have been arranged for Friday and Saturday July 25th and 26th. The Mayor of Eastbourne, in conjunction with the Eastbourne Division of the British Medical Association, has invited a party to visit that town. A special train will be provided, and after the arrival of the visitors, they will be entertained at lunch at the Town Hall; they will then drive round the neighbourhood, have tea on the pier, be entertained at dinner, and finish up

with a concert and firework display in Devonshire Park, returning to Brighton by another special train.

The Mayor of Lewes, Dr. Hugh Stott, has arranged for a visit to Lewes, the county town of Sussex, and one of the most picturesque. This old town is full of historic interest. The racecourse lies on the hill where Henry III was defeated by Simon de Montfort in 1264. In Southern High Street there is still in existence the old house where Anne of Cleves lived after being divorced by Henry VIII. Other noted inhabitants were Sir Thomas Browne, author of *Religio Medici*, and Sir Nicholas Pelham, who in 1545 defeated a French force which landed at Seaford. The old castle, with its interesting archaeological collection, is worth a visit, and also the church with its Norman round tower. In Queen Mary's time sixteen martyrs were burnt at the stake after being imprisoned in a cellar under the old Star Inn. A monument was erected a few years ago on Cliffe Hill to their memory. After visiting these places of interest the party will be entertained at tea by Mr. and Mrs. Frankfort Moore in their beautiful home.

At Arundel the Duke of Norfolk has thrown open his magnificent seat, Arundel Castle, which dates from the sixteenth century, but which has standing in its grounds, on a lofty mound, an ancient Norman keep. Adjoining the castle is the parish church. This church is probably the only church in England devoted to two distinct religions being divided by a brick wall between the chancel and the tower into a Roman Catholic and a Protestant portion. In the former the lady chapel contains the tombs of the Earls of Fitzalan and some interesting brasses. There is also in the town a second fine Catholic church, dedicated to St. Philip Neri. The Duke of Norfolk will entertain his visitors to tea after they have visited the town and castle, and will be assisted in every way possible by the Mayor of the town.

At Chichester Messrs. Shipham, of potted meat fame, will entertain a party. Here there are many buildings of great interest. The cathedral shows varied styles of architecture and presents one unique feature, the only example in this country, and that is a bell tower standing apart from the cathedral. The Gothic market cross, of fifteenth century date, stands in the centre of the town. St. Mary's Hospital, an old almshouse, the chapel of which was built in the fourteenth century, and contains some fine carving, is a most interesting building. Here, in little suites of rooms, each one self-contained, live old men and women elected to the charity, in comfort and respectability. The late King Edward frequently visited here during his trips to Goodwood, and showed his interest in the old people by many kindly acts.

At Tunbridge Wells the local Division has arranged to entertain a detachment of the conference at lunch, then to drive them to Penshurst, a fine mediæval mansion, the seat of Lord De L'Isle and Dudley. Afterwards the visitors will be received by the Mayor of the town, who will provide them with tea.

At Shoreham, Lancing College, with its fine chapel, and Bungalow Town will be visited, the doctors in the neighbourhood having made themselves responsible for the entertainment of a party. Tea will be provided at the College, and it is hoped that some exhibitions of flying will be arranged at the Shoreham Aërodrome, one of the best on the South Coast. The town boasts of two old churches, and possesses a very quaint little Sussex harbour.

At Worthing parties, after partaking of lunch as the guests of the Worthing Division, will be taken to view the celebrated glass houses where the fruit-growing industry of the neighbourhood is carried on. Some will proceed to Bignor, where there is a fine specimen of Roman pavement; others to Cissbury, with its prehistoric remains, and Sompington, with its old church and Saxon Tower.

At Portsmouth the local Division has invited a number of members to lunch and to view the well-known dockyards. Visits to battleships are also being arranged for.

A sea excursion will proceed to Boulogne, where, after viewing the lovely cathedral and the ancient town walls and the statue to Jenner (by the irony of fate the only one in the world) the Mayor of Boulogne will receive his English visitors to tea.

This list, not yet complete, will show that the members of the Association who come to Brighton, will have ample

choice of places to visit after the business work of the meeting is completed.

INTERESTING PLACES IN AND NEAR BRIGHTON.

Brighton is not a town with many industries of importance, but there are, of course, various businesses and manufactories, many of which are to be thrown open to members for inspection. Clark's Bread Factory, where the latest machinery for the making of bread without the intervention of the hands has been installed, will attract many visitors. Cox's Pill Manufactory and the Reason Electrical Works will also present many features of interest for those who go over them. Visits are being arranged to the works of the Sewers Board, with the main outfall at Rottingdean. This little village, situated about five miles from Brighton, with which it is connected by a good service of motor buses, is a popular resort, and many celebrities have lived here—for example, Sir Edward Burne-Jones, who designed the beautiful windows in the picturesque parish church, Mr. Rudyard Kipling, and William Black of literary fame, and now Sir Edward Carson, the Ulster leader.

The Corporation Electricity Works at Southwick, at the mouth of the Adur, the Brighton Railway Works, the waterworks, the special schools of the Brighton Education Committee—for example, the Mentally Defective School, the Home Training School, the Coombe Road School, built on the latest pattern and one of the best in England—are all to be open to members.

Many other places of interest, such as Captain Frazer's French garden situated on the London Road, about two miles out of Brighton, which attracted the great interest of his late Majesty King Edward VII, the Hove Bungalows, a group of cement houses, built right on the beach at Aldrington, with balconies eminently suitable for open-air treatment, will fill in spare hours.

The Sussex Art Club has decided to hold its annual exhibition during the conference week, and the exhibition of the School of Arts students' work will also be on view.

Garden parties, in addition to that of the Mayor of Hove already referred to, will be given at Roedean School, by the Misses Lawrence. This school is one of the finest girls' schools in England, standing in large grounds right on the cliff, half way to Rottingdean, and is well worth a visit. At Sylvan Lodge Dr. and Mrs. Holmes Meyrick, and at Wick School the head master, Mr. Thring, are also entertaining members at garden parties.

A Masonic reception has been arranged, the Worshipful Wardens of the Hove Ecclesia Lodge having extended a cordial invitation to all medical Masons to attend a special Lodge at the Old Ship Hotel, following the church service on Wednesday. Tea will be provided.

A visit to Brighton College, situated in Kemp Town, has been arranged, and an all-day cricket match in the grounds will probably be arranged.

This fine public school was founded in 1845, and erected from designs by Sir Gilbert Scott. In the early Eighties the school increased in numbers to about 200, and two large boarding houses were added, designed by Sir T. L. Jackson. The old sanatorium was also built at this time, but has since been adapted, as an engineering workshop, and a new sanatorium has been provided. In 1903 there were further additions in the shape of quarters for the day boys. During the last few years the school has been growing rapidly, and has recently reached the record number of 250 boys.

Plans have just been accepted by the council for the erection of a big schoolroom and gymnasium at a cost of about £6,000. The work is to be started immediately, and it is hoped that the ceremony of laying the foundation stone of the new buildings will take place on July 26th, and that some members of the Association will be present.

Among old boys who have achieved fame in the medical profession are Inspector-General H. C. Woods, R.N., C.B., C.V.O., honorary physician to the King; Mr. C. Higgins, consulting ophthalmic surgeon, Guy's Hospital; Deputy Inspector-General E. J. Sharwood; and Dr. J. M. Cotterill, President of the Royal College of Surgeons, Edinburgh.

The arrangements for golf are excellent. By the courtesy of the clubs in the town and neighbourhood the links are thrown open to the members of the Association

during the week of the meeting. Among those clubs which have granted this privilege are the following: The East Brighton, the Brighton and Hove, the West Hove, the Southdown, the Pyecumbe Club (five miles), Worthing (ten miles), and the Seaford (sixteen miles).

The Ulster Cup, open to all members of the Association, will be played for on Thursday, July 24th, at the East Brighton Golf Club, 18 holes, bogey play, under handicap (limited to 18). It would greatly facilitate the work of the Golf Subcommittee if intending competitors would as soon as possible enter their names, with the following particulars: (1) Golf clubs where they have their lowest handicap, together with that handicap. (2) Name of partner if possible. (3) Time at which they wish to start. Players may start at 9 a.m. Entries to be sent to the Honorary Secretary, Golf Subcommittee, 14, North Street, Brighton.

Ladies' Golf.—Lady visitors, who are members of recognized golf clubs, will be made temporary members of the Ladies' Golf Club at the Dyke. A competition will be arranged during the week, open to wives, daughters, and sisters of members of the Association.

Tennis grounds will be opened to both ladies and gentlemen, and the Croquet Association is holding its tournament (July 21st to July 26th) at the Sussex County Croquet Ground at Southwick. If sufficient members intimate their desire, a cricket match will be arranged between members or against another team. The principal clubs—the New Club, the Union, and the Hove Club—offer hospitality to the Association during their visit. The conductor of the Municipal Orchestra, Mr. Lyell-Taylor, will be glad to arrange to perform any special music desired, if members will intimate the same to him.

The Brighton and Sussex Medico-Chirurgical Society have given permission for the Association members to make use of their library and reading-room during the time of the visit of the conference.

Many inhabitants, both lay and medical, are arranging entertainments and hospitality; lunch and dinner parties are so numerous that one hopes the visitors to the town will survive them. In addition, such bodies as the Irish Graduates' Association and the National Temperance League are arranging their own functions—the former a lunch at the Metropole, the latter a breakfast at the Pavilion.

The Queen's Nurses have expressed a desire that members will visit their new home, the Brighton and Hove memorial to King Edward VII., recently opened in Wellington Road. It is a home up to date in every way, and has been specially designed to meet the complete requirements of the Queen's Nurses in the district.

This survey of the arrangements made for the instruction and entertainment of those members of the Association and their wives who attend the eighty-first Annual Meeting at Brighton, though by no means complete, shows that no stone is being left unturned to make their holiday a complete success, and to send them away from Brighton with a happy recollection of their visit.

LITERARY NOTES.

THE Académie Française has awarded the Grand Prix Broquette Gouin of the value of £400 to Professor Grasset of Montpellier. The prize is, in the words of the founder, intended to reward "the author of a work, philosophic, political, or literary, which shall be judged to be of a nature to inspire the love of the true, the beautiful, and the good." Professor Grasset, who has devoted his scientific life to the study of the nervous system, is the author of several works on questions of psychology, moral responsibility, and the philosophy of practical life. They are written in a lucid and attractive style, and have won for him a considerable reputation. This is the first time the prize has been awarded.

The June number of the *Arena* contains a long letter written by Mr. E. B. Sargent, who was a member of the Royal Commission on University Education in London, in which he answers a call for advice from the promoters of a new university in a distant part of the empire.

Mr. Sargent is a strong advocate of the establishment of residential facilities in a new university, and gives much expert advice on the subject in this letter. Mr. Aflalo furnishes some extremely useful hints on the subject of the traveller's budget. An article of special interest is one on women students' life in the Scottish universities. There is no reference to the University of Aberdeen, where, to judge from the local academic magazine, *Alma Mater*, and from the class lists, lady students take a prominent part in the life of the university. Besides a reproduction of a particularly fine drawing by Mr. John Key of Worcester College, Oxford, there are many other illustrations.

The cult of the bath, now regarded more or less as the hall-mark of the educated Englishman, is nevertheless of comparatively recent growth in this country, where even yet we can hardly hope to emulate the elaborate apparatus used by the ancient Greeks and Romans for the cleansing of the human body. Bathing, however, has at last been recognized as a powerful agent for the preservation of health and the prevention of disease, and for this reason, in many countries, baths are provided in the public schools for the use of those children who are unable to obtain them at home. The therapeutic properties of the school bath are discussed by Dr. R. Fortescue Fox in an article that appeared in the May number of *The Child*, in the course of which the writer states his reasons for preferring the douche to the tub bath or swimming pool now in vogue in English schools. "Experience has shown," says Dr. Fox, "that the routine use of douche baths at school has had the best effect on the physical and mental condition of the children," partly, no doubt, because there is less fatigue and less chance of infection with the douche than with the swimming bath, and also because the former is far more cleansing and invigorating than the ordinary plunge bath. It is, however, impossible to make hard and fast rules with regard to school bathing, since children's constitutions differ as widely as those of adults and require to be studied with equal care. The school bath, as Dr. Fox reminds us, has to meet needs of a very variable kind, and school bathing should therefore only be carried out under strict medical supervision, the advice of the school doctor being asked in every case in order that the child may derive full benefit from the treatment. The May number of *The Child* also contains a short account of the Alexandra Hospital for Children with Hip Disease by Mr. Stanley Smith, and an interesting description of the work of the Salvation Army amongst the children of the London slums, to which Mrs. General Booth has contributed an introduction.

George Borrow, "the walking lord of Gypsy Lore," as he has been called, was born in 1803 at Dumpling Green, near East Dereham. He was educated at Norwich Grammar School, and at various periods of his life he dwelt in Norwich, Great Yarmouth, and Oulton, near Lowestoft. It is now felt by his admirers that the time has come when the place of the author of *Lavengro* in English literature is sufficiently recognized to call for some permanent memorial of him in Norwich. The committee, among the members of which we note the names of the venerable Sir Peter Eade and Dr. H. Cooper Patten, Medical Officer of Health to the City of Norwich, has come to the conclusion that the most suitable form of memorial is the preservation of the house in which Borrow lived while in Norwich, and it is proposed to equip it as a permanent Borrow Museum. The Lord Mayor of Norwich (Mr. Arthur Michael Samuel) has offered to defray the cost of purchasing the freehold of the house, and at a meeting of the City Council, held on May 20th, it was resolved to accept the proposed gift, and maintain the house in trust as a permanent museum. The committee now confidently appeals for funds to alter the house into its original condition, to furnish it suitably, replacing such of the original furniture as can be recovered, and to secure by gift, loan, or purchase, books, manuscripts, letters, portraits, drawings, and other objects for exhibition in the museum. The formal presentation of the deeds of the house to the Corporation will be made the occasion for a celebration at Norwich on July 5th.

British Medical Journal.

SATURDAY, JUNE 7TH, 1913.

THE AMENDMENT OF THE INSURANCE ACT.

THE Government is pledged to introduce this session a bill to amend the Insurance Act, and the results of recent by-elections have produced a plentiful crop of rumours as to the matters which will and will not be dealt with in the bill that is being prepared. All these rumours should be received with the greatest reserve, for there is good reason to believe that the intention of the Government was, and probably still is, to avoid as far as possible the introduction into the amending bill of controversial matters. This may not be very easy of accomplishment, as upon some of the points to which the Government has undertaken to give attention there are differences of opinion.

The Government now has before it, in the considered Memorandum published in the SUPPLEMENT this week, the views of the British Medical Association as to the amendments immediately required in the Act and Regulations, and it is understood that it has been made acquainted also with the opinions of friendly societies, trade unions, and many labour members.

The medical profession will no doubt generally have recognized that, though there need not necessarily be conflict between the desires of labour and medicine with regard to amendments of the Act, its unpopularity with the insured, of which the by-elections are alleged to have given evidence, is not due to the same causes as render it distasteful to the profession, and that, so far as the Government may, as a matter of political tactics, be disposed to modify the existing system in the amending bill, changes introduced with any such motive are not likely materially to affect medical interests for the better.

The advanced stage of the session, the very large amount of other business which ought to be done, and the freely-expressed distaste of members of Parliament of all parties to undergo again the pains of an autumn session are all factors which will undoubtedly have weight with the Cabinet and tend to deter it from introducing a bill which goes beyond what it considers to be the irreducible minimum of amendment.

It seems clear that the bill must contain certain financial provisions; it must, for example, embody the provisions with regard to the additional sum for medical benefit, £1,877,000, promised by the Chancellor of the Exchequer last October, including the grant of money to assist in providing medical benefit for those persons insured under the Act who were 65 years of age at the appointed day. The Chancellor of the Exchequer has also undertaken to give attention to the position of the insured persons who subsequently become well-to-do. Under Section 1 (3) (b) such persons may continue as voluntary contributors if they have been insured for five years, and the justice of the medical objection that thereby a number of well-to-do people with incomes of more, sometimes far more, than

£160 may be able to take advantage of State-aided insurance is acknowledged.

Another point which it seems to be generally agreed must be dealt with in the amending bill is the case of the casual labourer, who may be subject to having a deduction of 4d. made from his wages for only an odd day's work in a week, or who, if unsuccessful in obtaining work on a Monday, sometimes feels himself obliged to put a 7d. stamp on his card in order not to be at a disadvantage on subsequent days of the week.

The Association has put in the forefront of its Memorandum certain points with regard to the definition of the services to be rendered as part of the contract to give medical benefit which it has on several previous occasions placed forcibly before the Government. They were in particular fully set out by the deputation appointed by the Representative Meeting of November last, which had an interview with the Chancellor of the Exchequer on November 25th and 26th. These points were with regard to the provision of the services of a second practitioner (especially for the purpose of administering an anaesthetic), the treatment of diseases due to misconduct, and the treatment of miscarriages, abortions, and their consequences arising within four weeks. The Chancellor of the Exchequer did not meet the Association on any one of these points, and the Memorandum raises them again, all the more strongly as the experience of the working of medical benefit under the Act has fully confirmed the contention that the present interpretation of medical benefit operates unfairly to the medical profession, and is contrary to public policy. There can be no question in the mind of any person, lay or medical, that a medical practitioner should not be expected or encouraged to give an anaesthetic while at the same time rendering some other service to the patient. The practice is dangerous, but an insured person has no claim upon any doctor other than the practitioner on whose list his name is included. The ease for the amendment of the system which makes it a duty of a practitioner under his agreement as drafted by the Commissioners to treat abortions and miscarriages as a part of the services he has undertaken to render, is very strong. The treatment of abortion, especially an early abortion, is a most anxious matter calling for the highest skill and judgement and making most serious demands upon the practitioner's time. Further, arguments of the same nature as those which weighed with the framers of the Act and led them to introduce maternity benefit as a special and separate form of benefit, arguments which have reference to the welfare of the woman and her possible future offspring and to the need for her to abstain from work and to receive careful treatment, apply with undiminished force—many experienced practitioners would say with even greater force—to abortion and miscarriage. It is not to the interests of the nation to encourage women to regard such events lightly.

The Memorandum submitted by the Association calls attention to the fact that Insurance Committees have with few exceptions failed to take advantage of the authority given to them under Section 15 (3) to require persons whose income exceeds a limit to be fixed by the Committee to make their own arrangements. The Association desires that the Act should be amended so as to make it incumbent upon the Insurance Commissioners to require Insurance Committees to adopt a local income limit, the limit to be subject to the approval of the Commissioners. The Memorandum also calls attention to the justice of so

amending the Act as to ensure that when the income from all sources of an insured person exceeds £160 per annum he should be required to make his own arrangements, and that in estimating the amount of income the total income from all sources should include any income independent of the personal exertions of the recipient, whether received by way of an allowance or otherwise. At the present time young men in receipt of a small salary, but in receipt also of a substantial allowance from their fathers, are compulsorily insured, and are therefore in a position to take advantage of the medical attendance provided under the arrangements with the Insurance Committee, and in some instances are actually taking advantage of such opportunities.

The Memorandum raises three points with regard to the representation of the profession on committees administering the Act, and recalls the fact that during the progress of the bill through Parliament the Association repeatedly drew attention to the defect in the composition of the Insurance Committees which gave to one interest a permanent majority over all the others. The effect of this, as was foreseen, is that the Committees are not so constituted as to be qualified to give a fair consideration to questions in which the interests of the dominant party are directly involved. A related point is that the Act did not give any direction as to the way in which District Committees shall be constituted. County Insurance Committees are required, after consultation with the County Council, to submit a scheme for the appointment of District Insurance Committees for the county, and there was an understanding that the profession should have representation on these District Committees corresponding to that which it has on the Insurance Committee. The understanding, however, was not embodied in the Act or Regulations, and the Association urges that this defect should be rectified by an amendment providing that the medical representatives should form the same proportion of a District Insurance Committee as of the County Insurance Committee. Similarly, the profession is not represented on the Committee of the Seamen's National Insurance Society, a body constituted for the purposes of the Insurance Act by the Board of Trade; its affairs are administered by representatives of that Board, of shipowners, and of members of the society in equal proportions. In the case of the home and coasting trade the ordinary rates of contribution apply, but in foreign-going ships the employer's contribution is reduced to 2d., and the seaman's is reduced by one-fifth. The insured persons are entitled to medical, sanatorium, sickness, disablement, and maternity benefits. The Association asks that the medical profession should be represented on the Committee of this official society in the same proportion as on Insurance Committees. It believes that by these reforms the administration of the Insurance Act will be rendered more efficient, and that there will be less risk of friction among the different sections if no one interest forms more than two-fifths of the total membership of the Committees.

With regard to temporary residents, the Memorandum distinguishes three classes—holiday-makers, convalescents, and persons who remove in the course of their employment. With regard to holiday-makers, the Association contends that they should not be entitled to medical treatment under the Act. With regard to persons removing in the course of their occupation, it urges that all such persons should be required to make their own arrangements, and not

merely certain classes of them, such as actors and commercial travellers. With regard to persons who go away to the country or seaside on account of ill health, the Association urges that the Act should be amended so as to procure the provision by the Government of a special central fund, apart from any moneys already allocated for medical benefit, to provide for the medical attendance and treatment of such persons when temporarily absent from home. We believe that some members of the Government are not unaware of the injustice of the present arrangement and are not insensible to the arguments which have been adduced for the establishment of such a central fund. It may be hoped that their views will prevail.

Among the other points dealt with in the Memorandum are the proposal that the plan of attempting to deter insured persons from unnecessary night calls by inflicting a penalty should be replaced by a system of making a special charge for all such calls; the suggestion that before a draft agreement is issued in its final form it should be submitted to the Local Medical Committee; the proposal that medical practitioners, if they so elect, should be authorized to dispense medicines to insured persons on their list in all cases where the patient is more than a mile from a chemist on the list; and the proposals with regard to the mode of appointment and tenure of office of medical referees.

MOCKERS AT MEDICINE.

LIKE Falstaff, the doctor is the cause that wit is in other men. From time immemorial he has been used as a target by jesters of all sorts, great and little, to such an extent that he might ask with Dr. Johnson, after hearing so much criticism of himself, Are we alive after all this satire? If ridicule could kill, the doctor would long ago have become extinct. But, as Byron says in speaking of the physicking of Don Juan:

This is the way physicians mend or ead us
Secundum artem; but although we sneer
 In health—when ill we call them to attend us
 Without the least propensity to jeer;
 While that "hiatus maxime defendas"
 'To be fill'd up by spade or mattock's near
 Instead of gliding graciously down Lethe
 We tease mild Baillie or soft Abernethy?

Those who have never known what it is to be ill look upon disease as Samuel Butler, the author of *Erewhon*, regarded it—as a crime which society should punish. Logically they should treat the doctor as a malefactor, and we should perhaps be grateful that they only scoff at medicine and its professors. Many, however, who laugh loudest at the doctor are merely bluffing; the least touch of indisposition sends them forthwith to the consulting room or the surgery, and though they may affect to treat the counsel of the oracle with contempt, they get the prescription made up, even though they may boast that they do not intend to take it. In such cases the doctor has the best of the joke, for he pockets his fee, and if his advice is disregarded that is the patient's concern.

A large class of those who gibe at the doctors is made up of people whose minds have an elective affinity with quackery. The more absurd the pretensions of the vendors of secret remedies, the blinder is the faith with which they are believed by those afflicted with this warp of the intelligence. They would say, with Tertullian, *Credo quia impossibile*. Of course, these misguided folk dislike the doctor, who is, in their eyes, the representative of the authority of science. Then there are the cranks who

believe in nobody but themselves, and who hold that fasting, deep breathing, dispensing with breakfast, or "living according to the laws of Nature"—so easy to do if one always knew them—will prevail or cure all diseases. Some again there are whose professed contempt of the doctor is merely a pose. Of this class Mr. Bernard Shaw may be taken as the type. Like Verges, "he will be talking" whether he has anything to say or not, and his denunciation of doctors is only a mountebank trick to dazzle the silly people who take him seriously. A French writer has recently called Mr. Shaw the Molière of the twentieth century, but the satire of *The Doctor's Dilemma* is like a shillelagh compared with the polished rapier of the creator of Diafoirus, Purgon, Destonandres, and the other medicine men whom he ridiculed. Molière belongs to an altogether different class of jester from those which have been mentioned. The shafts of his satire were barbed by the anger of a sick man against the art of medicine which could do nothing for his relief. He did not put on the cap and bells to amuse the groundlings; his wit was no *ignis fatuus*, but a scorching flame which burnt the pompous wig of pedantry and exposed the bareness beneath. Molière may justly be ranked among the reformers of medicine.

Another famous invalid who scoffed at medicine because it failed to cure him was Montaigne, who suffered much from renal colic and gravel. His contempt for medicine was more cheerful than that of Molière. Speaking of the art of healing as it was in his day, he says: "My conceit of it is both the worst and the best a man may imagine; for thanks be to God there is no commerce between us. I am contrary to others, for I ever despise it; and when I am sick, instead of entering into league or composition with it, I then beginne to hate and feare it most, and answer such as urge mee to take Physicke, that at least they will tarie till such time as I have recovered my health and strength againe; that then I may the better be enabled to endure the violence and hazard of their potions. I let nature worke, and presuppose unto my selfe, that she hath provided her selfe, both of teeth and claws, to defend her self from such assaults as shall beset her, and to maintaine this contexture or frame, whose dissolution it so much hateth. In lieu of bringing helpe unto her, when shee most striveth, and is combateth by sicknesse, I greatly feare lest I bring succor unto her adversarie, and surcharge her with new enemies." But though he despised the art, he was, like Molière himself, friendly with its professors. On this he says; "As for me I honour Physitions, not according to the common-reeeiv'd rule, for necessitie sake (for to this passage another of the Prophets may be alleaged who reprooved King Asa because he had recourse unto Physitions) but rather for love I heare unto themselves; having seene some and knowne diverse honest men amongst them and worthy all love and esteeme. *It is not them I blame but their Arte.*" He goes on to describe his relations with doctors when he was ill: "I send for them when I am sicke, if they may conveniently be found; and love to be entertained by them, rewarding them as other men doe. I give them authority to enjoyne me to keepe my selfe warme, if I love it better so than otherwise. They may chuse, be it either leekes or lettuce, what my broth shall be made withall, and appoint me either white or claret to drink; and so of other things else, indifferent to my taste, humour, or custome."

Nevertheless he attributes the recourse that is had to doctors to fear and credulity, and he maliciously notes

that they themselves when ill placed little trust in their own remedies. For himself he professed to prefer the remedies of old women to those of doctors, because they were harmless. There is (he says) no "poore Woman so simple, whose mumbling and muttering whose slobber-slabbers and drenches we doe not employ. As for mee, were I to buy any medicine, I would rather spend my money in this kinde of Physicke than in any other: because therein is no danger or hurt to be feared." He seems, however, to have got no relief from "this kinde of Physicke," for he visited the healing springs of France, Switzerland, Germany, and Italy, everywhere testing on himself the efficacy of the waters. He took careful notes of his symptoms, and looked for hopeful signs in these "Sybilline leaves," as he calls them. Whether he was a hypochondriac or not—a point which has been a good deal debated—he studied himself with minute attention and watched the effect of his self-prescribed remedies. He bore his sufferings bravely, and he may be excused if he thought lightly of the art which failed to relieve them.

It must be admitted that physicians in the days of the wig and the gold-headed cane brought a good deal of ridicule upon themselves by the gulf fixed between the largeness of their pretensions and the slenderness of their performance. We have now learnt the lesson taught by David Piteairn, who died as long ago as 1800. Asked his opinion of a certain book on fevers, he replied: "I do not like fever curers; we may guide fever—we cannot cure it. What would you think of a pilot who attempted to quell a storm? Either position is absurd. We must steer the ship as well as we can in a storm and in a fever. We can only employ patience and judicious measures to meet the difficulties of the case." As medicine has become more scientific it has become more humble. The sacerdotal dogmatism which used to prevail among doctors has now been banished from the ward, and has found a refuge in that very modern shrine, the laboratory. The debt which practical medicine owes to research is incalculable, and without it progress would be impossible. But the laboratory worker is not always in perfect sympathy with the practitioner, whom he is perhaps too apt to look down upon. And it cannot be denied that from the laboratory have come a number of vain things which have given cause for irreverent laughter to mockers at medicine.

A MONUMENTAL BILL.

BILL No. 47, presented to the House of Commons this session by Mr. Rendall and eleven other members, deserves mention, not only for what it contains of professional interest, but as a mine of information for curious persons with abundant leisure, as well as for those who wish to refer to Acts of Parliament since the time of Edward III until the present day, and for those who desire to obtain the titles of the various Acts of Parliament which relate to particular subjects. It was ordered to be printed on March 19th, contains 389 pages, and is issued by the Stationery Office at the price of 3s. 2d.

The purpose of the bill is to re-enact, with additional matter and amendments, the Interpretation Act, 1889, and the Short Titles Act, 1896. It consists of four parts and three schedules, and we are informed by its introducer that if it were passed into law it would save thousands of pounds every year to those engaged in litigation. It sets out the existing Acts which relate to particular subjects, as well as those Acts or parts of Acts which are repealed. The

first four parts of the bill consist of interpretations and the definitions of titles.

In the first schedule are set out various Acts of Parliament with their title and short title from the time of Edward III to the present day. In the second schedule the various Acts relating to particular subjects are grouped together under their short titles and indicated by collective titles, alphabetically arranged. Thus, under the Medical Acts we find nine statutes dating from the Medical Act of 21 and 22 Vict. to the University of Wales (Medical Graduates) Act, 1911. The third schedule contains a recital of the measures which are repealed.

The definitions relating to the medical profession are set out in Sections 20, 21, and 22 of the bill. It will be remembered that at the time of the passing of the Insurance Bill some medical men and some members of Parliament raised the question as to the expression used in the bill indicating a "legally qualified medical practitioner." Clause 20 of this bill shows that any one so described or described as a "duly qualified medical practitioner" or as "fully qualified" or as "registered," or described by any expression "importing a person recognized by law as a medical practitioner or member of the medical profession, shall mean a person registered under the Medical Act and any Act, past or future, amending the same." In Section 21 the expressions "General Medical Council," "medical corporation," "diploma," and "medical diploma" are defined. In Section 22 a midwife is defined to mean "a woman who is duly certified under the Midwives Act, 1902," and the Central Midwives Board is therein defined. Section 37 gives the meaning which is to be attached to the various benefits under the Insurance Act, and in Section 74 the different Royal Colleges of the medical profession are defined; but it is noticed that an omission occurred here, for no mention is made of the Faculty of Physicians and Surgeons of Glasgow.

It would be impossible within the compass of an article to give an indication of the numerous terms and expressions which are defined in the different sections of the bill. The expression "medical" includes surgical, and the expressions "medicine and medicines" include drugs, and the expression "drugs" includes medicine. The expression "woman" includes a girl, and the expression "man" includes a boy; but there appears to be nothing to show where the "child" ends and the boy or girl begins.

Apart from the professional interest, the second and third schedules provide abundant material both for entertainment and profit. The Habeas Corpus Act, 1679, is described as "An Act for the better securing the Liberty of the Subject and for Prevention of Imprisonments beyond the Seas." The *Cestui que Vie* Act, 1707, is described as "An Act for the more effectual Discovery of the Death of Persons pretended to be alive to the Prejudice of those who claim Estates after their Deaths." The Riot Act is described as "An Act for preventing Tumults and riotous Assemblies, and for the more speedy and effectual punishing the Rioters."

An Act which might perhaps provide food for controversialists in their platform utterances on one of our current political questions is "The Mortuaries (Bangor, etc.) Abolition Act, 1713," which is described as "An Act for taking away Mortuaries within the Dioceses of Bangor, Llandaff, St. David's, and St. Asaph, and giving a R^ecompense therefor to the Bishops of the said respective Dioceses." In a similar way "The Mortuaries (Chester) Act, 1755," illustrates the control of the Church at that time over mortuaries.

There are several Acts which relate to the punishment of witchcraft and similar impostures. The Witchcraft Act, 1835, is described as "An Act . . . for punishing such Persons as pretend to exercise or use any kind of Witchcraft, Sorcery, Inchantment, or Conjuratⁱon"; but it is to be feared that the records of the Acts of Parliament are strewn with ineffective efforts to improve and restrain by legislation the habits and beliefs of the people.

In 1744 the Gaming Act was directed to prevent "excessive and deceitful Gaming, and to restrain and prevent the excessive increase of Horse Races," and the Profane Oaths Act in the following year was intended "more effectually to prevent profane Cursing and Swearing." At that time and for some years afterwards Acts to prevent cattle theft, frauds by workmen, treason, the illicit sale of spirits, disorderly houses, murder, and so forth, appear to have occupied a considerable portion of the time of the Legislature; but few, perhaps, would expect an Act of Parliament which relates to the theft of vegetables to be thus described: "An Act the title of which begins with the words, 'An Act for repealing so much of an Act,' and ends with the words 'Parsnips, Pease, and Carrots.'"

The first Act that is mentioned relating to provision made for lying-in women appears in 1773, and is entitled "An Act for the better regulation of Lying-in Hospitals, and other places appropriated for the charitable Reception of pregnant Women; and also to provide for the Settlement of Bastard Children born in such Hospitals and Places."

At the present time, when the methods for dealing with persons of a refractory disposition and who commit outrages have entered so largely into public and parliamentary discussions, some of those who are not disposed to be mild-mannered in their method of treatment may regret the absence from our Statute Book of two Acts which were abolished in 1816 and 1820. In 1816 the Pillory Abolition Act was passed which was intended to "abolish the punishment of the pillory except in certain cases," and in 1820 the Whipping Act is described as "An Act to repeal an Act passed in the Fifty-seventh Year of the Reign of His late Majesty King George the Third, intituled 'An Act to Abolish the Punishment of Public Whipping on Female Offenders,' and to make further provisions in lieu thereof."

From the time of the passing of the Apothecaries Act in 1815, the number of Acts of Parliament dealing with public health, the sick and the poor, the protection of food and such like matters, shows a progressive increase, and during the later years they form a considerable proportion of the Acts recorded in this catalogue. It would, however, be inappropriate at this place to attempt to give a summary of them; but whether the bill under notice finds its way on to the Statute Book or not, a copy of it may well be obtained by those who are interested in these matters and for purposes of reference. The labour involved in its preparation will in that way, at all events, not have been entirely in vain, for it is impossible to avoid the conviction that as a private member's measure it is not likely to be passed into law. One who was disposed to scoff might also suggest that the fact that it is intended to reduce the cost of litigation does not provide it with a favourable handicap with that large body of members who belong to another learned profession, and any one of whom can prevent its second reading by being present in the House when the title of the bill is called after the termination of public business and rising in his place and saying, "I object."

BIRTHDAY HONOURS.

AMONG the announcements in the list of birthday honours are two which will excite particular interest and pleasure among all members of the medical profession. The work done by Sir Arbuthnot Lane has been and is an inspiration and stimulus to surgeons not only in this country, but all over the world, and the boldness of his speculations have been justified by the skill which has established their truth. The baronetcy now fittingly conferred upon him in recognition of his eminent services to the science and art of surgery happily coincides with the entry into the stage of convalescence of a princess at whose bedside two continents have watched with affectionate solicitude. Professor Schäfer has won the highest distinction in another field of the wide territory of medicine, and his influence also has been inspiring and stimulant. He combines in himself two of Mr. Balfour's classes of men of science, for he possesses not only the genius of research, but the power to teach and infuse into his pupils something of his own enthusiasm and energy. The knighthood conferred on Dr. Thomas Flitcroft of Bolton will be a source of particular gratification to members of the British Medical Association, for he has been an active worker for it as a member for many years of the Representative Body and of the Lancashire and Cheshire Branch, of which he is now President. He is also Chairman of the Local Medical Committee under the Insurance Act. The same honour, conferred on Dr. Herbert Smalley, Medical Inspector of Local Prisons and Superintending Officer of Convict Prisons, is a recognition of a long and honourable career in the public service. The knighthoods conferred upon Dr. A. J. Horne, ex-president of the Royal College of Physicians of Ireland, and Mr. R. H. Woods, ex-president of the Royal College of Surgeons of Ireland and President of the Irish Medical Association, are gratifying recognitions accorded to the medical profession in Ireland. A knighthood is also conferred upon Major E. S. Worthington, M.V.O., R.A.M.C., who served in South Africa, 1899-1902, has been medical officer to the Duke of Connaught, Governor-General of Canada, since 1911, and has been in constant attendance upon the Duchess of Connaught during her illness. The honour of knighthood is also conferred on Lieutenant-Colonel James Reid Roberts, C.I.E., I.M.S., surgeon to the Viceroy of India. A similar honour is conferred upon Dr. Alexander MacCormick, honorary surgeon to the Prince Alfred Hospital, Sydney, lecturer on surgery in the University of Sydney and honorary consulting surgeon to the Commonwealth military forces. Surgeon-General Henry Hamilton, C.B., I.M.S., retired, is promoted to K.C.B., and the decoration of C.B. is conferred upon Deputy-Surgeon General William Maxwell Craig, M.B., R.N.; Surgeon-General Louis Edward Anderson, Deputy Director of Medical Services, Ireland; and Lieutenant-Colonel John Crimmin, V.C., C.I.E., I.M.S. Dr. H. P. Keatinge, Director of the Kasr-el-Ainy Egyptian Government Hospital and Medical School; and Dr. A. H. Spurrier, late Medical Officer of Health at Zanzibar, receive the C.M.G. Lieutenant-Colonel Gerard Godfrey Giffard, I.M.S., Superintendent of the Government Maternity Hospital, Madras, receives the C.S.I.; and Major R. J. Blackham, R.A.M.C., commanding the Station Hospital, Jutogh, is made C.I.E. The Kaiser-i-Hind Gold Medal is conferred upon Lieutenant-Colonel P. Balfour Haig, I.M.S., Agency Surgeon, Bhopal, Central India, and the Rev. J. Buchanan, M.D., missionary, Amkut, Central India. The services of medical officers in the Territorial Force are recognized by the appointment of Colonel W. H. Bull, F.R.C.S., Assistant Director of Medical Services of the South Midland Territorial Division, and Colonel John Arnallt Jones, M.D., Assistant Director of the Medical Services of the Welsh Territorial Division, to be Honorary Surgeons, and of Colonel William Kinnear,

M.D., Assistant Director of Medical Services of the Highland Territorial Division, and Colonel Charles P. Oliver, M.D., Assistant Director of Medical Services of the Home Counties Territorial Division, to be Honorary Physicians to His Majesty.

PRELIMINARY EXAMINATION AND EDUCATION.

IN a note which will be found elsewhere in our columns Sir Henry Morris criticizes the report presented by its Education Committee to the General Medical Council, and in great part adopted during its recent session. He appears to regard the report as on the whole ill advised and ineffectual. Some years ago the Council decided that it was desirable to raise the standard of preliminary education, and the measures then decided upon were to take effect from January, 1914. The report presented last week was intended to provide the means for carrying out the intentions of the Council, and had relation to the standards of examination recognized for the purpose of admission to the *Students' Register*. An amendment was, however, moved that words should be inserted making it more clear that to this and this only the recommendations of the Committee referred. In this amendment, and in the speeches made in its favour it was thought that there was an echo of the old controversy between the Council and the Royal Colleges as to the powers of the Council. The amendment was carried, but did not end the discussions, for some thought that the recommendations, which entered into much detail, interfered with matters as to which the Council and its Committee were not experts. Attempts were made to refer the whole report back, but the Chairman of the Committee explained that to do so would almost be a breach of faith with the educational bodies with whom it had been in correspondence; some of them had modified their examinations to meet its wishes, and delay would cause serious inconvenience in the cases of those Indian and Colonial bodies which desired immediate guidance so as to make their examinations such as the Council would approve. Accordingly most of the recommendations were passed, including those affecting the recognition of certain examinations, some of which had been modified to meet the suggestions of the Committee. But a clause prescribing the percentage of marks which should suffice for a pass in the various subjects was thrown out altogether. This percentage was higher than that recommended in earlier reports, and, as Sir Henry Morris points out, its rejection leaves the bodies either without guidance, or with the guidance only of the old scale. It is open to question whether both the Committee, and apparently Sir Henry Morris also, do not attach too much importance to laying down the percentage of marks for a pass. Marks do not admit of being allotted with mathematical accuracy, and an examiner is much more likely to have in his mind the question whether the marks he is giving are pass marks, or more, or less, than to try precisely to appraise the merits of an answer in its relation to theoretical perfection. If this view be correct, then the question whether pass marks are to be 40 or 50 per cent. of full marks will not greatly affect the result. A more important matter is the proposal to abolish compensation between subjects—that is to say, to require that an excess of marks obtained in one subject shall not be allowed to compensate for a moderate deficiency in another. Such a rule is proper in an examination on professional subjects where a minimum knowledge cannot be dispensed with, but the case is different where the object is to ascertain, not that the candidate knows this or that thing, but merely that he has been educated up to such a point that he is in a position to profit by the teaching of a medical school. It is true that, as Sir Henry Morris points out, this prohibition is not embodied in the recommendations passed by the Council; but the passage stands in another part of the report, and it is not to be assumed that bodies

studying it in order to ascertain the views of the Council will discriminate very sharply between what has and what has not been passed as a definite recommendation; and thus the expression of the Committee's opinion may have its effect notwithstanding. The hope that some form of school-leaving certificate may be officially established in England and Ireland was voiced by Sir Francis Champneys, and met with cordial support; but the Council has already made representations upon this subject. It is obvious that this would be the easiest solution of all the difficulties connected with the testing of preliminary education, and there is reason to believe that the Board of Education is also of this opinion.

CERTIFICATES AND THE MEDICAL PROFESSION.

THERE is probably no body of men in the country called upon so frequently as the medical profession to give certificates, and none upon whose word more absolute reliance is placed by the public. It would seem that the very frequency with which this duty has to be performed has sometimes tended to produce some laxity, which should be carefully guarded against. Cases which within the last few years have come before the General Medical Council show that most serious consequences may follow on any such laxity. This observation is illustrated by a matter into which the Council inquired last week. It was reported to it that a practitioner had been convicted at the Central Criminal Court of improperly filling up declarations upon forms of application for passports, and had been fined £50. It appeared that he had no real knowledge of the persons who applied to him. The Council took a serious view of the case, because, although the declarations were not certificates relating to any medical matter, it was in virtue of being a registered medical practitioner that he was enabled to sign them, medical practitioners being one of the classes of persons whose certificates are accepted for the purpose. During the course of the hearing of the case attention was called to the fact that the Council had issued a special warning notice with regard to certificates of all kinds in 1911, and the President, whose remarks are reported in the SUPPLEMENT of May 31st, p. 493, quoted the operative parts of this notice in so far as they referred to the particular case. The notice issued in 1911 was in the form of a resolution adopted by the Council on November 30th in that year. In addition to passport declarations, it enumerated a number of other certificates which medical men may be called upon to sign, and, among these, certificates in connexion with sick benefit, insurance, and friendly societies were specified. The Insurance Act has probably added very largely to the number of certificates which have to be signed, and the need for the most punctilious regard to the terms and character of every certificate is evident in order that the honour and reputation of the medical profession may not suffer, as it must should it appear that the trust imposed in us to certify accurately is misplaced. The attitude taken up by the General Medical Council towards these practitioners who have been brought before it on charges of this kind shows a determination to deal severely with what it rightly regards as a grave danger to the character of the medical profession. The warning notice issued by the Council in 1911 and printed in the SUPPLEMENT to the JOURNAL of December 9th, 1911, p. 607, stated that as the Council had had evidence before it that some registered medical practitioners had given and signed untrue, misleading, or improper certificates, it gave notice that any registered medical practitioner shown to have given any improper certificate, whether relating to the matters enumerated in the notice or otherwise, was liable to be adjudged to be guilty of infamous conduct in a professional respect, and to have his name removed from the *Medical Register*.

MEDICAL DISTINCTION AND LONGEVITY.

As insurance statistics show, the medical profession as a class stands low compared with other occupations in respect of longevity. The preparation is long and severe and has necessarily to be carried out to a considerable extent under conditions of a kind likely to impair health. Then there is the struggle to obtain a footing, often in the face of circumstances that tend to break the spirit and undermine the constitution of a person of no more than ordinary strength. Even when fairly established in practice, a doctor's position is usually more or less precarious; his livelihood depends on the maintenance of his health, and he is more exposed than most men to disease and accident. The stress of competition leads to premature wearing out of vital power. Then there are other risks incident to the doctor's profession: he may be done to death by slanderous tongues, as occurred in a painful case recently before the law courts; or his heart may be broken by the ingratitude of patients or the wiles of unscrupulous rivals. These remarks hold good for the average practitioner. But if statistics recently published in the *Montpellier Medical* are to be accepted, there would seem to be a direct relation between distinction in medicine and longevity. The writer, whose name is not given, says that in the course of extensive researches he was struck by the longevity of most members of the medical profession who had left a mark in the history of science from antiquity to the present day. This induced him to work out some statistics of which he gives the results. Of 1,732 practitioners who had achieved distinction and whose exact age at death he was able to discover, he found that 88, or about 5 per cent., died at the age of 25 to 35 years; 122, or about 7 per cent., died between 35 and 45; 270, or about 15.6 per cent., died between 45 and 55; 173, or about 10 per cent., died between the ages of 55 and 60; 199, or about 11.5 per cent., died between 60 and 65; 229, or about 13.2 per cent., died between 65 and 70; 426, or about 24.6 per cent., died between 70 and 80; 205, or about 11.9 per cent., died between 80 and 90; while 20, or about 1.18 per cent., reached the patriarchal age of 90 and upwards. Thus about 37 per cent., or more than one-third, lived the allotted span of threescore and ten. Taking the nineteenth century alone, the proportion of longevity was found to be somewhat higher. Of the total of 1,732 cases, 472 belonged from the period from 1820 to the present time. Analysing these the writer found that 15, or about 3.1 per cent., died between 35 and 45; 62, or about 13.1 per cent., died between 45 and 55; 50, or about 10.6 per cent., died between 55 and 60; 65, or about 13.7 per cent., died between 60 and 65; 75, or about 15.8 per cent., died between 65 and 70; 133, or about 28 per cent., died between 70 and 80; 67, or about 13.8 per cent., died between 80 and 90; 5, or about 10.5 per cent., lived to be over 90. Thus more than 42 per cent. went beyond the biblical limit. The longevity was pretty much the same in all nations. It would appear from this that the activity of the brain is in direct proportion to the physical vitality of the body. The writer holds that this relation between distinction in medicine and longevity is not to be explained by the fact of greater length of days giving the opportunity for a larger output of scientific discovery. He points out that, taking the majority of the men, their reputation was made between 40 and 60. One-third died before reaching middle age. On the other hand, it cannot, we think, be denied that in the case of physicians, as of judges and other brain workers, eminence is largely a matter of survival. To many who seem destined for fame there comes in their early springtime the blind fury with the abhorred shears and sits the thin-spun life. Capricious fate thus leaves the path to glory open to others. When it is remembered that Bichat died at the age of 31, one cannot help wondering what he would have achieved had his life been spared

for thirty or forty years more. One thinks, too, of Roger Cotes, the mathematician, who died in youth, and of whom Newton said: "Ah, if Cotes had lived, we should have known something!"

ANTISEPTICS AND DISINFECTANTS.

DR. DAVID SOMMERVILLE, in his course of Cantor Lectures at the Society of Arts on antiseptics and disinfectants, dealt with the problem from its scientific side. In his first lecture he traced the experience of mankind with antiseptics from the days of the Assyrian, the Greek, and the Roman down to the work upon antibodies and upon the pathogenic organisms and their environment, which has issued from the laboratories during the last five years. The beginnings of antiseptics might, in fact, be looked for beyond the limits of human history, and the instinct of the animal to lick its wounds afforded an illustration of the use of saliva, which, like the blood and other animal fluids, had a slightly germicidal action. There is evidence that the ancients used a picturesque assortment of substances, including honey, oils, resins, gums, and tar, for disinfecting purposes, and that the washing of a wound in wine was widely practised. Aseptic and antiseptic surgery, said Dr. Sommerville, had had a painfully slow evolution, but all great discoveries, even those of Pasteur and Lister, were due to the crystallization by a clear-sighted individual of what had been simmering for scores of years or for centuries before him. In his second lecture, Dr. Sommerville dealt in greater detail with the composition and mode of action of the chemical substances now used as antiseptics and disinfectants. Metallic salts, he said, were germicidal through the metallic ion, and were more powerful in watery solution than when dissolved in alcohol or ether, because ionization in the latter class of solvent was feeble. In a comprehensive exposition of the subject he demonstrated that antiseptics possessed a variable action according to the species of germ present; that germicidal activity increased with elevation of temperature; that bacteria could acclimatize themselves to antiseptics; that acids did not depend on their chemical energy for their disinfectant properties, but on the degree of ionization to which they could be subjected, and that reactions in heterogeneous systems were accompanied by changes other than the purely chemical. He dealt also with the concentration of bodies on the surfaces of contact between the phases of heterogeneous systems, and showed that adsorption formed an important factor in disinfection. He considered it justifiable to accept the view that in the process of disinfection one or more of these three types of activity might be engaged—namely, ionization with diffusion, adsorption, and purely chemical action—and that this last type of change was usually preceded by the first and second when the disinfectant was an electrolyte. He dealt also with colloidal solutions and emulsions, and discussed the factors which govern the stability of emulsions. In his third and concluding lecture he entered very fully into the theory of the disinfecting process. He suggested that it might be assisted by the meeting of suitable side-chains or affinities in the microbial and disinfectant body respectively. He discussed the hypothesis of internal disinfection by taking Ehrlich's dioxy-diamido-arseno-benzol (salvarsan) as an example. The records of the application of this body to the disinfection of the treponemes of syphilis, he urged, went to support the view that the sterilization of the tissues within the body was quite possible. Many cases of infection occurred in which the intensity of the toxus was so great that the organism was unable to prepare the necessary antibodies. Such cases rapidly became fatal, as was exemplified in young children who died of diphtheria. A previous use of intelligent disinfection might have so attenuated, if not destroyed, the virulent organism that the body would have been able to respond with the necessary production

of antibodies. Death from diphtheria could be avoided in certain cases by the early and judicious use of disinfectants in the throat. There was, he considered, ample experimental evidence that the upper portion of the alimentary tract could be sufficiently disinfected to relieve certain distressing fermentations of that region; that the skin could be disinfected in acne and certain eczemas, and the throat and nose in catarrhal conditions; but in all these cases it was important that the method should be controlled by proper bacteriological examination. To such disinfections the higher phenoloids lent themselves admirably. The lecturer then entered upon a careful description of the Rideal-Walker drop-test method, and the modified method of the *Lancet* Commission, and rebutted certain American criticisms with regard to the former. As a general conclusion, he said that internal disinfection or chemotherapy had a bright outlook. But with regard to the routine disinfection of clothing and dwellings, carried out as much of it was in a perfunctory manner and without bacteriological control, the outlook was not so bright. If properly handled by competent teachers, this subject of antiseptics would form an interesting and valuable chapter in general education, and in education rather than in governments lay the hope of the future.

THE SKULL OF DESCARTES.

THERE is in the Paris Museum of Natural History a skull, which, according to tradition, once enclosed the brain of Descartes. The Academy of Fine Arts recently invited Dr. Paul Richer, Professor of Anatomy in the Paris School of Fine Arts, and a member both of the Academy of Medicine and the Academy of Fine Arts, to compare by scientific methods, in collaboration with M. Gaston Darboux, the supposed skull of Descartes with the different portraits of the famous philosopher. Dr. Richer himself is a sculptor and engraver of great talent; he is therefore particularly well equipped for the task which he was asked to undertake. The plan adopted by him was first to indicate on a plaster cast given him by the Museum certain distinctive characters which are well marked on the head of the portrait painted by Franz Hals. It is evidently on these resemblances that Cuvier based the opinion that the skull is authentic, which he expressed in 1821. He next drew a skull, as closely adapted as possible, resembling that outlined in the portrait. Then he made a drawing of the Museum skull posed with the same orientation and on the same scale as the head of the portrait. Lastly, he superimposed the two drawings. The first of these procedures is more exact than might "at first thinking," to use a phrase of Swift's, be supposed. As a matter of fact, on every head can be seen a certain number of well-defined bony points; these are particularly apparent in the painting of the Dutch master. In his first drawing Dr. Richer marked certain points—at the root of the bones of the nose, on the external orbital apophyses, and on the nasal spine. These same points were repeated on the cast of the skull in the Museum. By means of these marks it was easy to place with almost mathematical precision the skull in the position which Hals had given his model. The superimposition of the two drawings showed an almost absolute agreement. On the other hand, other drawings made under the same conditions of several skulls taken at random, showed notable discrepancies. The same experiment was repeated with the other portraits of Descartes, namely, that by Sebastian Bourdon in the Louvre; that of Beck, of which there is a copy in the Library of the Institute, the terra cotta medallion of the Versailles Museum, and an old portrait by an unknown painter belonging to M. Rulle, of Courbevoie. The comparison of the skulls in these different portraits with that of the Museum shows some striking resemblances, but never so complete an agreement as was found with the Hals portrait. Before Dr. Richer began his investigation

much the same procedure was employed by Dr. Verneau, Professor of Anthropology at the Museum, who came to the same conclusion. An account of his examination was given in *Aesculape* for November, 1912. As a matter of history it is known that the skull was detached from the philosopher's body in 1666 by Israel Planstrom, Captain of the Queen of Sweden's Guards, and it was given to the French nation by Berzelius. Now that the relic has been satisfactorily identified, it is suggested that it should be placed in the coffin which contains the decapitated skeleton of the philosopher. This is in the Church of Saint Germain des Prés, where it lies in one of the chapels between the remains of Mabillon and those of Montfaucon. Another suggestion is that the skeleton and skull might be solemnly transferred to the Pantheon in accordance with a decree of the Convention of October 2nd, 1793, to which effect was never given. At a meeting of the Académie des Sciences on January 20th, Professor Edmond Perrier declared that the identification having been made conclusively, it was no longer right that this relic of the great thinker should be left amidst the collections of the gallery of anthropology and palaeontology in the Museum. He undertook to have a kind of reliquary constructed in one of the rooms of the Museum where there are already relics of other famous men. There the skull of Descartes will be deposited, together with the documents establishing its authenticity.

FLOURISHES OF ADVERTISEMENT.

SOME time ago Mr. Justice Eve in giving a judgement was reported to have said: "The introduction of this preparation and its advent into this country was heralded by a flourish of advertisement, not overloaded with, but still not altogether devoid of, that picturesque hyperbole and flamboyant mendacity which in general seem to be inseparable adjuncts to the exploitation of a nerve tonic, a hair restorer, or an aperient." The deliverance is interesting in itself and comes with special weight from the lips of a judge. We thank Mr. Justice Eve for teaching us that particularly happy and appropriate phrase "flamboyant mendacity." It exactly expresses the style in which the vendors of many nostrums push their wares on a confiding and gullible public. In default of "flamboyant mendacity" they could not find a market. American vendors are in general past masters in the art of "picturesque hyperbole." To what an extent they have invaded this country our readers do not require to be told. But they seem to spread their nets all over the British Empire. We have received a circular from Barma which shows how the professors of the art of picturesque hyperbole adapt their style to the supposed weaknesses of the people among whom they hope to find a market. The substance to be sold is described as "a well known remedy which supersedes all tonics"; it is said to preserve the health, to increase the brain power, to "stand as a Safe Guard against all weakening losses," to purify the blood, to "regain lost manhood," to "regulate and cure females' complaints of menses and consequences thereof." We are assured that sixteen days' trial guarantees new life, and that being a compound of the most powerful and reliable drugs, it never fails even in the worst cases. It immediately shows its good effects "in improving of health, strength, vigor, and potency, removing old weak and despondent condition and strengthening muscular, circulative, and nutritive systems like magic and thus makes a man again healthy to love his tired life." It is invaluable "in irregularities of periodical illness in females and other diseases of the womb peculiar to the female sex and causing sterility on women kind," and so forth. It will be noted that the hand of the Babu is visible throughout; but it is requested that correspondence should be addressed to an American commercial association. Probably the vendor, if really an American, thought a native would know best how to reach the mind and

pocket of the East. The appeal, as is usual in literature of this kind addressed to the Oriental, is mainly to those who wish, in the words of the scribe, "to keep everlasting youth, so as to undergo any amount of waste and exertion, even in old age." But the claims made are much wider than the restoration of lost manhood, and may deceive numbers of ignorant people who have a right to be protected from the lures of traders on human weakness. The real cure for such evils is, of course, the diffusion of a knowledge of the elementary laws of health. But in the meantime the authorities should do everything in their power to check the distribution of such circulars.

DOCTORS AND INTEMPERANCE.

THE twenty-ninth report of Dalrymple House, the first established Home for Inebriates, shows that of 1,064 cases admitted and discharged since 1883, ignoring those of no occupation, the medical profession has supplied the second largest number of inmates. The numbers drawn from the professions of divinity, law, and medicine have been 25, 43, and 79 respectively. This disparity may be accounted for by the fact that neither in the clerical nor legal profession is there the same temptation to tide over the want of missing meals, or to whip up the weary system, overtaxed by long hours and fagged by loss of sleep, with the handy, seductive spirit bottle. Sociability is given as the cause of inebriety in more than half the cases admitted to the home; and not even upon the clergy do the claims of social life fall more insistently than upon the doctor. To most of his patients the doctor is something more than medical attendant. The relationship implies sociability. In some places it implies a good deal of it. And if the social glass cement the desire to keep on good terms with patients as well as neighbours, it may lead to spirit drinking in the daytime, between or in place of meals. It is well to know our faults and failings, but that type of doctor, by some strange paradox, said to be "cleverer drunk than sober," is almost if not quite extinct, and it would be interesting to know the numbers of admissions to the home for each complete year. In view of the greater sobriety of doctors, one would expect that the medical profession was not providing so great a proportion of inebriates as it did a quarter of a century ago. Dr. Hogg, the medical superintendent, says there is much misconception as to the home, and inmates have told him that they would have come long before they did had they known what the place and the treatment were like; 42 per cent. of the patients have done well, and Dr. Hogg holds that, when supervision and treatment are possible, alcohol may be withdrawn suddenly and at once, without fear of bad results to the inebriate.

THE ALTON HOME.

ON May 31st the Lord Mayor and a numerous company of invited guests visited Lord Mayor Treloar's Home for the Treatment of Surgical Tuberculosis at Alton. The excellent work which is being carried on there has been more than once noticed in our columns, and in this issue the Medical Superintendent (Dr. Gauvain) gives an account of some of the methods of treatment followed there. After seeing the wards and other parts of the hospital the visitors inspected the college, or technical school for all kinds of crippled boys. In this institution the pupils have not necessarily been treated at Alton, but come from all sorts of hospitals and homes, and are crippled by all manner of diseases as well as tuberculosis. Here the problem of how to help those crippled children who are not too severely maimed to earn a living would seem to have been solved, for a great many of those who have been trained there are now earning good wages, and the college authorities could easily find good places for more boys than are available at present. The best paid trade taught there is that of leather bag and case making, and the visitors were able to see for themselves how well

the boys had been taught, and many of them showed their practical appreciation of the results by making purchases. The more severely affected lads learn tailoring and boot making, which trades, although not so well paid as the leather work, have this advantage, that they can be carried on in the patients' own homes, thus saving journeys to and from work. An adequate nurses' home is much needed, and an appeal is now being made for £10,000 for the building and equipment of such a home to be called after Queen Alexandra. Before leaving, the Lord Mayor watched a number of the boys going through a series of Indian club and dumb-bell exercises. Although some of them had lost a limb and all were more or less crippled, they performed with surprising smartness and vigour. The presentation of gold medals to two nurses who had distinguished themselves in examinations followed, and after brief speeches from the Lord Mayor, the Chairman of the London County Council, and others the visitors returned by special train to London, carrying with them very pleasant impressions of the value of the work done in the hospital and college. We cannot help adding, however, that it seems to us a mistake to claim, as was done in the printed particulars supplied to the visitors, that the proportion of successful cases "reaches a figure not approached by any similar institution in the world," for such comparisons must necessarily be misleading, seeing that different institutions have various classes of cases to deal with, and different standards of success.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

A good deal of public interest has been aroused by the announcement that cases of epidemic cerebro-spinal meningitis have occurred recently at Westerham in Kent. The facts are not so alarming as some of the early statements suggested. Two children in one family, aged 8 and 11, sickened on May 20th; by May 25th they both showed definite signs of epidemic cerebro-spinal meningitis, and a diplococcus was found by lumbar puncture. One child has since died. Three other cases in one family were under suspicion, as they had been in contact with the first two, who were neighbours; these three patients were seized with vomiting, attended by some rise in temperature. They were, however, clearly not instances of cerebro-spinal meningitis, though they were isolated as a matter of precaution. There are no other cases known in Kent. Five other cases of epidemic cerebro-spinal meningitis have been notified in various parts of the county during the last six months; but in no instance has there been any real epidemic, as only one case has occurred in each locality at one time.

THE ANNUAL MEETING, BRIGHTON.

IN connexion with the annual meeting of the British Medical Association, to be held this year at Brighton, the usual railway concessions will be granted to members attending. Return tickets, which will be available from July 17th to July 28th inclusive, will be issued at the rate of a single fare and a third on the presentation of a voucher, which will be supplied to members notifying, on the form to be issued shortly with the list of hotels and lodgings, their intention of being present at Brighton. A separate voucher is required for each passenger. During the meeting reduced fares will also be granted to places within a radius of fifty miles of Brighton, including London. Members who propose travelling to and from Brighton daily should use the first half of the ticket on the first journey to and the return half on the last journey from Brighton, the reduced fares for the intermediate journeys being granted on production at the time of booking of the card of membership.

MR. H. BETHAM ROBINSON, Surgeon to St. Thomas's Hospital, is a candidate at the approaching election to the Council of the Royal College of Surgeons of England.

WE regret to record the death, after a prolonged illness due to infective endocarditis, of Mr. J. H. Targett, obstetric surgeon to Guy's Hospital. We hope to publish a notice of his career in an early issue.

AT the meeting of the Royal Anthropological Institute, to be held at the Royal College of Surgeons of England, on Tuesday next, at 2.30 p.m., Sir H. H. Johnston, G.C.M.G., K.C.B., will give a lecture illustrated by the epidiascope on racial migrations in Africa.

A MEETING of the Section of Surgery of the Royal Society of Medicine will be held at Birmingham on Tuesday next. The members will witness operations at the General Hospital and Queen's Hospital in the morning, and there will be an exhibition of surgical cases at the General Hospital in the afternoon, followed by an ordinary meeting at which Mr. Lawford Knaggs (Leeds) will read a paper on retroperitoneal rupture of the duodenum, and Mr. Jonathan Hutchinson a note on the treatment of Dupuytren's contraction by an improved method. After the meeting the members of the section will be entertained at dinner by the surgical staffs of the Queen's and General Hospitals. This, we believe, will be the first occasion on which the section has met outside London.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Mental Deficiency Bills.—The adjourned debate on the Mental Deficiency Bill took place on Tuesday, June 3rd, and the same process of obstruction from a small body of members, mainly on the Government side of the House, was employed as on earlier occasions. After an hour had been occupied by a discussion and division under the ten minutes rule on a private member's bill conferring additional rating powers on local authorities introduced by Mr. Wedgwood, the debate was resumed by Mr. Montagu Barlow, who contended that the amount provided by the Government of £150,000 a year was quite inadequate, and stated that if the 70,000 defectives existing in the country were to be properly provided for, it would involve in his opinion an annual cost of over £2,000,000. The bill was heartily supported by Dr. Chapple, but Mr. Pringle made an appeal on various grounds that it should not be proceeded with. Mr. Crooks, Mr. McCurdy, and Mr. Harry Lawson spoke in support of the measure, and at 6 o'clock, on the motion of the Home Secretary, the Speaker granted the closure. This was carried by 273 to 96, and the second reading was subsequently carried by 368 to 11. Another division was then taken against the bill being sent to Committee upstairs, but this was carried by 358 to 15. After an hour had been occupied in these three divisions, and as the House was due to rise at seven o'clock on occasion of the King's Birthday celebrations, only half an hour remained for the discussion of the Mental Deficiency and Lunacy (Scotland) Bill. It was briefly introduced by Mr. McKimmon Wood and supported by Sir George Younger, but on the motion of Mr. James Hogge, the debate was adjourned. In accordance with the anticipations in our notes of last week, the prospect for these bills and other minor measures grows daily worse.

Board of Trade Sight Tests.—Mr. Peto asked the President of the Board of Trade whether his attention had been drawn to a memorial signed by thirty leading ophthalmologists, who were of opinion that the sight tests of the Board of Trade were not satisfactory; and, if so, whether he would now reconsider the whole question of these tests. — Mr. Robertson said that careful consideration would be given to these and any other criticisms, but, as at present advised, he did not think that they disclosed any sufficient ground for reopening the question of the tests.

Mr. Peto also asked whether, in respect to officers

holding certificates who had been requested by the Board of Trade voluntarily to surrender their certificates through failing to pass the Board of Trade tests in either colour or form vision, the Board of Trade contemplated taking further action; and, if so, in what way.—Mr. Robertson replied that if any of the officers referred to were unwilling to surrender their certificates the Board of Trade would have no alternative but to order in due course inquiries, under the provisions of Section 471 of the Merchant Shipping Act, 1894, into their competency to hold the certificates.

Ten Years Building.—Mr. Wedgwood asked the President of the Local Government Board what was the total number of dwelling houses of all kinds built between the years 1901 and 1911, how many houses out of this total were built by local government authorities, and what was the estimated number of persons for whom housing accommodation had thus been provided by local government authorities and by private persons respectively?—Mr. Burns said that the figures necessary to give an answer to the precise question were not available. It appeared from Table I of the recently published Volume VI of the Census, that the number of inhabited houses in England and Wales exclusive of London increased by 879,381 between 1901 and 1911. This figure, however, took no account of demolitions, etc., during the intercensal period. Loans were sanctioned by the Local Government Board during that period for the erection of about 4,000 houses under Part III of the Housing of the Working Classes Act, 1890, by extra-metropolitan authorities.

Town Planning Schemes.—In reply to Sir Arthur Griffith-Boscawen, Mr. Burns said that one town planning scheme had been finally approved (Birmingham, Quinton, etc.); that three were before the Board awaiting final approval (East Birmingham, Rochdale, and Ruislip-Northwood), and that fifty others were in process of approval, and that altogether 150 towns and cities were making town planning schemes.

Hop-pickers.—Mr. George Roberts inquired as to the number of local authorities administering areas where labour for hop-picking was employed which had adopted by-laws and called attention to the conditions existing in the county of Hereford.—In reply Mr. Burns said: In only five out of some thirty-four districts in which imported hop-pickers are employed have the local authority failed to make by-laws. Legislation would be necessary to make the adoption of by-laws compulsory, but all these authorities have been urged to make by-laws. The districts had for the last four or five years been inspected by officers of the board, and they reported that the accommodation for hop-pickers was improving. Further visits are to be made this year.

Enteric Fever Inoculation (India).—Mr. Chancellor asked the Under Secretary of State for India if he was aware that the officer commanding the 1st Battalion Northumberland Fusiliers, now stationed at Mhow, India, had relegated to Class 2 service pay, under paragraph 686 of the King's Regulations, as being ineligible for active service, six privates, solely on the ground of their refusal to be inoculated against enteric fever; whether inoculation against this disease was compulsory on objecting soldiers; and, if not, what steps he proposed to take to ensure them against arbitrary penalties for exercising their right to refuse compliance with such orders in future. Mr. Montagu replied that inoculation against enteric fever was not compulsory, but in view of the fact that it was highly desirable in the interests of the soldiers themselves to preserve them from dangerous illness, every effort was made to persuade and convince soldiers that they should be inoculated voluntarily. The allegation which the hon. member made was quite untrue, and if he would look at the regulation he quoted he would see that it was obviously impossible.

Vaccination (Cow-Pox Virus).—Mr. Snowden asked the President of the Local Government Board whether he was prepared to follow a precedent set up by his prede-

cessor (1902) by ordering all vaccine or virus now in stock to be destroyed, and take steps to enforce the use of cow-pox virus only, as contemplated by the Vaccination Acts, seeing that the vaccine which failed to protect the members of the crew of His Majesty's ship *Conqueror* was derived from a secret unidentified strain of virus obtained from Cologne, and that there appeared to be no means of ascertaining whether such original foreign virus was free from variolous taint, in accordance with the provisions of Section 8 of the Vaccination Act, 1867.—Mr. Burns said that in the case referred to as a precedent, the lymph destroyed was not lymph prepared or issued by the vaccine establishment of the Local Government Board. The lymph obtained from Cologne was a sample of the current lymph of the vaccine institute of that town. During the six years since it was received a large series of calves had been vaccinated with lymph derived from this source, and the lymph from them had been used for a very large number of successful vaccinations.

Vaccination (Exemptions).—In reply to Mr. Peto, Mr. Burns promised to supply a table showing the increase or decrease in the number of vaccinations in the case of parents and children in each year from 1900 to 1912, and the number of exemptions granted. The power and the duty of taking proceedings against defaulters were vested in the vaccination officer under the Vaccination Acts without any direction from the guardians, and he did not consider it necessary to issue a further circular on the subject.

Foot and Mouth Disease Eradication.—In reply to Mr. C. Bathurst, Mr. Runciman said that he was aware that there had recently been several reports of outbreaks of foot and mouth disease in Great Britain, all of which had happily proved on investigation to be false alarms. The disease had been completely eradicated from Great Britain six months ago, and had not since broken out.

Bee Disease Bill.—In reply to Captain Murray, the President of the Board of Agriculture said that he was well aware of the widespread demand amongst bee-keepers and gardeners for the passing of this bill into law, and he hoped the second reading would be secured in the near future. There was no evidence that the bill was in any sense a controversial measure.

General Medical Council.

NOTES.

Passes and Rejections at the Final Examinations.—In accordance with recent custom the Examination Committee presented an analysis of the annual returns of the final examinations held by the licensing bodies. Amongst those bodies which require that medicine, surgery, and midwifery shall be passed at one time, the largest percentage of rejections is found at the University of London, which heads the list with 54.8, Bristol coming next with 50 per cent., and Queen's University, Belfast, following with 41.8; St. Andrews comes lowest with 13.3 per cent. of rejections. It is difficult to institute a fair comparison between these figures and those of bodies which allow the subjects to be passed separately, but adding together the percentages of rejections in the three separate subjects and dividing by three, neglecting decimal places, the following result is arrived at: The National University of Ireland rejected 33 per cent., Cambridge 31, and Dublin 22; the University of Glasgow 23, Edinburgh 20, and Aberdeen 18; the Scottish Conjoint Board rejected 55, the English Conjoint Board 38, and the Irish Conjoint Board 36 per cent. The percentage of rejections at St. Andrews is remarkably low (13.3), considering that all of the subjects must be passed at one time, though it should be noted that the figures relate to only fifteen candidates.

Exemptions.—The Examination Committee presented a report, which had evidently been considered with much

care, and constituted a strong indictment against a particular body. The attention of the Council had been drawn at a previous session to the fact that exemptions were granted from the earlier professional examinations to candidates who had passed in these subjects at examinations held by bodies whose qualifications do not receive recognition on the British Register. The Committee obtained returns which showed that these exemptions were more numerous than had been supposed, but that many of them were of a kind to which no exception could reasonably be taken. Thus the English Conjoint Board had granted during five years 124 such exemptions, but of these no fewer than 56 were on the ground that similar examinations had been passed at the University of Toronto, and other Canadian examinations figured in the list. It is probable that very shortly the qualifications of these Canadian bodies will be fully recognized. There were other examinations recognized for exemption, the standard of which is above suspicion. Hence it was clearly not desirable to lay down a hard and fast rule that no examinations, other than those conducted by bodies whose qualifications admit to the British Register, should be accepted as equivalents. Many—indeed most—of the licensing bodies publish lists of examinations which they are prepared to accept as the equivalent of their own, but other bodies stand in a less satisfactory position. The Apothecaries' Hall of Dublin appears not to publish any such list, and the wording of its regulation on the subject seems to open the door to all and sundry. The explanation offered by their representative that this was due to a typographical error, and that it did not say what it meant, did not commend itself, inasmuch as this published regulation governed the practice of the Hall, and its practice had included the recognition of examinations open to much question. The importance of the matter was considered to be increased when it was found that the Apothecaries' Hall, Dublin, had granted exemptions in the cases of 59.4 per cent. of those who had obtained its qualification in the past five years—a proportion more than six times higher than that of any other licensing body. It was also recalled that the Council has already advised that the first, second, and third examinations of the Indian Subordinate Medical Service, which are accepted by the Hall, should, in the absence of evidence as to their sufficiency, be refused recognition.

The Apothecaries' Hall, Dublin.—Last November the Council referred to the Examination Committee a proposal to discontinue the reports upon the examinations of the Apothecaries' Hall, Dublin. The Committee at this session presented a lengthy review of the whole history of this body as recorded in the minutes, and followed this up by giving under the letters X, Y, and Z the complete history of the passes and rejections of three gentlemen who had recently obtained the licence of this body. It was stated that these were the only three licentiates in whose cases it had been found possible to ascertain the whole of the facts. As this report has been sent to the body for its comments, it may be better to refrain from any further comment further than to observe that *prima facie* there seems to be a good deal to answer with respect to these three cases. The Committee seems to believe that there is evidence that in some instances a candidate has obtained a qualification from the Apothecaries' Hall, Dublin, and has then, as a registered practitioner, gone up for the separate diplomas of the Colleges of Surgeons or of Physicians, a proceeding which has met with varying success. The reports of the assistant examiners in surgery appointed by the Council will in future be confined to their own section of the examination, and an inspector is to be appointed for the whole examination. Further, the Apothecaries' Hall has been requested to send in the returns required under Section XVIII of the Medical Act, 1858, in a form containing, *inter alia*, the places and dates of the examinations passed, including such particulars as to the preliminary examination. As information upon this last point had been refused by the Hall, the opinion of the legal advisers to the Council was sought, and their reply was to the effect that the Council was entitled to ask for it. The detailed information is sought because "it is obvious that the candidates who seek this diploma are almost, if not entirely, those who have commenced their series of professional examinations

elsewhere." When it is provided it will enable the Committee to trace in detail, as has been done in the cases X, Y, Z, the complete career of those who qualify. All the recommendations of the Committee were adopted by the Council.

Alleged Personation.—A curious case was brought before the notice of the Council by the Medical Defence Union in which it was alleged that a person, who appears to have made use of several aliases, had improperly and irregularly procured the entry of the name of Anthony Ciaramelli, M.D. Univ. Naples in the foreign list, had practised here in this name, and had obtained himself to be put on the London panel for six districts. Dr. Antonio Ciaramelli is a real person practising in New York, and it was proved that the person who registered here was not Dr. Antonio Ciaramelli, and Dr. Bateman, the Secretary of the Union, was thanked and complimented by the President upon the manner in which the case had been presented. The only issue before the Council was whether the name should remain upon the *Medical Register*, and the Registrar was instructed to remove it.

The Pharmacopoeia.—Satisfactory progress is reported in the preparation of a new edition of the *Pharmacopoeia*, though no mention was made of the date when it may be expected. The Belgian Government proposes a conference for the establishment of a bureau for pharmacopoeial unification, and a delegate will be sent by the Council.

The Finances of the Council.—Owing to short sessions and to economies effected in various directions, in respect of which the Senior Treasurer paid a tribute to the zeal and success of the Registrar, Mr. Norman King, the accounts showed a surplus for 1912 of £1,105; in the previous year there had been a deficit of £1,370. It was mentioned, in estimating the future financial prospects of the Council, that the number of students registered in the year had risen to 1,397, almost exactly the average number for the past five years; it may be remembered that in the previous year there had been a material falling off. The dental fund shows a similar satisfactory result.

The Election of Committees.—Three methods of election to the several committees are in force. The Executive Committee and the Penal Cases Committee are elected by a ballot of the whole Council, the number of members taken from each Branch Council being prescribed by the by-laws. Certain other committees are elected by nominations sent in by the several Branch Councils, which meet during the session for this purpose, whilst other committees again are elected by nominations made in open Council. All members of committees are eligible for re-election, so that there is no automatic change in their constitution, and a survey of the results shows that, in fact, very little change does take place under any of the methods of election. From the point of view of continuity of action this is, no doubt, advantageous, if not carried too far, and may be taken as indicating the satisfaction of the Council with the work of its committees.

Alberta.—The Minutes of the Executive Committee contain the text of an amending Act which has been passed and assented to in the Province of Alberta. It contains some remarkable provisions. The examinations of candidates for admission to practise medicine, surgery, midwifery, osteopathy or homoeopathy are to be under the control of the University of Alberta, and, except as to osteopaths and homoeopaths, the subjects are to be such as prescribed by the Senate of the University, etc. A person who has, with a licence recognized by the American Osteopathic Association, practised for four months in Alberta, shall be granted a certificate, otherwise he must—and this applies to homoeopaths also—pass an examination prescribed by the Senate. A person licensed to practise one class of practice incurs a fine if he trespasses upon any other class of practice. It is rather difficult to see how this proviso is to be made operative; but the whole Act seems to stand in need of revision.

Scotland.

(FROM OUR SPECIAL CORRESPONDENTS.)

POST OFFICE SANATORIUM SOCIETY.

THE fourth biennial conference of the Post Office Sanatorium Society was held in Edinburgh on May 31st. On the previous evening there was a smoking concert in the North British Station Hotel. Dr. Kenneth Douglas, medical officer to the General Post Office, Edinburgh, who presided, after welcoming the members, made special reference to the splendid work which had been done by Sir Robert Philip in the fight against tuberculosis. He regarded the creation of the Victoria Dispensary as the starting-point of the tuberculosis campaign. He thought the work of their own society had also been a great success; that done in their sanatorium was now being overshadowed by other work in the same direction under the Insurance Act, but the treatment given in it would compare favourably with that in any of the smaller institutions in the country.

At the conference, Mr. W. H. Davies (London) presided, and there was a large attendance of delegates. Sir Robert Philip gave an address, in which he stated that the society represented insurance against illness, and that illness the one that counted for most in human life. It also represented the principle of voluntary insurance against sickness; it made the benefit attractive, and so did away with compulsion, which, in such matters, seemed a doubtful policy. The society, too, had a statesmanlike outlook upon tuberculosis, recognizing that it differed from all other diseases; no two cases of tuberculosis were the same; and so the amount of treatment required for any one case was to be given, and it was not to be limited to three or four months; to limit it was a fallacious system, whilst to extend it to a year or longer, if medical opinion recommended it, was a wise policy. In their sanatorium at Benenden they had shown that tuberculosis could be treated practically anywhere within the United Kingdom, and, with satisfactory conditions, they could effect cures. The Chairman stated that the membership of the society, which in 1911 had been 47,400, was now 50,000. Mr. Durrant (the Secretary) reported that since the formation of the society in 1906, 447 cases had been treated, of whom 242 had been restored, 149 had generally improved, 46 had been discharged unimproved, and 10 had died during treatment. In a little over 87 per cent., therefore, the condition had been improved, and in more than half the patients the disease had been arrested. The admission of wives of members to the benefits of sanatorium treatment led to some discussion; the committee of management did not think it feasible, but by a small majority the conference remitted the matter back to the committee. Discussion also took place on several matters relating to treatment at Benenden, delegates who had themselves been patients there expressing their opinions. One of these matters was a resolution as to the performance of work, first light exercise and then heavy work, in order that the patients might become confident they were no longer invalids; and Dr. T. D. Lister, the consulting physician of the society, argued for obedience to medical directions on the part of the patients, otherwise the patient would be prescribing his own medicine. The resolution, which was to the effect that the working patients at Benenden Sanatorium be granted an additional half holiday each week for the purpose of taking walking exercise outside the grounds, was lost on being put to the vote. Another resolution (from Liverpool), that the time was now ripe when sanatorium accommodation situated in some place in the North of England or South of Scotland should be provided for the Post Office Sanatorium Society, and that the National Executive should make arrangements as soon as possible, was carried by 17 votes to 11.

RED CROSS DEMONSTRATION IN EDINBURGH.

The cup, which is presented by Lord Rosebery for knowledge in practical and theoretical first aid, home nursing, and cooking, was handed on May 29th to No. 4 Midlothian (Graham) detachment (which was represented by Dr. Stewart, Blackhall) by General Johnstone; this detachment had gained 324 marks out of a possible total of

350. The detachment which came next with 319 marks was No. 10 Edinburgh, and then followed No. 6 Edinburgh with 317 marks; eleven teams in all completed. Brigade-Surgeon Lieutenant-Colonel Arnott, M.D., said that in 1912 there were seven women's Red Cross detachments in Edinburgh with a total strength of 193, and since then there had been raised and registered two men's detachments, bringing up the strength to about 230 or 240. There were difficulties in raising the men's detachments, which would, he believed, be at once solved if the St. Andrew's Ambulance Association, after training men for ambulance work in the piping times of peace, would hand them over to the Red Cross organization for service in a national emergency, such as an invasion, for which alone the Territorial Forces and the Red Cross Society were engaged. He was glad to report that they had been promised several suitable buildings as auxiliary hospitals, among which was the School of Domestic Economy, Atholl Crescent. Colonel Woodhouse, President of the Judging Committee, was thanked for the great interest he had shown in Red Cross work in Edinburgh.

LOCAL GOVERNMENT BOARD FOR SCOTLAND.

Dr. Ernest Watt, M.D. Glas., D.P.H. Camb., has been appointed an additional medical examiner of the Local Government Board, in consequence of the increased work thrown upon the Board by the National Insurance Act. Miss Mary Jennie Menzies, M.B., Ch.B. Edin., D.P.H., R.C.P.S. Edin. and Glas., has been appointed lady medical inspector in place of Miss Elizabeth M. Vail (resigned).

LOCAL GOVERNMENT BOARD REPORT.

The eighteenth annual report of the Local Government Board for Scotland, dealing with the year ended December 31st last, has recently been issued. It is stated that during the year, notwithstanding the exceptionally prosperous condition of the country, there was an increase of pauperism. Parish councils, stimulated by the economy of the rates secured by old age pensions, had pursued a more generous policy, but the increase might only be a reflex of the coal strike in the early months of the year. The Board did not consider that there had been any laxity in the administration of Poor Law funds, and was, indeed, convinced that the large measure of public attention the Poor Law had received during recent years had had a marked effect in improving the quality of the work done by the relief authorities. The number of poor of all classes, including dependants, in receipt of relief on May 15th, 1912, was 107,498, of whom 91,137 were sane and 16,361 lunatic. On the corresponding date in 1911 the number was 106,251. The increase of 1,247 represented a ratio per 1,000 of population of 23 in 1912, as against 22 in the previous year. The increase in the number of children separated from their parents was general all over the large town parishes, and was, no doubt, mainly due to the enforcement of the provisions of the Children Act of 1908. The ordinary receipts of the various parish councils amounted to £1,593,779. Of this sum, the expenditure on poor relief was £1,545,720 in the following proportions: Sane poor, outdoor, 37.75 per cent.; indoor sane poor, 24.37 per cent.; lunatic poor, 28.02 per cent.; and general administration, 9.86 per cent. Excluding general administrative charges—which cannot well be allocated—the cost per head of poor, including vagrants, worked out, on the basis of the number chargeable at May 15th, at: Sane poor, outdoor, £7 10s. 8d. a head; indoor sane poor, £27 10s. 10½d.; and lunatic poor, wherever situated, £26 9s. 4½d. The general administrative charges amounted to £1 8s. 4½d. a head of poor of all classes. The Board had sanctioned plans for a home which the Edinburgh Parish Council is erecting for the accommodation of young children, and for a home the Glasgow Parish Council is erecting for physically defective young persons over school age who are likely to be permanently chargeable to the parish. The report states that there is ample evidence of the ever-increasing interest taken by local authority and the public generally in the Housing Acts. So far as Scotland is concerned the Act consists mainly of two parts—(1) the housing of the working classes, and (2) town planning. The one may be said to deal with slums already created; the other empowers local authorities to deal with the prevention of slums. Particulars are given of action taken or proposed to be

taken at Rosyth, Dundee, and Edinburgh. The Board is giving particular attention to the subject of water supplies throughout the country, and the report discusses also the question of the treatment of insured persons suffering from tuberculosis, and the notification of pulmonary tuberculosis and administrative control.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

TESTIMONIAL TO DR. PHILIP G. LEE, CORK.

ON May 24th a largely attended meeting of the medical profession was held at the rooms of the Cork Medical and Surgical Society, when Dr. Lee was presented with a handsome bookcase, a solid silver tray, and a purse of sovereigns, subscribed for by the medical profession of the city of Cork, by the members of the Munster Branch of the British Medical Association, and by those of the Irish Medical Association residing in County Cork.

The presentation was made by Dr. Cotter, chairman of the medical profession in Cork, who said he had great pleasure in having been chosen as the medium to make this presentation on behalf of his colleagues. He spoke of the very many skirmishes Dr. Lee had been through during the past twenty years, fighting for the profession in the battle of clubs, and how he had always emerged with credit and upheld the dignity of the profession. Having referred to the great debt of gratitude owing to him, Dr. Cotter concluded by hoping that Dr. Lee would long continue to act as their able honorary secretary.

Dr. Lee, in returning thanks, said that everything he had done was with the one and only object of keeping his profession to the standard, or even a higher standard, that was set for it by their forefathers. He had therefore worked hard in the battle of the clubs in Cork, where work had been done that was not done elsewhere. The position of honorary secretary to the profession was one congenial to him, but their tribute to his endeavours was indeed too great. He concluded by saying that he would continue to work heartily in the future, and that this testimonial was regarded by him as the greatest honour he had ever received. It would be treasured by him, and by those whom he should leave behind.

On the tray was inscribed:

Presented to Dr. Philip G. Lee by the medical profession in Munster as a token of their appreciation of his invaluable services as honorary secretary for over twenty years. May, 1913.

LUNACY AND POPULATION.

During the Chief Secretary's recent visit to Ireland a deputation waited on him in connexion with a proposal to convert the Castlebar Prison into a department of the lunatic asylum. It was pointed out that since 1866 the population of the Castlebar Asylum had been slowly but surely increasing, and while the insane population was growing larger the ordinary population was steadily decreasing. In forty years the population of Mayo had fallen from 236,150 to 190,205, and at the same time the pauper lunatics in Castlebar Asylum had increased from 200 to over 800. Since 1890 the county had borrowed £55,052 to provide additions to the asylum, but despite this there were in the asylum 160 patients in excess of the accommodation the institution was intended to provide. The Asylum Committee and the county council were reluctant to incur any further liability in making additions, and it was suggested that the most businesslike way of dealing with the matter would be to ask the Irish Government to close the Castlebar Prison, which adjoined the asylum, and to make arrangements for its conversion into a department of the asylum. The Chief Secretary promised to give the matter his careful consideration.

TYPHUS FEVER.

At the last meeting of the Castlereagh Board of Guardians the medical officer of the workhouse reported that a family from Ballaghaderreen had been admitted to the workhouse hospital suffering from typhus fever. The family consists of twelve persons; the house of this family has been disinfected and closed.

MEDICAL OFFICERSHIP OF ACHILL.

At the last meeting of the Westport Board of Guardians a letter was read from Dr. T. H. Croly resigning his position as medical officer for Achill No. 1 Dispensary District owing to ill health after thirty-six years' service. The resignation was accepted with regret, and it was decided to advertise the appointment, and to consider Dr. Croly's superannuation allowance five weeks hence.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

NEWCASTLE-UPON-TYNE.

ROYAL VICTORIA INFIRMARY.

Presentation of Addresses to Professors Drummond and Sir Thomas Oliver.

At a crowded quarterly court of governors of the Royal Victoria Infirmary, held on May 29th, illuminated addresses were presented to Professors Drummond and Sir Thomas Oliver on the occasion of their retirement from the active staff—the former after thirty-four years' service and the latter after thirty-three. In the absence of the Chairman of the House Committee, Sir George Hare Philipson, who was attending the meetings of the General Medical Council in London, Sir Riley Lord presided. Addressing Dr. Drummond, the Chairman said that only once previously had his period of service as a physician been exceeded, and that was by the late Dr. Thomas Emerson Headlam, who had been connected with the infirmary for thirty-eight years. Dr. Drummond's association with the infirmary had been distinguished by faithful attention to duty and a careful observance of official responsibility. By distinctive ability and diagnostic acumen he had attained to a position of eminence in his profession and had maintained the traditions of the infirmary. In acknowledging the gift, Professor Drummond said that it was with mingled feelings he accepted the handsome expression of their kindness, for to the pleasure and gratitude was added the feeling of regret that the time had come when under statute he must relinquish his connexion with the active staff. For the moment the latter feeling outweighed the former. He had loved his work in the wards and he had appreciated the honour and privilege of having been connected with the office to which they had appointed him nearly thirty-five years ago.

The address to Professor Sir Thomas Oliver was framed in similarly eulogistic terms. It paid a tribute to his reputation as a scientific physician and to the investigations he had made as to the effects of industry on health, thus proving himself to be a benefactor to the industrial community. Sir Thomas Oliver thanked the chairman and governors for their kind appreciation of his services, and said that he thought the time had arrived when, for those who were to follow him in the infirmary, some alteration should be made in the retiring age limit or means taken to make the retirement more gradual by giving the physicians and surgeons five to ten beds, as was the practice in other large hospitals. It would be a distinct advantage to the institution itself, a gain to the teaching capabilities of the school, and not a disadvantage all round from a financial point of view. Sir Thomas spoke of the advances made by medicine and surgery during the last thirty-four years and of the changes which had come over the infirmary during that period. Of those who became his colleagues on his appointment only Sir George Hare Philipson, Dr. Hume, and Professor Drummond remained. He had appreciated much the honour which had been his of having been a member of a medical and surgical staff which had kept itself well abreast of the times, had been a good follower, and in not a few instances had led the way. It was to him a deep regret that the tie which had bound him to the infirmary for a third of a century must now be broken. He closed his speech with the consolatory remark that it was better to have been connected with that great infirmary and to bear the pang of separation from it, to have been privileged within that building to do something for the amelioration of the sufferings of one's

few men, even to have failed to attain to the ideal which, in the early part of his career as a young physician, he had set before him than not to have been connected with the infirmary at all and never to have attempted to reach the goal.

Both retiring physicians become consulting physicians to the infirmary. In this capacity—which gives them a seat on the monthly committee—it is hoped that they will still be able to exercise an influence on the affairs of the institution.

Pathological Chemist to the Infirmary.

Professor Bedson of the Armstrong College, on his retirement from the position of pathological chemist to the infirmary, was made an honorary life governor of the institution. It is desirable that services such as his should be recognized by his being made in addition consulting pathological chemist.

TYNEMOUTH INFIRMARY.

At the Tynemouth Victoria Jubilee Infirmary, North Shields, on May 31st, a large and representative gathering assembled, when the Mayor of Tynemouth handed over to the infirmary, on behalf of the town and as a memorial to the late King Edward, a new operating theatre, fully equipped, built in the newest style, and on the most approved methods. The mayor paid a well-deserved compliment to the honorary medical and surgical staff. Sir Thomas Oliver, who was present as the invited guest and who, it appeared, had been associated with the Tynemouth Infirmary movement at its inception thirty years ago, gave an address, for which he was thanked by Dr. L. Fraser, one of the senior members of the staff, and also by the vice-chairman of the institution.

BIRMINGHAM.

MEMORIAL TO THE LATE PROFESSOR JORDAN LLOYD.

In response to a very general desire that something should be done to perpetuate the memory of the late Professor Jordan Lloyd, who was a Joint Professor of Surgery in the University of Birmingham, and who was for thirty years honorary surgeon to the Queen's Hospital, a fund has been opened by the committee of the hospital, who are appealing for a substantial sum towards the endowment of a surgical ward in the Queen's Hospital. The ward will be called the "Jordan Lloyd Ward," and it is proposed to place either a bust or a portrait of Professor Jordan Lloyd in the ward. The first list of contributions which is printed in the appeal that has been issued amounts to about £1,400. An appeal signed by Dr. Douglas Stanley, its chairman, is made by the Medical Committee to members of the medical profession in Birmingham and the Midlands, and to those who worked with Mr. Jordan Lloyd and feel that they owe much to him as a teacher. Contributions should be sent to the treasurer of the Queen's Hospital, Mr. H. F. Keep, and the secretary will be pleased to forward a copy of the appeal on application.

SANATORIUM EXTENSION FOR CONSUMPTION.

The new scheme for the extension of the sanatorium accommodation for consumptives is to be presented to the Local Government Board as a whole. It is proposed to add to the Salterley Grange Sanatorium ebâlets for twenty patients, at an estimated cost of £1,703. At West Heath Hospital 22 additional beds are proposed, at a cost of £842. The extension of Yardley Road Sanatorium will provide for 142 additional beds, at an estimated cost of £28,512. When the extensions are completed the total accommodation will be 319 beds, of which 54 are for children, leaving 265 for adults. There are 90 beds reserved at Romsley, so that the total will be 355 for adults and 54 for children. It is difficult to state accurately the number of tuberculous persons in the city of Birmingham, but the Health Committee believe they exceed 10,000.

A definite undertaking has been received that a sum of £90 a bed, or three-fifths of the cost, whichever is least, will be contributed by the Local Government Board towards the capital cost. When the scheme is regarded as a whole it appears that £90 a bed is less than three-fifths of the total cost, for calculated on that basis the total grant will amount to £16,560, which leaves a sum of £14,497 to be found by the corporation.

The cost of maintenance can only be approximately estimated. Assuming that 95 per cent. of the beds are continuously occupied and the weekly cost of each bed for adults averages £1 7s. 6d. and for children £1, the total annual cost, including interest and sinking fund, will be about £26,700. The cost of the tuberculosis centre in Broad Street, including salaries of medical staff, tuberculosis visitors, etc., is estimated at about £5,000, so that the total expenditure of the corporation, when the scheme is in full working order, will be about £31,700 a year. The Local Insurance Committee will contribute at least £10,000 towards this annual expenditure. Representations as to the heavy burdens likely to be cast upon the corporation were made by various public bodies to the Local Government Board and to the Chancellor of the Exchequer, and in December last a circular-letter was issued by the Board announcing the decision that, in respect of schemes which included the treatment of insured persons and persons who were not insured, the Exchequer would pay half the cost of treatment after the receipts from the Local Insurance Committees had been taken into account. The position is therefore as follows:

| | |
|---|---------|
| Cost of sanatorium treatment ... | £26,700 |
| Cost of dispensary treatment, including cost of tuberculosis visitors ... | 5,000 |
| Total cost ... | 31,700 |
| Less payment from Local Insurance Committee ... | 10,000 |
| Contributions from Government ... | 10,850 |
| 20,850 | |
| Cost to be borne by Corporation ... | £10,850 |

During the financial year 1911-12, before the Insurance Act came into operation, the expenditure on tuberculosis amounted to £9,635, and this expenditure maintained only 90 beds. When, however, the new scheme is in operation, there will be 409 beds, and the dispensary work will be much increased, but the annual cost to the corporation will not be much more than formerly. For the present year, when only a portion of the proposed additional accommodation in the Corporation sanatoriums and at Romsley Hill will be ready for use, it is estimated that the total cost of maintenance will amount to £21,831. There will be about £10,000 to come from the Insurance Committee and £5,915 from the Government, so that for this year the corporation will be expending considerably less than in the previous year and will be treating a much larger of patients.

MANCHESTER AND DISTRICT.

THE MANCHESTER SCHEME FOR TREATMENT OF TUBERCULOSIS.

AFTER numerous changes and modifications, the scheme developed by the Sanitary Committee of the Manchester Corporation for dealing with cases of tuberculosis has been approved by the Insurance Commissioners, the Local Government Board, and the Treasury, as well as by the Manchester Insurance Committee. It has now received also the full approval of the Finance Committee of the Corporation. Dealing with the financial side of the question the Finance Committee shows that the total annual expenditure will be £41,612. Towards this the Insurance Committee will contribute £9,175. Of the remainder the Treasury will contribute one half, and, after deducting charges for treatment, the total additional charge on the rates will be £9,987, which is equivalent to a rate of 0.557d. in the £, that is just over a halfpenny rate. The Finance Committee points out that as a set-off against this there is a saving of about £7,000 in connexion with the transfer of fever patients from Baguley to Monsall. Certain other charges will, however, be increased, so that the net increase in the expenditure of the corporation will be £5,596, part of which is due to the increased expenditure in connexion with the notification of tuberculosis. The scheme provides for the following:

1. The use of the existing Hardman Street Dispensary of the Manchester Consumption Hospital.
2. The purchase of land in Hardman Street from the Board of the Consumption Hospital for the erection of new offices.
3. The enlargement and furnishing of the Baguley Hospital as a sanatorium, in which a new block with 100 beds will be provided for men, and a block with 50 beds for women.

4. The provision of new wards at Mousall Hospital for cases of fever hitherto treated at Baguley.

5. Purchase from the South Manchester Board of Guardians of the Abergely sanatorium.

The total capital outlay is £78,645, from which the Treasury grant of £22,500 is to be deducted, leaving a balance of £56,145, and the Sanitary Committee recommends that the Local Government Board be asked to sanction the borrowing of this amount.

Dr. Niven, the medical officer of health, has submitted a report on the scheme, the essential features of which he says are the establishment of a central dispensary and a linked system of treatment partly by private practitioners, partly at the dispensary, and partly at the Baguley, Crossley, and Abergely Sanatoriums. At the Hardman Street Dispensary it was originally intended to utilize the services of the five physicians each at a salary of £250 a year, but as one of them has retired, his place will be taken by a whole-time tuberculosis officer at the same salary. Besides attending to the patients at the dispensary, these five officers will act as consultants to private practitioners, and will visit Crossley Sanatorium once a month, and the Baguley Sanatorium as may be necessary. Eight nurses are also provided to visit the homes of patients. In addition to the whole-time officer replacing one of the physicians of the Hardman Street Dispensary, there are a senior whole-time tuberculosis officer at a salary of £500 and three juniors at salaries of £300. Thus the whole staff is composed of five whole-time officers, four part-time physicians, and in addition there are to be eight nurses, two clerks for the medical department, a secretary, a dispenser, a dentist, a general clerk, and two nurses at the dispensary. The services of an x-ray expert will be obtained as required. It is provided that fifty-four hours of treatment shall be given at the dispensary each week, and in this way it is expected that 378 cases will be seen in a week, and that, as on the average each case will be seen only fortnightly, 756 cases will be kept under treatment. In addition, the whole-time officers will give eight attendances a week of three hours each, which means that they can attend to 336 cases. Thus provision is made for continuous treatment at the dispensary of about 1,100 patients.

The Finance Committee having examined the scheme fully, now recommends the City Council to adopt it at its next meeting.

LONDON.

LONDON COUNTY COUNCIL.

Inquiry into Atmospheric Pollution.

THE General Purposes Committee on June 3rd recommended the London County Council to set aside £100 for an inquiry as to suspended impurities in the atmosphere in London. The report reminded the Council that the Committee for the Investigation of Atmospheric Pollution appointed at the International Exhibition and Conference held in London in 1912 directed attention to the lack of co-ordinated effort in estimating the distribution of suspended matter in the air, and the absence of reliable data indicating the effect of smoke prevention in atmospheric purification and diminishing the frequency of fogs. Among the municipalities which had agreed to set up apparatus and take observations were those of Birmingham, Glasgow, Hull, Leeds, Newcastle-on-Tyne, Plymouth, and York, and the General Purposes Committee was therefore of opinion that the co-operation of the Council should be afforded. The estimated cost of each instrument and the analysis of deposit was £21 for the first twelve months and a subsequent annual expenditure of about £12 for each instrument. Six instruments would prove adequate, at any rate in the early stages of the inquiry.

The estimate of £100 was approved.

The Milk and Dairies Bill, 1913.

It was urged in a report submitted by the Public Health Committee that the Milk and Dairies Bill, 1913, introduced into the House of Commons by the President of the Local Government Board involved the loss or entailment of many powers for dealing with infected milk already possessed by the London County Council. In particular the Committee objected that the power of taking samples of milk and of examining cows outside London was entirely lost under the bill. The necessity for the thorough and systematic inspection of the sources of

London's milk supply was shown by the fact that since July 1st, 1908, no fewer than 2,187 visits had been made by the Council's inspectors to farms outside London, 59,616 cows had been inspected, and the supply to London from 642 cows suffering from tuberculosis of the udder had been stopped. The inspectors now had special knowledge, and a register of the sources of supply had been compiled which was of great assistance in carrying out this protective work. Instead of this efficient machinery entirely under the Council's control, it was proposed that the protection of the milk supply of London should be distributed amongst various authorities throughout the country, which had no direct interest in the matter. It was a mistake, also, in the opinion of the Committee, to delegate to the twenty-nine borough councils such powers as remained to London in this connexion. A register such as that on which the efficient administration of the work largely depended could not be compiled and maintained by twenty-nine authorities without overlapping of effort. The Local Government Committee stated that the allocation of powers proposed by the bill, coupled with the repeal or curtailment of some of the Council's existing powers, would seriously affect the position of the Council as the central public health authority for London. These provisions appeared to be inconsistent with the declared wish of the Local Government Board that the Council should act as the central authority for London in the matter of the treatment of tuberculosis, and would render more difficult the preparation and organization of a comprehensive scheme to deal with that matter. The committee considered that the bill should provide for a clear division of duties between the Council and the sanitary authorities in London so as to avoid overlapping, duplication of administrative machinery, and unnecessary expense to local authorities.

The Council postponed consideration of the report.

THE NATIONAL HEALTH SOCIETY.

THE annual meeting of the National Health Society, at which the Duke of Devonshire presided, was held at Grosvenor House last week, when Princess Christian of Schleswig-Holstein presented the diplomas, medals, and certificates of the society to the successful candidates. A vote of thanks to the Princess was proposed by Sir James Crichton-Browne, who said that at the Hygienic Congress held in Paris ten days ago, M. Ribot, who was no mean authority on the subject, took a very alarming view of French vital statistics. The country was sick, he said, and the French race was withering away, for the consumption of alcohol and the neglect of hygiene were decimating the population. Happily the state of this country was not quite so bad, for the English death-rate was only 14 per 1,000 instead of 18 or 19 per 1,000, as in France. But the death-rate afforded no sure criterion of a nation's health. In the elementary schools only 25 per cent. of the children had sound teeth, 30 per cent. suffered from some defect of the eyes, and 4 per cent. from rickets; whilst no fewer than 80 per cent. were infected with tuberculosis. Moreover, there were 50,000 children in England who were mentally defective, and the number of lunatics was steadily increasing. To these grave symptoms must be added another—the comparative lack of intellectual vigour and the impairment of public spirit owing to the absorption of Englishmen in their own personal affairs, particularly in money-making and motoring, to the neglect of their vital interests, such as national defence. The medical inspection of school children was doing much to counteract the evil, but to have any lasting effects the work should begin at home. It was into the home that the National Health Society was carrying the lessons of hygiene, and it was thereby doing an inestimable service to the country. The motion was seconded by Sir E. Ray Lankester and carried unanimously.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

THE KING EDWARD VII MEMORIAL SANATORIUM AT LOTNI.

THE memorial to the late King Edward VII raised by the people of the United Provinces took the form of a sanatorium which was erected at Lotni at an altitude of

6,000 ft. on a site presented by His Highness the Nawab of Rampur. It commenced work in 1912, and the arrangements made permit of the reception of both paying and non-paying patients, natives and Europeans, male and female, and the building when quite complete will provide accommodation for 50 patients. Its superintendent, Major A. W. Cochrane, I.M.S., reports that the first patient arrived for treatment on May 17th, 1912, and that before the close of the year 54 patients had been admitted and 17 remained under treatment at the end of the year. The treatment usually consisted in generous diet, regulated exercise, and tuberculin injections. Nearly two-thirds of those admitted were already in the third stage of the disease (Turban), and so very good results could not be expected. Excluding 6 who stayed less than a month, they were as follows: 1 died, 6 left not improved, 5 improved, 7 much improved, and in 11 the disease was regarded as being arrested. Better results would probably have been obtained if patients had remained longer under treatment, but Orientals are impatient. Though the climate is damp and chilly the patients did not suffer from colds. The institute is supported by the memorial fund and a grant of Rs. 12,000 a year by the local government. Rs. 2,713 were received from paying patients.

ADVANCED SCIENCE IN THE PUNJAB.

The foundation of an advanced science research institute is suggested to commemorate Sir Louis Dane's governorship in the Punjab. It is proposed that the Punjab contribution of over five lakhs to the All-India Moslem University Fund should be reclaimed and devoted to this institute.

OFFICERS' FAMILIES' HOSPITAL FUND.

At a meeting of the committee of Lady Grover's Fund for officers' families' hospitals in Simla on May 2nd the annual report for the past year was considered. During the first year of the fund's existence 416 officers joined it and 6 ladies obtained the benefits the fund is intended to provide. The fund secures admission to a nursing home in London on payment of £2 10s. a week, the difference between that sum and the amount actually charged by the home being paid by the fund. The committee has now decided to extend the benefits of the scheme, as far as funds permit. It has been represented that ladies may not always find it convenient to go to London for treatment, and are thereby debarred, under existing rules, from obtaining any advantage from the fund. To meet such cases, and as a tentative measure, it has been decided to contribute a sum not exceeding £2 10s. a week to the expenses of those ladies who go into nursing homes in the British Isles outside London. Application for this assistance should be made to the Honorary Secretary of the London Committee, whose address is 21, Neville Street, Onslow Gardens, London, S.W., and must in every case be supported by a copy of the bill. The decision of the London Committee as to the amount of assistance given, being dependent on the funds available, will be final. Another innovation is the adoption of the system of regimental subscriptions at reduced rates. It has been decided that a regiment may subscribe for the wives of its officers at the rate of Rs.20 for three ladies, Rs.40 for six, and so on. Each subscriber under this rule will secure for his family the benefits of the fund for a calendar year from the date of subscription, whether he remains with his regiment or is transferred to any other form of employment. The fund was always open to regimental chaplains of the Church of Scotland serving with units in India, and has now been extended to all chaplains of the ecclesiastical establishments shown in the Indian Army List and to officers of the Royal Indian Marine.

PILGRIM SANITATION.

The Government of India has seriously taken up the question of the sanitation of pilgrims. Colonel Robertson, I.M.S., Sanitary Commissioner with the Government of India, accompanied by a small committee, has completed a tour of places of pilgrimage in the United Provinces and Bihar and Orissa. He will visit similar places in Bombay in July, and from the Western Presidency he will proceed to Madras. In all the provinces he will be associated with special provincial committees. On completion of his visits to the various parts of India he will submit a report to Government.

Special Correspondence.

PARIS.

Treatment of Sleeping Sickness.—Facial Hyperaemia.—Ether Cleansing of the Peritoneum.

DRS. TANON AND DUPONT have given a brief sketch of their work, experimental and clinical, in the treatment of sleeping sickness, to the Medical Society of the Hospitals. They employed the new arsenical compounds of Mounicyrat, 1116 and 1151. The trypanosomes disappeared from the human blood in three hours after a dose of 0.001 gram per kilo body weight; in other words, a man weighing 65 kilos (143 lb.) would require 0.065 gram as a dose. After four doses the cure appeared to be complete in cases in which the nervous centres had not already been attacked. In experiments on mice, monkeys, rats, and kids complete destruction of the organisms was observed in all the phases, not only in the blood, but also in the lymphatic glands.

To the same society Drs. Jacob and Debat made a communication regarding the treatment of facial erythrosis by gymnastic exercises of the facial and cervical muscles. They found the method most useful in subacute and chronic skin diseases of the face and scalp and of value in the treatment of flushing of the face, whether physical, post-prandial, or from other nervous cause. The muscles controlling the movements of the scalp, forehead, ears, alae nasi, and the face in general should be made to contract regularly and rhythmically for five minutes several times daily.

At a recent meeting of the Surgical Society a communication was made by M. Tesmain regarding the favourable results obtained by cleansing the abdominal cavity in peritonitis with ether. M. Anvey reported a case of hernia with localized peritonitis in which he had cleaned the abdominal cavity with one litre of ether. The patient made an excellent recovery, and no signs of peritonitis occurred. M. Souligoux confirmed the excellent results obtained with ether in the cleansing of the abdomen in peritonitis.

Correspondence.

ACUTE MENTAL HOSPITALS AND PSYCHIATRIC CLINICS.

SIR,—In your leading article on psychiatry and the general hospitals, published in the JOURNAL for May 17th, you convey an impression in regard to the present mode of dealing with the insane in this country which, I think, so far as the modern asylums are concerned, is erroneous, and ought not to pass unchallenged. In several of the modern asylums in England we have hospitals for the treatment of acute insanity. Seventeen years ago I read a paper on the hospital treatment of the insane before the Psychiatric Section of the Association at the annual meeting at Carlisle, in which I advocated the institution of acute hospitals, in conjunction with the existing asylums, for the treatment of the insane, and I suggested the desirability of separating the acute recoverable cases in order to overcome "the indiscriminate herding together or massing of mad folks in huge barracks" which, I agree with you, "does not place them in a condition favourable to recovery." Fifteen years ago, on being appointed superintendent of the new asylum at Bexley, I was enabled to put my suggestions into operation; and we have at this asylum two acute hospitals, one for each sex, which are conducted on hospital lines, and in which the cases of acute insanity receive that individual study, care, and treatment which it is impossible to give in the large wards of a barrack asylum.

The staff in these hospitals is large, the proportion of nurses to patients being double that in the wards in the main building, and the patients receive the services of the most experienced of the medical staff. The hospitals are fully equipped, so that all the modern methods of treatment can be carried out. The bulk of the recoverable cases are treated to convalescence in these hospitals, and are discharged from the institution, never having been

associated with the general body of the patients except at the entertainments. Each acute hospital stands in its own grounds, surrounded by gardens with extensive lawns, with no restraining fences of any kind, so that that prison element of ordinary asylum life is entirely absent.

I should like to say in addition that we have a well-equipped laboratory for both clinical and original research.

The success attending these methods in this institution led to the provision of acute hospitals in the asylums of London, which have been since built at Horton and Long Grove, and the new asylum which is being projected, the plans of which are in an advanced state of preparation, will also be similarly provided. The principle has also been carried out in many of the new asylums which have been erected by other counties and boroughs in recent years.

I am absolutely in agreement with that portion of your article which advocates the formation of psychiatric clinics in this country on the lines of those at Munich, Leipzig, Berlin, Giessen, and the Johns Hopkins Hospital at Baltimore; but I am doubtful of their success in rate-supported institutions and with our present lunacy laws. Not all counties and boroughs could run psychiatric clinics in conjunction with their asylums, but it would be an easy matter for them to provide acute hospitals.

It is a great pity that these existing institutions, furnished with such abundant facilities for psychiatric study, should be situated so far from the teaching centres, which naturally militates against their working in direct co-operation with the medical schools; and by the same reason the institutions are deprived of the advantage and the stimulus which would result from closer association with the other specialized branches of medicine.—I am, etc.,

London County Asylum,
Beckley, Kent, May 28th.

T. E. KNOWLES STANSFIELD.

EVIDENCE FOR AND AGAINST TUBERCULIN.

SIR,—As a matter of courtesy I should like to reply to the questions put to me by Dr. J. W. Allan (May 24th, p. 1140), though I still think that the reasons why one series of cases cannot be employed as a control and left entirely to Nature are obvious. The function of a physician is to heal or, at all events, to endeavour to do so to the best of his ability. It is in order to be assisted as individuals that patients come to us, and I think we are not entitled, without our patient's consent, to abrogate our function of healing or potential healing even for such a desirable object as Dr. Allan has in view—the attainment of more precise knowledge as to the value of our therapeutic weapons. If the position were put clearly before the patient and his friends, and he consented to be used in this way for the benefit of the race, well and good. But would he consent? I suggest that in such circumstances the material for a control series would be lacking.

With regard to the real good which, I think, results in some cases from appropriate doses of tuberculin, I quite admit that my favourable impressions have been based mainly upon increased energy and capacity for work where work had previously been out of the question, on returning relish for food where appetite had been indifferent or bad, on a feeling of well-being and brightness where malaise and a certain degree of mental depression had been the rule, on stationary or increasing weight where weight was being lost prior to this form of treatment.

In a number of cases there was no doubt whatever as to the pulmonary lesion having become quiescent. But without the slightest desire to disparage the value of routine chest examinations, I cannot refrain from suggesting that a symptom-complex of this kind is generally of more value as an index of improvement than auscultatory or percussion phenomena in a condition where *restitutio ad integrum* is impossible. I may add that, in my experience, some patients who were immunized rapidly presented a striking improvement in appearance, especially as regards anaemia, and that in some of them I have been able to satisfy myself that Löwenstein's observation of increased phagocytosis in the sputum is correct.

I do not wish to engage in any controversy on the curability or otherwise of bovine tuberculosis, as I have no practical knowledge of the subject, but I should like to ask whether Dr. Shaw's facts do, as a matter of fact,

"deal a staggering blow to the tuberculin propaganda"? Dr. Shaw himself asks: "Is it not a certainty that, if bovine tuberculosis could be cured by the use of tuberculin, its use for such purposes would be world-wide?"

If active immunity were as easily secured as passive immunity is in the case of diphtheria, for example, we might safely reply to Dr. Shaw's question in the affirmative. But it is well known that the elaboration of antibacterial substances in the blood in response to infection, or in response to the inoculation of bacterial vaccines, varies within wide limits in different individuals, and that the success of such a method of treatment depends largely upon a correct adaptation of dose to individual requirements.

It appears to me doubtful whether a cure (assuming tuberculin to be a cure) for tuberculous cattle which involved skilful manipulation of doses over a long period could justify itself commercially; and in this instance universal adoption of such therapy would be, I think, contingent solely upon commercial considerations.—I am, etc.,

J. STAVELEY DICK,

Honorary Clinical Pathologist, Northern Hospital,
Manchester, May 26th.

INTRAVENOUS INJECTIONS OF IODOFORM IN PULMONARY TUBERCLE.

SIR,—In your issue of May 24th there is a report of the discussion at the Royal Academy of Medicine, Ireland, on this subject on April 4th.

As the introducer of this method, will you allow me to protest against Dr. J. B. Coleman confusing it with two other methods of which I know nothing, and condemning it—obviously without trial—along with these? I refer to the intramuscular injection of iodoform benzoyl chloride and the intravenous injection of half-grain doses of iodoform followed by tuberculin and vaccines.

Iodoform is of no use in pulmonary tuberculosis unless injected intravenously, and to condemn it because when injected intramuscularly along with another powerful body the results are unsatisfactory, or because it fails in association with tuberculin and vaccines, is curious. Dr. Coleman retailed the toxic properties of iodoform and the supposed dangers of intravenous injections. Has he ever had a personal experience of either? If so, it is strange that during all the years I have used it I have never met with them. Dr. Coleman objects to any one using any drug unless he is conversant with its chemistry and mode of action. Can he throw the smallest beam of light on the chemistry of tuberculin or vaccines further than that they are proteins whose molecules are very complex and of enormous weight relatively to a simple body like iodoform? To combine iodoform with tuberculin and vaccines in the treatment of phthisis and after failure to lay the whole blame on iodoform is really doing it too much honour.

Is there any higher court of appeal in medicine than the patients who recover by a particular treatment? But the iodoform treatment is not entirely wanting in laboratory support. Dr. C. H. Higgins, of the Biological Laboratory, Ottawa (Department of Agriculture, Canada), voluntarily wrote to me that he had inoculated rabbits intralaryngeally with virulent bovine tubercle, and after an interval of twelve days had treated them with intravenous injections of $\frac{1}{16}$ grain of iodoform for some weeks, and saved them—a result, to quote his own words, "unique in his laboratory experience." One was afterwards killed, and the necropsy showed wide tuberculous disease; sections were made and stained. No tubercle bacilli were found, and only fresh scar tissue.

That iodoform has toxic properties we all know, and so have nitroglycerine, strychnine, morphine, etc., in much smaller doses than iodoform, yet he surely does not condemn these! But the most serious indictment of Dr. Coleman's paper is that he grounds the whole of his attack on iodoform, and not on the ethereal solution, which is totally different. Iodoform is a very stable body, but the ethereal solution is very unstable, decomposing rapidly and liberating free nascent iodine under the influence of light in the presence of oxygen or moisture. Freshly prepared it is pale straw coloured, but if exposed to sunlight it becomes as dark as the liniment of iodine in a few minutes. In the *Transactions of the Edinburgh*

Medico-Chirurgical Society for 1905, and the *Glasgow Medical Journal* for 1911, a theory as to its possible behaviour in the body is in print, so no need to occupy space by recapitulation here.

I have injected myself with an ethereal solution of iodoform, and let others do it to me. Professor Mathew Hay of Aberdeen, at the hospital here, has seen me give intravenous injections, and deliberately inject some air along with them to demonstrate that a little air is an absolutely negligible affair. In point of fact, a considerable quantity causes no symptoms whatsoever. This disposes of one imaginary risk. I have never known embolism to occur, although I have given thousands of injections. Thrombosis does occur, but is due to the operator's want of dexterity, and is only of importance in so far as it blocks the vein and cuts off one of the channels for administering the treatment. I have never seen iodoform poisoning. If it occurs it is due to an error in the dose or in the frequency of repetition. If there is no truth in the iodoform method, it will soon die; if there is, it will survive till superseded by something easier and better.—I am, etc.,

Dunblane, N.B., May 28th.

THOMAS W. DEWAR.

THE INTERNEURONIC SYNAPSE IN DISEASE.

SIR,—In thinking about hysteria in relation to possible synaptic disorder I did not overlook the fact that considerable analogy existed between the major symptoms (so-called) of that disease and epilepsy, which Dr. Yates points out, but the two affections are, I think, sufficiently (in the main) differentiated by their sex incidence.

We see hysterical evidences vastly more often amongst women than men, and feminine sensitiveness, address and intuition, rapidity of perception and jumping at conclusions, often wrong, would seem to indicate generally a very free synaptic conduction in that sex. The hysterical temperament and the major symptoms met with in hysteria are not one and the same thing; the latter are interesting phenomena occurring in individuals who possess abnormal nervous systems, and in my article I was referring more to this abnormal system than to the major symptoms.

Janet's theory, to which Dr. Yates refers, practically resolves itself into a solution of personality; to quote his words, this "tendency to the dissociation and emancipation of the systems of ideas and functions that constitute personality" might be explained by the abnormal, vague, and eccentric effects produced on the cortical centres which constitute such personality as a result of too diffuse and too intense stimulation, too little limitation to definite tracts, of given stimuli, producing a chaotic, indeterminate, and wholly abnormal ultimate consciousness. With regard to the major phenomena, it has to be recollected that relatively increased local synaptic resistance may of course result as a consequence of fright, etc., in an individual whose associative synapses generally presented abnormally little resistance to the passage of the impulse, and short-circuiting may shut out of association a large area.—I am, etc.,

County Asylum, Stafford, May 20th.

B. HENRY SHAW.

THE FORM AND POSITION OF THE STOMACH.

SIR,—I quoted Dr. Barclay's expressions, "half-way down the stomach," "the lowest part of the organ," and "the middle of the body," from his writings in the *Medical Chronicle* and not from his letter of May 3rd. The source of the quotations was quite clear.

If Dr. Barclay cares to read again my papers published five years ago, he will find all the spasmodic contractions to which he has recently drawn attention already described there, and depicted in Cunningham's diagrams and my *x*-ray pictures. As I said in my last letter, I think Dr. Barclay and I agree as to the findings by *x* rays, but differ in our interpretation thereof. We agree that one of these contractions occurs frequently at the junction of the cardiac and pyloric portions. The collection of fibres so contracting I have called the "middle sphincter," for brevity's sake and for want of a better name. I repeat that it marks the beginning of the pyloric, tubular part of

the stomach. Cunningham demonstrated the existence of a special bundle of fibres there. Dr. Barclay agrees with me that contraction occurs more frequently in this region than elsewhere, and I consider it of so much importance surgically that I think it deserves a special name, and if Dr. Barclay can suggest a better one I am quite ready to adopt it.

Add to this Dr. Barclay's admission in his last letter that my theory "would be a satisfactory explanation" of well-known clinical phenomena "but for the fact that no middle sphincter can be found." Cunningham showed the presence of the fibres anatomically; Dr. Barclay's skiagrams show them in action; and I have seen them in action on the screen, in skiagrams, on the operating table, under the use of general anaesthesia, and, still more markedly, under local anaesthesia of the abdominal wall, and the evidence of their presence in the *post-mortem* room. What further confirmation can reasonably be asked?

I should like to remark that all Dr. Barclay's statements in paragraph 3 of his last letter bring evidence against his theory that the stomach becomes mechanically canalized by the effect of gravity when food enters it. It is impossible to believe that all the striking changes in the organ which are mentioned by Dr. Barclay can be explained by his "gravity theory" alone! The muscular fibres of the stomach are there for a definite purpose. How can gravity act in four-footed animals or in human beings who are compelled to lie flat on their backs, often with the pelvis higher than the shoulders, for weeks or months on end, and yet the stomach discharges its functions perfectly well?

Dr. Barclay has not yet answered my question as to discrepancies between the interpretations of various radiographers regarding the position of the pylorus. Inuendo as to my powers of observation or knowledge of surface markings neither elevates the discussion (nor the umbilicus) nor supports his arguments.

Dr. Barclay's attempt to reconcile Dr. Jordan's interpretations with his own entirely fails. Dr. Barclay locates the pylorus opposite the second lumbar vertebra. Dr. Jordan places it "behind the umbilicus." While it is universally admitted that the umbilicus is not a fixed point, it is left for radiographers to suggest that it may reach as high as the second lumbar vertebra!—I am, etc.,

Aberdeen, June 2nd.

H. M. W. GRAY.

SYPHILIS AND CANCER OF THE TONGUE.

SIR,—I regret that Dr. Leitch should find that he is unable to accept my offer to exchange serums for comparison in investigating the relative proportion of cases of cancer of the tongue in which a positive Wassermann reaction has been obtained.

The antisyphilitic treatment to which Dr. Leitch refers frequently solely consists in the administration of potassium iodide; and since this drug is useful in clearing up other morbid exudates, a temporary improvement in cases of cancer of the tongue by no means indicates a syphilitic basis.

No argument of any validity has been advanced to convert my original observation—for example, that in tertiary syphilitic lesions of tongue, mouth, or pharynx a very strong positive Wassermann reaction is usually present. Why, then, in cases of cancer in these situations, with a lesion of much greater magnitude, is there not associated at least an equally strong reaction if syphilis plays such an active part as Mr. Ryall would have us believe? It is most unusual in cancer cases to get a strong positive Wassermann reaction even if one suspects a history of syphilis.

In this connexion a remark on the topographical distribution of cancer obtained from Dr. Powell White's recent work on *Tumours* is of interest:

We find that there are marked differences in the incidence in the different districts. For example, in England and Wales the great centres of industry, such as Monmouthshire, South Wales, Durham, and Lancashire, have a low cancer mortality; while in the more rural districts, such as Huntingdonshire, Cambridgeshire, and North Wales, the incidence is higher.

Perhaps Mr. Ryall would have us believe that syphilis, too, is correspondingly more marked in rural districts than in towns, for it is useless trying to explain the

etiology of cancer of the tongue apart from cancer of pharynx, lip, uterus, or indeed any other organ.

I am content, however, for the present merely to draw attention to the rarity of a strongly positive Wassermann reaction in such cases.

I keenly regret Dr. Leitch's inability to accept my offer for another reason. I believe the above conclusion to be of interest in the ultimate serum diagnosis of cancer. I freely admit that there is one possible source of error—and it is this which renders the whole question worth investigating—that there is in conjunction with cancer a condition in the serum which tends to neutralize a positive Wassermann reaction which otherwise would be manifest. It is this latter point which I wished to draw out in opening this discussion. Dr. Leitch will, I think, ultimately regret his "5 out of 7."—I am, etc.,

Manchester, May 29th.

ARNOLD RENSHAW.

PSEUDO-FRACTURES OF TRANSVERSE PROCESSES.

SIR.—I am much interested in Dr. Rhys's communication (p. 1105) relating to pseudo fractures of the lumbar transverse processes. True fractures are sometimes met with, and may be the cause of severe and persistent pain in the lumbar region; it is doubtful if they are diagnosed clinically. The usual history is a fall from a scaffold or down the hold of a ship. A few weeks ago I found all the right lumbar transverse processes except the first broken and displaced, one of them quite a fingerbreadth from the body to which it belonged.

The importance of these fractures is considerable from the medico-legal point of view, and given a case of persistent pain in the back after a fall or other injury in that region, a careful x-ray examination should always be carried out. It may save an honest man from a charge of malingering.

In the course of examining some hundreds of plates made of the lumbar region with a view of determining the presence or otherwise of urinary calculus, I have as a matter of interest paid attention to the many vagaries of Nature in her construction of the twelfth rib. I never feel sure whether she is engaged in some deep scheme of evolution for the benefit of posterity, or whether it is that she does not consider this structure worthy of any serious consideration. I do not think that two of these are ever found to be exactly the same, not even in the same patient. The difference may be small, or it may be only in the angle it makes with the spine, but there is always a difference. I need hardly say that only those plates made with the x-ray tube over the middle line are taken into consideration. In one case they were so short as to correspond almost exactly with the appearances shown in Dr. Rhys's paper (Fig. 2). By counting up from below I was satisfied that it was the twelfth dorsal vertebra. I have by me a plate that shows the same thing, but this time it is without doubt the first lumbar vertebra.

With regard to the appearances at the gap separating the outer portion of the process, the clear space bordered by a layer of very compact bone tissue so nearly resembles an articulation, that I have taken the view that these are really rudimentary ribs. The idea of incomplete ossification had not occurred to me, but I cannot help thinking that the appearances in my cases are rather against this view.

Referring again to Fig. 2 of Dr. Rhys's paper, I note that the two sides have been drawn differently. In my cases it has always been as shown on the left of the drawing. The process on the right side would more nearly correspond to my idea of incomplete ossification, but I have never seen this. It would be highly interesting and instructive if other radiologists would give us their views on this question. We have unique opportunities for illuminating many doubtful points in more senses than one.

Hand in hand with this morphological question we may note a similar apparent lack of decision in the structures near the opposite end of the dorsal vertebrae, though in a slightly different way. The first rib is perhaps too important a structure to be trifled with, but not so the seventh cervical vertebra. My only reason for introducing this is to raise the question as to what constitutes a cervical rib. The true rib is occasionally found, but not nearly so often as what I prefer to call an elongated

transverse process. Both may give rise to similar symptoms, and many medical men class them all under the term "cervical rib." It is not unlikely that many cases of true cervical rib never come under observation, since with the absence of rigidity pressure effects are trifling or entirely absent. This may account for the fact that by far the larger number of cases sent for x-ray examination have one or both transverse processes elongated. These are sometimes called "false" cervical ribs, but surely we can find a better term than one that merely tells us what they are *not*.

Thanks to radiography this condition is much more frequently detected now than ever before, and knowledge of the condition has greatly increased in consequence.

This matter of abnormal ribs near both ends of the dorsal vertebrae would make an excellent subject for a thesis, and I hope some one who has the time will deal with it.—I am, etc.,

London, W., May 25th.

REGINALD MORTON.

EXISTING UNSATISFACTORY CONDITION OF THE SCHOOL MEDICAL SERVICE.

SIR.—The opinions expressed by your correspondents, compiled with numerous private letters received in connexion with my communication to your columns of May 11th, leave no doubt that the school medical service of this country is in a very precarious condition. Both Dr. Graham and Dr. Turner bear testimony to the widespread discontent existing among members of this service, and as the one bases his opinion on a large number of letters received in consequence of his communication to your columns, and the other on replies to a circular letter, the reliability of their views cannot be questioned.

The letters I have myself received all indicate the same feeling; indeed, two inform me that the senders are leaving the service—a step which it is to be feared will ultimately be followed by all its best members unless some hope is held out of improved conditions in the near future.

One cannot help thinking that it is important, as a preliminary step, to try and secure more union between school doctors; at present opportunities for exchange of views appear to be confined to the press, while very few seem to know each other personally. I should be glad if any members of the school medical service, whether school medical officers or school medical inspectors, who share this view would be good enough to communicate with me. I think the solution of this part of the problem should present no difficulty.—I am, etc.,

ROBERT HUGHES, M.B.Lond., etc.,

School Medical Officer, County Borough of Stoke-on-Trent.

Stoke-on-Trent, June 2nd.

SIR.—I have read Dr. Priestley's letter with great interest, and I do not think the case could be put better. My object in writing is to express my whole-hearted agreement with his expressed opinions.

No one now doubts the onerous, exacting, and responsible duties of a school medical inspector. Frequently he possesses high degrees and has held house appointments, both at his own hospital and subsequently at special hospitals. He is often expected to do eye work and prescribe glasses. The pay may be £250 a year, and any opportunity to increase his income is firmly forbidden.

Presumably the advice of the school medical inspector is of value; if not, the inspection is useless. By means of Care Committees, nurses, etc., the parents are persuaded to act on the medical inspector's advice. If his advice be faulty the parents, who can ill afford it, pay a fee for nothing.

In this county the tuberculosis officer receives £500 a year; the school medical officer, who was in office years before the tuberculosis officer, receives £400. The reason for this difference in emolument is that the salary of the tuberculosis officer is provided partly or wholly out of Treasury funds. The school medical officer is maintained out of the rates.

School medical inspection was imposed upon local authorities at a time when their cup of bitterness was full, and the school medical service was not welcomed. It never will be welcomed till the cost is provided out of

Treasury funds. A man pays his Imperial taxes in sorrow, his rates in anger.

Not only is there no prospect for the school medical officers, but there is no security of tenure for their present positions. An adverse letter from the Board of Education may at any time displease the local authority, and as they cannot visit their displeasure upon the officials of the Board of Education, they make their own school medical officials suffer accordingly. This is not a fanciful supposition: it has actually happened.—I am, etc.,

Trowbridge, Wilts, May 27th.

R. H. BREMRIDGE.

TUBERCULOSIS OFFICERS.

Sir,—Dr. Wilson has flattered Dr. Graham and myself by saying he appreciates our "good intentions!" He objects to Dr. Graham's statement that we (tuberculosis officers) are "a junior branch of the public health service." By date of formation and range of salary we are at present a junior service, but this is a painful subject, and I will leave it to Dr. Graham.

He next objects to my statements that we "look forward to entering the main branch of the public health service," or that "the ranks of medical officers of health will be recruited from "tuberculosis officers." My full statement was: "The ranks of the medical officers of health in the future must be recruited from school medical officers, superintendents of infectious hospitals, and tuberculosis officers, and most of these officers look forward to entering the main branch of the public health service." He sums up his own views that to "suggest" the tuberculosis officer "is a stepping stone to the post of medical officer of health is an error, and creates the idea of a hybrid service. . . ."

In making this statement Dr. Wilson has brought in his own views as to the correct status and qualifications of a tuberculosis officer. They may be right or wrong, but they cannot alter the fact that there are tuberculosis officers who regard their present post as a stepping stone to the post of medical officer of health, and that many tuberculosis officers are of the "hybrid" variety. As I write I recollect two such tuberculosis officers who happen to be personal friends of mine. As a matter of fact there are several kinds of tuberculosis officer in existence. There is a city in Lancashire which has five tuberculosis officers. The chief tuberculosis officer is the medical officer of health. The detailed administrative work devolves on an acting chief tuberculosis officer, who also is a junior assistant medical officer of health. The other three assistant tuberculosis officers are clinicians. There are thus two "hybrid" and three pure tuberculosis officers in this city. Further, in populous counties the senior tuberculosis officer is very largely engaged in administrative work, and tends to become more or less of a "hybrid."

But I wish to urge that every tuberculosis officer, pure or otherwise, should actively support every effort for his inclusion in the Medical Officers of Health Superannuation Bill. This should especially appeal to Dr. Wilson, because if a tuberculosis officer is a real "hybrid"—that is, a part-time medical officer of health—he is included in the bill, but if a really pure tuberculosis officer like Dr. Wilson, he is left outside.—I am, etc.,

Preston, June 1st.

G. LISSANT COX.

The Serbices.

INDIAN MEDICAL SERVICE OFFICERS IN EDINBURGH.

THE annual dinner of the officers of the Indian Medical Service, retired or on the active list, took place in Edinburgh, in the Caledonian United Service Club, on Friday, May 30th. Sir Alexander Christison, Bart., was in the chair, and it was noted that there were some present whose service went back as far as the second Burmese war (1851). Among those who sat down were Surgeon Generals Turnbull, Hay, and Sinclair, C.S.I.; Colonel Sir Joseph Fyner, Bart., M.D., the superintendent of the Royal Infirmary; Brigade-Surgeon-Lieutenant-Colonel James Arnott, formerly professor of midwifery in Bombay; Colonel Cadell, of Bengal; and others.

The name of Deputy Surgeon-General W. James was omitted from the list of those present at the annual dinner of the Royal Navy Medical Club, published on May 31st, p. 1190.

Medico-Legal.

INTERPRETATION OF AN AGREEMENT.

Gates v. Russ.

IN the Chancery Division, on May 27th, Mr. Justice Sargant delivered judgement in an action between two medical men, each of whom conducts a clinical research laboratory in London. The point at issue was whether the defendant, by establishing his laboratory, had committed a breach of his agreement with the plaintiff, and Mr. Justice Sargant held that this was not the case.

The general facts were as follows: The defendant entered the service of the plaintiff in December, 1905, and left it in October, 1912. His duties were to act as one of the two qualified assistants of the plaintiff in the conduct of a clinical research laboratory, the ordinary hours of work daily being from 9 a.m. to 6 p.m. He signed no formal contract of service, but before being engaged was given a copy of a statement setting forth the nature of the work and conditions on which it was to be performed, and the salary to be paid and other like matters. The final paragraph stated that acceptance of the post would be taken as an agreement on the part of the candidate to all the foregoing conditions and as constituting a binding agreement between the two parties. The defendant was given a copy of this statement, and eventually accepted the post.

After holding it to the satisfaction of his principal for several years, as already indicated, he vacated it by common consent, and then opened in London a corresponding laboratory of his own. When doing so he did not endeavour, by circulars or otherwise, to obtain work from clients of his old principal, but nevertheless the latter held that by opening a clinical research laboratory at all in London the defendant had committed a breach of his agreement. One of the paragraphs in the statement mentioned said that the candidate selected would be required to enter into a bond not to engage in similar work within a distance of ten miles of this laboratory, either by himself or on the part of any institution of like character, under a penalty of £250; while part of another paragraph bound the holder of the post to co-operate in securing harmonious working of the laboratories.

On these facts the plaintiff asked for an injunction restraining the defendant from continuing to maintain the laboratory opened by him. The arguments put forward were to the following effect: The paragraph mentioned obviously referred not to the time during which the defendant was employed by the plaintiff, but to afterwards. It could not refer to the former, because the post held by the defendant was a whole-time post, the tenure of which could not possibly do the work covered by the condition. This was rendered clearer by the paragraph as to the tenant of the post being obliged to endeavour to promote harmonious working; there could be no harmonious working if the tenant were engaged in competitive work elsewhere. There was nothing in law to render invalid an agreement not to practise within a given limit during the whole period of life, and the condition was not more stringent or further reaching than was required for the reasonable protection of the plaintiff. Many of his clients resided at places outside a ten-mile limit, so the clause was not rendered unenforceable by undue stringency.

The reply put forward on the part of the defendant was to the effect that as a matter of fact he had read this condition as applying only to the time that he was actually employed by the plaintiff and not to any later period, and that that was the correct interpretation of the paragraph. Even if the contrary were the case, the wording of the paragraph was so ambiguous that the court ought not to hold that there had ever been any true consensus between the parties and therefore any enforceable agreement on the point. The argument that the condition could not possibly relate to the time during which the defendant was in the employ of the plaintiff because it was a whole-time post was not sustainable, because, as a matter of fact, during the whole of his service the defendant was doing other work as well. It was true that this was private research work and did not bring him remuneration, but the time occupied by it might have been employed by him in competitive work but for his interpretation of the existence of the paragraph in question.

Mr. Justice Sargant, after reviewing the facts of the case and the arguments on either side, held that he ought not to issue the injunction sought. It seemed to him that the natural interpretation of the disputed paragraph was that the condition laid down by it was co-extensive with the defendant's employment by the plaintiff, and did not apply after its termination. Such interpretation was all the more natural, because every other paragraph related to that time, and there was nothing to differentiate the paragraph in this particular from the rest. He agreed that by his decision the plaintiff would suffer a certain degree of hardship. On the other hand, it would be monstrous that a man should be deprived for the whole of his career from carrying on work which had been the principal work of his life, unless that obligation had been put before him in definite and clear terms. It would be a terrible conclusion if the defendant, having accepted the terms as they were put before him by the plaintiff, and finding nothing whatever in them to indicate in any way that he was fettering himself from carrying on his life's work after the termination of his employment with the plaintiff, found that in fact, by a difficult and elaborate construction of the agreement, words were introduced into a paragraph which made that paragraph apply not merely, like the

other paragraphs, to the time during which the defendant was working for the plaintiff, but to the whole of the rest of his life. Hence the action would be dismissed with costs.

In the course of his judgement Mr. Justice Sargant expressed the opinion that the case had been very fairly fought by both sides.

UNIVERSITY OF MANCHESTER.

RESIGNATION OF THE VICE-CHANCELLOR.

THE annual meeting of the Court of the University of Manchester was held on May 28th, the Chancellor, Lord Morley, presiding.

ANNUAL REPORT.

The Vice-Chancellor in presenting his annual report drew special attention to the fact that the number of students remained about steady. The actual increase on the year was three, but progress was indicated because the number of those who had taken honours and the full courses was larger than formerly. There had been a perceptible growth in the number of medical students. For some time there had been some anxiety on this point, but the arrangements made for medical education were now well recognized, and the number of students was increasing. The decision to admit women to the medical courses had proved successful, and the facilities now offered to women students were second to none in the kingdom. In the faculty of technology there had also been an increase, and he was satisfied that the arrangements made between the university and the School of Technology would be immensely helpful to both. With regard to the question of the superannuation of the teaching staff, the Board of Education had received most sympathetically the suggestions made by the university, and the Vice-Chancellor hoped that within the next few weeks an excellent scheme would be adopted which would allow of much elasticity to each university.

Number of Students.

The report showed that the number of students during the past session was as follows: All faculties, except medicine and technology, including 320 women students, 1,692. Faculty of Medicine, including 32 women students, 372. Faculty of Technology, including 2 women students, 246. This is a total of 1,710, or, allowing for 47 who have entered in both science and medicine, 1,655. In addition there are 201 persons attending evening classes, about 200 attending lectures on railway economics, and about 200 in courses in law and economics at the Bankers' Institute. In the Faculty of Medicine 134 were working for the degree examinations, 7 for the University of London, 10 for other universities, 2 for the F.R.C.S., 29 for the English Conjoint examination, 3 for the Scottish Triple qualification, 3 for the diploma in Psychological Medicine, 3 for the degree in Dentistry, 48 for the diploma in Dentistry of the Manchester University, and 15 for the diploma in Dentistry of the Royal Colleges of Surgeons and Physicians. Also 41 were working in special departments, namely, Medical, 5; Pharmaceutical, 5; and Public Health, 31.

Appointments in the Faculty of Medicine.

The report noted that A. Donald, M.D., M.R.C.P., had been appointed Professor of Gynaecology and Obstetrics, in succession to the late Sir William Sinclair, and W. K. Walls,

M.B., Lecturer in Clinical Obstetrics and Gynaecology; A. E. Boycott, B.Sc., M.A., M.D., of Guy's Hospital, had been appointed Professor of Pathology, in succession to Professor Lorran Smith, who had resigned on being appointed Professor of Pathology in the University of Edinburgh; Dr. E. S. Reynolds had been appointed Professor of Clinical Medicine, in succession to Dr. Judson Bury, whose professorship ceased on his retirement from the staff of the Manchester Royal Infirmary. Dr. William Sellers, Coroner for Salford, had been appointed Professor of Forensic Medicine, in succession to the late Dr. Dixon Mann; Dr. C. P. Lapage had succeeded Dr. Hutton as Lecturer in Diseases of Children, and Dr. G. H. Lancashire had succeeded Dr. Brooke as Lecturer in Skin Diseases.

HONORARY DEGREES.

The Court approved of the conferment of the following honorary degrees: LL.D., Mr. Jesse Haworth; Litt.D., Mr. T. E. Page and Mr. M. E. Sadler; M.Sc., Mr. R. W. Williamson. The conferment of the degree of D.Sc. on Professor Perkin for special distinction in chemical research was endorsed.

PROPOSED DIPLOMA IN OPHTHALMOLOGY.

Professor Elliot Smith moved the adoption of an ordinance instituting a diploma in ophthalmology. Dr. F. Shaw drew attention to the resolution recently passed by convocation in opposition to the ordinance; it was felt, he said, that it was not desirable, after a course of only six months, to confer a diploma which might give the public an erroneous idea of the amount of knowledge and experience of the holders. This was the first time a diploma had been proposed for a clinical subject, and if it were passed, the court could not logically refuse to give diplomas in all other clinical subjects. He moved, as an amendment, that the proposal be referred back. This was seconded by Mr. C. T. Needham, M.P., and carried.

RESIGNATION OF THE VICE-CHANCELLOR.

Sir Alfred Hopkinson then asked permission to withdraw while the court considered the letter which he had sent to the Chancellor, in which he begged to resign his position as Vice-Chancellor.

The Chancellor then read the letter, which stated that, having been engaged for over fifteen years continuously in the work of the university, Sir Alfred Hopkinson felt that the time had come when he should resign. He did so not for reasons of health nor from any desire to retire from active life, but simply because he believed that there was a period in the history of an institution when change was desirable and when a new administrative head might bring in fresh vigour and exercise a stronger influence than one who had held office so long as he had. While certain questions were pending, such as the position of the university with regard to Government grants and its relations to the Board of Education, it was impossible for him to take this step, but most of these questions were now settled, and the relations between the university and the city, county, and local authorities were of the most friendly character. During his tenure of office new buildings had been erected at a cost of £190,000, exclusive of the Whitworth Hall, for which Mr. Christie had provided, and all this sum of money, with the exception of a few hundreds, had been actually paid. No debts had been accumulated, and for some years the annual expenditure had not exceeded the income. The special problems that presented themselves at the time of his appointment and the reorganization of the university had now been dealt with, and he thought the moment now opportune for putting into new hands the new development work which the university would undertake. In conclusion, he thanked the Court for the kindness and generous support it had given him ever since his appointment.

After reading the letter, Lord Morley expressed his personal feeling of regret at the decision of Sir Alfred Hopkinson and the gratitude of the Court for the fidelity with which he had discharged his duties. Sir F. Forbes Adam then moved the following resolution:

The Court has heard with regret the intimation of the resignation of the Vice-Chancellor, and begs to express the earnest hope that in the interests of the university he will see his way to reconsider it.

This was seconded by Professor Weiss and supported by Sir William Mather and Lord Morley, and adopted unanimously with applause.

At a meeting of the Council on June 4th, however, it was announced that a letter had been received from Sir A. Hopkinson stating that he must adhere to his resolution, and desired to retire not later than October next. He will, however, retain the Christie Chair of Law in the university.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—*E. L. Jones, †E. M. Morris, *T. B. Paul, *C. G. Waddington.
MEDICINE.—*S. H. Andrews, *P. R. Cross, †A. C. Dickson, †T. H. W. Idris, *E. L. Jones, *W. R. Sadler.
FORENSIC MEDICINE.—S. H. Andrews, P. R. Cross, E. L. Jones, A. Y. Massey, W. R. Sadler.
MIDWIFERY.—D. T. Corke, W. H. Edmunds, E. L. Jones.

* Section I. † Section II.

The Diploma of the Society has been granted to Messrs. A. C. Dickson, W. H. Edmunds, E. L. Jones, and E. M. Morris.

Obituary.

THE death took place on May 16th of Dr. JAMES WILLETT, of Stockton Heath, a medical man who at the time of his death was one of the few Lancashire survivors of the old-fashioned type of country doctor. Dr. Willett, who became L.S.A. in 1857 and M.R.C.S. in 1862, was born and bred in the neighbourhood in which he practised, and was at one time medical officer of health for the area. He had given up practice for a good many years, but his personal qualities were such that he retained the trust and affection of his neighbours despite this fact and his advancing years. Until lately he was a member of the Warrington and Widnes Division of the British Medical Association, and the large gathering which attended his funeral on May 21st included a deputation from this body, as well as other members of the medical profession.

LIEUTENANT-COLONEL RICHARD CRAIG, late R.A.M.C., who died on May 5th, at the age of 67, was the son of the late Richard Craig of the Bank of Ireland. He took the diplomas of L.R.C.P. and L.R.C.S.Irel. in 1866, entered the service in March, 1868; was promoted to surgeon in March, 1873; and surgeon-major in 1880, retiring in January, 1892, with the rank of lieutenant-colonel. He served as senior medical officer of the Third Brigade with the Burmese expedition of 1886-83, and was awarded the medal with two clasps.

Public Health

AND

POOR LAW MEDICAL SERVICES.

BURNLEY GUARDIANS AND THEIR MEDICAL APPOINTMENTS.

THE position in the Burnley district has been from time to time recorded. The medical officers of the Burnley Union, acting on the advice of the Burnley Division of the Association, and after many attempts at negotiation with the Burnley Guardians, resigned their appointments some months ago as a protest against the salaries paid by the guardians. The Division had satisfied itself that these salaries were considerably less than those paid for similar work in many other unions. The guardians, after a long delay, during which the patients under their charge were attended as private patients by local doctors, succeeded in inducing the Local Government Board to sanction a plan for the redistribution of the appointments, at salaries which, though an improvement on the old scale, were yet considered by the Division to be below the standard set by other unions. The new proposals were vitiated also by the fact that the appointments were combined with those of the public vaccinators in a way which, while apparently raising the salary of the Poor Law medical officer, did so by lowering the real remuneration of the public vaccinator, a thoroughly bad system which has long been condemned by the Association, whose disapproval has been endorsed, in an academic way, by the Local Government Board and emphatically by the Royal Commission on the Poor Law. We regret to find, according to a report in the *Burnley Express* of May 31st, that three practitioners have been induced to make application for the fifteen appointments advertised. These gentlemen were appointed, and their applications led the guardians to express the hope, which we trust will be falsified, that other applications would follow. It is a matter of great difficulty to get any considerable number of the members of any calling to act together in a matter of this kind, but it was believed that the loyal way in which the local profession had stood by the former holders of the posts, and had declined to be cajoled into accepting the largely illusory improvements made by the guardians, would have received unanimous support when the crucial moment arrived.

The gentlemen who have been appointed no doubt thoroughly combed the cost before they applied for office, and came to the conclusion that the salary offered was, so far as they were concerned, adequate. As to that they are naturally the best judges. They are, of course, aware of the effect their action has produced, not only on the guardians who have accepted their services, but on their relations with their colleagues. In spite of this breach in the solidarity of the profession, we venture to express the hope that applications for the remaining twelve appointments will not be made. We do so not merely for the sake of again endorsing the spirited action taken by the Burnley Division, but because it has long been common knowledge that the remuneration offered for posts of this kind is in many cases far below what it should be, and such a depreciation of payment can only lead eventually to the lowering of the standard of service given, which is a bad thing for the profession and the public generally, and for the pauper patients in particular.

Medical News.

THE annual dinner of the Medico-Legal Society will be held at the Holborn Restaurant on Monday, June 23rd, at 7.30 p.m.

SIR DAVID GILL, for many years His Majesty's astronomer at the Cape of Good Hope, and President of the Research Defence Society, has been made a Commander of the Legion of Honour by the President of the French Republic.

THE University of Oxford has conferred the degree of D.Litt. honoris causa on Dr. John Wickham Legg. Dr. Legg, who was for some years assistant physician to St. Bartholomew's Hospital, is a recognized authority on liturgical literature.

THE Cavendish Lecture before the West London Medico-Chirurgical Society will be delivered by Sir Berkeley G. A. Moynihan, of Leeds, in the Town Hall, Kensington, on Friday, June 27th, at 8.15 p.m., the subject being the surgery of the large intestine.

AT the meeting of the Royal Society, on Thursday next, papers by Drs. Blacklock and Yorke on the trypanosomes causing dourine, and by J. G. and D. Thomson on the growth and sporulation of the benign and malignant tertian malarial parasites in the culture tube and in the human host will be read.

THE usual breakfast will be given by the National Temperance League at the annual meetings of the British Medical Association at Brighton. The President-elect, Dr. William Ainslie Hollis, M.A., F.R.C.P., has consented to preside, and Dr. Mary Scharlieb to speak after the breakfast, which will take place in the Banqueting Hall of the Royal Pavilion, on Thursday, July 24th.

MR. LITTLEWOOD, who, as already reported, has resigned his position as senior surgeon to the Leeds Infirmary to retire to the country, was recently entertained at a complimentary dinner by medical men in Yorkshire. The dinner took place at Leeds under the presidency of Mr. Pridgin Teale, and the toast of Mr. Littlewood's health was proposed by Dr. J. E. Eddison. The following evening Mr. Littlewood was entertained by the students of the medical school and presented with a silver cigar case.

WITH reference to a paragraph in the *JOURNAL* of May 17th, p. 1080, stating that a new medical building of the skyscraper order of architecture is in course of erection in New York, Dr. Charles Forsyth, of Hong Kong, writes that all the British doctors in Hong Kong have their consulting-rooms in the same building, which, though large, is not a skyscraper. The idea of a building let out to medical practitioners is, of course, not a new one. There are, we believe, several such buildings in the large cities in the United States, one or two of them at least having been erected fifteen or twenty years ago.

ON Wednesday, June 11th, the Anglo-German Exhibition will be opened at the Crystal Palace by the Lord Mayor of London. The exhibition, among a large variety of machinery, apparatus, industrial products, painting and sculpture, printing and so forth, includes sections of food supplies and education. There will also be a naval and military section. Every effort has been made to make the exhibition attractive as well as instructive by means of side shows and international athletic and gymnastic competitions. The exhibition is intended to increase the friendliness of the relations between this country and Germany.

A DINNER for past and present students of the Central London Ophthalmic Hospital was held on May 21st, at the Café Royal, London. Mr. Ernest Clarke, senior surgeon of the hospital, who presided, proposed the toast of "The Hospital and its Medical School," and spoke of its growth and success during the past few years, also of the fine new building which had lately been opened in Judd Street. Mr. Mayou (the Jean), in reply to the toast of "The Medical School," pointed out that its prosperity in the new quarters which afforded such excellent teaching facilities now seemed assured. The Chairman proposed the toast of "The Visitors," which was responded to by Mr. Sydney Stephenson and Mr. Leslie Paton, both of whom expressed their admiration of the new hospital.

THE *Daily Express*, which recently opened a subscription list for the purpose of providing the London hospitals with radium, received £10,375, and this sum has been distributed as follows: To the Middlesex Hospital, £1,100; to St. Bartholomew's, Charing Cross, the London, King's College, and St. George's Hospitals, £1,000 each; to the Westminster, the Metropolitan, the Seamen's, the West London, the Great Northern Hospitals, University College Hospital, and the Cancer Hospital, Fulham Road, £500

each; to the Prince of Wales Hospital, £275; and to the Chelsea Hospital for Women and to St. John's Hospital for Diseases of the Skin, £250 each. Some of the larger donors earmarked their contributions for certain institutions, and in respect of the rest our contemporary was guided in its allocation by a committee which, among other points, took into consideration the proportion of patients suitable for radium treatment which each institution was likely to have. It is calculated that for the lowest sum allocated—namely, £250—about 15 mg. are procurable, and that this is an amount with which a good deal of useful work can be done. In fulfilment of a promise made by Lord Glenconner (the Lord High Commissioner for Scotland) to Sir Joseph Fayrer (the superintendent of the Edinburgh Royal Infirmary), when he was paying his official visit to that institution last week (vide p. 1185), the High Commissioner has now intimated a donation of £1,000 to be employed in the purchase of radium to be used in the Infirmary.

The promoters of the National Health Exhibition, which was held at the Holland Park Skating Rink from May 16th to May 31st, have every reason to congratulate themselves upon the success of their attempt to interest the man in the street in the preservation of his own and his children's health. The exhibition, which was organized for the express purpose of instructing the lay public in the elements of domestic hygiene, was most attractively arranged; and even a cursory inspection of the exhibits could not fail to arouse the interest of the visitors in this important subject. Some extremely interesting exhibits were on view in the different sections, one of the most popular of which consisted of a number of incubators, each containing a living baby. Several stalls were given up to the display of dirt and germ destroying and labour-saving contrivances and unadulterated foodstuffs, whilst a series of pretty model rooms (including a charming nursery) gave a much-needed lesson in the art of furnishing a house according to the latest hygienic principles. Demonstrations in cooking were given daily at frequent intervals, and a variety of competitions were held in different subjects, for which gold, silver, and bronze medals and diplomas to the value of £100 were awarded.

At the annual meeting of the Glasgow University Club, London, on May 30th, it was resolved to hold this meeting in future before the autumn dinner instead of before the spring dinner, thus enabling complete accounts for the expired club year to be furnished. The accounts presented included a donation of fifty guineas to the Glasgow University Athletic Club, but nevertheless showed a balance in hand of over £70. A donation of ten guineas to the Lister Memorial Fund was approved, the sum being earmarked for a memorial in Glasgow itself. Mr. W. Craig Henderson, M.A., D.Sc., having resigned office as one of the honorary secretaries of the club after seven years' service, was awarded a vote of thanks and elected a vice-president. As president Lord Rosebery was re-elected for a further year, and Drs. D. S. Roxburgh and Andrew Wiley were appointed honorary secretary and honorary treasurer respectively. At the dinner which followed the same evening the chair was taken by Mr. Birrell, who, in addition to many other things, is the present Lord Rector of the university. After speaking of the newer universities, he said that, after all, there must be some preference shown towards those which, like Glasgow, dated back to pre-Reformation times. It was a pleasure to think of their long centuries of use, and there was something fascinating in studying their history. The toast to the Chairman was proposed by Surgeon-General Babbie, V.C., C.B., and that to the guests acknowledged by Dr. George Ogilvie. The dinner was well attended, and in the course of the evening it was mentioned that the club now numbers 357 members.

The members of the Aberdeen University Club, London, held their half-yearly dinner on May 21st. Dr. W. J. R. Simpson, Professor of Hygiene in King's College, London, was the chairman. Among those present were: Surgeon-General Sir James Porter, Sir Henry Craik, M.P., Sir Robert Burnet, Sir James Mackenzie Davidson, Dr. James Taylor, Professor Ashley W. Mackintosh, Mr. James Cantlie, Sir William Ramsay, Dr. James Galloway, and Sir John Collie and Mr. W. Hall Barron (joint secretaries). The Chairman, in proposing "The University and the University Club," mentioned that he graduated thirty-seven years ago. The professors who impressed him most were Struthers, Pirie, and Brazier. He believed there never would have been a Sir Patrick Manson if it had not been for the zoology professor in Aberdeen. Sir Patrick Manson's monumental work on the development of filaria in the mosquito, and his deduction from this as to what occurred in the mosquito in malaria, had, with Sir Ronald

Ross's discovery of the correctness of his deduction, established a new era in tropical medicine and sanitation. Manson's work ranked with that of Pasteur and Koch. He went on to say that he had been in many lands, and everywhere he had found Aberdeen graduates in prominent positions, except in West Africa where Scotsmen were scarce, for the reason, he had heard, that the pay was not enough for an Aberdonian. He believed that was being altered now. Professor Mackintosh proposed "The Guests," and Sir William Ramsay responded. Mr. Cantlie, in proposing the toast of "The Chairman," said that as Manson was the father of tropical medicine, Professor Simpson was the father of tropical hygiene. Professor Simpson feelingly expressed his thanks.

The Imperial Services Exhibition at Earl's Court, which was opened by the Duke of Connaught on Saturday, May 31st, affords a good opportunity for the general public to gain some insight into the different phases of life in the British Navy and Army, and incidentally proves with what care the health and well-being of the sailor and soldier are now guarded, both in peace and in war. A life-size model of the after-part of H.M.S. *Lion* enables the visitor to realize the surroundings in which the officers and crew of a modern battle cruiser live; the sick bay, with its spotless cots and big bath, presents a very attractive appearance. Close by is a miniature wireless telegraphy station, from which it is possible to transmit messages to the other side of the grounds, where an entrenched camp, blockhouse, and armoured train show how an invading army endeavours to protect itself from sudden onslaught and night attacks. In the Red Cross enclosure is a field hospital and a fully equipped hospital train, with medical officer, orderly, and nurses in attendance, whilst a number of Major Richardson's sentry and ambulance dogs are on view close at hand. A very large number of valuable curios, pictures, and trophies, including a collection of antique weapons from the Tower of London, are to be seen in the different buildings in the grounds; whilst, later on, it is hoped that the relics of the Scott expedition will be deposited for a time in the Prince's Hall. To the majority of visitors, however, the principal feature of the exhibition will be the magnificent spectacle of naval and aerial warfare in the Empress Hall, in which may be seen the bombardment of a town by a British fleet, every vessel of which is a replica of one of a battleship or cruiser now in commission. This interesting exhibition, which is one of the most attractive held at Earl's Court of recent years, has been organized and carried out by naval and military experts under the auspices of the Admiralty and the War Office, and the money taken at the gates is to be used entirely for the benefit of the sailors and soldiers of the United Kingdom.

The annual meeting of the Asylum Workers' Association was held at the house of the Medical Society of London, W., on May 28th, under the presidency of Sir John Jardine, K.C.I.E., M.P. The annual report, presented by the Honorary Secretary (Dr. G. E. Shuttleworth), showed some falling off of ordinary membership for 1912, which was attributed to an active trade union propaganda in asylums, but the finances continued sound, and much useful work had been carried on by the Central Executive Committee for the benefit of asylum staffs throughout the United Kingdom. Sir John Jardine, in moving the adoption of the report, referred to the bill he had recently introduced for extending the benefits of the Asylum Officers' Superannuation Act of 1909 so as to allow female officers and nurses to retire on pension after twenty-five years' service, independent of age, and men in charge of patients after the same period, if 50 years of age. Some concessions were also asked with regard to giving asylum committees power to award gratuities to the dependants of those dying in active service, and to those incapacitated for further service, though short of the pension age, by illnesses (for example, colitis), as well as by injuries, clearly attributable to asylum duties. Provision was also made for reckoning for pension service in Scottish parochial asylums, and for a wider definition of "established officer or servant," with power of appeal to the Lunacy Commissioners in cases of dispute. Sir John Jardine trusted that, considering the arduous lives of workers amongst the insane, these moderate demands would not be opposed by a Liberal Government. The adoption of the report was seconded by Dr. Campbell (of Laibert Asylum), supported by Dr. Drapes (of the Ennis-corthy Asylum) and Dr. Stewart (late of Dunmurry), and unanimously agreed to. Sir John Jardine was reappointed President for the ensuing year, and the executive committee and officers were elected. A resolution in support of Sir John Jardine's Asylum Officers' Superannuation Amendment Bill was enthusiastically carried.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Artiology, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National):—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

SOL asks for advice in the treatment of a girl, aged 12, who is quite healthy, but whose face is covered with freckles, present even in the winter.

DR. F. WILLIAM COCK, F.S.A. (1, Porchester Houses, Porchester Square, W.), asks where the preparation of the aortic aneurysm removed in 1847 from Robert Liston is. There is, he says, a persistent tradition that it is in existence, but he has been unable to locate it. It is not at University College, R.C.S. London, Edinburgh, Cambridge, or Norwich. In all probability the specimen was put up by William Cadge, who made the *post-mortem* examination.

SOMNAMBULISM.

ABER would be grateful for advice in the treatment of somnambulism in a young lady, aged 24. It commenced about nine months ago, during convalescence from a severe attack of diphtheria in which bradycardia was a predominant symptom. The patient often gets up two or three times the same night and walks to various parts of the house. The act seems to be preceded by a period of excitement, when the patient seems as if terrified. The general health is fairly good, though the patient has lost flesh during the last six months.

ANSWERS.

SUPERFLUOUS HAIR.

DR. DOUGLAS FRESHWATER (London) writes: I would refer "Derma" to my article on "Hairiness and its Treatment" in the *Practitioner* for May last. Probably, if the hairs are not too numerous, repeated rubbing with pumice stone would be the best treatment.

SOFT WATER AND IRON PIPES.

DR. E. NORTON (Capel Lodge, near Folkestone) writes: I think Dr. E. H. O. Sankey will find it advisable to abandon the use of iron pipes (either plain or galvanized), because hot, soft water eats into these very rapidly. I would suggest instead of them a copper boiler and pipes. He would then have clean water for baths and all household purposes. It also would be much hotter. The cost of copper pipes, etc., would probably be a third more than iron, but this would ultimately be saved in repairs. I am not aware of any danger to health; copper kettles, lined and unlined, have been in use for centuries.

SOFT CORNS.

J. M.—Reference to works on skin diseases will show that it is held that soft corns, like hard corns, are due to pressure or friction from tight or badly fitting boots, usually to a combination of these defects. The corn must be removed by soaking and scraping or by salicylic acid plaster. Crocker (*Diseases of the Skin*) continues as follows: "Soft corns should have the hard skin removed in one or other of the above ways; careful daily ablation with soap and water should be used, spirits of camphor painted on at night, and wool worn between the toes in the day time. All the numerous corn cures, if of any use, act on one or other of these principles. Duhring recommends the application of a 4 to 8 per cent. caustic potash solution after removing the thickened cuticle; it must be done cautiously, the part round being protected by a ring of plaster. Vigier's formula is also a good one: Salicylic acid, gr. 15; ext. cannab. ind., gr. 8; alcohol, ℥ xv; ether, ℥ xl; collodion flexile, ℥ lxxv. It is to be painted on with a brush three times a day for a week, when the corn can be easily picked off."

LETTERS, NOTES, ETC.

ARNETH'S METHOD OF PROGNOSIS IN PULMONARY TUBERCULOSIS.

DR. H. D. McCULLOCH (London) writes: The method suggested by Dr. J. B. H. Holroyd in the BRITISH MEDICAL JOURNAL of May 3rd is attractive, though from a different point of view

than that of the pathological haematologist. A question that must have occurred to many, and one that awaits answer, is, Why does the leucocyte become polymorphic; what is the cause of the transformation from the original mononuclear state?

The observations of Arneth led him to infer that "the cells with I or II nuclei were less resistant than the cells with III, IV, and V nuclei, and that when those less resistant cells were present in large numbers the severity of the cases varied directly as the number of these cells." Dr. Holroyd's observations confirm those of Arneth, whose normal standard appears very suggestive.

I have been inclined to ascribe polymorphism to the individual age and environmental experience of the leucocyte during its course of physiological existence—that is to say, the deformity of the original single nucleus inevitably follows upon its amoebic passage by penetration through variously dense tissues, which happen to be interposed between its gland or tissue of origin and the site or sites of the infective reagents on any part of the mucous membrane or defective cutaneous surface under the influence of chemiotaxis. The density of the walls of blood vessels during the egress or ingress of leucocytes may seem negligible, especially in vaso-dilator states, but the common occurrence of vaso-constriction on such occasions may be productive of polymorphic deformities on a more or less large scale. They may also conduce to an accession of blood platelets to the circulating blood as well by amputations of the leucocytic cytoplasm, as occurs under the vaso-constrictor effects, owing to the presence of toxic and purin pressor principles in young women anaemics.

I have recently drawn attention to this in a communication to the Physiological Society. I would suggest that the presence of the small percentage of I and II nuclei cells is indicative of the fact that these leucocytes are the last proliferations of the over-functional local leucopoietic tissues or glands, and that the large percentage of the III and IV nuclear leucocytes is indicative of their more remote source from the site of the lesion, and therefore of their greater efficiency.

TARAXACUM IN CANCER.

DR. A. STEVENSON (Sunderland) writes: I read with much interest Dr. Herbert J. Robson's note on the use of taraxacum in cancer, which appeared in the JOURNAL of May 25th, 1912; also the letters by "A. D." and Miss Evie Evans, M.B., on local applications of taraxacum juice, in the JOURNAL of July 15th, 1912, and Dr. Bain's article on taraxacum in partial intestinal obstruction in the JOURNAL of May 3rd, 1913. A patient of mine was operated upon by Professor Ranken Lyie, Newcastle, three months ago for a malignant tumour of the left ovary. When Dr. Lyie performed the operation he found secondary deposits in the liver and omentum, which he was unable to remove. After the patient left the hospital I again attended her, and had great difficulty in treating the sickness and constipation, which continued and increased as time went on. At last I gave taraxacum a trial, and after two or three doses the sickness stopped and the bowels became active. As the patient was very much emaciated her end was a matter of days, but during these few days she obtained much relief from the use of taraxacum. I can fully endorse all that Drs. Robson and Bain say in its favour.

SALVARSAN IN PERNICIOUS ANAEMIA.

DR. BYROM BRAMWELL (Edinburgh) writes: In my lecture on "The Salvarsan Treatment of Pernicious Anaemia," published in the BRITISH MEDICAL JOURNAL of May 24th, I state "salvarsan contains arsenic and mercury." It is, perhaps, unnecessary to say that this is a mistake. In the Address in Medicine, which I had the honour of delivering at the Birmingham meeting of the British Medical Association, the subject of which was "Mistakes," I said that, when one makes a mistake, one should always try and analyse that mistake, and find out the reason for it. How I got the idea that salvarsan contained mercury I do not know; an old house-physician writes me, saying that I made the same mistake at one of my clinics some two years ago. Perhaps some such mental process as the following was the origin of this mistake: Mercury produces great benefit in syphilis, salvarsan also produces remarkable benefit in syphilis—therefore, salvarsan contains mercury.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restante* letters addressed either in initials or numbers.

An Address

ON

THE CLINICAL IMPORTANCE OF THE SYMPATHETIC NERVOUS SYSTEM.

BY

S. A. KINNIER WILSON, M.D., B.Sc., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE WESTMINSTER HOSPITAL AND TO THE
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC,
QUEEN SQUARE, LONDON.

THE knowledge we possess to-day of the finer anatomy and of the physiology of the nervous system has been attained only at the expense of years of controversy. If there is much land still to be possessed, that which is now our heritage has been systematically explored and surveyed till we would fain believe it is a country with familiar and unchanging landmarks. Yet this is far from being the case, and while it would be a simple matter to find illustrations of the truth of this statement from other sections of neurology, we need not look beyond the sympathetic nervous system, which forms the subject of my remarks to-day, for a demonstration that will serve our purpose.

During the greater part of last century the anatomy and physiology of the sympathetic system was a *Haupt-tunmelplatz* of neurological discussion, and it was only with the magistral researches of Gaskell and of Langley that order took the place of confusion and experimental data of empiricism. These English physiologists laid a scientific foundation for the study of the question, which remains unshaken, and their terminology has been accepted by the schools of other countries. As junior students of physiology we become familiar with the complex lore of vaso-constrictors and vaso dilators, and even now we may not have forgotten our quondam interest in the behaviour of the vessels of the rabbit's ear under varying experimental conditions: but as practitioners of medicine it may be questioned whether we concern ourselves much with the application of our hardly-gained knowledge to the common clinical phenomena of disease that must daily obtrude themselves upon us. A little thought will convince us that disturbances in the realm of the sympathetic nervous system are probably more frequent than any other class of morbid symptom, and even a slight acquaintance with their interpretation would stand us in good stead.

But our knowledge of the functions of the sympathetic system has been notably modified and enlarged by recent discoveries of importance. Advances that have been made in regard to the nature and physiology of the ductless glands have thrown a flood of light on the former, and this we cannot afford to ignore. We are compelled to regard the sympathetic nervous system from a fresh viewpoint: the main principles of its action must be restated, and it is no exaggeration to say the gain thereby to clinical medicine is bound to be far-reaching. This is one of the aspects of the question to which special attention will be directed.

Before entering on it, however, I may be allowed to remind you of the salient features of the sympathetic system, as established by the work of Langley and various other investigators.

ANATOMICAL AND PHYSIOLOGICAL CONSIDERATIONS.

The sympathetic system, embryologically, is directly derived from the cerebro-spinal nervous system. As early as the sixth week of fetal existence the general development of the sympathetic system is complete, in the sense that its essential features can be traced even at that stage. It may be said very briefly that the ganglion cells of the sympathetic issue from the mass of nerve elements forming the neural crest, that they migrate thence at differing times and rates, those of the thoracic region always being in advance of the cranial and lumbo-sacral regions, and that on reaching their approximate final positions they proliferate and clump themselves into ganglion formations. The processes of the cells elongate into fibrillae and so a communicating network of fibres is produced, extending centrally to the cerebro-spinal system and peripherally to viscera. A number of sympathetic

cells are left behind, however, in the cerebro-spinal axis, and later we shall see how the central connexions of the sympathetic will serve to explain the appearance of sympathetic phenomena in central lesions.

When full development is attained, the sympathetic system is found to consist of two divisions. The first is the sympathetic system proper, often called the vertebral sympathetic, consisting of the chain of ganglia of the cervical, dorsal, and lumbar regions. The cervical set is collected into three sympathetic ganglia, but in the case of the thoracic and lumbar there is a ganglion corresponding to each segment of the spinal cord. These ganglia are connected, on the one hand, with the spinal cord at their own levels, except that the central connexions of the cervical ganglia arise, not from the cervical cord, but by the first and second dorsal roots: and, on the other hand, from these ganglia fibres pass peripherally, as a rule through the medium of secondarily formed plexuses or ganglia, to all the viscera of the thoracic and abdominal cavities, to the vascular system, to the skin with its glands and other appendages, and to the pelvic viscera and genitalia.

The second division of the sympathetic is known as the parasympathetic, or, preferably, the autonomic system. At the cranial and caudal extremities of the cerebro-spinal axis are situated three sympathetic centres, two at the former and one at the latter. These centres are in the cerebro-spinal system, and from them sympathetic fibres pass out, again through the medium of intercalated ganglia, to all the viscera of the body, and to all the structures enumerated above as supplied by the vertebral sympathetic. In the case of the autonomic system there is only one set of ganglia, and they are to be found, as a rule, in the immediate vicinity of, or actually in, the organs innervated, whereas the vertebral sympathetic system, as has been said, possesses two sets—one the vertebral chain, and the other the plexuses, coeliac, splanchnic, and so on. In the case of the cervical sympathetic, however, there is only one set of ganglia on the path to the structures innervated by it.

The sympathetic nervous system, therefore, presents this remarkable feature—that it gives a double nerve supply to the skin and its appendages, the glands, vascular system, the alimentary system from mouth to rectum, and the respiratory system, and the importance of this fact will be the more appreciated when it is stated that there is much evidence forthcoming to show that the two divisions—the vertebral sympathetic and the autonomic—are mutually antagonistic in their function, as we shall see subsequently.

Let us look at the sympathetic and autonomic supply a little more closely. It should be premised that not all of the anatomical details about to be mentioned have been satisfactorily established, and there is difference of opinion on some not unimportant points. As far as is agreed on at present, it may be said that the arrangements are as follows:

The autonomic system has three centres, the mesencephalic, the bulbar, and the sacral, or lumbo-sacral. From the first of these pass autonomic fibres by the oculo-motor nerve and ciliary ganglion to the sphincter iridis, constricting the pupil in their action. The corresponding vertebral sympathetic supply, antagonistic in its function, is constituted by pupil-dilating fibres from the cervical sympathetic in the neck, reaching the eye by a circuitous route via the carotid plexus and the superior division of the fifth or trigeminal nerve.

The bulbar autonomic centre is formed by sympathetic cells in relation to the facial, glosso-pharyngeal, and vagus nerves. Connected with the first two of these are the fibres passing out to supply mucous and salivary glands, the blood vessels of the mucous membranes of mouth and nose, the lacrimal glands, and so on. These are antagonized by vertebral sympathetic fibres running in the cervical sympathetic and reaching the same distribution by the elaborate route already described. We may not have forgotten the differences between the autonomic "chorda saliva" and the "sympathetic saliva" of our student days. In the autonomic facial fibres, probably, are vaso-constrictors to vessels and sweat glands, in the cervical sympathetic are vaso-dilators, and so on. But I shall not particularize further, lest we should be unable to see the wood for the trees.

* Read at the quarterly meeting of the East Anglian Branch at Colchester and illustrated with lantern slides.

The vagus centre, however, deserves our attention because of its great clinical importance. There is reason to believe it is the dorsal nucleus of the vagus which forms the autonomic vagal centre, but we need not delay over this vexed question. The vagus supply is extraordinarily wide. It furnishes sympathetic fibres, belonging of course to the autonomic system, to the heart and blood vessels generally, to the alimentary tract from mouth to colon, to the liver, pancreas and kidneys, to larynx, trachea, bronchi and lungs; its branches go both to smooth, non-striped muscle fibres in these various vessels and viscera, and to glandular organs therein contained. The autonomic vagal action is antagonized in all these—again it must be remarked that this is a generalization the truth of which has not as yet been established in every instance—by vertebral sympathetic fibres supplying the same structures and arriving via the visceral plexuses. Thus, to take the best known instance, there are cardio-inhibitory fibres in the vagus and accelerating fibres in the sympathetic. Again, the vagus contracts and the vertebral sympathetic dilates the coronary vessels. The sympathetic contains the constrictors for the blood vessels, the vagus the dilators, if there are such. In the sympathetic are the fibres for the sweat glands of the body, probably stimulating and not inhibiting fibres. The sympathetic fibres relax the smooth muscle fibres of oesophagus, cardiac sphincter, and stomach; the vagal fibres contract them. The latter contract the gall bladder; the former relax it. And so on.

Finally, in the lumbo-sacral part of the spinal cord is the third autonomic centre, from which fibres pass to the vessels of the rectum, anus, and external genitalia—vaso-dilator in function. The vaso-constrictors to the same are in the vertebral sympathetic system. Again, the sacral autonomic supplies the muscles of the colon, rectum, anus, urethra, bladder, and external genitalia, being chiefly concerned with contraction, while the corresponding sympathetic fibres are chiefly concerned with relaxation.

THE CENTRAL CONNEXIONS OF THE SYMPATHETIC.

A further anatomical matter that ought not to be passed over is the question of the central connexions of the sympathetic. It has been shown that the vertebral sympathetic system is an outgrowth from the cerebro-spinal. The efferent fibres joining the two arise from a definite tract running the length of the spinal cord from the lowermost cervical region to the lumbar. This is known as the intermedio-lateral tract, and it is composed of cells, readily distinguishable from those of the anterior and posterior horns, which are situated at the lateral extremity of the grey matter, where anterior and posterior horns meet. The nerve cells of this tract rise and fall in number in a more or less regular way for each segment of the cord. From them pass out efferent sympathetic fibres to join the chain of sympathetic ganglia, travelling by the anterior roots, and leaving the latter by the white rami communicantes immediately after the formation of the mixed nerve.

Now, it is inconceivable that the spinal sympathetic tracts should have no connexion with higher centres, and although it has been doubted whether there can be cerebral centres for the functioning of vasomotor nerves, sweat glands, the alimentary tract, and so on, we do know as a matter of fact that the spinal tracts already referred to are in association with bulbar sympathetic centres—not the autonomic bulbar centre of which we have been speaking—whose existence has been demonstrated in a conclusive fashion. And why should the system not be represented in the cerebrum itself? We may admit that the sympathetic system is very little under the influence of the will, but it is notably under the influence of moods and emotions. Anger, fear, shame express themselves outwardly by obvious sympathetic disturbances—by pallor, blushing, perspiration, dryness of mucous membranes—to mention but a few of the symptoms which will occur to every one; and if we believe, as there is evidence to show we should believe, that the emotions are placed at least as high as the basal ganglia, then the bulbar sympathetic centres must be represented anatomically still further cerebralwards. I shall refer to clinical cases which appear to bear this out a little later.

The sympathetic system further resembles the cerebro-spinal system in that it possesses afferent—that is,

sensory—as well as motor, or efferent, connexions with the latter. There is excellent evidence forthcoming to prove that the viscera have a sensibility of their own, impulses underlying the appreciation of which are conveyed by afferent sympathetic fibres leaving the sympathetic chain and passing by the posterior roots to the spinal cord like any of the other sensory impulses. Normally we are quite unconscious of the functional activity of our organs, and this no doubt suggests that sympathetic afferent sensory impulses do not reach the brain and become conscious, or, rather, so that we become conscious of them. At the same time, we do well not to negate the possibility of such an occurrence.

It is of course well known, as I may venture to remind you, that in certain diseased states of viscera sensory impulses from them reaching the cord are ultimately interpreted by our consciousness as proceeding from the area of skin supplied by the ordinary spinal nerves running into the same segments of the cord as are reached by the abnormal sympathetic afferent impulses. Thus in angina pectoris the patient may have paraesthesiae apparently in the distribution over the skin of the inside of the left arm and hand. In gastric ulcer he may have hyperaesthesia over the skin of the upper abdomen on the left. Other instances will at once suggest themselves. These zones of referred pain have been carefully worked out by Head and others, and they are of localizing value. But that there is a possibility of actual sympathetic sensory impulses reaching consciousness in certain diseased states seems to me the only satisfactory explanation of some of the symptoms of neurasthenia and also of hysteria.

From what has been said it will appear that the sympathetic system is at once dependent on, and independent of, the cerebro-spinal system. Owing to the central connexions which the former possesses, there may develop obvious sympathetic symptoms in organic and functional disease of brain, spinal cord, or peripheral nerves. What of its possible independence?

We have seen that a very large part indeed of our somatic structure, our circulatory system, respiratory system, alimentary system, genito-urinary system, the skin, mucous membranes, glands, and so on, are as it were slung between the nerve supply of the autonomic system on the one side and the sympathetic on the other, and that these are mutually antagonistic. It may be concluded that the result is the constant maintenance of tone in these organs, a tone which is constantly varying, but which is not constituted by alternating periods of rest and unrest. There is always activity in function. Is it possible that sympathetic ganglia have an autonomous activity of their own, and that there is a peripheral independence in them not possessed by any of the organs reached by the cerebro-spinal system? It would appear to be not merely possible, but probable. There are short reflex arcs in certain hollow viscera the physiological activity of which appears to be independent of central connexions. The movements of the ureters, peristaltic action of the intestine, and the mechanism of the heart-beat, are illustrations in point. And while, as far as I know, a wider application of the principle has not been made, it seems possible that not a few of the phenomena seen in vasomotor neuroses, to take but one example, may be due to increase or decrease of peripheral sympathetic activity produced by morbid agents whose action is quite independent of the central representations of the sympathetic system.

SYMPATHETIC SYMPTOM-COMPLEXES.

Enough has been said to support my original contention, that disturbances in the realm of the sympathetic nervous system as a class of morbid symptom must confront us almost daily, and I should like now to sketch a few of the symptom-complexes, the significance of which can be understood at once by reference to the anatomical and physiological data we have been considering.

First of all, we shall look at the occurrence of obvious sympathetic symptoms in central cerebral lesions.

Reference has already been made to the familiar symptomatology of the expression of the emotions. Under the influence of an emotion we turn pale, we blush, we perspire, we shiver or shudder; under the influence of emotion the throat and buccal membranes of the public speaker become dry. Under emotion we experience a

"thrill" all over our body; our cheeks "tingle." All these clearly are somatic phenomena produced through the sympathetic system; the last is the pilomotor reflex, known no doubt to many of my audience.

Now it seems reasonable, if not indeed essential, to suppose that if these generalized somatic symptoms are produced, as they clearly are produced, through the agency of the autonomic and sympathetic system, then the vagus centre and the bulbar sympathetic centre must be capable of being acted on from higher levels. For the stimuli evoking the emotion pass in to the brain centres by such sense avenues as the visual or the auditory path, and the lowest point at which such sensory impulses could pass over from the afferent to the efferent side is in the mid-brain, which is definitely above the bulbar level of which we have been speaking. There must, therefore, be a higher representation of the sympathetic centres than the medulla, and there is evidence to show that this representation is at least as high as the basal ganglia, the optic thalamus and corpus striatum. I have seen an ordinary case of left hemiplegia of capsular origin in which there was a permanent "goose-skin" on the affected side of the body. I have seen another case of hemiplegia in which the affected limbs were the seat of a vasomotor paresis with oedema, and such cases are not really very uncommon. They are often met with in infantile cerebral hemiplegia. In such instances the lesion is certainly not lower than the pons, and is probably higher. It is patent, therefore, that both the autonomic and the vertebral sympathetic systems are centrally represented, and though this has been denied by one or two investigators it is difficult to set aside the evidence which has accumulated.

We are on surer ground when we come to the bulbar sympathetic centres, the centres in the medulla oblongata.

We may take the autonomic vagal centre first.

There is a definite symptom-complex associated with disturbance of the vagal centre to which it is well to direct special attention. The condition clinically is known to our American friends as a "nerve storm," and the description is not inapt. It is known also as pseudo-angina, cardiac neurasthenia, and under other designations, but the term which Sir William Gowers proposed, and which I much prefer to use, is "vaso-vagal attack." The attacks are usually periodic, often resembling epilepsy in their periodicity, and it is quite possible that in some instances, at least, they are of the nature of epileptiform discharges in these lower centres. Commencing as a rule with an epigastric aura, the attack rapidly develops into palpitation, forcible or racing cardiac action, sometimes almost cessation of the same, suffocation, and difficulty in respiration; with this the patient usually experiences an indescribably distressing feeling of impending death, or of impending misery of some sort; at the same time the extremities are as though of marble in their icy coldness, then to this may succeed clammy perspiration or burning flushes all over, and at the same time there is often trembling and quivering of the musculature. The attack may last a few minutes, or it may be drawn out over hours. It may be complete, after the description just given, or it may be very partial and incomplete. In either form the condition is far indeed from uncommon, and I have personally seen many instances of it. It is self-evident, I think, after what we have learnt, that the whole vaso-vagal attack is a pure symptom-complex of a functional disturbance in the vagal autonomic centre, and as such it ought to be known. Nothing is more desirable, more imperatively called for, than to pick such attacks out of the rubbish heap of neurasthenia, with which they are constantly confounded, for the treatment of the two entities differs widely. Of course such an attack may occur as an episodic syndrome in the course of another disease, as can be well understood, but in its pure and uncomplicated form it is frequently met with, even in young people, and has scarcely received the attention it deserves. Its treatment with nitro-glycerine, in any form, but especially the liquor trinitrini, is often strikingly successful.

Apart from the vagal autonomic centre in the medulla there is a sympathetic centre in its neighbourhood—almost certainly in the substantia reticularis—which is a bulbar representation of the vertebral sympathetic system, and anatomically in continuity with it, or at least with the cervical part of it. As a result of a lesion involving

this part of the medulla, an interesting series of sympathetic symptoms may develop of central origin. The region concerned is in the distribution of the posterior inferior cerebellar artery, which I may remind you is a branch of the vertebral and winds round the side of the medulla on its way to the cerebellum via the inferior cerebellar peduncle. As it winds round it sends in small terminal branches to the medulla, which penetrate its substance, and if the vessel is occluded from thrombosis—a not infrequent lesion—the area of the medulla supplied often suffers from ischaemia, and among the characteristic symptoms of this complex is paralysis of the cervical sympathetic nerve and loss of sweating on the face on one side.

When we come to the spinal cord, one of the common clinical pictures is that of irritation or of paralysis of the cervical sympathetic nerve, which arises from Budge's centre in the lateral horn of grey matter of the first and second dorsal segments, mainly, and passes out to follow that circuitous route in the neck and head to which reference has already been made. We have seen that there must be a continuation cerebralwards of this centre, for identically the same symptoms can be produced by a lesion of the posterior inferior cerebellar artery, as far as the cervical sympathetic is concerned, as by a lesion of the upper dorsal cord, or a lesion of the nerve trunk itself. The localizing value of paralysis of the cervical sympathetic is often precious. It reveals itself by a very clear-cut syndrome, consisting in ptosis, myosis, and enophthalmos, with or without vasomotor and sweat disturbances over the face and upper part of the trunk. A rare concomitant of cervical sympathetic palsy, which, however, has come under my notice at least three times, is heterochromia iridis, a pigmentary change taking place in the iris on the affected side. Stimulation or irritation of the cervical sympathetic naturally produces an opposite effect—namely, exophthalmos, widening of the palpebral aperture, and mydriasis. Sometimes almost the only sign of a commencing palsy from defect of this nerve path is failure of the pupil to dilate to shade. It is well worth remembering, also, that cocaine may be used as a test of the integrity of the cervical sympathetic; a drop instilled into the eye will cause the pupil to dilate only if the nerve be normal; atropin or homatropin is of no value in this connexion.

Many organic lesions of the spinal cord are accompanied by obvious vasomotor and trophic changes, which are to be regarded as due to implication of the intermedio-lateral tract. In compression paraplegia from whatever cause arising it is often possible to detect the level of the compression by the simple device of injecting pilocarpin, a sixth of a grain, and observing, adequate precautions having been taken to protect the skin surfaces with a cradle, whether the drug has failed to produce sweating in the lower limbs and up to a given level on the trunk. A valuable case of poliomyelitis has been recorded where after the onset there was complete anidrosis of the lower limbs, and at the necropsy a haemorrhage was found in each intermedio-lateral tract. The vasomotor symptoms that often accompany transverse myelitis, spinal tumour, and other spinal cord conditions that need not further be specified, find a ready explanation in involvement of the important intermedio-lateral tracts.

The symptomatology of organic disease of the thoracic and abdominal sympathetic system, outside of the cord, is not at all well known, and yet evidence is steadily accumulating which will help us some day to differentiate more clearly between the various ganglia and plexuses than we can at present. Of course, it is recognized that many of the familiar visceral crises of tabes are occasioned by organic disease of the sympathetic plexuses supplying the viscera in question. Again, the abdominal symptoms of lead colic may be the result of irritation of the solar plexus. A syndrome of the solar plexus has been described, consisting in hyperaemia of the abdominal viscera, vomiting, diarrhoea, oliguria, and general loss of strength. Certain forms of visceral neuralgia, to which attention has again been drawn recently, may be associated with affections of the coeliac plexus. The relation of mucous colitis, of many of the symptoms of acute peritonitis, of certain forms of angina pectoris, and certain acute pulmonary conditions—to mention but a few—to disease of the thoracic and abdominal sympathetic

plexuses is a chapter of clinical pathology that has yet to be written.

THE PHARMACOLOGICAL ASPECT OF THE SYMPATHETIC SYSTEM; RELATION TO DUCTLESS GLANDS.

We must leave this part of our subject, however, only the fringe of which has been touched, to pass on to a view of the whole question which is eminently calculated, with the aid of further research, to lead to most fertile results. I refer to what may be called the "pharmacological" aspect of the sympathetic system, and the relation of the function of the latter to the function of the ductless gland system.

To appreciate this new standpoint we must begin by alluding to what is now called the chromaphil or chromaffin system of gland cells. It has long been recognized that the cortex of the suprarenal gland is distinct from the medulla of the same. The medulla is constituted by cells which possess this peculiarity, that they stain deeply when soaked in the salts of chromic acid—for example, potassium bichromate—becoming a rich brown colour. So characteristic is this reaction that such cells can readily be picked out in this fashion whatever be their situation; hence the expression chromaffin, or better chromaphil, to signify them. Now these chromaphil cells are found in many other places beside the medulla of the suprarenals. From the embryological standpoint they are known to originate in the same situation or *Anlage* as the cells which eventually reach and form the sympathetic chain of ganglia. In fact, we may speak of sympatho-chromaphil tissue. In every ganglion of the chain, then, on each side, and mostly lying in depressions on the dorsal portions of these ganglia, are rounded masses of chromaphil tissue, of exactly the same nature as the medulla of the suprarenal. Further, there is an unpaired strand of this tissue lying on the front of the abdominal aorta, and known as the aortic body or paraganglion of Kolm. Then they are found not merely in the sympathetic ganglia, but as a constant occurrence in many of the sympathetic plexuses, and they have been traced in the kidney, ureter, accessory suprarenals, prostate, ovary and epididymis, and in the carotid bodies. In the chromaphil system, therefore, we have a widespread tissue, intimately allied to the sympathetic system in origin and localization, which not only presents the histological peculiarities already specified, but is endowed with equally important physiological properties. Chromaphil tissue secretes a substance which has a definite and characteristic action on non-striated muscle fibres—in other words, on structures which are innervated by the sympathetic system.

No modern drug is more familiar to the physician than adrenalin. The important point about it is that adrenalin, which is the product of the secretion of the suprarenal medulla—that is, is derived from the sympatho-chromaphil system—acts solely on tissues innervated by the sympathetic. This is a striking fact. What are the effects of injection of adrenalin, or preferably "adrenin," since adrenalin has commercial associations? It causes a rise of blood pressure; it dilates the pupil; it contracts the muscles of the hairs; it excites the salivary and lacrymal glands, the liver, the muscular tissue of the uterus and vagina, of the vas deferens, the vesiculae seminales, the dartos muscle, and the muscular coat of the stomach. In no case does extract of adrenal correspond in its effect to what is produced by stimulation of cranial or sacral autonomic nerves; on the other hand, its effects are such as are produced by stimulation of some one or other sympathetic nerve.

There is, therefore, normally present in the body a secreting system which is normally producing a secretion with a definite pharmacological action on sympathetically-innervated tissue, and this tissue is thereby kept in a normal state of tone. If the secretion is defective, there is loss of sympathetic tone; if it is excessive, there is a pathological increase in sympathetic tone. In fact, our German *conféres* are already speaking of sympathicotonus and vagotonus, although, so far as I am aware, the expressions are not as yet employed in this country. Further, they speak of "adrenalin sensibility" and are using injections of adrenalin as a test for the functioning of the sympathetic system. The clinical and therapeutic importance of these facts must be at once apparent to us.

The question arises as to how adrenin acts, whether on

sympathetic centres or on sympathetic end-mechanisms, It has been shown that it acts mainly on end-mechanisms, and that, further, there are substances which are antagonistic in their action to adrenin. For instance, adrenin has no special action for the autonomous system, as has already been pointed out. The autonomous system, however, is stimulated by cholin and analogous poisons and paralysed by atropin. The sympathetic system is indifferent both to cholin and atropin. It would appear, therefore, that in the body are normally found certain "poisons"—for example, cholin and adrenin—which have autonomous-exciting and sympathetic-exciting actions respectively, which are mutually antagonistic and can compensate one another.

But the matter does not end here. We know that other internally secreting glands are controlled by the same system—to mention only one, the thyroid. The thyroid is supplied with vaso-constrictor and vaso-dilator nerves; on these, whichever is the sympathetic group (for there are differences of opinion on this matter), the internal secretion of the chromaphil system, it may be assumed, has a stimulating action. Again, between the suprarenals and the pancreas there is undoubtedly a very intimate relation. It has been shown, for instance, that neither puncture diabetes nor pancreatic diabetes can occur after removal of the suprarenal bodies. It has been shown, further, that in pancreatic diabetes adrenalin dropped on the conjunctiva will dilate the pupil, whereas it will not dilate it in this way in the normal eye, although these experiments require confirmation.

It is undesirable, however, though it would be easy, to amplify these interesting and difficult topics. I may recapitulate in a sentence and say that a substance normally secreted by the adrenal medulla passes into the general circulation and maintains the tone of all sympathetically-innervated tissue, including other ductless glands. The cells which secrete this substance are embryologically of sympathetic origin. Other substances are produced in the organism which have an antagonizing, neutralizing, or compensating effect when compared with that of the adrenal secretion, and they act rather on the autonomous system. Similarly, many commonly employed therapeutic agents have an action on one or other of these groups. Cocaine, atropine, caffeine, stimulate the sympathetic system and inhibit the autonomic system. Morphine, chloral, antipyrin inhibit the sympathetic system and stimulate the autonomic system.

APPLICATION OF PHYSIOLOGICAL FINDINGS TO CLINICAL MEDICINE.

The linking up of the sympathetic system and the ductless gland system is already proving to be a most important generalization in clinical medicine, and with increasing knowledge this importance will assuredly be intensified. There is a large group of diseases known as the angio-neuroses, included in which category are such conditions as Raynaud's disease in mild or severe variety, local pallor or "dead finger," local asphyxia, symmetrical gangrene, acroparaesthesia, sclerodermia, angioneurotic oedema, and so on—diseases obviously associated with disturbances of the sympathetic innervation of the vascular system. Now the frequency with which affections of one or other of the ductless glands are noted in such cases is remarkable. Disease of the thyroid is practically constant in sclerodermia. Myxoedematous patients constantly complain of feeling cold, and exhibit a malar flush; they often complain of acroparaesthesia. In Graves's disease vasomotor irritability is a cardinal feature. In fact vasomotor neuroses and disturbance of functions of other sympathetically-innervated tissue is an association that is no more than might be expected in view of what has been already said.

Again, many of the common symptoms of neurasthenia and hysteria are patently of sympathetic origin. Who of us has not seen the typical irregular red blotches appear on the skin of the neck and face as the neurasthenic subject "works himself up into a state"? The clammy hand, flushed or pallid features, dilated pupils, the innumerable paraesthesiae, the unwanted sensations in head or body, are surely of sympathetic parentage. In not a few cases of neurasthenia symptoms of this class are the chief or only manifestation of the disease. Here, then, is a condition of defective sympathicotonus; may it not have

much to do with impairment of function of the chromophil system? Addison's disease, for all its continued obscurity, may be regarded as at least to a great extent attributable to disease of the suprarenals. One of its characteristic features is asthenia, which is sometimes profound. And there does not appear to me any tenable distinction between the asthenia of Addison's disease and the asthenia of neurasthenia. Cases of the former are not infrequently diagnosed as ordinary neurasthenia at first. It is difficult to avoid the conclusion that defect of glandular function is responsible for much in the clinical picture of neurasthenia.

In the familiar symptoms of the climacteric how prominent are those which are derived from the sympathetic system. Palpitation, noises in the ears, "rush of blood to the head," hot and cold feelings, mist before the eyes, sweating, trembling, paraesthesiae of all sorts, sinking feelings, vertigo—who does not know the whole gamut of climacteric symptomatology? Analysis indicates at once the sympathetic origin of practically all of it, but why should this branch of the nervous system be disturbed? The answer is ready to hand. At the climacteric a physiological involution of glandular activity occurs, ovarian function alters, and thereby the function of other glands is thrown out of gear. Sympathetic tone is dependent on adrenal support, and until the glandular equilibrium is once more attained sympathetic symptoms are likely to occur. Let it not be supposed that the male sex is free from such glandular upset. The age of 63 was regarded by those of another generation as the crucial year for the male; but it is not necessary to postulate an actual climacteric—it suffices that the physician should be able to interpret the symptoms complained of in the light of what has been said.

The protean phenomena of hysteria can in many instances be readily explained by reference to sympathetic function. Not only are vasomotor symptoms of very common occurrence in that disease, but a vasomotor theory has even been advanced to account for the whole symptomatology. It is impossible, obviously, to subscribe to such a view; at the same time the tendency to-day is to ignore the somatic symptoms of the disease, especially those of vasomotor origin—a tendency which should, in my opinion, be discontinued. In hysterical paraplegia one often finds a vasomotor paresis; in hysterical anaesthesia failure to draw blood on pricking the skin is as easy to demonstrate to-day as it was 300 years ago. The results of such a failure, however, are not quite so serious from the patient's point of view as they were in the "good old days." In some cases of hysteria multiple cutaneous gangrene, so-called, is known to occur, and I have seen a case where the diagnosis of a somewhat simular skin condition was attended with the greatest difficulty. Dermatographia or urticaria scripta, no doubt, occurs as a more or less isolated phenomenon, yet in hysteria, above all other conditions, it is seen in marked degree.

The pathogenesis of the sympathetic impairment in hysteria is not easily elucidated. This is not the time to venture even on a brief attempt to sketch an adequate theory of hysteria, but I may remark that the occurrence of unmistakable sympathetic symptoms in that disease argues for the central representation of the sympathetic system, and the central control, in certain not yet clear conditions, of the ramifications of that system in viscera and blood vessels.

Many more conditions might be referred to in this connexion. I have said nothing of asthma, of migraine, even of transient symptoms which can scarcely be said to constitute a disease, such as blushing, local sweating, etc., although it may be remarked that in these and other morbid states of a like kind good results are being obtained by treatment on opotherapeutic lines. I have given only a brief account of some of the chief features of interest revealed by a study of the sympathetic system and its relations, but it may serve to show that the fresh light which is being thrown on sympathetic function by recent investigations exemplifies once more the mutual interdependence of scientific research and medical practice.

THE late Mr. Charles George Lee, Honorary Surgeon, Liverpool Eye and Ear Infirmary, left estate valued at £7,638.

VARIETIES AND TREATMENT OF CHOREA.*

BY

FREDERICK LANGMEAD, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, TO THE ROYAL EYEB HOSPITAL, AND TO THE SEAMAN'S HOSPITAL, GREENWICH.

CHOREA is insidious in its onset. The child who becomes the subject of chorea is usually nervous, excitable, and imaginative. She is easily frightened. At school, though by no means a dunce, she lacks concentration of thought and perseverance. Her attention wanders from the work to the creations of her active mind. It is easily diverted by all manner of extraneous and trivial circumstances.

Chorea begins as an accentuation of this psychical unrest. Before the actual movements appear the patient becomes more excitable, more irritable, more emotional, and less reliable. The distinction between when the mental state should be called choreic and when it should be regarded merely as evidence of a neurotic disposition is subtle. There are some who look on the many symptoms of nervous instability to which choreic children are liable as evidence of a rheumatic toxæmia, whilst others speak of chorea as especially prone to attack neurotic children. A compromise between these opinions is probably nearer the truth, for, if we accept the former view, we must acknowledge a persistent rheumatic toxæmia dating from very early life, whilst if we ignore it we shut our eyes to the very obvious psychical disturbances which a definite attack of chorea brings with it.

As evidence of the ill-balanced and hyper-excitement mental state is the frequent occurrence in the history of the same child of such functional errors as night terrors or day terrors, somnambulism, enuresis, nervous diarrhoea, and tic.

Long before the chorea is recognizable by its erratic movements the child's school work deteriorates. It becomes inaccurate, slovenly, and uneven. Perhaps this is best shown in writing and arithmetic. The letters and figures are badly formed, irregular and wavy, crowded in some places, spaced in others, and sloping at various angles. This falling off is readily detected by the teacher, who metes out punishment which he believes to be condign, but which is, of course, unmerited, and may precipitate symptoms of a more obvious form. The attack is then not unnaturally laid by the parents at the teacher's door.

Forms.

In almost every case, in addition to the erratic pseudo-purposive movements and the psychical changes, there are also some loss of power and some sign of cardiac affection. The loss of power is denoted by the characteristic crouching attitude when the child sits up, due to weakness of the back muscles and those which hold the head erect. The grip is feeble, and there is atony of the muscles and laxity of joints. The signs found by examination of the heart in many cases are merely those which may accompany functional disturbance—rapidity, a short, sharp, and rather slapping first sound, approximation of these sounds, and sometimes irregularity. A slight systolic murmur and slight dilatation may be present, and probably indicate a local rheumatic toxæmia or infection, especially if a mid-diastolic murmur or so-called reduplicated second sound are heard at the apex. In many cases signs of previous valvular disease are found.

The mental state when the chorea is readily recognizable is usually ill-balanced and the emotions are beyond control. It has been aptly likened to April weather, sunshine and shower alternating in quick succession. Tears flow as part of real distress for which there is no adequate reason or perhaps no reason at all.

Each of these four factors which contribute to the clinical picture of chorea—namely, erratic movements, psychical disturbance, weakness, and cardiac changes—may be exaggerated, so that it assumes the dominant part, and in this way four chief forms occur: (1) Motor, (2) maniacal, (3) paralytic, (4) cardiac, to which two other forms may be added, (5) latent, and (6) residual.

In the motor form the movements take the chief place,

* Based on a lecture delivered at the Hospital for Sick Children, Great Ormond Street.

and may be so severe that the child is unable to sleep or feed, and is in danger of death from exhaustion.

In the *manic* form the child is seriously ill and has all the appearance of one suffering from severe toxæmia. The temperature, which is usually only slightly raised in chorea, may in this form reach 105° or higher, and often remits from 102° to 99°. Sores are present on the lips, the tongue is coated, dry, and sometimes fissured. Hallucinations are not uncommon and the patient exhibits a considerable degree of mental distress, crying and moaning in bouts and howling in a manner reminiscent of a caged animal. A feature of these cases, which so far as I know has not attracted attention, is a dry, harsh, scaly skin, especially of the hands, which are often sore and cracked. The prognosis is usually favourable in spite of the alarming nature of the symptoms. Permanent mental derangement is very exceptional. Usually when the violence of the toxæmia is over the child recovers fairly rapidly, and the chorea is ended more quickly than in the more chronic and milder varieties.

The *paralytic* form usually supervenes upon one in which the movements have been active. Its most striking feature is the extreme atony of the voluntary muscles. On palpation they feel soft and almost downy, an attribute which has given origin to the term *chorea mollis*, by which this form is sometimes known. If the patient be taken out of bed the head falls back entirely unsupported and the limbs fall down as though lifeless. Grimacing and slight twitching of the limbs can still be seen. Generally the pupils are dilated and react feebly to light. The knee-jerks are lost in most cases. A special characteristic, more in evidence in this form than in others, is aphasia. For weeks, even for months, no attempt is made to speak. Motions and urine are passed incontinently, probably rather because the child is unable either by speech or gesture to signify its needs than from actual sphincter weakness. In spite of the apathetic state, of the aphasia, and of the incontinence, there is little or no dulling of the mind, for when the child is better it will be found that she remembers what has been going on under her observation, even to the minutest details. Such cases are always protracted and convalescence is slow, but ultimately, perhaps after several months, complete recovery occurs.

The term "*cardiac form*" has been applied to those cases in which the heart is seriously affected, whilst the signs of chorea are proportionately slight. Pericarditis, myocarditis, and endocarditis may each or severally accompany chorea, but they should more properly be regarded not as chorea of the heart but as indications of rheumatic heart disease. It is doubtful whether true chorea cordis is ever so obvious as to justify us in naming a special form of chorea after it. Indeed, some have denied its existence, and regard all cardiac signs in chorea as due to local infection or intoxication by the rheumatic organism.

Latent chorea especially deserves attention, for it is a form of the disease which is little recognized and frequently overlooked. Moreover, it is important, for coincident with it serious crippling of the heart may be in course of development. This is more particularly true of mitral stenosis, as Dr. Poynton has recently indicated.

It is diagnosed by regarding unconsidered trifles. Slight fidgetiness and mild psychical unrest, with deterioration of school work, especially in writing and arithmetic, and a weakened mental concentration may be the only indications of chorea. The diagnosis is assisted by signs of mild rheumatism other than chorea, signs which taken alone carry little conviction, but when considered together, indicate a smouldering rheumatic infection. Such are epigastric pain, growing pains, epistaxis, anaemia, and recurrent tonsillitis.

In this respect the *ocular phenomena* which I have described afford, I think, considerable help. The pupils are frequently dilated in chorea, and the action of the iris muscle is abnormal. Perhaps the most striking pupillary sign is hippus or a rhythmical contraction and dilatation. Not infrequently the pupils are unequal, an inequality which increases when contraction is induced by light or accommodation, the iris in the more dilated eye reacting more sluggishly than its fellow. When the choreic attack is over the pupils again become equal in size and activity.

Alteration in the shape of the pupils may occur. Thus the usual circular orifice may become oval or irregular, to regain its normal shape when the attack has subsided. Lastly, its position may be altered so that it becomes eccentric, and on contraction this eccentricity is increased, the pupil usually travelling upwards and inwards. The only explanation I can give for these various phenomena is that the iris muscle shares with other muscles inco-ordinate movements, paresis and atony. In such a case the heart's action is often rapid and may be irregular, whilst dilatation and murmurs generally appear sooner or later. As has already been mentioned, a mid-diastolic murmur is likely to be heard. Such a murmur often indicates the advent of mitral stenosis, being gradually replaced by one presystolic in time and rough and rumbling in quality.

Residual chorea is the name given to a condition which persists, sometimes for several weeks after the disease has ceased to be active. It may have all the features of latent chorea. Indeed, in such cases it is really a form of latent chorea, for, in spite of the absence of active signs of the disease, the heart may become steadily more affected, showing that the rheumatic infection is still smouldering on, although its virulence has diminished. In other cases the movements become automatic, so that those characteristic of chorea persist although the disease proper is over. In yet others the child lies almost motionless and aphasic, though generally still grimacing slightly.

Treatment.

A very astute physician, so I have been told, once said that one of the most dangerous attributes of chorea is its treatment. While it is active, rest both to body and mind is essential. All occasion for excitement or fear should be carefully avoided. It is common knowledge that such events as a birthday party or a Christmas tree are followed not infrequently by an accentuation of the symptoms. In hospital in all but the mildest cases recovery is quicker if the child be screened off from the others in the ward. Where the movements are severe enough to cause the child to hit and bruise herself against the side of the cot it must be suitably padded.

The food need not be restricted in any way, for an ample diet is required to supply the loss of energy, which may be very considerable. In cases of difficult mastication and swallowing, semi-solid foods will usually be found the most satisfactory. In quite exceptional cases oesophageal or nasal feeding may be necessary.

During the time in which I was Medical Registrar at this hospital I had an exceptional opportunity of judging the respective merits of some of the most lauded drugs employed in chorea. In one ward large doses of sodium salicylate were used; in another arsenic was pushed; in a third—in most cases—no drug was administered. Though watching these cases for a considerable time, I was unable to assure myself that progress was quicker or more sustained in one ward than another.

Sodium salicylate, however, has a special sphere of usefulness in this condition, for although its effect on the chorea itself may be unconvincing it strikes at the root of the matter. Chorea I believe to be always rheumatic, at least in part, and therefore I always administer sodium salicylate lest fresh rheumatic manifestations develop which might thus be avoided. If there is any rise of temperature the use of salicylate seems to me imperatively to be called for. I cannot altogether follow my respected teacher Dr. Lees, who gives as much as 400 to 500 grains daily, and has given even more, for I am not sure that such doses do more good than those which are smaller (10 to 20 grains three times daily). On the other hand, his cases show that there are no grounds for that fear of the cardiac depressant effect of salicylates which is so generally entertained. There are a few important points to be remembered when salicylates are given to children. It is essential that before the treatment is started the bowels should be opened freely, and it is a good rule before increasing the dose to be sure that an evacuation has taken place during the preceding twelve hours.

The ill effects of the drug which are most to be feared are those of acid intoxication. Vomiting is succeeded by drowsiness, which if untreated leads to air-hunger and coma. The breath smells of acetone, and acetone is found in the urine. A few deaths have occurred. Such a catastrophe may be avoided if the bowels are not

allowed to be constipated and if sodium bicarbonate is administered at the same time in double the amount. With the onset of acetoneuria, vomiting, or drowsiness the salicylate should be stopped temporarily. I have been able to collect twelve cases of acid intoxication following the administration of salicylates, and in every one constipation had been present.

Arsenic, in spite of its general employment, ought not to be recommended, in my opinion. Its good effects are difficult to see, but its bad effects are occasionally only too obvious. Severe gastritis is apt to be set up, and not a few cases of arsenical neuritis have followed.

The good results claimed for ergot by Dr. Eustace Smith have not been obtained by most other physicians.

Sedatives such as trional, chloral, bromides, sulphonal, and chloretone are widely used. Of these sulphonal is far too dangerous a drug to employ in this condition. Chloretone is sometimes useful in doses of from 3 to 5 grains thrice daily; but, although it has only been used extensively for a few years, already cases of poisoning have been noted. To obtain sleep in maniacal or very restless forms of chorea, chloral and bromides are valuable, especially if combined with a warm pack.

After-treatment is important. When the chorea is no longer active, the child often remains apathetic, scarcely moving in bed, and occasionally refusing to speak. Good co-ordination may not be re-established for several weeks. Power is still feeble. In such cases absolute rest is no longer indicated, and does more harm than good. Massage and easy exercises should be employed, and the child should be encouraged to test her powers of motion and speech.

While still in bed such easy re-education exercises as touching the nose, apposing the fingers of the two hands individually, making figures or houses with bricks or dominoes, and playing draughts, are all useful. Later, the cribbage board supplies a more difficult exercise, the patient being instructed to put the peg into particular holes—for example, into every second or fifth. Still more exacting is the building of card houses. The legs may be re-educated to perform co-ordinate movement in a similar manner. The following exercise is useful to begin with: Heel to toe, heel to shin, heel to knee, done first with one leg, then the other. Fraenkel's boards may be used when co-ordination has begun to improve. When the patient gets up the leg movements may be corrected still more by encouraging her to walk on a certain plank or along a straight line, or on a particular part of the pattern of the carpet. By such simple devices as these recovery may be hastened considerably.

ON AVOIDABLE DIFFICULTIES IN THE HAND-FEEDING OF INFANTS.

By EUSTACE SMITH, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

So much has been written on the subject of infant feeding that it seems almost to require an apology from any one who ventures to add another to the many contributions which are made on this subject. The comparative values of raw milk and sterilized milk, of whole milk and milk diluted, of the various proprietary foods, of the usefulness of added sugar and cream—all these matters are discussed and rediscussed, and not without benefit to the reader, for the results of a man's own personal experience can never be anything but welcome. One cannot, however, avoid remarking that the writers, ably as they descant upon their several views, rarely ask themselves why it is that the infant should so often show a helpless incapacity to digest the food provided for him however skilfully this may be chosen, or however carefully it may be prepared.

Now the majority of children at birth are healthy and fairly vigorous, and a healthy normal child has a digestive capacity which as a rule adapts itself readily to a food chosen with judgement—that is, with due regard to the age of the infant and the probable competency of its stomach. If the child give trouble and show signs of acidity and flatulence, it does so in most cases because the digestive organs are already in a state of derange-

ment. We must remember that a newborn baby is suddenly transported from a temperature of 100° F. in which he has grown and developed, to a temperature of 65° or 70°. This is its first shock: an abrupt drop of 30° or more in the warmth of its surroundings. The child is then, after more or less delay, bathed—often very leisurely; dried slowly, and afterwards laid quite uncovered upon his nurse's lap while she attends to the navel and sews on a flannel bandage. The exposure of the sensitive body during all this time, with little or no protection, to a temperature 30° below that to which it has been accustomed must constitute a second shock of no little severity. Many vigorous infants, no doubt, bear this exposure without obvious signs of injury, and if fed with discretion, especially if they have the advantage of a nurse's or mother's breast, give little trouble to their attendants. On the other hand, infants of low resisting power often by this means contract a serious chill which at once disorders the stomach and causes them to digest with difficulty even their mother's milk. They vomit after taking the breast or show signs of flatulence and discomfort, so that the mother, after a short trial, is instructed by her medical adviser to give up all idea of nursing, from the mistaken notion that her milk is unsuited to her child. If brought up by hand and fed from a bottle, such infants suffer still more urgently from vomiting, flatulence, and abdominal pain. For all this trouble the food chosen is generally held to be accountable, and change after change is made in the hope of hitting upon something which will be welcome to the stomach and put an end to the distressing symptoms, quite regardless of the fact that while the derangement persists no food can be expected to agree. If now the real nature of the difficulty be recognized and proper steps are taken, the signs of uneasiness begin to abate and finally disappear, for as the catarrh subsides the digestive processes recover their normal vigour. In that case the food last experimented with gets the whole credit of the improvement. But if the treatment be injudicious or incomplete, if the proper steps are not taken to avoid unnecessary exposure and protect the infant from further chills, the disorder of the stomach not only remains unrelieved but suffers almost daily a fresh impulse, so that that which was in the beginning a merely temporary upset becomes a confirmed disorder which drugs and changes of diet alone have little power to correct. It is only by attention to the simple cause of the trouble that we can have any hope of bringing the child's organs into a more manageable state and paving the way for his eventual recovery. Any one who examines an infant suffering from obstinate marasmus of this purely functional character will commonly find the feet icily cold, and probably the legs and thighs as well nearly as high as the hips. It is impossible that with such a condition of the circulation a child's digestive energies can be anything but unsatisfactory, and it is hopeless to expect an improvement as long as this state of things is allowed to continue.

It is by no means for the first time that I urge this vital matter upon the notice of the profession; but I find it very difficult to gain for it the attention it deserves. In spite of the consideration, which no one would venture to dispute, that to ensure completeness of digestion we must have healthy digestive organs to work upon, the means by which soundness of these organs is to be determined and maintained are too often completely ignored. The family practitioner is too apt to regard such domestic matters as washing, clothing, and nursery management in general as lying outside his province, to be left without hesitation or inquiry to the discretion of the child's mother or nurse. In some cases, no doubt, this can be done without risk of harm; but it is not every nurse, or even every mother, who is intelligent, careful, and accurate, and whose reports can be accepted as strictly in accordance with the facts. Without any intention to deceive, very wrong impressions may be conveyed; for loose thinkers are often poor observers, whose statements of fact must be received with caution, and only accepted if confirmed. Such persons are far too ready to mistake assumptions for realities, and to declare that to be right which they do not certainly know to be wrong. I should find it very difficult to say how often I have been told that an infant's feet were quite warm when the application of my hand has shown me that they were the exact contrary. I submit, then,

that care in these matters is as important—is even more important—than the choice of a food; and that a practitioner who neglects them is doing only half his duty, and is, moreover, setting up obstacles in his own path, and unwittingly creating difficulties which more prudent conduct would avoid.

I have ventured elsewhere¹ to formulate three simple rules for the hand-feeding of infants. These if carefully observed would, I am sure, make the rearing of bottle-fed infants a far easier matter than it often proves to be. I have no desire to claim any novelty for these rules, unless, indeed, it be new to bring simple reason and common sense to bear upon our task, taking account only of plain facts and leaving theoretical considerations on one side.

The first rule is directed to the maintaining of the warmth of the surface and the avoidance of chills from exposure:

1. Take care that the infant is bathed as quickly as possible in hot water, and that his feet and legs are never allowed to get cold.

The second rule aims at encouraging the digestive processes by variety of flavour in the food. This is a matter of great importance to hand-fed babies, especially to those whose digestive deficiencies have already been a cause of anxiety. An infant, it is true, will digest his mother's milk morning, noon, and night, and want no change. He is taking his natural food which his healthy organs are specially constructed to digest, and he draws it straight from the gland, fresh, pure, and uncontaminated by noxious germs. A hand-fed baby, on the contrary, whose food is only something like that provided by Nature, and is often far from pure, is apt to resent the monotony of his artificial diet. In any case, his stomach should have every advantage we can give it, and we learn from ourselves that variety in diet is an active aid to normal digestion. Therefore:

2. See that a sufficient variety of flavour is contained in the several meals.

It will usually be sufficient to give two differently tasting foods alternately in the day and a third for the night. In exceptional cases, however, a greater variety than this is required.

The third rule relates to cleanliness, etc.:

3. See that the feeding apparatus is absolutely clean, the food fresh, and the sanitary arrangements generally in good order.

Milk should be kept outside the living room; cream is only to be used when quite fresh; foods are not to be allowed to stand for hours after being mixed; and highly perishable articles such as whey, barley water, etc., must be made fresh and fresh as required. At any rate, whey is not to be depended upon after four hours nor barley water after six.

These rules, as I have said, are nothing more than reasonable precautions, and any thoughtful person might frame them for himself. I believe the neglect of them—and that the first two are continually neglected no practical physician would venture to deny—is due to the attention of the family medical adviser being too entirely engrossed with the conflicting claims of the legion of foods, digestives, and modified milks which are pressed upon his notice; and also, and perhaps chiefly, to his feeling that the nursery arrangements are none of his business, and must be left to the attention of the person who is responsible for them. Experience has, however, shown me that this is leaning upon a very feeble support, too apt to fail us at our need. In any case, it does not absolve the medical attendant from the duty of himself keeping an eye on these matters, for I think I am quite within the mark when I say that more than half of the cases where difficulties arise in the course of hand-feeding—cases in which the infant digests with difficulty, frequently vomits, and suffers continually from flatulence and discomfort—are due solely to breaches of the above rules. Owing to neglect of these precautions many young children contract a catarrh during the first few weeks or even the first few days of their lives. This mishap may so heighten their susceptibility as to be a cause, not only of serious trouble during the first twelve months, but of much anxiety for years afterwards. In every case of

difficulty in the bottle feeding of an infant the practitioner should personally look into the conditions in which the child is being brought up, and do his best to remedy without delay any carelessness or neglect in the nursery. By this means he will be far more likely to bring about the result he desires than by any ingenuity he may show in devising a food, or care in prescribing the exact proportions of casein, sugar, and cream to be allotted to the several meals.

ORAL SEPSIS IN GENERAL PRACTICE.

By ARTHUR MILLS, M.D.,

KINGSKETTLE, PIPE.

Soon after starting practice in this country district in Fifeshire I became impressed with the number of patients who sought my advice and who were suffering from what at first sight appeared to be a marked degree of anaemia. These patients were most frequently women, but, as a rule, considerably over the age that one associates with chlorosis. Their complaints were various in character, but usually referred to a disordered state of the digestive organs, want of appetite, flatulence, pain, and sometimes vomiting. Occasionally they volunteered the information that they had frequent "bilious attacks," or that they "suffered from their liver." On the other hand, the symptoms complained of were not infrequently those which could be more easily attributed to their apparently anaemic condition, namely, breathlessness on exertion, weakness, giddiness, and palpitation. Constipation was the rule in these cases, but rarely a very urgent symptom, and once or twice an attack of diarrhoea was the immediate cause of my being consulted. The one feature which led me to group these patients together as being of one type was the very evident pallor of the face and mucous membranes. The face had a pasty-white appearance quite unlike chlorosis, and the mucous membranes were decidedly pale.

At first my efforts in the way of treatment of these patients were directed to relieving the stomach symptoms with suitable drugs and diet, regulating the bowels, and then administering iron, the idea, of course, being to improve the blood condition, which I believed then to be the true cause of their trouble. The stomach symptoms were frequently relieved for the time being, but the blood condition appeared to be affected very little, and sooner or later the patient returned to repeat the story. All this was in marked contrast to the behaviour of a typical case of chlorosis which I treated about this time in the usual manner. The foul odour of the breath in one of these cases led me to make a more careful examination of the mouth than usual. I found that the patient had a large number of decayed stumps, that the gums were swollen and red, that they bled easily on pressure, and that pus could easily be expressed from between tooth and gum, in many places. I persuaded this patient to have her decayed stumps removed, ordered her a mouth wash of hydrogen peroxide, recommended the frequent use of a toothbrush, and afterwards prescribed iron in the usual manner. She made a rapid and complete recovery. Similar cases, and others where the condition of the mouth was by no means so evidently bad, responded equally well to this treatment.

According to Dr. William Hunter, the credit of having recognized the fact that indigestion may be caused by a foul condition of the mouth belongs to Professor Miller; but Dr. Hunter himself appears to have been the first to emphasize the importance of septic conditions in the mouth as a cause of disease.¹ He originated the name "oral sepsis," intending it to cover not only pyorrhoea alveolaris, which is only one (and a comparatively rare one) of a large number of possible pathological conditions in the mouth, but "every other form of trouble, dental and oral, producible by septic infection for which an appropriate adjective can be found," the essential feature of all being that they are produced by pus organisms.² It is in this sense that the term "oral sepsis" is now used, and it covers, amongst others, all such common conditions as dental caries, stomatitis (numerous forms), gingivitis, alveolar abscess, and pyorrhoea alveolaris.

Although there has been a tendency to attach more and more importance to this subject within recent years, yet modern textbooks of medicine devote little or no space to it, and it is probable that the general practitioner does not yet value oral sepsis at its true worth as a direct and indirect cause of many disorders and ailments which he is called upon to treat.

I have kept a record for the past four years of all those patients who have come under my care and in whom this condition appeared to have a direct bearing upon the case. They number 80—61 females and 19 males—and are of all ages between 7 and 70. Many of the commonest forms of oral sepsis appear to be quite frequently unaccompanied by any degree of pain, and it is of interest to note that of these 80 patients only 8 came to me with the condition of the mouth as their complaint.

The cases can be conveniently arranged into groups.

GROUP I.—*Oral Sepsis associated with "Indigestion" and Symptoms suggesting Anaemia.*

This group comprises 36 cases—27 females and 9 males. Want of appetite, pain in the stomach, flatulence, irregular attacks of vomiting—known in this district as "bilious attacks"—lassitude, breathlessness, giddiness, palpitation, were the most frequent complaints of these patients. All without exception were sallow and anaemic in appearance; 12 were young women between the ages of 19 and 25, and in each of these 12 cases a rapid and complete recovery took place after due attention had been paid to the septic condition of the mouth. Iron was administered in the majority of instances, but in 4 cases at least recovery followed without its use, and to all appearances as quickly and as completely. The remaining 24 of this group ranged in age between 25 and 70. Recovery in these cases, though not so rapid, was also the rule. It appears to be more difficult to persuade these older patients to submit to the necessary treatment. Many become recalcitrant to a low level of health, and accept weakness and lassitude, "indigestion," and a frequent "bilious attack" as part of their destined lot; 10 of these 24 are of this description and remain untreated.

GROUP II.—*Oral Sepsis and Disorders of Menstruation.*

The following are notes on 6 cases in this group:

(a) Did not menstruate till the age of 16. She had been systematically dosed with iron from the age of 14½ onwards. Menstruation started six weeks after the mouth condition had been treated.

(b) Menstruation started at the age of 17, three months after the treatment of her oral sepsis. She had also been treated with iron for long periods previously.

(c) First menstruated at 20, over a year after some attempt had been made to deal with the mouth. The menstrual periods are still very irregular and a recent examination of the mouth disclosed three or four decayed stumps, surrounded by soft red gum discharging pus, and an extremely dirty tooth plate.

(d) Age now 23, menstruated at 14, and for a few years was quite regular and had little discomfort. About three years ago began to suffer from pain, sickness, and vomiting for one or two days at each period. She also lost her appetite and suffered from an occasional "bilious attack." Her periods have now become very irregular, and she frequently misses five, six, or seven weeks. There is a perfectly clear history in this case of marked oral sepsis from the age of 16 onwards. Her pallor is very striking. She has taken iron on different occasions for three months at a time with no appreciable effect.

(e) Menstruated first at 15½. Her periods were then very irregular and she had frequent attacks of sickness and vomiting and the appetite was poor. She had five months' amenorrhoea at the end of 1911 and beginning of 1912, at which time she had a chronic alveolar abscess. The whole of the upper teeth, which were extremely bad, were removed; her periods immediately returned and the dyspepsia ceased. She came to me again on November 1st, 1912, complaining that she had again missed five and seven weeks and that a fortnight before she had had an attack of sickness and vomiting. She had numerous decayed stumps in the lower jaw. These were removed on November 3rd. She menstruated on November 14th (nine weeks after her previous period) and subsequently on December 16th, and then middle of January, and there is now no complaint of "indigestion." This patient also suffered from interesting symptoms of arthritis, described in the appropriate group.

(f) Well-marked oral sepsis. She did not menstruate till she reached the age of 19. In this case the mouth was not treated. Dosing with iron, however, had no effect whatever, as she had had no iron for six months previous to the onset of menstruation.

GROUP III.—*Oral Sepsis and Vomiting in Pregnancy.*

The notes of the 3 cases in this group are as follows:

(a) Mouth untreated; suffered for five months from incessant sickness and vomiting, and was confined to bed for two months previous to her labour.

(b) I was called repeatedly to see this patient in the early months of pregnancy, as she was suffering from persistent vomiting. Most of the usual remedies were tried with no effect. Removal of septic stumps, and the frequent use of a mouth wash was followed in a week by almost complete relief. At the end of another week she was perfectly well. She had then completed the fourth month, however, when some amelioration in her condition might naturally have been expected.

(c) Consulted me when she had been seven weeks pregnant. She complained of constant vomiting for the previous four weeks, growing worse every day, and said that she could not retain even a mouthful of water. She was extremely anxious not to take to bed. Her mouth was in a filthy condition. I immediately removed twelve teeth and several stumps. The roots of one or two molars were fringed with foul smelling granulations. She was also ordered the frequent use of a mouth wash. At the end of one week there was well-marked improvement, and thereafter she suffered only from a little sickness in the mornings. The morning sickness ceased at the end of the third month.

GROUP IV.—*Oral Sepsis and the Climacteric.*

The 9 women in this group suffered greatly from the usual disagreeable symptoms associated with the menopause as well as from disorders of digestion. Three of them complained also of recurring attacks of an eczematous rash over the face and neck and wrists. In 5 the oral sepsis was treated, and they were soon rid of the greater part of their symptoms. The number treated included 2 of those who suffered from skin trouble, and in these 2 cases the rash did not reappear.

GROUP V.—*Oral Sepsis associated with other Localized Suppurations.*

From the following record of 9 cases it would appear that oral sepsis tends to lower the resisting powers of the individual to pyogenic infection in other parts of the body. In each of the following cases oral sepsis was a very marked condition:

(a) Had an anal abscess.
(b) A carbuncle.
(c) A septic hand twice within six months without history of injury.

(d) A septic adenitis (buhe) following a scratch in the region of the vulva.

(e) A septic prepatellar buritis.

(f) An indolent corneal ulcer of nine months' duration. After the mouth was treated the ulcer gradually healed, though no change whatever was made in the local treatment.

(g) Three attacks of furunculosis in 1903, 1911, and 1912, a whitlow in July, 1912, and in August of the same year a septic finger following a slight bruise with no abrasion of the skin. The mouth was treated in September, 1912. There has been no further trouble.

(h) A septic tonsillitis in March, 1912, a septic hand in October, 1912, following a slight bruise without abrasion of the skin. This patient also suffered in 1911 and 1912 from severe acne vulgaris. Numerous septic stumps were removed in October, 1912, the tartar was removed from his sound teeth, and toothbrush and mouth wash were ordered.

(i) An indolent sore over an interphalangeal joint of many months' duration. This was supposed to be tuberculous, but looked more like a chilblain that had refused to heal. It healed up at once after treating the oral sepsis.

GROUP VI.—*Oral Sepsis and Arthritis (10 Cases).*

This forms an interesting group, and in it the direct relationship between the two conditions appeared most evident.

(a), (b), (c), (d), and (e) were 5 cases of true rheumatoid arthritis, and in each the onset of the disease was preceded by a well marked septic condition of the mouth. Treatment of the mouth was carried out thoroughly in 2 cases, and was quickly followed by very great improvement. Both have since been entirely free from "active" pains, their troubles now being associated with the already deformed and partially ankylosed joints.

(f) Had an attack of rheumatic fever on September 16th, 1912. He was treated with sodium salicylate, and on the fifth day pulse and temperature were normal and there was no pain or swelling in the joints, though there was some stiffness. I was called again to see him on October 9th, as he was suffering from pain and stiffness in several joints, and he was unable to walk. The temperature was normal and there was no swelling or redness of the joints. He had no appetite, felt languid and weak, and showed marked pallor. The sodium salicylate had been

stopped on September 30th. A large number of decayed stumps were removed, and a mouth wash was prescribed and sulphur as an aperient. In a week he was walking about, and in another week had returned to work.

This case is in accordance with Rolleston's statement in his Hunterian Lectures on acute arthritis of doubtful origin, that a patient who has oral sepsis may recover from the rheumatic attack and subsequently suffer from arthritis due to infection derived from the mouth.

(g) A case very similar to the above, where the mouth was untreated. She was confined to bed for five months, and has made anything but a complete recovery.

(h) A woman of 60; complained of pain and stiffness in one knee of seven months' duration, growing gradually worse. On attempting to walk there was a decided limp, and she evidently suffered great pain. She also complained of some pain in the left shoulder, and one metacarpophalangeal joint was thickened and tender. She had a poor appetite, felt very weak, and looked "anaemic." Her mouth was thoroughly treated and she was ordered an iron and quinine mixture. In ten days she walked without a limp, and in three weeks was practically well.

(i) This patient's menstrual and digestive symptoms are recorded in Group II. She consulted me on November 1st, when she had had pain and swelling in two interphalangeal joints, and in one wrist, of three or four days' duration. Pulse and temperature were normal. The mouth was treated (numerous stumps removed) on November 3rd. On November 8th she complained of pain and swelling in another small joint, stiffness of both wrists in the morning, and pain in the left shoulder, and on November 14th, when the joints were almost well, she had an extremely tender, red, inflamed spot over one internal malleolus, with great swelling of the foot. Complete rest and hot fomentations for two days was followed by recovery. This patient has had no further trouble.

(j) This was a boy of 6½ who had had his tonsils removed on September 10th. I was called on October 7th, to find him suffering from rheumatic fever, and a few days later he had an attack of pericarditis. Dental caries had been very extensive from the age of 3 onwards. One decayed tooth had been broken when having his tonsils removed, and at the site of this broken tooth there was a mass of pulpy granulation tissue discharging pus.

Why we should be so careful to obtain a sepsis in, say, an amputation of a finger and make no effort whatever to obtain the same condition in an amputation of a tonsil I am at a loss to understand. It is generally agreed, too, that the path of infection in rheumatic fever is by the tonsils, and it is also well known that an attack frequently follows at an early date after the removal of the tonsils. It is surely, therefore, not at all unlikely that that attack is either directly caused, or at least predisposed to, by oral sepsis.

OTHER CASES.

Besides the groups of cases mentioned above, some individual cases appear worthy of fuller description.

A. A man, aged about 45, consulted me because he had vomited once or twice during the preceding few days, was "unable to eat anything," and was "growing yellow." When I saw him he was suffering from typical catarrhal jaundice. Inquiry elicited the facts that he had had a very poor appetite for six or eight months and had been feeling anything but fit for his work. His mouth was not one of the worst, but the necessary treatment was undertaken, and he made a rapid and permanent recovery.

B. A woman, aged 32, was operated upon for a ruptured ectopic pregnancy. She was out of bed in three weeks and made a perfect recovery up to a certain point, but remained very anaemic for eight months. During that time she had all the advantages of fresh air and sunshine and good food, and was systematically dosed with iron. Treatment of her septic mouth was then quickly followed by a return to normal condition.

C. A man of 50, who, when I was consulted, was suffering from a severe attack of acute gastritis. He was very feverish and in great distress, the vomiting having been severe for two days. The mouth was one of the worst in my record, and the odour was perceptible immediately on entering the room. His wife informed me that "his breath had been like that since ever she knew him," and that "he had suffered from his stomach for many years." I was also informed that "he had tried everything," and that his daily diet for many months had consisted of a little milk pudding. Two of the lower incisors were easily removed with the aid of a pair of dressing forceps and scissors. Attention was given daily to the mouth, and it was quickly got into better condition. This attack of gastritis occurred eighteen months ago, since when the patient has enjoyed excellent health.

D. This woman had a severe attack of brachial neuritis, probably predisposed to by a long spell of oral sepsis and the consequent malnutrition.

E. A case of chronic phthisis of four years' duration had come to this district for a change of air. The cough was not at all troublesome, but she complained of "want of appetite and indigestion." The condition of her mouth was very bad indeed,

but she informed me that she had been told "she was too weak to have anything done to it." Removal of the offending stumps was not at all difficult, and was quickly followed by improvement in the appetite and digestion. It must be admitted that in such a case as this the treatment of even a slight degree of oral sepsis might be all-important.

F. A woman, aged 46, had suffered from well-marked oral sepsis for at least ten years. A year and a half ago she had an attack of appendicitis, possibly a direct result of the septic mouth. For some time previous to this, and up to the time when she consulted me, she had felt tired and out of sorts. She complained of intense pain over the eyes coming on a few minutes after attempting sewing or reading. She reported that she had had her glasses "strengthened" three times in three months. She was using 3.50 dioptries, although refraction showed she had barely 1 dioptre of hypermetropia. This was a case of severe asthenopia the result of oral sepsis. Optic neuritis was also well marked, and acuteness of vision was subnormal. Three weeks after the mouth was thoroughly treated these symptoms had disappeared.

G. I was called to see this woman, who had been in bed for three or four months. I was told that she had had an attack of cardiac failure, that she had had extensive dropsy, and that the abdomen had been tapped. She had evidently had a very serious illness. About a fortnight previous to my visit she had had intense headaches, but the pain in the head had gone, and she had become gradually more and more "stupid." She was only semi-conscious, was unable to speak, asked for nothing, but swallowed liquid food and water when they were given to her, and suffered from complete incontinence of urine and faeces. Her temperature was subnormal, and her pulse 72 and irregular. She had well-marked cardiac murmurs. The mouth emitted a very foul odour, and she wore an upper artificial plate. Inquiry elicited the fact that the plate had not been out since she took it to bed. It was removed with some difficulty, and there was brought away with it a very septic tooth to which it was attached. Her lower incisors were also in a filthy condition. Treatment of the mouth was at once instituted. Improvement set in almost immediately. In a week the patient was quite sensible, and in fourteen days she was feeding herself, and had complete control over urine and faeces. Thereafter she made a perfect recovery.

As in a large majority of these cases of oral sepsis pallor of the skin and mucous membranes had been well marked, an appearance which Hunter records in 78 cases out of 1,000 out-patients coming under his notice during twelve months, an effort was made to learn something of the character and degree of the anaemia which this condition produces. Examinations of the blood were made in six cases chosen from amongst those in whom this appearance of pallor was most striking. The results were as follows:

| | | |
|-----------------------|-----|---------------------------------------|
| <i>Females:</i> | | |

These figures would show that oral sepsis in the forms in which it is commonly met with does not of itself necessarily produce an appreciable degree of true anaemia, but rather a condition of pseudo-anaemia such as is commonly observed in a person suffering from nausea. The same condition is observed in Bright's disease, and in some forms of heart disease, where we know that a marked pallor may exist with haemoglobin and corpuscles nearly normal.

This finding has of course nothing to do with the possibility of oral sepsis being the cause of certain malignant forms of anaemia as described by Hunter and Dalton.

The general appearance of the patient appears to be no index whatsoever as to the condition of the blood. After making these six examinations I took a specimen of blood from a young perfectly healthy pregnant woman. By no stretch of the imagination could she be described as looking "anaemic" and yet her blood only showed 68 per cent. haemoglobin and 3,900,000 reds.

CONCLUSIONS.

1. That oral sepsis is a very prevalent condition. That its effects are definite and far-reaching, and that it must form a very important factor in the general health of the community.

2. That, as many forms of oral sepsis are not associated with pain, the patient rarely complains of the condition of the mouth, and as his general appearance and symptoms are frequently strongly suggestive of anaemia, the true state of the case may easily be overlooked.

3. That it is a common cause of disorders of the stomach, is directly associated with different forms of arthritis, and that it either predisposes the individual to, or at times directly gives rise to, suppurative processes in other parts of the body.

4. That at critical periods in the life of an individual, as for example at puberty, during pregnancy, at the climacteric or in the course of a chronic disease, it may be the all-important factor in the case.

AUTOGENOUS VACCINES IN THE TREATMENT OF CHRONIC JOINT AFFECTIONS

(RHEUMATOID ARTHRITIS AND GONORRHOEAL ARTHRITIS).

By BASIL HUGHES, F.R.C.S.

PATHOLOGIST TO THE ROYAL INFIRMARY, BRADFORD.

RHEUMATOID ARTHRITIS is, I think, a misleading term. I would prefer to call the condition "metastatic arthritis" --that is, metastatic to some infective focus in the body.

The joint is swollen and more painful at times than at others; the muscles around the joint show marked wasting. On palpation the local temperature may be slightly raised, the synovial membrane is thickened and fringing of it may be felt. On movement of the joint a soft crackling is felt, very different to the bony creaking felt in osteo-arthritis, which latter I consider to be quite a different disease, although in more elderly subjects rheumatoid arthritis may pass on to a condition of osteo-arthritis. Further, in some cases of rheumatoid arthritis there is a considerable quantity of free fluid in the joint cavity, and lateral mobility in the joint itself can be obtained.

Pathologically, rheumatoid arthritis presents features of a chronic infection, the synovial membrane is pinker than normal, it is soft and succulent, and often villous processes project from it. The articular ends of the bones beneath the articular cartilages show rarefaction, while microscopically there is present some extent of round-celled infiltration in the synovial membrane. Although the synovial membrane is thickened, it does not show a tendency to ulcerate or undergo destructive changes, as in the case of tubercle, and possibly syphilis.

I have repeatedly tried to obtain cultures from the fluid aspirated from these joints, using various culture media, but in no case with success. It has been suggested, and I think feebly, that the organisms present are in such a low state of virulence and numbers that they will not grow; others have said that the organisms lie hidden in the connective tissues of the synovial membrane, but a very careful search in a series of cases failed to reveal any such organisms. Other observers assert that they have been able to grow organisms from these joints, and have produced this villous type of rheumatoid arthritis in rabbits by inoculating the animal with this organism; but such observations have not been confirmed.

I think we can safely say that the cause is not a form of tubercle. There is no tendency to caseation or to the formation of abscesses and sinuses or to destruction of articular cartilage. Von Pirquet's reaction has invariably been negative; this fact, though proving nothing, at any rate helps in excluding tubercle.

Further, I think we can exclude syphilis. It is true there is a type of syphilitic rheumatoid arthritis, but it is rare, and rheumatoid joints do not resemble syphilitic joints. Out of a large number of cases tested only a very small percentage have given a positive Wassermann reaction. The majority gave a negative history of syphilis, and those who gave a positive Wassermann reaction and in whom there was other evidence of syphilis did not respond to antisyphilitic treatment only, as far as their joints were

concerned. I would, however, suggest that the Wassermann reaction be tried in these cases, for if it be positive it is well to administer antisyphilitic treatment along with treatment appropriate for the joint condition.

I have been interested some five years in this disease, and am becoming more convinced that rheumatoid arthritis is due to metastasis from some infective focus. The disease attacks the young and middle-aged, and in children there is that form called Still's disease, the cause of which is not yet ascertained.

Metastatic arthritis may commence at so early an age as 15 or 16. Commonly we see it in young women at 18 years and upwards. From 35 years onwards to the menopause it is again common. Frequently it is said to follow parturition, and other diseases affecting the female genital organs.

The three main points in the treatment of this disease are:

1. To find the infecting organisms.
2. Having found them, to raise the opsonic index of the individual against these organisms; this is most quickly accomplished by the use of autogenous vaccines.
3. Having rendered the patient artificially immune, to remove where possible the primary focus and apply local treatment to the affected joints.

The commonest foci of infection in my cases have been the following:

The Teeth.

Pyorrhoea alveolaris is frequently associated with rheumatoid arthritis. I have frequently seen cases who have been to American dentists and have been fitted with a dental plate. On removing the plate a series of stumps have been disclosed beneath it, bathed in pus of a most offensive kind containing a very mixed infection. Gold crowns are also bugbears. A dentist friend, by way of experiment, placed a gold crown over a carious molar tooth of his own and awaited results. He developed joint pains, rheumatic pains about the shoulders and back, which subsided immediately the crown was removed. The tonsillar crypts are also another source of infection. I have at present a case of a woman suffering from a very progressive type of rheumatoid arthritis, the primary focus being a pair of caseous, dirty tonsils, causing her, amongst other things, to have a most offensive breath.

In cases of pyorrhoea I have found the following form of treatment give most satisfactory results, and in a number of cases cure.

The mouth should be thoroughly washed and the teeth scrubbed for two or three days with normal saline solution without antiseptics. This gets rid of all extraneous matter from the teeth. At the end of three days a small quantity of pus is squeezed up from the gum, a slide taken, and agar tubes inoculated.

It has been a well-marked phenomenon that in these cases of mouth infection there is marked breaking up of the leucocytes seen on the slide taken, and very few of the organisms are intracellular. In brief, there is a poor attempt at phagocytosis. A vaccine is prepared and an initial dose, varying with the patient, given. After the second injection, if a second slide be taken and stained, it is often remarkable to see the phagocytosis present. It is now evident that the opsonic index is increasing, and this is the time to remove the septic stumps and bad teeth.

I have known cases in which doctors have advised patients to have their teeth removed for this condition. The whole mouth has been cleared at one sitting, and after all this the patient's joint condition has become worse. The teeth should be removed two or three only at a time, and this only after the opsonic index has been raised. Otherwise a large raw surface for absorption is opened up to organisms to which the patient has but poor resistance. If many stumps are removed while the patient's immunity is being artificially increased by means of autogenous vaccines, anaphylactic symptoms appear.

This treatment of joints associated with pyorrhoea has given such gratifying results that I now use it as a routine procedure.

In caseous tonsils a vaccine should be prepared and given, and then enucleation of the tonsils performed.

The Nose and Naso-pharynx.

Rheumatoid arthritis in connexion with septic polypi in the nasal cavities is not uncommon. In a girl aged 18, who had rheumatoid arthritis well started in the joints of the fingers of both hands, a vaccine containing *Micrococcus catarrhalis* and *Staphylococcus aureus* was made from her own discharge. There was in this pus no attempt at all at phagocytosis. She was vaccinated, but phagocytosis was most marked after the second inoculation of the vaccine. The polypi were then removed and she made a complete recovery from her joint trouble, having had no recurrence, either in the joints or of the polypi.

Chronic suppuration in the sphenoidal and frontal sinuses and in the antrum of Highmore are again possible foci of infection. I have opened a knee-joint for acute pneumococcal infection following on a pneumococcal infection of the maxillary antrum.

Chronic Otorrhoea.

I have seen one case of rheumatoid arthritis of both knee-joints clear up in a middle-aged woman after vaccine inoculation combined with clearing out of the antrum and middle ear. Here, again, few bacteria were intracellular. It is therefore very important in cases of these metastatic joints to make a thorough examination to exclude a primary focus in the mouth, nose, throat, and ear.

The Lungs.

Rheumatoid joints have been associated with bronchitis and bronchiectasis. I remember a case of the disease associated with bronchitis in which the pneumo-bacillus was isolated. A vaccine was prepared and given and the joint condition improved markedly, and finally the patient went back to work.

The Intestinal Tract.

Rheumatoid arthritis is often associated with dyspepsia, and I have seen it in association with chronic gastric ulcer and chronic appendicitis. With both these conditions there is a degree of intestinal stasis. I have frequently opened the abdomen and found the condition of pericolicitis of a membranous kind affecting peristalsis. I can recall cases of marked amelioration in rheumatoid joints after gastro-enterostomy and ileo-sigmoidostomy, and Mr. Arbuthnot Lane has had cures. In this type of case vaccines do not produce much benefit. The condition causing the stasis must be removed. An x-ray examination should be made after a bismuth meal and any stasis or kinks looked for. If the intestine can be proved to be working efficiently, a very careful bacteriological examination of the urine should be made. If organisms are found—notably *B. coli*, in the absence of intestinal stasis—a vaccine should be made, and in this special type of case I have seen a great deal of good follow.

Leucorrhoea.

This often dates from a confinement, and in a number of cases I have examined I have found a displaced uterus and retention of some products of conception which have become adherent to the uterine wall. Any inflammatory condition in the uterine annexes will by contraction tend to deviate the uterus and cause passive congestion with leucorrhoea. Cultures taken from inside the cervix in these cases have shown mixed infections, the commonest form of organisms being the *B. coli*, a diplococcus, and staphylococci.

The vaccine base should be given prior to rectifying the uterus, so as to raise the immunity. I have seen many cases made worse by curettings and other operative procedures performed when the patient's immunity was low, but I have never seen anything but good follow when the surgical procedures have followed the second inoculation of the vaccine.

When once the primary focus is out off and the patient's immunity raised to the particular infection, local treatment by Bier's bandage, Scott's dressing, etc., to induce an artificial hyperaemia with blood now enriched with opsonins, may be instituted. It is useless to resort to these local measures, and baths and spa treatment alone; the symptoms only and not the cause are treated. For contractions I usually apply extension during vaccine treatment. I have not seen drug cataphoresis do any good.

Chronic Gonorrhoeal Arthritis.

I believe this to be due to a mixed infection of the gonococcus and staphylococcus. The joints are characteristic. There is swelling and often oedema in the tendon sheaths around, well seen in the wrist-joint, marked pain, and a very early tendency to stiffness and limitation of movement of a most obdurate character. Adhesions form both within the joint and around it within the fibrous capsule, tending early to fix it. Any attempt at forcible movement is painful and only tends to again light up the trouble.

A vaccine should be made from the urethra by inserting the loop well into the meatus. The gonococcus grows best on slightly alkaline agar the surface of which has been smeared with decomplexitized blood serum. I am very indebted to Dr. D'Este Emery for drawing my attention to this and sending me some tubes.

I give 100 million gonococci and 150 million staphylococci for a preliminary dose, and increase it to even 500 million gonococci and 1,000 million staphylococci, provided the reaction is not great. After the second dose an anaesthetic is given, and the adhesions in the joint broken down. I have seen no harm follow this proceeding, and with massage and daily movements while under the influence of vaccines I have patients back at their work again whose joints have been given up as hopeless. Bought vaccines do not appear to act so well as autogenous in these cases, and this has been most marked in some of my cases. Gonococcal arthritis is perhaps one of the types of case which best lends itself to autogenous vaccination.

Combined with this the chronic gleet should receive attention, and the best method I find is massaging the penis over a stout metal bougie passed into the urethra, followed by the insertion of a protargol bougie. Copiba should at the same time be administered by the mouth.

VACCINES IN THE TREATMENT OF CHRONIC BRONCHITIS AND OF ASTHMA.*

By J. H. HARVEY PIRIE, M.D., F.R.C.P.E.,
FORMERLY ASSISTANT PATHOLOGIST, ROYAL INFIRMARY, EDINBURGH.

CHRONIC bronchitis, with a tendency to frequently recurring acute attacks, and asthma, with or without bronchitis, have this at least in common from the point of view with which I am here concerned—namely, that they are frequently obstinate in their character and difficult to cure. Any method, therefore, which gives better or more permanent prospects of relief than those commonly in use seems worthy of trial, and I hope to show by a survey of the cases I have had under treatment during the past three years that in vaccine therapy we have a remedy which, if it does not always effect a complete cure, does, at least in most instances, give considerable relief, even in cases where other measures have failed more or less completely.

RECURRENT BRONCHITIS.

The cases upon which this opinion is based are selected ones—not in the sense that I have picked out all those in which the results are good and discarded the others, but in the following respects: (1) All are cases in which the complaint was of some standing. (2) All have been under other forms of treatment for varying periods, but with more or less want of success. As, however, in most instances the other methods of treatment (medicinal, hygienic, etc.) were continued with, any difference in the results may fairly be attributed to the additional factor—that is, the vaccine. (3) Only those which have been under observation, or have been followed up, for some time have been included. This excludes cases which have only been under treatment quite recently and in which it is too soon to speak with any certainty as to the results; also those in which treatment was only carried out for very short periods and then, for one reason or another, given up. If the latter group were included, the failures would certainly bulk larger, but it would hardly be fair to judge a method by cases in which treatment had not been given a reasonably long trial.

* Read before the Medico-Chirurgical Society of Glasgow.

Autogenous vaccines were always employed, prepared usually from the sputum (obtained as free from contamination as possible, after cleansing of the mouth by brushing and rinsing out with boiled water), occasionally from swabs taken from the naso-pharynx. The details of preparation of the vaccine have been modified from time to time, but it has been my invariable practice to include in it all organisms found abundantly both in film preparations and in culture, so as to make as certain as possible of including the actual offending germs. I believe this is essential, because at present we have really no satisfactory method of determining which of the organisms found are pathogenic and which are not. It has also been my endeavour to employ always strains of organisms but little removed from those occurring in the human subject, and latterly nothing more remote than the first subcultures have been used. By making the original cultures fairly thin, it is usually possible to obtain pure growths in the next generation; where this has not been the case mixed growths have been employed to make up the vaccine, as potency is to my mind more important than extreme accuracy in dosage of the individual organisms in a mixed vaccine. Another important point in making subcultures, especially in dealing with such organisms as the streptococci and the *M. catarrhalis* group, is that they should be made from several colonies, and not from one only. So many strains of these organisms are probably quite non-pathogenic that, until better means of differentiating them are found, it is necessary to include a good representation so as to ensure having some of value.

Chronic or Frequently Recurrent Bronchitis.

Bacteriology of 16 cases:

| | | | | |
|------------------------------|-----|-----|-----|-----------|
| Pneumococci | ... | ... | ... | 12 cases. |
| <i>M. catarrhalis</i> group | ... | ... | ... | 12 " |
| Streptococci | ... | ... | ... | 6 " |
| Staphylococci | ... | ... | ... | 5 " |
| Bacilli of Friedländer group | ... | ... | ... | 5 " |
| <i>M. paratetragenus</i> ... | ... | ... | ... | 3 " |
| Unidentified organisms | ... | ... | ... | 2 " |

Mixed growths occurred in all cases, and the vaccines have generally contained two or three organisms, sometimes even four. The most striking difference between this table and that given by Allen¹ is the complete absence of the *B. influenzae*. This may be partly due to the fact that I have not always used blood-agar for cultures, but as film preparations were invariably examined I think the chief reason is the rarity of this organism in Scotland at the present time. In this connexion it may be stated that the epidemic of so-called influenza prevalent here this winter has, in my experience, been caused invariably either by pneumococci or streptococci.

The following are short notes of 6 representative cases out of these 16:

CASE I.

M., aged 40. Chronic bronchitis and pharyngitis. In October, 1911, his sputum showed pneumococci and a few staphylococci. Doses containing 50 million of the former organism only were put up and sent to his medical attendant with instructions to give a half-dose at once when any acute exacerbation threatened, otherwise to give a full dose once a week. The attacks were reported later to be cut short by this plan, and also to be less frequent. In December, 1912, the sputum showed pneumococci and *M. catarrhalis* to be dominant, and a fresh vaccine containing 50 million of the former and 200 million of the latter was sent with similar instructions. The latest report (March, 1913) states that the patient "has been able for work all winter, and has only had two comparatively trivial attacks of bronchitis." (Greatly benefited.)

CASE II.

F., aged 14, who for several years has suffered from almost constant nasal and bronchial catarrh with acute "influenzal" attacks. Neither the nasal nor the bronchial secretion showed the presence of any *B. influenzae*, but from growths obtained a vaccine was prepared containing 25 million pneumococci, 100 million *M. catarrhalis*, and 60 million of an organism of the *B. Friedländer* group. Treatment with this at first, and later with double these amounts, for a period of six months at from seven to ten day intervals, has greatly improved the patient's general health and lessened the tendency to acute attacks, but there is still wheezing in the chest and a good deal of nasal discharge. Treatment is being continued with still larger doses. (Greatly benefited.)

CASE III.

M., aged 23, undergoing treatment for nasal obstruction, and who for two years has had increased susceptibility to attacks of bronchitis. Sputum contained abundant pneumococci and no other organism grew in cultures. Three months' treatment

with doses ranging from 40 to 200 million resulted in complete freedom from bronchitis which has lasted up to date for almost a year. In this case, however, the honours must probably be shared between the vaccine and the surgical measures in the nose. (Cure.)

CASE IV.

F., aged 22, who for three years has suffered from chronic bronchial catarrh, worst in winter, with frequent "catching of colds," which often amount to actual bronchiopneumonia. She is free from cough at times, but there are always rales to be heard in the chest. Tuberculosis was suspected for a time, but tubercle bacilli have never been found in the sputum. Examination of the sputum at various times constantly yielded pneumococci and *M. catarrhalis* with occasionally *M. paratetragenus* or staphylococci. Vaccine treatment carried out practically without intermission for a year, the dosage being pushed up to 200 million pneumococci and 500 million of each of the other organisms. After that treatment was stopped. Result one year later: Complete freedom from acute bronchial attacks, although there are still some moist sounds in the chest and occasional cough, but not sufficient to bother the patient much. (Practically cured.)

CASE V.

F., aged 44, who had resided for a number of years in the East Indies. Since her return to this country about five years ago she has suffered from almost constant bronchitis. Before coming under my care she had undergone almost a year's vaccine treatment in London, but with very little benefit. Careful examination revealed nothing wrong beyond the bronchitis. Under treatment for six months with vaccines of several organisms—pneumococci, streptococci, *M. catarrhalis*, and pneumo-bacilli. The composition of the vaccine was varied several times, and the dosage was pushed until as much as 1,000 million *M. catarrhalis* and 500 million of mixed pneumococci-streptococci were being given, doses which gave the patient considerable general discomfort, but which did not result in any amelioration of the symptoms. The treatment was then given up, and this winter the patient has spent in South Africa, to see the effect of a warmer and drier climate, but with what result so far I have not heard. (Failure.)

CASE VI.

M., aged about 40, with chronic naso-pharyngeal catarrh and crepitations near one apex (tubercle pretty well excluded), every now and again bronchitis and bronchiopneumonia. In March, 1912, sputum gave a growth of pneumococci, *M. catarrhalis*, and a minute motile Gram-negative bacillus (which grew on ordinary agar). The patient was given a vaccine containing these three organisms for about five months, with resulting considerable improvement both in his general health and in the local condition. In November, 1912, up till which time he had been free from any bad colds, his sputum and naso-pharyngeal secretions were examined, and on this occasion a growth of *M. catarrhalis* and streptococci was obtained. The patient was put on a vaccine of these organisms, and this winter, although his general health has not been good, he has only had one bad attack of tonsillitis and pharyngitis, which, however, did not extend further down the respiratory tract. (Considerably improved.)

Summary of Results of Treatment in the Sixteen Cases.

In 7 cases there is now such almost complete freedom from colds and bronchitis that they may be considered as practically cured.

In 4 there has been marked improvement, although they cannot be said to be quite cured; two of these are still under treatment.

In 4 the improvement has only been slight. In none of these was treatment persevered with for over four months.

In 1 case there was no improvement even after eighteen months of vaccine treatment.

From these figures it may be said that vaccine therapy does hold out very considerable hope of effecting improvement in chronic bronchitis even in cases which have proved resistant to other modes of treatment, but—and there is always a but—it cannot be said to be certain of doing so, and in all cases it should be made clear to the patient at the outset that fairly long continued or repeated courses of inoculation are likely to be necessary to obtain good and lasting results. The average length of time for which these 16 cases were under treatment, constantly or intermittently, was nine and a half months.

I would now advise any patient, even when supposed to be cured, to have occasionally a few protective inoculations against any organisms to which they are specially sensitive, and more especially before the onset of winter. For this purpose either an autogenous vaccine might be employed, or one of the several so-called "combined vaccines for colds" which are on the market, and which aim at producing immunity against all of the commoner cold-causing germs. I have no personal experience of the use of these, but one objection which they seem open to as regards their use in Scotland is that none of them are suited in their composition to the infections which are

most common here at the present time, however suitable they may be for other parts of the country.

The dosage of the vaccines employed has varied considerably in the different cases, but the general tendency has been to increase the amounts given, pushing the dose in each individual case until one is arrived at which produces after inoculation some definite reaction in the way of general discomfort, slight feverishness usually, and not infrequently some temporary aggravation in the amount of the bronchial secretion.

Vaccine treatment is not, of course, recommended to the exclusion of other measures, but simply as an "extra" where these fail to give satisfactory relief. The ordinary medicinal and hygienic measures applicable should be employed, and, in particular, I consider it highly important to cleanse the nose and naso-pharynx at least twice daily with some form of douche and swab to remove mechanically at least some of the offending organisms which are constantly lurking in these situations, ready to infect the lower respiratory passages when given a suitable opportunity.

ASTHMA.

In the case of asthma we have to deal with a disease which is different from bronchitis, in that it is by no means of purely bacterial origin, but without going into the vexed questions of its etiology and pathology, I shall merely say here that I am of opinion that in many cases microbial infection is one, and an important one, of the factors which may precipitate an asthmatic attack. This is probably especially the case where there is bronchitis or infection of some other part of the respiratory tract associated with the spasmodic asthmatic attacks.

Asthma. Bacteriology of 15 cases :

| | present in all cases. |
|------------------------------------|-----------------------|
| Pneumococci | 14 " |
| <i>M. catarrhalis</i> group | 8 " |
| Staphylococci | 6 " |
| Streptococci | 6 " |
| B. of Friedländer group | 3 " |
| Diphtheroid bacilli | 1 case. |
| <i>M. paratuberculosis</i> | 1 " |
| <i>B. influenzae</i> | 1 " |
| Unidentified organism | " |

Mixed infections are commoner in my cases than in those recorded by Allen.¹ The pneumococcus found in my cases seems to take the place of the streptococci which he records from 96 per cent. of his. Many of his streptococci occurred either in exceedingly long chains or as a form which he calls *S. marinus*, the individuals being large and some of them in each chain Gram-negative. I have met with both forms amongst my cases. Carmalt Jones regards an organism which probably belongs to the *Micrococcus catarrhalis* group as a possible cause of asthma.

CASE I.

F., aged 28, who has suffered from bronchitis with occasional asthmatic attacks—not, however, of a very severe nature—for several years. The first examination of the sputum, obtained during an attack, gave a growth of *M. catarrhalis* and diphtheroid bacilli, and a vaccine was prepared containing 100 million of each. A half-dose was given first, then three full doses. A second examination of the sputum showed the presence also of pneumococci; 25 million of these were added to the vaccine and administration continued weekly for three months, the dosage being gradually pushed to double the original amounts. Treatment was then stopped, and four months later (April, 1913) the patient reported that she had been free from asthmatic attacks, although she still had some bronchial catarrh. (Considerable improvement.)

CASE II.

F., aged 37, with chronic bronchitis and asthma of long standing. Greatly emaciated. Organisms: Pneumococci and *M. catarrhalis*. A dose of vaccine, containing only 16 million of the former and 50 million of the latter, brought on next day an attack of acute bronchitis. A subsequent injection of half those amounts was also followed by considerable reaction. Treatment was persevered with for three months at about ten-day intervals; in no instance was a bigger dose than 20 million pneumococci and 60 million *M. catarrhalis* given, and every dose was followed by considerable discomfort and frequently by an actual asthmatic attack. As no improvement was taking place, further treatment was declined. (Failure.)

CASE III.

F., aged circa 40. Severe asthmatic attacks for several years; no bronchitis. Also suffers from cystitis. Cultures from the sputum on several occasions always yielded pneumococci and *M. catarrhalis*. Treatment was commenced with 12½ million of the former and 100 million of the latter, the dosage being soon increased to double those amounts. Injections weekly were

continued over a period of almost ten months, with the result that the attacks are becoming much less frequent and less severe. Treatment is being continued. (Considerable improvement.)

CASE IV.

M., aged 51, had suffered from bronchitis and asthma since childhood, and had also an old tuberculous lesion at one apex, which has for many years appeared to be quite quiescent. First culture almost pure pneumococci, a few *M. catarrhalis*, diphtheroid bacilli. After two months' weekly injections and diphtheroid vaccine in doses of from 50 to 120 million there was distinct improvement in the patient's breathlessness and in the frequency of the asthmatic attacks. A second examination of the sputum gave a growth of the same organisms, but a vaccine was made up containing pneumococci 100 million, *M. catarrhalis* 150 million, and diphtheroid bacilli 25 million. Treatment with this was continued for three months, injections being given weekly. At the end of this time the patient volunteered the statement that his asthma was very much improved, and that although he seemed to be bringing up more sputum, it came very much more easily. He then wished to try without further treatment, and since that time—nearly a year ago—has not been heard from. (Considerably improved.)

CASE V.

F., aged 50, with bronchitis and asthma of ten years' standing. Organisms from sputum: Pneumococci, long-chained streptococci, and abundant bacilli of the Friedländer group; on a later occasion a few colonies of *M. catarrhalis*. Treatment for four months with a vaccine of mixed streptococci and pneumococci 60 to 180 million, and bacilli 200 to 400 million produced some improvement, but not sufficient to induce the patient to continue treatment for longer, as she objected to the pain and stiffness incidental to the injections. (Slight improvement.)

CASE VI.

M., aged 40, who has suffered from asthma since infancy. Cultures both from the sputum and direct from the naso-pharynx gave a growth of pneumococci, *M. catarrhalis*, some streptococci corresponding in character to Allen's *S. marinus*, and a few leptothrix-like organisms. Four months' treatment with pneumococcal-streptococcal (25 to 100 million) and *M. catarrhalis* (100 to 200 million) vaccine has produced very distinct improvement. Treatment is being persevered with. (Considerable benefit.)

CASE VII.

F., aged 20, with asthma, bronchitis, and nasal catarrh of ten years' standing. The patient has had nine operations on the nose, with in one instance about a year's relief from asthma. She has also tried residence abroad, and is particularly careful in looking after herself, but withal has very frequently to have recourse to sprays and other asthmatic remedies. Before treatment was commenced she was showing no tendency to improvement either in frequency or severity of attacks, but was rather drifting into chronic invalidism. Examination of swabs and sputa on numerous occasions always showed the presence of pneumococci and *M. catarrhalis*, and at times of such organisms as staphylococci, streptococci, diphtheroid bacilli, *M. paratuberculosis*, and bacilli of the Friedländer group. The vaccines employed have always contained the first two organisms, and at times some one or more of the others; comparatively small doses have been employed throughout. Treatment was commenced in May, 1911, and has been kept up since that time, the injections being given as a rule weekly. In the summer of 1911 she was comparatively well, but this was not unusual, as she was always freer in summer than in winter. The winter of 1911-12, however, showed a marked improvement upon any past winter for a number of years. In the summer of 1912 the injections were reduced for a time to fortnightly, but as in the autumn there was a tendency to recurrence of attacks, the vaccines were again given weekly, and have been continued so up till the present time. The patient has come through this winter—a particularly trying one—with only one cold, which soon cleared up, and a very slight asthmatic attack, and she has been able to participate in all sorts of exercise and social events. (Practically cured.)

CASE VIII.

F., aged 55, for many years had been troubled with frequently recurring attacks of bronchitis and asthma, especially in winter; latterly they had been becoming more common and less easy to throw off. In September, 1910, sputum gave a growth of *M. catarrhalis* and pneumococci, and a vaccine was prepared containing 200 million of the former and 25 million of the latter. Twelve doses of this were given at intervals of about a week, save for two intermissions during acute attacks. During January and February, 1911, the patient was free from acute exacerbations, but in March had an attack, when, in addition to the same organisms as before, pneumo-bacilli were obtained in culture. A fresh vaccine containing 300 million *M. catarrhalis*, 50 million pneumococci, pneumo-bacilli in amounts ranging from 50 to 200 million, was made up and given weekly. In May the patient stated that she had passed the best winter and spring she had had for twelve years. Vaccines stopped in June, 1911, and the patient remained almost free from colds till January, 1912, when a fairly severe attack occurred, the organisms found being pneumococci and pneumo-bacilli. A small dose of vaccine was given and the attack cleared up quickly, then four larger doses were given during the next

mouth. She had one further slight asthmatic turn in April. During the summer of 1912 she remained quite free; this winter she has not been under observation, but at Christmas time she wrote saying she had had no further attacks. (Practically cured.)

CASE IX.

F., aged 18, with bronchorrhoea, constant colds, and asthma of at least six years' standing. Tonsils and adenoids have been removed, but without much improvement. In January, 1912, she was put on an autogenous vaccine of pneumococci (75 million) and *M. catarrhalis* (200 million) weekly. In September on one containing pneumococci 125, pneumobacilli 100, *M. catarrhalis* 300, and staphylococci 500 million. In December, 1912, the dosage was commenced to be pushed. Pneumococci 200 up to 500, *M. catarrhalis* 300 to 800, and staphylococci 300 to 800 million, with excellent results. The patient at the present time (April, 1913) has been free from asthma for four months, although she still has some bronchial discharge, and catches cold rather freely. Treatment is being continued, but now with rather smaller doses. (Much improved.)

Summary.

Of the 15 cases 6 must be excluded from the present survey as having been for too short a time under treatment to state the permanency of the results; of the remaining 9 (those given above)—

- 2 may be regarded as practically cured and free from asthma;
- 5 have been considerably improved;
- 1 shows only slight improvement; and
- 1 has not been benefited at all.

These figures are, as might be expected, not quite so favourable as in the case of simple chronic bronchitis, but they are at least sufficiently encouraging to warrant a trial of vaccines in intractable cases of asthma. Here again, however, prolonged treatment is necessary. My cases have been receiving injections, constantly or intermittently, for, on an average, over ten months, and in the two instances in which the best results have been obtained for nearly as long as two years.

With regard to dosage, I have not found it advisable to push the amounts to the same extent as in chronic bronchitis. Asthmatics are usually too sensitive, and large doses are apt even to excite actual attacks. Only in one instance (Case IX) have doses which I would consider at all large been found of advantage.

Even more than in the case of bronchitis must other possible factors in the causation of the spasmodic dyspnoea be attended to if good results are to be obtained, particularly the state of the whole respiratory and alimentary tracts. In a recent paper Charlton Briscoe² lays stress upon septic absorption as playing a prominent part in the production of asthma, and insists on the importance of discovering the source of this absorption, and its removal if possible, also the employment of constitutional and special treatment by drugs, etc. The place for vaccines is as an adjunct to those methods when they do not produce the desired results. With this opinion I am in substantial agreement.

It should be stated that whilst I am wholly responsible for the vaccine treatment in most of the cases, in some instances treatment was commenced by the late Dr. James Miller, but the patients have since been under my charge.

THE Medical Chamber of Vienna has decided to make a careful investigation in the municipal schools of Austria with reference to scholastic hygiene. When the investigation is complete the results will be taken as a basis for the formulation of principles to be applied to the whole scholastic medical service throughout the country. The details will be left to the local authorities. In the meantime a society of school hygiene has been formed at Vienna.

COURSES of training in hygiene and tropical medicine for missionaries were established two years ago by the Institute for Foreign Missions in Lombardy. At the present time some thirty young priests who propose to work as missionaries are receiving instruction. On April 5th they were examined by a commission composed of three doctors. There were also present at the examinations Dr. Voganò, Bishop of Ezane, the Director of the Institute, and other clerics connected with foreign missions.

MEDICAL, SURGICAL, OBSTETRICAL.

POISONING BY MORPHINE AND ATROPINE.

POISONING by morphine and atropine is so uncommon that the following case seems worth recording.

A young woman was found in bed unconscious at 7.30 a.m. She was cyanosed, the breathing was shallow and irregular, tending to the Cheyne-Stokes in character. The pupils were equal and contracted, but not to pin-points, and the conjunctivae were injected. There was complete absence of reflexes. The skin was dry and the pulse small—120. A letter was found written to her mother which made it clear that it was a case of suicide. An empty hypodermic tube was found which when full would have contained $2\frac{1}{2}$ grains of morphine. Subsequently, after death, two other tubes were found hidden under the mattress of her bed. In all, supposing the tubes had originally been full, she would have taken 7 grains of morphine, and $\frac{1}{2}$ grain of atropine. She had vomited, apparently in the night, and possibly after the first doses of morphine, so that the exact amount taken is uncertain.

It is unnecessary to go into the details of the treatment. The stomach was washed out with solution of potassium permanganate, and injections of strychnine were given subsequently. Artificial respiration was performed, and she was bled on two occasions. The bleedings appeared to do good for a time, as she breathed better and was less blue afterwards.

At 10 p.m. the corneal reflex had returned, but she was still unconscious. At 2 a.m. she was found to have a temperature of 105° F. She was very blue, and breathing in short jerky respirations, with intervals in which she did not breathe at all. The corneal reflex was again lost. With artificial respiration, etc., she lingered on till 10.45 a.m. The heart continued to beat for a short time after respirations had ceased.

Post mortem the brain, lungs, kidneys, and other internal organs were deeply congested. The right heart was full of venous blood, and there were *ante-mortem* clots in the left ventricle. There was only an ounce or two of urine in the bladder.

The points of interest in the case are:

1. The length of time that elapsed from the time she was found until death, 27½ hours later. As she was deeply comatose when found but was heard moving in her room at about 1 a.m., it seems probable that she took the poison at that hour, which would make the time about 33 hours. I can find no record of anything approaching this time before death in opium or morphine poisoning. Was the prolongation of life due to the atropine?

2. The quiet pulse, which varied, but was generally at about 120, I consider due to the paralysis of the vagus inhibitory centre.

3. The absence of sweating (again atropine), combined with the almost total suppression of urine, are perhaps answerable for the high temperature during the last eight hours of life. In fact, did she in the end die of uræmic poisoning?

ETIOLOGY OF BERI-BERI.

I NOTICE on perusing your columns from time to time that it seems to be more or less accepted nowadays by a large section of the profession that beri-beri should be looked upon as a "deficiency" disease—in other words, that it is due to the consumption of rice from which the pericarp has been removed, the pericarp being supposed to contain a necessary essential towards the upkeep of the nerve fibre. Now during ten years of residence in Southern Nigeria I saw a number of cases of beri-beri. Of these, however, four stand out clearly in my memory; they were young Englishmen whose houses I visited every day, with whom I on numerous occasions had lunch or dinner, as the case may have been, and consequently whose mode of life I was thoroughly acquainted with. With regard to these cases I can guarantee that they lived as well as any ordinary young men would live in England. There was at all times an abundance of fresh food on the table: chicken, mutton, fish, fruit, and vegetables were always at hand, and although they may

have had a little polished rice with curry occasionally they had no greater percentage of it than any ordinary person in England. One of these patients died; the others recovered on going home.

I would beg some of the recent school of tropical pathology to give an explanation of the above cases, and would ask them what particular hypothetical substance they would postulate as having been absent from the food in question. None of these men was alcoholic.

A USEFUL SIGN IN ACUTE APPENDICITIS.

In October, 1912, I began to notice a marked state of congestion of the right superficial circumflex iliac vein in cases of acute appendicitis.

At first I thought this might be merely a coincidence, but its regular appearance when I was on the outlook for it makes that extremely unlikely; in fact, I have never failed to find it in my own cases, and the senior house-surgeon at our infirmary reports that he has always seen it in the cases coming under the care of my colleagues. Therefore I think it must be nearly always present and distinguishable.

The congestion is often so marked that a glance at the abdomen reveals it at once; in other cases it is not so prominent, but still quite distinguishable. Nowadays, if I find this condition, and the history or other symptoms suggest appendicitis, I am led to make a more careful examination than I would perhaps otherwise make, and in every case so far I have been able to verify my diagnosis on the table.

The condition, I imagine, may be due to pressure on the external iliac or common iliac vein, or simply to general congestion of that region.

Only once in the past six months have I operated upon an appendix case in the quiescent stage, and in that case the vein did not show up at all.

It may be that attention has been drawn to this condition before, but if so I have not seen it; and it appears to me, if my experience be verified by others, that here we have a readily recognized additional sign of acute appendicitis.

JOHN BLAIR,

Honorary Surgeon, Royal Albert Edward Infirmary, Wigan.

TWO CASES OF FRACTURE IN THE REGION OF THE WRIST-JOINT.

CASE I.—*Impacted Colles's Fracture in a Woman aged 93.*

I WAS sent for on February 3rd, 1913, to see an old lady, aged 93, who had fallen early the same morning and had hurt her left wrist. I found a typical impacted Colles's fracture, which, having regard to the extreme age of the patient, I did not think held out much prospect of a satisfactory result. As the bones were very tightly impacted I obtained assistance and administered chloroform; I then managed with considerable difficulty to reduce the fracture, and set it on Carr's splints.

There was very little swelling, and I commenced passive movements of the fingers on the second day, and of the wrist-joint at the end of a week. As the patient was very feeble the splints were kept on for six weeks, so as to protect the arm in case of another fall, but they were removed for a short time daily in order that the arm might be carefully rubbed, and the joints moved. At the end of that time complete union had taken place, with perfectly free movement of the wrist and radio-ulnar joints.

An x-ray photo, which was taken about three months after the accident, was interesting, as showing how, even in a patient at the age of 93, excellent results may be obtained after a badly impacted fracture, and also to what a small degree callus had been thrown out round the site of the injury.

CASE II.—*Vertical Fracture of Lower End of Radius.*

On April 15th, 1913, I was called to see another case of injury to the wrist. The patient, a lady aged 52, a professional pianist, had fallen on her left wrist whilst avoiding a motor car; there was considerable swelling, but no deformity. She complained of slight pain, which

was greatly increased on extreme flexion, but I could only detect a slight ridge on the posterior aspect of the radius running in a longitudinal direction, and extending 2 in. upwards from its carpal end, which was painful on pressure; no crepitus could be obtained.

As I was in some doubt as to the exact nature of the injury, I sent the patient to Dr. Stanley Melville, who kindly skiagraphed her. The print showed that there was a fracture of the lower end of the radius, running upwards from the radio-carpal joint, and separating the lower and inner portion of the bone.

In the meantime I applied a Carr's splint, and had the joint gently massaged from the third day onwards, passive movements being commenced on the eleventh day. The splint was worn for five weeks, and at the end of six weeks the joint had practically recovered, except for slight pain on extreme flexion.

The patient was able to resume her occupation fully at the end of four months, and now at the end of six months since her accident she has complete use of her hand with no pain, even on extreme movement.

Kensington.

REDUCTION EN MASSE OF INGUINAL HERNIA.

I WAS called on a Sunday night to see a man, aged about 46, who stated that he had suffered for some time from a rupture (right inguinal). After lifting a weight it suddenly came down. He pushed it back himself, using considerable force; he at once experienced pain, and vomited.

I found him somewhat pale, with a moderate amount of pain about the region of the right internal ring, with slight tenderness and resistance, but nothing very striking; the pulse and temperature were about normal. I felt then that probably some injury had occurred to the bowel when he pushed it back. I prescribed a simple bismuth and soda mixture, with 10 minims of liq. morphinae. Both pain and vomiting, however, continued for a few days. An enema was ordered, with some result, including flatus; but after this nothing was passing through the bowel.

Three or four days after my first visit I had a consultation with the late Dr. Rawlings, of Dorking, who drew my attention to visible peristalsis above and towards the right side of the internal ring. This increased the suspicion that reduction might have occurred *en masse*. Dr. Rawlings advised the discontinuance of the morphine lest symptoms should be masked. At this date the vomiting had stopped, but the moderate pain continued, and still nothing passed. I saw him again that afternoon and night, but the symptoms were no worse. Next morning he was fairly comfortable except for the moderate pain. The pulse and temperature gave no assistance in diagnosis. I again consulted with Dr. Rawlings, and we eventually decided to send him to hospital by motor. He says that the pain was considerable on the way to London. Mr. Berry operated the same evening at the Royal Free Hospital, and found a definite band of the sac tightly gripping the bowel, which although very dark had not lost its lustre. The patient recovered, and when last I saw him was doing his work and supporting his home.

In my opinion this case illustrates the comparatively moderate symptoms which may accompany a severe abdominal lesion, and may serve at some future time to put a fellow practitioner on his guard.

THYROID SUBSTANCE IN ECLAMPSIA.

OBSTETRICIANS seem to be unwilling to admit the possibility of thyroid gland substance being a cure or even a palliative of the albuminuria and skin swelling which always precede yet are not always followed by eclampsia.

The influence of thyroid gland substance in these conditions (I speak of two observations) is so marked, the relief of giddiness, swelling, and check to albuminuria are so pronounced, that it is impossible to overlook the beneficial effects of the medicament.

It is not difficult to propound a theory which might explain the necessity of the exhibition of thyroid gland. There are individuals in whom the thyroid secretion is always less than normal. With such persons the thyroid may be unable to meet the extra demands of pregnancy,

A more complex theory rests on the more than suspected connexion of the thyroid and the urogenital system in both sexes. Suppose an individual in whom the ovarian secretion is less than average, though apparently sufficient to meet the requirements of the system. Let such an individual become pregnant; then as the ovaries are more or less quiescent in pregnancy, the ovarian secretion becomes diminished, if not entirely suppressed; the interdependence of ovary and thyroid is disturbed, with the effect of inhibiting to a greater or less extent the influence of the thyroid secretion.

Under either theory moderate diet and restricted activity of the patient are indicated, in order that the waste products of work and digestion may not impose too great a task on the embarrassed thyroid.

The prophylactic treatment of eclampsia by thyroid gland substance should be given an extended trial, for I do not find that objectors quote failures.

It is, of course, necessary to distinguish pre-existing nephritis or valvular heart disease from the albuminuria due to pregnancy alone.

BRIGHTON INFIRMARY.

PERFORATED GASTRIC ULCER IN A CHILD AGED 11 MONTHS.

(By A. HAROLD DUCKETT, M.B., Ch.B. Aberd., Assistant Medical Officer to the Institution.)

ON May 9th I received an urgent call to see a child who had arrived at the receiving ward, and on arrival I found it had just expired. It was a male child, and appeared to be so terribly emaciated and small for its age that I at first thought its death was due to marasmus accelerated by neglect, but on making a *post-mortem* examination I found another explanation. I took the following notes.

The child weighed 7 lb. 6 oz., and there were on the right thigh and right side of the chest some superficial abscesses. In the thorax I found nothing organically wrong; no bronchopneumonic signs, nor was there anywhere any evidence of tubercle. In the peritoneal cavity there was evidence of food, and on closer examination I discovered a large perforation in the stomach wall near the lesser

curvature. The margin of the ulcer was in a state of necrosis, and there was slight congestion round it. There were no further ulcers visible there nor in the intestine. Traces of milk were evident in the stomach, but nothing in the nature of harder food anywhere.

As to the history of the case, I could get but little help from the mother, except that the child had been "weakly" from birth, and during the past month had often vomited after food.

The symptoms of cases of this nature have usually dated from birth, and have been attributed either to injury at delivery or embolism of the umbilical vein, but the mother says the birth was uneventful. One would not expect a single ulcer if the case were tuberculous, and the tuberculous ulcers do not apparently give rise to any definite symptoms. This case might possibly be consequent on acute gastritis, but I have put it down to be one of "simple perforating ulcer," possibly due to embolism of one of the gastric arteries or of their branches, accelerated by lowered vitality and necrosis. The accompanying photograph illustrates the size and position of the ulcer.

THE late Dr. Samson Gemmill, Regius Professor of the Practice of Medicine in the University of Glasgow, left estate valued at £109,565 8s. 8d.

THE third annual meeting of the Canadian Public Health Association will be held in Regina, Saskatchewan, in September (18th to 20th) under the presidency of Dr. John W. S. McCullough, Toronto.

Reports of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

At a meeting on June 4th, Dr. PLAYFAIR in the chair, Dr. R. A. FLEMING, speaking of the *Cause of death in lobar pneumonia*, said that in autopsies of acute lobar pneumonia colourless blood in the right heart was more frequently present than in cases of death from other diseases. This thrombosis was generally regarded as agonal, but might it not in many cases have been present for hours or days before death? By *ante-mortem* clotting he meant those firm opaque fibrin clots sometimes to be found in the right auricle and ventricle and often extending far into the branches of the pulmonary arteries; they were sometimes firmly adherent to such structures as the pectinate muscles in the auricle, the chordae tendineae of the tricuspid valve, and the columnae carneae of the ventricle. In 61 autopsies of acute lobar pneumonia made by himself there was such *ante-mortem* thrombosis in 39, and in 16 of these the clot was adherent; while in 160 consecutive cases of other diseases there was right-sided thrombosis in only 20, and in 17 there was either bronchopneumonia or some acute suppurative condition. He therefore believed that in lobar pneumonia *ante-mortem* thrombosis took place some considerable time before death in more cases than were generally believed. Among the factors predisposing to this were the high carbonic acid content of the blood, and the excess of thrombokinase derived from disintegrating leucocytes, and this was also indicated by the shortened coagulation time of the blood. Further, there were signs by which this more protracted *ante-mortem* thrombosis could be recognized clinically—namely, an increasing fullness of the jugular veins in the neck, and especially a weakening of the second sound in the pulmonary area. In four recent autopsies he had had the opportunity of confirming the value of these clinical signs. The treatment of every case of pneumonia should take into consideration the danger of *ante-mortem* thrombosis, and should include the exhibition of strophanthus or digitalis in suitable doses from the first, the use of diffusible stimulants such as spirits of ammonia and chloroform, the administration of oxygen, and occasional change of the patient's posture. Further, bleeding should never be performed unless in very robust persons. Dr. GOODALL alluded to investigations made by Dr. Ewart and himself which showed that the coagulation time diminished up to the crisis, and thereafter again slowly lengthened. This depended not on temperature nor on the gross number of leucocytes, but on the number of degenerated leucocytes. The blood plates had recently been shown to be an important source of thrombokinase. Dr. W. T. RICHIE agreed as to the importance of diagnosing dilatation of the right heart in pneumonia, and for this a dusky tint of the ears, nose, and lips, and a weakening of the first sound were useful. He did not agree that digitalis was needed in every case of pneumonia, but where it was it should be given intravenously if an immediate effect were desired. Dr. EASON said that potassium iodide delayed the blood-coagulation time, and he had used it in a large series of cases of pneumonia with good results. Dr. FLEMING replied. Dr. A. NIMIAN BRUCE communicated the results of an investigation into *Multiple neuromata of the central nervous system*. It was begun by the late Dr. Alexander Bruce and finished by Dr. J. W. Dawson. The case was that of a man who died when aged 30 years, and who had shown since birth extreme spastic paraplegia with contractures. The autopsy revealed nodules scattered irregularly through the grey and white matter of the spinal cord, which proved to be neuromata, consisting of nerve fibres with well-formed axis cylinders and medullary sheaths, but without nerve cells. They were definitely related to blood vessels, and could be traced along them round the periphery of the cord from the anterior nerve roots and into the white matter. Nodules were also discovered in the pons and medulla which were different in not being circumscribed, and also in their structure, which was not of nerve fibres but of fusiform nerve cells, which in places were joined end to end, forming cell chains. In these fusiform cells

it was possible to trace the development of an axis cylinder and of a myelin sheath. Dr. A. N. BRUCE then explained the two main views of the development of nerve fibres, the central outgrowth theory, and the peripheral theory of multicellular chains. The investigation of these neuromata had shown that it was not possible to explain their formation on the "central outgrowth" theory, and they seemed to lend support to that of "peripheral cell chains" and of the multicellular structure of the peripheral nerve fibre. The case was thus not only of great interest as a pathological rarity, but of high importance as throwing light upon the still unsettled question of the development of the peripheral nerve fibre.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

At a meeting on June 4th, Sir ANDERSON CRITCHETT in the chair, Mr. BISHOP HARMAN brought forward: (1) A case of *Melanotic growth connected with the iris* and seeming to originate from it. Mr. JESSOP inclined to the view that it sprang from the ciliary body, and pushed the iris on one side, causing flattening of the edge of the pupil. He agreed that it was a melanotic sarcoma. Mr. TREACHER COLLINS mentioned a case of *Melanoma of the iris*, malignant characters having arisen later. He agreed that in the present case the origin of the growth was probably the ciliary body. A possibility in Mr. Harman's case was that it was a cyst, such as Mr. Coats had described, with agglutination of the ciliary processes. (2) A case of spontaneous recovery from *Detachment of the retina*. The patient had had complete detachment for three months, and during it she was in bed three times; she refused operation. Shortly after that date the sight suddenly came back, and now there was no trace of any detachment; all that could be seen were one or two cobwebby lines in the disc. She had vision $\frac{3}{5}$, one-letter. She had 10 D. of myopia, but there had been no accident of any kind. She was a cook in a good family, and one February night she walked out from a hot room to the cold air, and her description was that something black suddenly fell over her eye, and she could not see anything more with it. Mr. GODFRE described the case of a child which came to Glasgow Eye Infirmary with detached retina, and in whom three months later the retina became reattached. Two months afterwards it again became detached, only to again become attached. There was fair vision, and no iritis. Mr. RAYNER BATTEN said he had a case with nearly 20 degrees of myopia and detachment. Detachment occurred also in the other eye, and the patient was so blind for a year or two that she had to be led about. Later she came and said she saw a glimmer of light, and from that date her sight began to return; she accepted her lenses again, and was able to find her way about. He believed her vision was $\frac{2}{5}$. Mr. HERBERT PARSONS said he, like others, was sceptical about spontaneous recovery from detachment being possible until he had a case which altered his view. It occurred in hospital, and, though a little later the patient was very carefully examined, no trace of the detachment could be detected—not even streaks to mark what had occurred. Eighteen months later, however, he came with a relapse. Mr. MACNAB described a case of double detachment which underwent spontaneous cure. In another case in which the condition occurred there had been irido-cyclitis, and he believed it was due to tubercle of the eye; there was a large vitreous opacity, and very extensive detachment; the eye was very soft, being practically devoid of tension; the cornea could be seen to be dull and crinkled. Vision was reduced to mere perception of light. He gave tuberculin and vaccine cultivated from the patient's own *coli bacilli*. For four months now the tension had been normal, and the patient could count fingers at five or six metres. Mr. JESSOP reminded the meeting that when the Ophthalmological Society discussed the subject only one case was reported as having been cured, and that was spoken to by Mr. Nettleship and Sir John Tweedy. Many cases of cure of the condition had been reported, but they had not been lasting. Mr. ORMOND did not share Mr. Jessop's scepticism, and described a case of his own in a patient who had been

treated by glasses for high myopia, and a little later she said her vision suddenly went in one eye. She had obvious detachment of the outer side of the retina. He did a sclero-puncture and removed some fluid, and in three days the detachment had disappeared. He had seen her a number of times since; and the attachment remained absolute. Vision was $\frac{3}{5}$. Mr. LESLIE PARON reminded the meeting that Mr. Harman's case was one of spontaneous reattachment, not after operation. He was more optimistic than Mr. Jessop on the subject. He had seen a case of thirty-five years' standing cured after operation, though it was a double case. In another case, that of a lady with 15 D. of myopia and vision $\frac{1}{2}$ in either eye, there was detachment in one eye, resulting in blindness, and that was followed by detachment in the other eye. After operation her vision was better than before the detachment. In the case of a girl with detachment, she was put on her back and treated with mercury and iodide, and in three months the retina had become reattached, leaving only a curious distribution of retinal pigment. In a series of 28 cases of detachment, which he had looked up, 7 were cured. Mr. NETTLESHP and Mr. JESSOP suggested that in the near future a further discussion on the subject should be held by the section. Mr. NETTLESHP said he had records in his case-books of several cases of detachment which had recovered.

SCOTTISH OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.

At a meeting on May 31st, Dr. BROWN KELLY, who was in the chair, contributed a paper entitled *Nasal thermometry*, this being a description of a method of determining the influence of the nose on the temperature of the inspired air. Some tables shown exhibited the difference in temperature between the inspired and expired air, and the variations which occurred in varying degrees of patency of the nasal passages. Dr. W. S. SYME reported a case of *Otogenous temporo-sphenoidal abscess* in which the capsule, a very thick one, had been removed by operation. The abscess had evidently been present for some considerable time, and only gave rise to symptoms after the patient had received a blow on the head. The abscess was opened and drained, and two days later the patient became comatose. The drainage tube was removed and the opening in the dura enlarged. A necrotic mass presented, and on removal was found to be the capsule of the abscess. The patient did well for six weeks and the abscess cavity filled up, but he ultimately died with a second abscess in the frontal region. Dr. ALBERT A. GRAY, in a lantern demonstration, traced the *Evolution of the inner ear* in regard to the round window and the aqueduct of the cochlea from reptiles to birds and mammals. The varying size of the aqueduct and the relation of the round window to the cochlea and to the aqueduct at different stages of evolution was clearly shown. He also gave a microscopic demonstration of the changes in the labyrinth found in cases of otosclerosis and deaf-mutism, and of a nerve ganglion in the human temporal bone hitherto unrecognized and recently discovered by him. The following were among the exhibits:—Dr. BROWN KELLY: (1) A man with *Double abductor paralysis* of the larynx and other symptoms of central nervous disease, due probably to patchy gummatous lepto-meningitis of the medulla and of the cord in the cervical and lumbo-sacral regions. (2) A child recovered from osteomyelitis of the superior maxilla, the so-called *Empyema of the antrum* of infants. (3) A woman with *Papillomata* growing from the region of the middle meatus; it was pointed out that, like similar growths in the larynx, they had a great tendency to recur. (4) Two cases, a woman and a girl, with *Congenital closure of the posterior nares*. Both had been operated on, but difficulty was experienced in keeping the openings patent. (5) Three cases of *Dermoids* of the anterior border of the nose. Dr. J. R. DREVER: Two patients with *Chronic oedema of the face*. In both there was purulent nasal discharge, from which an autogenous vaccine had been prepared, and was used with beneficial results to the facial as well as to the nasal condition. Dr. J. L. HOWIE: A case of *Congenital defect of the external ear*. Dr. WALKER

DOWNIE: A case of *Carcinoma of the nose*, and a specimen of *Epithelioma of the auricle*. Dr. J. G. CONNAL: (1) A woman on whom he had operated for aural suppuration with labyrinthine symptoms. The radical mastoid operation was performed, and a fistula of the external horizontal canal was found. No pus came from the fistula, and no granulations were present in the neighbourhood, hence the labyrinth was not opened. The woman recovered. (2) A man in whom was exemplified the difficulty sometimes arising in deciding whether a laryngeal lesion is malignant, syphilitic, or tuberculous. In this case one cord was dark-red and swollen and restricted in movement. As the condition was improving under anti-syphilitic treatment opinion inclined towards syphilis. Dr. JAMES ADAM: A case of superficial *Ulceration of the pharynx, palate, and larynx*. At first sight it appeared undoubtedly syphilitic, but it had remained stationary for over two years despite anti-syphilitic treatment. The Wassermann reaction was doubtful. Pneumococcal infection, tubercle, syphilis, and pemphigus were opinions offered as to its nature.

LONDON DERMATOLOGICAL SOCIETY.

At a meeting on May 20th, Dr. MORGAN DOCKRELL in the chair, the following were among the exhibits: Dr. J. L. BUNCH: (1) A case of a woman, aged 50 years, who complained of suffering from great skin irritation caused by the presence of various kinds of supposed lice, specimens of which she brought with her. She was evidently a case of *pediculi cerebri*. (2) The case of a man who had been in the West Indies and had a discharging pigmented lesion on the right forearm; it suggested tuberculosis, syphilis, or Delhi boil; also (3) a case of late secondary and or early tertiary lesions on the face of an Italian. The PRESIDENT: A case of sloughing *Ulceration of the penis* in a young man, which at one time looked like an epithelioma. A section examined under the microscope revealed a thickening of the stratum corneum and granulosum; the mucosa was thickened, but the basal layer was intact. Dr. GRIFFITH: Some *Chromogenic ringworm fungus*, which had changed from violet to grey. Dr. KNOWSLEY SIBLEY: A case of *Diphtheritic dermatitis* in a man aged 55, sent him by Dr. N. J. Williams. For some six months he had had recurrent acute attacks of facial dermatitis, always commencing at the eyes, and rapidly spreading over the face to the sides of the neck. Dr. Galbraith had recently found the Klebs-Loeffler bacillus from the discharge from the right external auditory meatus. He had now had an injection of 5,000 units of antitoxin and was already much better. Dr. HOWARD HUMPHRIS read a paper entitled *Electricity in some diseases of the skin*.

THE Section of Odontology of the Royal Society of Medicine, at a meeting on May 26th, elected the following officers: President, Mr. C. F. Rilot; Vice-Presidents, Messrs. C. Robbins, W. B. Paterson, J. H. Badcock, J. C. Foran, A. W. W. Baker, and G. G. Campion; Honorary Secretaries, Messrs. J. H. Mummery, R. McKay, and F. Coleman; Curator, Mr. J. F. Colyer. Representatives on the Library, Finance, and Editorial Committees of the society and a council of nineteen members were also appointed.

M. E. MALVOZ recently presented to the Académie Royale de Médecine de Belgique a report setting forth the results of a ten years' campaign against ankylostomiasis in the province of Liège. It began in 1903, when a dispensary was opened for the threefold purpose of undertaking periodical examinations in the population of the different coalfields, of insisting on the microscopic control of the dejecta of all persons working in the mines, and of subjecting carriers of parasites discovered by these investigations to an expulsive treatment, whether they felt ill or not. Up to the end of 1912 there were examined 186,040 samples of dejecta, and 8,898 infected persons were submitted to antiparasitic treatment. The result was a very considerable diminution of the general percentage of those infected in the whole of the coalfields of the Bassin de Liège. In 1902 the average was 23 per cent.; in 1912 it had fallen to 2 per cent. In other words, whereas formerly 1 in 4 of the miners was infected, now the parasite was found in only 1 in 50. The great coalfields of the Ans-Montegnée plateau, which were the most infected of the whole district—more than 50 per cent. of the miners suffering from the disease—are now virtually free from ankylostomiasis.

Reviews.

INDIAN MEDICINE.

It is claimed by natives of India that their civilization is the oldest in the world, and that their medicine is as old as their civilization. Whether or not this claim be historically justified, it is certain that in their ancient medical books there are traces of knowledge which is comparatively recent in the West. We therefore welcome Mr. BHISHAGRATNA'S translation of the works of Sushruta, the father of Hindu surgery, because, he says, few of his countrymen and fewer Western scientists "have the opportunity of reading the vast medical literature of ancient India in the original, and of thus forming an independent opinion of the solid and uncontrovertible truths and principles of the science of life and cure that underlie these works of ancient wisdom."¹ The work is to be completed in three solid volumes. The first is now before us; the second has, it is stated by the translator, already appeared, and the third is in the press. Sushruta's work, as originally written, seems to consist of only a few doubtful fragments, the work which now goes by his name being described as "only a recension, or rather a recension of recensions made by Nagarjuna, who is identified with the founder of the Madhyamika School of Buddhist philosophy." Nagarjuna is believed to have flourished in the third or fourth century B.C., and the original work of Sushruta must have been written at least two centuries earlier.

It is often said that Indian medicine was the offspring of the influence of Greek medicine; and, in fact, from the close similarity between the *Samhita* and the aphorisms of Hippocrates, many Western scholars have concluded not only that the inspiration came from Greece, but that Sushruta is Hippocrates in an Indian disguise. On the other hand Mr. Bhishagratna seems inclined to argue that Pythagoras, who introduced the healing art into Greece, brought it from India, where he was initiated into the mysteries of the Brahmins.

Verses on medicine, hygiene, and surgery are scattered through the four Vedas. Vedic India recognized specialism. There were not only surgeons and physicians, but magic doctors, poison curers, and demon doctors. In the Vedic age, before Sushruta, the standard of medical ethics must have been very low, for we read that physicians had to go forth into the open street and call out for patients. Nowadays we have subtler methods of crying our wares. From the fact that the Vedic doctors lived in houses surrounded by gardens of medicinal herbs, it may be inferred that they compounded their own medicines. The translator gives a sketch of the origin of Ayurvedic surgery, which at first was called into being by the necessities of war. In the Rigvedas mention is made of the amputation of legs, which were replaced by iron substitutes, of the plucking out of injured eyes, and of the extraction of arrows. Sushruta first gathered into a systematic form the surgical experiences of the older practitioners and collected the fragments of medicine scattered through Vedic literature. Plastic and especially rhinoplastic operations were, as every one knows, commonly performed in India many centuries before anything of the same kind was attempted in Europe. The demand doubtless created the supply, as cutting off the nose was a very common form of punishment for conjugal infidelity and many other offences. The method of healing these deformities by the transplantation of living skin flaps is an Indian invention. Sushruta is also credited with the discovery of the art of couching for cataract. Limbs were amputated, abdominal sections were performed, fractures were set, dislocations reduced, hernias returned, haemorrhoids and fistulae removed. Where the intestines are injured Sushruta advises that the protruded part be gently replaced; when severed the cut ends should be brought together and living black ants applied. The body of the ant was then cut off, and the heads were left to serve the purpose for which

¹ An English Translation of the Sushruta Samhita, based on the Original Sanskrit Text. Edited and published by Kaviraj Kunja Lal Bhishagratna. With a full and comprehensive introduction, translation of different readings, notes, comparative views, index, glossary and plates. In three volumes. Vol. I, Sutrasthanam. Calcutta: S. I. Bhaduri, No. 10, Kashi Ghose's Lane, 1907. (Demy 8vo, pp. 650; plates 4. Rs. 15, or 21.)

modern surgeons now, curiously enough, often use small clasping hooks in place of sutures for the superficial skin layer of wounds.

In dealing with midwifery Sushruta describes the different movements of the fetus during the process of parturition, the application of forceps in difficult cases, operations such as craniotomy and Caesarean section when delivery was otherwise impossible. Sushruta is said also to have been the first to insist on dissection of dead bodies as indispensable to a student of surgery. To gain skill in surgical operations pupils were enjoined to try their knives repeatedly, first on natural and artificial objects resembling the diseased parts of the body before undertaking an operation. Incision, for example, was practised on plants of various kinds, evacuation on leather bags filled with water and on the bladders of dead animals, scarification on the hides of animals on which the hair was allowed to remain. Venesection was practised on the vessels of dead animals and on the stalks of the water lily, the art of packing cavities and probing on bamboo reeds, the extraction of solid bodies on various fruits, and suturing on pieces of cloth or hide. Ligaturing and bandaging were practised on dummies, cauterization on pieces of flesh, and catheterization on unbaked earthen vessels filled with water. The quartering of sacrificial animals afforded opportunities for the study of practical anatomy. We are told also that Sushruta anticipated the homoeopathic theory. After closely investigating the various views as to what it is in the drug that cures, it is stated that he inclined to the opinion "that it is the potency of the drug that is curative, though he observes that inasmuch as potency cannot exist independently of a drug, a drug is of primary interest for all practical purposes in therapy." This explanation reminds us of the answer of the candidate for the doctor's degree in the *Malade Imaginaire*, who, when asked why opium causes sleep, satisfied the examiners with the affirmation that *Opium facit dormire quia est in eo virtus dormitiva*. Ayurvedic physicians recognized two different sets of principles in the domain of practical therapeutics, which may be stated in terms of Western medicine as the laws of similars and contraries. In addition to these, Sushruta lays great stress on the value of psychotherapy in certain forms of mental or nervous disorders.

There is an anticipation of some of our modern prophets in the following:

A good and proper diet in disease is worth a hundred medicines, and no amount of medication can do good to a patient who does not observe a strict regimen of diet.

Sushruta emphasizes the importance of cleanliness of both spirit and body in the prevention of disease.

It is impossible to discuss Hindu medicine here in detail. Much of the book is unintelligible to the Western reader even in its English dress. But there is much in it that is interesting to the student of medical history, and if we do not accept altogether Mr. Bliishagratna's claim that practically the whole art of healing came from India, enough remains after a liberal discount to entitle Sushruta to a niche in the Pantheon of medicine.

PATHOLOGY AND TREATMENT OF DISEASES OF THE HAND.

The surgical treatment of suppurative infections of the tendon sheaths of the hand and the fascial planes of the forearm is often a source of worry and anxiety to both patient and doctor. The former watches the process with the haunting fear that the ultimate result may be physical disability, and the latter is concerned to prevent the upward extension to new areas and obviate tendon fixation and contracture. Dr. ALLEN B. KANAVEL, in his volume *Infections of the Hand*,² presents a very complete study of these conditions. He has made numerous experimental and anatomical investigations, and now presents a record of these and the surgical deductions to be drawn. The experiments are of great interest. Their object is to show the precise limits and branches of the palmar spaces by means of injections into the tendon sheaths of the fingers

of materials impervious to x rays and to demonstrate their relation to the bones. The anatomical researches are also characterized by great thoroughness. Figures are given showing the various structures in the hand in cross section at eight different levels, and in the forearm at several levels. If infection reaches any tendon sheath at any point Dr. Kanavel can demonstrate all the possible travellings of the pus.

The same thorough patient methods are found in the sections devoted to diagnosis and treatment. The author has apparently had the benefit of working in a large outdoor clinic, and has had the assistance of friends in the surgical work. Some of his conclusions are therefore interesting, and his results seem to be uniformly good.

He is more than doubtful of the value of Bier's treatment by passive hyperaemia in infections of the hand; he thinks it may be an aid, but not much more. Operation in suppurative teno-synovitis should, he says, always be performed under general anaesthesia and in a bloodless field. Where the process is virulent and acute the Esmarch bandage is left on the arm (decidedly slacker than for operative purposes, practically Bier's hyperaemia) for twelve to eighteen hours after operation. This is done not so much for therapeutic effects as to prevent the rapid absorption of virulent toxins.

In the treatment of carbuncle excision is condemned; the method approved is to make crucial incisions, beginning wide of the indurated area, and to undercut the flaps so formed. The propriety of operating with due regard to the various anatomical considerations involved, not in haphazard fashion but with system, is pointed out.

We have pleasure in recommending this work to the notice of practitioners, not that they may read it through, but that they may refer to it for plenty of information on the possibilities of infections of the hand. We feel bound to say that the book is too big. If such a limited bit of surgery requires 447 pages for the telling of its story, where and when shall we see the whole tale of the science and art of surgery? Dr. Kanavel's work would be more valuable if it were mercilessly cut down with careful excision of all the redundances and more precise enunciation of broad general principles.

VERTEBRATE OSTEOLOGY.

ADVANCED students in anatomy and teachers of osteology must frequently feel the need of a good work of reference on the osteology of the vertebrate kingdom. A valuable book for this purpose, as well as for obtaining a detailed account of the comparative anatomy of bones, is *The Vertebrate Skeleton*,³ by Professor S. H. REYNOLDS, M.A., of which a second edition has recently been published. Professor Reynolds's work since 1897—the date of the first edition—has been increasingly, and latterly almost exclusively, geological. He tells us that he had thought at first of merely revising the book without bringing it up to date, but, fortunately, Professor S. W. Williston, the distinguished palaeontologist, learning that the new edition was in progress, offered to revise the section devoted to reptiles, and this induced the author himself to bring the whole book more up to date. This decision has led to considerable improvements in the volume, which can be confidently recommended as an admirable account of the vertebrate skeleton. We would particularly emphasize the value of Professor Williston's contribution to the osteology of the reptilia, the chapters devoted to which he has practically rewritten, and has contributed, in addition, some notes on the bones of birds and the stegocephalia. The whole volume constitutes an admirable contribution to comparative osteology, and medical students, and medical men, will find therein much that throws light on the skeleton of the human subject.

PIONEERS.

It is a long time since we have read a more enjoyable book than Dr. VICTOR ROBINSON'S *Pathfinders in Medicine*.⁴

² *Infections of the Hand: a Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand, and Forearm*. By Allen B. Kanavel, M.D., Assistant Professor of Surgery, North-Western University Medical School, London: Baillière, Tindall, and Cox. 1912. (Med. 8vo, pp. 460; figs. 133. 15s. net.)

³ *The Vertebrate Skeleton*. By S. H. Reynolds, M.A., Professor of Geology in the University of Bristol. Second edition. Cambridge University Press, 1913. (Demy 8vo, pp. 551; figs. 144. 15s. net.)

⁴ *Pathfinders in Medicine*. By Victor Robinson. With a letter from Ernst Haeckel and an introduction by Abraham Jacobi. New York: Medical Review of Reviews. 1912. (Med. 8vo, pp. 317; 16 illustrations. 10s.)

Every page teems with interest and sparkles with vivacity and humour. The book, too, has real value as a contribution to the biographical history of medicine and science. The author has a style of his own, a style with great merits, and, some will think, obvious faults. It is a flamboyant style, with a tendency to rhapsody and floridity; but the unflagging vigour and eloquence help to atone for a few sins of taste. Professional books are apt to be timidly academic; it is quite a refreshing change, therefore, to meet with a medical writer whose erudition serves not for the mitigation but merely for the enrichment of his robust human quality, one who, by the exercise of a vivid imagination, breathes life into the dry records of the past. Here one may learn many facts that are apt to be forgotten with regard to the anticipation by great men of discoveries for which the world at large had centuries to wait; as, for example, how Galen, eighteen hundred years ago, noted that "those who sleep in the same bed with consumptives fall into consumption, also those who live long with them, eat and drink with them, or wear their clothes and linen"; or how Arctæus of Cappadocia (so completely "the forgotten physician" that the date of his birth cannot otherwise be determined than as falling in one of the first three centuries of our era), by revealing in his writings his practice of auscultation, anticipated by at least fourteen centuries the discovery of Laënnec. Dr. Robinson has even a good word to say for Paracelsus; and indeed it is hard to refute the claim for immortality on behalf of the man who not only was the first to describe zinc and to insist on the therapeutic value of metals in general, but to whom we are indebted for the internal administration of mercury in syphilis. From the *Christianismi Restauratio* of Michael Servetus (a book which, by reason of its theological heterodoxy, excited the wrath of Calvin and so cost its author his life) Dr. Robinson quotes a remarkable passage describing the pulmonary circulation in clear and accurate language. "So effectually was the edition destroyed that Harvey knew not his true precursor." He quotes Realdus Columbus but not Servetus. Full of historical as well as of professional interest is the chapter on "Ambroise Paré, that quaint and delicious writer, "the surgeon of princes and the prince of surgeons," who, by his accidental discovery of the injurious results of the barbarous practice of cauterizing gunshot wounds with scalding oil, effected a revolution in their treatment. There can be few more vivid passages in the literature of our calling than that cited by Dr. Robinson in which Paré describes the horrors of the plague as witnessed by himself. That it is impossible for Dr. Robinson to be otherwise than entertaining is proved by the fact that his chapter on Henry Cavendish makes quite interesting reading. For surely no more methodical, emotionless, or unsocial being ever walked the earth than that eminent chemist, physicist and mathematician who weighed the planet, discovered hydrogen and demonstrated the composition of water. Among the "pathfinders" whose careers are discussed are "Scheele the Apothecary," "Hunter the Natural Philosopher," "Jenner and Vaccination," "Laënnec and Auscultation," "Simpson and Chloroform," Semmelweis, Schleiden, and Schwann. An eloquent panegyric upon "Darwin, Saint of Science," brings the book to a close. The dedication is to Ernst Haeckel, whose letter of acknowledgement is reproduced in facsimile. The author evidently belongs to the same school of thought.

BURDETT'S HOSPITALS AND CHARITIES.

In the edition of *Burdett's Hospitals and Charities*⁵ for 1913 the most novel chapter is one dealing with the interaction of the National Insurance Act and the hospitals. Sir HENRY BURDETT'S view, as we understand him, is that the Insurance Act was from the very beginning only workable thanks to the existence of the hospitals, that already they have done a great deal of work for the insured, and that as time goes on the demands made upon them are bound to increase because all panel medical officers will practically be acting as recruiting sergeants in regard to them. Taking the figures of the actuaries as to probable sickness on the one hand and the number of

beds available in hospitals on the other, he thinks it likely that the insured will require for their use the majority of beds at present in existence. As the voluntary hospitals cannot be given up entirely to the insured, the accommodation, he holds, must somehow be supplemented and the voluntary hospitals at the same time relieved of the added expense thrown upon them. Not long ago, when it was desired to get over the evil of sleeping out on the Embankment, the Local Government Board took advantage of its special powers in relation to the metropolis and put the Metropolitan Asylums Board into a position to co-ordinate and control, with excellent effect, the whole of the agencies, official and unofficial, for dealing with casuals. When, again, beds for tuberculosis patients were required, there was plenty of accommodation in the institutions of the Metropolitan Asylums Board, but since the Act excluded Poor Law authorities from dealing with the tuberculous insured this accommodation could not be utilized as it stood. In this case the difficulty was got over by the London County Council making an arrangement with the Metropolitan Asylums Board by which it took over some of its institutions and placed them at the disposition of the London Insurance Committee. In framing a National Insurance Amendment Act a hint should be taken from these two facts. The amending Act Sir Henry Burdett considers should enable the Local Government Board to divest Poor Law infirmaries of such Poor Law character as they possess and throw them open to the insured, enable the Board and municipalities throughout the country to lend money to voluntary hospitals for building purposes at 3 per cent. interest, plus 1 per cent. by way of sinking fund, giving power at the same time to reimburse voluntary hospitals the actual *pro rata* cost of treating insured persons as in-patients. In these ways both the immediate and future needs created by the Insurance Act would, he argues, be met, and the hospital system of the country be perfected without any additional charge on the ratepayers, and without interference with the present status of voluntary institutions. The latter, as also complete co-ordination and co-operation of all existing agencies for the indoor treatment of the sick, he regards as essentials. The rest of the contents of this valuable reference book are on all-fours with those of its immediate predecessor, but, in regard to the future, a statement of interest is made in the introductory chapter. Sir Henry Burdett removed last year one of its very few blots by taking as the basis of his useful commentaries the same figures as those supplied in the general text, and in the next edition he proposes, it would appear, to recast the volume altogether, with the object of bringing it out, if possible, much earlier in the year and therefore much closer to the date to which the figures supplied for the most part relate. In this connexion he urges once more the desirability of all hospitals adopting the same financial year, and suggests that since very many institutions have already fallen into line in the matter there can be no insuperable difficulty in the way provided secretaries will undertake the trouble involved. Both these theses are absolutely sound.

NOTES ON BOOKS.

THERE are not many enterprises that, like Minerva, can boast that they sprang full grown from the head of their progenitors. The history of most human undertakings is one of obscure beginnings and constant struggles against difficulties and disappointments of every kind; and particularly is this the case with regard to philanthropic works that are dependent upon the goodwill and generosity of the public. Mr. B. BURFORD RAWLINGS, in his book *A Hospital in the Making*,⁶ gives an interesting account of the modest beginnings of what is now the famous National Hospital for the Paralysed and Epileptic. Founded in 1860 by Mr. Edward Chandler and his sisters, whose sympathy for the helpless victims of paralysis had been aroused by the illness of a near relative, the work of the National Hospital was for some years carried on in a private house in Queen Square, which contained ten beds destined for persons of either sex suffering from paralysis and other affections of the nervous system. Small as it was, the new establishment was at that time the only

⁵ *Burdett's Hospitals and Charities, 1913*. By Sir Henry Burdett, K.C.B., K.C.V.O. London: The Scientific Press, 1913. (Cr. 8vo, pp. 976. 10s. 6d. net.)

⁶ *A Hospital in the Making. A history of the National Hospital for the Paralysed and Epileptic (Albany Memorial), 1859-1901*. By B. Burford Rawlings. Published by Sir Isaac Pitman and Sons, Ltd., 1, Amen Corner, London, E.C. 1913. (17p. 27s. 5s.)

hospital in England where such diseases were admitted; and Mr. Rawlings has traced its gradual growth and development from the day of its opening down to the year 1901, when his long connexion with it ceased. The book gives a vivid picture of the working of a large charitable institution; and incidentally shows the salutary change in public feeling in regard to the care of the sick poor, evinced by the higher standard of comfort and the increased and unremitting care for the welfare of hospital patients. But as a record of the development of an institution in which some of the greatest advances in medicine and surgery have been made it is less satisfactory. Anyone ignorant of the facts might easily gather that the "making" of the hospital was mainly the work of Mr. Burford Rawlings. Valuable as that work may have been in its own sphere, it cannot be too strongly insisted on that the economic and administrative management of a hospital is altogether secondary to the work of the medical staff. While the book may be accepted as a record of Mr. Burford Rawlings's association with the National Hospital for the Paralysed and Epileptic, it is a very inadequate history of an institution which the fame of its medical staff has made a Mecca of neurology, visited by scientific pilgrims from every part of the world.

MEDICINAL AND DIETETIC ARTICLES.

Soluble Salts of Acetyl-salicylic Acid.

WE have received from Mr. W. Martindale (10, New Cavendish Street, London, W.) samples of tylicalsin and tyllithin, which are respectively the calcium and lithium salts of acetyl-salicylic acid. Both are white powders having a slight sweetish taste and a faint acetous odour. They are very readily soluble in water, and their solutions rapidly undergo hydrolysis in the presence of alkali, showing salicylate in considerable quantity after a very short time. The advantage presented by these salts over acetyl-salicylic acid is, of course, their far greater solubility, favouring rapidity of action. They are supplied in 7½-grain tablets or in powder.

Standardized Thyroid Preparations.

A good deal of work has been done in recent years in the analysis of thyroid glands derived from sheep raised in different localities and killed at different times of the year. The results have revealed wide variations in the amount of iodine contained in the glands, and as the activity has been shown to be due to the organic compounds of iodine these differences are of serious importance. Standardization in accordance with the amount of organically combined iodine appears, therefore, to be a wise course. Mr. W. Martindale (10, New Cavendish Street, London, W.) has submitted a sample of liquor thyroidei standardized to contain 0.025 gram of iodine in organic combination per 100 c.c.m., and also prepares the desiccated gland containing 0.2 per cent. of organic iodine, the latter being further supplied in the form of tablets of different strengths.

MEDICAL AND SURGICAL APPLIANCES.

A Portable Ward Screen.

COLONEL W. G. PRIDMORE, I.M.S., draws attention to a portable ward screen made to his design in Rangoon, and regarded at the general hospital in that city, where it is now in use, as a decided improvement on other appliances of like purpose. In its construction materials locally obtainable have been used, and found quite satisfactory. The skeleton of the screen consists of a frame of ¾-in. steel tubing, with the side bars 2 ft. 11¼ in. apart, the top bar 5 ft. 1½ in. from the ground, and the bottom bar 14 in. from the ground. It is supported by bent segments of the same material, which, like the horizontal bars, are attached to the uprights by T-joints. The tubing forming the e feet is filled with lead, so as to secure stability. The framing is coated with a manganese paint, which is easily renewable, and converted into a screen by drawing over it an envelope of white cotton. Strings and buttons are thus avoided, and provided the envelope is changed regularly the screen always has a clean, neat appearance. The bringing of several screens into close apposition when so desired is rendered possible by making one foot of each screen lower than its fellow, and lengthening the corresponding upright accordingly.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).

SUBSECTION OF CHEMICAL PATHOLOGY.

THE Subsection of Chemical Pathology has been constituted this year for the first time as a separate section apart from the Section of General Pathology. It will meet under the presidency of Dr. F. Gowland Hopkins, F.R.S. The meetings will be held in the Mechanical Theatre of the Royal College of Science, South Kensington.

Discussions.

On Thursday, August 7th, the subject for the morning discussion will be the pathological conditions due to defects of diet. The discussion will be opened by the President of the Subsection, who will be followed by Dr. H. Schaumann, of Hamburg.

On Friday, August 8th, a joint discussion will be held with the Section of Bacteriology and Immunity on the subject of cancer, the chemical aspects of which will be discussed by Professor Carl Neuberg, of Berlin, and Dr. E. Freund, of Vienna.

On Saturday, August 9th, the subject will be the clinical applications of pathological chemistry. The discussion will be opened by Professor Otto Folin, of Boston, U.S.A., and Dr. A. E. Garrod, of London.

On Monday, August 11th, Professor Otto Cohnheim, of Heidelberg, will open a discussion on the chemical pathology of the alimentary tract. Dr. G. Barger, of London, will speak next.

On Tuesday, August 12th, a joint discussion will be held with the Section of Physiology on the subject of the endogenous metabolism of proteins. Dr. E. Aberhalden, of Halle, and Dr. H. Dakin, of New York, will act as reporters on this subject.

The discussion on the subject of the clinical applications of pathological chemistry will, it is hoped, draw a large audience, as it is intended to bring forward many points in which chemical investigations have important bearings on diagnosis and treatment. The joint discussions also, with the Sections of Immunity and Physiology, will be of especial interest, as the subjects under discussion—cancer, and the endogenous metabolism of proteins respectively—will be approached from different points of view by the representatives of the respective sections.

The afternoons will be given up to the reading and discussion of independent papers. The number of papers at present submitted by English authors are few; further papers will therefore be acceptable. The titles must be sent as soon as possible to the central office. Among the subjects treated in the papers already received are the following:

The Recognition of Pancreatic Insufficiency.

The Ferments of the Gastric Juice in Carcinoma of the Stomach.

The Action of Light on Animal Chemistry.

The Ferments of the Blood in Normal and Pathological Conditions.

Sulphaemoglobinaemia.

It is proposed to have a Sectional dinner.

A Museum Subcommittee has been formed for the purpose of arranging for exhibits of interest from the point of view of Pathological Chemistry. Professor Walker Hall is Chairman and Dr. H. Maclean Acting Secretary. The exhibits will be shown in the General Museum.

The Secretary of the Section is Dr. J. F. Gaskell, 23, Ladbroke Grove, W., and Dr. G. Barger has undertaken the duties of Editor of the *Transactions* of the Section.

THE National League for Physical Education and Improvement has recently added to its series of health publications a new health poster and two health leaflets. The poster deals in a graphic manner with the evils arising from the use of push-carts for very young children, showing on the one side a young baby huddled up in a push-cart with the lower part of its body exposed to draughts and its chest contracted, and on the other side the same child undressed, with its spine much bent as the result of the use of these cheap instruments of torture. The poster is printed on stout manilla paper in life colours, from a design by the Nurses' Social Union. One of the leaflets deals with the hygiene of a bedroom such as a village mother would have, and explains in the simplest language what should be done in order to keep such rooms healthy. The other leaflet is on "Food and Drink," and is equally suitable for distribution by health or district visitors, or in schools where domestic economy and hygiene is taught.

THE PROGRESS OF CREMATION.

THE *Transactions* of the Cremation Society of England (No. XXVI), recently issued, contains the report of the council of the society for 1912. It states that during the year ended December 31st, 1912, 125 cremations were carried out at the society's crematorium near Woking, as compared with 114 in 1911. With two trifling exceptions there has been an increase at each of the crematoriums in Great Britain during the past year. The total number of cremations in 1912 in Great Britain was 1,134, as compared with 1,023 for 1911. Of this total 591 took place at Golder's Green. The appended table gives the figures for Great Britain during the last twenty-eight years.

Annual Meeting of Society.

At the annual general meeting of members of the society, Sir Charles Cameron, President, who was in the chair, in moving the adoption of the report, said that the movement was progressing in Great Britain steadily, though by no means so rapidly as he would like. The progress made was shown by the fact that during the eleven years that elapsed between the opening of Woking Crematorium in 1885—the first establishment in this country—and that of the fourth, which was opened at Liverpool in 1896—those at Manchester (1892) and Glasgow (1895) being the second and third respectively—the number of cremations in Great Britain was less by 62 than the total for the twelve months of last year. In the thirteen years from 1896 nine other crematoriums had come into existence, and 11,118 bodies had been burnt. The number of cremations in each ensuing year had surpassed that of most of the preceding ones, and last year's figure of 1,134 accounted for more than a tenth of the aggregate number during the twenty-eight years the society had been in existence. Since 1904 the annual number of cremations in Great Britain had doubled. So far as they had been received, the figures for 1913 showed an increase over those of 1912, and should the movement continue to progress in the future as it had done in the past, as there was every prospect it would, the present generation might hope to see the practical fruit of the society's work in the solution—at least to a very large extent—of the problem which every generation found more difficult, where to find ground for the burial of the nation's dead. Sir Charles Cameron went on to say that, although cremation had been legalized in Prussia only within the last two years, the number of cremations in that country was close on 9,000. Making allowance for the difference of population, the number of cremations per 100,000 inhabitants was about three times as great in Germany as in this country; and the present rate of progress in Germany might be judged by the fact that the number of cremations in 1912 exceeded that of 1911 by over 1,300—a figure larger than the entire number

of cremations in Great Britain in the last and busiest year of the society. The statistics for the United States were incomplete, but, according to the latest information available, the number of cremations there last year amounted to between 7,000 and 8,000. But the most practical recognition of the advantages of that mode of disposal of the dead was at St. Gall in Switzerland, a town of some 20,000 or 25,000 inhabitants, where the municipality had provided facilities for cremation, and would only allow the ashes of cremated persons to be interred within its jurisdiction. The fact that there were 201 cremations at St. Gall in 1912, which would represent a death-rate of some 13 per 1,000, would indicate that the number still clinging to earth burial must be very inconsiderable. It was plain, therefore, that the cremation movement had commended itself to every section of the community. He had no information how far this was the case throughout Germany, but in certain districts it certainly held good to a very great extent. Thus in Possneck, a small town in Saxe-Meiningen, in 1912, out of 123 adults deceased, 62, or over 50 per cent., were cremated. In this country, on the other hand, the adoption of the method had hitherto for the most part been confined to the more highly educated section of the population. Among those whose bodies were cremated at Golder's Green during 1912 were the late Bishop of Truro, Sir Frederick Wallis, Sir Henry Butlin, Mr. John Troutbeck (coroner for Westminster), Lady Rendel, Mrs. Lecky, and Sir John Tollemache Sinclair. [It may be added that quite recently the remains of Lady Dorothy Nevill, Lord Ashbourne, and Mr. Alfred Austin, the poet laureate, were cremated there. The remains of Lord Rendel were cremated the other day at Woking.] But the prejudice among the poorer section of the population seemed at last to be giving way, and among the bodies cremated at Golder's Green and Woking in 1912 were those of over a score of working men.

Cremation Abroad.

The following facts, which are given in the *Transactions* of the Cremation Society of England, bring up to date the information given in the *BRITISH MEDICAL JOURNAL* of February 23rd, 1911, and April 27th, 1912:

Germany: Five new crematoriums were opened in 1912—at Berlin, Frankfurt-on-the-Main, Hagen, Wiesbaden, and Munich. The Municipality of Freiburg in Baden has sanctioned the erection of a crematory. The total number in operation in the German Empire is 34. The number of cremations during 1912 was 8,858, and the total number cremated since the opening of the first crematorium at Gotha in 1879 to December 31st, 1912, was 46,387. *France:* There are crematoriums at Paris, Père Lachaise, Lyons, Marseilles, Rheims, and Rouen. *Switzerland:* There are ten—at Zurich, Basle, Geneva, St. Gall, Bern, Lausanne, Chaux de Fonds, Winterthur, Bienne, Aarau. The total number cremated from 1889, when the Zurich crematorium was opened, to 1912 was 9,332. *Italy:* There are crematoriums in operation at Asti, Alessandria, Bra, Bologna,

* Golder's Green Crematorium in operation.

Brescia, Como, Cremona, Florence, Genoa, Leghorn, Lodi, Milan, Modena, Mantua, Novara, Padua, Pisa, Pistoia, Perugia, Rome, Siena, Spezia, San Remo, Turin, Udine, Verona, Varese, and Venice. *Scandinavia*: There are crematories at Stockholm and Gothenburg in Sweden, at Bergen and Christiania in Norway, and at Copenhagen in Denmark. *Belgium*: Cremation is not yet legalized, but an active propaganda is carried on with that object. *North America*: There are 41 crematoriums—43 in the States and 1 in Canada. In 1932 there were 33 in the States, and in that year there were 3,200 cremations. From the latest statistics available about 7,250 were carried out in 1912, and the total number since the opening of the first crematorium in 1876 is now more than 65,000. *South America*: Crematories exist or are in course of construction at Rio de Janeiro, Buenos Aires, and Montevideo. *Asia*: Setting aside India, Siam, Tibet, and Japan, where cremation is the customary way of disposing of the dead, a crematorium for the special use of Europeans has been established at Calcutta, and one in Shanghai. *Australia*: A crematorium was established in Adelaide in 1903, and a society has been formed in New South Wales for the purpose of establishing one in Sydney. *New Zealand*: The City Council of Wellington has erected a crematorium, and the Auckland Cremation Society is urging the council of that city to establish one. *South Africa*: A movement has been set on foot for the establishment of a cremation society in South Africa, with a view to the erection of crematoriums at Cape Town and Johannesburg.

OPENING OF EXTENSIONS TO HARROGATE SPA ESTABLISHMENTS.

HARROGATE has long been favourably known to the medical profession as a well-organized and enterprising health resort which is never content to rest on its laurels. Considerable extensions of its bathing facilities have recently been made, and on Saturday, June 7th, these were formally opened by Sir David Burnett, Lord Mayor of London, who visited Harrogate in civic state. The Corporation of Harrogate, acting in conjunction with the Harrogate Medical Society and the Great Northern and North-Eastern Railway Companies, invited a large number of prominent members of the medical profession to be their guests over the week-end, and all concerned in the arrangements are to be congratulated on the thoughtful way in which everything was devised for the comfort of the guests, and the almost royal hospitality which was shown. A special train conveyed the Lord Mayor, the Lady Mayoress, the Sheriffs of the City of London, Alderman Sir Thomas Crosby, M.D., LL.D., and several other members of the civic party, and a number of London medical men to Harrogate. On arrival the guests were distributed among the principal hotels of the town, the Lord Mayor and Sheriffs being housed at the Queen Hotel, and a large medical contingent at the Majestic.

The extensions opened on Saturday were a new Pump Room joining the Royal Pump Room, better known as the "Old Sulphur Well." This new building has been found necessary to accommodate the large number of visitors using this water, the average number of drinkers before nine in the morning last season being about 2,700. The extension more than doubles the old area of the Royal Pump Room, and forms a cheerful and comfortable promenade. Extensions have also been made to the Victoria Baths, once the chief bathing establishment of the town; this, though supplemented in 1897 by the Royal Baths, to which additions were made at great expense so recently as 1910, has been found to be inadequate to meet the needs of the rapidly increasing number of bathers. A new wing has been added to the Prince of Wales Bath at Starbeck, and an important addition has been made to the amenities of the town, as well as to its wealth of mineral springs, by the acquisition by the Corporation of the Harlow Car estate, which consists of an hotel, a suite of baths, and seven mineral springs. This estate is to be developed on Continental spa lines, and no doubt in the near future will be found richly to repay the sagacious enterprise of the Corporation and testify to the administrative capacity of Mr. Henry J. Buckland.

The opening ceremony, performed by the Lord Mayor, was a most picturesque event. The civic party in full state arrived at the Royal Baths, where a large body of the public was in waiting. The streets on the route were gaily decorated. Amongst those on the platform were the Bishop of Ripon, Lord Faber, the Hon. Edward Wood, M.P. for the division, and many other distinguished people, but the gathering of Yorkshire Lord Mayors and Mayors was probably unique. Almost, if not

quite, all of the heads of the municipalities in Yorkshire were there, a fact to which the Mayor of Harrogate (Mr. J. S. Rowntree) referred with pardonable pride; and a typical Yorkshire assembly they formed, radiating an air of justifiable satisfaction with their county, their hosts, and the towns which they represented, which was pleasantly characteristic of the proceedings of the week-end. Yorkshire is quite convinced that it is the greatest county in England—not only in size—and the municipal fathers on the platform were there to emphasize the fact that Harrogate, in showing the world what a watering-place should be, was proving herself worthy of the county. The ceremony was commendably short, the main item, apart from the ceremonial opening of the extensions, being a concise and business-like statement by Mr. Councillor Sheffield, Chairman of the Spa Establishments, showing the marvellous progress of the institutions under his care. He made a claim which was amply verified by the visitors afterwards—namely, that Harrogate was second to no spa in the world, either in the amplitude of its natural resources or in the ability and courage with which it had utilized and developed them. After tea the medical visitors were shown over the various bathing establishments, and the completeness of the arrangements made a great impression on those to whom Harrogate was previously unknown, except by repute. A mere list of the various kinds of baths is bewildering. Harrogate has over eighty different kinds of springs, of which all but sixteen are used for bathing purposes. It is mainly through its sulphur waters that Harrogate has become famous, but to the various combinations of sulphur baths the management has added all kinds of massage, inunction, electric light, and mechanical treatments. Peat is brought from the Yorkshire moors, brine from Cleveland, and, in short, there seems to be hardly any form of therapy known to bathing establishments of this kind which cannot be supplied at Harrogate, and supplied in comfort. It is probably true to say, with small reservations, that the medical man can obtain at Harrogate for his patients all the therapeutic advantages offered by Continental spas, combined with beautiful surroundings and a most invigorating air. Full particulars of the different forms of treatment available at Harrogate can be obtained from the general manager, Mr. Buckland. Harrogate also possesses very fine hotels, probably as good as can be found anywhere, and boarding-houses to suit almost every purse.

On Saturday evening the guests of the Corporation were entertained to dinner in the Majestic Hotel, and over 300 guests sat down. This large number was easily accommodated in the fine dining-room, the only difficulty, and one inseparable from such a vast room, being a little trouble in hearing some of the speakers. The Mayor of HARROGATE was supported by the Lord Mayor of London, by the Lord Mayors of York, Leeds, and Bradford, and the Mayors of the Yorkshire boroughs. Amongst the prominent representatives of the medical profession were Sir James Barr (President of the British Medical Association), Sir James Crichton-Browne, Sir Alexander Dempsey, Sir John Moore, Sir C. Nixon, and Sir Peter O'Connell.

SIR JAMES BARR proposed the health of the Lord Mayor, Aldermen, Sheriffs, and Corporation of London, to which the Lord Mayor responded in very happy vein. Sir J. CRICHTON-BROWNE proposed "The Harrogate Medical Society" with his usual skill and glowing rhetoric, mentioning the names of some of the well-known Harrogate physicians of earlier times. His story of the Irish doctor who had difficulty in naming the diseases from which his patients were suffering deserves reproduction. The doctor adopted the method of using the titles of George Meredith's books. A patient who was suffering from appendicitis was told he had "Diana of the Crossways"; indigestion was christened "Sandra Belloni"; while alopecia was designated "The Shaving of Shagpat." Dr. CAMPBELL BOYD, President of the Society, in response, made a witty reply, which was received with great applause. The toast of "The Guests" was proposed by Lord FABER, and responded to by that wonderful octogenarian, Sir THOMAS CROSBY, whose voice was distinctly heard all over the room. Mr. SPENCER LEIGH HUGHES, M.P., a noted after-dinner speaker, who also responded, lived well up to his reputation, and kept his audience in a continual chuckle. An excellent dinner and a well-planned

toast list were brought to an end by the toast of "The Mayor and Harrogate Spa," moved by Alderman Sir CHARLES WAKEFIELD and responded to by the Mayor, who must be heartily congratulated on this as well as on the other items of the week-end's programme in which he took part. The visitors then proceeded to the Kursaal, which, with characteristic Yorkshire absence of mock modesty, boldly proclaims outside, its claim to be "the handsomest concert hall in England"—and certainly does not belie the claim inside. The Kursaal Orchestra, under the leadership of Mr. Julian Clifford, is too well known as one of the finest orchestras in the country to need any praise here.

On Sunday morning the civic party went to church, and afterwards paid a private visit to the bathing establishment. In the afternoon the whole party was taken in motor cars to Fountains Abbey and Ripon, and was thus given an opportunity to judge for themselves of another of Harrogate's claims—namely, that it is a beautiful town set amidst some of the most beautiful scenery in this or any other country, and, judging by the freely expressed admiration of the party, the patriotic Yorkshiremen will have no reason to quarrel with the verdict. After tea at the Ripon Hydropathic the guests were motored back to Harrogate, and those of the London party who were not staying overnight were brought to the station and left at 6.30 in the special train, in which dinner was served. All concerned—the Corporation of Harrogate, the Harrogate Medical Society, and the Great Northern and North-Eastern Railways—have every reason to congratulate themselves on the success of the whole affair. Harrogate looked its best, the welcome of the people was warm, the hospitality was worthy of the county—we cannot say more; the natural and other advantages of Harrogate from a holiday and medical point of view were brought fully home to the visitors, and everything went, so far as one could see, without a hitch. Special thanks are due to Dr. Shepherd Boyd, President of the Harrogate Medical Society, and to Mr. Buckland, manager of the baths. It is not difficult to understand Harrogate's continued and well-deserved success as a health resort when the irresistible combination of a fine town possessing many natural advantages with an enterprising corporation, a medical faculty ready to make the best use of all therapeutic facilities, and a manager always ready to meet all demands upon the bathing arrangements, are taken into consideration.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

THE FOOD AND DRUGS ACTS AND SECRET REMEDIES.

ON June 5th evidence was given on behalf of the Local Government Board by Dr. A. W. J. MacFadden, Chief Inspector of Foods under the Board. He explained the relation of the Board to the work of public analysts throughout the country, and mentioned that the Board had received representations in favour of the removal of the exemption of proprietary medicines from the operation of Section 6 of the Food and Drugs Act. His view was that control of proprietary medicines could not be secured by that means unless the Sale of Food and Drugs Acts were extended to require full declaration of the nature and amount of the ingredients, the declaration having the force of a warranty. Without expressing an opinion as to the desirability of requiring such a declaration, he pointed out that it would require troublesome and costly analytical work. As to the proposal, made by several witnesses, to secure a more limited control in regard to certain dangerous or potent drugs in proprietary medicines, it would require the amendment of the Sale of Food and Drugs Acts to provide for a statement on the label of the name and dose of the drug, to constitute such a label a warranty and to punish any breach with a substantial penalty. The witness outlined the provisions of the United States law as regards "misbranding" and of the West Australian Health Act, 1911, for controlling false declarations. If any legislation on similar lines were contemplated for this country, he did not think it would be practicable to provide it by means of extensions of the Sale of Food and Drugs Acts,

because these measures placed responsibility primarily on local authorities. It would be necessary in the case under discussion for owners of proprietary articles to submit their advertisements and labels to a central authority. Such a scheme would not be without difficulty, and it would involve a form of censorship similar to that exercised in Australia and the United States.

In reply to the Chairman, the witness said that the Sale of Food and Drugs Acts affected the proprietary medicine trade very little, and no extension could make them applicable. It would be necessary for Parliament to make a fresh start, and create a new body with new powers.

Questioned by various members of the Committee as to the West Australian law, the witness agreed that its provisions, which he thought admirable, might not be applicable to this country.

At the invitation of the Chairman, Dr. MacFadden outlined his personal views as to a method of regulating the trade in proprietary medicines. He would set up a censorship of labels and advertisements, not to deal with all advertisements and other announcements, but with those brought to the notice of the authorities. On the censorship committee the General Medical Council and the Pharmaceutical Society would be represented. It would be necessary for the Committee to have the maker's formula before it; this might be disclosed obligatorily but in confidence. He would give the Committee power to prohibit sale until the statements accompanying a proprietary medicine were such as the Committee could approve.

SUGGESTED ALTERATIONS IN THE LAW.

Mr. Guy Stephenson, Assistant Director of Public Prosecutions, who gave evidence at an earlier stage of the inquiry (BRITISH MEDICAL JOURNAL, June 15th, 1912, p. 1373), was recalled. He said that since he was last before the Committee he had considered the law as to proprietary articles, and, after discussing the question with Sir Charles Mathews, the Director of Public Prosecutions, he was prepared to put forward some suggestions for the alteration of the law. It might be possible to set up by legislation machinery similar to that provided by the Food and Drugs Acts. He suggested that a staff of inspectors or other officials might be created by statute; it would be their duty to be on the look-out for offences with regard to proprietary medicines, and to make a search of the files of newspapers with a view of finding any advertisements of an undesirable character. The inspectors would also purchase medicines and submit them to an analyst. He did not think this suggestion could be carried out without an alteration of the law making the vendor liable, quite apart from his knowledge of the contents of a medicine. To be effective the statement on the label of the formula of a proprietary medicine, as suggested by the British Medical Association, would have to be couched in popular language. As to the proposal to make the label a warranty, the witness remarked that, from a legal point of view, the question what was and what was not a warranty was very difficult to define.

In reply to questions, the witness reiterated his opinion that entirely new legislation was necessary to deal with the traffic in proprietary medicines. The onus of proof must be thrown on the vendor; he would have to show that he had reasonable belief in the efficacy of his preparation.

DR. GEORGE TEMPLETON, an account of whose death in the Hardanger Glacier, Norway, was published in the BRITISH MEDICAL JOURNAL of April 19th, left estate of the gross value of £9,429, of which the net personalty has been sworn at £9,262.

A "Travel Study Tour" of American Physicians to the Seventeenth International Congress of Medicine will start from New York on July 3rd. About seventy-five doctors will take part in the tour. In co-operation with the International Committee for post-graduate medical education, arrangements have been made for visiting clinics and hospitals in Paris, Munich, Vienna, Berlin, Dresden, Cologne, Brussels, and elsewhere, and for inspecting the health resorts of Carlsbad, Marienbad, Nauheim, Wiesbaden, and Homburg. The tour will end in London, where the travellers will arrive in time to attend the International Medical Congress.

AN EPIDEMIC CHARACTERIZED BY ADENITIS, TONSILLITIS, AND CARDIAC COMPLICATIONS.

A CORRESPONDENT sends us the following account of an epidemic which has occurred in an institution to which he is medical officer. The disorder is, he believes, of a novel type. He writes:

The most obvious, though not the most important, feature of the disease is the swelling of the lymphatic glands in the neck, and their exceptional tenderness, causing in most cases a noticeable stiffness of the neck. The glands affected are chiefly those behind and beneath the jaw and in the anterior triangle of the neck, with very occasionally implication of the salivary glands. These lymphatic glands are sometimes so enlarged that they simulate a severe case of mumps. Associated with this is a condition of the tonsil which varies from a slight rash to an apparently pronounced and extensive diphtheritic membrane.

There is no apparent connexion between the severity of the throat trouble and the extent or the tenderness of the enlarged glands in the neck.

In three of my cases the trouble was in the larynx, and not obvious in the tonsils. In these, hoarseness and an irritating cough took the place of pain on swallowing.

In two cases there was a doubtful mottling of the neck and upper chest, which at the time I thought might be the precursor of the rash of scarlatina or German measles. In each case the mottling faded away within two hours.

One case developed orchitis, a painless, not very tender swelling of the body of the testis.

Two developed great swelling and induration of one tonsil and palate (though both tonsils were affected), pushing the faucial opening well over to the other side and almost obliterating it. There was a very small amount of deep-seated pus in these swellings. Several of the patients complained of the discomfort caused by the oedematous and greatly elongated uvula. I have been told about, but have not seen, cases of extensive cellulitis of the head and neck, with deep-seated suppuration in the neck.

About three-fourths of the cases were mild, with slight symptoms and no appreciable rise of temperature. The most dangerous cases commenced with trivial symptoms in the throat and neck—two of them with headache and high temperature, the others with scarcely any rise of temperature and no headache—so that I have come to look upon greatly inflamed tonsils and glands as rather favourable signs except for the local disturbance which they may cause.

In one case the patient had rigors with axillary temperatures of 106.4° F., 106.6°, 105.6°, 105°. He also had hæmorrhage from the nose and lower bowels, and incontinence of urine. An examination of the blood showed streptococci. He is being inoculated with a vaccine made from his blood by my colleague.

Three other cases (and a possible fourth which may not have been this disease) developed heart mischief. The condition of each was the same, but of a different type to anything I have seen before. In each case there were no symptoms to call attention to the heart, and the patients were convalescent. But for the fact that, realizing the toxic nature of the disease, I was carefully examining all hearts every night and morning, I should never have noticed the insidious commencement. First there was the slightest possible *f-f* at one of the valves, followed a few hours later by a marked murmur. Two days later there were loud murmurs over the aortic and mitral regions and the heart was dilated, the apex having moved about $\frac{3}{4}$ in. to the left. It was more difficult to say what valve or surrounding myocardium was not affected than to say what was, so rapid and so extensive was the infective process. During the whole process the temperature remained subnormal, and the patients in two of the cases seemed unaware that anything particular had happened to them. Apparently the myocardium is affected in all except the slightest cases of this disease, for there is often unaccountable weakness for weeks after all other symptoms have disappeared.

None of the patients had sugar in the urine, and none

had albumen, except that those with high temperatures had a small amount temporarily, and a distinct amount appeared in one who became insane. About half the cases had been in contact with previous cases; in the other half I was unable to satisfy myself as to the source of infection. In the case of those who had been in contact the period of incubation appeared to be about four days.

I have treated between 40 and 50 cases, but I did not recognize the nature of the disease in the case of the first ten or twelve; I imagined them to be cases of mixed infection. It was not until a colleague pointed out to me the definite grouping of symptoms in his own cases that I saw I had been mistaken, and realized that he was correct in considering the disease to be a new one.

It is not the mortality of the disease, which appears to be low, but the insidious nature of the heart affection, that inclines me to look upon this complication as an especially dangerous one, and one against which every practitioner should be on his guard.

AUTOMOBILES FOR MEDICAL MEN.

THE "G.R. CAR."

WE recently had an opportunity of testing the G.R. car over a fifty mile very hilly route, and, on the basis of the experience gained in this and other ways, feel justified in believing that the car would be found to meet admirably the needs of medical practice. Though known as the Georges Richard or "G.R. car," it might, but for trade considerations, be equally well called a Unic, for its chassis is built throughout at Puteaux by the makers of the Unic, and on the same lines. The only difference seems to be that the Unic cars, which have long had an excellent reputation for durability, are for the most part larger cars, and of greater horse-power. Avoiding as far as possible purely technical details, which any one can obtain for himself from the pamphlet relating to this car, and into which we have not space to enter, it may be said that the Georges Richard is a 10 to 12 h.p. four-cylinder car, which was found to travel exceedingly smoothly at rates shown by the speedometer to range from five to over forty miles an hour. The engine performed its work very quietly, this being no doubt largely due to the valve lifters, though easily adjustable, being enclosed by a plate, and the various gears engaged with marked freedom from jar (the leather below the main portion of the clutch is fitted with laminated springs). Equally notable was the ease with which different rates of progress could be secured solely through the operation of the throttle, thanks largely, no doubt, to the excellence of the carburetter. There was indirect evidence of this in the appearance of the tyres of the car tested; they were ordinary Michelin tyres, which had not, we were assured, been changed since the car commenced the 4,600 miles shown by the speedometer to have been run, yet were in a condition very much better than could have been the case had frequent resort to the brakes been needed. As for cost, though there is nothing "cheap" about this car, its price, considering all things, is quite low. The chassis alone (including wire wheels with Captain detachable rims, plain tyres, and a kit of tools) costs £235, while fitted with a three-seat coupé body the price is £330. This body opens and closes easily, and provides ready access to the seat of the person who is driving. Other bodies obtainable are a two-seater (£300), and a four-seater torpedo body (£320). They are made in this country to the order of the concessionaires of the G.R. car, Messrs. Mann and Overton, 10, Lower Grosvenor Place, S.W., who have a branch at Whitworth Street, Manchester. A good many Unic cars, it may be noted, are running in London as taxicabs, and there is reason to believe that their average petrol consumption is low.

AUTO-CYCLES.

The Motosacoche Company informs us that of its two machines, the one which it principally recommends to medical men is the 2½-h.p. car. It is a light weight machine, built not with a view to racing but to reliability, the protection of the rider from dirt, ease of control, and a minimum of expense on running and upkeep. In regard to these points it is stated that from 130 to 140 miles can be run on a single gallon of petrol, while the engine and all oily parts are so covered that the wearing of any special costume is superfluous: even trouser clips are not absolutely necessary. There is nothing gymnastic in the method of mounting, and, thanks to the sim-

licity of the mechanism, any one who can ride an ordinary cycle can ride a Motosacoche forthwith. It is made with a special variable gear which, being operated not by the hand but by the foot, allows rates of speed from walking speed upwards being secured. Other points on which emphasis is laid are silence, capacity for hill mounting, and obviation of the risk of being delayed when called to start suddenly upon an unexpected journey by the provision of an appliance for dropping petrol direct into the cylinders when the engine is cold; this can be done without soiling the hands. These claims, judging from a communication from a member of the Association some time ago and from letters from medical men in the firm's possession, seem well founded. The price of the ordinary machine is £38, or £42 when provided with the variable gear here mentioned. It may be added that the Motosacoche has been a winner of medals, competitions, and trials of the reliability order ever since 1907. The address of the firm for letters is College Park, Willesden Junction, N.W.

THE DE DION BOUTON CARS.

Under the title of *The Doctor and the Car* Messrs. De Dion Bouton, of Great Marlborough Street, have brought out a booklet setting forth the general advantages in practice of using cars in place of horse-driven vehicles, and concluding with copies of detailed accounts of the expenses supplied by a large number of medical users of De Dion cars. These accounts are of distinct interest both to those who already use automobiles and to those who are wondering whether they can afford the expense. Most of these relate to small cars, which, as made by Messrs. De Dion, early won so much popularity.

The demand for such cars still continues, but side by side there would appear to be arising a corresponding demand for more expensive vehicles with numerous cylinders; indeed, the firm is now marketing a chassis with eight cylinders. A booklet relating to the latter can be obtained on application, as also one containing much testimony to the satisfaction given by the "DX" model put upon the market at the end of last year. The latter is a four-cylinder car, of 66 mm. bore and 120 mm. stroke. The chassis as it is being built this year keeps the frame rather higher from the ground than did the 1912 model, and provides more ground clearance; and the frame, too, is somewhat longer. The price of this chassis is £283. Of the eight-cylinder cars there are three models, two being of 26 h.p. and one of 50 h.p. Their prices run from £475 to £650. It is now generally admitted that six cylinders are an advantage, and it is claimed that these eight-cylinder cars are even smoother in torque than the best of sixes. In any case the literature concerning them is worth perusal.

A MOTOR CAR AT WORK.

At Brooklands, on May 19th, a new fourteen hours speed record was created by a standard 15.8-h.p. Argyll car, single sleeve valve engine, fitted with worm driven rear axle. The car covered 1,016 miles in fourteen hours, at an average speed of 72.57 miles an hour. The company send us some curious calculations, which may interest those arithmetically inclined, and certainly give a striking general impression of the high pitch of mechanical and structural perfection to which motor cars have been brought. We are told that the engine turned at the rate of 40 revolutions a second, or 2,400 revolutions a minute, for the fourteen hours, making altogether over 2,000,000 revolutions during the period; each piston travelled the length of the cylinder 80 times a second, equal to over 34 ft. a second. During each second of the fourteen hours of the run 80 charges of petrol gas were drawn into the engine cylinders, exploded, and exhausted.

THE British Fire Prevention Committee has established the nucleus of a technical library, which is to be known as the International Fire Library. It already has some 2,000 books, dealing specifically with matters of fire prevention, fire service, and fire loss, and desires to call attention to the fact that it will be glad to receive any books, pamphlets, or reports bearing on the subject, which authors, public authorities, publishers or collectors may be able to spare. They should be addressed to the Honorary Chief Librarian, the International Fire Library, 8, Waterloo Place, S.W. The same body has also recently issued another of its red books relating to fire tests with textile fabrics. It refers to experiments with a flame-proofing solution known as Snowdon's. This solution was found to have no injurious effect upon the textiles with which experiments were conducted, and to render them thoroughly flame-resisting. Its utility, however, so far as wearing garments are concerned, is seriously limited by the fact that the solution must be reapplied each time the garments are washed.

LITERARY NOTES.

It is announced that Messrs. Constable are about to publish a work entitled *The Unexpurgated Case against Woman Suffrage*, by Sir Almerth Wright, F.R.S. The book is said to be written with the object of showing "that the Woman's Suffrage Movement has no real intellectual or moral sanction, and that there are very weighty reasons why the suffrage should not be conceded to women." As an addendum to the book is printed Sir Almerth Wright's letter on "Militant Hysteria" which appeared in the *Times*.

Dr. Francis J. Hall, of the Peking Union Medical College, is preparing for publication a second Chinese edition of Sir William Osler's *Practice of Medicine*.

At the Aberdeen graduates' dinner, a brief account of which appeared in the *JOURNAL* of June 7th, Mr. Cantlio recited the following verses in honour of the Chairman, Professor W. J. R. Simpson:

His heart's in the Tropics, his hopes they are high,
His heart's in Uganda a-chasing the fly.
The rat and the flea, in vain do they try
Tae plague us wi' sickness when Simpson is nigh.

At his presence the tsetse-fly skunks in the tree,
The trypanosome trembles sac frichtened is he,
O' the comma bacillus a full stop he's made,
An' na langer we fear for a cholera raid.

Wi' his heart in his wark an' his pen in his han'
Oh! ne'er was made a mair glorious stan',
For Simpson has fought in lands overseas
Tae shield oor compatriots frae plague an' disease.

Sae fare ye weel, oor laddie, God's speed on yer track
We'll look after yer little anes until ye come back,
And may be we'll see til't whan ye're far away
That the C.M.G. ye earned shall be fronted wi' "K."

In the *JOURNAL* of May 31st we quoted an epitaph on Lockyer, described by Mr. E. V. Lucas as "the Cockle and Holloway, Beecham and Carter of his time—the middle of the seventeenth century." In *Nugae Chirurgicae, a Biographical Miscellany, illustrative of a collection of professional portraits*, by William Wadd, Surgeon Extraordinary to George IV, the following concluding lines are given:

This verse is lost: his Pills embalm him safe
To future times, without an Epitaph.

We take this opportunity of correcting a misprint in the first line as cited by Mr. Lucas and reproduced in the *JOURNAL*, where "Pith" should be "Pills." Lionel Lockyer died in 1672. Under a bust of him, sculptured by J. Start, appear the following lines:

The true Effigies here you may behold
Of him, who, for preventing others' ill,
Hath gained a Medicine far exceeding Gold,
And known to all the world for Lockyer's Pill.

In reference to an article entitled Francis Bacon on Medicine, which appeared in the *BRITISH MEDICAL JOURNAL* of April 26th, p. 896, Dr. W. J. Rutherford (Renfrew) has sent us an extract from Macaulay's essay in which the subject is dealt with from a somewhat different point of view. Comparing the philosophy of Bacon with that of Plato, Macaulay says:

It is curious to observe how differently these great men estimated the value of every kind of knowledge. . . . To Plato, the science of medicine appeared to be of very disputable advantage (*Republic*, Book 3). He did not indeed object to quick cures for acute disorders, or for injuries produced by accidents. But the art which resists the slow sap of a chronic disease, which repairs frames enervated by lust, swollen by gluttony, or inflamed by wine, which encourages sensuality by mitigating the natural punishment of the sensualist, and prolongs existence when the intellect has ceased to retain its entire energy, had no share of his esteem. A life protracted by medical skill he pronounced to be a long death. The exercise of the art of medicine ought, he said, to be tolerated so far as that art may serve to cure the occasional distempers of men whose constitutions are good. As to those who have bad constitutions, let them die; and the sooner the better. Such men are unfit for war, for magistracy, for the management of their domestic affairs, for severe study and speculation. If they engage in any vigorous mental exercise, they are troubled with giddiness and fulness of the head, all of which they lay to the account of philosophy. The best thing that can happen to such wretches is to have done with life at once. He quotes mythical authority in support of this doctrine; and reminds his disciples that the practice of the sons of Aesculapius, as described by Homer, extended only to the cure of external injuries.

Far different was the philosophy of Bacon. Of all the

sciences, that which he seems to have regarded with the greatest interest was the science which, in Plato's opinion, would not be tolerated in a well regulated community. To make men perfect was no part of Bacon's plan. His humble aim was to make imperfect men comfortable. The beneficence of his philosophy resembled the beneficence of the common Father, whose sun rises on the evil and the good, whose rain descends for the just and the unjust. In Plato's opinion man was made for philosophy; in Bacon's opinion philosophy was made for man; it was a means to an end; and that end was to increase the pleasures and to mitigate the pains of millions who are not and cannot be philosophers. That a valetudinarian who took great pleasure in being wheeled along his terrace, who relished his boiled chicken and his weak wine and water, and who enjoyed a hearty laugh over the Queen of Navarre's tales, should be treated as *caput lupinum* because he could not read the *Timæus* without a headache, was a notion which the humane spirit of the English school of wisdom altogether rejected. Bacon would not have thought it beneath the dignity of a philosopher to contrive an improved garden chair for such a valetudinarian, to devise some way of rendering his medicines more palatable, to invent repasts which he might enjoy, and pillows on which he might sleep soundly; and this though these might not be the smallest hope that the mind of the poor invalid would ever rise to the contemplation of the ideal beautiful and the ideal good. As Plato had cited the religious legends of Greece to justify his contempt for the more recondite parts of the art of healing, Bacon vindicated the dignity of that art by appealing to the example of Christ, and reminded men that the great Physician of the soul did not disclaim to be also the physician of the body (*de Augmentis*, lib. 4, cap. 2).

* * * * *

A philosophy which should enable a man to feel perfectly happy, while in agonies of pain would be better than a philosophy which assuages pain. But we know that there are remedies which will assuage pain; and we know that the ancient sages liked the toothache just as little as their neighbours.

Macaulay was a Philistine, though a Philistine of genius, and his article on Bacon is a proof of his Philistinism. But in regard to medicine, we do not think the most enthusiastic disciple of the great philosopher could seriously say, *Mallem errare cum Platone*.

It was stated in the *JOURNAL* of June 7th that the first award of the Broquette-Gouin, of the value of £400, had been made to Professor Grasset of Montpellier. We are now enabled to add that the professor has decided to give the sum to the Medical Faculty of the University for the purpose of founding a special prize for students.

SCIENCE NOTES.

DR. ROBERT BROOM, Keeper of Vertebrate Palaeontology in the South African Museum, in his Croonian Lecture before the Royal Society, on June 5th, sketched a theory of the origin of mammals, which for its full development would have required a course of half a dozen lectures at least. Dr. Broom went to South Africa some fifteen years ago with the intention of studying the subject, for there is there an opportunity unequalled anywhere else of palaeontological research in a region some two thousand miles square with a depth of strata measuring seventeen hundred feet. The particular merit of the theory which Dr. Broom has elaborated seems to be that it takes full account of the struggle for life of carnivorous races in face of a decrease in the numbers of the herbivorous animals on which they preyed, and the effect of this on the direction of specific evolution. In the lecture he sought to trace the evolution of mammals from Cotylosaurians through carnivorous lines from the Upper Carboniferous period to that of the Lower Jurassic. He argued that in the types of animal along this carnivorous line—that is to say, in the Lower Permian period the *Therocephalia*, in the Middle and Upper Permian the *Gorgonopsia*, and in the Triassic the *Cynodonts*—the skull is very mammal-like. In the Lower Jurassic strata he said the *cynodonts* were so mammal-like and the mammals so *cynodont*-like that in no single case was it possible to be absolutely certain which was which. This line of argument was illustrated by a long series of drawings. He suggested that the small *gorgonopsians* fed almost exclusively on the comparatively slow-moving small herbivorous *anomodonts*. When in the Triassic period the last named became rare, the carnivorous animals which had subsisted on them had to seek other

prey, lizard-like and more active, and the consequent necessity for increased activity in the pursuers resulted in the *cynodonts*, and finally in the mammals. In Upper Triassic times the larger *cynodonts* preyed upon the last *anomodont*, *Kamucocyberia*, and carried on their existence so long as these *anomodonts* survived, but died out with them about the end of the Trias or in Rhoetic times. The small *cynodonts*, having neither small *anomodonts* nor small *cotylosaurs* to feed on, were forced to hunt the very active long-limbed *thecondonts*. The greatly increased activity brought about that series of changes which formed the mammals—the flexible skin with hair, the four-chambered heart and warm blood, the loose jaw with teeth for mastication, an increased development of tactile sensation, and a great increase of cerebral power. Not improbably the attacks of the newly evolved *cynodont* or mammalian type brought about a corresponding evolution in the *pseudosuchian thecondonts* which ultimately resulted in the formation of dinosaurs and birds.

The question as to whether or not the laws of reflection are obeyed by the x rays formed the subject of an interesting lecture given by Professor C. G. Barkla before the Roentgen Society on June 3rd. This line of investigation was started some months ago, he said, by three German physicists—Friedrich, Knipping, and Laue—who proved that when a fine beam of x rays was transmitted through a crystal the image obtained on a photographic plate placed on the other side of the crystal included not only a representation of the direct beam, but also a series of secondary pencils round the central impression. The interference pattern thus produced was explained on the spreading-wave hypothesis. It was subsequently discovered by W. L. Bragg that x rays could be reflected from the cleavage planes of crystals. Professor Barkla said that in his own experiments he used an ordinary x -ray tube, and made the rays emerge from a pinhole aperture. A thin sheet of rock salt or other crystal was placed at a distance of 40 or 50 cm. from the anticathode, and by observing the effects obtained on a photographic plate he was able to demonstrate that the laws of reflection did appertain to the Roentgen radiations. He exhibited a large number of photographic results, the general effect being that of various feeble secondary pencils arranged, often in what appeared to be concentric circles around the central and more or less opaque patch due to the direct beam. Given sufficient photographic exposure, he looked, he said, as though there might be an indefinite number of these secondary pencils. No part of Professor Barkla's lecture was more illuminating than that in which he showed why crystal was the chosen medium for the order of effects. With a surface of mercury or a polished metal, while the free electrons emitted secondary waves in all directions, there was destructive interference in practically every direction, so that the effect was effaced. Each molecule in a surface sent out a train of rays, but unless certain relations held between the distances from one molecule to another there would be destructive interference. The rays were not reflected regularly from a surface of mercury, because such a surface, while appearing to be a plane, had irregularities of molecular structure which were large as compared with the wave-length of the Roentgen radiation. A surface of the desired regularity was, however, provided by the layers in a crystal, where the molecules were arranged perfectly in definite planes, and with sufficient regularity to produce regular reflection. The reflection itself was due to the vibration of the constituent electrons with the molecules of the crystal, such vibration being set up by the impinging rays. The intensity of this secondary effect, in the experiments so far carried out, was not more than 1 per cent. of the intensity of the direct beam. Professor Barkla thought it possible that an elliptical reflector might be arranged with sheets of mica, and that radiation be brought to a point focus, though whether the more intense beam thus produced would be of any use in secondary ray therapeutics he could not say. He concluded by reaffirming the certainty that x rays were regularly reflected exactly as light from regular planes in the crystal, and that the photographic results were due to an interference effect with the secondary radiation.

British Medical Journal.

SATURDAY, JUNE 14TH, 1913.

CREMATION.

As will be seen from the article which appears at p. 1279, the progress of cremation in this country is steady, though disappointingly slow. It is now nearly forty years since the Cremation Society of England was founded by Sir Henry Thompson, and notwithstanding the most strenuous efforts to bring home to the people at large the advantages of this method of disposing of the dead, it cannot be said that these are yet properly appreciated.

The attitude of the press, whose function is supposed to be to mould public opinion, but which more often simply reflects it, is on the whole one of indifference. This is sufficient to prove that cremation makes little or no appeal to the ordinary man. It is hardly to be expected that it should, for most men try to put from them the thought of death till the grim spectre rises before them. Though among the cultivated classes cremation may almost be said to be becoming fashionable, the people as a whole still prefer earth burial: the poor particularly look askance at cremation. Sir Charles Cameron, in his presidential address at the annual meeting of the society, thought it strange that this should be so, since it is much cheaper than interment in the ordinary way. We think he has overlooked the fact that to the poor a burial is a function which is celebrated with all the pomp and circumstance that the funeral money will cover. They find a curious pleasure in the trappings of death, and think that by having these as costly as they can they do honour to the dead, besides making a brave show before the neighbours. The very cheapness of cremation may be an additional objection to it in the eyes of the poor. The fact, however, that the bodies of over a score of working men were burnt at Golder's Green in the course of 1912 may be taken to show that cremation is beginning to penetrate to new social strata.

We have said that although progress in this country is slow it has been steady. Since 1904 the yearly number of cremations in Great Britain has doubled. But the number is still an insignificant fraction of the whole number of deaths. It is more encouraging for those interested, as all doctors should be, in the adoption of what *Truth* only the other day called the more sensible and sanitary method of having one's remains disposed of, to look abroad, especially at Germany and Switzerland. Although this method of disposal of the dead has become lawful in Prussia only within the last two years, the number of cremations in 1912 was 9,000, while for the whole of Germany it was three times as great as in this country. In Switzerland there is a municipality, that of Saint Gall, so enlightened that it will not allow earth burial within the limits of its jurisdiction; cremation is compulsory in this sense that if the friends of a deceased person wish the remains to be buried in the ordinary way, the body must be taken elsewhere. This enactment seems to have been accepted by the inhabitants with little demur.

We need not again labour the points in favour of cremation which have so often been urged in the *JOURNAL*. We need only repeat that the sanitary argument is irrefutable, and the safeguards against crime are much stricter than in the case of ordinary burial. The religious prejudice has to a large extent died out. The Roman Catholic Church, indeed, still refuses to sanction the burning of the dead. But, as we have explained on previous occasions, this is not for any doctrinal reasons; it is a purely disciplinary measure, which could be rescinded at any time. Doubtless it will be rescinded in time, but it is a pity that a body of world-wide influence should not lead in a matter which must necessarily become of vital importance to the welfare of the living instead of waiting till it has to follow in the rear of a general advance. There is nothing whatever antagonistic to religious sentiment or belief in cremation. This is practically acknowledged by Rome itself, which permits of the burning of bodies in times of epidemic and war, when regard for the safety of the living makes it imperative that the bodies of the dead should be disposed of quickly.

Among the advantages of cremation, it has been pointed out more than once in the *JOURNAL* that it offers a means of reviving the beautiful old custom of burial in churches. The authorities of Westminster Abbey, we believe, now make it a rule that persons whose remains are to find a resting-place in that venerable building must first be cremated. The council of the Cremation Society states that in August last a chapel under the choir of St. Columba, Pont Street, Belgravia, was consecrated for the purpose of receiving and preserving the urns containing the ashes of persons who had been cremated. A Faculty was granted in January of last year for the immurement in the north wall of Coychurch Parish Church, and near Mr. Arthur J. Williams's family pew, of a sealed urn or casket containing the cremated ashes of the late occupier, who was formerly M.P. for South Glamorgan.

In a brief summary of the report of the Cremation Society of England the *Times* speaks of the argument that "cremation removes the possibility of being buried alive" as "singular." We should have thought it was a matter of common knowledge that this fear haunts many people throughout life, and has led not a few persons, including that very strong-minded lady Miss Frances Power Cobbe, to leave directions in their will that a doctor should make sure by thrusting a knife into the heart. Premature burial, although there is an association for its prevention which enjoys the patronage of Mr. George Greenwood, M.P., Miss Lind-af-Hageby, Dr. Josiah Oldfield, and Dr. Stenson Hooker, must be extremely rare. But it is impossible to deny that it has occurred and may happen again. Edgar Allen Poe has pictured the horrors of such an event. His description is well known but will bear quotation here: "Fearful, indeed, the suspicion—but more fearful the doom! It may be asserted without hesitation that no event is so terribly well adapted to inspire the supremeness of bodily and of mental distress, as is burial before death. The unendurable oppression of the lungs—the stifling fumes of the damp earth—the clinging of the death garments—the rigid embrace of the narrow house—the blackness of the absolute night—the silence like a sea that overwhelms—the unseen but palpable presence of the Conqueror Worm—these things, with thoughts of the air and grass above, with memory of dear friends who would fly to save us if but informed of our fate, and with consciousness that of this fate they can never be

informed—that our hopeless portion is that of the really dead—these considerations, I say, carry into the heart, which still palpitates, a degree of appalling and intolerable horror, from which the most daring imagination must recoil. We know of nothing so agonizing upon earth; we can dream of nothing half so hideous in the realms of the nethermost hell." These horrors, of course, are largely created by the morbid fancy of a poet; if premature burial did occur, the person would probably die without recovering consciousness. Still it is a dreadful idea, and it is scarcely singular that among the advantages of cremation should be included the fact that it removes the fear of such a doom.

We congratulate the Cremation Society of England on the pioneer work it has already done, and we hope that it will be encouraged to develop its beneficent activity. It deserves the active support of the public, and especially of the medical profession. The clergy might do much to promote a sanitary reform which, in the interests of the living, cannot be too quickly brought about. Medical practitioners should take every opportunity that comes in their way of urging the adoption of cremation. That it will in time become universal in civilized countries is practically certain, and burial will be looked upon as a "method of barbarism." No person of decent sensibility who has seen, in the Pargello at Florence, Gaetano Julio Zunbo's famous models in coloured wax of corpses rotting in the grave, could bear to think of the bodies of those whom he loved exposed to such slow and hideous corruption. The earth burial of bodies is at once a danger to the living and a desecration of the dead.

THE PROVISION OF TUBERCULOSIS SANATORIUMS FOR LONDON.

WITHIN five weeks from this date a year will have elapsed since the clauses of the National Insurance Act relating to sanatorium benefit came into operation, yet the machinery for giving these clauses full effect is still lacking in many districts, especially perhaps in London. It is true that in addition to arrangements for domiciliary treatment there are some tuberculosis dispensaries and their annexes either in operation or in process of formation, and that the London Insurance Committee can dispose of a certain number of beds for indoor treatment at sundry voluntary hospitals and public institutions; but these are only parts of the mechanism, and a practical scheme for linking them up with other elements and converting the whole into an effective combined system has not yet been completed.

Looking back at the steps that have been taken in the matter it is not easy to see who, if any one, has been responsible for the delay, while it is difficult, and at times impossible, to discover any true co-ordination between the activities exhibited by the various bodies concerned. One thing alone is certain—namely, that since the Act was passed neither the London County Council, nor the Metropolitan Asylums Board, nor the Metropolitan Borough Councils, nor the medical profession in London, have shown any inclination towards an obstructive policy, but, on the contrary, have all done, each within its own field of operation, everything that it could to give as much effect to the sanatorium clauses of the Act as circumstances have permitted.

Probably the initial error lay in the haste with which the sanatorium clauses, in common with many other clauses of the original bill, were adopted by Parliament; while it is certain that one of the diffi-

culties in the way of the evolution of a proper scheme for London is due to the inclusion in Clause 16 (1) almost at the last moment of a sentence which aimed at preventing administration of the sanatorium benefit falling into the hands of Poor Law authorities. Those responsible for the wording of this sentence no doubt forgot for the moment that the circumstances of London are quite special, and that the Metropolitan Asylums Board, which plays such an important part therein, is, though largely representative of Poor Law authorities, a body whose operations extend far beyond Poor Law work.

It is an instructive fact that, despite the sentence in question in the Act, the Departmental Committee on Tuberculosis, in its interim report issued on April 30th, 1912¹—that is, many months after the Act was passed—nevertheless mentioned Poor Law hospitals as being among the places which should be utilized for indoor treatment, and specifically suggested the institutions of the Metropolitan Asylums Board in this connexion. Indeed, it would almost seem as if the Local Government Board itself at this time and for some time later was under the impression that the sentence in question could be set aside, for it was not until October that this Board pointed out to the London County Council² that it was found that, in default of legislation, the provision of sanatoriums by the Metropolitan Asylums Board as such was impossible, and hinted that the London County Council should therefore step into the breach and get round the difficulty somehow. The result was a conference between the County Council, the London Insurance Committee, and the Metropolitan Asylums Board, which led to an arrangement³ by which the latter placed its Downs Hospital under the nominal control of the London County Council (like accommodation at its Northern Hospital, Winchmore Hill, being subsequently added), the London County Council in its turn placing them at the disposition of the London Insurance Committee.

It was even later, namely, in the middle of December, that the London County Council was definitely informed by the Local Government Board that it would have to play a distinct part in giving effect to the clauses relating to sanatorium benefit, a matter on which there had been room for considerable doubt.⁴ Even then it was told that its direct activities would be limited to providing indoor treatment, since the provision of tuberculosis dispensaries and the work connected with them had already been allocated to the various metropolitan borough councils. Nevertheless the Local Government Board wished the London County Council to draw up and submit to it a comprehensive scheme for administration by it of the sanatorium clauses throughout London and in regard to all aspects of tuberculosis.⁵ On receipt of this communication the Council acted promptly, and less than two months later adopted a report on the subject from its Public Health Committee. This report⁶ did not pretend to put forward any complete scheme, but showed that the aim should be the co-ordination of all existing institutions and agencies in London for the treatment of tuberculosis, and indicated the general fashion in which this might be done. Practically this is how the question still stands, though at a meeting in May the County Council, on a further report from its Public Health Committee,⁷ decided

to instruct its Parliamentary Committee to endeavour to get the Metropolitan Asylums Board placed legislatively in a position to form an active unit in any scheme that the Council might frame for dealing with tuberculosis.

It seems unlikely that the promised Insurance Amendment Act will contain anything relating to this particular point, and meantime the present arrangement with the Metropolitan Asylums Board will doubtless be maintained. Its merit is that it provides approximately 600 beds for cases of tuberculosis, which at present could not be found elsewhere, and that to this extent it obviates the necessity of undertaking heavy sanatorium building expenditure such as would be necessary were the London Insurance Committee solely dependent on the accommodation available at ordinary institutions. Its demerits are that so round-about an arrangement is essentially unbusinesslike, and that it utilizes only to a very limited degree the very valuable machinery long since created by the Metropolitan Asylums Board. This body, which is responsible for the treatment of all cases of specific infectious disorders arising within the metropolitan area, controls as many as 8,500 hospital beds, and these are available for the whole community without distinction—indeed, less than 5 per cent. of them are habitually occupied by Poor Law cases; in addition, it also possesses two large hospitals for children, which, with certain connected sanatoriums at the seaside, provide further accommodation for 2,000 patients, a large percentage of the children admitted being tuberculous.

If the legal difficulties mentioned were removed two benefits, it is suggested, would follow. Instead of making temporary arrangements for the accommodation of a certain number of tuberculosis patients the Board would very likely be able to provide out of its own resources so much accommodation that the London County Council would never need to build sanatoriums of its own and to create all the new machinery connected with their administration. The Board itself would also benefit. At present it suffers from the fact that while it has to maintain a large number of fully-staffed institutions it is dependent for work on the rise and fall in the incidence of zymotic disease. With a constant new source of work such as would be provided by tuberculous patients it could, as occasion arose, make any necessary interchange of staff, rearrange the distribution of beds, and effect many economies. The financial questions seem hitherto to have received inadequate attention. It is stated that the funds of the London Insurance Committee will not be sufficient to pay for many more persons than are now under treatment, and that it is unlikely that the portion which may be allotted to London out of the capital sum provided under the Act for building would relieve the rate-payers of much of the cost if the London County Council were compelled to embark upon a scheme for building sanatoriums on a large scale.

For these and other reasons it seems certain that the London County Council will not be obstructed in obtaining the legislation mentioned, and it is clear that the Local Government Board would co-operate. It is by no means certain, however, that the House of Commons would prove amenable on the point, despite the fact that the Metropolitan Asylums Board is not truly a Poor Law authority. But should the House approve, and should it be ready to apply the same underlying principle (as recommended by the Departmental Committee on Tuberculosis) to the whole country, a very broad vista would be opened up.

CORONERS' INQUESTS.

THE discussion upon the utility of the coroners' inquest, raised recently by Dr. Brend before the Medico-Legal Society, although breaking no new ground, served a very useful end. It clearly showed that, notwithstanding the fact that it is generally admitted that the law dealing with this subject demands amendment, there exists nevertheless a very wide divergence of opinion as to the nature and extent of the reforms required. The discussion has helped to make it clear that the present confused and unsatisfactory condition of things is in a large measure attributable to the absence of any clear definition of the actual fundamental purpose of the inquiry. A coroner's inquest is held presumably for the purpose of ascertaining the cause of death. Although the cause of death can be considered from various aspects, such as the legal or the scientific or what, for want of a better term, may be described as the commercial, as exemplified by the point of view of an insurance company or of an employer or other person liable to be called upon for compensation, the Coroners Act, while stating the conditions under which an inquest shall be held, contains no pronouncement as to the actual purpose it is to serve.

In consequence of the absence of any guiding principle in the matter, every coroner has been compelled to become a law unto himself, and to select such reasons as seem good to him for holding an inquest. The result is that there is a very marked divergence in the practice of coroners, for each has to form his own conception of his duties. The fact that a coroner is justified in the exercise of his absolute discretion, so long as he keeps within the four corners of the Act, was made clear in certain correspondence between the then Lord Chancellor and the British Medical Association in 1904, in which it was stated that a coroner is not bound to take his law from any one and can only be removed from office for actual misconduct. To this same cause is largely due the fact that the scientific value attaching to coroners' verdicts usually is negligible. Such findings as "accidental death" and "death from natural causes" have no meaning or value as far as vital statistics are concerned. They merely serve to eliminate questions of negligence or foul play. The records show that such verdicts as "felo-de-se" and "suicide during temporary insanity" are interchangeable terms and vary largely in accordance with the idiosyncrasies of particular coroners. It would be easy to multiply instances of the kind, and it is a serious matter that the statistics relating to this large and most important class of death are vague and misleading and contribute nothing of real value to the study of sociological problems. They must remain in this unsatisfactory state until the fundamental purpose of the inquest is defined and regulations made to ensure that all such inquiries shall have a definite purpose and be conducted upon definite lines, and shall not, as at present, depend upon the unfettered decision of an individual, who may himself be somewhat vague as to his real duties in the matter.

It is, indeed, easy to prefer a serious indictment against the existing procedure, but it is more difficult to formulate suggestions for reform, owing to the wide divergence of opinion that exists on the subject, and to the fact that coroners may claim some vested interests, to which, no doubt, they will jealously cling; but it is difficult to see how any reform of the law relating to coroners can be usefully considered apart from the question of

reform of the law relating to death certification and registration, as the two subjects are inseparably bound together, the one being, in fact, the complement of the other. Any satisfactory amendment of the present system of certification and registration must of necessity be accompanied by certain alterations in the duties of coroners, whose mission, when all is said and done, is solely to deal with those cases in which a registrar is unable to accept a certificate without a coroner's authorization, a coroner being, in fact, the last link in the chain forged by the Registration Acts. Logically, he would appear to be definitely concerned with determining the pathological cause of death, as information regarding other matters is not provided for on death certificates. This view is strengthened by the fact that there already exists, quite independently of the coroner, special machinery for dealing with all the important issues that arise at inquests, with the exception of the determination of the actual pathological cause of death.

The matters arising out of inquests that come before magistrates' courts and county courts form a very small part of their work, and it is difficult to see what useful purpose would be served by interfering with the present useful function of these courts, as would be the case if their intervention was abolished and the inquest made a legal court of first inquiry, as suggested by some reformers.

The determination of the pathological cause of death could easily be made the fundamental object of the inquest without necessarily limiting the inquiry to that particular point, for there seems to be a large body of opinion that some really useful purposes are served under present conditions, more especially by means of the publicity of the inquiry, and its more or less conversational character.

It is claimed for this publicity that it acts as a deterrent, and that much useful information regarding general questions of health and the nature and prevention of accidents is thereby disseminated, while the legal profession seems to attach great value to the admission of hearsay evidence, which renders it possible to conduct a fishing inquiry in cases where, though no individual is clearly implicated, suspicious circumstances may exist. On the other hand, this publicity is frequently the cause of pressure being put upon medical men either to disguise the true facts or to avoid an inquest, owing to the very great distress that is caused to those concerned, by the very nature of the proceedings, a distress which is not infrequently grievously aggravated by the needlessly intimate nature of the questions that are put. As the laws of evidence are not observed in a coroner's court, it may happen that facts may be elicited which cannot be offered as evidence before another tribunal, but, being reported in the newspapers, become matters of public knowledge, and so in a sense may be said to prejudice the case. This, in fact, a coroner's warrant of committal absolutely does, for it commits an individual for trial as guilty of a certain charge, whereas a magistrate's warrant merely indicates that there is sufficient *prima facie* evidence to justify further inquiry.

Any scheme for reform of the law relating to coroners that does not include amendment of the Registration Acts must, as already indicated, be insufficient, and may be said to begin in the middle. Existing conditions must be carefully considered, and satisfactory reforms will have to be based upon broad views if they are to obtain the support necessary. This will not be readily forthcoming if there is any suggestion that they rest upon special pleading on behalf of either of the great professions interested in the question.

FUTURE ANNUAL MEETINGS.

As already announced, the Aberdeen Branch has invited the British Medical Association to hold its annual meeting in that university city next year, 1914; and in making this announcement we ventured to say that it would be received with great pleasure by members of the Association. We believe that the further announcement that we are now in a position to make will be received with equal satisfaction; it is that the Branch Council of the Cambridge and Huntingdon Branch has adopted a resolution recommending the Branch to invite the Association to hold its annual meeting in 1915 in Cambridge. If anything could add to the pleasure with which this announcement will be received it is the fact that it is intended to invite Sir Clifford Allbutt, Regius Professor of Medicine in the University of Cambridge, to fill the office of President.

HOSPITALS AND RESEARCH.

MR. G. W. E. RUSSELL is a writer with a delightful sense of humour and a gift of happy phrase, and he has seen history in the making and many of the men who helped to make it at such close quarters that his comments are always interesting and often informing. But, as George III said of Shakespeare, there is a good deal of nonsense in his writings; this is especially noticeable when he abandons the position of a critical observer of *choses vucs* and allows himself to be carried away by prejudice. In his recently published *Half Lengths* there is an essay in which, after making suggestions as to the uses to which wealth may be put, he goes on to say: "Hospitals again—here is a boundless field for the rich man's activities. It would be no contemptible ambition to build in the heart of some great city or on the hills which surround it an imitation of the German Hospital at Alexandria with its miles of marble corridors and its plenitude of appliances which make illness a luxury; all worked by 'sweet societies' of trained Deaconesses who labour for no other reward than the love and gratitude of the patients. Only let the rich man beware lest the disingenuousness of 'research' bring evil out of his intended good, and pervert the place of healing into a torture-chamber or a shambles." We are sorry to be obliged to say that in this passage Mr. Russell himself is disingenuous. He has been connected with the management of a well-known hospital, and in that capacity he must have learnt, if he learnt nothing else, that there are no "torture-chambers" or "shambles" in such institutions. He should leave such appeals to the "gods," to Mr. Stephen Coleridge and Miss Lind-af-Hageby, who have not had his opportunities of knowing the truth. A hospital in which clinical and pathological research is neglected must be unprogressive, and therefore cannot adequately fulfil the function for which it exists. The absence of research means stagnation. It is the sick poor who suffer, for gradually methods of treatment are improved, often revolutionized, by the results of research. Mr. Balfour put this point with admirable clearness the other day at Guy's Hospital, when he said that to look upon a hospital merely as a place where those who were sick or hurt went for healing was a very narrow view, because, unless it was also a place in which the future leaders of the medical profession were to be trained, its usefulness would die out with the present generation. It was at least as important that the great hospitals should be made efficient training grounds for the physicians and surgeons of the future as that they should afford a field for their beneficent enterprise. He insisted that to carry out that work effectively not only teachers but researchers were required. While to Mr. Russell "research" suggests "torture chambers" and "shambles," to the larger and more enlightened mind of Mr. Balfour it is a necessary means of progress. It offers the only hope of solving the many problems which stand

in the way of the advance of knowledge and baffle our power of curing, relieving, or preventing disease. We repeat, it is false that scientific "torture-chambers" exist anywhere in this country. Mr. Russell's insinuation that there are such places in our hospitals is worse than disingenuous: it is a calumny on a body of men whose ethical standards and moral character are, we do not hesitate to say, higher than those of any other profession whatever. Fortunately for mankind these men let the fanatics rave. But in the interest of the public the spirit which inspires their work and the lofty end to which it is directed should protect them against abuse which is as foolish as it is malicious.

MENTAL DEFICIENCY BILL.

DURING the last few days two appeals for the Mental Deficiency Bill have been published. The first, which is inspired by the fear, very generally entertained, that the Government will this year again drop the bill, is a direct request that sufficient time may be set aside to pass it. The appeal is signed by laymen interested in the subject as members of educational authorities or for other reasons, and by physicians who on various grounds are specially qualified to speak for the profession. It points out that "the principle of the compulsory education and training of defectives has long been conceded by the Education Acts dealing with blind, deaf, and epileptic children. It can hardly be regarded as anything more than a cruel inadvertence that in most parts of the country a feeble-minded child cannot at present be protected, unless its misfortune happens to be complicated by epilepsy. When, at the age of 16, a child who has already been under care and observation for several years still exhibits such mental deficiency as to render it incapable of self-protection and self-control, it is surely no unreasonable interference with the liberty of the subject to extend our care of it through years of special danger and temptation, and as long as may continue to be necessary, with the safeguards (provided by the bill) of short-period certification, and periodical visits by independent authorities armed with the power of immediate discharge." The opposition to the bill last year came from a very small number of members but was very determined. Mr. Wedgwood, who was one of those who opposed, has now written to the *Times* stating that he is in a position to assure both the Mental Deficiency Bill and the Elementary Education (Epileptic and Defective Children) Bill a rapid passage during the present session if two conditions are complied with—first, that the children must not be taken to the "homes" or "special schools" against their parents' wish, and, secondly, that the "homes" must be homes and not prisons, the inmates being as free to leave as they are to leave the existing admirable institutions. As to the second condition at least, it is not easy to see how any compromise could be made without destroying the efficiency of the bill. The second appeal is in the form of a letter addressed to the Home Secretary and signed by medical teachers and practitioners and teachers in various departments of physiology, biology, and anthropology in the great centres of learning in the three kingdoms. The letter urges that should the bill become law care should be taken in its administration to secure the continuous prosecution of research into the conditions on which mental deficiency depends and into the means by which it may be remedied or prevented. It is pointed out that the conditions must be due either to defective formation and development of the active structures of some portion or portions of the brain, or to defective formation or supply of the fluids by which these structures are surrounded and by which they are stimulated to activity. The last point is illustrated by a reference to the influence of the thyroid and other so-called ductless glands. The signatories expressed the hope that any system of treatment useful in the case of some of the lower defectives would

be still more useful in raising the level of those above them, and would furnish a first step towards a system of education founded upon physiology. They point out also that the careful study of the imperfect brain development and simple intellectual functions of defectives might throw valuable light on the more complicated acts and conditions of the normal individual. The importance of utilizing for the general benefit of the community the facilities for scientific study which institutions established under the bill would afford is insisted on, and it is urged that the duty of so utilizing them should be committed to men of science fully cognizant with all that is known in relation to the subject and able to point out the direction in which further inquiry should be pursued. To this end it is asked that there should be an adequate representation of biological science on any commission to which the administration of the law may be entrusted.

VACCINES IN DERMATOLOGY.

WIGGITT's methods are neither widely known nor generally accepted on the Continent, and it is therefore of great interest to read the results of some experiments, and the conclusions reached from them, by such recognized authorities as R. Sabouraud and H. Noiré.¹ The first part of the paper is devoted to a detailed description of the technique adopted in the preparation of the vaccines. The organisms used were staphylococci obtained from furuncles which the authors term deep or subcutaneous, the morococcus of Unna (identical with the polymorph coccus of Cedererentz), and termed superficial or surface coccus, inasmuch as it is never found in boils, sycosis, or carbuncles; and thirdly, Sabouraud's seborrhoeic microbaciillus commonly found in the acne comedone, and exceedingly difficult to cultivate. After an accurate description of dosage methods which accord with those in vogue with us, the authors reach the following conclusions: (1) The lesions most favourable for the treatment are undoubtedly furuncles. They have not so far met with any unfavourable results, and improvement—sometimes cure—was manifest after the first or second injection. (2) Less satisfactory results were obtained in the case of staphylococcal folliculitis and sycosis. Improvement up to a point was the rule, and then other methods were required for the residual pustules. But the patients themselves were convinced that no other methods had afforded equal relief. (3) Morococcus vaccine has no influence on lesions due to staphylococcus infection—for example, boils—nor is their injection followed by any sort of local or general reaction. The effect of this vaccine on lesions supposed to be caused by the morococcus (for example, pityriasis alba capitis, acne pustulosa, etc.) is not satisfactory, and the writers are of opinion that the failure is due to the fact that the organism is symbiotic, and that a vaccine to be successful must be composite and contain just those organisms present in each individual case. (4) The extreme difficulty of the cultivation of the microbaciillus and the fact that it is comparatively non-virulent is responsible for the less imposing results obtained in acne and seborrhoea oleosa. But there are cases which respond after the first injection, and with weekly progressive doses go on to complete cure in four or five weeks. Others, again, especially acne furuncles of the neck and nape of the neck and acne necrotica of the temples and scalp, fail to react with the microbaciillus vaccine alone, and are rapidly influenced if staphylococcus vaccine is combined with it. There are probably cases in which a mixed vaccine of the microbaciillus and the morococcus would be successful, as should theoretically be the case in pityriasis seborrhoeica. No positive results were obtained in progressive seborrhoeic alopecia. The authors emphasize the complete absence of all dangerous complications or subsidiary effects. They consider autogenous vaccines

¹ *Annales de dermat. et de syph.*, vol. iv, No. 5, May, 1913.

unnecessary in cases of furunculosis, and are of opinion that estimation of the opsonic index is not to be relied on as a guide to treatment. They advise a more general use of vaccines in French dermatological circles.

HEALTH OF POTTERY WORKERS.

THE trend of modern legislation towards improving the health of the people is nowhere more evident than in the rules and regulations governing the hours and conditions of work of those employed in operating the great industries. Masters and men alike are now realizing that success in business requires above all things the physical fitness of the workers employed. That the masters thoroughly grasp the importance of this is evidenced by the opening, on Monday, June 9th, of an exhibition in the King's Hall, at Stoke-on-Trent, of appliances designed to carry out the latest Home Office Regulations in regard to the pottery trade. The exhibition has been promoted by the Joint Committee of Pottery Manufacturers of Great Britain, and is being held in the very centre of the industry. The holding of such an exhibition reflects great credit upon the promoters whilst evincing strongly the keen desire of all concerned to carry out the new regulations as efficiently as possible regardless of expense. The present code of rules for the pottery trade was drawn up by a Home Office Departmental Committee, upon which both employers and workpeople were represented. The new rules aim in the main at reducing, as far as possible, the dangers arising from contact with lead and in preventing the spread of dust, the two factors which together are responsible for most of the mischief to pottery workers. In addition, they deal with the carrying of weights by young people and females, and for the first time they restrict the working hours of adult males engaged in processes involving contact with lead. The regular medical examination of all such workpeople is required once in each calendar month; the keeping or eating of any food in a room where lead processes are carried out is strictly prohibited, while suitable overalls, including head coverings provided by the employer, have by regulation to be worn by the workpeople. The employer also has to provide milk, or cocoa made with milk, to all women and young persons employed in lead processes who commence work before 9 a.m. When it is considered that working in pottery has never been remarkably unhealthy, the thorough and detailed character of the new regulations shows how anxious all parties are to prevent any disease which can be directly attributed to the occupation of the patient. The object of the exhibition at Stoke-on-Trent is to bring before masters and men alike the various appliances which must be employed in order that the regulations may be adequately fulfilled. The exhibits consist mostly of ventilating plant, including dust-exhaust apparatus, models showing how efficient protection of exposed machinery may be effected, non-absorbable dust-proof material for overalls, and so on. It is particularly the wish of the Joint Committee that the operatives themselves shall attend the exhibition in large numbers, and to this object lectures have been arranged, which they may attend free of charge. Dr. T. M. Legge, Home Office Medical Inspector of Factories, will give a lecture on "How to keep fit," and Mr. W. Burton, F.C.S., a well-known authority on matters connected with the pottery industry, will give two lectures dealing with the new regulations. The exhibition was opened by Mr. Ellis Griffith, K.C., M.P., Parliamentary Under Secretary to the Home Office, whilst the presence with him on the platform of Sir Arthur Whitelegge, H.M. Chief Inspector of Factories, was further proof of the sympathy felt in official circles with the objects of the exhibition. In his opening speech Mr. Ellis Griffith expressed the hope that the exhibits might be found some permanent resting place

where they could be kept together and from time to time new apparatus added as it was devised, so that a complete set of contrivances for use in pottery workshops might be always available for inspection. It is to be hoped that this exhibition at Stoke-on-Trent will meet with the full measure of success it deserves, and thus in a practical manner demonstrate the public approbation of the wisdom and far-sightedness of the promoters. The exhibition will remain open until June 21st.

THE INFLUENCE OF THE CORSET ON ART.

MUCH has been written as to the baleful effects of tight lacing, but the corset finds champions even among medical men at the present day. Like most other matters, the question is one of degree. We are not here concerned, however, with the effect of the corset on health, but with its influence on art. In the March number of *Aesculape* Dr. Felix Regnault points out that the female figure presents two well-marked types: one built on large lines, though somewhat short and expressive more of vigour than of grace; the other tall and slender—"linked sweetness long drawn out," if we may divert Milton's phrase from its proper application. This has in all ages been generally regarded as the true aesthetic type. To fashion themselves like unto it women have employed from the remotest time various artifices—high-heeled shoes, towering pyramids of hair on the head, and especially compression of the body with corsets. The artificially slim waist is seen in the wall paintings of dancing women of the palace of Minos in Crete three thousand years before the siege of Troy; when these were discovered by Mr. Arthur Evans, a Frenchman who happened to be present exclaimed, *Mais ce sont des Parisiennes!* In ancient Egypt both men and women strove to mould their figure to an aesthetic slenderness by means of a small corset going up from the waist to the breast, and often kept in place by two braces. In this way the chest was compressed so as to give it a cylindrical shape, as is seen in statues of the God Ammon-Rá, the Goddess Cneph or Chnouphis, and many others. The shoulders were pushed upwards to a horizontal position. The Egyptian artists, therefore, generally represented men with a long, thin body, broad, square shoulders, and arms hanging far from the bust. The ephod of the Jews and the chitonisens of the Cretans were used for the same purpose. Greek and Roman women used long bandages of cloth (*fasciae*) to compress the bust. These supported hanging breasts, while at the same time the upper part of the thorax was squeezed to hide their bulging. In children the use of these bands tended to push up one shoulder and produce scoliosis. This fashion, which lasted from the second century before Christ to the second century A.D., was denounced by Galen, and by lay writers such as Martial, Terence, Catullus, Ovid, Petronius, Tacitus, and others. The influence of the bandages on Greek art is visible especially on the terra-cotta statuettes intended for the common people. These often represent women abnormally tall and slender, and some of them show evident signs of compression. They are seen especially on some Smyrna terra-cottas of the second century B.C., and on others from Myrina. Compression of the bust from the breast to the hip is seen in the famous painting of the Three Graces found at Pompeii. In the Middle Ages women had the same ideal. In the twelfth century they wore gowns moulded to the chest and abdomen so tightly that they could not bend their bodies or even their arms. A century later they squeezed the upper part of the trunk and made the abdomen project in such a way that Jehan de Meung, who lived between 1280 and 1320, bluntly says that it was often impossible to tell the empty from the pregnant. Gothic art represents women as long and slender, tight-laced in their clothes so that the ribs, the breast, and even the umbilicus are outlined under the stuff. But it does not reproduce nude bodies deformed by exaggerated compression. In the fifteenth

century women compressed the chest either with stays fitted to the figure or with the strings of their gowns. Under Charles VII they used cloth bandages passed round the bust in the ancient manner. They thought the projection of the abdomen caused by this was beautiful, and it was considered good form to present a belly as protuberant as that of a woman several months gone with child. The artists of the fifteenth and the beginning of the sixteenth century reproduced these deformities from the models they had before them. In Italy, at the Renaissance the cult of the antique preserved artists from these ugly shapes, and since then the classical tradition has been maintained. On the other hand, the realistic art of the Flemish and German artists produced during more than a century a great abundance of deformed Eves and other unaesthetic nudities. In the seventeenth century we find Riolan, and in the eighteenth Winslow, condemning whalebone stays which went up to the armpits, and like the Roman *fasciae* caused curvature of the spine. In the nineteenth century the corset compressed only the lower part of the thorax. The result of tight lacing in the modern sense is deformity of the lower part of the chest, and as a consequence displacement of the underlying viscera, such as the liver and the stomach, and more or less serious interference with their functions. But inequality of the shoulders is seldom, if ever, seen. Now the fashion has changed once more, and the corset has gone further in its descent. It encases the abdomen, the buttocks, and the upper part of the thighs. At all costs women wish to look long and slim. To that end fine, close-fitting tights have replaced the petticoat, and the gown is moulded over attenuated figures, the outline of which is distinctly visible. Artists no longer take as models the compressed and stiffened figures represented and exaggerated in fashion plates.

IS TYPHUS A COMMON DISEASE ?

AT a meeting last December of the Johns Hopkins Hospital Medical Society, Dr. J. W. Anderson put forward a suggestion to the effect that typhus is probably a much commoner disease in American, Canadian, and other cities than is generally believed. The disorder which Brill of New York differentiated some ten years ago both from typhoid and paratyphoid fever, and which has come to be known by his name, was proved conclusively by Goldberger and Anderson some eighteen months ago to be really typhus fever, and at the same time they subscribed to the view that the transmission of typhus fever from patient to patient is brought about certainly by the bites of body lice, and possibly those of head lice, but not by those of bed bugs. They also put forward reasons for believing that the buccal and pharyngeal secretions from human cases of typhus are innocuous, and that the disease is never transmitted except in the fashion indicated. On the basis of these facts, and especially of the identification of Brill's disease—a fairly common disorder in New York—Dr. Anderson at the meeting in question asked whether it was not possible that many mild cases of typhus occurred, but escaped recognition. If it were true the fact would provide a solution of one of the well known problems regarding typhus fever—namely, the occurrence of epidemics after long intervals from any other outbreaks and at a great distance from any known focus of the disease. It would certainly not be remarkable that a benign form of a disease, often regarded nowadays as a species of medical curiosity, should fail of recognition, and point is incidentally given to the suggestion by a recent letter in the *Irish Times* in regard to a recent outbreak of typhus fever in Connought. The object of the letter, which is anonymous, is to point out the probability of the disorder in this instance being transmitted by body lice, but incidentally the writer mentions that some years ago he admitted to an institution of which

he was in charge a number of cases which he regarded as influenza, and which he identified as typhus fever only when a case with very definite symptoms was eventually sent in. This letter evoked from another medical correspondent, also writing anonymously, a letter containing a statement to the effect that immunity from the bites of body lice and other like vermin can be secured by the simple process of taking one sulphur lozenge daily, it being added that travelling showmen and their kin are well aware of this fact, and have assured the writer of the complete efficacy of the plan. The amount of sulphur contained in a sulphur lozenge is small, and the amount which would reach the skin after its introduction into the stomach is naturally smaller, but since there is no scientific knowledge of the degree of antipathy, if any, which body lice experience towards sulphur, it is impossible to say that the suggestion is quite unfounded.

THE LOT OF THE CONGRESS SECRETARY.

THE Congress season is upon us, and those who have undertaken to organize these meetings are working at the highest pressure. The preparation is—*si parca licet componere magnis*—something like the mobilizing of an army, and all who have a hand in it must feel the strain. But the lot of the general secretary is particularly unhappy. Some hints for the guidance, if not the encouragement, of these officers, may be found in a skit written by Dr. F. Berlioz, general secretary of a congress of hydrology held some years ago at Aix-les-Bains. It is cast in the form of the Decalogue as it is taught to French children; but the duties of the general secretary of a congress are so numerous and multifarious that the author has been unable to compress them within the limits of ten commandments. As any attempt at translation would spoil them, we give the lines in the original:

| | |
|-----------------------------------|------------------------------------|
| Longtemps d'avance tu prendras | Ton président tu honoreras |
| Pour ne pas choir pitusement. | Et les vices pareillement. |
| La semaine tu travailleras | Les délégués tu placeras |
| Et le dimanche même ment. | En bon poste naturellement. |
| Nuit et jour tu penses | Les dames tu accueilleras |
| A recruter des adhérents. | De ton sourire gracieusement. |
| Des circulaires tu enverras | Des discours tu prononceras |
| Et des avis pareillement. | Aussi courts qu'intéressants. |
| Les rapporteurs tu presseras | Des toasts tu porteras |
| Pour leur travail très souvent. | Le plus possible spirituellement. |
| L'imprimeur tu surveilleras | Des excursions tu organiseras |
| Car il retarde tout le temps. | Et des banquets agréablement. |
| L'administration tu solliciteras | Quand toutes choses bien fait |
| Et l'on t'écouterà courtoisement. | tu auras |
| Aux compagnies tu demanderas | Les congressistes seront contents. |
| Des permis résolument; | Après tu te reposeras |
| Et tu les obtiendras | Si tu le peux un court moment |
| En général facilement. | Et puis tu reprendras |
| | Ton labeur quotidiennement. |

Every one who has had to do with the arrangements for a congress will feel the force of the injunctions to work all the week and also on Sunday; to beat up adherents; to flood the medical world with circulars and notices; to harass the illustrious beings who have promised addresses and papers; to apply constant stimulation to the dilatory printer; to be a "sturdy beggar" from Government officials, railway companies, etc.; to be careful in assigning places of honour to delegates—we have known the most deplorable consequences follow some supposed affront to the dignity of a delegate; to cultivate a winning smile for the ladies; to be brief and as witty as Nature allows in speech-making; to organize excursions, garden parties, dinners, and all manner of entertainments. But M. Berlioz is too optimistic when he says that when one has spent oneself in the effort to make things go well the congressists will be satisfied. The most that the over-worked and over-worried general secretary can hope for is to escape abuse. And when the hurly-burly's o'er he must find comfort in the feeling that virtue is its own reward.

THE ANTHROPOMETRY OF AMERICAN IMMIGRANTS.

IN 1908 Professor Franz Boas, the well-known anthropologist, was instructed by the United States Immigration Commission to investigate the physical characteristics of immigrants. He has now presented his report,¹ which comprises most of the statistical data and an account of the results attained. The racial types examined were Bohemians, Slovaks and Hungarians, Poles, Hebrews, Sicilians, Neapolitans, and Scottish. The features studied were stature, weight, length of head, width of head, width of face, and colour of hair. The wealth of statistics provided can be gauged by the fact that in a volume of 573 pages nearly 500 consist of tables or diagrams. Professor Boas finds that the varying physical types represented among the immigrants tend to be modified, converging towards a uniform type. Thus the East European Hebrew, who has a very round head, becomes more long-headed; the South Italian, who in Italy has a very long head, becomes more short-headed, these two divergent forms thus tending to approach a uniform type so far as roundness of the head is concerned. In order to avoid the introduction of any fallacy due to the differing composition of the immigrant population at different times, parents were compared with their own children born before and after immigration. Combining all his results, Dr. Boas finds, for instance, that "children born less than ten years after the arrival of their mothers in America lose 0.9 unit in their cephalic index, and those born ten years or more after their mothers' arrival in America lose 1.9 units in their cephalic index, as compared to foreign-born children." Professor Boas believes that the observed results are to be attributed to the action of the environment. In discussing the suggestion that changes in physical type might be produced by a selective death-rate, certain types being less fitted to survive in the new environment, he observes: "On the whole, it seems to my mind the burden of proof would lie entirely on those who claim such a correlation between head index, width of face, etc., and death-rate—a correlation which, I think, is highly improbable, and which could be proposed only to sustain the theory of selection, not on account of any available facts. I grant the desirability of settling the question by actual observations, but until these are available we may point out that the very suddenness of the changes after immigration and the absence of changes due to selection by mortality among the adult foreign-born would require such a complicated adjustment of cause and effect in regard to the correlation of mortality and bodily form that the theory would become improbable on account of its complexity." As will have been gathered from what has already been said, an immense amount of labour has been expended upon this research, and all students of anthropology must be grateful both to Dr. Boas and to the United States Commission. We cannot, however, say that the report itself is adequate to sustain the very far-reaching and important conclusions indicated. The text shows signs of undue compression, with the result that the statistical processes do not, in the absence of detailed justification, appear satisfactory or complete; this is, perhaps, especially noticeable in the sections treating of heredity, while some of the age and sex corrections need further explanation. Again, the logic of some passages is not above criticism, that we have quoted above being a case in point. The labours of many naturalists, especially, perhaps, those of Poulton and his fellow workers in the field of mimicry and protective resemblance, have demonstrated that phenomena of great complexity, some apparently being reactions to the direct environment, can be adequately accounted for with the aid of a selection hypothesis. There is no inherent improbability in sup-

posing that the operation of a selective death-rate may have had a good deal to do with the results Dr. Boas has observed, and others besides the pure "Neo-Darwinians" will object that this possibility requires something more than verbal criticism. We trust that Dr. Boas may see his way to publish a somewhat less compressed discussion of a problem of such great theoretical and practical importance.

THE LIVINGSTONE CENTENARY.

COMMEMORATION is an annual festival at Livingstone College, but this year it was made the occasion of celebrating the centenary of the birth of David Livingstone, after whom the college is named. In the course of the proceedings which took place on June 7th, the Principal (Dr. Haiford) mentioned that few of the speakers at various meetings held during the centenary celebrations in May had recognized the close relation between Livingstone's medical training and the great contributions which he made to knowledge of the African continent. It was felt to be appropriate that this should be emphasized at Livingstone College, where missionaries received medical training in order to fit them to go forth as missionary pioneers. A large number of its old students had gone to Central Africa to follow in the footsteps of Livingstone, and others were to be found in almost every part of the world. Wherever they worked they carried with them the spirit of Livingstone in endeavouring to exercise their powers of observation, a large-hearted sympathy, and a readiness to co-operate with other Christian missionaries. A short speech was also delivered by Sir Alfred Pearco Gould, who after dwelling on the distinction which should be drawn between medical missionaries and missionaries who had received elementary medical training, said that he would like to see every missionary undergo nine months' training at the college before going abroad; those who had not done so should when on furlough take advantage of the opportunity of study thrown open to them. The college, it may be mentioned, has prepared a souvenir of the Livingstone centenary containing coloured reproductions of various pictures of Livingstone in its possession, and these are on sale for the benefit of the Centenary Fund, by which it is hoped to clear off a mortgage on the property, effect certain improvements, and form the nucleus of an endowment.

TUBERCULIN DISPENSARIES.

At a meeting of the Tuberculin Dispensary League, held on June 6th, at 70, Chester Square, the Earl of Denbigh in the chair, Dr. W. Camac Wilkinson delivered an address in which he expressed the opinion that the only satisfactory method of dealing with tuberculous patients under the conditions laid down by the Insurance Act was by means of the tuberculin dispensary. Sanatorium treatment, he said, was inadequate because, owing to the enormous cost of the erection and maintenance of large buildings, it was impossible to provide accommodation for all those who needed treatment; whilst among the working classes, where consumption was always most rife, there were innumerable cases in which the patient could afford neither the time nor the money for the course of treatment extending over many months. It was therefore obvious that the sanatorium system was impracticable as applied to the poor. The tuberculin dispensaries, on the other hand, provided expert treatment, which did not involve the patient's absence from home or the loss of his occupation, and, money not being needed for building purposes, the funds were devoted entirely to the patients. Tuberculosis, continued the speaker, killed some 55,000 persons every year in England and Wales, and there were, in all, about 220,000 tuberculous patients in this country who required treatment. Sanatoriums could only deal with about 20,000 cases, and

¹ *Change in Bodily Form of Descendants of Immigrants*. By Franz Boas, Ph.D. New York: Columbia University Press, 1912. (Kos. 8vo, pp. 285; figs. 53, tables 73 + xxxvi. Price 7s. 6d. net.)

the approximate yearly cost of their maintenance amounted to about £600,000. It would therefore cost over £6,000,000 a year to treat every case of tuberculosis in a sanatorium, whereas it was estimated that the tuberculin dispensaries could deal with 70 per cent. of these cases, and secure for the same amount of money that provided sanatorium treatment for 10 per cent. with only 50 per cent. of cures. Moreover, the individual results of the dispensaries were better than those of the sanatoriums, and the treatment itself was popular with the patients. Dr. Wilkinson's views were heartily endorsed by Mr. Charles Bathurst, M.P., who proposed a vote of thanks, which was passed unanimously. This brought the meeting to a close.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Dogs Bill.—By one of those parliamentary incidents which an expert parliamentarian like Sir Frederick Baubury, who has charge of the Dogs Bill, knows how to make use of, this bill was read a second time on Friday, June 6th. It had been anticipated that the whole sitting would be devoted to the report stage of a bill introduced by Mr. Pearce, the Member for Limehouse, to increase the hours of polling, so that they would extend from 7 a.m. until 9 p.m. The bill, as introduced and as passed through Committee, applied to parliamentary and local elections generally, but by one of those compromises which are often arranged in the House of Commons between the two sides, the opposition to the bill was suddenly withdrawn about 2 o'clock, the arrangement made being that the bill should only apply to parliamentary elections, and that the extended hours should be provided when asked for in writing by a duly nominated candidate on the day of his nomination. The Dogs Bill was the second order of the day, and, as the House had emptied after the compromise on the Polling Hours Bill, Sir Frederick Baubury got his second reading without opposition in a few moments. The bill prohibits experiments on dogs for all purposes. It has been sent to Grand Committee A, to which, in accordance with the usual practice, fifteen other members have been added. We understand that it will be strongly opposed in Committee, and in all probability drastic amendments will be introduced. It will then still have to pass the report and third reading stages in the House of Commons for a private member's bill. The chances at these two stages are very slight indeed. The opponents of the measure, however, should certainly be on the alert, as the sponsor of the bill is an old parliamentary hand, full of skill and knowledge of procedure.

Sir Victor Horsley.—Lord Robert Cecil asked the Home Secretary whether he had laid a complaint before the Royal College of Surgeons about Sir Victor Horsley; if so, what was the nature of the complaint; and whether he had refused to give to Sir Victor Horsley any information as to its nature.—Mr. McKenna said: Sir Victor Horsley made certain public statements reflecting very seriously upon the professional conduct and skill of two medical officers in the prison service. In justice to those officers, I considered it my duty to bring to the notice of the Royal College of Surgeons the statements made by him and the facts of the case as already stated by me in substance in this House. Having laid this full statement before them, I left the matter in their hands. In reply to Sir Victor Horsley's request for information, I have referred him to the Royal College of Surgeons. The communication of the contents of my letter is a matter entirely in their discretion.

Lord Robert Cecil: May I ask the right hon. gentleman whether he does not think, before making a complaint, or at the time of making a complaint, against a gentleman in the position of Sir Victor Horsley, it would have been better and fairer to have sent a copy of the complaint to

the gentleman in question? Mr. King: Does not the right hon. gentleman think that the same rule would apply to Sir Victor Horsley's own conduct?—Mr. McKenna: Yes, Sir; I think if the rule were a good one it would apply, no matter what the position of the person may be. In this particular case nothing was communicated to the Royal College of Surgeons except what was made public, either by Sir Victor Horsley or by me in this House. I thought it my duty to bring his public statement to the notice of the Royal College of Surgeons.

Lord Robert Cecil: Have not the Royal College of Surgeons jurisdiction to consider, judge, and inflict penalties on any member of that body who is guilty of conduct which they regard as unprofessional?—Mr. McKenna: The whole of this complaint is within the knowledge of the accused person. I have communicated to the Royal College of Surgeons the attacks made by Sir Victor Horsley on prison officials.

Lord Robert Cecil: Will the right hon. gentleman now send a copy of the communication he made to the Royal College of Surgeons to Sir Victor Horsley?—Mr. McKenna: No, Sir; I adhere to the view I took originally, that it is a matter within the discretion of the Royal College of Surgeons. I have not marked my letter private, and they are perfectly at liberty to send my letter to Sir Victor Horsley.

Lord Robert Cecil: Will the right hon. gentleman say what objection he has to conveying to Sir Victor Horsley his letter, which must be of great importance to him?—Mr. McKenna: I personally have not the slightest objection; but I wrote my letter to the Royal College of Surgeons, and it is for them to communicate with Sir Victor Horsley.

Factory Inspectors.—In reply to Mr. Gill, Mr. Ellis Griffith said that the Secretary of State had decided to relieve some of the larger districts which, in consequence of the growth in the amount of work, had become unwieldy, and it was proposed to increase the number of districts from fifty-two to sixty-two and that the changes would involve an addition of six inspectors and two inspectors' assistants, together with the appointment of another medical inspector, two lady inspectors and an inspector of junior rank to assist in the work of electrical inspection, making a total increase of twelve. In further reply to Mr. Gill, Mr. McKenna said that superintending and certain special inspectors receive a night allowance of £1 for subsistence when away from home; that inspectors below the rank of superintending inspector receive 15s., and assistants 10s., and that inspectors are authorized to travel by rail first-class, and assistants and other inspectors second-class, or third if there is no second.

Grant for the Highlands and Islands.—In reply to Major Hope, the Secretary to the Treasury said that the special grant of £10,000 made for the benefit of insured persons in the Highlands and Islands was included in the Supplementary Estimates. The question of making a grant for uninsured persons and of providing for its administration was under consideration.

Housing Reform in Wales.—Mr. Edgar Jones asked the President of the Local Government Board whether, having regard to the need of housing reform in Wales, he was prepared to sanction a Provisional Order, under Section 10 of the Local Government Act, 1888, for transferring the powers of the Local Government Board under the Housing Acts to a central administrative council representing all the county councils in Wales.—Mr. Herbert Lewis, who replied, said that it was doubtful whether the proposal could be carried out under the Section.

Cost of Lunatics and Lunatic Asylums.—In reply to Mr. Campion, the President of the Local Government Board stated that the total amount expended by local authorities in England and Wales, otherwise than out of loans, on lunatics and lunatic asylums in the year 1910-11 was £4,100,000. It was estimated that of this sum some £1,200,000 might be regarded as defrayed out of Exchequer grants, £2,250,000 out of rates, and the balance from other sources.

Scotland.

(FROM OUR SPECIAL CORRESPONDENTS.)

THE REGIUS PROFESSOR OF MEDICINE IN GLASGOW.

DR. T. K. MONRO has been appointed Regius Professor of Medicine. It is understood that there were no applicants outside of Glasgow, though it is no doubt sometimes a good thing for a great teaching school to have an outsider brought in to spread new ideas and state fresh views. There has, however, been considerable resentment felt among the local profession that so many of the recent appointments have fallen to graduates of other schools, and it is therefore with great satisfaction that the news of Dr. Monro's appointment has been received, as it is agreed that in him the university has obtained a man well fitted to maintain and extend its reputation. The two previous holders of the chair were by no means young when they were promoted; but Professor Monro, who took his first medical degree in 1883 and has been physician to the Glasgow Royal Infirmary for some time, is still a comparatively young man, and this will be an advantage to the university in dealing with any changes that may be considered to be required.

VETERINARY INSPECTION.

In order to enable the staff of the Local Government Board of Scotland to undertake heavy duties in connexion with the supervision of meat inspection and the inspection of dairies, Professor Gerald Rowley Leighton, M.D., F.R.S. Edin., has been appointed a veterinary inspector. Dr. Leighton is at present the professor of pathology, bacteriology, and meat inspection in the Royal (Dick) Veterinary College, Edinburgh. He is a graduate (M.B., C.M.) of Edinburgh University of 1895. He is the author of works on *British Serpents* (1901), on *British Lizards* (1903), on *The Meat Industry and Meat Inspection* (1910), and on *Scientific Christianity* (1911); and he has written papers on Canine Hydronephrosis, the Evolution of Immunity, and The Pathology of Canker in Serpents. For a time at the beginning of his professional life he was in private practice in Herefordshire.

EDINBURGH UNIVERSITY MEDICAL YEAR BOOK.

For the third year in succession Dr. Duncan C. L. Fitzwilliams has edited the handy guide book to things medical in Edinburgh University known as the *Edinburgh University Medical Year Book*. It will be, and indeed it has already been, of great service to former Edinburgh graduates who may wish to keep in touch with their Alma Mater, giving them information about the present residence and doings of old companions, and about the new developments in post-graduate teaching and the like. There are articles on Lord Lister, on the late Dr. George A. Gibson, on Professor Lorrain Smith, along with photographs of these and of other well-known Edinburgh men; there are full details of the various post-graduate courses, lists of the various local resident and non-resident posts open to graduates in the many hospitals with which Edinburgh is supplied; notes on athletic matters, and a list of the names and addresses of the graduates, arranged alphabetically and also geographically. The title of the work excludes more than scanty references to the great extramural school, with its staff of nearly sixty lecturers, which has in the past been so fruitful a training ground for the university teachers and professors.

MARINE BIOLOGICAL ASSOCIATION.

An appeal to the public will shortly be made for greater financial support for the marine biological research station at Millport on the Firth of Clyde. It appears that there have been during recent years some differences in the West of Scotland Marine Biological Association, but at the recent annual general meeting the chairman intimated that affairs were now being put into a satisfactory condition. It is proposed to secure a sailing boat with motor auxiliary as the funds do not yet permit of the steamer *Mermaid* being put in commission. A clear income of at least £550 is required to carry out the work of the station effectively.

Ireland.

(FROM OUR SPECIAL CORRESPONDENTS.)

EXTENSION OF MEDICAL BENEFIT TO IRELAND.

THE statements which have been made in the press to the effect that it is not the intention of the Government to include the extension of medical benefit to urban districts in Ireland among the provisions of the promised Insurance Act Amendment Bill seem to have been welcomed both by employers and by employees. The former consider that it would involve a very considerable tax, accompanied by a great deal of trouble, and the employees are becoming confirmed in the opinion that they were better off before the Act was introduced, and that the difficulty of forcing the societies to pay sick benefit is very great. The friendly societies alone stand to gain by the extension of medical benefit, as most of them provide, or are at least supposed to provide, medical attendance as an extra benefit; they would, therefore, receive the extra contributions for what they are supposed to be giving now without them. The method of giving medical benefit adopted by most of the societies would seem to be to send the insured person either to a general hospital, the union hospital, or the dispensary doctor. A special committee appointed by the Belfast Board of Guardians has reported that in its opinion the effect of the Act has been to increase the number of dispensary patients and of those seeking admission into the workhouse hospitals.

THE MENTAL DEFICIENCY BILL.

The omission of Ireland from the Mental Deficiency Bill is very much regretted by those acquainted with the circumstances of the country, although it does not appear that anything very active is being done to remedy the defect. The need for the extension has on several occasions been pointed out in these columns. The pauper insane population of Ireland is, relatively to the total population, appallingly large, and it is steadily increasing. The floating population of the Irish workhouses is largely recruited from the ranks of the classes with which this bill proposes to deal. Though the number of illegitimate births in Ireland is small, it is said that the majority occur in districts where workhouses are situated, and that every workhouse has a *clientèle* of feeble-minded young women who are the mothers of one or more illegitimate children. The Mental Deficiency Bill would give Ireland the power to control the productive forces of insanity. In the first place, it would remove all defectives from the workhouses; and, in the next place, it would enable several counties to join in making provision for special institutions. There is not a single special school in the whole of Ireland for such defective children, while England has nearly 200. Nearly three-quarters of the feeble-minded are the children of the insane or of epileptics or of neuropaths, and there is need of more restriction upon the personal liberty of the feeble-minded and degenerate.

NURSING CONFERENCE IN DUBLIN.

Last week the Nursing Conference met for the first time in Ireland. On June 3rd a reception was given in the Royal College of Surgeons. The guests were received on behalf of the Irish Nursing Association by matrons of the various Dublin hospitals. The principal feature of the proceedings was the pageant of nursing, adapted from the pageant and masque of the evolution of trained nursing, by the courtesy of Mrs. Bedford Fenwick, the author and designer, who was present. There was a very large attendance of members of the medical and nursing professions in Dublin. On June 4th the serious business of the conference was commenced at the Royal College of Physicians, the chair being taken by Mrs. Bedford Fenwick, Honorary President. Miss Huxley, President of the Irish Nurses' Association, gave an address of welcome. Miss L. V. Haughton, Matron, Guy's Hospital, London, read a paper on the preliminary training of probationers; Miss B. Butler, Assistant Matron, St. Bartholomew's Hospital, London, read a paper dealing with reciprocal hospital training; and Miss Musson, Matron, General Hospital, Birmingham, dealt with the subject of post-graduate training for

trained nurses. These papers were followed by an interesting discussion showing the importance of the financial question in arranging for the training of nurses. The President said that it must be recognized by parents that if they were going to put their children into a profession they must pay for it. At the basis of all was the awakening of the professional conscience of women, who realized that they must give of their best to the sick, and could not unless they were properly educated to do it. At the afternoon session two papers were read on the training of the masseuse and on professional ideals with regard to massage workers, and were followed by a discussion. The delegates visited the Rotunda Hospital. In the evening tableaux illustrating the history of nursing from the earliest times were shown at the Abbey Theatre, and were followed by an Irish play.

The morning of June 5th was occupied with a discussion on the registration of nurses, and the following resolution was passed by a large majority :

This meeting desires to record its earnest conviction that it is absolutely necessary, both in the interest of the professional status of nurses and of the public whom they serve, that provision should be made for their registration by the State, and that such registration should be under the supervision of a central professional authority, and that admission to the register of those who have fulfilled the prescribed conditions should be by the single portal of a State examination. This meeting regrets that the Prime Minister has not so far found time for the discussion of the question in the House of Commons, and urges that facilities may be given for the second reading of the Nurses Registration Bill at the earliest possible date.

In the afternoon the question of the legal status of midwives and Poor Law and school nursing were considered. A garden party was given at the Zoological Gardens, and the Lord Lieutenant, in the course of a short address of welcome, apologized for the absence of Lady Aberdeen at the Congress of the International Council of Women in Paris. In the evening there was a banquet in the Mansion House, with Miss Huxley, President I.N.A., in the chair. On June 6th, after a short meeting at the College of Physicians in the morning, when votes of thanks were passed, the majority of the delegates made an excursion to Glendalough, while the remainder made excursions to Howth and Killiney. The Irish Nurses' Association is to be congratulated on the success of the whole undertaking.

DR. STEEL, ARTICLAVE, COUNTY DERRY.

Dr. J. A. Steel, J.P., has been the popular and trusted dispensary medical officer for Articlave for nearly thirty-five years. On the occasion of his marriage the opportunity was taken by the residents of showing their appreciation of his services, both as a public medical officer and as a trusted private attendant. On the evening of May 30th, at a large and enthusiastic meeting in the Mark Memorial Hall, Articlave, he was presented with an illuminated address and a purse of sovereigns, and Mrs. Steel received a handsome clock with chimes. The profession joins with the donors in their best wishes and congratulations to Dr. and Mrs. Steel.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

BIRMINGHAM.

BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.

In the ninety-first annual report presented to the annual meeting of this society, held recently, the directors stated that the good work of granting relief to those in need of the society's assistance had been accomplished as usual in a quiet and unostentatious manner. The directors had good reason to believe that the help so given had been urgently needed, and gratefully received in every case. The invested funds amounted to over £16,000. Twenty-seven annuitants received help during the past year, two of these being annuitants for the first time. The annual value of the grants ranged from £36 to £18, and the sum expended on grants and donations in 1912 was £683. Two annuitants had died, so that at the end of the year twenty-five were receiving grants from the society. One member received a donation of £15. The

total income was £783, and the expenses £751, leaving a balance of £32. The number of benefit members at the end of the year was 385, an increase of 10 on the previous year. Fifteen new members joined the society, and 5 left either from death or other causes. The directors drew attention to the large number of practitioners in the district who had not yet become members of the society, and urged all interested in the welfare of their professional friends, who were not yet members, to make a special effort to induce them to join. It is estimated that there are nearly 4,000 medical practitioners living in the area covered by this society. Mr. F. Marsh was elected president for the ensuing year; Mr. W. Flewitt, president-elect; Mr. Leedham-Green of Birmingham and Dr. E. N. Nelson of Nuneaton, vice-presidents; Mr. F. Marsh and Mr. W. F. Haslam, treasurers; Dr. Smallwood Savage, honorary auditor; and Dr. Sawyer, honorary secretary. Dr. Stacey Wilson was elected a trustee to fill the vacancy caused by the death of Sir Thomas Chavasse.

West Indies.

AN INTERCOLONIAL TUBERCULOSIS CONFERENCE.

An important intercolonial conference on tuberculosis, which met in Port of Spain, Trinidad, last March, was attended by delegates from most of the colonies in the West Indies, as also by a delegate from Great Britain (Dr. Cecil Wall), and by representatives from Columbia, Surinam, Venezuela, and Porto Rico. It lasted a week, the sessions being interspersed, as elsewhere, by excursions and social entertainments on a large scale. The inaugural meeting took place in the council chamber of the island, and was opened by Sir R. G. le Hunte, G.C.M.G., the Governor, in the presence of a large and distinguished audience.

The Hon. Dr. H. L. Clare, the president of the conference and surgeon-general of Trinidad, then delivered an address in which he gave an illuminating survey of the subject of tuberculosis from the point of view both of governments and individuals, and in addition brought its numerous problems into focus with the special circumstances of the West Indies. Every one in Trinidad, from the Governor and Lady Hunte downwards, had co-operated in endeavouring to make the conference a success, and the speaker hoped the result would be the formation of a kind of central pivot of well co-ordinated scientific and workable data from which might emerge the scheme best adapted to the requirements and capacity of each West Indian island. They might also look forward hopefully to a day not far off when there would be constituted a central West Indian bureau of tuberculosis, which would store all available information on the subject as it was collected from the various islands, and from which would emanate comparative statements as to progress made and valuable suggestions for future guidance. The holding of intercolonial conferences was no novelty, as several had been held on subjects of inter-island interest, such as quarantine, shipping, and foreign trade. But the present was the first West Indian medical conference, and it was right that, dealing as it did with tuberculosis, it should be held in Trinidad, since their zealous honorary secretary, Dr. G. H. Masson, enjoyed the distinction of being the pioneer of any organized effort in the West Indies to grapple with the great white plague. With tropical diseases all West Indians were familiar, but tuberculosis, despite its devastating prevalence, had attracted comparatively little attention either in official reports or among the public. The prevalence of other forms of the disease than the pulmonary was comparatively slight in the West Indies as compared with other countries. The general trend of present medical opinion seemed to favour the view that these other forms were usually of bovine origin, and if this were really the case their relative exemption from surgical tuberculosis was probably due to the fact that although the conditions in which milk cattle were kept were not invariably ideal, they were, from a tuberculosis point of view, incomparably better than those which prevailed in Great Britain and other countries where bovine tuberculosis was prevalent. In the West Indies the cattle lived all the year round in the open air, and, even when delicate and possibly

already infected cattle were imported, their progeny tended to remain free from tuberculosis. Nevertheless it was desirable that the milk traffic of the islands should be kept under observation and suitable measures applied when necessary. Dr. Clare also gave a detailed history of notification as applied to tuberculosis and of aëro-therapy, and drew attention briefly to the outstanding points of tuberculin treatment. In regard to the first subject, he urged the conference and the medical profession throughout the West Indies to insist on the advantages of notification. They should explain the enormous impetus that official knowledge and record of every case would bring to the progress of the tuberculosis crusade, and make it clear that notification was not a tyrannous inquisition but a procedure which would prove a beneficent influence to those already infected and a source of protection to the community at large such as was unattainable in any other way.

Dr. Masson's contribution took the form of an elaborate review of the prevalence and distribution of tuberculosis in Trinidad and Tobago during the last quinquennium, accompanied by diagrams and charts showing the mortality due to it, and comparing this with other rates. The tuberculosis death-rate was 2.29 per 1,000 in 1907-8, and 2.08 per 1,000 in 1911-12; while the same disease caused 8.81 per cent. of the total deaths. The fact was also brought out that quite early in the nineteenth century tuberculosis was believed to be more prevalent in the West Indies than elsewhere, and was then ascribed to the overcrowding of bedrooms and a dislike of ventilation at night. This cause still operated, and not merely among the poorer classes. Another factor of importance was the special susceptibility to tuberculous infection of the negro race, from which the majority of the population had sprung. In addition, both natives and Europeans showed a lack of resistance in lung affections; as in many other tropical countries, excessive heat and a high degree of atmospheric humidity appeared to have a prejudicial effect on the respiratory organs, and gave rise to a high death-rate from non-tuberculous respiratory disease, as well as from phthisis. Hence the practice prevalent among European medical men of sending to the West Indies cases of tuberculosis for the betterment of their health was ill-advised, especially in the hotter months of the year. Its unhappy results had no doubt at one time or another been painfully impressed on West Indian practitioners. A further possible factor in the increased incidence of tuberculosis in the West Indies was that the climate and the receptivity of the bulk of the population together served, perhaps, to supply the tubercle bacillus with an environment which enabled it to take on a greater degree of virulence than in more temperate zones.

The net outcome of the conference was the adoption of a series of resolutions to the following effect:

The first—moved by Dr. Cecil Wall, seconded by Dr. Nœc (Martinique)—expressed the opinion that the tuberculosis measures adopted in the colonies and countries represented by the conference ought to include (a) notification, (b) housing reform, and (c) the establishment of tuberculosis dispensaries and other measures for the detection, prevention, and treatment of the disease.

The second—moved by Dr. J. E. Godfrey (British Guiana), seconded by Dr. J. F. Hutson (Barbados)—urged the foundation of an antituberculosis association in every West Indian colony in which one did not already exist.

The third—moved by Dr. MacDonald (Jamaica), seconded by Mr. P. T. Saunders (of the Department of Agriculture)—suggested that the measures adopted by the various Governments should include one aiming also at stamping out bovine tuberculosis where it existed and at preventing its importation.

The fourth—moved by Dr. M. P. Duke (Leeward Islands), seconded by Dr. W. Tucker (Bermuda)—advocated the addition of elementary hygiene and sanitation to the code of schools throughout the West Indian colonies.

The final resolution—moved by Dr. G. H. K. Ross (Jamaica), seconded by the Hon. Dr. E. F. Hatton (Windward Islands)—stated an opinion that the attempt to control tuberculosis would greatly be aided by efficient registration of births, deaths, and marriages.

This conference, which was undoubtedly a great success, included a tuberculosis exhibition and a cinematographic

display of the work done at Edinburgh, accompanied by a verbal description from Dr. Cecil Wall. It is proposed to hold a second conference two years hence in British Guiana.

Correspondence.

DIACHYLON OR DUTY: A CALL TO ACTION.

SIR,—It is very gratifying to find Sir Thomas Oliver taking up the question of diachylon as an abortifacient with such vigour and thoroughness. At the same time his letter carries with it a certain sadness, for it shows that this pernicious evil is still spreading and that from its small beginnings in the Midlands it has now extended to the very North of England. In 1906 the late Dr. W. B. Ransom of Nottingham and I tried to arouse the profession and the public to this evil and published a joint paper in your journal on plumbism from the ingestion of diachylon as an abortifacient.¹ For the purpose of that paper I made inquiries from leading members of the profession in all the large centres of population in the United Kingdom, and at that time I was able to write that "at Newcastle-on-Tyne it appears to be quite unknown," whilst in and around Sheffield I obtained records of about 200 cases in two years. Sir Thomas Oliver's cases are dated 1911, so that within five years it has travelled far, but by so doing has happily secured us a strong champion. His statements as to the original place of origin of this evil, and his references "from memory" to the names of those who first brought it to light, are somewhat meagre and require considerable modification. They omit the names of some who have spent considerable time and trouble in trying to get this practice stopped. Some of those who were most active are, unfortunately, no longer with us, and I am sure Sir Thomas would be the first to desire that their work should not be forgotten. The earliest cases recorded in literature occurred not in the Potteries but at Leicester, and were published by the late Dr. F. M. Pope in this JOURNAL (1893, vol. ii, p. 9). From then onwards cases were from time to time reported by Crooke of Birmingham, Bell Taylor, Ransom, Scott, Jacob and Trotman of Nottingham, Wrangham of Leicester, Layton of Walsall, and others. Leicester and Nottingham were the chief seats of the trouble. It did not spread north to the Sheffield district until soon after the beginning of the new century. From 1902 onwards the number of cases increased very rapidly, and at the Yorkshire Branch of the British Medical Association meeting at Bradford in January, 1905, I was able to record no fewer than 30 cases I had seen personally.² The evil became so crying in the Midlands that in 1906 Ransom and I determined to publish a joint paper (referred to above), and to take such other steps as we could to awaken interest in the subject, and induce the authorities to take action if possible.

We succeeded in getting the British Medical Association to appoint a special committee of inquiry, before which Drs. Pope, Ransom, and myself appeared and gave evidence. The suggestions we then made were chiefly: (1) That diachylon should be placed on the poisons schedule, and (2) that all cases of plumbism in women should be compulsorily notified. We also approached the various members of Parliament representing the districts affected, and they promised their help. But it was largely in vain. In spite of reports from coroners of deaths from this cause, several of which have occurred in this district; in spite of prosecutions at Nottingham and Sheffield, in which vendors of these pills were given long sentences of penal servitude; and in spite of the strong resolutions of the British Medical Association Committee, the reply from the authorities was that "nothing could be done."

So the evil continues. Fresh cases are constantly cropping up; within the last month we have had two at the Sheffield Royal Hospital. The numbers in this district are not so great as they were a few years ago for the simple reason that trade is booming and wages are good. But let us once get back to a period of trade depression such as there was about 1903 to 1906, and the number of

¹ BRITISH MEDICAL JOURNAL, February 24th, 1906.

² BRITISH MEDICAL JOURNAL, March 18th, 1904.

cases will go up by leaps and bounds unless something drastic is done. For the misfortune is that it is a simple and effective means of killing the fetus, and the public know it! How great is the price to be paid in health and suffering they do not care.

Some months ago I received an invitation to read a paper on this subject in the Section of Medical Jurisprudence at the International Congress of Medicine to be held in London next August. Possibly with the support of Sir Thomas Oliver's weighty influence it might be possible to get that Section to express an opinion on the subject which would arouse the authorities to action more effectively than we have hitherto been able to do. Any movement in that direction would have my personal active support, for the present state of things is an intolerable scandal.

In conclusion, I should like once more to tender my thanks to Sir Thomas Oliver for his powerful and inspiring paper.—I am, etc.,

Sheffield, June 9th.

ARTHUR J. HALL.

SIR,—Now that Sir Thomas Oliver has lent the weight of his authority to the effort to stamp out this deplorable traffic, it is to be hoped that an earnest endeavour may be made to urge upon the Government the imperative need of an attempt to repress it. Notification, not merely of industrial, but of *all* cases of blood poisoning, would, I believe, be of real service, as Sir Thomas Oliver suggests. It was a proposition I also put forward twelve years ago in this JOURNAL (vol. ii, 1901). But to be effectual it is necessary that medical men should be ready to recognize the different pictures which diachylon produces. I could almost wish that it might be raised to the dignity of a separate disease, and have a heading all to itself in the textbooks of medicine.

Whenever a woman complains of (1) severe gastrointestinal symptoms, with headache, weakness, and a lemon-coloured skin; or (2) presents symptoms and signs of a polyneuritis, not infrequently with ocular symptoms, I would say: Inquire into her menstrual history and look at her gums. The artist's signature will often unexpectedly be found there.—I am, etc.,

Bradford, June 10th.

W. WRANGHAM.

ACUTE MENTAL HOSPITALS AND PSYCHIATRIC CLINICS.

SIR,—I do not think Dr. Stansfield would desire to claim a precedence in regard to the separate hospital idea in asylums which is not according to fact. He says that seventeen years ago he advocated the institution of acute hospitals in conjunction with the existing asylums, and fifteen years ago had this carried out at Bexley. Now in 1882, over thirty years ago, we instituted at the Royal Edinburgh Asylum such a separate hospital, with a nursing staff twice the strength of the ordinary wards, where, also, the probationers were trained. The Scottish Commissioners in Lunacy took up the idea warmly, and urged it on all the Scottish asylums. Montrose and Larbert Asylums followed in a few years, and soon almost every institution in Scotland had such hospitals. The Commissioners would, in fact, pass no new plans that had not separate blocks for new and acute and sick patients. As a matter of fact, England was somewhat slow in taking up the idea and carrying it out. Now it is a *sine qua non* in every up-to-date institution all over the world. The medical idea is thereby sustained, and should pervade the whole treatment of the unsound in mind.—I am, etc.,

Edinburgh, June 9th.

T. S. CLOUSTON.

RHEUMATOID ARTHRITIS.

SIR,—Dr. Chalmers Watson does not understand what I mean by parting with the substance for the shadow. Well, I suppose I should have recognized the fact that he is a Scotsman (some of my friends object to being called Scotchmen even when they take the barley-bree), but to make up for my apparent lack of perception I shall now proceed with a surgical operation. I was under the impression that I had given him a tangible cause for rheumatoid arthritis, but he immediately throws that to the one side and sets up in its place an imaginary bacterium of whose nature, or even existence, he offers no proof, because he thinks that such view is "most consistent with available clinical and pathological data." My

idea of a bacterial disease is one which comports with all the postulates of Koch, and when Dr. Chalmers Watson, or any one else, has proven to the satisfaction of any first-class bacteriologist, such as Sir Almroth Wright, that he has conformed to all the postulates of Koch, and has really discovered a specific germ which causes what we at present understand by rheumatoid arthritis, then I shall gladly welcome the discovery and praise the discoverer. It is most fortunate that Koch laid down his postulates, otherwise we would have been overwhelmed with numerous varieties of specific bacteria which would have been discovered by highly imaginative clinicians. The so-called practical clinician of the present day is a most hopeless individual; when he runs up against a difficulty he stares it in the face and passes on.

It is just over twenty years since Schüller¹ found, in his observations on 116 cases of "chronic rheumatic arthritis," "short thick bacilli, the central portions of which are notched or grooved, while the poles present a collection of bright granules." Cultures of these bacilli were made, and when injected into rabbits they produced non-suppurative joint affections; similar organisms were removed from the joints of the affected rabbits, and these bacilli could again be cultivated, and the fresh cultures again reproduced the disease in other rabbits. This is much better proof than anything that my present opponents offer. Fortunately or unfortunately these bacilli are not found in all cases of chronic arthritis, and there are many other organisms which set up an inflammation in the synovial membranes of the joints, such as the gonococcus, the pneumococcus, and the meningococcus.

In 1886 Dr. Alfred Mantle of Harrogate found micrococci and short bacilli in the knee-joints and blood of 16 cases of acute rheumatism. In 1892 Sahlbi found the *Staphylococcus citreus* in the joints of a patient who died from acute rheumatism. In the present day there are several bacteriologists who claim to have isolated a diplococcus or streptococcus which they say is the cause of rheumatic fever; but they are not agreed among themselves, and each one claims that his particular coccus is the specific one. The so-called practical clinician goes much further. He does not trouble his brains about any specific organism; it is sufficient for him to find, or rather get someone else to find for him, a streptococcus in the faeces, if it cannot be found elsewhere, and forthwith the patient is submitted to a prolonged course of a so-called autogenous vaccine. This is what they call scientific medicine, but the pitiable tales which the patients have afterwards to tell are somewhat disheartening.

Dr. Chalmers Watson thinks that I have "not quite grasped his position"; but candidly I think that his bacteriological position is so nebulous that there is nothing to grasp. Not content with the cultivation of his own imagination, he wants to make your readers believe that I am in the same happy frame of mind though I do not know it. Because I would clear away all offending organisms, whatever their nature, that are in the outposts, and because I say that there are often acid-forming organisms both in the mouth and the stomach, Dr. Watson thinks that I must really believe in the bacterial origin of rheumatoid arthritis, and there is no use in my denying the soft impeachment. Be that as it may, I shall remain obdurate until Dr. Chalmers Watson can show me how these organisms can be made to comport with Koch's postulates. From my point of view it does not matter very much what the acid is so long as it does not, like most of the mineral acids, form stable neutral salts, and so long as it has a greater affinity for calcium than for the alkaline metals. Nor does it matter very much whether the acid is generated in the stomach or introduced from without. It is a question both of calcium starvation and calcium elimination.

His conclusion about the "instructive correspondence" is really past a joke, and I must bring my operation at once to a close. To be so blind he must be very much overweighted with the importance of his own contributions. In my opinion I have never previously in the whole course of my existence had to refute so much unadulterated twaddle. Of course, it would be downright ingratitude not to exempt Dr. Chalmers Watson from this sweeping statement, and I can really assure him that I not only exclude him but I really never meant to

¹ *American Journal of the Medical Sciences*, 1893.

include him. On the contrary, I must express to him my thanks for his high appreciation of my work, which it appears only requires a few finishing touches by his master-mind to make it a perfect work of art. Of course, neither do I include my friends and supporters, Dr. George E. Bowler and Dr. Percy Newell.

I have had two letters from another Edinboro' Scot who has not a good word to say for my work. He is a medical man of high qualifications and a chronic rheumatic to boot. He thinks that I have not proved my theory of acidosis, that the medical public are beginning to view communications as to cures with suspicion. He is especially irate at my condemnation of oatmeal in this disease, on account of its decalcifying effects, and, funnily enough, he takes me for a brither Scot. He indignantly asks, "Are we invertebrate?" (Some of them are, though I do not blame the oatmeal.) He suggests that the Londener who drinks hard water should have no rheumatoid arthritis. He wants thousands of cases from which he can draw his inductions. (By that time he will probably have found that the wicked have ceased from troubling and the weary are at rest.) He suggests that if I have not time myself to examine the blood for acidosis I should get some young Liverpool chemist to do so—of course, he magnanimously says, under my supervision—but, Scotch like, he makes no offer of a contribution towards the expenses. He himself "used Wright's method some ten or twelve years ago, without much result," using sensitive litmus as his indicator. I thought my account of the Scottish chemist who found sulphuric acid and the suboxide of copper in Scotch whisky would have saved me from this criticism. This gentleman knows very well that the blood is practically always alkaline, and the plasma more so than the serum. If the blood were acid even to sensitive litmus it would cease to take up any lime from any tissues but itself, because the heart would immediately stop. It is not a question of free acidity but of diminished alkalinity, and an increase in the acid radicles which are loosely united with bases from which they readily part in the presence of lime. The acid of the stomach is always united with some base when it enters the blood. If you add to a strong solution of sodium salicylate some carbonate of lime or magnesia you will get an intensely alkaline solution of caustic soda caused by the acid radicle laying hold of the calcium or magnesium. He says:

The medical public are thoroughly suspicious of the various nostrums held up to them—fresh air cures, radium, living microbes for injection, ionization, etc. . . . I may state that I am perfectly familiar in my own person with a two years' trial of free ingestion of rhubarb, acid, acid fruits to act the popular view, while of late I tried and have had tried on myself vaccines and serums—results *nil*. I should, however, be sorry to forego oatmeal, once chief of Scotia's food.

Poor man, I am sorry for him; the treatment seems to me worse than the disease.

I have read Dr. Preston King's letter about half a dozen times, and I really find very little to answer except his peculiar way of mixing up the cause and the treatment. I can again assure him that the first part of the treatment is to remove the cause, and there is not much use in giving lime salts until you have removed the cause which is rapidly eliminating them.

I have plainly told Dr. Craig that I did not believe that Sir Robert Christison ever uttered the statement which he (Dr. Craig) attributed to him. He makes no direct attempt to answer this, and prudently drops the calcium-laden straw. Instead, he tells us that:

At a meeting of the Balneological and Climatological Section of the Royal Society of Medicine in April of this year, when the gentlemen present consisted of physicians to whom, if there be any truth in the statement that "an ounce of practice is worth a ton of theory," we must look for guidance in the treatment of this disease, one of the speakers, on advising copious water drinking for rheumatoid arthritis, stated that "the presence or absence of some lime is of no importance whatever," confirming Sir Robert Christison's wise statement of forty years ago.

The only report of this meeting of the Section of Balneology and Climatology which I can find appeared in the BRITISH MEDICAL JOURNAL of May 3rd, 1913, p. 940, and in your report there is not one word about rheumatoid

arthritis or lime. In fact the discussion was on "the significance, treatment, and prognosis of high blood pressure." From what I know of some of the gentlemen who took part in the discussion, I am sure they would be among the first to repudiate the old stupid wheeze about an ounce of practice and a ton of theory. Not only does he fail to substantiate the view with which he credits Sir Robert Christison, but he also fails to give any reference to the lime salts having been used and discredited, as he says, in this disease. Personally I have not come across any ancient or modern textbook in which any mention is made of the use of lime salts in rheumatoid arthritis. In a previous letter he stated:

So far as I can learn, about a third of the practitioners of Britain are at present treating this disease with serums, with results much superior to what were obtained by the ancient treatment recommended by Dr. Luff and Sir James Barr.

It is well known that with the exception of anti-diphtheritic and antitetanic serums, there is now very little sale for any of the serums, and the only serum that I know of on the market for rheumatism is an antistreptococcus serum prepared by Burroughs, Wellcome, and Co. Again Dr. Craig says, "Are we to believe that neither of the writers has any experience of the antirheumatic serums now in common use?" As there is no serum in the market under such a name perhaps he will tell us something about it.

He wants to know what I mean when I say that the finely stencilled lines of absorption occurred at the edges of the bones where the blood supply comes from the periosteum. I mean exactly what I say, and I can put the facts in no plainer language. I have no doubt Dr. Thurstan Holland will be pleased to show him the plates which he exhibited to me.—I am, etc.,

Liverpool, May 31st.

JAMES BARR.

SIR,—There must be many of your readers who cannot but deplore the tone of Sir James Barr's recent letters on the subject of rheumatoid arthritis, and who think that the dignity of the President of the Association would be more suitably upheld by a style of a less bombastic and self-satisfied character.—I am, etc.,

Brighton, June 2nd.

JOHN C. UHTHOFF.

EVIDENCE FOR AND AGAINST TUBERCULIN.

SIR,—I am much obliged to Dr. J. Stavely Dick for his courteous and ingenuous reply (June 7th, page 1249), but I fail to see that there is any impropriety in treating one set of patients with tuberculin and another set without tuberculin and comparing the results. If the former set gave the best results, then the latter could also have a course of tuberculin if desired. I do not think the "controls" in such a trial have any particular grievance.

As to bovine tuberculosis, I can only say: If it has been cured by bovine tuberculin, let us have the details of cases in which that result has been obtained.

Dr. Dick says, with regard to the real good obtained from appropriate doses of tuberculin, that his "favourable impressions have been based mainly upon increased energy and capacity for work . . . on returning relish for food . . . a feeling of well-being and brightness . . . on stationary or increasing weight. . . ." But I can assure Dr. Dick that I have seen all these improvements take place in patients undergoing sanatorium treatment without tuberculin. "In a number of cases," he adds, "there was no doubt whatever as to the pulmonary lesion having become quiescent." But even that result may (sometimes) be observed in cases treated only with fresh air, good food, rest, and regulated exercise. I quite agree with Dr. Dick that the patient's general condition (appetite, weight, strength, and feeling of well-being) has to be taken into consideration, as well as the physical signs in the chest. But I hold that if a patient with, say, a moist, crackling rale in one of his apices, still has his moist, crackling rale in the same place after a course of tuberculin injections, then he is not cured. If his appetite is good, and he is free from pyrexia, and his weight keeps up, we may conclude that the recuperative agencies in his system are in the ascendant, and that is a matter for satisfaction. But the active local mischief is still present, and, if the

resisting factors in the system fail, the disease reasserts itself, and the patient goes downhill.

I am of opinion that Dr. Batty Shaw's investigations are worthy of all praise.—I am, etc.,

Bellefield Sanatorium,
Lanark, June 17th.

JAMES W. ALLAN.

THE BIONOMICS OF THE RAT-FLEA.

SIR,—I see from your issue of May 31st that Mr. Strickland has questioned the correctness of Dr. Nicoll's explanation of the apparent lengthy fast of specimens of *Ceratophyllus fasciatus*.

I am, like Mr. Strickland, unfortunate in that my own breeding experiments with fleas, covering a period of two years, are not yet published. They will, I trust, be available ere long in the *Journal of Hygiene and Parasitology*. Meanwhile I can in a few words possibly throw some light on this particular question.

The egg period of this species occupies from about four to twelve days, according to the temperature, which is of course a most important factor. The active larval life may be anything from 10 to 114 days, and probably this is not the extreme limit in either direction. After the larva has spun its cocoon it may rest within it for over 400 days. The pupal period, so far as it is possible to determine, does not exceed about 10 or 12 days, but this is admittedly only a rough estimate. When the adult flea has shed the flimsy pupal envelope it does not always emerge from its cocoon, but may continue to rest for a longer or shorter period. As in the case of the pupal period, it is only possible to arrive at an estimate as to the length of time occupied by this rest—all the available evidence being circumstantial. I should not care to estimate it at more than two or three weeks, but it may be much longer.

Emergence is frequently in response to some mechanical stimulus, such as the disturbance of the box containing the cocoons.

Mr. Strickland's inability to find cocoons is, of course, beside the mark, as they must have been present, even if the fleas had emerged from them, unless the rubbish he refers to was not that from which the fleas had been bred, but was used as cover for adult fleas which had never been fed. He is correct, however, in concluding that the adult fleas are able to make lengthy fasts, but this appears only to be possible before feeding and breeding commences, while the fat bodies carried over from the larval period are unexhausted.

I have, however, no records of such lengthy periods as he suggests; under the most favourable conditions that I could devise the longest adult life without food was thirty-one days. This was when the fleas were put into a filter paper tube which was buried in sand kept at a low temperature (45° or 50° F.) in a cellar where the humidity was over 90. If allowed to bury themselves freely in the sand—the other conditions remaining the same—they were able to endure a longer period; the longest life noted was ninety-five days.

My own view is that the occurrence of adult fleas in breeding cages long after the host has been removed, is to be accounted for by the larval rest within the cocoon.—I am, etc.,

A. W. BACOT.

Entomological Department, Lister Institute,
London, S.W., June 4th.

A CONSTITUTIONAL POINT.

SIR,—A constitutional position of interest especially to the members of our profession has just been created by the action of Mr. McKenna, the Home Secretary, and Sir Rickman J. Godlee, the President of the Royal College of Surgeons.

On March 18th, 1913, Mr. McKenna made a personal attack upon me by name in the House of Commons. On May 1st I wrote to him asking him to publicly withdraw his statements, they being from evidence in my possession inaccurate in several respects, and the same time giving him the proofs of these inaccuracies. Further correspondence ensued but without any material result.

Whilst this correspondence was still proceeding it came to my knowledge that Mr. McKenna had lodged a complaint against me at the Royal College of Surgeons without informing me that he was doing so or had done so. On discovering this I at once wrote to the President

(Sir R. J. Godlee), and requested that a copy of the document or documents containing the Home Secretary's charges be furnished to me so that I might deal with them.

Sir R. J. Godlee, who did not reply until he received a letter from my solicitor, declined to accede to my request. This request I made not only as a Fellow of the College, but also as a citizen of a country which prides itself on the fact that every one who is accused is entitled to know at once exactly what charges are made against him with a view to being enabled to reply to them should he wish to do so.

I also wrote to Mr. McKenna, making the same request. He also, whilst admitting that he lodged charges against me, declined to inform me of the nature and detail of his accusations.

It appears to me to be extraordinary for a Minister of the Crown to make a complaint concerning a professional man's reputation without giving him notice, and further, for the President of our College to refrain in his turn from informing the professional man thus complained against that such charges had been made, and to refuse to disclose the nature of them when asked to do so.

I mention this incident as evidencing the pressing need for reform in the present constitution of the Royal College of Surgeons.—I am, etc.,

London, W., June 9th.

VICTOR HORSLEY.

ANTIVIVISECTION.

SIR,—I, in company with the rest of the profession, have received a circular from the "Church Antivivisection League," in which we are asked to allow our names to be added to a list of doctors who do not believe in "vivisection." We are told in the circular that "there is a growing disinclination to believe that the medical man who countenances experiments on helpless animals will refrain from experiments on his equally helpless patients."

Our reward for allowing our names to be added to this list is evidently to be found in the following extract from the circular: "We are often asked by antivivisectionists for the names of antivivisectionist doctors in their respective neighbourhoods." It is to be hoped that none of our honourable profession will lend themselves to this form of touting. The list of doctors, it is stated, will be printed and circulated with the report of the league.—I am, etc.,

H. W. OGLE-SCAN, M.R.C.S., L.R.C.P.

London, N.W., June 9th.

MISS FRANCES POWER COBBE.

SIR.—My attention has been called to the following passage in an article, "The Ethics of Antivivisection," in your issue of May 3rd: "Miss Frances Power Cobbe made the strange boast that she loved animals by nature and her own kind only by grace." I think the quotation is not quite correct; certainly this was not said as a boast.

If, however, Miss Cobbe loved her own kind only by grace, she must have been abundantly endowed with it, for she spent her life in doing good to her fellow creatures. For many years she worked for the poor in their homes and in the workhouses; later she was instrumental in passing laws for the protection of women; and she was ceaseless, to the very end of her life, in her efforts to make all around her happy. I am, etc.,

London, W., June 8th.

HELEN L. COBBE.

Our authority for the statement to which Miss Cobbe refers is Sir Mount Stuart Elphinstone Grant Duff's *Notes from a Diary*. Under March, 1899, there is the following entry: "Miss Cobbe," remarked Lecky, "used to say: 'I love dogs by nature; human beings only by grace.'" With this may be compared another passage in the same *Diary* (August, 1895), where it is recorded: "We spoke of Miss Cobbe, and Paul said, 'I got into frightful trouble with her once, in the most innocent way. I used the expression 'the lower animals.' 'Lower animals!' she said; 'I acknowledge no such distinction—unless, indeed, you refer to married men.'" We need not argue with our correspondent whether or not these things were said by way of boast. The tone and taste of the latter remark, we think, sufficiently indicate Miss Cobbe's feelings towards those at least of her fellow creatures who had the misfortune to belong to the male sex.

Public Health

AND

POOR LAW MEDICAL SERVICES.

THE NURSING OF THE SICK POOR.

THE Workhouse Nursing Association, of which H.R.H. Princess Christian is the president, recently submitted a memorandum to the Poor Law Orders Committee, suggesting amendments to several of the provisions of the Poor Law Institutions Draft Order now under the consideration of the committee, which, in the opinion of the association, would if adopted be retrograde rather than progressive as regards nursing administration in rural workhouse infirmaries and sick wards.

On June 4th the Hon. Mrs. John Talbot, a vice-president of the association and the chairman of the Executive Committee, together with Miss Gibson (late matron of Birmingham Infirmary), Mr. Henry Dixon Kimber (the honorary legal adviser to the association), and Miss R. V. Gill (the secretary), had a long interview with the Poor Law Orders Committee, as representatives of the association, in order to emphasize and explain more fully the views of the Workhouse Nursing Association on the seriousness of their objections to several matters to which attention had been drawn in the memorandum, and to urge the importance of giving effect to certain alterations in the proposed Order which were recommended by the association.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on May 21st.

Brown Animal Sanatory Institution.

The annual report of the Superintendent of the Brown Animal Sanatory Institution for 1912 was presented. It stated that 5,546 animals had received treatment at the hospital as out-patients and 470 as in-patients. The five lectures required under the will of the late Mr. Brown had been delivered by Mr. Twort, M.R.C.S., L.R.C.P., the Superintendent, the subject selected being a comparative study of tuberculosis and John's disease. The report gave a list of ten investigations which had been carried out by different workers in the laboratories during the year.

Anatomy and the B.Sc. Honours Degree in Anthropology.

It was resolved:

That the Examination in Anatomy forming part of the Second Examination for Medical Degrees, Part II, be accepted as the Examination in respect of Anatomy taken as a subsidiary subject for the B.Sc. Honours Degree in Anthropology for Internal and External Students.

External Council.

Sir William Collins has been added to the Council for external students for the remainder of the year 1912-13, in the place of the Rev. Professor W. H. Bennett, resigned.

Lecture by Professor Benedict.

A special lecture on the work of the Carnegie Nutrition Laboratory in Boston will be given in the Physiological Laboratory of the University on Friday, June 20th, at 5 p.m., by Professor F. G. Benedict, Director of the Carnegie Laboratory. The lecture, which will be free, will be addressed to advanced students of the University and others interested in the subject.

Rogers Prize.

The subject of the essay or dissertation for the Rogers Prize, 1914, will be the nature of pyrexia and its relation to micro-organisms. The latest date for the reception of essays is April 30th, 1914. Copies of the regulations for the award of the prize can be obtained on application to the Academic Registrar.

Officers' Training Corps.

The annual inspection of the University Contingent of the Officers' Training Corps will be held by Brigadier-General D. Henderson, C.B., D.S.O., in Hyde Park, on Saturday afternoon, June 28th. Applications for reserved seats should be addressed to the Adjutant at the University.

London (Royal Free Hospital) School of Medicine for Women.

Mr. F. D. Acland, M.P., has accepted the chairmanship of the Council, and Mrs. Willey, M.D., M.S., has been appointed Lecturer in Midwifery to succeed Mrs. Scharlieb, M.D., M.S., resigned.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

It appears that neither of the retiring members of the Council, Mr. Edmund Owen and Mr. Golding-Bird, seeks re-election. The six candidates are Mr. J. E. Lane of St. Mary's Hospital (Fellow, December 14th, 1882; Member, 1886); Mr. L. A. Dunn of Guy's Hospital (Fellow, June 12th, 1884; Member, 1882); Mr. Jonathan Hutchinson of the London Hospital (Fellow, November 13th, 1884; Member, 1880); Mr. H. B. Robinson of St. Thomas's Hospital (Fellow, June 9th, 1887; Member, 1885);

Mr. Walter G. Spencer of the Westminster Hospital (Fellow, June 9th, 1887; Member, 1885); and Mr. H. J. Waring of St. Bartholomew's Hospital (Fellow, October 15th, 1891; Member, 1890).

There are four vacancies to be filled, and the candidates first and second on the poll will hold their seats for the full term of eight years, namely, till July, 1921. The substitute for the late Mr. Clinton Dent, re-elected in 1911, will fill up the remaining six years, retiring in 1919, whilst Mr. Bruce Clarke's substitute will serve on the Council for two years, as Mr. Clarke was elected in 1907. No provincial Fellow has come forward on this occasion.

The Services.

INDIAN MEDICAL SERVICE.

ANNUAL DINNER IN LONDON.

THE customary annual dinner of the Indian Medical Service in London was held in the Hotel Cecil on June 10th, when the Director-General of the Indian Medical Service, Sir C. P. Lukis, K.C.S.I., was in the chair, and the guests were: The Marquess of Crewe, Secretary of State for India, Sir Thomas W. Holderness, Under Secretary of State for India, Sir Francis Champneys, President of the Royal Society of Medicine, Sir W. Watson Cheyne, Bart., President of the Medical Society of London, and the Editors of the BRITISH MEDICAL JOURNAL and *Lancet*.

After giving the toasts of the King and Queen and other members of the Royal Family, Sir C. P. Lukis said that he had been requested to break through the rule against making speeches after the annual dinner in order to mark the honour done to the service by the presence of the Secretary of State. Speaking after four years' experience as Director-General, he asserted that during that period steady progress had been made, and that in many respects the conditions of service had been greatly improved. Annual increments of pension after seventeen years' service had been granted, the fee rules, to which many officers took exception, had been modified in a most satisfactory manner, brevets had been awarded for distinguished service other than in the field, the rules for accelerated promotion had been amended, large grants had been given for financing medical research and for the establishment of a school of tropical medicine in connexion with the Calcutta Medical College, the King George Medical College had been opened in Lucknow, and a medical school for the central provinces was to be started in Nagpur. Three new appointments, moreover, had been sanctioned, namely, a whole-time professorship of pathology at Bombay, a residency surgency at Seistan, and a directorship of the Pasteur Institute in Burma. The Indian Government had shown in a most practical manner its appreciation of the value of the services of individual officers. Formerly it was a common complaint that medical officers did not receive a fair share of honours and that professional merit met with no recognition. This might have been true in the past, but was so no longer. At no time in the history of the service had honours and rewards been given to it so liberally as during the past few years, and he mentioned the names of Surgeon-Generals Branfoot, Charles, and Bannerman, Colonel Giffard, and Majors Glen Liston and Leonard Rogers as proofs that professional merit did not pass unrecognized. He denied that the men now entering the service were not up to the former standard. He found that, taking the service as a whole, 71 per cent. of the officers possessed higher medical qualifications, whilst the average for lieutenants was 73.5 per cent., or 2.5 per cent. higher than the average for the service as a whole. That afforded clear proof that there was no falling off in the standard, and from his experience as Director-General he could vouch for the fact that it had many exceptionally brilliant men amongst its younger officers. The Indian Medical Service still offered a magnificent career to men of the right stamp. Changed conditions would undoubtedly arise and competition would be keener, but this need cause no alarm. One of the most remarkable developments of recent years had been the sanitary awakening of India, and when the medical needs of that vast country were remembered, the belief was justifiable that ample room would be found both for the Indian service, for the sister service, and for the independent medical practitioner. In conclusion, he proposed the health of the Secretary of State for India, expressing to him the thanks of the service for the sympathetic consideration he had shown in regard to all matters affecting either the general welfare of the service or personal interest of individual officers.

The Marquess of Crewe, in response, expressed his general agreement with the Director-General's view of

the prospects of the service and his deep sympathy with its work and aims. He referred to signs of the awakening of India to the meaning of sanitation, and to the great scope for work in the future which this opened up. He agreed that the large number of Indian gentlemen who were now entering the medical profession and making themselves thoroughly competent members of it must affect the Indian Medical Service, but he held strongly that there was room for both.

The following is a list of officers who attended the dinner, the number being unusually large :

Surgeon-Generals.—Sir A. M. Branfoot, K.C.I.E., Sir R. Havelock Charles, G.C.V.O., J. Cleghorn, C.S.I., J. P. Greany, G. Hay, Sir L. D. Spencer, K.C.B.

Colonels.—C. W. Carr-Calthrop, G. W. P. Dennys, D. French-Mullen, B. B. Grayfoot, G. F. A. Harris, P. Hehir, D. E. Hughes, C. C. Little, M. D. Moriarty, R. D. Murray, A. Porter, P. A. Weir.

Lieutenant-Colonels.—W. Alpin, J. Anderson, R. J. Baker, R. H. Castor, W. H. Cadge, J. T. Calvert, D. G. Crawford, P. J. Freyer, C. R. M. Green, H. Greany, E. A. W. Hall, J. Jackson, E. Jennings, E. R. Johnson, D. F. Keegan, M. A. Ker, D. P. MacDonald, W. Molesworth, T. R. Mulroney, W. H. Ogilvie, K. Prasad, W. G. Pridmore, J. J. Pratt, W. H. B. Robinson, W. H. Thornhill, D. Warliker, H. R. Woolbert, H. G. J. Wortabet.

Majors.—W. R. Battye, R. Bonstead, P. F. Chapman, S. R. Christophers, De V. Condon, A. T. Gage, A. A. Gibbs, C. M. Goodbody, E. Hutcheson, H. F. G. Hutchinson, J. H. Hugo, W. Lethbridge, E. A. C. Matthews, J. H. MacDonald, F. O. N. Mell, O. St. John Moses, C. R. Pearce, E. L. Perry, Sir R. Ross, K.C.B., F.R.S., S. A. Ruzzak, R. F. Standage, J. W. Watson, J. M. Woolley.

Captains.—F. F. Barnard, C. H. Barber, F. Powell Connor, W. T. Finlayson, C. A. Gill, D. P. Goll, D. L. Graham, J. B. D. Hunter, H. H. G. Knapp, J. L. Lunham, G. E. Malcolmson, E. Selby Phipson, R. D. Saigol, H. B. Steen, J. Taylor.

Lieutenant.—Bennet Hance.

NEW WARRANT.

A Warrant dated June 3rd, 1913, cancelling and replacing the Warrants of March 13th, 1908, and August 8th, 1911, has been issued. The following notes indicate the general substance of the several paragraphs :

1. Provides that substantive rank shall be as follows: Surgeon-General ranking as Major-General, Colonel, Lieutenant-Colonel, Major, Captain, Lieutenant; the Director-General, I.M.S., is to hold the substantive rank of Surgeon-General, but may rank as Lieutenant-General if approved by the Secretary of State.

2. An officer will not be permitted to remain in the service if at any time during the first three years from the date of his first commission his retention therein is, in the opinion of the Secretary of State, undesirable.

3. A Lieutenant is eligible for promotion to the rank of captain on completing three years' full pay service if he has previously passed the required examination and is in all other respects qualified and recommended. If an officer has not passed the prescribed examinations he may, if he has not had a reasonable opportunity of passing them, be provisionally promoted, subject to his passing the examinations when an opportunity is afforded.

4. A captain is eligible for promotion to major on completing nine years' full pay service in the rank of captain. The period may be reduced by six months if an officer produces satisfactory evidence of progress in any branch of knowledge likely to increase his efficiency. If a captain is prevented by the exigencies of service from obtaining an opportunity of qualifying for such accelerated promotion, the concession will remain open to him for four years after his promotion to the rank of major in the ordinary course, but any antedate granted will be without adjustment of pay.

5. A major is eligible for promotion to the rank of lieutenant-colonel on completing eight years' full-pay service in the rank of major, including any period covered by antedated promotion without adjustment of pay.

6. Time on half pay not exceeding one year will be reckoned as service for promotion under Articles 3, 4, and 5, if removal to half pay has been in consequence of medical unfitness caused by duty, military or civil.

7. For distinguished service in the field or for meritorious or distinguished service other than in the field a captain after six years' service and a major or a lieutenant-colonel may be promoted to the next higher rank by brevet.

8. A certain number of lieutenant-colonels may be specially selected for increased pay for ability and merit.

9. Promotion from the rank of lieutenant-colonel with increased pay to colonel and from colonel to surgeon-general will be given by selection for ability and merit.

10. A lieutenant-colonel may also be promoted to the rank of colonel, and a colonel to the rank of surgeon-general for distinguished service in the field. "In any case the officer shall remain supernumerary in the higher rank until the vacancy to which, in the ordinary course, he would have been promoted, or, in the case of an officer promoted to the rank of colonel, until selection for the rank of surgeon-general."

11. Exchanges between officers of the I.M.S. and the R.A.M.C., of the same rank and below that of major, and

transfers of officers below the rank of major may be permitted on conditions, one of which is that the officer transferred is placed for seniority below that of officers holding the same rank at the time of his transfer, and shall not be promoted until the officer next above him is promoted, or has been refused promotion.

12. Medical officers will be placed on the retired list at the following ages: Director-general 62, surgeon-general and colonel 60, lieutenant-colonel and major 55. A lieutenant-colonel who entered before April 1st, 1911, and who has been specially selected for increased pay if he attains the age of 55 before becoming entitled to the pension for thirty years' service, may be retained until the completion of such service, or in any special case an officer may be continued in employment.

13. An officer appointed after September 11th, 1890, who may retire on pension before completing thirty years' service, will be liable till he completes 55 years of age to be recalled to duty in case of emergency.

14. Six of the most meritorious officers of the Indian Medical Service on the active list shall be named honorary physicians and honorary surgeons to the King, and they shall relinquish such appointment on retirement. On appointment as honorary physician or honorary surgeon an officer under the rank of colonel may be promoted to the brevet rank of colonel.

VOLUNTARY AID DETACHMENTS.

HUNTINGDONSHIRE on May 12th was the scene of a sham fight to which special interest attached by reason of the co-operation of three Voluntary Aid Detachments; indeed, the work of the day was specially arranged to that end by Lieutenant-Colonel E. J. Cross, M.D., the officer commanding the Eastern Mounted Brigade Field Ambulance. Early in the morning a detachment of the 5th Bedfordshire Regiment carried out a sham fight against an invading force near Weston Wood, and incurred 75 casualties, small and great. News of a heavy engagement was then dispatched to a wagon and tent station established by the field ambulance mentioned, and meantime the men applied their first aid dressings themselves, each wounded man having a label attached to him descriptive of his injury. Soon after light wagon and stretcher parties from the field ambulance arrived, and collecting the wounded took them to the wagon station, where they were treated and classified. The tent hospital was then cleared for further work by handing over the patients to the Voluntary Aid Detachments which had established hospitals at three farms; and one of these hospitals was subsequently evacuated on receipt of information that the enemy was close at hand. Each of the Voluntary Aid Detachments turned out fully supplied with doctors, nurses, pharmacists, bearer squads, wagon drivers, and transport officers, and all members had an excellent opportunity of seeing exactly the sort of work they would have to do in actual warfare. The medical men engaged during the day were Lieutenant-Colonel E. J. Cross, Captain W. Archibald, and Lieutenant G. C. Kay Sharp, of the Eastern Mounted Brigade Field Ambulance; while Drs. Robinson, Harrison, and Williams were in medical charge of the Voluntary Aid Detachments.

Obituary.

JAMES HENRY TARGETT, M.S., F.R.C.S.,

OBSTETRIC SURGEON, GUY'S HOSPITAL.

It is with great regret that we have to announce the death of James Henry Targett, at the age of 51, after a long illness. He was born in Wiltshire, and went to school for two years at Warminster. Owing to delicate health his education was continued with a private tutor at Salisbury. This frailty of constitution attended him throughout, and for this reason, perhaps, the energies that most men devote in part to outside pursuits were by him spent entirely on subjects in connexion with his profession.

He entered Guy's Hospital as a student in October, 1878. He graduated M.B.Lond., with honours in forensic medicine in 1883, the B.S. with honours in 1885, and M.S. in 1887. He took the diploma of F.R.C.S. Eng. in 1886. He was appointed surgical registrar at Guy's Hospital in 1885, and held this post till 1887, when he became assistant curator to the museum. In 1889 he was appointed demonstrator of anatomy, and in 1895 demonstrator of surgical pathology and morbid histology. In 1897 he became obstetric registrar and tutor, and assistant obstetric physician the year following. In 1903, on the retirement of Dr. Galabin, he became obstetric physician, the title of the post being changed to that of obstetric surgeon when he became the senior in the department.

During the earlier years of his connexion with Guy's Hospital he was doing much work outside. All through his career he had a strong bent towards pathological anatomy, and in this subject he became deservedly a recognized authority. Following on his curatorship at

Guy's he was appointed pathological assistant to the Museum of the Royal College of Surgeons in January, 1888, Sir Frederic Eve being at that time curator. He succeeded to the post of curator in 1890, and held it till March, 1897. One who knew his work there speaks of him as an able and energetic curator, who added a large number of specimens to the collection, and by his tact made many people friends to the museum. As a writer of reports, whether clinical or pathological, he was probably unequalled. He wrote apparently with ease, and could at once and in the simplest terms give a clear picture in words of any specimen he had to describe. During this period of his work he contributed numerous papers to the *Transactions* of the Pathological Society, of which he was secretary in 1895 and 1896. He edited appendices to the catalogue of the Royal College of Surgeons, and gave the Erasmus Wilson Lectures on pathology in 1893 and the two years following. He was also holding appointments as assistant surgeon at the Evelina Hospital, and later as surgeon to out-patients at the Samaritan Free Hospital. We may gratefully recall that during this period of his career he gave his assistance to this JOURNAL, contributing many reviews on pathological subjects.

Following on these years devoted in the main to pathology, came the time when his energies were absorbed mainly in his clinical work as an obstetric surgeon. And here the interest in and devotion to his work that characterized him throughout earned for him before very long a recognized and honoured position. In 1910 and 1911 he was secretary to the Obstetrical Society.

His was a charming personality. Kind and gentle in disposition, he was as slow to take offence as he was incapable of giving it. No man had a more honourable and upright standard of life always before him. He never spared himself when work was concerned. His energy at times seemed feverish, and he probably wore out a system frail from the commencement. In 1911 he underwent an operation for appendical abscess, and his health no doubt suffered further from the sad loss of his only boy in that year. The illness which terminated fatally was of long duration. He was taken ill in September, 1912, and it was not till Tuesday, May 27th, 1913, that the end came.

J. LLOYD THOMAS,

DEPUTY SURGEON-GENERAL, R.N.

We have to record with regret the death of Deputy Surgeon-General John Lloyd Thomas; it took place at his residence, Penmon, in the Isle of Anglesey. During his services in China he contracted sprue, which not only rendered him unfit for active work for long periods during several years, but seriously undermined his constitution, and no doubt contributed to his untimely death.

John Lloyd Thomas was born on September 3rd, 1856; he received his medical education at the Middlesex Hospital and Queen's College, Birmingham, and was for a period obstetric house-surgeon to the Queen's Hospital in that city. He entered the Royal Navy Medical Service in February, 1884, and served first in the *Temeraire* on the Mediterranean station, and afterwards from 1887 to 1889 on the *Britannia* in the Home Fleet. In 1889 he went to the West Indies in the *Bellerophon*, and from May, 1891, to April, 1892, was at the Jamaica Hospital in special charge of yellow fever cases; and in 1893 he wrote a practical essay on yellow fever which received high commendation. In 1894 he went to China in the *Porpoise*, and in the following year attended the wounded Chinese soldiers and sailors at Chefoo during the China-Japanese war; his services were favourably noted, and he was promoted staff surgeon in 1896. After a term of service from 1897 to 1899 in the Royal Naval Barracks, Portsmouth, he went out again to China in the *Endymion* in 1899. In the following year he served with the second Peking Expedition, and the excellent health of the brigade was attributed in a large measure to the sanitary arrangements made under his supervision. He was specially promoted fleet surgeon for these services, and received also from the Emperor of China the Order of the Double Dragon, first division of the third class. He came home in 1902, already unfortunately suffering from the disabling disease which was to shorten his life. After a somewhat prolonged period of sick leave he so far recovered that, with the aid of his cheery temperament

and sanguine outlook on life, he was able to do a good deal of public work, serving on the Council of the British Medical Association as a representative of his service; acting as President of the Navy, Army, and Ambulance Section of the Annual Meeting of the Association in 1903, and representing the Admiralty at the meeting of the Association of Military Surgeons, U.S.A., in 1905. He served at the Royal Naval Barracks, Chatham, in 1906-1908, and for the two following years in the drill ships *Daedalus* and *Eagle*. He retired in September, 1911, with the honorary rank of Deputy Surgeon-General, and went to reside at Penmon, Anglesey, a county in which he had shortly before served the office of High Sheriff.

WE regret to record the death of Dr. CHARLES DALLEY NUTTALL, of St. Albans, on June 1st, after a long illness. Born in Leicester, and a member of a family connected for several generations with the profession of medicine, Dr. Nuttall was a student of St. Bartholomew's Hospital, and became M.R.C.S., L.R.C.P. in 1884. Subsequently he acted for a considerable period as clinical assistant at the City of London Hospital for Diseases of the Chest, and then settled in practice in his native town, where he was surgeon to the provident dispensary, and acquired a considerable practice. After some years he broke down in health and gave up work altogether for a time, but later on took up a practice of a lighter kind in St. Albans. The improvement in his health was, however, only temporary, and for the last three years he had done very little work. During his residence in Leicester Dr. Nuttall was a well-known figure in the hunting field, and when in good health frequently played an official part at athletic meetings in different parts of the country. As a young man he was an excellent performer on the running path, his best distance being the quarter mile, and it was largely due to his abilities in this direction that St. Bartholomew's became the holder of the Inter-Hospitals Challenge Cup in the early Eighties. Dr. Nuttall, who married the eldest daughter of the late Dr. J. St. Thomas Clarke, of Leicester, is survived by his wife, but left no children.

DR. LYTTELTON STEWART FORBES WINSLOW, who died on June 8th in his seventieth year, was a son of Dr. Forbes Winslow, who for a number of years was a leading authority on insanity. He was educated at Rugby and Cambridge, where he took the M.B. degree in 1870. He was also D.C.L. of Oxford and LL.D. of Cambridge. He appeared as an expert witness in many trials both in this country and in America, and wrote a number of articles on subjects connected with his province of practice. In 1910 he published an autobiographical volume entitled *Recollections of Forty Years*, which was reviewed in the BRITISH MEDICAL JOURNAL of July 8th, 1911 (p. 76). His opinion on any case that happened to interest the public was apparently highly valued by some newspapers, but with his own profession it carried less weight. Dr. Forbes Winslow, who was twice married, leaves a widow and three sons and a daughter.

News has been received in England of the sudden death at sea in the Far East of Dr. O. E. HIGGINS, of Earl's Court, S.W. Dr. Higgins, who entered the medical profession somewhat late in life, was a student at St. Mary's Hospital; he took the diplomas of M.R.C.S., L.R.C.P. in 1889, and graduated M.B. Durh. in the following year. Before entering the medical school he had been at Cambridge, where he was a scholar of Emmanuel College, and achieved first-class honours in the classical tripos of 1880. After filling at the hospital a number of resident appointments, he established himself in Holloway and practised there until some two years ago, when he moved to Earl's Court. His death, which took place in the 58th year of his age, was due to cerebral haemorrhage.

AT the recent examination for sanitary inspectors under the Public Health (London) Act, 1891, held by the Sanitary Inspectors Examination Board, twenty-one candidates, of whom twelve were women, passed.

A BILL restricting the sale and dispensing of cocaine and encaine, their salts and preparations, has passed the New York State Legislature, and has been signed by the Governor. It is to come into effect immediately.

Medical News.

THE Royal Society of Arts has issued invitations to a conversazione at the Natural History Museum, Cromwell Road, S.W., on the evening of Tuesday, June 17th.

THE usual ladies' conversazione of the Royal Society was given on Wednesday evening last. Most of the objects had been shown at the first conversazione, but on this occasion the Antarctic drawings of the late Dr. Edward A. Wilson lent by his widow were displayed.

AN invention by Alderman John Whitaker now being tested at Rishton, near Blackburn, will, it is hoped, among other advantages, dispense with "shuttle kissing," a practice which, however small may be the danger of infection attached to it, is at best a dirty process.

THE annual luncheon of the Continental Anglo-American Medical Society, which is usually held during the annual meeting of the British Medical Association, will be held this year in London on August 7th during the meeting of the International Medical Congress.

MR. ARNOLD JAMES, who has been on the staff of the Metropolitan Hospital Sunday Fund for some years, has been selected by its General Purposes Committee to succeed the late Sir Edmund Hay Currie in the office of secretary.

THE Harben lectures of the Royal Institute of Public Health will be delivered by Professor J. Bordet of Brussels, at 37, Russell Square, W.C., on June 16th, 18th, and 20th, at 5 p.m. The first lecture will deal with anaphylaxis, the second with coagulation of the blood, and the third with microbial variability in relation to sero-diagnosis.

IN a paper in the *Journal of the American Medical Association*, Detwiler, of Omaha, states that he has repeated the experiments of E. H. Ross with the jelly method and has examined scrapings from chancres, the peripheral blood and fluid squeezed from punctured lymph-nodes of syphilitic patients, and has found the parasites and followed most of the phases described by Ross.

WE understand that there has been no fresh cases of cerebro-spinal meningitis at Westerham or in Kent. Dr. Tew, M.O.H. for West Kent, has reported the death of one of the patients at Westerham—a boy aged 11. The schools have been closed and disinfected, and certain books and articles used there destroyed. Complete arrangements have been made to deal with any future cases should they arise.

FRESH accommodation for the nurses is projected at the West London Hospital; they are at present scattered in several houses and rather crowded therein. The late Duke of Abercorn, who was for long the president of the hospital and very anxious to see the nursing staff properly housed, started an appeal fund for this purpose, and in view of these facts and as a tribute to his services, it is proposed to call the building, when erected, the Abercorn Home for Nurses. So far, only about a quarter of the £12,000 deemed to be necessary has been got together, and contributions, however small, will be gratefully received by the Chairman of the Abercorn Memorial Executive Committee, Lord Arthur Hill.

THE different di-electric capacities of Purbeck sand, chalk, and stone were demonstrated by Dr. Mahomed of Bournemouth, by means of an apparatus constructed by him, at a meeting of the Balneological and Climatological Section of the Royal Society of Medicine in that town on May 31st. Dr. Mahomed assumed that negative ions were given off by metals in a glowing state in the undercrust of the earth, and hence surmised that the di-electric properties of the earth would cause an induced positive charge in the atmosphere. He also showed some charts illustrative of the varying potential exhibited when electric currents passed from gravel and sand to chalk, and vice versa.

A CONVERSAZIONE was given at the Royal College of Surgeons of England by Sir Rickman and Lady Godlee on the evening of June 5th, and proved a great success. The theatre from 9.30 onwards was the scene of four successive exhibitions of the cinematographic pictures of big game in Africa, obtained by Mr. Kearton, and in the council room sundry historical specimens, the Hunterian manuscripts, and other objects of lay as well as professional interest were on view. In the conservator's room Dr. Keith provided a demonstration of microscopic specimens and of relics of prehistoric man; and in Room I of the museum Mr. Burne had on view a number of natural history specimens, while in Room III Mr. Shattock provided a corresponding collection of pathological specimens. Meanwhile, and throughout the evening, the Greenhill

String Quartette discoursed sweet music, and refreshments were served in the library.

PENSIONS for its members and associate members have been provided by the governing boards of the Rockefeller Institute for Medical Research, New York, and have been financially secured by the generosity of Mr. John D. Rockefeller, who has for this purpose increased the endowment of the institute by a gift to it of securities amounting to about 500,000 dols. in value. The pension rules which have been adopted provide three-quarters pay pensions for members of the institute retiring at the age of 65 after fifteen or more years of service, and pensions of from one-half to three-quarters of full pay, according to the length of service, for members and associate members who retire at 60 years of age. There is also a provision for total disability after ten years of service, and for widows and orphaned children, at one-half the scale upon which members of the staff are pensioned.

THE fourth annual congress of the British Hospitals Association is to be held at Oxford in the last week of this month. It will be opened at 10 a.m. on June 26th by an address from the president of the congress, Sir William Osler, and a discussion on the National Insurance Act and its effect on the hospitals, with a view to the proposed amendment of the Act, will follow. In the afternoon of the same day a discussion on tuberculosis and the general hospitals will be introduced by an address from Sir Thomas Oliver, while on the next day (June 27th) a debate on the upkeep of hospitals will follow the reading of a paper on the subject by Mr. Keith Young, F.R.I.B.A. By permission of the Vice-Chancellor of the University the meetings will take place in the Examination Schools. In connexion with the conference a series of visits to places of interest has been arranged for Friday afternoon and Saturday. The business meeting of the association and the election of officers will take place on Friday. The present chairman is Dr. D. J. MacKintosh, of the Western Infirmary, Glasgow, and the secretaries are Messrs. Conrad Thies and A. Hayes, whose official address is 14, Victoria Street, Westminster.

THE dinner of the Durham University Medical Graduates' Association, which took place under the chairmanship of the President of the Association, Dr. Edridge-Green, on May 30th, brought together a large gathering, the guests including the Vice-Chancellor of the University (Sir George Hare Philipson), the Directors-General of both the Royal Naval and Army Medical Services, and the President of the Royal Society of Medicine (Sir Francis Champneys). Professor E. H. Starling, who proposed the toast to the chairman, referred to Dr. Edridge-Green's valuable and assiduous work in connexion with the subject of colour blindness, a work which still awaited adequate recognition. In acknowledging the toast, Dr. Edridge-Green mentioned that it was from Professor Starling himself that he had received much of the encouragement and support that he required at a time when he was in despair as to the progress of his crusade. In response to the toast to the services, Surgeon-General A. W. May, C.B., Director-General R.N., drew attention to the dearth of candidates for his department, and asked those in touch with newly qualified men to use their influence in obtaining for it recruits. The speeches during the evening were pleasantly interspersed with songs supplied by a number of professional singers.

THE Medico-Chirurgical Society of Bradford, which has now been fifty years in existence, duly celebrated its foundation by holding its annual dinner on the anniversary date, May 28th. There are now only two survivors of the original members, but both of these, Dr. David Goyder and Dr. Harry Meade, were able to be present. The former acknowledged the toast to the society, and gave some account of its earlier history; it had much scientific work standing to its credit, but was perhaps chiefly renowned, he said, in connexion with anthrax, a subject early associated with the name of one of the society's members, the late Dr. J. H. Bell, and at the present time with that of its existing President, Dr. F. W. Eurich. Dr. Goyder, who was for many years a representative of the Yorkshire Branch on the Central Council of the British Medical Association, and not long ago received the well-merited honour of being elected to the position of permanent Vice-President of the Yorkshire Branch of the Association, acted as Honorary Secretary of the Bradford Medico-Chirurgical Society for as long as twenty-five years; he became M.D.St.And. and L.R.C.S. in 1860, this being likewise the year in which Dr. Meade—also a member of the British Medical Association—became M.R.C.S., L.S.A. Both are on the staff of the Bradford Royal Infirmary, the former as consulting physician, the latter as consulting surgeon.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National).—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2650, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

A. W., who has employed male fern in the treatment of *Taenia solium* without success, after careful preparation of the patient, asks for further advice.

AMOEBIÆ HAEMATURIA.

W. (Transvaal) writes: During 1912 amoebic dysentery carried off an enormous number of Kafir children. We have it every year, but never so bad in my seventeen years' experience of the Cape native territories. Usually, when the rains set in, the dysentery becomes less frequent, and this year we had no proper rain till the summer was over. While the epidemic was at its height I saw two adult natives who had haematuria with some pain on micturition; though that is unusual, I expected to find bitharzia ova, and instead I found amoebae. The urine was strongly acid, like the faeces in dysentery. Has amoebic haematuria been noted elsewhere?

DOUBLE CHIN.

JUNO asks for advice in the treatment of a double chin in a young lady not otherwise obese.

We are advised that on general principles, unless the double chin is very unsightly, it is better to leave it alone. Gentle massage night and morning with soft grease and firm pressure with a bandage might be of some service, but the treatment should be carefully watched so that the tone of the parts is not diminished.

INCOME TAX.

E. M. H. asks what sums should be deducted in making his income-tax return (1) for the cost of purchase of a new motor car, and (2) the expense of having his old car (which he is still keeping) put in repair.

So long as "E. M. H." retains his old car for professional purposes the purchase of a second car is, strictly interpreted, an investment of further capital in his practice, and therefore no portion of the cost of the new car can properly be deducted. On the other hand, the amount spent on putting the old car in repair is a legitimate deduction in arriving at the "balance of profits and gains" of his practice.

ANSWERS.

F. C. W.—A *First German Course for Science Students*, comprising a reader and outline of grammar with diagrams and vocabulary, by H. G. Fiedler, Professor of German in the University of Birmingham, and F. E. Sandbach, Lecturer in German at the University of Birmingham (Alexander Moring, Limited, the De La More Press, 32, George Street, Hanover Square, London, W., 1906); or *German Grammar for Science Students*, by W. A. Osborne, M.B., D.Sc., Professor of Physiology and Histology in the University of Melbourne, and Ethel E. Osborne, M.Sc. (Whittaker and Co., 2, White Hart Street, Paternoster Square, London, E.C., 1906), would probably fulfil our correspondent's requirements as a guide in teaching himself to read scientific articles.

LETTERS, NOTES, ETC.

FRACTURE OF CERVICAL VERTEBRA BY MUSCULAR ACTION.
DR. A. A. ANGELIS (Walworth) sends us the following note with regard to the death of a young man found dead in a swimming bath: Although I attended immediately the body was discovered and made a careful examination of all the surroundings I could not find any marks of external violence or any signs indicating that the man struck the concrete of the bath. On post-mortem examination I found a fracture of the body and arch of the fourth vertebra (cervical), and on giving evidence at the inquest I expressed the opinion that in the absence of any other cause to account for the broken neck the only explanation, although very uncommon, might be a sudden retraction of the head to avert collision with the bottom on jumping into the water. Such cases are recorded in South's edition of *Chelius's Surgery*.

TREATMENT OF WHOOPING-COUGH.

M.R.C.S., who in the JOURNAL of October 19th, 1912, recommended potassium bicarbonate in the treatment of whooping-cough, informs us that he has received a letter from a reader who then tried the method stating that it proved beneficial in the case of his own daughter.

SCARCITY OF SHIP SURGEONS.

Pegasus writes: In addition to the reasons mentioned by "Late Ship Surgeon" as a cause of the difficulty steamship companies experience in obtaining suitable surgeons, perhaps the enclosed letter, which was handed to me on joining the ship, may furnish additional explanation. My feelings on receipt of it were to leave the ship forthwith. I have acted as ship surgeon on various lines, but never previously received such an insulting letter from the owners.

The letter, which is addressed "The Doctor, S.S. _____, London," is couched in the following terms—the italics are in the original letter:

"Dear Sir,
"You are employed on board this steamer as medical adviser to the crew and passengers from the time she leaves here until her return to this port.

"Your specific duty, among others, is to give all possible professional attention to the crew as well as passengers, so please see this is done. Should the Master find it necessary to report neglect on your part in this respect, we shall have to treat the matter seriously and in a form that will be as disagreeable to you as to ourselves.

"Yours faithfully,
"_____,"

MASONIC RECEPTION AT BRIGHTON.

DR. C. H. BENHAM, J.W., 1466 (14, North Street, Brighton), writes: May I, as one of the Wardens of the Hova Ecclesia Lodge, take the liberty of correcting the paragraph on p. 1231 of your issue of June 7th? This paragraph was written by one who is not a member of the craft, and the invitation should be worded as follows: "The Worshipful Master and Wardens of the Hova Ecclesia Lodge, No. 1466, extend a cordial invitation," etc. May I take this opportunity of reminding all Brethren who intend to be present that an early reply will greatly lighten the labours of those who are arranging for this reception? This may be sent to me at the address which appears above. We hope to have a hearty response.

STATUES OF JENNER.

DR. CLIPPINGDALE (London) writes: In the article in last week's JOURNAL dealing with the excursions at the forthcoming meeting at Brighton it is stated (p. 1231) that the statue of Jenner at Boulogne is "by the irony of fate, the only one in the world." Things are not as bad as this. The Japanese, who are devoted admirers of Jenner, have erected a statue to his memory at Tokio; there is another statue in Berlin, another in Brünn (Austria), another in Gloucester Cathedral, and another in Kensington Gardens. The statue in Kensington Gardens afforded an illustration of the prophet being without honour in his own country during the Jenner celebrations a few years ago. Having read in the paper that on a certain day the Medical Faculty in Berlin would proceed to the Jenner statue in that city and lay upon it a wreath of laurel, I went to Kensington Gardens to see if the statue there was similarly honoured. I found, however, only a group of children playing near it, eating oranges and depositing upon the pedestal bits of discarded orange peel.

A DISCLAIMER.

DR. HUGH T. ASHBY (Manchester) writes: An article appeared in a local daily paper on June 2nd on Child Welfare and Adenoids with my name attached to it. May I be allowed to make it quite clear that the article was not written by me and that my name was put in quite unauthorized?

STANDARD OF PRELIMINARY EXAMINATIONS: A CORRECTION.
SIR HENRY MORRIS has drawn our attention to a printer's error in his article on the General Medical Council and the proposed alteration in the standard of preliminary examinations (BRITISH MEDICAL JOURNAL, June 7th, p. 1217). Line 12 of the article should read: "average yearly number of the five preceding years," and not as printed.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|--------|
| Eight lines and under | ... | ... | 0 4 0 |
| Each additional line | ... | ... | 0 0 6 |
| A whole column | ... | ... | 2 13 4 |
| A page | ... | ... | 8 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restante* letters addressed either in initials or numbers.

The Ingleby Lecture

ON

SPINAL ANAESTHESIA BY TROPACOCAINE;

WITH A REVIEW OF 1,295 CASES.

DELIVERED AT THE UNIVERSITY OF BIRMINGHAM.

By J. T. J. MORRISON, M.A.CANTAB., M.Sc.BIRM.,
F.R.C.S.ENG.,

SENIOR SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM, AND
PROFESSOR OF FORENSIC MEDICINE IN THE UNIVERSITY.

In the first place I offer my acknowledgements to the Council of the University for assigning to me the honourable duty of delivering this lecture. The roll of the Ingleby Trust includes the names of many distinguished men with whom it is a privilege to be associated. At the same time, I do not forget that the worth of their lectures as a permanent asset to medical literature increases the responsibility resting upon their successors.

And next a tribute is due to the memory of John Tomlinson Ingleby. By his talents and character he gained distinction among his contemporaries as an obstetric physician and teacher. The lectureship was founded in 1876—thirty-one years after his death—to promote the diffusion of medical knowledge, and to link with this purpose the name of a bygone worthy who did much in his generation to build up the reputation of the Birmingham Medical School.

Since Ingleby's day the field of medicine has broadened in all directions in correspondence with the introduction of modern tools and methods from the loom of scientific progress. In particular, the quest for better means of annulling pain during surgical operations has been keen and incessant, with the outcome that there is now at the service of surgery a wide latitude both in regard to drugs and their mode of application. A generation ago an operator had to choose between the suspension of consciousness by narcotics and the numbing of skin by means of ice and salt or ether spray. The arrival of local anaesthetics, together with the experimental study of their properties, marks a new period, and must be reckoned one of the notable medical events in the first decade of the twentieth century.

From the standpoint of minimal disturbance of the nervous system it is an immense gain if surgical procedures can be carried through without functional impairment of the highest centres, and with no derangement, or at most a transient one, of the normal physiology of the medullary centres. On theoretical grounds, therefore, given various methods of inducing surgical anaesthesia, including one which acts selectively on peripheral nerves while exempting the functions of the brain from harmful interference, that method is to be preferred; and it is now a daily commonplace of the operation theatre that the achievement of this result, notwithstanding surgical manipulations of the greatest severity, is practicable by means of a single needle puncture and the injection of a few drops of fluid into the spinal sac.

A procedure of such extraordinary simplicity and efficacy deserves more attentive study and wider adoption than it has yet received in this country, and if this does not appear from what I proceed to say on various aspects of the subject, I shall do less than justice to a convincing array of facts and considerations.

HISTORY.

For the introduction of spinal anaesthesia surgery owes a debt to the chemists and experimental pharmacologists who investigated the properties of the coca plant. *Erythroxylon* (that is red-wood) *coca* is indigenous in South America, where for centuries the leaf has had a vogue with the natives because of its supposed power to ward off the onset of fatigue during prolonged exertion. The alkaloid cocaine was described under that name in 1859 by Niemann, whose report mentioned the numb sensation produced by the drug on the tongue. Several years earlier the alkaloid had been isolated by Gadecke, the

actual but now almost forgotten discoverer, and by him named "erythroxyline." Scant attention was paid to the subject until, in 1879, von Aurep carried out a research on the sensory effects of cocaine on the skin. His observations led him to suggest the use of the drug as a local therapeutic agent in man, and although the suggestion was not at once followed up, his experimental work became fairly well known.

The year 1834 is of special note because it dates the famous discovery of the action of cocaine on mucous membranes. The credit of this advance belongs to Köller, at that time a medical student in Vienna. Having tested the action of cocaine on his tongue, Köller reasoned that a similar anaesthesia, innocuous to the tissues, would be likely to result from the application of the drug to the conjunctiva. He put his ingenious idea to the proof, published his findings, and inaugurated a revolution in ophthalmic surgery. Not content with this conquest he proceeded to deal with the laryngeal and other mucous membranes on the same lines. (One may recall in passing another important discovery made by a medical student, namely, the vaso-dilator action of amyl nitrite, which was described by Lauder Brunton when he was an undergraduate in Edinburgh.) From 1834 cocaine ceased to be a mere therapeutic curiosity; it became an invaluable agent pressed into the world-wide service of medicine.

The logical extension of the use of the alkaloid as a local anaesthetic soon followed, American surgeons leading the way. Halsted seems to have been the first to inject a solution along the course of sensory nerves; he operated on a case of talipes by this means in 1834. W. O. Moore described in the *New York Medical Journal* of January, 1885, the effects of auto-injection into his arm. Within a period of eight hours he injected at intervals no less than $3\frac{1}{2}$ grains of cocaine, and on regaining consciousness he says, "I might have exclaimed with Cowper, 'I awoke, like a toad out of Acheron, covered with the ooze and slime of melancholy.'" Which is a less cause of wonder than his survival to tell the tale. He concludes that amputation would be feasible by injecting over the site of the nerves supplying an extremity.

The pioneer of spinal cocainization was Leonard Corning of New York. He conceived the idea of acting on the cord by injecting directly on to the dural sheath, and published an article in October, 1885, on spinal anaesthesia and local medication of the cord by "a procedure in therapy which possesses the merit of novelty." Following up an instructive experiment on a dog, he operated on a neurasthenic patient, his purpose being to annul sensory conduction in the cord. Through the eleventh dorsal space he injected 30 minims of a 3 per cent. solution of cocaine hydrochlorate. As there was no tingling in six minutes (no doubt because the injection was not deep enough), the dose was repeated. This produced impaired sensation in the lumbar regions, lower limbs, penis, and scrotum; motor power remaining unaffected. The passage of a sound was scarcely perceived, whereas it previously caused much pain. Corning adds, "When the patient left my office an hour or more after the injections, sensibility was still impaired to a marked degree, and the patellar tendon reflexes were abolished." Headache and vertigo were complained of the next day. He suggests that such local medication might be useful in strychnine poisoning, tetanus, and hydrophobia; and concludes with the cautious remark, "Whether the method will ever find an application as a substitute for etherization in genito-urinary surgery, further experience alone can show."

Corning thus laid the foundation of the modern procedure. Holding the view that a drug inserted locally acted on the nerves of the part only by way of the blood vessels, he was content to place his solution in contact with the venous plexuses, and it would appear that in the case cited he did not puncture the cerebro-spinal sac. His example was not widely copied, perhaps because cocaine was soon found to be too dangerous a drug for indiscriminate use, or in doses exceeding half a grain. Meanwhile, as surgeons became familiar with lumbar puncture (introduced by Quincke in 1891), further possibilities were indicated, and in 1898 Bier introduced the present method of injection into the subarachnoid space. From observations on lower animals he proceeded to note the effects on man, and his assistant, Hildebrand, and

himself submitted themselves and six patients to the operation. Cocaine was the drug used, and complete analgesia of the lower half of the body was readily induced in every case, while in one patient the effect reached to the scalp. The by-effects, however, were most unpleasant, in the form of vomiting, giddiness, and severe headache. Hildebrand suffered from these symptoms, although just after the injection he was able to dine well and smoke several cigars. Bier thought the troubles were due to escape of cerebro-spinal fluid, and that rest in bed would prevent them; but experience failed to confirm his opinion. On the strength of his observations Bier was convinced that cocaine was too forbidding an agent, and, pending the discovery of a less toxic substance, he dropped the procedure. Bier's work cannot be too highly praised.

Touffer of Paris continued using cocaine, and in 1900 he reported to the Academy of Medicine a series of over eighty cases in which he had injected cocaine through the third or fourth lumbar space and induced anaesthesia as high as the umbilicus. So satisfied was he with the results that he announced his intention to aim at a higher level of anaesthesia with a view to operations on the liver, stomach, and thorax.

Robert Jones was the first British surgeon to publish his results. In 1904 he read a paper at Liverpool on spinal cocainization, relating cases and advocating the method for suitable operations.

The discovery of stovaine by Fourneau, and the exposition of its properties by Pouchet in 1904, attracted wide attention and gave a fresh impetus to the subject. Prior to this, in 1891, Giesel had isolated the new alkaloid tropacocaine, naming it benzoyl-pseudotropine. In 1892 it was tested physiologically by Chadbourne, who named it tropacocaine and reported that it was less than half as toxic as cocaine, and much weaker in its action on motor functions. Led by the advocacy of Schwartz several German surgeons tested the drug, with favourable results. This alkaloid has been much used in Germany, but in France and Britain stovaine has been more in evidence, and its use has been strongly advocated by Barker, McGavin, Gray, and others who have given it extensive trial. Novocain was discovered by Einhorn in 1904; it has been employed with great success by Canny Ryall. The present lecture is a further contribution to the possibilities of tropacocaine based on several years' experience.

Barker has done more than any other surgeon in this country to bring spinal anaesthesia to the notice of the profession and advance our knowledge of the subject. He uses a compound solution composed of stovaine 5 parts, glucose 5 parts, and distilled water 90 parts, all by weight. Having a specific gravity of 1.023 as against that of cerebro-spinal fluid which is 1.007, it sinks on injection to a level which can be regulated by adjustment of the patient's spine.

Gray has written valuable and suggestive papers. He substitutes dextrin for glucose, and claims that it is superior in respect of its indiffusibility.

Babeock of Philadelphia recommends a solution made lighter than cerebro-spinal fluid by the addition of alcohol.

PHARMACOLOGY.

As cocaine was the first substance introduced for spinal anaesthesia it remains the standard by which recent drugs are compared as to their toxic and anaesthetic properties. The list of substitutes includes tropacocaine, stovaine, novocain, and alypin. Of these, tropacocaine, like cocaine, is a vegetable alkaloid, all the others being synthetic compounds, and tropacocaine can also be built up artificially. The radicle benzoyl is common to them all except stovaine, which is a benzoate. Both the alkaloids are contained in coca leaves; but it is remarkable that the plant grown in Java, where it is not indigenous, yields a larger percentage of tropacocaine than the Peruvian plant, which fact explains why the commercial alkaloid is obtained from the Javanese leaf.

Each of the five substances named is freely soluble in water, and the solution can be sterilized at 115° C., except that of cocaine which decomposes on boiling. Stovaine will not stand sterilization by exposure to a high temperature as well as its allies, but its antiseptic nature compensates for this drawback. They are all protoplasmic

poisons. Le Brocq estimates their relative toxicity as follows:

Taking cocaine as represented by 1—then alypin is 1.25, stovaine 0.625, tropacocaine 0.5, and novocain 0.49.

Injected into the tissues they have a selective action on nerve fibres, especially centripetal conductors, whereby the function of these is suspended, and a temporary block interposed between the centre and the periphery. In this respect the power of cocaine is surpassed by stovaine, and equalled by each of the other drugs. The bias of selection goes beyond a preference for inhibiting nerves rather than other structures, and sensory rather than motor fibres. It is much more discriminating, inasmuch as it does not stop all the composite functions of an afferent nerve simultaneously or to the same degree; so that the epieritic, protopathic, and deep sensibilities are variously affected. Taking tropacocaine as a type, we find that it subdues the perception of pain before stopping the sensations of touch, temperature, pressure, and position. Hence some clinicians prefer to describe the result as a condition of analgesia: this description is too restricted, and it is unnecessary to drop the term "spinal anaesthesia" originally proposed by Corning. When the action is complete the patient is not conscious of having any part of the body below the ribs.

For clinical purposes the list of agents has been narrowed down to three—stovaine, tropacocaine, and novocain. The aqueous solution of stovaine gives an acid reaction, and is easily rendered inert by a trace of alkali; some of the reported failures of stovaine to produce anaesthesia have been accounted for by the fact that the solution was stored in ampoules of glass containing soluble soda. In a 5 per cent. solution it has a haemolytic action, causing the red corpuscles to swell and break up. Tropacocaine gives a neutral solution in water, and is less irritating to the tissues than stovaine; it is also said to have less inhibitory power over motor nerves. Novocain is a very similar substance: its anodyne effect seems to be more fleeting, but against this can be offset its virtue as a non-irritant to the tissues in the strength ordinarily employed. This property gives novocain pre-eminence as a local anaesthetic.

TECHNIQUE.

The spinal anaesthetist should think surgically and wear gloves. He is doing a piece of work that is simple enough, but demanding strict cleanliness of skin and apparatus, and my practice is to make the puncture myself. For the patient's back a coat of iodine solution is sufficient.

The instruments should be reserved strictly for the sole purpose of spinal anaesthesia. I use a Record syringe, which is easily sterilized, and steel needles made to my design by Down Brothers. The point is short and sharp, and the stem opens funnelwise into the base, so that the steel wire stylet can be promptly slipped into the canal. Everyone knows the difficulty of inserting a wire into a shouldered hollow needle except from the pointed end. Delay caused by boggling attempts to clear the eye of the needle when *in situ* should be specially avoided in the case of nervous patients. The needles vary in length from 6.5 cm. to 8 cm., and in diameter from 16 to 18 standard wire gauge. A needle must be discarded if it becomes brittle from repeated rusting, or it may break when being inserted, an accident which has happened in my hands: the piece was promptly extracted, and no ill result followed.

Tropacocaine in the form of a solution of the natural alkaloid can be obtained from the manufacturing chemist in glass ampoules. My earliest supplies came from a German firm, but the quantity did not always accord with the label, nor was the strength of the solution apparently uniform. Lately I have been supplied with a reliable preparation by Allen and Hanburys. Each ampoule contains 1.5 c.cm. (say 25 minims) of a 5 per cent. neutral solution in normal saline, having a specific gravity of 1.016, and freezing at -1.13° C.

The dose is graded according to the patient's weight, allowance being also made for the modifying factors of age, state of health, and the desired level of anaesthesia. A dose of 1 grain of tropacocaine—that is, 20 minims of the 5 per cent. solution—is suitable for a healthy person weighing about 11 st. The maximum single dose I have given is 24 minims. For a child 1 year old 4 minims

would be enough. Debility and old age are indications for decreasing the quantity injected, and in such conditions I never leave more than 1 c.cm. in the syringe—that is, 17 minims—and since 2 minims remain in the needle, 15 minims is the maximum quantity injected, representing $\frac{3}{4}$ grain, or about 5 cg. After the lapse of forty or fifty minutes, if sensation is returning before the operation is finished, I give a second injection of 8 to 12 minims; alternatively—and as a rule this is the more convenient course when a very few minutes are needed—the last stage of the operation is done with the aid of a general anaesthetic, and it is impressive to see what a surprisingly small amount will suffice, deep narcosis being quite unnecessary.

The patient may be seated or lie on either side, but in the sitting position the puncture is more conveniently made and the needle less likely to stray from the right path. When well enough he sits on the side of the table with his feet on a chair, and leans well forward to round the back and separate the spinous processes; and with elbows on thighs he rests his head on his hands. In cases of serious abdominal disease or of great debility the lateral posture is always necessary, and must also be adopted if a second, and smaller, injection has to be given before the operation is finished. The back is curled into an arch by approximating the chin to the knees, and whenever this is impossible, owing to abdominal distension or other cause, any twist of the spine should be carefully noted and allowed for on insertion of the needle. By attention to this detail a puncture can always be made unless there is unusual deformity.

With regard to the site of puncture, the place of election is the second lumbar interspinous space. Here the needle enters below the spinal cord between the divisions of the cauda equina, and the interval between the spines is well marked; but the third space is almost equally accessible, and I often choose it. A valuable guide in counting the lumbar spaces is a line drawn across the back from the highest point of one iliac crest to the other; this line touches the fourth lumbar spinous process. A successful injection at the site mentioned produces anaesthesia of the lower limbs and trunk as high as the umbilicus, and by raising the pelvis on a sandbag sensation is lost up to the nipple line. For operations on the upper abdomen and kidney I inject through the tenth or eleventh dorsal interspace for choice, and although I have on several occasions gone as high as the ninth, I have come to the conclusion that the tenth dorsal space marks the highest limit beyond which it is not prudent to apply the procedure.

The needle, armed with stylet, is inserted in the middle line, just above the lower spine of the selected space, and is pushed steadily in the sagittal plane to a depth varying in adults from 4 cm. to 8 cm. From infancy to adolescence the distance of the dura from the skin varies between 1 cm. and 4 cm. In the lumbar region the track of the needle is almost perpendicular to the surface, with a slight inclination upwards, the angle between the needle and the skin being about 80°. In the dorsal region the upward deviation increases conformably to the overlapping of the spinous processes. If the point of the needle encounters bone in its path to the theca it must be partially withdrawn and then pushed home in a slightly altered direction. In rare instances it may be necessary to explore another space before entry is effected; most exceptionally the attempt may have to be abandoned, owing to crookedness of the column, unusual bony formation (as in osteo-arthritis), or extreme fatness of the patient preventing definition of the spines. Beneath the skin some resistance will be felt when piercing the supraspinous and interspinous ligaments, and to a less degree at the dura mater; the former may be so hard as to render a lateral puncture preferable, but the needle is then more likely to prick a nerve within the theca.

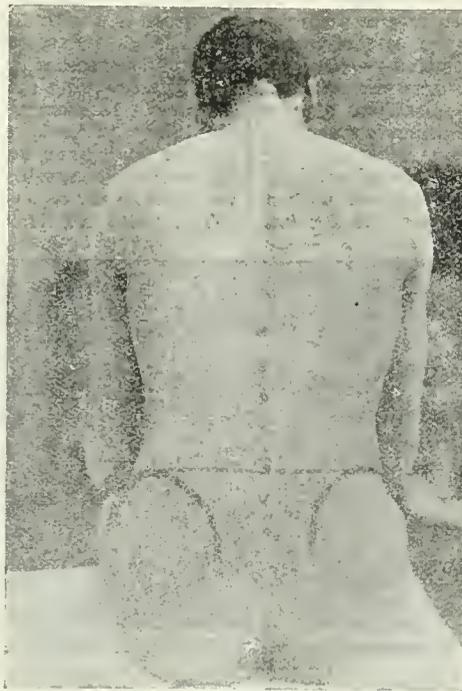

Fig. 1.—Showing the line which defines the fourth lumbar spine.

The act of piercing the dura mater is perceived by the sudden loss of resistance.

Assuming a satisfactory puncture into the subarachnoid space, on withdrawing the stylet cerebro-spinal fluid at once flows out in drops or in a jet which intermits with the respiratory movements.

Above the first lumbar space the stylet must be withdrawn as soon as the ligaments are pierced, and the needle then pushed cautiously through the dura mater. A scanty tapping may be due to one of several causes:

1. Low tension of the sac.
2. Occlusion of the eye of the needle by a fragment of tissue picked up *en route* or by a nerve within the sac.
3. Incomplete puncture of the theca, so that the eye is not entirely within the sac.
4. Perforation of the space, so that the needle's point is up against the posterior common ligament and the eye partly outside the sac.

One or other of the following means will generally succeed in increasing the flow: Making the patient cough, rotating the needle, inserting the stylet to clear the eye, varying the depth of puncture, aspirating with a syringe. In this connexion the observations of Lusk are pertinent. In several dissections he found the arachnoid and cord adherent posteriorly, so that the subarachnoid sac could only be reached by perforating the cord. Below the cord similar adhesions were found in some cases between the arachnoid and nerve bundles of the cauda equina.

Fig. 2.—Position of choice, with the patient sitting up. The injection is being made in the middle line through the second lumbar interspinous space.

Abnormalities of the sac undoubtedly occur and may prevent easy access to the cerebro-spinal fluid. If only blood escapes, the needle should be withdrawn and another space punctured.

A free outflow of cerebro-spinal fluid is ideal, for it proves that the needle is so placed as to ensure delivery of the full dose of anaesthetic into the subarachnoid space. Injection of a portion of the solution outside the theca explains most cases of imperfect anaesthesia, and must be guarded against by correct insertion of the needle and avoidance of displacement when connecting the syringe.

I collect and throw away 1 to 2 drachms of cerebro-spinal fluid, and attaching the syringe charged with a suitable dose from an ampoule, I draw, if possible, 2 c.cm. into the barrel to warm the dose; the mixture is then slowly injected. Stoppage of the flow when aspirating implies that a nerve filament has been drawn into the eye of the needle, and without further ado the injection is made, although little or no fluid has run into the syringe. As a rule it is not advisable to inject unless there has been a free escape of cerebro-spinal fluid; but the rule is not absolute, and exceptionally I have found it better to wait and see the result of injection before making a second puncture. Care must be taken not to disconnect the syringe before removing the needle. On removal of the needle the spot is sealed with collodion.

My object in abstracting fluid is to delay absorption by reducing the tension of the sac. Perhaps, too, hypertension due to irritation of the sac is not so likely to occur, and thereby the tendency to headache is diminished.

The patient, lying recumbent and with his hands resting on his head, is next brought into the theatre; and the field of operation is hidden from him by a towel hung upon a wire frame stretched above his chest. Over this the surgeon can glance at will to observe the patient's face.

PHENOMENA OF SPINAL ANAESTHESIA.

The earliest effects are subjective. In less than a minute there is a feeling of increased warmth in the feet, quickly followed by tingling merging into numbness, which flows wavelike to the thighs in the next two or three

Fig. 4.—Injection in the lateral position.

minutes. Impaired tactile sensibility deepening into anaesthesia comes on rapidly, first in the coccygeal and anal regions, then in the feet, and travels upwards to the trunk. A common remark at this stage is "My legs are sleepy." The upper limit varies with site of injection, dose of anaesthetic, and posture of spine; it frequently reaches the nipple line, and may extend to the clavicles and upper limbs. Above the level of lost sensation there is a zone of blunted feeling several inches wide.

Objectively the knee-jerks soon disappear, and, a little later, the plantar and cremasteric reflexes. With the onset of motor paresis the patient notices that the lower limbs feel heavy, and until reassured he may be uneasy on finding that he cannot lift his feet from the table. Loss of motor power follows the lead of anaesthesia, but is never so high or complete. In particular the abdominal

muscles become quite flaccid, and in acute peritoneal conditions the contrast to the previous board-like hardness is remarkable. In high anaesthesia the intercostal muscles are put out of function from below up to a variable level. Breathing may thus become almost entirely diaphragmatic in association with diminished rate and depth of respiration. This produces a sense of pressure on the chest, and another symptom which may be termed the "xiphoid tug," that is, a dragging sensation referred to the end of the sternum. Intercostal paresis is, however, by no means invariably present, even with anaesthesia above the nipples, as I have repeatedly demonstrated by directing the patient to cough. Yawning as a sign of air-hunger is very rare in my experience of tropacocaine.

The pulse-rate is not uniformly affected; as a rule it is first accelerated and slows down later on; exceptionally it may show no alteration. Some degree of syncope is common, and is accompanied by pallor of the face and sweating of the brow. One patient, a healthy young man operated on for radical cure of hernia, fainted on the table. An incident of such extreme rarity is matched by the case of another man who fainted in the anteroom before any preparation was made for injecting him; the cause here was clearly emotional. These conditions are not serious, and are combated by a whiff of smelling salts, or a tablespoonful of whisky, or other

and strychnine *sub cut.* Bathing the face with cold water is also refreshing.

Vomiting is another incident of faintness. It is uncommon, and never violent nor continuous. By raising the blood pressure it does more good than harm, and as it is soon over it scarcely delays the operation. Priapism is comparatively common to the extent of moderate turgescence. Relaxation of the anal sphincter and unconscious escape of the rectal contents occur not very infrequently. I have known this happen after relief of a strangulated hernia before the patient left the theatre. Very often it is simply the return of the residue of an enema, and in abdominal operations the advantage exceeds the inconvenience.

The most dangerous, and happily the rarest, symptom is stoppage of breathing. This occurred in one instance

Fig. 5.—Showing green which hides the field of operation from the patient.

Fig. 5.—Showing pelvis raised on a sandbag.

only among the series of 1,295 reviewed. The facts of the case are as follows:

Stoppage of Breathing.

H. R., aged 69, seen in consultation with Dr. Alfred Stanley of Leamington. He was suffering from jaundice due, in my opinion, to cancer blocking the common duct. As the patient thought his disease might be gall stones, he requested me to explore, and he was admitted to the Queen's Hospital for this purpose. I decided to operate under spinal anaesthesia, and injected 1 c.cm. of a 5 per cent. solution of tropacocaine into the tenth dorsal space, the patient being in the sitting posture. Within three minutes, and while lying on his back talking quietly to me, his speech and breathing suddenly failed. Ether and strychnine were at once injected, and artificial respiration begun by a combination of the Sylvester and Laborde methods. Each pull on the tongue evoked contractions of the sterno-hyoid and sterno-thyroid muscles, but there was no perceptible

response by the diaphragm. After three minutes (the time is, of course, estimated, as attention was concentrated on recovery), as I was not satisfied with the entry of air, I opened the trachea. At that time faint heart beats could be detected, but there was no pulse at the wrist. Artificial respiration was maintained for about five minutes longer before natural breathing returned, and the pulse reappeared at the wrist. His condition became so good that it was possible to open the abdomen and ascertain the presence of a hard growth in the head of the pancreas. The abdominal and tracheal wounds healed by first intention, and the patient left the hospital ten days later apparently none the worse for his alarming experience. I heard subsequently that the disease had pursued its gradual course to the inevitable end.

In another case of jaundice the depth of respiratory depression made it advisable to give artificial help. The notes are as follows:

Jaundice: Respiratory Depression.

A woman, aged 73, sent to me by Dr. Ainscow of Warley. Suffering from gall stones, diabetes, bronchitis, an intermittent heart, and rigid arteries, she was a bad subject for any operation or anaesthetic. Two hours before operation a small dose of scopolomorphine was given subcutaneously. The anaesthesia induced by 1 c.cm. of tropacocaine solution in the tenth dorsal space was very satisfactory, and all went well until the gall bladder was being emptied of its eighty-six stones, when the breathing became very shallow. After rhythmic pressure on the chest for a minute or two natural breathing became deeper and no further aid was required. Three stones were removed from the common duct, which was drained, and the gall bladder excised. She was very cheerful and pleased with herself when she called to see me a few weeks ago, though troubled with bronchitis and shortness of breath. I do not think I have tested the value of spinal anaesthesia more severely than in this case.

The anaesthesia lasts from thirty to ninety minutes, the average duration being about sixty minutes, and it ebbs through a stage of gradual recession. The variations depend mainly on the dose relatively to the particular patient—that is to say, the same dose will have a more prolonged effect on a light or asthenic patient than on one who is heavier and more vigorous. I am strongly opposed to giving a dose calculated to act far beyond the requirements of the operation, for if the anaesthesia recedes too soon a second injection of a half-dose can be given, or recourse may be had to general anaesthesia. The receding stage of blunted sensation is quite adequate for much operative work when reinforced by the twilight sleep of scopolomorphine.

It is of interest to note the behaviour of patients on the table. Even to the most phlegmatic the prospect of an operation is not alluring, while to the highly-strung it may bring acute apprehension. Fear adds considerably to the risk of general anaesthesia and is not allayed by strange odours and bewildering sensations. Not seldom there is physical pain to boot. Now in both these relations, the psychic and the physical, spinal anaesthesia offers a genuine advantage. Forewarned of the needle and its effects, the patient regards the momentary prick as a trivial matter, and with the rapid onset of anaesthesia anxiety is replaced by an emotion of pleased surprise which is the best possible calmative. While the house-surgeon is taking notes, the ward sister stands by to give attention and to divert the patient with quiet conversation. Most patients prefer this course; those who have had scopolomorphine go to sleep; others do the same without the aid of drugs; children are amused with a toy; now and then a cup of tea or a cigarette is asked for and given; and on occasion a patient indulges in singing or whistling. A question sometimes asked after an operation is finished is, "When am I going to have my operation?" and the patient is incredulous on being told that the diseased appendix or painful piles have been removed.

In no class of case is the benign effect more obvious and gratifying than in acute abdominal conditions such as fulminating appendicitis or perforated ulcer. Within five minutes of the injection the agonizing pain is subdued, the face loses its expression of suffering, and the erstwhile rigid muscles, now toneless, permit deep palpation which is unperceived by the patient.

In fine, the general attitude is one of placid self-possession and complete mental detachment from the surgical proceedings in progress. Those who have not witnessed the procedure will find a new sensation in the strange, I had almost said uncanny, experience of hearing a patient quietly chatting with the nurse while his viscera are being short-circuited or his gall bladder emptied.

By-effects.

In a large majority of the cases by-effects are conspicuously absent, and with the return of sensation the normal physiological state is resumed, apart from any disability incidental to surgical operation. The patient, having suffered no mental clouding, returns to his books and conversation, or goes to sleep. Food may be given with discretion, and this is a boon to old and weakly people; but, in view of possible vomiting, the first meal should be small and simple.

The ward scenes after spinal anaesthesia are in marked contrast to what is commonly presented after ether and chloroform. The absence of noisy crying, restlessness, and bouts of vomiting, does away with the need of special attention, and is appreciated both by the nurses and other patients.

The most objectionable by-effect is headache, and it is also the most capricious and puzzling. In 5 per cent. of the cases it is severe, persisting for several days; and in another 10 per cent. it is more or less present. Why so many should go scot free I cannot say, nor can I explain cases of which the following is a type. A woman aged 32, sent to me by Dr. Worsley of Coventry; after spinal injection for colotomy she had two sad days of headache, whereas on two subsequent occasions when she had similar doses of tropacocaine for operation on a recto-vaginal fistula and removal of sutures there was no discomfort. With regard to adults, apart from the fact that persons prone to headache on slight cause furnish the largest group, I know no ascertained relation to age, sex, disease, site of puncture, or posture of the patient. Since the symptom is met with after puncture without injection, a slight lesion is obviously an exciting cause, and altered tension of the sac is a not unreasonable conjecture. As a disagreeable sequel of anaesthetics it is not peculiar to spinal injection, and its importance need not be unduly magnified. Nor is it necessary to put suggestive questions to patients with a view to eliciting a complaint of headache. The common type is occipital, and it is aggravated by movement of the head. Aspirin in 10-grain doses is a good remedy, but not a specific.

Vomiting occurred in 7 per cent. of the cases—a proportion which can be reduced by deducting gastric and gall stone cases. As a rule it is a trivial symptom quite unlike what is frequently noticed after general anaesthesia. Indeed the comparative immunity from post-operative vomiting is a strong recommendation of the procedure; the patient is not sick or sorry; he is spared the strain of movements which would cause pain and delay repair; he has less need of anodynes; and nutrition being unhindered, he has a comfortable sense of well-being.

A less frequent trouble is backache, which may be complained of as a dull feeling along the spine, never serious, and gone in a day or two. Tolerance of this symptom, as of headache, varies with a patient's neurotic tendency and sensitiveness to pain in general.

Notes were made on the urine of 20 patients, taken at random, who were free from albuminuria before operation. After injection, albumen was found in the urine of 5 of these as follows: 2 showed a faint haze in the first specimen only; 2 showed a faint haze in the first specimen and in each subsequent specimen for thirty-two and thirty-five hours respectively; 1 showed a faint haze in the third and fourth specimens passed at the fifteenth and twentieth hours respectively. So far as they go, these few observations indicate that tropacocaine is not an intense protoplasmic poison, and that in this respect it compares favourably with other anaesthetics.

A slight rise of temperature is exceedingly common after any major operation. I find no proof that tropacocaine augments this tendency. In a series of 20 cases, 11 showed a rise of temperature ranging from half a degree to two degrees, in 6 there was a fall of a fraction of a degree, and in 3 the temperature remained normal.

Retention of urine needing a catheter is uncommon, and in the few cases coming under my notice the cause was largely psychic.

No case of the 1,295 reviewed has come to my knowledge in which any lasting ill effect has followed the injection. Some observers have reported the occurrence of ocular and other paralyses persisting for weeks and in the case of the sixth cranial nerve for months. Such untoward results are very infrequent after spinal anaesthesia

with any drug, and are not unknown after simple lumbar puncture; but to whatever extent they may be attributable to other agents, I have not encountered a single instance of them as a sequel of injection with tropacocaine.

Lastly, the spinal method is exempt from several grave concomitants of ether and chloroform—namely, pneumonia, bronchitis, and acid intoxication.

BIOLOGICAL AND PHYSICAL DATA.

An inquiry into what happens within and beyond the cerebro-spinal sac when an anaesthetic is injected opens up a number of questions that are more easily asked than answered. Problems yet unsolved have elicited ingenious guesses, which in their turn have given rise to profitable debate and research; but further investigation is demanded if the gaps in our knowledge are to be bridged.

The average volume of cerebro spinal fluid in an adult is estimated at about 70 c.cm., that is, $2\frac{1}{2}$ fluid ounces nearly. It is derived from the blood plasma through the agency of the choroid plexus, but whether by dialysis or secretion physiologists are not agreed. The cells of the basement membrane look like those of secretory organs, and the fluid itself closely resembles the secretion of the lacrimal glands. Specimens examined by me immediately after collection were neutral to the phenolphthalein test, but became alkaline on short exposure to the air, probably owing to oxidation of proteins. This observation conflicts with Tuffier's statement that the cerebro-spinal fluid is distinctly alkaline. The specific gravity of my specimens averaged 1.007.

When an alien fluid is injected into the spinal canal it is distributed by three forces—propulsion, gravitation, and diffusion. Bier suggests another factor—namely, displacement of the column of fluid by change of posture. This seems very dubious, and is only mentioned because of the respect due to so great an authority on spinal anaesthesia.

Forceful injection would propel currents of the solution in various directions, and is to be deprecated. With gentle injection propulsion is negligible.

Gravitation can be taken advantage of within limits to localize the solution in a chosen part of the canal. Since the specific gravity of tropacocaine solution is 1.016, it begins to sink through the lighter cerebro-spinal fluid to a level determined by posture—upright, lateral, or dorsal; and its action is most evident on the nerve filaments over which the concentrated solution flows, and with which it remains longest in contact by temporary stasis.

Diffusion is of the utmost importance, for it results in uniform blending of the fluids throughout the sub-arachnoid space, and the drug, in an attenuated form, is thus brought into close relation with that part of the nervous system which lies beneath the cranial wall of the sac. So rapid is the movement that Rehn found methylene blue in the lateral ventricle of a horse ten minutes after injection with a solution of sugar into the lumbar region of the sac. When the anaesthetic solution is a mixture of diffusible substances, each component diffuses at its proper rate, as in a test tube, subject to the selective action, if any, of the mural cells. Hence the continuous action of the drug at its original 5 per cent. strength is very brief in whatever part it may reach by gravitation with a heavy menstruum.

By osmosis through the pia matral sheath tropacocaine invades the spinal nerve roots in the sac, and inhibits their conductivity. The same statement probably holds good in regard to the spinal cord to a degree far short of complete transverse blocking.

When the drug diffuses into the cranium it is similarly conveyed by osmosis to the medulla and other underlying nervous structures. This appears to be a consideration of greater weight than is generally held, and I suggest that the contingent risks of spinal anaesthesia by the drugs now in use would be largely reduced if their toxic effect on the medulla could be counteracted. Attenuation of 1 grain of alkaloid in 2 oz. of cerebro-spinal fluid is not sufficient protection to the medullary centres when their stability has been undermined by serious disease. Nor should it be overlooked that the action of poisons inserted in the cerebro-spinal sac is far more intense on the nervous system than when they are conveyed by the blood stream.

Falkenheim and Naunym have shown that drainage from the cranio-vertebral canal is mainly via the cranial portion and into the venous sinuses. The diverticula of the sac projecting into the longitudinal and cavernous sinuses (Paechionian bodies) afford an easy route directly into the blood, but probably the theca is everywhere permeable. Mestrégat holds that permeability is only in one direction—namely, from the cerebro-spinal sac to the blood. The outward current is far from sluggish, for Leonard Hill has found methylene blue in the bladder and stomach within twenty minutes of its injection into the sac. Since the freezing-point of cerebro-spinal fluid is -0.59° C. and of the tropacocaine solution -1.13° C., the osmotic pressure is increased.

Little is known as to how long an anaesthetic may remain in the spinal canal. Rehn noted the presence of tropacocaine, novocain, and stovaine in the sac three hours after injection, and his observations led him to conclude that tropacocaine was the first to be eliminated by the kidneys and stovaine the last. Barker has found stovaine still present in the sac twenty-four hours after injection; in a specimen he obtained forty-six hours after he could find no stovaine, but the fluid was turbid and contained leucocytes. In one instance in which I withdrew cerebro-spinal fluid forty-one hours after injection of tropacocaine an analysis made for me by Allen and Hanburys detected no trace of an alkaloid; moreover, the fluid was perfectly clear and free from opalescence. Barker has detected traces of stovaine in the urine as late as the seventy-fifth hour after injection; this substance is therefore expelled very slowly.

Lowering of Blood Pressure.

The danger incidental to spinal anaesthesia lurks in the lowering of blood pressure. A rapidly induced and transient depression equal to 30 mm. of mercury may be tolerated by a person in sound general health, whereas in the presence of grave morbid conditions the consequence may be alarming.

In a number of cases I have had the blood pressure noted during operation; as a rule it fell within three minutes of injection, reaching the lowest point in about ten minutes; and I have known the descent amount to 50 mm. of mercury. But in some cases there was no fall of blood pressure, and in one a rise was noted.

I attribute the phenomena of faintness and respiratory depression to three causes acting in sequence and then in conjunction: (1) Blocking of afferent paths; (2) paralysis of intercostal muscles; (3) toxic impairment of medullary centres.

1. The area of the body switched off temporarily from functional connexion with the central nervous system is very extensive. In normal states every tissue emits a continuous stream of organic sense impulses flowing to the centres and influencing their functions. A single impulse, to be sure, is minute, but the abrupt interception of multitudinous impulses, however small in the unit, cannot be a light matter, and may derange the complex mechanism of the great centres beyond recovery. Such an event, though possible in any case of extreme asthenia, is of very rare occurrence; but more or less depression of the blood pressure is frequent.

In the case cited above dangerous signs ensued within three minutes of injection. Setting aside as negligible quantities the slight change of tension in the cerebro-spinal sac and the minute dose of alkaloid absorbed into the circulation, afferent blocking appears to be the proximate cause of the phenomena.

2. The observations of Gray and Parsons, confirmed by their research work in this university, prove that a rapid fall of blood pressure is associated with impairment of thoracic breathing as the dorsal nerves become inhibited and the intercostal muscles put out of action. This factor, however, does not operate in every case.

3. Toxic effects on the medulla may reasonably be expected to coincide with diffusion of the drug into the cranium, and are probably reinforced by the small amount circulating in the blood stream. Not infrequently low arterial tension and faintness supervene ten to twenty minutes after injection, in spite of ample costal breathing. The additional factor that has here come into play is poisoning of the medullary centres.

SCOPE OF THE PROCEDURE.

No progressive step in surgery can escape the ordeal of a probationary stage for the appraisal of its value, and during the past ten years spinal anaesthesia has been submitted to stringent tests at the hands of many operators bent on learning the facts about its alleged merits and demerits. Speaking for myself after unbiassed and ample experience, I am convinced that spinal anaesthesia has established its claim to be considered a distinct advance in practice and its right to a recognized place in our equipment. This is far from implying that other methods can be dispensed with; but the time has come to concede that spinal anaesthesia is entitled to a deservedly high position in their company.

Region.

The best way of demonstrating the possibilities of the procedure is to point out what has been done by its aid. Accordingly, I submit a table giving a broad classification of my cases at the Queen's Hospital:

SPINAL ANAESTHESIA BY TROPACOCAINE.

List of Operations.

| | | | |
|-------------------------------|-----|------------------------------|-------|
| Ablation of penis | 1 | For hernia (umbilical) ... | 4 |
| Ablation of penis and testes | 1 | For hernia (ventral) ... | 11 |
| Amputation through knee | 3 | For hydrocele | 36 |
| Amputation through leg ... | 4 | For ruptured ectopic gesta- | |
| Amputation through thigh | 10 | tion | 2 |
| Appendicectomy (acute | | Gastro-enterostomy ... | 7 |
| stage) | 61 | Gastrostomy | 3 |
| Appendicectomy (quiet | | Jejuno-jejunosomy ... | 1 |
| stage) | 85 | Laparotomy | 24 |
| Cholecystectomy | 5 | Nephrectomy | 5 |
| Cholecystostomy | 13 | Nephropexy | 30 |
| Choledochotomy | 3 | Nephrotomy | 8 |
| Colotomy | 10 | Oophorectomy | 1 |
| Cystotomy and cystoscopy | 36 | Orchectomy | 10 |
| Division of anal fistula ... | 92 | Ovariectomy | 2 |
| Enterectomy | 3 | Plating and suturing bones | 12 |
| Excision of rectum | 3 | Prostatectomy | 5 |
| Excision of semilunar car- | | Sciatic nerve stretching ... | 3 |
| tilage | 12 | Sequestromy | 13 |
| Excision of tumours | 30 | Ureterotomy | 2 |
| Excision of varicocele | 63 | Urethrotomy | 18 |
| Excision of varicose veins | 63 | Miscellaneous | 67 |
| For haemorrhoids | 124 | | |
| For hernia (femoral) | 34 | Total | 1,295 |
| For hernia (inguinal) ... | 375 | | |

These cases, which are consecutive and in no way selected, have been open to observation in a public institution, and under the close scrutiny of a succession of house-surgeons whose interest and assistance I cordially acknowledge. My records show that many types of sub-diaphragmatic operations have been successfully performed under tropacocaine. I do not advocate carrying the upper limit above the diaphragm (although in one case I resected a piece of the sixth rib), but the table definitely proves that below the costal border any operation is practicable under spinal anaesthesia.

Jonnesco of Bucharest uses the method for all his operative work, employing for the purpose a mixture of stovaine and strychnine. By injecting through the first dorsal space he is able to operate painlessly on any part of the head or upper limb at pleasure. In this country Jonnesco's practice has very few adherents, and the reports which have come to my knowledge are so discouraging that I am opposed to this extension pending the introduction of safer means.

As at present advised, therefore, I exclude from the legitimate province of spinal anaesthesia all parts of the body above the level of the xiphisternum.

With regard to the suitability of the patient, the question may be considered in relation to age, disease, and psychic state.

Age.

I am not aware of any prohibitive age limit at either extreme of life, certainly not after the age of 1 year. The youngest in my series was a case of intussusception in a baby 11 months old, sent by Dr. Kirby of Smethwick. The dose I injected—namely, 6 minims—was needlessly large and induced shallow breathing, though not to a degree requiring artificial respiration. The stillness of the abdomen rendered the operation of laparotomy and reduction of bowel from the splenic flexure a simple matter, and recovery was uninterrupted. In a child aged 2 years a dose of 5 minims had to be supplemented by a second injection of 4 minims, after which he showed his

indifference to the proceedings by going to sleep during the operation for radical cure of his hernia.

The oldest case in the series was a man, aged 81, for whom I did partial resection of a carcinomatous bladder. Here, too, the method was very successful, and a good recovery followed. (In private the method answered well in an operation on a lady, aged 95, whom I saw in consultation with Dr. J. H. Brice, of Edgbaston. She was suffering from intestinal obstruction, for which sub-umbilical colotomy was performed; this gave temporary relief but not a new lease of life, and she died from exhaustion the next day. The nurse, who was prejudiced against spinal anaesthesia by what she had seen of stovaine injection elsewhere, expressed great satisfaction on noting the patient's good general condition and freedom from pain during the operation.)

Physical State.

Coming to the question of a patient's physical condition of disease or health in its bearing on spinal anaesthesia, what here follows is to be taken subject to the provisoes that the proposed operation is within the region assigned to the method, and that the contraindications mentioned below are excluded. The ground is partly cleared by the fact that opinion is unanimously in favour of the method where there is serious respiratory trouble, impending uraemia, diabetes, and heart disease with broken compensation. It is also held to be preferable when an emergency operation has to be done on a patient who has just had a meal. These points are settled by consent, and the wide field beyond will be more or less occupied by spinal anaesthesia according to a surgeon's confidence in the method. My own experience tallies with that of others who have found the results so satisfactory that they have come to apply the method wherever feasible, irrespective of the patient's physical state. I have dealt with all gradations between robust health and extreme illness. Healthy persons—for example, young men requiring radical cure of hernia—give no anxiety either at the time or afterwards, and, so far as I know, a fatality in this group has never been recorded. At the other end of the scale, where the power of resistance is reduced to the verge of zero and life is trembling in the balance, the weight of a feather may turn the issue the wrong way. In these circumstances it is perilous to add to the ravages of disease the burdens imposed by emotional disturbance, an anaesthetic, and an operation; and not only is the death-rate necessarily high, but it is also impossible to assess the proportionate influence of the several adverse factors. Hence the fallacy of figures purporting to measure the comparative risks of anaesthetics. I believe, however, that in the critical conditions here contemplated spinal anaesthesia offers the best chance, however slender that chance may be; and I am satisfied that the formidable element of surgical shock is excluded by the barrier set in the path of afferent impulses. The power of preventing shock or the increase of existing shock is precisely the attribute above all others which distinguishes spinal anaesthesia as a means of life-saving in connexion with surgical acts of unusual hazard.

Acute abdominal lesions present a specially promising field for several reasons. Not only is there immunity from systemic surgical shock, but the local form which results in paresis and subsequent distension of bowel is likewise in abeyance. Moreover, the muscular walls offer no resistance to retraction of the wound or to its closure by sutures; and the intestines show no tendency to gush from the cavity, partly because of the remarkable stillness resulting from quiet breathing and the absence of forcible straining, and partly because peristalsis is not inhibited. Handling and replacement of protruding loops of bowel are thus minimized and exploration greatly simplified. Further, there is an important post-operative advantage in the relative non-liability to vomiting with its attendant risks of disturbance of the wound and abdominal contents. Taken collectively these favourable features constitute a strong plea in support of the method, and I have proved their value in many cases, among which may be cited closure of perforated typhoid and other ulcers, resection of gangrenous bowel, and operations for acute intestinal obstruction and septic peritonitis.

No surgeon who has given the procedure a reasonably

extended trial will entertain the smallest doubt that by its aid he has saved lives which would otherwise have been lost; and no surgeon who intends to keep in touch with progressive methods would feel justified in ignoring the evidence now forthcoming as to the utility and relative safety of spinal anaesthesia.

Chronic alcoholics are welcome neither to the anaesthetist nor to the surgeon; but they are relatively good subjects for the spinal method, in the sense that they are very obnoxious to ether and chloroform—hard to get under, and hard to keep under within safe limits of narcosis. A patient of this type reaps the full benefit of the physical calm peculiar to spinal anaesthesia in all stages before, during, and after operation. Within three or four minutes of the injection he passes without struggle or excitement into a state of quiescence marked by paresis of all muscles below the ribs, and this condition is maintained throughout and beyond an average operation. Whether the patient be an alcoholic or not, and whatever the form of his disease, violent muscular efforts during or just before an operation are always injurious, and in some abdominal conditions are attended by grave risks. The absence of all physical excitement is one of the most attractive features of spinal anaesthesia.

I have not found acute haemorrhage a deterrent. Two cases of ruptured ectopic gestation with copious bleeding were dealt with on the same day—one, a patient aged 29, sent to me by Dr. Mold of Halesowen; the other aged 24—and both did well in every respect.

Psychic State.

Familiarity with narcosis as the only means to an operation is apt to produce a prejudice in its favour, and it might be supposed that all patients would prefer not being conscious during an operation. I find, on the contrary, that few object to the spinal method on that ground; the point of view of many is well expressed by the remark of the man who said he objected to chloroform because he wished to be present at the operation. Once anaesthesia is established, all misgiving vanishes and confidence comes to the most timid.

I have been repeatedly told by patients who have experienced both methods that their preference was strongly in favour of the spinal. As the public become more acquainted with the possibilities of the procedure a larger number of patients will ask for its benefits.

Common to all methods is the factor of some measure of dread with which an operation is generally anticipated. At times this amounts to positive terror, which a nervous patient may be quite unable to control, and which may be more than embarrassing to the anaesthetist and his helpers who are called upon to overcome resistance by force. It is a great relief to all concerned to know that such a distressing and dangerous stage before the performance of a critical operation can be avoided by the use of spinal anaesthesia within its province.

On the other hand, there is undoubtedly a class of patients, more numerous in private than in hospital practice, who dread the idea of consciousness while undergoing an operation, and in the best interests of these complete oblivion of their surroundings may be necessary. If so, it is quite practicable to make use of general and spinal anaesthesia in sequence. Very excitable, sensitive persons are not satisfactory subjects for anaesthesia, but they should not be ruled out of the benefit of the spinal method as though their psychic condition were an absolute contraindication. Hysterical, neurotic women often prove most amenable to tropacocaine, especially if given scopolamine in advance. Without this supplement emotional persons respond to the moral atmosphere of cheerfulness created by the bearing and remarks of the surgeon and nurses. Before giving the injection I make a point of explaining to patients the steps of the procedure, and the change of sensation it is intended to produce; they are thus prepared for what follows, and generally show a pleased interest in the phenomena. It does more harm than good to worry nervous patients by testing for anaesthesia, or by asking questions that suggest the possibility of pain, particularly when the action of the drug falls short of a complete blocking of all impulses, for they will probably imagine a great deal and misinterpret vague sensations as pain, besides becoming more self-centred. The twofold aim with such persons is to gain their

confidence and divert their attention from the actual operation.

CONTRAINDICATIONS.

I have made it an invariable rule to require a patient to remain in bed for several days after spinal injection, and I certainly would not sanction the procedure unless it was going to be followed by at least twenty-four hours' complete rest. Otherwise I should expect trouble from by-effects. Out-patient practice is clearly outside the pale, and is, therefore, an emphatic contraindication.

And so is the presence of septic inflammation, suppuration, or eruptions near the desired site of puncture. I have met with several cases where I have declined to give an injection because of one or other of these conditions.

I have not knowingly used the method in a case of disease of the central nervous system; any such disease would make one hesitate; and above all, cerebral tumour must be deemed an absolute bar because of the risk attaching to alteration of intracranial pressure.

Reviewing a long series embracing various local and constitutional states I see no case made out for adding to the foregoing short list of conditions positively contraindicating spinal anaesthesia by tropacocaine. It has been urged that pyaemia is a deterrent; this may be so, but it is not a common disease, and the occasions in its course when the procedure might be suggested are few and far between; no such occasion has presented itself to me. More important than the label of a particular disease is the question of how far the power of resistance has been sapped by morbid processes.

FAILURES.

In three cases I have failed to enter the theca owing to spinal abnormality, complicated in one case by obesity. The latter condition prevents exact definition of the spines; if I had to deal with such a case where spinal anaesthesia was specially indicated owing, for example, to severe bronchitis, I would not hesitate to incise through the fat with the aid of local anaesthesia so as to make palpation of an interspinous space possible. In like circumstances of urgency an incision may also be advisable in a case of bony deformity.

In 14 cases—that is, a fraction over 1 per cent.—there was no anaesthesia, or it was too slight to be of service, and a general anaesthetic was administered. It is to be presumed that the prescribed dose of the drug was too small, or that a portion was not lodged within the cerebrospinal sac, or that the solution rapidly leaked into the extradural space. Whatever the explanation of these exceptional failures, the possibility of their occurrence must not be forgotten, and provision should always be at hand for the induction of general anaesthesia. Moreover, when sensation returns before an operation is completed, a general anaesthetic will often meet the indication better than a second spinal injection. There are 19 cases of that class in my list.

It is seen that a general anaesthetic was required on 36 occasions—throughout in 17 operations, and during the later stage in 19. On the whole series this gives a percentage of 2.8 nearly.

MORTALITY.

In the series here reviewed, reserving 1 case for separate record, there was no death attributable to the spinal injection. The total number of deaths was 21, which gives a death-rate of 1.6 (nearly) from all causes. The case referred to belongs to the thirteenth hundred of the series, and is summarized as follows:

The patient was a woman, aged 56, sent to me by Dr. Ewart Ashton, of West Smethwick. She had been bed-ridden for months suffering from calculous pyonephrosis, and was worn out with hectic fever and pain. She was also diabetic, and on admission it was obvious that she was desperately ill. A general anaesthetic could not be entertained, and it seemed improbable that local anaesthesia would suffice for the operation required on the left kidney.

Accordingly 15 minims of tropacocaine solution, that is, $\frac{1}{2}$ of a grain, was injected between the twelfth dorsal and first lumbar vertebrae, the patient being on her left side. The anaesthesia was perfect, and the patient's condition was no worse throughout the operation, which consisted in the evacuation of about one pint of pus and several calculi; no attempt being made to remove the adherent shell of the obsolete left kidney. The cavity was lightly packed with gauze and the wound partly closed with sutures. Shortly after removal to the ward she became collapsed, and despite prompt treatment with injections of

ether and strychnine, she died about fifty minutes after the spinal injection.

Permission to make a formal *post-mortem* examination was refused, but the right kidney and the heart were examined through the operation wound. There was no haemorrhage into the wound. The kidney was hydro-nephrotic, contained calculi, and its cortex was thin. The heart was fatty, and its musculature very soft.

Reflecting on this case it is difficult to say what part, if any, tropacocaine had on the issue. The patient had put off surgical help until too late, and her frail tenure of life was nearing its limit. Whether she would have survived the operation under any form of anaesthesia is a question on which critics will form their own judgement. One thing is clear: her condition was not worsened during the anaesthetic stage, and the collapse coincided with the return of sensation as the effect of the drug receded and painful impulses flowed to the medulla. It is also possible that hyperaemia of the wall of the large abscess on escape of its contents increased the liability to syncope and cerebral anaemia.

COMBINATION OF ANAESTHETIC DRUGS AND METHODS.

Attempts have been made to achieve better results by injecting a mixed solution of a spinal anaesthetic and some other drug. Thus adrenalin or suprarenin borate has been combined with tropacocaine, stovaine, and novocain respectively, and by rendering tissues anaemic it might be expected to delay absorption, and so prolong anaesthesia, besides raising the blood pressure. Some acquaintance with the compound tropacocaine preparation did not disclose to me any superiority over the simple solution.

Another combination of stovaine advocated by Jonnesco for very high anaesthesia is with neutral strychnine sulphate. By its power of increasing the reflex excitability of the cord strychnine probably helps the transit of weak impulses between the neurons, and may thus fortify the respiratory mechanism. Nevertheless it cannot be relied on as an absolute safeguard, for fatal respiratory failure has followed its use, and has even been ascribed to spasm caused by the strychnine. The unquestionable risks of very high anaesthesia, whether mitigated by strychnine or not, are too great to justify the procedure at present; and for low anaesthesia strychnine has a tendency to shorten the duration.

Atropine and other substances are being tried, and an improved combination may yet be discovered.

The spinal method may also be used advantageously in sequence when a double anaesthesia, central and peripheral, is indicated. Thus it may be preceded by scopolamine and morphine given under the skin, or it may be followed or preceded by inhalation drugs. In cases of nephropexy it is my rule to give a subcutaneous injection of scopolamine $\frac{2}{100}$ grain, and morphine $\frac{1}{8}$ grain, one hour before operation; and I adopt the same practice generally in cases where the element of neurosis is conspicuous, or where the operation is near the diaphragm or likely to be prolonged. Quite commonly when this is done the patient sleeps through the operation with perfectly quiet breathing and no tendency to vomit.

If a general anaesthetic follows the spinal very little is wanted to induce sleep. I have on several occasions found it advisable to reverse the order of succession, beginning with light inhalation narcosis, and following up with the spinal method; here, too, the quantity of vapour inhaled has been very small.

CONCLUSIONS.

Admitting the high claims of stovaine and novocain, but restricting my remarks to tropacocaine, I sum up the position of spinal anaesthesia as follows:

1. It is a procedure of proved value and simple technique.
2. Its province is subdiaphragmatic operations.
3. There is no prohibitive age limit.
4. By blocking afferent paths it prevents surgical shock.
5. It induces muscular relaxation, quiet breathing, and abdominal stillness, and thus conduces to rapidity and safety in abdominal surgery.
6. Used with discretion in conditions of extreme asthenia and instability of the medullary centres due to toxæmia, exhausting disease, traumatic shock, and old age, it is superior to ether and chloroform.

7. It promotes the patient's comfort and nutrition in the post-operative stage.

8. Its scope is amplified with the aid of scopolamine and morphine.

9. By lowering blood pressure it tends to faintness and respiratory depression. The patient should therefore be carefully watched after injection, and treated as required by means of diffusible stimulants, pituitrin, saline infusion, and artificial respiration.

10. In a small percentage of cases it is inadequate, and must be supplemented by general anaesthesia.

11. It increases the possibilities of surgery by facilitating the work of a surgeon in the absence of a competent anaesthetist or assistant.

12. The procedure should be taught in medical schools.

THE LACRYMAL GLAND IN SURGICAL ANAESTHESIA.

By L. T. RUTHERFORD, B.A. CANTAB., M.R.C.S.,
L.R.C.P.,

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

A SERIES of careful observations on the behaviour of the lacrymal apparatus during the administration of certain anaesthetics has shown that the presence or absence of the lacrymal secretion is a useful and constant indication of the depth of narcosis. In over 200 cases, where the behaviour of the lacrymal glands was noted, it was found that the information thereby gained was constant and accurate, as shown by the presence of other signs and the subsequent progress of the cases.

It may seem surprising that any point of importance to the anaesthetist should have escaped attention, or at any rate mention, for so long a period, and the explanation appears to be that, since in the excitement stage of anaesthesia the lacrymal secretion is copious and the inner canthi become flooded, unless the pools of secretion be wiped away, no further indication of the lacrymal activity will attract attention. It may be that those who have observed the phenomenon of the lacrymal secretion have tested its value carefully and found it useless; in which case one can only regret that no mention of such work has been made in recent textbooks.

In an uncomplicated case, where anaesthesia is induced by the administration of chloroform or ether, the anaesthetist has no difficulty in regulating the amount of anaesthetic required by carefully observing the well-known signs of anaesthesia. In other cases the patients may react abnormally to the drug in one or two respects, as, for example, when the pupils remain large throughout the administration or when the corneal reflex is abolished abnormally early. Such cases present no real difficulty, since the abnormality is easily recognized and avoided. But cases are occasionally met with in which the anaesthetist has the greatest difficulty in securing a quiet anaesthesia, and where, in maintaining a constantly flaccid abdomen or other desirable condition, the resources of his craft are taxed to the utmost. It is in cases such as these that every sign or symptom is of value, and, although in no case can we afford to neglect a reliable sign, it is here especially that the lacrymal activity is of service.

I will now discuss (1) the behaviour of the lacrymal glands during the various stages of anaesthesia, and (2) the special importance of the lacrymal secretion in differentiating the dilated pupil of overdose from that of impending vomiting.

I.

The symptoms and signs observed during the inhalation of chloroform will suffice to illustrate the stages of anaesthesia seen when chloroform, ether, or a combination of these drugs is administered. Four stages are usually described: (1) A preliminary stage; (2) an excitement stage; (3) a stage of surgical anaesthesia; and (4) a stage of overdose.

The preliminary stage appears during the inhalation of the first few breaths of anaesthetic, and is made up of many components. The vapour irritates the nasal and bronchial mucous membrane, and reflex coughing and

salivation, with holding of the breath and slowing of the heart may be observed. Next, we notice disturbances of judgement, loss of memory and self-control, and often emotional tendencies. The special senses are next affected, and analgesia is well marked. The pulse-rate increases, and the blood pressure begins to rise; with this rise of blood pressure the respiratory-rate is increased. The pupils are now widely dilated. Here the first stage ends, and delirium, varying from shouting and singing to inarticulate muttering, ushers in the excitement stage.

In the first stage the activity of the lacrymal glands varies according to the strength of the irritation in the nose and tubes, and, if no vapour impinges on the cornea, the canthi may remain dry. With the onset of the excitement stage, however, the lacrymal glands become excessively active, and pools of secretion appear at the inner canthi, and from thence overflow on to the face. Tonic and clonic muscular spasms, coughing, retching, and vomiting may also be observed at this stage. The reflexes are diminished, and the patient is unconscious. The third stage is indicated by a general muscular relaxation, which at times appears quite suddenly, a loss of body reflexes, a steadying of the respiratory rhythm, a fall in blood pressure and temperature, and a decrease in the size of the pupils. During this stage of surgical anaesthesia the lacrymal glands cease to secrete, and the canthi, if dried after the excitement stage, remain so. The cessation of the lacrymal secretion usually takes place a few breaths before the complete abolition of the corneal reflex, although the disappearance of reflex and secretion may occur simultaneously.

The fourth stage, or stage of overdose leading to bulbar paralysis, is ushered in by dilating pupils, and this is followed by a fall of blood pressure, a loss of bladder and rectal reflexes, a shallowing and cessation of respiration, and a great depression of the cardiac muscle (in the case of chloroform). Here, in the stage of overdose, we find that the lacrymal glands are inactive. The canthi are dry, the pupils are widely dilated and inactive to light, the corneal reflexes are abolished, and the tone of the orbicularis palpebrarum is diminished.

Such, then, are the four stages seen in some cases of chloroform narcosis, and may be found similarly described in every textbook, with this exception—that the textbooks make no mention of the lacrymal activity.

We find that in the first stage the internal canthi may be wet or dry, in the second stage the lacrymal glands are always active, and in the third stage that the lacrymal secretion ceases at the same time as the earliest reflexes disappear, and that this cessation usually precedes the abolition of the corneal reflex by a very short interval. The slight variability in the time of cessation of the lacrymal secretion is of no practical importance, for in no case do the glands continue to secrete *after* the abolition of the normal corneal reflex (the term "normal corneal reflex" is used here purposely to distinguish it from the "diminished corneal reflex" observed after a time in an eye which has been continuously or carelessly tested). The moment at which the lacrymal secretion is first observed, after its cessation under the influence of chloroform or ether, is of the utmost importance, and provides a reliable indication of the exact moment at which to continue the administration, if a satisfactory surgical anaesthesia is to be prolonged. The time of the cessation of the lacrymal secretion during the induction period corresponds almost exactly with the time of its reappearance during the recovery period, and it is on this account that the "canthal" tear is so valuable, for it indicates when present that the corneal reflex is (or should be) obtainable, and that the amount of the anaesthetic is as much as is compatible with successful anaesthesia. If, then, we administer our anaesthetic in quantities just calculated to abolish the lacrymal secretion and then wait, if at any time in doubt, until the secretion again appears, we may feel confident that we are well on the safe side of the border line between deep surgical anaesthesia and an overdose.

The exhibition of such drugs as morphine, hyoscine, and atropine in a large number of cases completely abolishes the lacrymal secretion, and here it must also be noted that there are certain individuals, usually children under 10 years of age, in whom the lacrymal glands appear to be unaffected by the narcotics, and who, while under the

influence of chloroform or ether, show no evidence of lacrymal gland activity. Such cases are rare, and do not detract from the value of the secretory phenomenon, since the absence of the secretion is evident during the excitement period, and hence this sign is neglected for the rest of the anaesthesia.

II.

The special importance of the presence or absence of the lacrymal secretion in differentiating the dilated pupil of overdose from that of impending vomiting is at once apparent. Those who affirm that it is possible to elicit a corneal reflex when the dilated pupil of "impending" vomiting is present will consider that no further differentiation is necessary; those who agree with me that only in the dilated pupil of "immediate" vomiting is it possible to obtain such a reflex will admit the value of a further test. The condition of the pupils in impending vomiting and in overdose are very similar; both may be inactive to light, neither retains a corneal reflex as a rule, and the accompanying signs and symptoms may give but little assistance to the administrator. It is in such cases that the value of the canthal pools is evident. If the canthi have been kept dry up to the moment at which the pupils commence to dilate, and if they remain dry after the pupils are dilated, then the anaesthetist should at once withhold the anaesthetic and prepare to deal with a case of relative or absolute overdose; but if the canthi are seen to be flooded with tears then the anaesthetic must be pressed to secure an adequate anaesthesia by abolishing the vomiting reflex.

Those who are experienced in the administration of anaesthetics and who subconsciously observe every little detail during the administration will affirm that at no stage should the administrator be in doubt as to the depth of narcosis. Nevertheless, it must be remembered that a large proportion of medical men called upon to act as anaesthetists have had but little experience with narcotics, and to such people, especially, an easily remembered and reliable indication of the depth of narcosis is valuable.

In some of the cases examined it was possible to show that although the corneal reflex could not be evoked during the stage of "impending" vomiting, nevertheless it reappeared occasionally a few seconds before vomiting actually commenced, in that period of time which has been alluded to as the period of "immediate" vomiting.

In the course of the investigations undertaken to establish the reliability of the lacrymal activity as a means of regulating the amount of the narcotic employed, over 200 cases were anaesthetized for operations varying in severity from the opening of a superficial abscess to the resection of several inches of intestine. Naturally many slight variations in the behaviour of the lacrymal glands were observed; but these variations were of no practical importance, and may be divided into variations (a) in the quantity of the secretion, and (b) in the time at which the secretion appeared and disappeared relative to the presence or absence of the corneal reflex. This latter variation has already been discussed. As regards the former, when chloroform is administered alone the quantity of the lacrymal secretion is usually small. During the administration of ether the lacrymal secretion is abundant, and in giving mixtures containing ether, the quantity of secretion does not fall much below that observed when ether is given alone.

CONCLUSIONS.

In conclusion, I would insist on the truth of the following three statements:

1. That since the appearance of a lacrymal secretion during anaesthesia is a constant phenomenon, it therefore deserves mention in books devoted to the subject of anaesthetics.
2. That the lacrymal secretion, bearing as it does a definite relation to the depth of narcosis, is of value to the anaesthetist.
3. That since the behaviour of the lacrymal glands under anaesthesia is almost constant, and since the exceptions to the general rule are easily recognized, the value of this sign as an aid to the administration of an anaesthetic must be at once apparent.

SLEEPING SICKNESS AND BIG GAME :

A PROPOSED EXPERIMENT.

By WARRINGTON YORKE, M.D.,

DIRECTOR OF THE RUNCORN RESEARCH LABORATORIES OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

DURING the years 1908 and 1909 the diagnosis of several cases of human trypanosomiasis amongst Europeans, who had never been in contact with *Glossina palpalis*, drew attention to the occurrence of the disease in portions of Rhodesia and Nyasaland in which this particular insect does not exist.

In 1910 it was shown that the parasite causing the disease in Rhodesia and Nyasaland differed in certain respects from that causing sleeping sickness in other portions of tropical Africa. The name *Trypanosoma rhodesiense* was given to this new parasite. Since these discoveries many cases of sleeping sickness have been found in Rhodesia and Nyasaland, and in 1911 Dr. Kinghorn and I were sent to North-Eastern Rhodesia to investigate and report upon the conditions governing the spread of the disease in that country.

The first problem we had to solve was to ascertain the vector responsible for the spread of sleeping sickness in a country where *Glossina palpalis* does not exist. Now, although *Glossina palpalis* has not been found either in Nyasaland or in the Luangwa Valley of Rhodesia, yet *Glossina morsitans*, the tsetse fly which is known to cause "fly" disease in domestic stock, is present in enormous numbers, and it was soon proved by Dr. Kinghorn and myself that it is this fly that is responsible for the spread of human trypanosomiasis. This discovery is one of great practical significance: for whereas the former fly, *Glossina palpalis*, is limited in its distribution to watercourses, and never found far from the banks of certain rivers or the lake shores, the latter, *Glossina morsitans*, is ubiquitous, its distribution being quite independent of water. Hence it is obvious that it is impossible to attempt to deal with sleeping sickness in Rhodesia and Nyasaland by any such simple method as removing the native population away from the watercourses and lake shores, a procedure which was attended with such remarkable results in Uganda. The problem of preventing the spread of sleeping sickness in these countries, which a few years ago were thought to be in no danger, is one of infinitely greater difficulty than was that which had to be faced in Uganda.

A large number of wild *Glossina morsitans* were examined in the Luangwa Valley in order to ascertain what proportion were capable of infecting man with trypanosomiasis. This information is important, as it affords an approximate idea of the potential danger of the district. We found that 1 in 500 wild *Glossina morsitans* was infective. As this was far too large a proportion to have been infected from the comparatively few infected human beings, it was evident that some other host than man must serve as the reservoir from which the fly derives its infection. With the object of ascertaining what was the chief vertebrate reservoir of the virus, we examined 250 wild animals (including elephant, rhinoceros, hippopotamus, lion, buffalo, fourteen different kinds of antelope, caracal, galago, squirrel, genet, hunting dog, giant rats, and wild rabbits), 256 monkeys, 35 domestic stock, 142 wild rats, and 15 wild mice, making a total of 698. The results were striking: a large proportion of the antelope were found to be infected with the parasites which cause sleeping sickness in man and trypanosomiasis in domestic stock. As a conservative estimate, the percentage of game infected with the trypanosomes of man or domestic stock might at Nawalia in the Luangwa Valley be placed at 50, and at Ngoa on the Congo Zambesi watershed at 35.

Beyond stating that the figures in the accompanying tables refer only to the trypanosomes causing disease in man and his flocks and herds, it is unnecessary here to go into details as to their exact nomenclature. I might mention, however, that at Nawalia in the Luangwa Valley 16 per cent. and at Ngoa on the Congo Zambesi watershed 3.3 per cent. of the wild animals were infected with the human trypanosome, *T. rhodesiense*.

TABLE I.—Percentage of Various Species of Game Found Infected with Trypanosomes Pathogenic to Man or Domestic Stock at Nawalia, Luangwa Valley.

| Animal. | Number Examined. | Percentage Harbouring Trypanosomes. |
|-------------------|------------------|-------------------------------------|
| Bushbuck | 9 | 66.6 |
| Waterbuck | 28 | 60.7 |
| Kudu | 7 | 57.1 |
| Hartebeest | 6 | 16.6 |
| Roan | 8 | 12.5 |
| Warthog | 9 | 11.1 |
| Puku | 10 | 10.0 |
| Mpala | 29 | 6.9 |

TABLE II.—Percentage of Various Species of Game Found Infected with Trypanosomes Pathogenic to Man or Domestic Stock at Ngoa, Congo Zambesi Watershed.

| Animal. | Number Examined. | Percentage Harbouring Trypanosomes. |
|------------------|------------------|-------------------------------------|
| Sitatunga | 2 | 50.0 |
| Waterbuck | 27 | 44.4 |
| Eland | 15 | 26.6 |
| Duiker | 9 | 22.2 |
| Roan | 5 | 20.0 |
| Puku | 8 | 12.5 |

This investigation, therefore, made it clear that the main reservoir of the trypanosomes of man and domestic stock is the big game.

Having ascertained these two essential facts—namely, that the tsetse fly, *Glossina morsitans*, is the agent by which the disease is spread and that the big game is the inexhaustible reservoir of the virus which causes the disease—we are faced with the problem of what, in the light of this knowledge, can be done to stamp out sleeping sickness or to limit its spread in Nyasaland and Rhodesia. Obviously the most satisfactory means of prevention would be the extermination of *Glossina morsitans*, which conveys the parasite from one vertebrate host to another. Unfortunately, however, this is out of the question at the present state of our knowledge. The only known method of getting rid of the fly from a district is by clearing away the bush. In the immediate vicinity of villages such a procedure is doubtless feasible, and would be attended by valuable results, and natives should be encouraged to do everything possible in this direction. The labour involved in clearing large tracts of country would, however, be so great that this method can be at once set aside as impracticable. Moreover, it must be remembered that not only would the country have to be cleared, but it would require to be kept cleared. Every one who has had experience of tropical Africa is familiar with the dense shrub growth which springs up in the site of old garden clearings two or three years after the natives have ceased cultivating the land. This shrub growth is exceedingly favourable to *Glossina morsitans*, so that, unless the country be kept constantly cleared, the last state of the district is worse than the first.

At present little is known of the bionomics of *Glossina morsitans*. Investigations so far carried out indicate that this tsetse fly has no breeding-places which are peculiar to it, but that its pupae are deposited in a more or less haphazard manner in hollow trees and excavations where they are not likely to be disturbed by game birds. Regarding the liability of the fly to disease and of its natural enemies practically nothing is known. Much more information is required on this subject, but it seems only too obvious that the investigations will be beset by great difficulties, and that knowledge will only be forthcoming as the result of much slow and tedious work. In fact, to those familiar with *morsitans* country the extermination of the fly must seem an almost impossible procedure.

In Uganda, where the disease is spread by *Glossina*

palpalis, the removal of the population a short distance away from the lake shores and watercourses was followed by most excellent results. Such a measure, however, is impossible in Nyasaland and Rhodesia, where the vector, *Glossina morsitans*, is practically ubiquitous in its distribution and not limited to watercourses as is *Glossina palpalis*.

In view of the impossibility of exterminating the fly and of the equal impossibility of removing the population from the fly belts, we must consider the only way that remains of combating the disease—that is, the advisability of attempting to destroy the reservoir of the virus. It is obvious that the mere isolation of infected human beings is futile in view of the fact that the main reservoir of the virus is the blood of the big game.

Since the beginning of last year, when Dr. Kinghorn and I published our paper announcing the fact that a large proportion of the wild fauna of Africa harboured the trypanosomes of man and domestic stock, a considerable polemic has arisen over the question of the advisability of attempting to exterminate the big game in the vicinity of human habitations in fly areas.

In discussing this subject it appears to me that I could not do better than state briefly what I suggest should be done and then reply to some of the more important criticisms which have been directed against these proposals.

In the first place, I consider that a decisive scientific experiment, the nature of which I will outline later, should be undertaken with a view to ascertaining the effects of completely eradicating the game in a limited area. As some years must elapse before the results of such an experiment would be known, I suggest that in the meantime the restrictions relating to the killing of game by Europeans and natives should be removed in those portions of the fly areas which are in the vicinity of human habitations.

It has been suggested that if the game be destroyed in any district, the fly, being deprived of its natural source of food, might turn its attention solely to man and his flocks and herds. It appears to me that little importance should be attached to this hypothesis; cattle do not, as a rule, live in the presence of *Glossina morsitans*, and the fly does not invade villages around which there is a clearing, even though at the present time they could by so doing obtain food, perhaps, still more readily than they do in the bush. Moreover, if the game be removed the reservoir of the infection is destroyed, and therefore in a short time the fly would tend to become non-infective. The bite of non-infective *Glossina morsitans* hurts nobody. Finally, there is absolutely no evidence indicating that if the big game in any particular district were slaughtered the tsetse fly, unable to obtain blood from these animals, would attack man and domestic stock to a greater extent than at present. It might equally well be urged that if the food supply of the fly be removed the fly would disappear. There is, moreover, a considerable amount of evidence that the tsetse fly spreads with the game. For example, since the rinderpest swept through Central and South Africa sixteen or seventeen years ago the big game has increased enormously in numbers, and with this increase in game there has been a corresponding increase of tsetse fly. Although *Glossina morsitans* was present in enormous numbers at Nawaia, in the Inangwa Valley, when we were working there, and natives sent out to collect the flies had no difficulty in capturing large quantities within a short distance of the laboratory, the magistrate who was stationed there in 1905 told me that he only occasionally saw tsetse flies at that time.

Again, it has been suggested that the big game might be only one of the reservoirs of the disease, and that the infection might equally well be harboured by the small vermin.

It must be remembered, however, that the small vermin is to a considerable extent nocturnal in its habits; and although *Glossina morsitans* does occasionally bite at night, especially when the moon is full, yet nobody who has lived in "fly" areas can have any doubt that this is exceptional, and that for practical purposes the fly feeds in the daytime only. Dr. Kinghorn and I examined a large number of small vermin—rats, mice, wild rabbits, etc.—without finding a single instance of natural infec-

tion with a pathogenic trypanosome. Furthermore, it must be remarked that there is no evidence to show that the small vermin are tolerant of the human trypanosome, as are the big game. In those which we infected experimentally the disease ran an acute course and the animals died. If this be the case with the majority of the small vermin they cannot have the same significance as reservoirs of the virus as have the big game, which can probably harbour the parasite for long periods without exhibiting signs of disease.

The theory has been advanced that cattle and other domestic stock might harbour the human parasite for considerable periods without detriment to health. This, however, is not the case. We found that the trypanosome rapidly kills horses, cattle, donkeys, goats, and dogs. Moreover, even if the human parasite failed to kill domestic stock, these would still die from the ordinary cattle trypanosomes, such as *T. pecorum*, *T. nanum*, and *T. vivax*, with which the wild *Glossina morsitans* is heavily infected; so that it is obvious that domestic stock cannot have the same significance as a reservoir of the infection as the antelope, which are tolerant of the trypanosomes pathogenic to man and domestic stock.

The hypothesis that human beings can harbour the parasites for long periods without detriment to health, and thus act as reservoirs of the virus in the same way as the game, is one which I cannot support. Amongst the cases discovered by us several—presumably recently infected—presented practically no symptoms, the only indication of the disease being the presence of trypanosomes in the blood, yet without exception they were all dead within six months.

We return, therefore, to the original position. The game is the natural reservoir of the infection; the part of the tsetse fly, *Glossina morsitans*, is to transfer the virus from the big game to man and his flocks and herds. At the present state of our knowledge we are unable to attack successfully the tsetse fly, nor, unfortunately, is there any prospect of our being able to do so in the near future.

Whether anything would be gained in this direction by slaughtering the big game is still a moot point, therefore I will not consider this side of the question, but advocate the advisability of attempting to drive back the game from inhabited regions solely because the game are the reservoir of the infection.

I might point out here that whether or not other flies, besides *Glossina morsitans*, be proved eventually to transmit the human trypanosome, does not affect the question, further than that, if this be shown to be the case, it simply emphasizes the difficulty of successfully attacking the transmitting agents and demonstrates clearly that if anything is to be done it must be in the direction of destroying the reservoir from which *Glossina morsitans* and the other (hypothetical) vectors derive their infection.

It has been asserted that the proposal to slaughter all game animals in an infected district is unsound in principle, because the game when harried would betake itself to places difficult of access to man or scatter in small herds or in pairs or singly over wide areas, and that should this occur it is highly probable that it might be followed by tsetse, thus spreading the danger of infection to wide areas now free from game and fly.

To such criticism as this it is not difficult to reply. If the game when harassed betook itself to places difficult of access to man, surely this is exactly what is desired. In such places it would no longer be a menace to civilization.

Regarding the second alternative, that the hunted game might scatter into small herds or in pairs and be followed by the tsetse fly, thus spreading the infection over large districts, the obvious rejoinder is that should this occur the game must be destroyed in the new areas, provided these happen to be inhabited regions. Such a contingency is, however, very unlikely, as it is very questionable if small herds of hunted game scattering over wide areas would cause the tsetse fly to migrate with them.

The Colonial Secretary has said that "To talk of the extermination of the wild fauna of a subcontinent is to talk wild nonsense." This is perfectly true, but it is no reason why the game in a definite limited area should not be destroyed. It was further stated that an attempt made in Nyasaland to get the game in a certain area killed off was, after twelve months, unsuccessful, though the natives

were encouraged to shoot. This, again, is no argument against the policy suggested, but merely a confession that the experiment was not efficiently performed.

Such experiments as these are unsatisfactory and do not yield any definite results. For reliable information to be obtained it is necessary that the work should be done in a scientific manner, and on a sufficiently large scale in some particular district. A locality which is fairly well populated, and which contains plenty of tsetse fly and game should be chosen. An exact census of the population should be made, and the proportion suffering from trypanosomiasis determined. The same must be done in the case of the domestic animals, if such exist. An index of the percentage of infective tsetse fly must be ascertained. This is most important, as it gives a definite idea of the potential danger of the district. Finally, the game must be completely eradicated, and at the same time the percentage infected with the human and cattle trypanosomes determined, and when once the game has been driven out it must be kept back by vigorous action and not allowed to return. After an interval of some years the population, domestic stock, and tsetse fly must again be carefully examined. Then we should be in a position to decide definitely whether or not driving the wild fauna back from the sites of human habitations in fly areas would be advantageous on a general scale in tropical Africa. As such an experiment as this would take some years to accomplish, I consider that for the present the game laws should be removed in fly areas, and that Europeans and natives should be allowed to kill what they like, especially in the inhabited portions of these areas.

Recently sleeping sickness was discovered in a certain isolated fly belt—the Sebungwe district of Southern Rhodesia—which is roughly about 2,500 square miles in size. On a hurried survey some twelve cases of the disease were found, including one European. The human trypanosome was also found in certain of the antelope in the area. It has been said that the proper way to deal with the situation is to remove the entire population from the fly belt. This at first sight appears an admirable plan, and will certainly save the inhabitants. Is there, however, not another side to the question? When the population is withdrawn there will be established all the conditions of a game reserve. The wild animals will increase and gradually spread and probably with them the fly, until the invasion of surrounding districts demands further removals. Surely it is preferable to make a reasonable attempt to stamp out the disease than at the first alarm to abandon such regions to the game and fly without even attempting to dispute the ground with them.

It is for such reasons as these that I venture to suggest the desirability of undertaking the decisive experiment which I have outlined, as it is only by this means that the exact knowledge necessary for our future guidance can be acquired.

A BILL, making insurance against disease and invalidity compulsory in Belgium, was presented to the Chamber some time ago by the Government. The organization of the service will be confided to the mutual aid societies, to recognized federations, and to mutualist local committees. The State and the employers will contribute, but in a less proportion than those directly interested. The insured will have a right to medical treatment and to a supply of such medicines as may be required; they will also receive one franc a day, starting from the tenth day of illness onwards. Permanent invalids will be pensioned. The maternity benefit will be thirty francs. The annual tax for non-members of mutual aid societies will be eighteen francs, of which twelve will be allocated for disease, and six for invalidity.

PRELIMINARY REPORT ON AN OUTBREAK OF FEBRILE DISEASE IN AN INDUSTRIAL SCHOOL.

By K. M. DUNCAN, M.B. GLASG., F.R.C.S. ENG.,

MEDICAL OFFICER, ST. THOMAS'S INDUSTRIAL SCHOOL; HONORARY ASSISTANT SURGEON, PRESTON ROYAL INFIRMARY.

THE cases which form the subject of this communication occurred during the years 1910 and 1911 in St. Thomas's Industrial School, Preston. I have not been able, so far, to complete the investigation to my satisfaction, and hence have delayed recording the cases. At the time when the epidemic terminated I had the strong suspicion that there was a "carrier" in the school. There has not been a chance of clearing up this point since 1911, but on reading the full and careful report by Drs. McGowan and McNeil on a somewhat similar epidemic which occurred in Tranent Industrial School, and was referred to in a note in the *BRITISH MEDICAL JOURNAL* of May 31st, p. 1178, I thought I might place my experience of an unusual series of cases before the profession.

Clinical Description.

The clinical description of the epidemic in the Preston school tallies exactly with that in the Tranent and other schools, noted in the report mentioned. To put it as briefly as possible, we had to deal with an illness of sudden onset, marked by headache, epigastric pain, vomiting in mild cases of undigested food, but in severe cases of large quantities of a distinctly greenish or yellowish fluid, accompanied in some cases by intense prostration, a temperature varying from normal to 105°, by herpes labialis in a certain proportion, and in 5 cases by definite consolidation at the base of the lungs. In the very worst cases there was a true septicaemic condition. Three of the boys were found dead in bed, having retired apparently well the previous evening; four others died within twenty-four hours of the onset of headache or vomiting. It will be noticed that only five of my cases developed any definite pneumonic condition, although over 80 boys attacked were carefully examined by me.

Post-mortem Findings.

At the first *post-mortem* examination made the thyroid and thymus were greatly enlarged, the spleen was slightly enlarged but otherwise normal, and Peyer's patches and mesenteric glands were very pronounced. The lungs were congested but crepitant. Dr. Delépine examined the stomach contents for traces of poison, with a negative result. In the second *post-mortem* examination a similar enlargement of the lymphoid structures was found, with marked congestion at the bases of both lungs, but no actual hepatization. At the third and fourth *post-mortem* examinations similar appearances were found. In neither case could I definitely make up my mind that the lungs showed anything beyond hypostatic congestion, nor were the thyroid and thymus so much enlarged as in the first two cases.

I was able to satisfy the coroner's jury in each case by declaring that I considered the deaths due to a pneumococcal or influenzal poison epidemic in the school, and acting virulently on boys suffering from status lymphaticus. I did not feel satisfied, though I thought I was on pretty good ground, as I knew that three of my teachers—the late Sir William Gairdner, the late Dr. Finlayson, and the late Professor Gemmill—had reported on what seemed to be an exactly similar series of cases occurring in a school in Glasgow in 1888, when the diagnoses severally made were malignant influenza, abortive pneumonia, and pneumonia complicating some unknown intoxication.

At the next *post-mortem* examination the findings were so like what I have seen in an early case of enteric fever that I thought it probable there might be some intestinal poison at work. The Peyer's patches and solitary follicles were distinctly congested and enlarged, and the corresponding mesenteric glands varied from the size of a bean to the size of a walnut and were much congested. The spleen was enlarged and soft. The thymus was only slightly enlarged. The thyroid was enlarged and dotted with pin-point abscesses. Loops of bile, punctures from the spleen, scrapings from the mesenteric glands and

Peyer's patches and from the pin-point abscesses in the thyroid were inoculated into bouillon. I consulted my friend, Dr. J. J. Buchan, M.O.H. St. Helens, who suggested to me that I should try the agglutinating reactions of serum from boys suffering from the disease with the different strains of intestinal bacilli which he had in his laboratory. Dr. Buchan has my sincerest thanks, as, but for the use of his laboratory and materials and the fact that he corroborated and checked my results, I could not have continued the investigations.

Bacteriological Results.

From the spleen, Peyer's patches, mesenteric glands, abscesses in the thyroid, and from the faeces in two cases, a bacillus was obtained which was actively motile. The growth on agar gave the usual *coli*-typhoid appearance. The bacillus was negative to Gram, did not produce indol, did not clot litmus milk. On Conradi-Drigalski plates bluish colonies, much smaller than the red colonies of *Bacillus coli* used as a control, and on picric acid green and McConkey's bile salt media colonies quite distinct from the *Bacillus coli* colonies were grown.

Agglutination Results.

Briefly, the *Bacillus coli*, typhoid bacillus, and Gaertner's bacillus were excluded at once, as even after two hours in a dilution of 1 to 50 there was no agglutination with blood taken from boys who were ill. The laboratory paratyphoid B and the laboratory aertrycke bacillus agglutinated the same serum in dilutions of 1 to 50 almost immediately and 1 to 100 in a few minutes. Some of the specimens taken from boys who had recovered from the disease for some time agglutinated the laboratory paratyphoid B bacillus, but not the laboratory aertrycke bacillus. The bacillus cultivated from the *post-mortem* examination was negative to a case of typhoid, but agglutinated each blood that was positive to the laboratory paratyphoid B.

Whether the bacillus isolated is actually the paratyphoid B or not, there can be no doubt it is closely related to that organism, as it gave similar cultural reactions, and agglutinated the same bloods. Each boy who was ill was positive both to the paratyphoid B and the bacillus isolated. Some of the boys who had not been ill gave negative reactions to both, though some gave positive reactions. Some of these latter admitted having had "the headache," which even in the case of boys who had been evidently affected was almost all that could be obtained in the way of complaint.

The question of the presence of a "carrier" in the school was considered seriously, but the demands of a general practice debarred me from systematically testing the blood of each boy. However, the last *post-mortem* examination I did inclined me more than ever to this idea, though I was not, unfortunately, able to make any further progress in the investigation. The liver in this case was a beautiful specimen of hobnailed cirrhosis. The boy was aged 12, there was no history or suspicion of syphilis. He died after a few hours' illness, but had had an attack of great severity about six months before. It seemed quite a plausible inference that there had been some chronic absorption from the bowel producing cirrhosis of the liver.

I think, then, that this epidemic deserves to be placed alongside of the other recorded epidemics. The descriptions of these resemble the Preston epidemic just as closely as they resemble the Tranent one; and the mere fact that in this latter epidemic the infective agent was the pneumococcus, in view of the atypical form of pneumonia that is present in these epidemics, does not warrant the conclusion that all such outbreaks are due to abortive pneumonia. The diagnosis of the late Professor Gemmell showed his superlative powers as a clinician when he wrote in 1888, "They seemed all to be victims of the same poison, although, in some, owing probably to personal idiosyncrasy, aided by favourable atmospheric conditions, it issued in pneumonia."

The epidemic at Birkdale Farm School, reported on by Dr. Coupland, though diagnosed as pneumonia, was not due to the pneumococcus. It is over two years since I read the report, and I am writing from memory, but I think the organism was said to be a motile bacillus. In this connexion it is interesting to recall the epidemic of

pneumonia in Middlesbrough in 1888, investigated by Dr. Ballard and Professor Klein. There were over 1,600 cases, with more than 300 deaths. According to Professor Klein, the germ at work was a motile bacillus, and from the description of the cultural appearances of this organism on gelatine, given in the *Treatise on Hygiene*, by Stevenson and Murphy, the appearances resembled more those of the *coli*-typhoid group than the pneumococcus. It is also of interest to recall the observation that bacon bought in the infected districts gave rise to pneumonia in mice fed upon it. Considering that paratyphoid B belongs to the meat-poisoning group, this fact may be of importance. However, I made nothing of my investigations in this direction in the Preston cases.

In view of the positive finding of the pneumococcus in the Tranent epidemic and the positive finding of a bacillus of the *coli*-typhoid group in the Preston epidemic, I think the search for a solution of the problem may well continue. It is only too likely that a chance for further investigation will present itself before long, considering the histories of the industrial schools of the country. I am, however, not sure that this type of disease is limited to the inmates of these institutions, as I cannot help being struck with the frequency with which at coroners' inquiries, deaths from acute conditions of a few hours' duration are returned as deaths from acute pneumonia. It seems to me possible that there are toxæmias of alimentary origin masquerading up and down the country as malignant influenza, gastric influenza, and fulminant pneumonia, in addition to the undoubted diseases of these names. It is in the hope that some one with sufficient time, and the fortune to meet cases of this class, may still further investigate the subject, and to keep the question of the naming of the disease open till we have further knowledge, that I have written this communication.

NOTES OF A CASE OF "NODULAR LEUKAEMIA."

BY

ROBERT REID, M.D.,

PHYSICIAN TO THE THRONE HOSPITALS, BELFAST;

WILLIAM CALWELL, M.D.,

PHYSICIAN TO THE ROYAL VICTORIA HOSPITAL AND CONSULTING PHYSICIAN TO THE THRONE CONSUMPTIVE HOSPITAL;

AND

W. W. D. THOMSON, M.B.,

RIDDEL DEMONSTRATOR OF PATHOLOGY, QUEEN'S UNIVERSITY, BELFAST.

G. M., a boy aged 10, was seen by Dr. Reid, on November 2nd, 1912, for pain in his right hip and leg. As no improvement followed rest in bed, Dr. Reid admitted him to the Throne Children's Hospital on November 13th. The pain closely resembled that of right hip-joint disease, and splints were applied; but the pain soon developed in the other side. On December 8th enlarged glands were found below the left lower jaw; some teeth were loose and were removed. Within a few days a swelling appeared above the right zygoma, and subsequently above the left, and later in the groins. He was rapidly losing flesh, but there were as yet no head symptoms.

On December 15th there was loss of vision in the right eye and later in the left, and slight proptosis. Some spinal fluid was withdrawn by Mr. Stevenson and examined by Dr. Thomson. On December 27th he was seen also by Dr. Calwell and Dr. Thomson, and at this date his condition was much worse; he was only partially conscious; he did what he was told if he was given time; his answers were fairly intelligent, but delayed, and were chiefly in monosyllables; there were large symmetrical swellings above each zygoma, and the proptosis was more marked; there were sordes on the lips; the abdomen was full and tender; it was examined with difficulty, but no enlargement of liver, spleen, or kidney was detected; all the lymphatic glands—cervical, axillary, inguinal—were enlarged and shotty; on the skin generally, and on that of the abdomen in particular, there were palpable minute millet-seed-like nodules; there was some head retraction, well-marked Kernig's sign, and priapism; he was now blind, and later became deaf; there was also paralysis of

both lower extremities with anaesthesia, and unconscious action of both bowels and bladder; flexion of legs caused pain; one optic disc presented some neuritis, the other was clear. There was also epistaxis a day or so before death. The temperature varied from 98° F. to 100° F., but on December 26th it began to be sharply intermittent, and reached 104° F. on January 1st; it was subnormal before death, which took place on January 3rd. Unfortunately a photograph was not obtained nor a *post-mortem* examination allowed.

REPORT BY DR. THOMSON.

The spinal fluid sent to me was so haemorrhagic that a cytological examination was of no value; a slight growth on agar was due to a staphylococcus, and as it was not again discovered it was probably a contamination.

At a subsequent examination of the patient on December 27th the following results were obtained:

Blood.—The coagulability was delayed; the serum showed distinct lipaemia; fat was extracted from it.

| | | | |
|-----------------------|-----|-----|---------------------|
| Red cells | ... | ... | 2,800,000 per c.mm. |
| Haemoglobin | ... | ... | 55 per cent. |
| Colour index | ... | ... | 1 (practically). |
| White cells | ... | ... | 5,640 per c.mm. |
| Differential count: | | | |
| Polymorphonuclears... | ... | ... | 12 per cent. |
| Large lymphocytes | ... | ... | 49 " |
| Small lymphocytes | ... | ... | 17 " |
| Transitional | ... | ... | 12 " |
| Myelocytes | ... | ... | 10 " |

There was no poikilocytosis; no nucleated reds were found and no chromatophilia.

A blood culture gave a negative result.

Urine.—No albumen. No sugar, no Bence-Jones's substance. Nucleo-proteins were present in rather increased amount.

Lumbar Puncture made by Dr. Thomson. —The fluid escaped at high pressure and again seemed almost like pure blood; fat was again present in large amount in the serum; a culture gave a negative result.

It was intended to confirm or modify these results of the physical examination and of the blood count by repeated similar investigations, but the rapid course of the disease prevented the accomplishment.

REMARKS BY DR. CALWELL.

Although these notes are not complete, we thought the case of sufficient importance to warrant us in putting on record such facts as we have. There seems to be little doubt that it falls under the broad category of "nodular leukaemia," as described by Dr. Gordon Ward in the Section of Medicine of the Royal Society of Medicine in 1912, and in type it most closely resembles "chloroma." The zygomatic swellings were marked; the early pain in the hip and leg, which finally developed into paraplegia, was presumably due to analogous deposit in the spinal column, and such a deposit would no doubt account for the deeply blood-stained fluid removed on both the occasions of lumbar puncture. The blindness, the deafness, the priapism, are all classical symptoms; the rapid course of the affection was in keeping with the diagnosis.

The result of the blood examination shows a remarkable smallness of white blood count; whether this paucity would have been found to be a constant factor on further examination cannot be argued; such a number has been found, and enormous rises and falls in the white blood count have been put on record by most authorities; in one case it is given as 800 per c.mm. The differential count is also interesting; the great increase of large lymphocytes and the presence of a considerable number of myelocytes is characteristic. Galland and others say that the blood picture in leukaemia is by no means constant; so that the blood examination in this case confirms what has been already so often noticed, that neither in number or character of the red, nor in differential count of the white, have we a definite and final arbiter in the subclassification. In this case, however, the blood count sharply differentiates it from the series of cases given by Robert Hutchison, in the first number of the *Quarterly Journal of Medicine*, of suprarenal sarcoma in children with metastases in the skull, in which temporal swellings were present; but a blood count showed a simple marked secondary anaemia. Frew, however, in a later number endeavours to prove that such cases come under the term "carcinoma," and gives details of cases in which the

differential count shows a very marked disturbance; such cases would widen the boundaries still further.

The usual conception of "leukaemia" rests on the differential count of the white corpuscles: in the acute form there is an excess of lymphocytes and profound constitutional disturbance, and often an early fatal issue; in the chronic or marrow form, symptoms are frequently delayed till late in the course of the disease, and we find an excess of myelocytes. In his paper Dr. Gordon Ward describes "nodular leukaemia" as embracing all cases of leukaemia in which nodules of leukaemic growth have been found in various parts of the body, and have been obvious to sight or inference during life. It is purely a clinical term. He mentions a great variety of titles, such as mycosis fungoides, chloroma, Mikulicz's disease, and others, and points out that lately facts have come to light which, apparently, link the affections described under these names closely together: cases of mycosis fungoides occur with a blood picture of leukaemia; cases of leukaemia occur in which nodules indistinguishable from those of mycosis fungoides have developed; similar nodules are found in chloroma; the green colour of chloroma may be present only in a minority of skull tumours, and may be found in the glands and marrow of leukaemia in which there were no tumours.

Whether we can rope in all the affections enumerated by Dr. Gordon Ward, and also by Dr. Treadgold,¹ is a matter for future investigation. We can distinguish the leukaemias from even extreme cases of leucocytosis, and also from cases of pure sarcomatosis; the blood picture, however, varies, not only in different patients, but also in the same patient from time to time; probably these differences are due to the type of cell becoming more and more primitive. "The variety and severity of the affection," says Treadgold, "varies with the part of the haemopoietic apparatus affected, with the intensity of the stimulus, and with the ability of the organism to withstand it." And one has thorough sympathy with him in his complaint regarding the cumbersome terminology that is suggested in each new article.

It might be considered more correct to use the term "infiltrating leukaemia" and not "nodular"; the collections of cells are not always circumscribed; oedematous infiltration may be found about the face, neck, scalp, and this may at times have a greenish colour; definite nodules of fair consistency are most common in the bones, especially those of the skull, but have also been found in the pelvis and vertebral column; they may occur also in the skin and subcutaneous tissue—indeed, wherever lymphoid tissue is found. The nodules vary in size, from that of a pin's head to that of a fist. They do not occur in the epidermis, but may ulcerate through it. The colour varies from that of the surrounding skin to yellow, red, purple, greenish. Minute nodules are found on the gums and in the submucous tissue of the alimentary tract. Parkes Weber points out that the pre-mycotic infiltration of mycosis fungoides may be sufficient to make the skin fall in rolls, and that this affection corresponds to Kaposi's lymphodermia perniciosa.

The more constant employment of the oxydase reaction, as described by Dunn in the April number of the *Quarterly Journal of Medicine*, 1913, may in future prove of service. His conclusions state that the occurrence of a positive indophenol-oxydase reaction in large non-granular cells in acute leukaemia is a certain proof of their myeloid nature, and enables a diagnosis of acute myeloid leukaemia to be readily made from blood examination; but that the reaction is negative in the more embryonic forms of marrow cells; cases of acute myeloid leukaemia may occur, in which the type of blood formation is so embryonic that the oxydase reaction is valueless for differential diagnosis; but even in such cases the histological characters of the large leucocytes may render a diagnosis possible. It seems, however, thus to fail us just where it would have been of great service—namely, the origin of the embryonic type of white cell.

A CASE ILLUSTRATING GREAT TENACITY OF LIFE.

By A. TURNBULL, M.B., CH.B. GLASG.,

DEMONSTRATOR OF ANATOMY IN THE UNIVERSITY OF GLASGOW.

THE case of the French Zouave who lived for some time after practically the whole of the head except the brain had been removed by a cannon ball is one of the classical instances of tenacity to life. Weinelchner in 1881 reported that a man had lived and been conscious for twelve hours after a fall and injuries which included fracture of the cervical spine, with laceration of the cord, paralysis (motor and sensory) of all the limbs, rupture of the sternum, bleeding into pericardial and abdominal cavities, and laceration of the spleen. Erichsen (*Lancet*, 1870) reported on a man who, after leaping a distance of 60 ft. down a hoist, lived for ten days, although suffering from (1) fracture of seven ribs; (2) perforation of the apex of the right lung; (3) tearing of the pericardium; (4) complete fracture of first lumbar vertebra; (5) pulverization of the right os calcis.

Mr. D'Arcy Power read a paper in 1890 to the Pathological Society of London, indicating that considerable laceration can take place in the spleen and in the kidney with very slight symptoms, unless a large blood vessel is implicated.

If urgent haemorrhage does not immediately follow injury, the most extreme internal injuries can often be undergone with a minimum manifestation of shock. The following case will bear this statement out, and emphatically illustrates the powers of tenacity of life in the human frame:

P. H., a dock labourer aged 45, was admitted on December 31st, 1909, to the Western Infirmary, Glasgow, about 9 p.m. About noon on the same day he had fallen down the hold of a ship, but details of the accident were not forthcoming. For some time after the accident he remained in a dazed condition. He then recovered sufficiently to walk home, a distance of half a mile at least.

He went to bed, but began to experience increasing pain in the left chest and side, especially over the lower ribs. A doctor was called in, and recommended that he should be conveyed to hospital, but thought so lightly of the condition that he held out hopes of the patient's speedy dismissal. There was some delay in the arrival of an ambulance, and the man was *in extremis* on his arrival in hospital. In the afternoon, according to the statement of the relatives, he had passed "a bowelful" of red blood from the rectum.

On admission no external marks of injury were visible except a cut over and some bruising of the left eye. Yet the patient was suffering from great shock; he was semi-delirious and extremely blanched, the lips and mucous membrane being livid white. The pupils were dilated and equal, and no sign of fracture of the skull could be recognized. If there had been epistaxis it had ceased prior to admission, and there was no bleeding from the ears. There was no marked abdominal distension, but tenderness was elicited on pressure on the abdomen and on the left chest. Some dullness existed in the left iliac and lumbar regions. He could both move his legs and feet, and there were no symptoms of injury to the spinal cord.

The patient rapidly sank into unconsciousness, and died with symptoms pointing to internal haemorrhage about an hour after admission.

Necropsy.

A *post-mortem* examination was made by Dr. Robert Muir, Professor of Pathology in Glasgow University, to whom I am indebted for the following report:

A well-developed muscular man, with rigor mortis still present. There was a fresh ecchymosis of the left eyelids, but no subconjunctival haemorrhage. A small fresh incised wound, 1½ in. long, was found over the left supraorbital ridge. There was no external evidence of injury to trunk.

Head.—A fracture of the frontal bone is found extending down on the left side to the inner end of the supraorbital ridge. This part measures 2½ in., and has a small offshoot on either side. On the base of the skull the fracture is traced along the left orbital plate and across the sella turcica to the right middle fossa, ending just above the base of the petrous bone on the right side. A slight diffuse subarachnoid haemorrhage is present, especially over the posterior part of the right parietal lobe. No gross lesions in brain or pons.

Thorax.—A fracture is found through the first left costal cartilage near the sternum, and some tearing up of the sterno-clavicular ligaments and fibro-plate; no actual dislocation. The second, third, fourth, fifth, and sixth ribs are broken through about their middles. The parietal pleura is torn over the broken ends of the third and fourth ribs, and 6 oz. of blood is found in the left pleural sac. The eleventh rib is fractured towards the exterior end. Both lungs oedematous, otherwise healthy; no perforation of left lung, only slight bruising. Heart fairly normal.

Abdomen.—Two pints of fresh blood are found in the abdominal cavity. The spleen is extensively lacerated. There is much haemorrhage into the connective tissue round the left kidney and suprarenal. The left kidney is markedly crushed and lacerated. The right kidney is uninjured, as also is the liver. The oesophagus, stomach, and intestine are uninjured. No blood in the rectal faeces and no injury to the bladder. No injuries to the testes or column.

This man, therefore, walked half a mile after receiving:

1. A fractured skull.
2. Extensive fractures of the ribs.
3. Pulping of the spleen.
4. Pulping of the kidney and lesions in the vicinity of the solar plexus.

The bowlful of blood had probably been passed by the urethra from the ruptured kidney.

He was a tall and powerful man, but to achieve the above feat showed a retentive tenacity above the ordinary. It is seldom that such an extraordinary case is met with, and therefore it was deemed desirable to report it.

THE INFLUENCE OF MARIENBAD SULPHATE WATER ON ALBUMINURIA.

By MAX PORGES, M.D.,

MARIENBAD.

ALTHOUGH our ideas of the importance of albumen and casts in the urine have materially changed during the past decade, yet their presence must still be considered a fact of pathological moment. We know also that there are a number of pathological states in which the kidneys show a defect of function producing a temporary appearance of albumen and casts.

For many years I have been impressed with the fact that the presence of albumen with or without casts is very constant among the patients who come to Marienbad. The same observation has been published already by Dr. Zörkendörfer, director of the Balneological Institute,¹ who found either albumen or casts in 80 per cent. of his patients. Pfanz,² who has published cases that have been for a long time under observation, likewise draws attention to the frequency of this phenomenon.

The patients who are seen in Marienbad may be classed for the most part in four groups: (1) The obese; (2) the arterio-sclerotic; (3) those of the gouty-rheumatic diathesis; and (4) the plethoric.

If we analyse these cases the fact emerges that it is in the class of plethorics, and more particularly in those affected with plethora abdominalis, that albuminuria and casts make their appearance in the largest percentage. The arthritic and the gouty appear to be also subject to this kind of albuminuria.

Furthermore we have observed that this form of albuminuria with casts is very favourably influenced by the use of sulphate waters. In those cases in which there was well-established chronic nephritis, with rise in blood pressure, uraemic symptoms, and cardiac hypertrophy, it was scarcely possible to point to any favourable influence; on the other hand, we must be especially careful to avoid overburdening the heart by the use of mineral waters. But when the albuminuria is a symptom of disturbance in renal circulation, the unloading of the abdominal vessels will manifestly exercise a favourable influence on the nephritis, and consequently on the albuminuria.

In these cases it is generally a question of individuals who lead a sedentary life, are frequently overfed, often give the impression that their abdominal circulation is disturbed, and frequently suffer from haemorrhoids. There is often also constipation; nevertheless this is certainly not the reason for the albuminuria, as one could assume it *a priori* to be a symptom of enteric auto-intoxication.³ Indeed, in a whole series of these cases not only is there no constipation, but rather frequent evacuation of stools, and even diarrhoea, existing as a symptom of intestinal catarrh due to this stasis. These patients generally exhibit a much distended abdomen, with symptoms of meteorism; the diaphragm is raised, and there is the characteristic displacement in the area of cardiac dullness described by Schütz.⁴ The subjective symptoms consist in a feeling of plethora after meals, severe flatulence, and

a slight dyspnoea on exertion. The quantities of albumen vary between mere traces and 0.5 per cent., and the cylinders from two to fifteen in a specimen.

After using sulphate water for three or four weeks both the albumen and the cylinders disappear completely, and at the same time the symptoms of plethora are removed. The course is an equally favourable one in the case of a combination of arthritis and gout with abdominal plethora. If the patient becomes exposed to the old injurious influences after the albuminuria has gone, there is a fresh onset, after some time, of the excretion of albumen and cylinders, but this promptly disappears if the sulphate water be taken afresh. I have had this typical condition under observation in a patient for sixteen years, without so far any permanent mischief resulting to the kidneys.

In spite of the fact that the albuminuria and cylindruria taken by themselves in subjects of plethora do not, in my opinion, represent any serious pathological factor, it is nevertheless important to abolish the abdominal circulatory disturbance in good time by the aid of sulphate waters, as permanent mischief to the kidneys is certainly likely to result from the onset of injurious influences coming from some other quarter.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THREE CASES OF ECLAMPSIA.

CASE I.—In June, 1906, I was called at 9 p.m. to Mrs. L., aged 39, about two miles in the country, for her fourth confinement. On arrival I found the child (a small girl, about eight and a half months) born, and the afterbirth just come away. There was no trouble with the labour. On putting the binder on, I was struck with the swelling of the legs, which seemed more than is frequently found in hard-working multipara. She told me they had been big for some time. She had had three natural confinements previously and three miscarriages. She had diarrhoea all the day the baby was born.

Next morning she complained of feeling sick and not sleeping. The oedema of the legs was less, but the face looked puffy. She had passed a fair amount of urine. The husband came to me in the evening and said she was better, but feeling sick still. I gave her a mixture with some bromide. I was called at 5 a.m. and found her unconscious, face flushed and puffy, pulse 120 and bounding. She had had fits at 9 p.m., 2 a.m., and 5 a.m. I gave her some chloroform and gr. $\frac{1}{2}$ of morphine, which quieted her. I left about an hour later, but was called again almost at once to hear that she had had another very bad fit. I gave gr. $\frac{1}{2}$ morphine, which caused a severe fit. I also gave 20 grains of chloral and potassium bromide by the rectum and drew off some urine, which was nearly solid with albumen. She had four fits during the day, and could not be roused at all. She had a succession of fits from 1.30 a.m. to 2.30 a.m., gradually became weaker, and died at 1 p.m.

CASE II.—I was called to a primipara, aged 24, at 7 a.m. on February 27th, 1909. She had fits at 6 a.m., 6.30, 7, 7.30, 7.45, 8.15, 11.20, 11.45, and 2.30. I gave her morphine gr. $\frac{1}{2}$ at once. At 9 a.m., under chloroform, I dilated the os with Hegar's dilators, and put in a Barnes's bag. At noon I removed the bag, under chloroform, got my hand in the vagina, and dilated the os with the fingers. I then passed a sound, punctured the membranes, seized a leg, and delivered. The baby weighed 3 $\frac{1}{2}$ lb., and did not live long. At 3 p.m. I gave her gr. iij of calomel and mj of erofou oil. She had severe fits at 5 p.m. and 7 p.m., when I again gave morphine gr. $\frac{1}{2}$. She had a good night and no more fits. Next day she passed water freely, and gradually convalesced.

CASE III.—The patient was a primipara, aged 26, living about four miles away over the downs, to which I could only walk as there is no road. The confinement—on February 8th, 1913—was normal. Low forceps were

used and a few whiffs of chloroform given. This was at 10 a.m. I was called back at 2 p.m. and found the patient quite unconscious. From her mother's description she had evidently had a fit. I gave her morphine gr. $\frac{1}{2}$, and injected two pints of saline under the breasts; her pulse was 120. Next morning she was in the same condition except that she was paralysed down the left side. What little urine was in the bladder was full of albumen. She gradually became more feeble, and died early the next morning. The mother told me that her daughter had been quite well whilst carrying but her feet had been slightly swollen.

It used to be taught that eclampsia coming on after labour was usually mild and the patient mostly recovered. With me the opposite has been the case. Possibly in a hospital, with all the latest treatment at hand, they might have recovered, but I am rather doubtful of it. It is very difficult to have to treat a serious case several miles from home over the downs with only the next-door neighbour as midwife.

APPENDICITIS COMPLICATING EXTRAUTERINE PREGNANCY.

On September 19th, 1912, I was called to see a married woman, aged 23, complaining of pain and swelling in the left iliac region, which two days previously had been sufficiently acute to make her faint. She looked pale; temperature normal, pulse 102, respirations 18 per minute. Great tenderness and a distinct swelling in the left iliac region fully an inch above Poupert's ligament. Menstruation had been regular, but at her usual period three weeks before it had been scant, and she had continued to see a little every day. Micturition had been more frequent and accompanied by pain, as was also every movement of the bowels. The breasts were fuller than usual, and a drop of clear fluid could easily be expressed from the nipple.

The previous history showed that the pain had existed for at least twelve months, lasting a few days at a time and then disappearing for some weeks, but she was always conscious of discomfort in that region. This was aggravated by taking food and when the bowels were moved. She had lost flesh. Vaginal examination revealed a large firm swelling in Douglas's pouch, extending into the left broad ligament, with great tenderness in that region. An early abortion was diagnosed, and the pain and swelling on the left side regarded as inflammatory.

She was kept in bed, and the pain became easier and the metrorrhagia lessened; but on September 24th she had another attack of severe pain, and when I saw her next morning the pulse was 120 per minute, temperature subnormal, and the discharge profuse and offensive. The following day the uterus was curetted under an anaesthetic. No membrane was seen, but the discharge ceased. The pain and swelling, however, persisted, and four days after the curetting milk could be expressed from the breasts. A diagnosis of extrauterine pregnancy was then finally adopted. Hence on October 3rd I opened the abdomen through the inner border of the left rectus and found in the swelling not only the expected sac, but also the appendix and a loop of small bowel, these both being inflamed. There was also a large clot of blood. I completed the operation by removing the sac, the left Fallopian tube, the appendix, and the clot, and by stitching up the loop of bowel, which had been slightly torn in separating it. The patient made an uneventful recovery.

What had happened was that an old-standing appendicitis (the appendix extending to the left side) had set up an inflammation and formed adhesions round the left broad ligament. An extrauterine pregnancy had then taken place in the Fallopian tube on the left side, and had ruptured about six weeks, causing the collapse and swelling from the resultant haemorrhage, which was limited by the adhesions formed as a result of the appendicitis.

The condition of the tissue, especially the friability of the broad ligament, added to the difficulty of the operation, more particularly with regard to the vessels. The sickness (which resembled the sickness of pregnancy after the

curetting, and persisted until the second operation) disappeared immediately afterwards, as did also the milk from the breasts.

Dr. Findlay examined the case and gave the anaesthetic on both occasions at the patient's home.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

TAUNTON AND SOMERSET HOSPITAL.

A CASE OF CARCINOMA OF THE DESCENDING COLON IN A MAN AGED 27.

(By CHAS. FARRANT, Surgeon to the Hospital.)

W. C. S., a baker by trade, and a heavy eater and drinker, was first seen by Dr. Aleock, of Creech St. Michael, on February 7th, complaining of pains in the stomach and sickness—chiefly in the morning—and loss of appetite. The bowels were not confined.

He improved under a mixture containing bismuth and soda until February 16th, when he complained of a return of the pains, which were severe, he said, all day. He vomited milk, but retained beef-tea and broth. His tongue was very dirty. There was some slight abdominal tenderness and a little distension. His temperature was normal. The bowels acted at 10 p.m. He had a bad night, with pain and sickness, and on the following morning his tongue was dirty, and the distension had increased. He was given an enema which brought away a few scybala and much flatus: this was followed by great relief. On February 18th and 19th he was better; there was not so much distension, and not so much vomiting.

On February 20th he was admitted to hospital on Dr. Aleock's advice. He vomited some green mucus, which had no faecal smell. He did not look ill; the tongue was dry, and the abdomen moderately distended. There was no tenderness or rigidity. Repeated enemata brought away some scybala and much flatus, and the distension was diminished.

For the next few days he remained very much the same. The bowels were kept open with enemata, and there was no increase of distension.

On February 24th, as there was no improvement in his condition, he was anaesthetized and examined with the sigmoidoscope, but nothing was found.

The abdomen was then opened to the left of the middle line by an incision about 4 in. long, with its centre below the umbilicus. A constriction was found in the descending colon. The wound was enlarged, and an attempt made to bring the affected gut outside, when unfortunately it burst just above the constriction, causing an escape of faeces. The hole was quickly clamped and everything mopped clean. The mesentery was then perforated and two pairs of intestinal clamps applied above and below the growth, which was then removed. An end-to-end anastomosis was made and the abdomen closed.

The patient left the table in a very feeble state, and, never rallying from the operation, died three hours after.

The growth was flat, about the size of a florin, with a depressed centre and thickened rolled edges. A piece was removed and examined by the Clinical Research Association, which reported as follows:

This growth is a columnar-celled carcinoma composed of very irregular alveoli lined by proliferating columnar epithelium. These are infiltrating the submucous and muscle coats, and contrast very clearly with the normal mucous membrane.

On May 6th Dr. Woodrow Wilson, President of the United States of America, received a representative joint delegation from the American Medical Association and a Committee on the Conservation of Health of the American Academy of Sciences, which urged the expediency of the establishment of a Cabinet department of public health. The delegation consisted of Professor Irving Fisher, Dr. A. Jacobi, Dr. G. H. Simmons, Dr. Harvey W. Wyley, Dr. Favill, and Dr. John B. Murphy.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

At a meeting on June 5th, Dr. AMAND ROUTH, President, in the chair, Dr. R. H. PARAMORE, in a paper on the *Intra-abdominal pressure in pregnancy*, said that his measurement of the pressure in the rectum in 24 cases of pregnancy showed that such pressure increased in pregnancy. This was the case whether the patient was standing or lying. It had been thought by those who had previously investigated the pressure in the rectum that this increase was due to an increase in the visceral weight, and that the pressure above the pregnant uterus was not increased. Hörmann, who made many investigations in all sorts of cases, came to this opinion. That authority's conclusion was, however, untenable, since the rectal pressure did not vary merely with increase of visceral weight, nor, indeed, with increase of visceral volume. The speaker, from a consideration of the intra-abdominal pressure in the non-pregnant, held that the visceral weight played some part in the production of the pressure, but that the compression of the visceral mass caused by the concerted reactions of the abdominal wall, thoracic diaphragm, and pelvic floor was much more important. That this compression was greater in pregnant than in non-pregnant women was shown by the change in musculature. It was in the well-developed women who became pregnant that higher pressure values were obtained, and it was in these that the toxæmia of pregnancy was so liable to occur. Dr. GRIFFITH said he was satisfied that Dr. Paramore had proved that intra-abdominal pressure was increased in pregnancy with primigravidae. But he had offered no evidence in the case of multigravidae with lax abdominal walls, and in them it was highly improbable that there was any similar increase except that directly due to the increased weight of the uterus and its contents. The author appeared to think that there was something wonderful about the ascent of the uterus, but he (the speaker) did not think it differed from ascent of the bladder due to distension—that is, the base of the organ remained at the same level. The PRESIDENT did not think that Dr. Paramore had sufficiently proved his first point to advance his main theory that the toxæmias of pregnancy were due to exaggerated increase of intra-abdominal pressure. The preliminary point now brought forward, that the increase of intra-abdominal pressure observed by him and others in pregnancy was due to the increased tone or tonic contractions of the muscles of the abdominal wall and thoracic diaphragm when at rest, had not been proved by him. Mr. GLENDING said that the only reliable method of estimating intra-abdominal pressure was by a manometer introduced into the peritoneal cavity; the author had measured the intravisceral pressure, which was not at all the same thing. Dr. EDEN said that although the author's conclusions were not in themselves unreasonable, his paper failed to carry conviction because it consisted of too little fact and too much theory. The absence of control observations on non-pregnant women, and upon other common forms of abdominal distension such as ovarian and fibroid tumours, greatly weakened the case. Again, the conclusions he drew from the association of muscularity and corpulency—namely, that the abdominal muscles became hypertrophied as the result of an increase of intra-abdominal fat, did not appear sound; it was quite feasible that these persons were unusually muscular before they became corpulent. The author would find it very difficult to establish a mechanical theory of toxæmia, in view of the careful scientific work of recent years which pointed so strongly to biochemical causes.

SECTION OF LARYNGOLOGY.

At a meeting on June 6th, Mr. HERBERT TILLEY, President, in the chair, the following were among the exhibits: The PRESIDENT: A case shown in illustration of the effect of time in obliterating extensive frontal scars. Dr. LAMBERT LACK: A *Nasal osteoma* recurrent in the region above the inferior turbinal of a woman aged 31. Nino

years ago a large osteoma had been ablated by the curette. Mr. H. J. DAVIS: Notes of a case of *Cavernous thrombosis* following tonsillitis in a boy aged 10 which terminated fatally in eighteen days. Antistreptococcus serum was injected on the ninth day, and only *Staphylococcus albus* resulted from a blood cultivation. The cavernous symptoms were definite on the fourteenth day. Infection had probably taken place by the facial vein. Incisions and doses of liq. ammon. fort.—5 minims in water every two hours—were of no avail, though such treatment diminished the tendency to thrombosis. The tonsillitis was on the left side, and the thrombosis symptoms were on this side only. Mr. O'MALLEY regarded the sphenoidal venous system as the route of infection, and in this Sir STCLAIR THOMSON concurred, adducing the evidence of sphenoidal sinus cases. Dr. FITZGERALD POWELL also quoted instances of the extension of thrombosis to the cavernous sinus along the petrosal sinus in petrous necrosis. Dr. JOHNSON HORNE: A man aged 36 with a *Prominent superior ventricular band* concealing the vocal cord, and raised the question whether this was due to early tuberculosis of the laryngeal sac or a deformity. Examination of the sputum and chest were negative. Sir STCLAIR THOMSON considered the larynx to be free from disease. Dr. DAN MCKENZIE regarded the appearance as due to a prominent superior band, while in Dr. WILLIAM HILL's opinion the sac was affected. Dr. DAN MCKENZIE: A case of *Sinusitis oculcerans* of the frontal sinus. In the first operation, which was directed to relieve the pus tension, in stripping up the frontal periosteum the elevator passed through the soft bone sinus and posterior wall through the dura, and inflicted a 3 mm. wound. The anterior wall was removed and the dural wound opened and a gauze drain inserted. As progress was good, six weeks later an attempt was made, after a modified Killian operation, to establish an infundibulum, which caused great reaction and necessitated a return to drainage through the skin incision. Subsequently the removal of a track leading to the optic foramen and softened bone in the outer angle resulted in healing. Dr. DAN MCKENZIE recorded a death after *Tonsillotomy* in a boy aged 9 who had had subacute middle-ear catarrh. Three days after the operation an incision over the oedematous neck allowed fetid pus to be delivered by Hilton's method for the deeper planes. Two days later pneumonic symptoms appeared, and the patient died. The organisms obtained from the pleural and cervical cavities were similar to those indigenous in the mouth. The teeth were sound, but the usual precaution of using a lysol mouth wash had been omitted. The case appeared to be a septicaemia from mouth infection. The primary infection was probably pneumococcal.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a meeting on June 6th, Dr. G. P. SHUTER, President, in the chair, Mr. T. JEFFERSON FAULDER, in a paper on *Enucleation of the tonsils*, said that he had ascertained that at least 40,000 operations for tonsils and adenoids were performed in the London hospitals alone during the year 1909, and it was therefore important to have an exact appreciation of the indications for operation and the best method of procedure. He had come to the conclusion that if it was found necessary to interfere with the tonsil surgically, it should in all, or nearly all, cases be completely removed. By complete removal he meant removal of the faucial part of the tonsil with its capsule, the lingual prolongation not being interfered with. Perhaps one of the most urgent reasons in support of his proposition was the fact that under previous conditions repeated operations were necessary. He was called to operate upon many cases where two, three, and even four operations had already been performed, and to his mind this constituted one of the most serious indictments of all against partial removal of a condemned tonsil. Partial removal was liable to set up recurrent tonsillitis and rapidly recurring hypertrophy in patients who had never suffered from sore throat before, and it was the recognition of this very fact which led to the evolution of the various methods of enucleation. With regard to the method best adapted for carrying out removal of the tonsil, it must be

observed that the surgeon's object in using the guillotine was always to remove as much of the tonsil as possible. In using the guillotine in the original way it happened not uncommonly that so much tonsil was removed as to amount to enucleation. For this result, however, a very special kind of tonsil was essential—namely, a tonsil pedunculated, projecting, and not at all embedded—one with a capsular area very much less than that of the free surface, a variety relatively uncommon. But enucleation of embedded tonsils could be carried out with the guillotine as well as by any other method. All methods aiming at complete removal, whether by volsellum and forceps, wire snare, scissors, periosteal elevator, blunt knife or guillotine, were dissection methods, and he maintained that dissection by the guillotine had several advantages of its own. It took no longer to remove completely both tonsils by this method than it did to remove pieces of them. Mr. Faulder then demonstrated the principle of the method of operating, introduced by Sluder, with the aid of a phantom. Objections to total removal with reference to the hypothetical internal secretion of the tonsil were next dealt with, and the question of the protective value of a diseased tonsil appeared to have much the same academic value. He could not help thinking that this theory of protection arose from the appearance of the hypertrophied tonsils projecting in the narrow fauces like fortified Gibraltars, but he had come to the conclusion that they more resembled Scylla and Charybdis. Though the tonsils might act as filters they very easily became choked filters, a danger to sanitation. Finally he took up the question of post-operative bleeding. He was satisfied that the bleeding during and after the operation under consideration was very much less than that after tonsillotomy with a sharp instrument, and that patients lost less blood from enucleation by this method than by any other. Secondary haemorrhage from the third to the fifth day had occurred, but was excessively rare. As occasional cases of bleeding occurred whatever operation was performed it was necessary to be prepared for them, and his observations pointed to the adenoids being the source of trouble much more frequently than the tonsils. A firm pad of gauze damped with adrenalin was usually sufficient if held in position for a few minutes. The tonsil clamps shown were most efficient, although uncomfortable. Metal clip sutures might be used for clipping the pillars of the fauces together or for clipping the pillars to a roll of gauze placed in the tonsil cavity. What he had sought to do in his paper was to press for careful selection of cases, but at the same time for more thorough treatment. The PRESIDENT said Sluder's method was a less serious procedure than dissection, and appeared to achieve equally satisfactory results in most cases, but where it might be necessary to remove the whole tonsil, as in the case of diphtheria carriers, a dissecting operation was indicated. Dr. H. J. DAVIS strongly recommended Sluder's operation as performed with a blunt-bladed tonsillectome, and showed that surgeon's instruments presented to him by the inventor. They were far and away the best of the many instruments he had used for enucleating tonsils. Dr. M. E. LEICESTER agreed with Mr. Faulder that in operating on children no special instrument was required so long as the one selected was the right size, but in adults, where previous tonsillotomy had resulted in repeated attacks of tonsillitis, the tissues were thick and tough, and required a specially adapted instrument. Mr. O. L. ADDISON saw no reason for leaving any part of the tonsil, and thought the only satisfactory way in the majority of cases was to remove the entire tonsil with its capsule and lingual prolongation by the blunt dissection method originally introduced by Mr. Waugh. Mr. H. TYRRELL GRAY agreed with Mr. Faulder that complete removal of a diseased tonsil was essential, but enucleation with a guillotine lacked precision, and any method which failed to remove the lingual prolongation was unsound. None of the recent innovations on Waugh's method of blunt dissection appeared adequate. Mr. J. F. O'MALLEY recorded his high appreciation of Waugh's operation, but did not consider it essential, in the majority of cases, to remove the process of lymphoid tissue which connected the tonsil with the tongue, and did not like the depth of anaesthesia required in that operation. Mr. T. JEFFERSON FAULDER, in his reply to comments, mentioned that the

percentage of successful cases depended to some extent upon the selection, but he agreed with those speakers who put it at not less than 90 per cent.

EDINBURGH OBSTETRICAL SOCIETY.

At a meeting on June 11th, Dr. HAIG FERGUSON in the chair, Dr. BERRY HART discussed the *Pressure experienced by the fetus in utero*, referring especially to the work of Murk Jansen on achondroplasia, who believed that the shortening of the four limbs and of the basi cranii in this condition was due to extra local pressure from the amniotic fluid or the wall of the amnion. The speaker reasoned that, in addition to the liquor amnii, there was the intra-abdominal pressure, and the pressure exerted on the fetus must be uniform and equable. It was impossible to see how local pressure could have any influence in preventing growth in a symmetrical way. The explanation was to be found in the discovery that the bones affected in achondroplasia largely depended for their growth during fetal life upon endochondral ossification, the cause of the deficient growth being a premature arrest or absence of this process. The bony skeleton consisted of three great sections—the bones developed in early endochondral ossification, those developed in late endochondral ossification, and those developing in membrane. This division suggested the existence of Mendelian unit characters concerned in the formation of the skeleton. These, according to Weismann, would reside in the zygote as determinants, and, according to the author, achondroplasia corresponds to a loss of a growth factor for the bones developing in early endochondral ossification. This loss occurred with the extrusion of the polar bodies at fertilization and gave a variation analogous to the mutation of De Vries. Two rare specimens of *Hydatid mole in utero* were shown, the first by Dr. HAIG FERGUSON. The patient, 49 years old, had been married for eight years, and had had three abortions previously. She missed two periods, and on November 27th, 1912, commenced to bleed, this continuing to the operation on December 22nd. When seen then there was severe anaemia, breathlessness, and an abdominal swelling extending as far as the umbilicus. The diagnosis lay between a fibroid with pregnancy, placenta praevia, and hydatid mole. In view of the uncertain diagnosis and the danger which forcible dilatation of a rigid cervix in an exhausted woman would mean, hysterectomy was decided upon. There was free fluid in the abdomen, possibly indicating erosion of the uterine wall, and this, taken with the age of the patient, determined the author to perform supravaginal hysterectomy. On opening the abdomen 2 quarts of fluid escaped. Recovery was good. The second specimen, shown by Dr. J. W. BALLANTYNE, was obtained *post mortem* from a woman who died of haemorrhage immediately after reaching hospital. She was 47 years old and was three months pregnant. The uterus was enlarged to the size of a seven months pregnancy. Dr. JAMES YOUNG described the pathological features of the two cases. In the first case the wall of the uterus was about one-third of an inch thick throughout. There was no evidence of erosion of the uterine muscle of a malignant nature. In front the uterine cavity was seen and intervening between it and the hydatid mole there was a fibrinous layer—the decidua reflexa—that is, the mole was situated entirely within the mucosa of the uterus, the bleeding coming through the thin reflexa. Microscopically, appearances similar to those usually present in regions of chorionic activity were seen. The second specimen showed appearances like those seen in the above. In it the decidua reflexa was better preserved, although the hydatid mole was larger and in it definite decidual cells were seen.

WARWICK AND LEAMINGTON MEDICAL SOCIETY.

At a meeting on June 6th, Dr. ARNOLD MORRIS in the chair, Mr. BERNARD RICE in opening a discussion on *Appendicitis* gave an historical account of the disease. The first recorded case was in 1750, and from that time its increase had been gradual, but during the last decade had without doubt become much more frequent. He was at a loss to account for this, but inclined to look with favour on

the influenzal theory and that connected with the use of enamelled saucepans. In diagnosis it was important to bear in mind the similarity of symptoms sometimes found in cases of movable kidney and also ovarian disease. The condition of the pulse was the safest guide. In regard to treatment, he agreed that all cases of diagnosed appendicitis required operation, and generally immediate operation. On the other hand he deprecated hard and fast rules, and called to mind cases in which he had regretted immediate operative interference, whilst he could not recollect any case of his in which waiting for a few hours under strict observation had been at all prejudicial to his patient's interest.

Reviews.

BIOCHEMISTRY.

IN a small volume of some 400 pages Professor CARL OPPENHEIMER¹ has endeavoured to place before the student, and in particular the practitioner, the present position of biochemistry, and has succeeded in producing a most useful book for those who have not the opportunity or leisure for consulting the longer works and ever-growing literature on this most important subject. He has omitted all detailed description of the elementary substances and analytical composition of the body and also all methods, and has thus made room for the latest phases of knowledge in regard to those many great problems of biochemistry which so closely affect the nutrition of the body and the pathology and treatment of disease. In dealing with carbohydrates the author, using a simile suggested by Bernard, happily compares the glycogen dépôt of the body with the daily deposits of cash which are paid in and out of a bank, while the fat dépôts, mobilized with greater difficulty, are comparable to the paper securities which have to be realized before they can be used. The carbohydrates of the body can be utilized for the production of some, although not very much, energy at times of oxygen want, being then broken down into lactic acid. Neither protein nor fat can be so used, and the body does everything to conserve a store of glycogen against such need. In the chapter on ferments we find fibrin ferment still holds its own, but a note is added in which the modern work is mentioned whereby doubt is thrown on the ferment nature of coagulation of the blood which is ascribed to a precipitative change occurring in the colloidal blood proteins. Discussing the theory of muscle work the author puts forward the hypothesis of Zuntz that the contractile muscle element (sarcous element) explodes a molecule of food-stuff, and so produces in a confined space a high temperature, for example, 2,000° C. While this is almost instantly reduced again to a low temperature by the surrounding fluid, it suffices to produce an osmotic change in the muscle element which causes the entry of fluid and the swelling and shortening of the element. Thus the muscle is compared to an internal combustion engine.

Mr. SIDNEY COLE has brought out the third edition of his excellent laboratory book on *Practical Physiological Chemistry*.² Every exercise in this book has been worked through by the author, and the instructions are so given, and notes added, that the student who cares can reach and understand the stated results. Mr. Cole deals with his subject in the spirit of modern chemical science, explains on the ionic hypothesis the falling out of precipitates in colloidal solution such as the proteins form, gives the proper physical and chemical ideas concerning the reaction of the body fluids, and sets forth the recent improved methods of identifying and estimating the quantities of important physiological substances. Thus, in the chapter on the urine we find Folin's micro-chemical methods of estimating total nitrogen, ammonia, urea and urea acid, and Benedict's methods of estimating urea. In the estimation of total nitrogen by Folin's micro-chemical method a small volume of

¹*Grundriss der Biochemie*. By Professor Carl Oppenheimer. Leipzig: G. Thieme, 1912. (Post 8vo, pp. 407, 9s.)

²*Practical Physiological Chemistry*. By Sidney W. Cole, M.A. Third edition. Cambridge: W. Heffer and Sons, Ltd. 1913. (Demy 8vo, pp. 240; figs. 13. 7s. 6d. net.)

urine is decomposed by sulphuric acid as in Kjeldahl's method; the ammonia is drawn over into acid and the solution treated with Nessler's reagent; the amount of ammonia is determined colorimetrically (using a Dubosq colorimeter) by comparison with a standard solution of ammonium sulphate simultaneously Nesslerized. In estimating urea the urine is treated with potassium acetate and acetic acid and boiled. The boiling point of the mixture is about 155° C., and at this temperature the urea is rapidly hydrolyzed to CO₂ and ammonia; caustic potash is added, and the ammonia aspirated into acid, and the determination proceeds as above. In estimating uric acid, Folin's uric acid reagent is used; this becomes coloured blue, and is compared colorimetrically with a standard solution of uric acid similarly treated. Mr. Cole says these methods of Folin are reliable, and may be quickly performed with but small amount of apparatus. He urges their clinical use and importance. The hypobronite method of estimating urea is too inaccurate to be of much value. In dealing with the acidity of gastric juice the author points out that the estimation of free HCl is practically that of the concentration of hydrogen ions in the gastric contents. HCl is very freely dissociated into H and Cl ions in such dilutions as those found in the stomach. But weak acids, as lactic and butyric, are only slightly dissociated. The addition of protein to a solution of HCl decreases the concentration of H ions, owing to the formation of a compound that only dissociates to a relatively small extent. The estimation of the free HCl is best done by the electrical method. The use of indicators is not advised. According to the latest researches it is certain that even Toepper's reagent (dimethylamido-*o*-benzene) reacts with an excess of butyric and lactic acids, and also with HCl in combination with protein. The simplest clinical method that gives results at all comparable with the electrical method is that of titrating with standard NaOH until no reaction for free HCl is obtained with Gunsberg's reagent. This method, however, is rather tedious.

CLINICAL MEDICINE.

It is not often that the opportunity presents itself of reviewing such a work as *Clinical Medicine*,³ by Drs. JUDSON BURY and RAMSBOTTOM, the last edition of which was issued (by Dr. Bury) something like thirteen years ago. When the important additions which have been made to the means of studying the manifestations of disease are remembered, the thought occurs that probably the work which appeared in its first and second editions under the name of Dr. Judson Bury alone would on this occasion present but little semblance to its predecessors. Fortunately for the modern student of medicine, it will be found, however, that whilst no pains have been spared to adjust the subject matter of the former editions to present-day knowledge, the principles which guided Dr. Judson Bury in the former editions have not been departed from. The salient feature of this guide to the study of clinical medicine is the graphic presentation to the student of the almost endless objective and subjective manifestations which are discoverable at the bedside. Numerous illustrations of objective signs will be found scattered through the work; their faithfulness is, as a rule, remarkable, though it must be admitted that a few are so crude that it would be well to replace them by others more in keeping which are so excellent (for example, Figs. 2, 12, 30, and 265). Besides pointing out with such success the objective manifestation of disease, the authors have contrived to write a book which is most readable; it is no mere piece of scissors and paste compilation, and the reader need fear no forbidding tables; or if he does find a few tables, he will also discover that their severity has been toned down by admirably written descriptions. The authors have called to their assistance three other workers in spinal subjects—Drs. Barclay, Wild, and Loveday—who have made themselves

responsible for additions or revisions of sections dealing with Roentgen rays, diseases of the skin and its appendages, and the examination of the blood; indeed, the chapter dealing with the radiographic investigations contains one of the best accounts of the application of *x* rays to clinical medicine which a student could read. Favourable comment must also be passed on the section dealing with the examination of the digestive system and abdominal organs, and were we asked for pages which would exemplify the admirable principles on which the book has been written we would refer to p. 314 and 315, where the authors continue in moderate space to give an excellent differential diagnosis of the causes of ascites. It might be expected that the thoroughness of the revision of this edition might best be estimated by a study of the chapter dealing with the examination of the nervous system. It will not be found wanting, for most clearly described will be found those newer conceptions of the course of sensations—paths which we owe to Dr. Heard and his co-workers. We cannot close the volume without expressing gratitude to the authors for a presentation of their subject which is at once most pleasurable and instructive not only to the early student, who will find within its covers reliable guidance, but also to the senior student and practitioner who wishes to keep abreast in matters connected with clinical medicine.

The treatise by Dr. EMILE SERGENT⁴ on the elementary technics of clinical medicine and semiology is primarily intended for students as an introductory to clinical work. The omission of propaedeutics from the curriculum in the Medical School of Paris has induced Dr. Sergent to organize, with the help of his house-physicians, a series of tutorial classes in order to initiate the students into the usual methods of examining patients; for however well stocked the memory of the novice may be with the systematic descriptions of diseases, he is necessarily embarrassed in the presence of a given case in his endeavour to make a diagnosis, unless he has previously been taught how to collect and to appreciate the requisite data for this purpose. This enterprise has proved so satisfactory to his pupils that at their special request Dr. Sergent has published this book to enable them to refer to the incalculated lessons whenever they deem it necessary. The manual, which is very complete, contains short accounts of the symptoms of most forms of internal diseases with their significance and their conditional diagnostic imports. It also contains instructions for the making of chemical, microscopic, and radiological investigations more immediately suitable for the bedside. All statements in it are concise and easily intelligible; there are also 173 figures in the text and two coloured plates. We have no doubt that the book amply fulfils the purpose for which it is designed and will be most useful not only for students but also for the busy practitioner.

A GERMAN PRACTICE OF MEDICINE.

We have already reviewed the first volume of Dr. KINDBOERG'S practice of medicine⁵ in the issue of December 11th, 1911, of this JOURNAL. The plan adopted in that volume has been continued in the second, and we are pleased to say with as signal success. Wherever medicine is brought into close contact with the modern developments of the ancillary sciences, whether chemical, physical, anatomical, or physiological, the writer intercalates passages which briefly explain what those developments are, so that the reader is spared the time and trouble of referring to text-books on these subjects. Nothing is taken for granted, and it is assumed that the reader is desirous of knowing not only what it is that medicine borrows from other sciences, but what are the reasons for this adoption. The author has succeeded in the present volume as completely as in the first. Occasionally this plan leads to rather curious results; for example, whilst nearly four pages are given to the study of acute rheumatism, two pages are devoted to the chemical study of salicylates. The present volume concerns itself with those diseases which are con-

³ *Clinical Medicine*. By Judson S. Bury, M.D., F.R.C.P., R.Sc. Vict., Consulting Physician to the Manchester Royal Infirmary; Examiner in Medicine to the Royal College of Physicians, London; formerly Professor of Clinical Medicine in the University of Manchester, and Albert Ramsbottom, M.D., M.R.C.P., Assistant Physician to the Royal Infirmary, Manchester. Third edition. London: Charles Griffin and Co., Ltd. 1912. (Med. 8vo, pp. 550; illustrations 305, plates 10. 17s. 6d. net.)

⁴ *Technique clinique médicale et sémiologie élémentaires*. By Dr. Emile Sergent. Paris: A. Maloine, 1913. (Cr. 8vo, pp. 780; 175 figures, 2 planches en couleurs. Fr. 15.)

⁵ *Theorie und Praxis der Inneren Medizin*. Ein Lehrbuch für Studierende und Aerzte. Von Dr. Erich Kindborg in Bonn. Zweiter Band. Berlin: S. Karger, 1912. (Imp. 8vo, pp. 617; 74 illustrations, Mk. 10.)

sidered to be due to errors of metabolism, to diseases of the organs of locomotion and to those of the digestive organs. As one would expect, Dr. Kindborg is able to give very good accounts of the first and last of these disorders, the study of which has been so much advanced by Continental workers. He is not without a sense of humour, and has his gibe on page 325 about the specialist and the use of the "stomach pump." It is also clear that Dr. Kindborg throughout his volume justifies his concluding sentence in the introduction, in which he says he has endeavoured to give the reader not only an account of the facts and theories of medicine, but also to express what are his own individual views and experiences. This can be seen when, in his remarks upon the meaning of catalepsy on p. 225, "flexibilitas cerea" is shown to be a condition of "transcortical motor apraxia" homologous to "transcortical motor aphasia." Dr. Kindborg gives an excellent account of the physiology and anatomy of muscles, and refers to the newer teaching of Weichardt as to the existence of "fatigue toxins" which operate like bacterial ones, even to the extent of leading possibly to the development of "fatigue antitoxins." Were we asked to state what is the specially interesting as apart from the merely instructive feature of this book, we would say it was the "asides" which Dr. Kindborg so adroitly introduces into what is a readable account of the accepted ideas of medicine. We have referred to some, but on page 142 is another especially interesting: here it will be found that he tilts at the views of Kionka, Kobert, and others according to which the good effects of colchicum in gout are attributed to the stimulant action of the drug upon the liver activity. With Umber and Schittenhelm and Brugsch he considers that colchicum has no "specific" effect—has no power, that is, of acting at the seat of the disorder upon the actual cause of the disorder; it is merely an "anaesthetic." The wonder is that Dr. Kindborg cannot see that probably salicylates act in much the same way, that is, as anaesthetics or anodynes in rheumatic fever. We cannot close the review without a word of praise for the excellent diet charts, for the tables contrasting the types of diabetes, for others showing the different reactions of the urine to 10 per cent. ferric chloride solution under varying circumstances, for the calorie values of common foods, and for the excellent accounts of radium and the physiology of the intestinal tract with special reference to the ferments.

PROSTITUTION.

THE recent output of literature devoted to the discussion of sex problems has gained dimensions which are alarming enough to the busy man who wishes to keep his knowledge of these and kindred subjects up to date. A few decades earlier the purely scientific aspect of these problems was much neglected; and what many medical men of a past generation would scarcely touch, is now carefully dissected, analysed, labelled, and docketed. The fearless discussion of matters hitherto largely shrouded in mystery has done much to put them on a more healthy and physiological basis; but there is also a common tendency at present to burden them with a mass of tedious and nauseous detail scarcely germane to their fundamental principles. This criticism is applicable to the voluminous work by Dr. IWAN BLOCH⁶ on the subject of prostitution. The first volume alone runs to 870 pages, and deals mainly with the historical aspect of the subject. In his introduction Dr. Bloch urges the importance of regarding prostitution as a central factor from which other problems of sex radiate, and on which they largely depend. The eradication of prostitution is not, he claims, merely of interest in its bearing on venereal disease; it is also of vast ethical importance. Since the publication of Parent-Duchâtelet in 1836 it has not, he states, been scientifically analysed; and he holds that the time is now ripe for an objective and systematic scrutiny of a state of affairs the continuance of which is challenged. Among the modern movements which may tend to check prostitution must, he says, be included socialism and the emancipation of women. The latter, according to the author, may succeed in demonstrating that prostitution is not the "necessary evil" it has so long been called. He

reviews in detail the history of prostitution among savage tribes, among the Grecians and Romans, and during the Middle Ages among the followers of Christianity and Mohammedanism. An interesting account is given of the laws enacted by Solon, whose aims were the preservation of the sanctity of marriage and the free indulgence of the passions out of wedlock. Solon, in other words, legalized prostitution to preserve the sanctity of marriage. This attitude was, in the author's opinion, erroneous; but it has been an unconscionably long time in dying. As might be expected, Martial and Juvenal are largely drawn on by the author, whose classical quotations are numerous. The amours of Clodia-Lesbia and of Valeria Messalina, the wife of the Emperor Claudius, are cited as classical examples of nymphomania and greed leading to scarcely credible excesses. Dr. Bloch's book should prove of value as a work of reference; but its very bulk and encyclopaedic dimensions reduce its usefulness to the average reader.

CONVERGENCE IN EVOLUTION.

PROFESSOR ARTHUR WILLEY is so well known to all zoologists that any contribution from his pen is always eagerly anticipated. His last book, *Convergence in Evolution*,⁷ will therefore be widely read.

The subject of convergence is one which has received much attention in recent years. It is also a subject of no little complexity. Formerly structural resemblances were regarded as indicative of phylogenetic affinity. Now, however, we know that such resemblances may occur as the result of similar factors operating on organisms quite unrelated to one another, that is to say, they are convergent. In the words of the author, the term "convergence" is applied to resemblances "which are not derived by inheritance from common ancestors, but which result from independent functional adaptation to similar ends."

The realization of the facts of convergence has shown that the difficulties in establishing genetic affinities are very much greater than used to be supposed. This has led to a division of morphology into homogenetic or normal morphology and convergent morphology; and comparative anatomists of to-day will doubtless all agree with Professor Willey in regarding each division as of equal importance. He considers convergence in its broadest aspects, and rather from the physiological standpoint. The earlier chapters focus ideas which have probably been at the back of many men's minds without having been definitely formulated. The author shows how animals may be roughly classified into the Phancrozoa and the Cryptozoa, the exposed and the concealed animals; or into the Elentherozoa and the Statozoa, the free and the fixed. Such divisions are, of course, rough and imperfect, nevertheless the mere suggestion of such a classification is of considerable interest, as it draws attention to certain characters and habits common to animals belonging to widely separated groups.

All such characteristics the author rightly includes under the term "convergent"—a term too often restricted to internal anatomical structures, and for which Lankester has suggested the name "Homoplasy." The various aspects of mimicry, warning colorations, and social instincts are likewise so regarded. The "tropisms" or tendencies to reaction are referred to in relation to the causation of convergence, but only in a tentative manner, as must necessarily be the case in the present inadequate state of our knowledge.

The book is very interesting and very suggestive. If it perhaps leaves a vague feeling of insufficiency, the cause is to be found rather in the lack of sufficient knowledge to enable us to crystallize our ideas than to the author's ability to give them lucid expression. The publication of the *Origin of Species* necessarily gave an enormous impetus to detailed anatomical investigation; with this zoologists are now becoming somewhat surfeited. We require to know more of the why and the wherefore; to correlate and to generalize. It is to such a book as

⁶ *Die Prostitution*. Von Dr. Med. Iwan Bloch. Vol. i. Berlin: Louis Marcus. 1912. (Roy. 8vo, pp. 905. Mk. 10.)

⁷ *Convergence in Evolution*. By Arthur Willey, D.Sc.Lond., Hon. M.A. (Camb.), F.R.S., Strathcona Professor of Zoology in the McGill University, Montreal. London: John Murray. 1911. (Demy 8vo, pp. 177. 7s. 6d.)

this that we look for refreshment, stimulation, and suggestion. Its dedication to Sir E. Ray Lankester is most appropriate.

PLANT-GALLS.

THE nature and causation of plant-galls is a subject which has excited the curiosity and aroused the interests of observers of nature from the earliest times. More than one Greek writer referred to them, and many are the superstitious which centre around these pathological growths and still retain their hold among the rural population.

The latest writer upon the subject is Mr. E. W. STANTON, curator of the Educational Museum at Haslemere. The introduction to his book on *British Plant-galls*⁸ is written by Sir JONATHAN HUTCHINSON. It is essentially a book of reference, and as such should prove useful to all workers at the subject. More than half the volume is taken up with classification of the plants that may be affected, of the parasites which may attack the various plants, and with a bibliography. The remainder of the text is mainly devoted to somewhat detailed descriptions of the gall and correlated parasites. It is not a book to read, but to refer to. It seems a matter for regret that so little is said about the causation of the galls. It is true that our knowledge is not extensive, but the general reader would be interested in learning something about the ferments which are known to cause galls in certain plants. The information as to the economic aspects of the subject also is scanty, and more details about such subjects as these would undoubtedly have made the book attractive to a wider circle of readers. There are several very good coloured plates, for which Miss Mary K. Spittal is responsible. The descriptions of the plates are all placed at the end of the book. This arrangement is somewhat distracting—the account of the gall is on one page, the corresponding plate in another part, and the description of the plate at the end of the book. If another edition is called for, the suggestion is offered that to place the description on the page facing the plate would be much more comfortable for the reader. While thus criticizing the book, we cannot but add a word of praise for the patient labour which the author has obviously expended upon it.

NOTES ON BOOKS.

AT this time of day no demonstration of the value of the microscope in the daily work of the public analyst and the pharmacist is needed. The microscope will furnish, with the expenditure of a minimum of material and often of a minimum of time, information concerning the substances analysed that cannot be obtained by any other means. There is scarcely a food or drug that cannot be recognized, or an adulterant that cannot be detected, by its help. Mr. GREENISH's book on *The Microscopical Examination of Foods and Drugs*,⁹ of which we welcome a new edition, is so arranged that the student passes gradually from the simpler to the more complex examinations, acquiring as he proceeds a knowledge of the various tests and operations that are in general use. The starches and spores are described first; then follow careful descriptions of the methods of preparation and of the microscopical appearances of the wood fibres, stems, leaves, flowers, bark, seeds, fruits, rhizomes, or roots of such plants as are most likely to be met with by the analyst and the pharmacist. Of the substances which were not described in the first edition we may mention saffron, which is introduced as an example of part of a flower, almond as a type of the oily seeds now much in use as alimentary substances, and fennel fruit as a type of umbelliferous fruits. Liquorice, gentian, and calumba have been added to the section dealing with the roots. The new chapter on the more common adulterants of preserved foods and drugs and the general scheme for the examination of powders are valuable features. The book is clearly written, the type good, and

the illustrations, which are, of course, of prime importance in a work of this kind, are excellent and abundant.

Mr. CARL HANSEL'S *Introductory Electricity and Magnetism*¹⁰ is certainly not a book for the easy chair. It is a book for the work bench, to be held in one hand while the other grasps a bar magnet or operates a switch. As a manual for students preparing for elementary examinations in the subject, it is ably and carefully compiled, and we suppose that we ought to be grateful to an author, especially one who can write so clearly and well, for sacrificing his literary conscience by breaking up his pages into regular alternations of exercises, examples, and sets of questions. But even in a class book an occasional excursion into history and theory might be tolerated, and some sort of bibliography would be acceptable to those who, having accomplished this considerable trial flight, have the desire still to soar.

The rapidity with which edition follows edition of professional lexicons is a proof how new methods and new discoveries demand the introduction of new terms, for the days are long past when experts wittily invented names which sounded learned and really deceived the general public. Dr. JOHN PRICE, the editor of *Hoblyn's Dictionary*,¹¹ has not overlooked this phenomenon. The book is amongst the best of its class and in form highly convenient, but the editor has to exercise great judgement lest the new editions grow bulky. The original author, in preparing the tenth edition, made the scholarship of his lexicon more uniformly accurate than before, and went so far as to indicate how unclassical and hybrid were such words as "mentagra." "Why not adopt the term *genivagra*, from γενειον, the chin?" The present editor has retained several philological rebukes of this kind. We may note, by the way, in regard to "the term" in the sentence just quoted, that one of the most distinguished medico-literary censors strongly objects to "term" when applied so as to be clearly synonymous with "name," yet many leading physicians and surgeons never scruple to do this, and the same we see is the case with the compiler and editor of this dictionary. However, whether new words introduced by authorities and specialists be "names" or "terms," dictionaries are sought for in order that those who consult them may find out what the unfamiliar words signify. This edition supplies one want. There are a great many "new terms," owing, as Dr. Price observes in his preface, to recent advances in bacteriological science. He has turned to Muir and Ritchie's textbook for correct definitions, and so has done us good service. Nor need we groan at the perfectly necessary scientific words coined to denominate germs and their vagaries; at the worst, they are far less objectionable than the denomination of new surgical methods by the names of new operators. Following in Hoblyn's footsteps, Dr. Price has not overlooked scholarship, for he has freely consulted Murray's *New English Dictionary*, to which he admits his indebtedness.

The *Leeds Pharmacopœia*¹² has been drawn up by a committee appointed jointly by the Local Medical and Pharmaceutical Committees under the Insurance Act, with a view to facilitating the ordering and dispensing of medicines. It contains about a hundred formulæ for mixtures, lotions, pills, etc. The *British Pharmaceutical Codex* and the pharmacopœias of the Leeds Public Dispensary and of various hospitals have been largely utilized in compiling it. Special attention is drawn in the preface to the parogens, a class of compounds adopted from the *Codex*; the basis of these is a mixture of paraffin (hard, soft, or liquid, as required) with an ammonia soap, and medicaments such as iodine can be rendered easy of absorption by the skin by exhibiting them in this form. The appearance of these compounds in the *Leeds Pharmacopœia* is evidence of the intention of the compilers that the saving of time to prescribers and dispensers which the book is intended to effect shall not be gained at the price of neglecting improved forms of medicines.

MEDICAL AND SURGICAL APPLIANCES.

A Tuberculin Syringe.

MESSRS. BURROUGHS, WELLCOME AND CO. have recently brought out a syringe which is primarily intended for the administration of tuberculin injections, but could equally well be used for hypodermic medication of any kind. It consists, apart from the needle, of three separate parts—a syringe barrel, a plunger, and a nozzle. All three are of glass, the latter being of blue glass, while the barrel, which holds just 1 c.c.m., is marked in red in twentieths of a cubic centimetre. Being of glass the whole is easily sterilizable, while experiment shows that the piston fits the barrel so accurately that leakage does not occur. To this extent this new syringe does not differ from many others of the same order, but nevertheless there is a difference of material interest—namely, the syringe barrel is of such narrow calibre that there is a considerable distance between the graduating lines. This fact, coupled with the difference of colour between plunger and barrel, should make accurate measurement of a dose easy. The syringe, therefore, has definite practical merit.

A Retractor.

Mr. STANLEY BOYD, F.R.C.S. (Surgeon to Charing Cross Hospital), writes: The advantage and frequent necessity of dispensing with the hand of assistants is acknowledged. The simple retractor illustrated here has often enabled

me to do so with comfort. The Holborn Surgical Instrument Company make it with claws $\frac{1}{2}$ in. and 1 in. deep, the latter for the deeper wounds. With two of the retractors—one holding open the fat and external oblique, the other the internal oblique and transversalis—removal of an appendix by the muscle-splitting incision can be easily carried out.

Hypodermic Medication.

Under the title of "hypotubes," Messrs. Evans, Sons, Lescher, and Webb are now issuing hypodermic solutions and vaccines of various kinds put up in a manner designed to do away with the use of hypodermic syringes. The solution is placed in collapsible tin tubes which end not in a cap but a closed nozzle, which is so shaped as to fit accurately into the neck of a hypodermic needle. To inject the fluid the end of the nozzle is pricked and inserted into the neck of a needle, which in its turn is inserted under the skin; the fluid is then injected by squeezing the tube flat. The end of every nozzle, it is stated, is carefully sterilized, and the tubes are sent out with this nozzle covered by an india-rubber cap, while a suitable pricker and a needle are supplied, already sterilized, in a small glass tube filled with rectified spirit and plugged with a rubber stopper. The needle and pricker are carried in this tube in a metal support, and since their asepticity is maintained by the rectified spirit they can be used as often as desired. The device is certainly ingenious, and there seems no reason why it should not prove effective and gain considerable popularity.

The Chlorometer.

The Rideal-Evans Chlorometer is an ingenious little instrument for detecting and measuring traces of chlorine or other strong oxidizing agents in water. It is intended to be used as an adjunct to the treatment of water or sewage effluent by the chlorine process, in order to ascertain whether sufficient and yet not too much chlorine has been employed, so that a trace, and only a trace, remains in excess. It consists essentially of a primary battery, in which the plates are of copper and platinum and the water to be tested is the fluid of the cell. In such a combination no measurable current is produced unless something is present to combine with the hydrogen which must be set free; a trace of "available" chlorine provides the necessary attraction for the hydrogen and causes a current to be produced, and the amount of current is a measure of the amount of "available" chlorine, while chloride does not interfere. The instrument is made by Messrs. Siemens, Brothers and Co., Ltd. (Woolwich), who also supply a descriptive pamphlet on its applications.

UNDER the will of the late Mr. John Kinnaird of Birmam, the City and County Infirmary, Perth, and the Northern Infirmary, Perth, each receives a bequest of £1,000, and, subject to certain life interests, are to share the residue of the estate with three other charitable institutions. The personal estate of the testator was sworn at a value of £21,275, in addition to other property.

THE PARLIAMENTARY COMMITTEE ON
PROPRIETARY MEDICINES.

THE REGULATION OF IMPORTATION INTO AUSTRALIA.

THE Committee of the House of Commons appointed to inquire into the sale and advertisement of proprietary medicines held its last public sitting on June 12th. It began to take evidence at its meeting on May 9th, 1912.

Evidence was now given by Dr. W. P. Norris, chief medical officer for the Australian Commonwealth in London, and until recently Director of Quarantine and medical adviser under the Commerce Act to the Commonwealth in Australia.

The Chairman (Sir Henry Norman) asked the witness if he would first give a general outline of the reasons which caused the Commonwealth Government to undertake restrictive action in regard to proprietary medicines.

Dr. Norris said that following the inception of the Commonwealth the protection of the public in regard to the sale of secret remedies was discussed in the House, questions were asked by members on various sides of the House, and in the end the general feeling was crystallized in the Commerce Act, 1905. The Act dealt with a large number of matters as regards false trades description, and a special section (15) specifically mentioned articles used for food or drink by man, or used in the preparation of all such articles; medicines for external and internal use; apparel; jewellery; seeds and plants. All the procedure in connexion with proprietary medicines had been the outcome of that section. A power of prohibition of importation under the Customs Act was also operative. The Commerce Act prohibited the importation of any specified goods unless there was applied to them a description of a prescribed character.

The Principles Governing Regulation.

As to the principles upon which the regulations had been enforced, the witness said the question had not been dealt with from the standpoint of the interests of the medical profession, but purely from that of the interests of the public. The following were the considerations the department kept in view:

1. The protection of the person using or obtaining a proprietary medicine from injury, direct or indirect.
2. The protection of the public from injury. There were remedies offered for the cure of communicable disease; these could never be considered only from the standpoint of the person using them; the public interest was paramount.
3. The protection of the person from prejudice as a purchaser. Where it was considered that extravagant value was emphasized in printed matter, that was objected to, so that the public would not be deceived in that respect. If a thing was said to be of enormous value and plainly it was not, objection was made. While remedies put forward for serious diseases were kept chiefly in view, criticism was not limited to those. It was held that the public, necessarily relatively ignorant on such subjects, needed protection from exploitation which might waste their material substance.
4. It was held that the function of medical science and practice was to deal with the morbid condition itself in the light of all the facts of medical science, and on a consideration of the personal factors of the case as distinct from the mere symptoms. A competent diagnosis and estimation of all the facts of the case were essential antecedents to rational treatment.
5. It was a primary principle of medical science that there should be proper and prompt publicity regarding all actual or supposed remedial agents, and that it was wrong to conceal, for purposes of personal gain, the existence of facts regarding such agents. In reply to a question, the witness said this was the view of the medical profession generally, but the Commonwealth authorities might be taken as having endorsed it, having permitted official action to take place on those lines.
6. It was held that in view of the public importance of health and disease, any person engaging in the proprietary medicine trade might reasonably be required by the public to manifest in the descriptions and recommendations of a preparation a knowledge and appreciation of the facts of medical science and practice. This was the sole basis of

the legitimate practice of the healing art, and where it was not manifested there was no reason why the person or his trade should be protected in any way.

7. It was held that all useful remedies, recognized as such, were the product of pharmacological and related research and clinical practice.

The witness mentioned the safeguards which had been adopted by the department, without outside pressure, whereby an aggrieved manufacturer could submit the printing matter in dispute, with samples of the preparation, and the departmental criticism, to an independent public authority. (The authority of a professor of a university or the medical department of the English Local Government Board would be accepted.) This right of a manufacturer had rarely been exercised; manufacturers had fallen into line with the suggestions of the department.

In regard to the alteration of labels some proprietors had been willing, others had been desirous of compromising, and others adopted a defiant attitude until they saw that their goods would be prohibited if they did not give way. As to the possibility of a label being altered after a preparation had been admitted into the Commonwealth, the witness said it was held by some that owing to a defect in the Constitution the Commonwealth Government could not follow up goods inside the Commonwealth; he added that in practice it did not pay the manufacturers to alter the labels of each separate package.

In reply to Sir Philip Magnus, the witness said the law he was describing applied wholly to imported goods. There was an increasing trade in articles manufactured within the Commonwealth, and only in one or two cases did State action appear to be adequate. There was, however, a movement to bring the various States into line, and this had crystallized into legislation in the cases of New South Wales, West Australia, and, he thought, Queensland and Tasmania. The first legislation was that passed by Victoria.

In reply to Mr. Glyn-Jones, the witness said that if a manufacturer could not obtain sanction of his printed matter and sent it apart from the packages to an agent in Australia for the agent to put up the medicine and the labels together, he believed the Commonwealth would have power to stop it.

Mr. Glyn-Jones: Suppose a manufacturer establishes a factory in Australia, can he use the labels that would not be passed at the port of entry?

The Witness: He can; it has been done.

The Censorship of Printed Matter.

The witness proceeded to describe the lines of action taken by the Commonwealth in dealing with proprietary medicines. First, the principle of declaration was applied. In certain cases a special label was required to be placed on the package, or the declaration of specified therapeutic agents was required. The principle of censorship was applied. Suggestions would be made for amendment, or in certain cases prohibition was the action taken. If persons refused to alter the wording they were told that their preparations might be prohibited.

The Chairman: Judging from the evidence we have had, you have required alteration very frequently?

The Witness: Yes, in an enormous number of cases. Nearly all printed matter submitted requires radical alteration.

Continuing, the witness said the principle of the registration of the formula was only operative in West Australia, and perhaps Queensland and Tasmania. The Acts under which this was done were quite recent, and their effect could not yet be estimated. The witness gave instances of the claims in advertising matter that would not be permitted unless satisfactory proof of their bona fides were given—for example, a claim that a remedy was unique; that the maker was the "discoverer" of the remedy; that the remedy was "prepared from a famous doctor's formula." Doctors' testimonials were investigated as far as possible, and testimonials from chemists were objected to. Replying to Mr. Glyn-Jones, the witness said he meant testimonials from analytical chemists or testimonials from pharmacists which involved difficult medical questions: chemists were supposed to have a knowledge of materia medica. Objection was also taken to the growing practice of recommending other prepara-

tions by the same firm in the printed matter accompanying a particular preparation. Invitations to correspond with the makers were distinctly not encouraged. All misleading statements were objected to at once, an extravagant misstatement was condemned, but a puff, readily recognizable as such, was tolerated, not approved. Superlatives were objected to, and the department tried as far as it could in fairness to the maker to mitigate the effect on the public of vaunting statements in advertisements. The term "cure" would be objected to.

In reply to a question, the witness said the term "lightning cough cure" would not be accepted, nor would the phrase "the only cure." He had been looking through the shops of London, and he noticed this phrase frequently; in Australia it would not be allowed. The word "the" was objectionable when used in a certain way. The word "specific" and the expression "skin food" were not allowed. Recommendations for the routine use of proprietary medicines were objected to; the department did not think any one should become a medicine drinker. It took this line apart altogether from the question of habit-forming drugs; the unqualified advice to "take one of our pills once a week" would not be approved. The department had taken a strong line on the alcohol question. All claims that alcoholic beverages might have a medicinal value were eliminated. Alcoholic beverages must be sold as such and not as medicines. He did not class medicated wines as beverages; these were scrutinized very carefully. They were looked on with grave suspicion, and it would not be tolerated that they should be recommended for general use. It was held that medicated wines had a distinct tendency to the unconscious establishment of a taste for alcohol. "Guarantees of cure" were objected to, not only on account of the unsoundness of the claim, but because it was found on investigation that very few of the so-called guarantees could be held to be such in law. In the case of a wine containing a coca extract, it was required that it should be made clear on the label or other printed matter that there was a danger of drug-habit-forming.

The department took a particularly strong line in the case of any preparation sold for the treatment of a communicable disease, because there they held that private interest gave place to public interest. With any remedy for gonorrhoea and its local sequelae a definite statement was required to be placed prominently on the label to the following effect:

Note.—In any case under treatment, if the disease does not yield promptly and completely to treatment, medical assistance should be obtained at once.

The danger of spreading the disease, even after apparent cure, is very great, and a reliable medical opinion as to cure should always be obtained.

In the case of a cure for an infective disease the public danger was required to be pointed out on the label. In some cases preparations such as those he had just mentioned were objected to entirely; the precautions he had described were the least that was required. The witness added that there had been nothing but approval from the public of the regulation of the traffic. The department had not been considered to be acting in a high-handed way, and its relations with the importers themselves had been on the whole friendly. He could not say whether the trade in secret remedies had grown very much recently in Australia; they would naturally be taken somewhat freely owing to the scattered nature of the population, and to the fact that doctors did not dispense to any extent. More proprietary medicines went to Australia from this country than from the United States; they were now arriving from Japan also.

Suggestions for Future Legislation.

The witness proceeded to make suggestions as to future legislation. He would like to see uniform labelling of proprietary medicines in all English-speaking countries, and he regarded this as being likely to be a convenience to the trade as saving it from the necessity of labelling specially for the different countries. There was room in legislation for all the means of dealing with the subject that now operated. The principle of the public declaration of a formula or the presence of active drugs was

useful, but had drawbacks. The public was not necessarily advantaged by the declaration of the formula; it only thought it knew; the lodgement of the formula confidentially with a public authority might be of just as much advantage to the public. Any Act should prohibit the advertising of the fact that a public authority had passed the preparation and pamphlets accompanying. There was certainly room for the protection of the public by the scrutiny and correction of printed matter. There should be frequent addenda to the *Pharmacopoeia* in the form of supplementary lists. Unless some good reason were shown he would not allow the well-known drugs to be advertised under different fancy trade names; on the other hand, protection should be afforded to any one who could show that he was the discoverer. Advertisements should be dealt with carefully; the New South Wales Pure Food Law, 1903, gave power to prohibit the advertisement of any article in contravention of a notification of the public department concerned.

The Chairman: I suppose one may fairly sum up the general attitude of the Australian Government by saying it claims nothing but the application of common sense and medical knowledge in dealing with this question?

The Witness: That is so; the work has not been done in the interests of medicine or pharmacists as such, but for the public.

In reply to Sir Philip Magnus, the witness said there was a movement, which was gathering force, to extend to each State the regulative methods applied by the Commonwealth Government to imported proprietary medicines.

Sir Philip Magnus asked if the principle laid down by the witness of competent diagnosis as an essential was fully carried into effect, would it not prevent the sale of any proprietary medicine whatever. The witness replied that it would distinctly limit them.

Sir Philip Magnus: Does the scrutiny of advertisements apply to announcements in the public press as well as to printed matter?

The Witness: The scrutiny does, but unfortunately the censorship does not. We cannot touch the press under the Commonwealth Act, but some of the States are taking the power to do so. I think a weak point of our present machinery is that we cannot follow a medicine into the various States.

Mr. Lawson asked whether the driving force which produced the Acts was enthusiasm for public health so much as fiscal protection. The witness replied that the idea of fiscal protection had nothing to do with the matter. It was not a left-handed method of obtaining fiscal protection. Any growth of proprietary articles manufactured in Australia that might have occurred was entirely unforeseen, and as the Commonwealth was seeking power to control those, it was evidently not in sympathy with such a method of obtaining fiscal protection. He also said that the laws affecting advertising in the different States were not rigidly enforced at present. It would not be right to say the laws had remained largely a dead letter. In New South Wales, where the provisions had been in operation for some time, there had been test cases; elsewhere the laws had only recently been passed, and it would not be fair to judge them.

In reply to Mr. Newton, who asked the size and cost of the department which controlled proprietary medicines under the Commonwealth Government, the witness said that two doctors, himself and a colleague, had done the work of skilled scrutiny. The analytical work had been done as part of the ordinary routine of the Commonwealth laboratories; there was a small clerical staff, and occasionally leading physicians, surgeons, and veterinary officers were consulted. Often as many as twenty or thirty investigations in a week were made.

Mr. Newton: Does any serious delay to commerce occur through the operation of these regulations?

Dr. Norris replied that goods were released at first, even if some amendment was required, unless it was an extreme case where there would be positive danger to the public in admitting the preparation. Ample time was given for correspondence between England and Australia. Less objectionable printed matter was now received from importers; they were beginning to put their houses in order.

Mr. Glyn-Jones: If your principles were put in force to

the full extent it would mean the prevention of any proprietary medicine trade at all?

The Witness: This trade does not seem to me to meet any public need so much as to engender by advertisement an unnatural sense of need.

The trade should be prevented if possible?—It should be very rigidly regulated.

Is it not dangerous to place in the hands of two permanent officials the right of prohibiting any particular trade without appeal to an outside body whose decision would be final?—The only prohibitions are in the case of preparations considered positively injurious. These are not made by the officers of the department, but by the Governor-General in Council. The prohibitions are published as Orders in Council.

In reply to further questions, the witness said that when the suggestions for amendment of printed matter made by the department were not at first acceptable to the importer, it was not a matter of compromise. The department insisted on its full requirements; the only option given was in the matter of terminology.

At the conclusion of his examination the witness said he wished to add that, in regard to the suggestion of several witnesses that cancer and consumption "cures" should be prohibited entirely, he would like, in view of their experience in Australia, to extend the list to include cures for tumours of all kinds, epilepsy cures, diabetes cures, and those preparations with a vague description of mental symptoms—hypochondriasis or mental depression.

The Chairman said the Committee was much indebted to Dr. Norris for his extremely valuable evidence.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).

SECTION OF GENERAL PATHOLOGY.

The president of this section is Professor Shattock. The section will meet in the Royal College of Science.

The first discussion, jointly with the Section of Anatomy, is on the excitatory and connecting muscular system of the heart. The anatomical side will be taken by Professor His. Dr. Jesué will speak on localization of function, and Dr. T. Lewis and Dr. Ivy Mackenzie will also contribute to introducing this subject, which has been deeply studied during the last few years.

The pathology of fats and lipoids is another subject on which much work has been done recently. It will be introduced by Dr. Iyer Hang of Lund and Dr. Sigmund Fränkel of Vienna, whose views are well known to be divergent.

The third subject, the grafting of normal tissues, will be introduced by Professor Borst and Dr. Burrows; the fourth, the pathology of shock, will be introduced by Dr. Crile and Professor Yandell Henderson; and the last—the effect of radio-active substances on the tissues—will be opened by Dr. Hertwig and Dr. Lazarus-Barlow.

Among the contributors of independent papers are Professors Aschoff, Adami, Warthin, Dr. Charles Singer, Professors Brodie and Mackenzie, and among the subjects so treated are hyperblastosis, tetany, gastric ulcer, the influence of asphyxia on the kidney, and the rigidity of calcified arteries.

Further information can be obtained from Dr. Leonard Dudgeon (acting secretary), St. Thomas's Hospital.

The International Association of Medical Psychology and Psychotherapeutics will hold its annual meeting this year in Vienna on September 18th and 19th, under the presidency of Professor H. Bernheim, of Paris.

A BILL has recently been passed by the New York State Legislature and signed by the Governor, which provides that where women are required to undergo physical examination with a view to obtaining employment, such examination shall be made by women doctors.

A SYNDICATE of urology is being formed under the auspices of the *Revue Pratique des Maladies des organes génito-urinaires*, of Lille, and very many doctors from all parts of France have already joined. The head-quarters of the syndicate will be in Paris, and its object is to group all practitioners who take an interest in urology, so that they may know each other better and discuss their professional interests.

Nova et Vetera.

EARLY REFERENCES TO TROPICAL MEDICINE.

In the BRITISH MEDICAL JOURNAL of November 23rd, 1912, we gave an account of an interesting paper by Dr. Charles Singer, which appeared in the *Annals of Tropical Medicine and Parasitology* for May, 1912. A further paper by Dr. Singer on the subject appeared in the October number of the same periodical. In it he deals with the question of yaws and syphilis; some early references to dracontiasis or guinea-worm, and the measures taken in Paris in 1533 to prevent the spread of the plague.

Under the first of these heads Dr. Singer tells us that we owe the first accounts of yaws to the Spanish chroniclers, notably to Fernandez de Oviedo, whose *Natural Historia de las Indias* and *Cronica de las Indias* appeared in 1526 and 1547 respectively. He called the disease "bubas." Fuller descriptions are given by André Thevet in his *France Antarctique*, published in Paris in 1558. He calls the disease "pians," and compares it to the syphilis then spreading over Europe. Framboesia is still known in the French Antilles as "pians," which is said to be a native term for strawberry. An anonymous English translation of Thevet's book was published in 1568. Thevet expressed the opinion that "pians" was the result of too much "earnall and fleshely frequentation of man with the woma," and he adds:

This sickness is no other thyng than the pocks that raineth and hath power over all Europe, specially among the Frenchmen: For of us it is named the Frenche pockes, the whyche disease as the Frenchmen wright, was first taken at a voyage into Naples, and thether it was broughte by the Spanyardes, from the West Indies. For before it was discovered and made subiecte to the Spanyardes there was no mention thereof. It is not onely here in Europe but also in Grecia, in Asia and in Affrica.

This "wylde man's evyll" was conveyed by contagion like syphilis, and the symptoms were similar; further, "if it be waxen old it is harde (and dangerous) to heale; for sometimes it dothe afflict them even to the death." The passage quoted above is, Dr. Singer hints, a deliberate perversion of Thevet's statement. This is an amusing illustration of the manner in which writers of the sixteenth century strove to thrust the discredit of having imported syphilis into Europe on some other nationality than their own:

The final responsibility has been left with the poor Indian inhabitant of the Western Isles, whose exclusion from the republic of letters has prevented his views from reaching us.

What Thevet says is that the points of similarity which he indicates made him "think that the disease was probably no other than that beautiful pox now so rife in Europe which has falsely been fastened on the French nation." One recalls Ancient Pistol's lament that his Doll "is dead i' the spital of malady of France." Thevet, when he speaks of "the pockes . . . taken at a voyage into Naples, and thether it was broughte by the Spanyardes from the West Indies," is referring to the terrible epidemic of syphilis which broke out in Italy in 1493-94, and quickly spread over Europe. Having regard to the origin of this outbreak he thought it would be more reasonable to call it the Spanish disease.

Another argument in favour of the identity of the two diseases is based on the principle *Naturam morbi ostendit curatio*. The disease was cured by drinking a certain decoction of the bark of a tree named by the natives *Hinouake*, or guaiacum, which in Europe continued to be used in the treatment of syphilis long after the introduction of mercury as an internal remedy about the middle of the sixteenth century. This argument was used by Oviedo himself. He says:

I was often amused in Italy by hearing the Italians speak of the "French disease," whilst the French call it the "disease of Naples." But of a truth they would better hit its name off if they called it the disease of the Indies. And that this is the truth may be gathered from this chapter and from many experiments already made with holy wood and guayacan, wherewith especially, better than with any other medicine, this terrible pustulous disease is cured and healed.

The use of guaiacum as a native treatment of yaws survived its use in syphilis. In the eighteenth century it was still commonly administered (as *lignum vitæ* or *lignum sanctum*) to infected negroes by planters in the West Indies and other parts of tropical America.

The guinea-worm disease was recognized in very early times, and, according to Dr. Singer, some have even held that the fiery serpents which tormented the children of Israel in the desert were filariae. References to the disease were made by Plutarch, Galen, and Aetius, while Paulus Aegineta devotes a whole chapter to the *Dracunculus*. The Arabian physicians gave full accounts, evidently founded on first-hand knowledge of the disease. In the sixteenth century the Portuguese Jew, Amatus Lusitanus, who was physician to Pope Julius III, had to leave Italy on the death of his protector, and found a refuge in Salonica. There he had the opportunity of observing what he calls the "Turkish disease." He speaks of it as

a dangerous malady which develops not only in the country from which it takes its name, but also in Egypt, India, and other countries, as the Arabian physicians, especially Avicenna and Avenzoar, do teach, describing it as the Medina vein.

This name, *Vena Medinensis*, is explained by the fact that the disease was said by Avicenna to be commonest at Medina. In respect of treatment Amatus quotes a physician learned in Arabic, as giving the following advice:

First, the patient ties the end of the vein or nerve round a small piece of wood, and this he winds little by little till the last part of the worm is drawn out. As the structure is often three cubits long, the treatment may last many days before the sufferer is altogether free from pain and inconvenience. Many adopt a cataplasm or cold suffusion, as Seranus, Leonides, and Paulus of Egina recommend.

On this passage he comments to the following effect:

Authors are in doubt as to whether this is a nerve, a vein, or a worm. But I have seen the condition with my own eyes, and can bear witness that a thin white worm in many coils was drawn forth . . . and if it should be broken in the process much pain and general disturbance ensues.

Another sixteenth century writer, the Dutch explorer Linschoten, described the disease, and the Latin version of his account of his travels, published in 1599, contains what is believed to be the first representation of the guinea-worm in a printed book. About the middle of the seventeenth century De la Motte Lambert, Bishop of Beirut, made a pastoral tour in the Far East, and a record of his experiences was published. Crossing Persia from Ispahan to the coast he passed through Lar, the capital of Lariston, which is not very far from Bandar Abbas. The water supply, not only of the town but of the country between Lar and Gomeron, was very bad, and was the cause of severe and mortal diseases. To this may, the Bishop says, be

attributed certain worms of a prodigious length, which engender in the thighs and legs. These worms lie hid, tortuously entwined in the flesh. When detected, a little incision is made to get at the head, this is attached to a piece of stick, and the stick turned a little each day. The worm, which is often six feet long, is thus wound out into a skein. Should it break, the part which remains will cause a dangerous corruption. The way to avoid this worm is to drink only wine, or if water is used, only such as has been carefully filtered through linen.

Dr. Singer mentions another writer, G. H. Velschius, who brought together in a large volume entitled *De Vena Medinensi* every reference he could find to the *Dracunculus*. His imagination seems to have been haunted by the worm, which he saw everywhere—on ancient Roman emblems, in the signs of the Zodiac, in the serpent on many antique coins, in many Greek sculptures, in architectural details, and in drawings of Albrecht Dürer and other artists. Dr. Singer says:

The very emblem of our profession gives him one of his best opportunities, and in the serpents coiling round the staff of Aesculapius he distinguishes a guinea-worm which that distinguished physician has just extracted by entwining it around a piece of wood.

Of the measures taken in Paris to prevent the spread of the plague in 1533 nothing more need be said here than that the general regulations are similar to the Orders conceived and published by the Lord Mayor and Aldermen of the City of London concerning the infection of the Plague, 1665. These may be found in Defoe's famous *Journal of the Plague Year*.

All who are interested in the history of medicine and in tropical diseases owe a debt of gratitude to Dr. Singer for his researches. He has brought wide learning and tireless industry to the performance of a difficult task. We congratulate him on the result of what has evidently been a labour of love.

FRANZENSBAD.

BY A MEMBER OF THE FRANZENSBAD ASSOCIATION OF MEDICAL MEN.

FRANZENSBAD is situated in the western extremity of Bohemia, in the vicinity of Carlsbad, on a tableland about 450 metres above sea level, bordered by the Erz Mountains, the Fichtel Mountains, and the Bohemian Forest. It is protected by these mountains from the north and west winds, and has a mild mountain climate, with a medium summer temperature of 59° F. It has twelve mineral springs, a stratum of ferruginous mud, a source of dry carbonic acid gas, and in the near neighbourhood a source rich in radium.

The twelve springs yield in abundance bright and clear water, containing large quantities of carbonic acid gas, of carbonic ferrous-oxide, and of sodium salts in varying quantities. The chief constituents of the waters most used internally for diseases of the stomach and for atony of the bowels, such as the Salzquelle and the Wiesenquelle, are sodium salts; the water of the Franzensquelle, Neuquelle, and Stahlquelle, used for cases of anaemia and weakness, contains more iron. A third group, the Nataliequelle and Stefaniequelle, contain small quantities of salts, among which lithium carbonate is most prominent; they are used in the uric acid diathesis, gout, and chronic kidney trouble.

Mud Baths.

Franzensbad's most powerful remedy is the ferruginous mud. The mud stratum, situated in a basin surrounding the town, measures four kilometres in length, half to one kilometre in breadth, and is two to six metres deep. The mud has been formed by the penetration of the mineral springs into marshy vegetation, impregnating it with iron and alkaline salts. Such iron mineral mud can be produced only in a place which possesses a marsh and chalybeate springs penetrating it. The mud is not suitable for use when fresh. The quantity required must be removed from under the turf, and exposed to the air from autumn till spring, when a chemical change takes place, the insoluble combinations (mostly the sulphate of iron) being changed to soluble sulphates. Franzensbad mud, when ready for use, contains about 10 per cent. iron sulphate and a considerable percentage of sulphuric acid, both of which are strongly stimulating to the skin, act as astringents and tonics, and have at the same time a strong antimycotic quality. The mud is ground in mills, sifted, and mixed with the warmed water of the Franzensbad springs in different proportions to form a paste more or less thick. Its action is due to its mineral ingredients, to its temperature, and to its weight.

The Franzensbad iron-mud baths are used in cases of general weakness and anaemia, of chronic inflammations, mostly of the peritoneum and the sexual organs of women and in sterility, and also in arthritis deformans, gout and chronic rheumatism, neurasthenia, hysteria, neuralgia, and paralysis. The mud is also used for mud-packing and for mud poultices—mostly in such cases as inflammations of the abdomen, rheumatism, arthritis, or neuralgia of the extremities and joints, in which the application of mud is necessary at a higher temperature and for a longer period than would be possible with a complete mud bath.

Carbonic Acid Baths.

These are of two types—mineral and steel baths charged with carbonic acid gas, and dry carbonic acid baths. The water for the baths is prepared in different gradations without the addition of artificial carbonic acid gas, and are used in cardiac disorders, anaemia, weakness, and neurasthenia.

Franzensbad possesses also a gas well, which produces great quantities (12 litres per minute) of nearly pure dry carbonic acid gas; this is conducted to the special gas bath-house built over the gas spring. It is introduced into a basin about one metre deep, in which the patients

sit or stand clothed; the gas stimulates the skin, and an acceleration of the circulation is felt as a slowly-increasing, agreeable warmth, spreading all over the abdomen. These gas baths are used in cases of anaesthesia and hyperaesthesia, of neuralgia and paralysis, of amenorrhoea and oligomenorrhoea, of frigidity and of childlessness.

The public frequenting Franzensbad consists mostly of three groups: (1) Ladies suffering from different women's diseases, slowness and irregularity of the sexual functions, and principally from childlessness; (2) patients affected with debility, weakness of the nervous system, diseases and irregular functions of the heart and circulation; (3) people suffering from rheumatism and gout, and the uric acid diathesis and its consequences.

Visitors to Franzensbad will find bath-houses arranged with every requisite comfort, and excellent hotels, and boarding-houses surrounded by beautiful grounds and gardens.

LITERARY NOTES.

At a meeting of the Académie de Médecine, on June 3rd, Professor Pozzi, on behalf of Dr. Georges Hervé, Professor in the School of Anthropology, presented what he described as a very interesting study on the bust of Quesnay, by the famous eighteenth century sculptor Vassé, which is now in the Royal Museum at Brussels. Dr. Hervé's essay was read to the French Society of Medical History in April last. Dr. Pozzi described Quesnay, an account of whom was given in the *JOURNAL* of June 7th, 1913, p. 1214, as one of the most vigorous intelligences of the eighteenth century. He added that Dr. Hervé's work is well written and richly documented, and gives a living picture of the man. The bust was exhibited in the Salon in 1771. The portrait reproduced in the *JOURNAL* of June 7th was painted by Fredou, and engraved by J. C. François in 1767. There are several other portraits of Quesnay—one painted by J. Chevalier in 1745, and engraved by J. G. Wille in 1747; one done in 1764 for the Académie de Chirurgie by an artist unnamed. This is now in the Paris Faculty of Medicine. Besides the bust of Vassé already mentioned there is a posthumous one done by Houdon, and exhibited in the Salon of 1781; and one by Leroux on the monument erected in the commune of Méré, the birthplace of Quesnay, on the initiative of M. Allain-Lacanu in 1896.

We have received a copy of the May number of the *British Review*, with which is incorporated the *Oxford and Cambridge Review*. This periodical is printed in a style that must make it a joy to those whose eyes are beginning to fail. Mr. R. A. Scott-James writes with excellent sense on the popular taste. He says the finest literature is not that which is most read, and the writer concludes that the finest ideas are not those which are most easily embraced. "The outlet which the majority of men find for their superfluous energy is not through the channel of fine ideas. Such literature as they read is for distraction and not for the vigorous use of their faculties." This, says the writer, is a matter of supreme importance, because this new reading habit of the million has turned the energies of authors and publishers from the few to the many. "It has introduced into the literary profession a demagogic habit, and has set up a quantitative instead of a qualitative habit." Dr. F. W. Macran discusses idealism and the Christian Faith, and Mr. L. F. Salzmann gives an amusing description of sea travel in the Middle Ages. He quotes a fifteenth century rhymester's description of the accommodation for passengers on the boats plying to Santiago:

A sak of strawe were there ryght good,
For som must lyg them in theyr hood;
I had as lefe be in the wood
Without mete or drynk:
For when that we shall go to bedde
The pumpe was nygh our beddes hede,
A man were as good to be dede
As smell thereof the styng!

Another writer of the same period, William Wey, gives the following advice to intending travellers by the boats plying between Venice and the Holy Land:

Furste, yf ye goo in a galey make youre covenante by tymo
wyth the patrone and chese yow a place in the seyde galey in the

overest stage; for in the lowyst under hyt is ryght smolderyng hote and stynkyng.

That the diet was not exactly that of one of our modern floating palaces may be gathered from the following advice to the traveller:

Ordeygne yowre byscokte to have wyth yow; for thow ye schall be at the tabyl wyth yowre patrone, notwithstondyng ye schal oft tyme have nede to yowre vytelys, bred, chese, eggys, frute and bakyn, wyne and other, to make yowre colasyan; for sum tyme ye sohal have febyl bred, wyne and stynkyng water.

For these reasons the writer says it is well to take a barrel of water and one of wine, and, in view of the habits of pilgrims and sailors, it is hinted that a prudent man should keep both barrels in a chest with other stores under lock and key. The more luxurious passenger would also take care to lay in a good store of fruits and spices, "confectyunnys, confortatyvys, laxatyvys and restoratyvys," while the complete traveller's outfit would include, beside a feather bed, which would cost three ducats when new, and could be resold for half that amount at the end of the voyage, a "lytyl cawdren and fryng pan," with plates, dishes and glasses. As an afterthought William Wey adds the advice to buy "a cage for half a dosen of hennys or chiekyng to have wyth yow in the galey." So equipped the traveller did not need to fear any shortage of provisions, and could rest with equanimity while his ship lay becalmed, "waltyryng and walowynge in the see."

The *Bulletin of the Johns Hopkins Hospital* for May contains an article by August Schachner on Ephraim McDowell, the "father of ovariectomy." He was born on November 11th, 1771, in Virginia, and after a period of pupilage under Dr. Alexander Humphreys, of Staunton, Virginia, a graduate of Edinburgh, he went himself to what was called the "Modern Athens" to complete his education. There he came under the influence of John Bell, who, in lecturing on diseases of the ovary, suggested that it might be possible to extirpate the diseased parts, though not daring to advise surgeons to attempt the operation. The seed fell upon good ground. McDowell seems to have left Edinburgh without a degree, and in 1795 returned to America, settling in practice at Danville in Kentucky, where he remained till his death. On December 13th, 1809, he was called to see a Mrs. Crawford, who was thought to be pregnant and to have gone beyond her time. McDowell, after examination, explained to her the nature of her condition and what he proposed to do for her relief. The first account of the operation was not published till seven years later. It may be interesting to reproduce it here, though it is well known to specialists:

In December, 1809, I was called to see a Mrs. Crawford who had for several months thought herself pregnant. She was affected with pains similar to labour pains from which she could find no relief. So strong was the presumption of her being in the last stage of pregnancy that two physicians who were consulted on her case requested my aid in delivering her. The abdomen was considerably enlarged and had the appearance of pregnancy though the inclination of the tumour was to one side admitting of an easy removal to the other. Upon examination per vaginam I found nothing in the uterus which induced the conclusion that it must be an enlarged ovarium. Having never seen so large a substance extracted nor heard of an attempt or success attending any operation such as this required, I gave to the unhappy woman information of her dangerous situation. She appeared willing to undergo an experiment which I promised to perform if she would come to Danville (the town where I lived), a distance of sixty miles from a place of residence. This appeared almost impracticable by any, even the most favourable conveyance, though she performed the journey in a few days on horseback. With the assistance of my nephew and colleague, James McDowell, I commenced the operation which was concluded as follows: Having placed her on a table of the ordinary height on her back and removed all her dressing which might in any way impede the operation, I made an incision about three inches from the musculus rectus abdominis on the left side continuing the same nine inches in length, parallel with the fibres of the above named muscle, extending into the cavity of the abdomen, the parietes of which were a good deal contused which we ascribed to the resting of the tumour on the horn of the saddle during her journey. The tumour then appeared full in view, but was so large that we could not take it away entire. We put a strong ligature around the Fallopian tube near the uterus and then cut open the tumour which was the ovarium and fibrous part of the Fallopian tube very much enlarged.

We took out fifteen pounds of a dirty gelatinous looking substance after which we cut through the Fallopian tube and extracted the sac which weighed seven and one-half pounds. As soon as the external opening was made, the intestines rushed out upon the table and so completely was the abdomen filled by the tumour that they could not be replaced during the operation which was terminated in about twenty-five minutes. We then turned her upon her left side so as to permit the blood to escape after which we closed the external opening with the interrupted suture leaving out the lower end of the incision, the ligature which surrounded the Fallopian tube. Between every two stitches we put a strip of adhesive plaster which by keeping the parts in contact hastened the healing of the incision. We then applied the usual dressings, put her to bed, and prescribed a strict observance of the antiphlogistic regimen. In five days I visited her, and much to my astonishment found her engaged in making up her bed. I gave her particular caution for the future and in twenty-five days she returned home as she came in good health which she continues to enjoy.

One scarcely knows which to admire most, the boldness and skill of the surgeon or the courage and endurance of the patient, who rode sixty miles resting her tumour on the horn of her saddle, and getting up to make her bed five days after the operation. As a further proof of McDowell's resolution it must be added that an excited mob gathered outside his house awaiting the issue of the operation; had the woman died, the surgeon would have been lynched. Mrs. Crawford had five children, all born before the operation. She survived the operation thirty-three years, dying in 1842 at the age of 78. It is believed that the original report was sent in 1816 to John Bell, but, in Bell's absence in Italy, fell into the hands of Lizars. Another copy was sent to Dr. Physic, of Philadelphia, with a request that it should be published if found worthy. This, like the other, received no attention: McDowell's nephew William, the bearer of the report to Physic, then turned to Thomas C. James, Professor of Midwifery in the University of Pennsylvania, and one of the editors of the *Eclectic Repertory*, who published it (vol. vii, 1817). McDowell's second operation was performed in 1813 upon a negress. The ovary was exposed and incised but not removed, as it was firmly adherent to the bladder and the fundus. She recovered, had no more pain, and was able to pursue her occupation. The third, which was the last included in the first report, was performed in May, 1816, upon a negress. In this case he removed a scirrhus ovarium weighing 6 lb. Two other cases were described in a second communication published in the *Eclectic Repertory*. One was operated upon in April, 1817. It was a scirrhus ovarium weighing 5 lb. The patient recovered from the operation, but it gave more trouble than the others at the time, and the result was not so satisfactory. The fifth—operated upon in May, 1819—had been tapped four times before the operation. There were many adhesions. Sixteen litres of gelatinous fluid were discharged from the tumour and abdomen. Death from peritonitis occurred on the third day. The tumour was a dermoid cyst. These were the only cases McDowell reported. How many he actually did is not known. Samuel D. Gross collected three additional cases, all white. Of these eight cases five operations were complete and three incomplete. Of the complete operations, two in white women and three in negresses, there was one death among the latter, giving a mortality for these operations of 20 per cent. His nephew William, who was at one time his partner, says his uncle performed the operation thirteen times in all. He also performed lithotomy thirty-two times without a death, one of his patients being James J. Polk, afterwards President of the United States. McDowell's first reports were received with indifference and incredulity, in some quarters with ridicule. His first paper attracted no attention till it was published in connexion with one of Lizars's failures. This aroused Europe and later America to the importance of his work.

W. Waddl, in his *Nugae Canorae* (1827), tells of a Count de Viry who carried his desire for secrecy in regard to his ailments to such a degree that he called a surgeon to dress an ulcer on his leg and when a similar one broke out on the other he sent for a different surgeon. He wished apparently that his right leg might not know what was the matter with his left. To a person who inquired for him, his secretary said: "He is dead, but he does not wish it to be known."

British Medical Journal.

SATURDAY, JUNE 21st, 1913.

UNIFIED STANDARDS FOR FOODS AND DRUGS.

THE simpler conditions of a smaller community and the absence of conservative traditions and of the dead-weight of old vested interests sometimes enable the Colonies to devise and put into force legislation on matters in regard to which, in Great Britain, it is generally admitted that something ought to be done, though the difficulty of satisfying the various interests concerned and the constant congestion of parliamentary business effectually prevent any considerable steps being taken. The recently published report of a Royal Commission, appointed in Australia about a year ago to take and collate evidence from those principally affected by legislation in regard to the sale of foods and drugs, contains a good deal which illustrates the truth of this generalization, and it is of some interest from the point of view of the admitted need for further legislation on the subject in this country. Dr. J. Ashburton Thompson, Chief Medical Officer of the Government of New South Wales, was the sole Commissioner, and the special purpose of the inquiry was the making of recommendations for setting up uniform standards for foods and drugs in all the States of the Australian Commonwealth.

The actual state of the law at present is by no means uniform in the several States. New South Wales, apparently, is in general somewhat ahead of the others, but it is more especially in the regulations and standards under the various State laws that the want of uniformity is greatest. Before the appointment of this Commission, however, some important steps had been taken in the same direction. In 1910 a conference was held of principal medical officers, public analysts, representatives of commercial interests on the advisory boards of the various States, and representatives of the Commonwealth Government, and this conference included in its report a code of definitions and standards, to which all the members had agreed and by which they had undertaken to be guided. The report of this conference and its proposed code have since been before the country, but have not been enforced by legislation, and the business of the Royal Commission was largely to receive and collate the views of those chiefly concerned, on the report of the conference, as a preliminary to the institution of regulations for the whole Commonwealth or uniform regulations in the several States. The 165 witnesses included manufacturers, dealers, analysts, medical officers, etc., and the report of the Commissioner on the evidence must therefore carry much weight. Among the general conclusions it is stated that "the result of the directed inquiry shows quite clearly that satisfaction with the law, and in a general sense with the regulations thus far made under it, is felt and has been expressed"; and, in dealing with the grocery trade, that "The Secretary and the President of the Grocers' Association of Victoria, which is the mouthpiece of

the trade in that State . . . testified that the effect of the Act in general was entirely favourable to their trade"; and again, in connexion with aerated waters, cordials, etc., after discussing certain criticisms, the Commissioner adds: "Notwithstanding the opinions which have been noticed above, as well as others of less importance, the conference recommendations were generally welcomed, and, with the Acts on which they are based, were thought to have purified trade and to have done much good already."

It is recommended that the inquiry now concluded should be followed by the holding of a further conference of Commonwealth and State officials, to draw up a code for adoption in all the States; and it is wisely pointed out that "experience has shown, however, that the most carefully drawn code must be revised from time to time for addition of new regulations and more accurate wording of some of the approved regulations. This work can be done only by the conference. This body, then, must be regarded as liable to be reconvened either every year, or perhaps every second year."

Of the recommendations in regard to particular trades, it is perhaps those concerned with drugs and medicines that are of principal interest to the medical profession. One of the resolutions of the conference expressed an opinion that repetition of physicians' prescriptions by pharmacists at the request of the persons who happen to possess them should be restricted by law; but some of the witnesses thought that the responsibility should be thrown on the physician, who would direct whether the prescription should be repeated, and if so, how often; "this," comments the Commissioner, "seems a reasonable suggestion." Another resolution of the conference "requests that the law may be so altered that pharmacists shall be required to declare the presence in any mixture devised and supplied by them of any drug of which declaration is required by notice on the label": this was objected to, and "the objections raised were, first, that declaration of the names of drugs on labels was inexpedient, and would give patients information which had better be withheld from them, and then, secondly, that the requirement would interfere with, and limit, the pharmacists' power of prescribing. By some witnesses this power was described as a 'right' to prescribe, enjoyed by them from time immemorial until the New South Wales law was made." It is pointed out, however, that "pharmacists have no right to prescribe other than that enjoyed by every citizen, and exercised by each person at his proper risk. The nature of the pharmacists' business leads to their being asked to prescribe rather frequently, and they are, doubtless, often unable to avoid doing so; but the impropriety of seeking, and the danger of taking, medicines prescribed by persons who have some chemical knowledge of the nature of drugs, but no knowledge at all of the human body, are generally known."

In regard to proprietary medicines, the Proprietary Articles Section of the London Chamber of Commerce sent out a representative to put before the Commissioner the views of the members of that section. Objection was raised by this witness, among other things, to the recommendation that proprietary medicines containing more than 2½ per cent. of alcohol should bear on the label a declaration of the amount present. It was urged that instead of this the law should be made the same as the Canadian Act of 1908, which requires that no proprietary medicine shall be sold "if it contains alcohol in excess of the amount required as a solvent or preservative, or does not contain sufficient medica-

tion to prevent its use as an alcoholic beverage." Another recommendation which was objected to on behalf of the owners of proprietary articles is that a proprietary medicine containing any drug in a list which is set forth—44 being named and others included as classes—should bear on the label a declaration of the presence of such drug and of the quantity or proportion present. It was asked that this should not apply to medicines the proprietor of which made a statutory declaration that "the doses of the drugs they contain do not exceed those prescribed by the *British Pharmacopoeia*"; but the list contains many drugs which are not in the *British Pharmacopoeia*, a point which appears to have escaped the notice of the Commissioner. His comment on this part of the evidence is "the reasons advanced by him were not clear, but the whole consisted in a statement of the witness's belief that the inscription would frighten the public and prevent them from purchasing, which, in country places far from physicians, would be against the public good." The same witness urged the financial importance of the interests which he represented, estimating the stocks of proprietary medicines held by various traders in the Commonwealth at £3,125,000, and the amount spent by the proprietors in advertising in Australian newspapers as £160,000 annually.

The Commissioner's final comment on the evidence on this subject is unfortunately as true here as in Australia: "The extent to which the daily press profits by this trade will also be thought to indicate some further difficulty in regulating it."

SLEEPING SICKNESS AND BIG GAME.

THE discovery made by Yorke and Kinghorn during their expedition in 1911 to North-Eastern Rhodesia that the trypanosome *T. rhodesiense*, the infective agent of sleeping sickness in Rhodesia and Nyasaland, was carried by *Glossina morsitans*—the tsetse fly which causes nagana, the fly disease of domestic stock—put a new complexion upon a problem already sufficiently difficult of solution. It had been supposed that the only insect vector of sleeping sickness was *Glossina palpalis*, a species limited in its distribution to watercourses and never found far from the banks of certain rivers or the lake shores. *Glossina morsitans* is independent of water and may occur in any part of the bush. This was disquieting enough, but Yorke and Kinghorn went on to show that the big game in the two districts examined—the Luangwa Valley and part of the Congo Zambesi watershed—were tolerant of *T. rhodesiense*, and that a large percentage carried it in their blood. It appeared therefore that the big game acted as a reservoir of the parasite, and in view of the practical impossibility of exterminating *G. morsitans* Dr. Yorke was led to make the suggestion that the big game in the districts infected with the Rhodesian trypanosome should be killed off or greatly reduced—a result which the native hunters and European sportsmen would be ready enough to accomplish.

The *Proceedings* of the Zoological Society for June contain a paper by Dr. Yorke in which he developed the same argument as in the paper published elsewhere in this issue (p. 1315), and also give in an appendix the opinions of several authorities on parasitology or on the fauna of South Africa. Mr. Guy Marshall, who spoke as one who had resided thirteen years in Southern Rhodesia, questioned whether there was any evidence that human trypanosomiasis was

spreading north or south of the Zambesi river. He admitted that there was in Rhodesia and Nyasaland a very virulent form of trypanosomiasis carried by a *Glossina* with a wide local distribution and a much more persistent biter than *G. palpalis*, and, further, that a considerable percentage of the game was infected by *T. rhodesiense*. The existence of sleeping sickness in the district had been known for nearly five years, and he contended that its incidence in Nyasaland and Rhodesia presented a striking similarity with that found in West Africa. He argued that this fact taken in conjunction with other considerations strongly suggested that it was not a new disease, but one which had already been endemic for some years, though, as occurred earlier in West Africa, it had escaped detection. To these arguments Dr. Yorke replied that the question whether the disease were new or old was of secondary importance—the matter of primary importance being whether it was spreading. Though it was difficult to answer the question from the statistics available he believed that there was strong evidence that during the past few years sleeping sickness had been on the increase. It was not until the end of 1909 that the first white case was discovered, and since then, although the Luangwa Valley had been closed a number of Europeans had contracted the disease in North-Eastern Rhodesia. Before 1909 scientific experts had travelled through the Luangwa Valley without discovering a single case, either native or European. Another argument advanced by Mr. Marshall was that there was good evidence that the natives of West Africa were very largely immune to *T. gambiense*, and that there was no good reason for assuming that a similar power of resistance to *T. rhodesiense* might not exist in East Africa. In reply to this point Dr. Yorke stated that there was no evidence that human beings could harbour the parasites for long periods as did the wild fanna without exhibiting signs of the disease. Among the cases he had observed, several presented practically no symptoms when discovered, the only indication being the presence of trypanosomes in the blood, yet without exception all were dead within six months.

Professor Minchin, who accepted all the statements of fact in Dr. Yorke's paper, said that the two African trypanosomes deadly to man—*T. gambiense* and *T. rhodesiense*—were members of the large group typified by *T. brucei*; he believed that all the species of the *brucei* group were primitively parasitic upon wild ungulates, but that many had been carried by the agency of biting flies to other vertebrate hosts, in which they had been able to maintain themselves; that the wild ungulates were the natural hosts of these trypanosomes was, he argued, shown by the fact that the group was harmless to the wild ungulates but deadly to other animals. Professor Minchin urged that the utmost caution should be exhibited in putting into practice administrative measures based upon the data so far established; he thought it probable that if the tsetse flies in the bush were deprived of their natural hosts they would migrate in search of food, which they would find in human beings and in the cattle surrounding their habitation; it was within the bounds of possibility that the wholesale destruction of big game might lead to a condition of things more dangerous and disastrous than that existing at present. To this Dr. Yorke replied that cattle were not as a rule found in villages in fly districts, and that the fly did not invade villages around which there was a clearing, even though by so doing they could obtain food more readily than in the bush. To a suggestion by

Mr. Walter Rothschild that after the extermination of the game the fly would be driven to attacking monkeys, rats, and mice, Dr. Yorke replied that if this occurred these animals would quickly succumb, and would therefore not have the same significance as reservoirs of the disease as the big game, which are tolerant of the parasite. In reply to some observations by Sir Henry Seton-Karr, Dr. Yorke contended that the connexion between big game and sleeping sickness had been fully established, and that, even if there were other reservoirs of the virus, that was no reason why the main reservoirs should not be destroyed. While admitting Sir Henry Seton-Karr's contention that the greater freedom of intercourse among tribes under white protection had played a part in the spread of the disease, he contended that if civilization was to continue this freedom of intercourse must also continue, and it was therefore all the more essential to endeavour to render the tsetse flies as non-infective as possible by destroying the reservoir of the virus in the big game. In answer to a question by Sir Alfred Sharpe, K.C.M.G., as to the varieties of tsetses proved to be carriers of trypanosomes of sleeping sickness, Dr. Yorke said that it had been established that *Glossina morsitans* transmitted sleeping sickness under natural conditions—a fact which showed that it was almost hopeless to attempt to get rid of the trypanosome agent. If, therefore, anything was to be done, it must be in the direction of destroying the reservoir from which the *Glossina morsitans* and other hypothetical vectors derived their infection.

Dr. Yorke's suggestion is not that the whole of the game in tropical Africa should be destroyed, but that the restriction in fly areas should be removed, and natives and Europeans encouraged to kill game in those areas, especially in the vicinity of human habitations. We believe the suggestion that the attack must be directed against the reservoir, in view of the apparent hopelessness of materially diminishing the numbers of the transmitting insect, to be sound and based on scientific principles. If the natives were given a free hand with the game, and European large game sportsmen allowed to shoot as many antelopes as they liked, the stock would soon be enormously reduced, with a proportionate reduction of the risk of the game being a danger to man, black or white.

CONSTITUTIONAL REFORM.

WE venture to invite the careful attention of all members of the Association to the report of the Council on the reform of the present constitution of the Association, adopted by it at its special meeting on June 13th and referred to the Divisions. It is published in the SUPPLEMENT, and prefixed to it is a short account of the proceedings at the meeting of the Council at which it was discussed. It will be seen that the Council expresses its concurrence with the view put forward by the Metropolitan Counties and other Branches, and endorsed by the Organization Committee, to the effect that the Representative Body should cease to be an assembly of delegates bound to vote in a given way irrespective of the evidence placed before them at the Representative Meeting, by other members of that body, by the Council, or by the logic of events which have taken place since the meetings of the Divisions at which they were instructed. The view that the object to be aimed at is a body with deliberative powers consisting of men of judgement and honesty of purpose

trusted by those who elect them and believed by their constituents to represent the feelings and opinions of the constituency is accepted. The Council also agrees with the opinion that the Representative Meeting is too large and ought to be reduced, but recognizes the difficulties in the way, and regards the reduction of the number of constituencies as inadvisable and more or less impracticable.

The Metropolitan Counties Branch recommended that the Council should be elected by the Representative Body with the exception of those members who would sit *ex officio* or as representatives of Colonial Branches. The Organization Committee pointed out the difficulties which stand in the way of this change, desirable as it may appear as a logical development of the present constitution. The Council after a long discussion finally expressed the opinion that no change should be made in the present method of election.

Difficulties which have occurred during the last two years in taking prompt action in the interests of the Association and the profession at large are within the recollection of every member. They have led many members to the view that the Representative Body should delegate its powers in the interval between one of its meetings and another to the Council. This policy it is thought would contribute to efficiency, while at the same time it would be adequately safeguarded by the regulations which give to seven constituencies the right to requisition a Special Representative Meeting.

Following on this report is another in which the Council, after indicating reasons why it can seldom or never be necessary to take a plebiscite of the whole body of members of the Association, submits to the Divisions the arguments in favour of introducing a system under which an appeal by a postal vote could be made to the members of the Association resident in an area such as England, Wales, Scotland, Ireland, or a Dominion.

Several other suggestions concerning proposals for alteration in the scope and constitution of the Association will be dealt with in a supplementary report of the Council to be issued in the JOURNAL of July 5th after the quarterly meeting of the Council on July 2nd.

THE DISCUSSION OF THE AMENDING INSURANCE BILL.

THOUGH no date seems yet to have been fixed for the introduction of the Insurance Act Amendment Bill, the intention of the Prime Minister appears to have been to refer it, after it had been read a second time, to a Grand Committee. This has caused much dissatisfaction, both among members of the House of Commons and outside. The Insurance Act has been the chief piece of social legislation accomplished by the present Government, and whatever view may be held as to the merits or demerits of its conception, public opinion demands that the amendments it is admitted to require shall be fully understood and the arguments in debate fully brought to public notice; this will not be the case if it is sent upstairs. The bill ought not to be withdrawn from the consideration of the whole House, for it deals with matters in which the constituents of every member are nearly interested. Moreover, discussions in Grand Committee always tend to be less full and less thorough than in Committee of the whole House, and the reports published in the press are always meagre. It is now admitted on all hands that the haste with which the concluding stages of the bill itself were hurried through at the end of 1911 was mistaken, and is, in part at least, responsible for the need of amendment at this early date. On every

ground, therefore, we hope that the clauses of the amending bill will be discussed not in the comparative obscurity of a Committee room but on the floor of the House.

THE AIMS OF EUGENICS.

THE annual general meeting of the Eugenics Education Society was held at the Grafton Galleries on Thursday, June 12th, when Major Leonard Darwin, who was elected to his third year of office, delivered the presidential address. The speaker, in commenting on the progress made by the society during the past year, said that one good effect of the promulgation of its doctrines was the establishment of several new branches in different parts of the country, those at Manchester and Glasgow being among the most recent, whilst the International Eugenic Congress held in London last year had resulted in the foundation of a number of similar societies abroad. But much remained to be done, and further support was needed for the eugenic movement, both as regards volunteers and supplies. Moreover, it was the right kind of support that was needed, for there was always a danger that eugenics would become a mere dumping ground for cranks. This was possibly due to the fact that the more thoughtful classes in the community stood aloof and took little interest in the movement, no doubt because of a misconception of the aims of the eugenists. It was necessary, therefore, that they should be made to understand what these aims were, and that eugenics did not mean the establishment of stud farms for the breeding of giants and geniuses, but rather the improvement of posterity by means of a more thorough knowledge of the laws of heredity. After speaking of the dangers of national degeneracy, Major Darwin pointed out that the expenditure on law, police, the poor, and lunatic asylums in the United Kingdom amounted to £48,000,000 and the impost for national insurance to £25,000,000 a year, and the latter sum could either be diminished or the benefits increased if there were fewer of the unfit amongst the insured. By the elimination of the unfit, moreover, the rate of wages would inevitably be raised. Eugenic reform, therefore, if successful, would lower taxation, raise wages, facilitate commercial competition, and increase the security of the country in time of war. In things immaterial also great benefits would also be felt; for a diminution in the number of the insane, the criminal, the feeble-minded, the diseased, and the wastrel, annually brought into the world, would mean the removal of a terrible burden of unmerited misery, whilst an increase in the output of men and women of character and ability would not only add to the reputation of a country, but also to the happiness of its inhabitants in many ways. These were the benefits which it was held to be in the power of this generation to bestow on the country in the future by resolutely grappling at the present moment with the problem of human heredity. The social reformer had long been busy in his attempts to improve the environment of the people, and his efforts merited the warmest approval. Progress in the evolutionary sense, however, was not thus certainly promoted, and might not be promoted at all. What was really needed was an intellectual campaign which would make the path of eugenic reform stand out more clearly by increasing the knowledge of the laws of heredity, and a moral campaign to make our fellow-countrymen ready to accept the sacrifices necessary to ensure the racial progress of their country in the future.

MEDICINE AT OXFORD IN THE MID-VICTORIAN PERIOD.

ALTHOUGH a medical school has existed at Oxford from a very remote period, and degrees in physic were conferred as early as the thirteenth or fourteenth century, science can scarcely be said to have flourished in the

"home of lost causes" till Sir Henry Acland, by his indefatigable efforts, made the "lost medical school" a living thing. When he was appointed Regius Professor of Medicine in 1857, he found it in a state of suspended animation nigh unto death. There were not forty men on the books of all the colleges and halls who could legitimately append "M.D." or "M.B." to their names. It is significant that a candidate for the degree of M.D. was allowed such latitude in the choice of a subject for his thesis that it was said at one time that the distinction might have been conferred for a knowledge of volcanoes or for an acquaintance with the atomic theory or the botany of Virgil. If the Oxford doctor of that day added some knowledge of the elements of medicine to his more elegant accomplishments, he had done all that was expected of him. How little science was thought of is amusingly shown by the following story related by Mr. A. R. Bradley, son of a former head master of Marlborough, in a recently published book.¹ It was, he says, told to him by his uncle, the late Dr. Edward Fox of Clifton, who had been in the sixth form at Shrewsbury under the famous scholar, Dr. Kennedy. Fox went on to Balliol, and, being intended for the medical profession, he applied his very considerable talents to scientific studies, and took a first class in the then newly-instituted science school. He was actually the first "first class" in the Oxford Science School. Writing confidentially and light-heartedly to his old chief for the usual half-holiday for the boys in honour of the occasion, he received a characteristic reply of kindly indignation from that severe classic. Every one, wrote Kennedy, knew that no master rejoiced more in his pupils' classical triumphs than he, while even mathematical honours gave him no little gratification. He was always pleased to hear, too, of successes in athletics, and for personal reasons he congratulated his old pupil on achieving such measure of success as he had deliberately limited himself to; but really to ask for a half-holiday for science honours was, in short—well, a most audacious proposal! It may be remembered that Charles Darwin, when he was at Shrewsbury, was taken to task by Dr. Butler for wasting time that should have been given to the classics on such useless subjects as chemistry.

HYDRO-APPENDIX.

OWING to the great frequency of inflammation of the vermiform appendix and consequent operations for its relief, many unrecognized morbid conditions of that structure have recently been brought to light. Amongst them is a disease homologous, as far as the mechanism of the change in the tube and cystic duct is concerned, to hydrosalpinx and dilated gall bladder. It would appear, however, that the pathology is different, for the obstruction which brings about dilatation of part of the appendix is always tuberculous. This is an assertion important to remember whenever a cystic tumour is detected in the right iliac region, especially in considering prognosis after removal. Jaboulay seems to have been the first to distinguish this disease, when he removed an appendix from a boy aged 16 in 1898; five years later Lesueur wrote on dilatations of the appendix associated with tuberculosis, but the distensions—circumscribed cavities holding cheesy matter or pus—are not dilatations homologous to a hydrosalpinx. The contents of a true hydro-appendix are clear and mucous. About a dozen cases have been observed, all in French hospitals, and out of these only two have been reported, and both in theses. As the contents of the cystic appendix are clear, the operator might be misled, overlooking the tuberculous nature of the disease. An instructive monograph on the condition has been published recently by M. Duroux, who has worked under M. Jaboulay.²

¹ *Other Days; Recollections of Rural England and Old Virginia*. 1860-1880. Constable and Co.

² De l'Hydro-Appendicite, *Revue de gynéc. et de chirurg.-abdom.* February, 1913, p. 143.

in Lyons. He distinguishes two forms. The dilatation may be general, and then the appendix assumes the form of a banana, and in a female patient might well be taken for a certain type of hydrosalpinx, especially if free adhesions involving the pelvic viscera adjacent to the right iliac region are present. The most characteristic form of hydro-appendix shows irregular dilatation. A bilocular type, a basal unilocular variety, and an apical unilocular form are figured by M. Daroux. In all three drawings the relations of the meso-appendix and caecum clearly indicate the seat of the cystic structure. Eleven cases are recorded in full. In nine the patients were males, and two of these males were children. In all, relief was sought on account of the characteristic symptoms of inflamed appendix, excepting in one instance in which the patient died in hospital of chronic phthisis and haemoptysis; this was the only case where no operation was undertaken. Intermittent attacks and variations in the size of the swelling, the latter so familiar in hydrosalpinx, were frequent. Out of the ten cases operated on all recovered excepting a man aged 32, who had once been under treatment for phthisis which subsided. The wound was drained, but the tract ulcerated and could not be induced to heal. Miliary tuberculosis developed, and the patient died three months after the removal of the appendix. One patient was in good health five years after the operation; another, a boy aged 8, was well about six months after the appendix was removed, and so was a man aged 29, who had suffered nine years before from phthisis with pleurisy and haemoptysis. The other cases operated on were lost sight of. The necessary treatment of hydro-appendix is clear, but the study of a larger series of cases than that which M. Duroux has collected with great labour is necessary before definite conclusions can be reached. More than one case already recorded suggests that operative interference is perilous when tuberculous processes are going on elsewhere.

DEATH BY LIGHTNING.

SEVERAL deaths by lightning stroke have already occurred in this summer of quick atmospheric changes. Many people otherwise strong-minded enough are apt to lose their wits in a thunderstorm, and if they do not take refuge in the coal cellar or ring consecrated bells by way of conjuration, they are made acutely uncomfortable. Their fears may be, at least partly, allayed by an article in *Knowledge* for June. Mr. Marriott, the Secretary of the Royal Meteorological Society, says there that during the ten years 1901-10 the Registrar-General reported 124 fatal instances of lightning stroke in England and Wales—108 in men and 16 in women—a yearly average of only 12.4 deaths, or 0.36 per million living. In the twenty-nine years 1852-80 there were 546 such deaths, the yearly average for that period being 18.8, or 0.88 per annum per million living. The annual death-rate from lightning varies widely in different parts of England. In the north Midlands from 1852 to 1910 it was 1.8 annually per million living, in the metropolitan district only 0.13. On the Continent much higher yearly death-rates are found. In Hungary the annual death-rate from lightning is said to be 16 per million living (Milham); in Styria and Carinthia about 10 per million; in Prussia 4.4; in France and in Sweden 3; in Belgium 2, so far as the imperfect statistics available go (McAdie and Henry). In the United States of America the annual death-rate per million is high—about 10—in consequence of the frequency of thunderstorms on the one hand and of the large percentage of the inhabitants engaged in outdoor labour on the other; about 700 or 800 deaths from lightning were estimated to occur in the United States every year by Henry in 1900 to a population of 76 millions. Many more people are struck by lightning than are killed. For example, Jack records an instance in which a church was struck; 300 people were in it, 100

were injured and mostly made unconscious, 30 had to take to their beds, but only 6 were killed. Weber gives an account of 92 people struck in Schleswig-Holstein; 10 were killed, 20 paralysed, 55 stupefied, and 7 only slightly injured. In 1905 a tent with 250 people in it was struck and 60 were left on the ground in various states of insensibility, 1 was killed outright, another breathed for some minutes before dying, the rest recovered.

BALNEOLOGY AND CLIMATOLOGY.

AN interesting feature of the approaching Annual Meeting in Brighton is the inclusion for the first time among the authorized sections of one devoted to the subject of balneology and climatology. No doubt this is in a measure due to the fact that the meeting is to be held at a well-known health resort, but it is also a tribute to the improved position attained by these sister departments of medicine. Judged by the evidence of the oldest historical document to which the public at large has access treatment of diseases by balneological processes is among the most ancient practices of civilized man; but curiously enough, despite this fact, balneology and its companion have somewhat lagged behind other special branches of scientific medicine and surgery. Probably this is owing to their progress having been handicapped by several circumstances. A study of the index of the transactions of any balneological and climatological association or society will show that in practice it is not always easy to decide what subjects truly fall within their scope; while another obstacle has been the sometimes inevitable association of some balneological and climatological practice or theory with the material prosperity of a particular health resort. Furthermore, quite apart from such factors, both balneology and climatology present peculiar difficulties as scientific therapeutic studies. If they are approached from the clinical standpoint and an attempt is made to judge the accuracy of the theories concerned in them by the result of their application in a given case, there is always the difficulty of deciding how much is due to balneological and how much to climatological factors; while, when approached from the laboratory standpoint, they involve consideration of many of the most delicate problems of biochemistry. No doubt all these facts have been borne in mind by the officers of the new Section, since of the two subjects which they have chosen for special discussion one is sea-bathing and the other the international aspects of British health resorts. The first will afford an opportunity for endeavouring to distinguish what results, favourable or unfavourable, of sea-bathing are due to this form of treatment itself as distinct from its surroundings. It is by no means an easy question for an ordinary practitioner to decide, since in the case of a very large number of patients indulgence in sea-bathing means in addition change of climate, change of habit, and relaxation from the ordinary cares of existence. The second discussion, one may feel assured, will lead to its being shown that the topical associations of balneology and climatology, to which allusion has been made, are not inevitable, and that within the area of the British Isles there are facilities for almost every form of balneological and most forms of climatological treatment.

THE HALO OF BEAUTY.

In the June number of the *Girl's Own Paper* and *Woman's Magazine* "An Old-Fashioned Person" writes on the troubles of the pretty girl. She tells us that she herself was a pretty girl, and of course we have no reason for doubting her word. But when she says that "in her girlhood she was so native to her element that the laws of hygiene scarcely applied to her," we can only wonder, while a little puzzled as to her meaning. We know, of course, that Thomas Walker, the author of *The Original*,

claims that by diet he reached a state of health in which he did not need to wash his face. His skin by some mysterious exhalation "repelled impurity." The "Old-Fashioned Person," however, was not only "gloriously independent of soap," and needed no starch bags for her complexion like other girls, but she never perspired, and did not tan or freckle. All this, however, is a trifle, for she goes on to say: "I was so full of life and so heartily well that I believe I gave off a sort of quivering iridescence that 'charmed' certain beholders. I do not expect the reader to understand this. I don't understand it myself—but several times I have seen strange manifestations of quivering vibrations rendering the human face and form transparent to the gaze, and edged at every outline with the colours of the prism. This is doubtless in the eye of the beholder; but there is something, too, in the object, or else we would oftener see people and things in this prismatic and quivering light—this strange halo that surrounds the pretty girl. . . . I do not know, but I believe there is a sixteen-year-old halo that a girl's face wears which must belong to the astral life—her angel prototype maybe trying to stand between her and an unkind world." We can only say that the privilege of seeing this halo of beauty has been so far denied to our grosser vision. The healthy sixteen-year-old girl as we know her glows with health, but her appetite is too carnal to be compatible with any visible manifestation of the astral life. Does the angel prototype desert the young girl when she sheds her halo? We gather that this takes place, for the "Old-Fashioned Person" believes that the time is not far off when women will be courted for other possessions than beauty. This, we take it, is a necessary consequence of the loss of the sixteen-year halo. A frivolous person might say that there are other "possessions" for which women are often courted. But it is mental qualities which, according to the "Old-fashioned Person," will attract men. This, she says, will be a great change, and will have a decided effect upon beauty. If you ask what effect, you are told that "it has so long been women's chief business to retain what is called her 'charm' for man, and she has resorted to such base means to do so, that in her new position before the world I believe she will scorn to employ the artificial, the immodest, and the loud." This is sound doctrine, and the lady is evidently a strong believer in the influence of the mind, if not on the body, at any rate, on its appearance. She says: "Could this world of ours drop all false beliefs and take up the only true idea which is simply the practice of good, all people would become more beautiful with a beauty that age cannot destroy." This is highly edifying, but regard for truth compels us to state that we have seen many excellent persons whose looks sadly belied the inward grace of their souls. When some one said to Sir Francis Barnard, "*Punch* is not so good as it was," he replied, "My dear fellow, it never was." This may serve as a general formula of reply to the *laudator temporis acti*. The "Old-fashioned Person" tells us that forty years ago the pretty girl was a genuine article; that bleached hair had never been heard of; that face powder was but "a vague accessory of Satan," and that low necks were utterly tabooed. All which propositions, as Teufelsdröckh says about the maxims on dandyism which he extracted from *Pelham*, we, for the present, content ourselves with modestly but peremptorily denying. Women have always been open to Hamlet's taunt: "God hath given you one face, and you make yourselves another." The "yellow topper" was as common in the early seventies as she is to-day; and it may be added that, to go no further back, the art of bleaching the hair was familiar to the Venetian ladies of the time of Titian. The connexion between face powder and Satan was not clearly recognized, and "low necks" were enforced at Court with a rigour which paid

no heed to age or state of health. Certainly gowns did not then, as a rule, begin so late or leave off so early as they do now, and the outlines of the female figure were not so ungracefully displayed. On the other hand, there was, of course, the "halo of beauty." Perhaps the modern high school girl, devoted to hockey and cricket, can take care of herself without the help of an "angel prototype."

THE ENDOWMENT OF MEDICAL EDUCATION IN AMERICA.

It is announced that Mr. Andrew Carnegie has offered to give to Vanderbilt University, Nashville, Tennessee, £200,000 for the development of its medical department. Of this amount the sum of £40,000 is to be given at once for the erection and equipment of laboratories, while the balance (£160,000) is to be given as an endowment, the income of which will be paid annually for the support of the medical department. A condition of the gift is that the direction of the educational and scientific work of the department shall be entrusted by the trustees to a small board of seven members, three of whom are to be eminent in medical and scientific work. The *Journal of the American Medical Association*, from which we take this information, states that Vanderbilt University has always enforced reasonably high standards of preliminary and medical education, and Mr. Carnegie's gift will, it is hoped, enable it to overcome the difficulties it has hitherto met with in carrying out its work.

HOW A HOSPITAL AUTOCRAT WAS TAMED.

THE relations between the medical staff and the lay administrators of a hospital are not seldom strained. There may sometimes be faults on both sides, but we think there can be no question that the friction is, for the most part, caused by fussy interference and attempts at actual usurpation of authority, which are not unaturally resented by the doctors. This state of things is from every point of view deplorable and interferes with efficiency. Examples could be given from many hospitals in this country. We prefer to give one from abroad. A curious instance of the lengths to which administrators are apt to magnify their office is related of the director of a Paris hospital, a worthy man but rather jealous of his authority, and disposed to play the petty tyrant over the residents. He was always seeking for occasions to assert himself in this way. One morning he issued a ukase forbidding residents to receive any cases of emergency unless a precise diagnosis of the disease was entered on the card of admission. This caused something like dismay, the residents being naturally aggrieved at being asked to make a snapshot diagnosis in cases where the very princes of science were often at a loss. They took counsel together, and one of them, who has since risen to eminence, conceived the brilliant idea of recording a uniform and extravagant diagnosis in every case. From that time all emergency cases of every kind were entered under the head of anencephaly. The director at first congratulated himself on having discovered grievous laxity among the residents. Hitherto these gentlemen had evidently been receiving anencephalous patients without knowing it. The cases were labelled pneumonia, rheumatism, and so forth, and the patients were admitted without the disease being recognized. The good man thought with satisfaction of the progress in science he had been the means of making. Soon, however, he became alarmed at the number of anencephalics admitted. The disease raged in Paris with appalling severity. Accordingly he warned his clerks and other subordinates to adopt the strictest hygienic measures to protect themselves and their children from the devastating scourge. In the meantime the epidemic ran its course and the registers of the hospital overflowed with entries of anencephaly. Then came a statistician who was collecting cases to illustrate some novel

theory. He was astounded to read case after case of this kind: Stonecenter, aged 65, anencephalic; washerwoman, aged 42, anencephalic. He counted up to 130 of such entries. Astonished at the number of cases of anencephaly in persons of such ages, he had an interview with the director which opened the eyes of that functionary. He fulminated against the residents, but to no purpose, and the obnoxious decree was rescinded. By way of revenge he soon afterwards issued a new edict forbidding the routine making of *post-mortem* examinations. Again the residents met, and thenceforward all deaths were entered as "suspicion of poisoning." Now, in such cases the French law requires a *post-mortem* examination to be made, and this must be done in the presence of the director, a commissioner of police, and a doctor not connected with the hospital. The result was that the unhappy director had to spend a large part of his time in the dead-house. Soon the commissioner of police, who was also a victim of the suggested prevalence of poisoning, devoted the hospital and the director to the devil and declined to allow himself to be disturbed, for of course no trace of poisoning was ever found. The director, whose health was suffering, had to make a sacrifice of his bureaucratic obstinacy, and thenceforward he ceased to trouble the residents and allowed them to do their work in the accustomed way.

PAYMENT BY POETRY.

In his *Toyage en Italie*, Théophile Gautier relates that he saw in an Italian city a sonnet inscribed on a wall in a conspicuous place in praise of a doctor who had cured someone of a disease of the liver. This sonnet, which was written in the most florid style and packed with mythological allusions, recorded the fact that the Parcae had tried to slit the thin-spun thread of a patient's life, but were foiled by the art of the doctor. That learned man, accompanied by Aesculapins and Hygiea, had, it appeared, descended to the lower regions where he blunted the scissiors of Atropos and entwined with fresh yarn the spindle of Clotho; the web of life was then woven anew by Lachesis. Gautier was pleased with what he called "this ancient and naïve way of expressing gratitude." Wordsworth says, "With this key Shakespeare unlocked his heart," and we are willing to believe that the author of the sonnet mentioned by Gautier did the same. But did he unlock his purse? If all patients were to pay their doctors in sonnets the medical crisis would be considerably more acute than it now is. We can only hope that the doctor celebrated in the manner related by Gautier was a lover of poetry and had a soul above any sordid wish to be paid for his skill in some less ethereal currency. But perhaps the poetical advertisement on the wall brought a solid return. Even taking this result into account, what a dreadful thought it would be for any man with the most elementary sense of humour to have his praises sung in classic verse and published as a poster!

THE FRIEDMANN CURE FOR TUBERCULOSIS.

According to the *Medical Record* of June 7th, the Board of Health of New York, at a meeting held on May 29th, adopted a resolution constituting an amendment to the Sanitary Code, the immediate effect of which was the closing of the Friedmann Institute in that city. The adoption of the amendment followed a meeting of the Advisory Board of the Board of Health at which the latter was recommended to take action. A resolution was passed that: "Whereas certain tests of the efficiency and safety of an alleged cure for tuberculosis now being made in this city are now being rendered unsatisfactory, unscientific, and practically futile through the insistence of the originator of the alleged remedy on conditions which involve inadequate observations, inaccurate methods of administration and the insistence on secrecy regarding the substances employed

in some phases of the treatment; and whereas evidence is already at hand to show that the so-called remedy not only does not fulfil the promises of efficiency and safety under which its use was at first permitted in this city, but, on the contrary, during its administration many patients have suffered serious and unduly rapid progress of their disease; therefore the use of living bacterial organisms in the inoculation of human beings for the prevention or treatment of disease is prohibited in New York City until after full and complete data regarding the method of use, including a specimen of the culture and other agents employed therewith, and a full account of the details of preparation, dosage, and administration shall have been submitted to the Board of Health, and until permission shall have been granted in writing for the use of the same."

We regret to have to record the death at Keswick, after a short illness, of Dr. Maclaren, consulting surgeon to the Cumberland Infirmary, Carlisle. Some account of his career will be given in an early issue.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Local Government Board.

IN connexion with the vote for the Local Government Board, an interesting debate occurred in the House of Commons on June 12th.

Mr. Walter Long moved a reduction of the Vote by £100, and said that he did so not on any grounds of personal hostility to the President of the Local Government Board, for he shared in the feeling of great admiration for the strong commonsense and courage with which Mr. Burns dealt with the many problems which confronted him. During his long tenure of office Mr. Burns on the whole had had a very free hand, and it was interesting to reflect upon the fact that it was left to what it was said was the most Radical Government the country had ever had to find in more than one of its Ministers a most determined autocrat. With reference to the laws affecting public health, Mr. Long said that the determination of the State to make certain contributions in respect to the salaries of certain local officials, and to give the Local Government Board power to exercise discretion in the appointment of those officials, taking at the same time the responsibility of paying portion of their salaries, was one of the greatest steps ever made in connexion with this most important branch of local government. On the question of the housing of the working classes, the President, in his opinion, had been guilty of a very great failure in the discharge of his duty. There was probably something like 100,000 new houses of a decent class required for the working classes. It had been suggested that local authorities should be given power to do the work, and that the State should contribute to the cost. Some members opposite could not hear this question discussed without immediately taking the view that it was an attempt to place on the State a burden which ought to be borne by the landowners. He would support the appointment of a Committee not composed of landowners, but to be drawn from the critics of landowners entirely, to inquire what the true state of the case was as regards the landowners of this country. He firmly believed that the large landowners had provided a sufficient number of good cottages for labourers, and denied altogether that any proposal to lighten the burden in connexion with cottage building by the local authorities would necessarily involve giving relief to the owners of the land. He was willing to abide by the decision of such a Committee on this question. Mr. Long then referred to what he regarded as the smallness of the results arising from the Act of 1909, and criticized adversely the action of the Local Government Board. With regard to vaccination, he said that he deplored the large increase in the number of

unvaccinated children, and could not help thinking that some day the results might be very grave. In his opinion this state of things was partly due to the insufficient remuneration of vaccination officers. They were paid under the old system of fees; the fees had decreased as the cases had decreased, and a large number of men in the country were doing work of the most important character on wholly insufficient remuneration.

Sir A. Griffith Boscawen said Mr. Burns had claimed that he could do everything necessary with regard to housing under the present law. If the law was now sufficient the administration must be very much at fault. The state of housing in towns and country districts, as well as in mining districts, in many parts of the country was deplorable. Sir William Lever had said that there were 100,000 deaths every year from overcrowding—a bigger number than were killed during the South African war. Mr. Burns's Housing Act had indeed done more harm than good, since it was better to have even insanitary houses for people to live in than no houses at all. During the first two and a half years after the passing of the Housing and Town Planning Act, only 315 houses were provided by local authorities; 100,000 cottages were needed at once, and at that rate of progress it would take a very long period to obtain them. A new administration and a new law, and, he ventured to think, a new President of the Local Government Board, were wanted if this matter was to be satisfactorily dealt with.

Lord Henry Cavendish Bentinck said that the President of the Board of Agriculture had stated that 100,000 cottages were necessary to be built in the next five years. Since the Act of 1909 came into operation loans for 3,000 cottages had been sanctioned, and at that rate it would take something like a hundred years before existing requirements were satisfied. It was a serious reflection on the Liberal Government and the Liberal Party generally that there were only about 2,000 fewer children in workhouses than there were when they came into office.

Mr. Leif Jenes called attention to the question of water supplies.

Mr. Herbert Lewis said that a survey of the whole of the water supplies of the country was recommended by a Select Committee in 1878 and by a Joint Committee of the two Houses of Parliament in 1910. In view of the fact that the House in 1910 ordered a return, the Local Government Board sent out requests for information and received 3,000 separate statements, the facts in which were being tabulated. The return was new in the printers' hands, and would be issued shortly. The information received dealt with all sources of water, private as well as public.

Mr. Hills referred to the number of cases of death due to starvation. The President had told the House that there were ninety-eight such deaths last year, forty of which were in London. He hoped that the Board's inspectors who inquired into such deaths made adequate inquiries as to whether Poor Law relief had been refused.

Mr. Astor called attention to the administration of sanatorium benefit, which, he said, was at present chaotic, largely owing to the fault of the President of the Local Government Board. There had been enormous difficulties with regard to this benefit. The Departmental Committee which had been appointed to make recommendations reported in April, 1912, yet it was not until December that the President appointed the London County Council as the central organizing authority for London to deal with tuberculosis. He also strongly condemned the delay in issuing the order approving of the domiciliary treatment of tuberculous persons, and stated that the Departmental Committee over which he had presided fully intended the County Council to be the authority for London, and only pointed out that use could be made of some of the beds under the Metropolitan Asylums Board.

Mr. Cave referred to the unjust treatment by the Local Government Board of vaccination officers, who had suffered considerable loss owing to the operation of the Vaccination Exemption Act of 1907. These men had been promised some compensation, but they still suffered large loss. He suggested that a General Order should be issued by the President authorizing boards of guardians to grant compensation to these officers.

Mr. Lewis Haslam referred to the treatment of children under the Poor Law.

Mr. Chaplin called attention to the great increase in the number of exemptions from vaccination since the President of the Local Government Board had made it possible for a parent to obtain an exemption by making a statutory declaration. When the President took office in 1906, the exemptions were 52,000; in 1907, 57,000, and in 1908, 162,000; in 1909, 190,000; in 1910, 230,000; and in 1911, 248,000; and in 1912, 276,000. This startling increase, he pointed out, was equivalent to 31 per cent. of the births.

Mr. G. Toulmin appealed to the President of the Local Government Board to hasten the extinction of the system of retaining children in workhouses.

Mr. Burns, in reply, said he felt so strongly the representations which had been made in regard to rural water supplies that the Board had prepared a bill, which was presented last year; it was on the paper this year, and if its passage into law could be secured there was no reason why the immediately critical aspect of the question should not be solved. With reference to Poor Law children, a great deal had been done in the last three or four years to secure their removal from workhouses and institutions where institutional treatment was not so good as could be secured in cottage, scattered or other homes. Since June, 1910, 100 boards of guardians had provided for Poor Law children accommodation away from the workhouses, in or about which only 8,000 were now left. In 1912 there were only 221 children between the ages of 3 and 16 in workhouses in London. In 1913 there were only 165, and of these 165, 74 were in separate buildings, and the remainder only in workhouses temporarily, being on their way to other places. Mr. Burns said that these figures were an earnest of the promise he had made to the House that he would accelerate the disappearance of children altogether from all workhouses. It had been pointed out that in one year 98 persons died of starvation in the United Kingdom, 40 of whom were in London. No stone would be left unturned to prevent such tragedies, but it must be remembered that the victims did not apply to the guardians for relief, and that some of them had money in their possession when they died, varying from a sovereign to £8 or £10. Great progress had been made with regard to out-relief to children, especially when it was remembered that 40 per cent. of the pauperism was due to widowhood, desertion, or orphanhood. The department and its staff had attended to the matter of sanatoriums with such signal success that even Mr. Astor did not produce any instance of a patient entitled to sanatorium treatment who did not receive it. Months before July 26th, and during the time Mr. Astor's own committee was sitting, the Local Government Board, the London County Council, the Metropolitan Asylums Board, and all the other authorities had made arrangements in anticipation for sanatoriums being provided as from July 15th onwards. They had really done a great deal of devoted and able work in trying to provide sanatoriums. So far as the Local Government Board was concerned, the figures provided an answer to much of the idle criticism and factious talk with reference to sanatoriums. Since July last 208 sanatoriums with 7,500 beds had been provided, and 192 dispensaries which were attended by many thousands of people. Forty-nine county councils out of 62, 66 county boroughs out of 75, and 25 metropolitan borough councils had got into working provisional schemes for tuberculosis sanatoriums and dispensaries, and, speaking generally, there was a margin of beds over those who required them. On July 15th there were in London anything from 800 to 1,500 empty beds in the possession of the Metropolitan Asylums Board, and it would have been the grossest folly to have thrown upon the County Council the cost of providing surplus beds and sanatoriums. In England and Wales there were 1,400 vaccination officers, of whom only 100 gave the whole of their time to their duties. Grievances had been alleged in respect of 658, and of those 594 had received gratuities, increased fees, and other forms of compensation. Of the 100 whole-timers, 90 were in office before the passing of the Act of 1907. In respect of 70, there had been alleged grievances, and 68 of them had been given compensation. He had devoted a great deal of attention to speeding-up and accelerating housing in both rural and urban areas. It was said nothing had been done, but in

the two years ending March, 1912, under the new Act 56,000 houses had been made fit for occupation and nearly as many more had been made fit under the Public Health Act of 1891 through the local authorities being screwed up in recent years by the Local Government Board to do this work. No less than 72,000 representations as to unfit houses had been made in the same period, and in the last three years loans amounting to £800,000 had been sanctioned to rural and urban authorities by the Public Works Loans Commissioners for housing. When it was said that nothing was being done with regard to housing, the answer was the fact that in 1912 there were in existence 180,000 more houses of £15 annual value and under than there were in 1909.

The vote was agreed to by 255 votes to 178.

Mental Deficiency Bill in Grand Committee.

The Mental Deficiency Bill came before Grand Committee B of the House of Commons on June 12th. Sir D. Brynmor Jones was in the chair, and the Home Secretary, assisted by Mr. Ellis Griffith, Under Secretary, was in charge of the bill. On Clause 1, which contains the definition of defectives under the four heads (a) idiots, (b) imbeciles, (c) feeble-minded persons, (d) moral imbeciles, Mr. Martin moved to omit feeble-minded persons defined in the bill as—

Persons in whose case there exists from birth or from an early age mental defectiveness not amounting to imbecility yet so pronounced that they require care, supervision, and control, for their own protection or for the protection of others, or, in the case of children, are incapable of receiving proper benefits from the instruction in ordinary schools.

Mr. McKenna opposed the amendment on the ground that it struck at a vital principle of the bill. The subclause concerned only children who had been declared to be mentally defective by the local education authority, but a child between the ages of 7 and 21 could not be confined without appeal or at the sole discretion of the local authority, and no child could be interned for life on the decision of a single magistrate. Mr. E. Jones pointed out that any such child could only be put into an institution at the instance of the parent or guardian. After some further discussion, the amendment was negatived.

On the last paragraph of the clause, in which moral imbeciles were defined as

persons who from an early age display some permanent mental defect with strong vicious or criminal propensities on which punishment has little or no deterrent effect,

an amendment was moved to strike out the words after "propensities," but Mr. McKenna said that the criminal propensity would be difficult to establish unless it manifested itself in some overt act. The desire was to save such persons from being punished for offences for which they had no moral responsibility, but to treat them humanely in homes instead of sending them to prison. The amendment was rejected by 19 to 3, several members declining to vote, and the clause was then agreed to.

On Clause 2, rendering defectives subject to be dealt with under the Act by being sent to or placed in an institution for defectives or placed under guardianship, Mr. Harris moved to omit the first subparagraph, which authorized the defective to be dealt with under the Act by being sent to an institution "at the instance of his parent, or guardian if he is an idiot or imbecile or under the age of 21." Mr. McKenna said that he thought that if a parent or guardian wished to bring the child under the operation of the bill it ought to be within his power to do so without having to apply to the court. The provision for the protection of the child in the later clauses were exceedingly strong, but he would be willing that Clause 3 should be amended so as to require the certificates of two medical practitioners.

At the second sitting of the Committee on June 17th the consideration of Clause 2 was resumed, and Mr. Martin moved to leave out the paragraph which brought within the scope of the Act a woman "who is in receipt of poor relief at the time of giving birth to an illegitimate child or when pregnant of such child." Mr. Ellis Griffith said that guardians in many parts of the country had asked that the bill should contain such a provision. Mr. Hills objected that the object was not to put a woman into a home because she was in poverty and her child was

illegitimate, but because she was defective, and because it was likely that the child would be defective. Mr. Ellis Griffith undertook to reconsider the phraseology of the paragraph.

On the second part of the clause an amendment was agreed to altering the age at which notification might be made by the local education authority to the local authority under the Act to the age of 7 years; in the bill the age was 5. The subclause was also amended by leaving out the words "three months" in the following paragraph and making it apply to children about to be withdrawn from a special school:

Who on or within three months before attaining the age of 16 are discharged from a special school or class, and in whose case the local education authority are of opinion that it would be to their benefit that they should be sent to an institution or placed under guardianship.

Sir Norman Helme moved an amendment providing that such notice should be given by the local education authority to the local authority in the case of any defective children over the age of 7 who needed permanent care, provided the consent of the parent or guardian was obtained. This amendment met with a good deal of support, but was opposed by the Home Secretary and defeated by 16 to 12. The clause was still under discussion when the Committee adjourned.

Mental Deficiency Bill (Scotland).—In reply to Major Hope, who referred to the increase of the Treasury grant for England and Wales for mentally defective children from £4 4s. to £6, and who inquired whether a similar increase of grant was to apply to Scotland, Mr. McKinnon Wood said that he could not at present give a definite answer, but that the matter was under consideration.

Grants to Reformatory and Industrial Schools.—Mr. King asked the Secretary of State for the Home Department what was the total amount paid from the Home Office votes for educational purposes in this country, indicating, in addition to the total amount, the sums paid in respect of reformatory and industrial schools, prison education, and all other educational purposes.—Mr. McKenna said the total sum paid towards the cost of reformatory and industrial schools in England and Wales in 1912-13 was £220,826. It was not possible to say how much of this sum was for maintenance and how much for education. The pay and allowances of the officers employed in prisons and Borstal institutions in teaching prisoners, including trade instructors, amounted to £14,500 a year.

Lead Poisoning.—In reply to Mr. Snowden, Mr. McKenna said that he was aware that the number of fatal cases of lead poisoning included in the annual returns for 1910-12 was twice as large as the number for the years 1902-4, but the Medical Inspector of Factories regarded this not as indicating an increase in the actual number of fatal cases, but as due to the recognition that diseases such as chronic interstitial nephritis and cerebral haemorrhage might be sequelae of lead poisoning, and also to the greater inclination to certify deaths of lead workers from associated diseases, such as phthisis, gastric ulcer, etc., as having been accelerated by lead poisoning. Better tests of the effect of administrative action for the prevention of lead poisoning would be a comparison of the number of cases in which death was due to acute lead poisoning, and in non-fatal cases a comparison of the proportion of severe as distinguished from slight cases. In 1910-12 the number of deaths due to acute lead poisoning was six only as compared with fourteen in 1902-4, and the percentage of severe cases 18.2 as compared with 30.4 in 1902-4.

Colour Vision Tests.—Mr. Lynch asked the President of the Board of Trade whether he could state how many officers of the mercantile marine who had previously passed the Board of Trade tests had failed in the tests of colour vision introduced on April 1st; and how many men had passed the wool test and failed with the lantern test, and vice versa. Mr. Robertson said that the total number of officers in possession of certificates of competency who were examined in the above tests during the

period April 1st to May 31st was 409: Failed in lantern test only: Six certificated officers failed in both local and special examinations; two failed in local examinations, but special examinations had not yet been held. Failed in wool test only: None. Failed in both lantern and wool tests: Three certificated officers failed in both local and special examinations: one had failed in the local examination, but had not yet been specially examined. Thus nine certificated officers had failed to pass the new tests; and three having failed at local examinations were awaiting special examinations before a final decision was given.

The Dogs Bill.—Notice of a number of amendments to this bill has been given by Dr. Chapple, Sir Henry Craik, and Sir Philip Magnus. The Standing Committee A, to which the bill is remitted, was called for on Monday, June 16th. No quorum was obtained, and the consideration of the bill was adjourned till Wednesday, June 25th.

Bovine Tuberculosis and Johne's Disease.—Mr. C. Bathurst asked the President of the Board of Agriculture if he would state how, under the Tuberculosis Order of 1913, bovine tuberculosis with emaciation was being distinguished from Johne's disease in cases where the owner did not consent to the application of the tuberculin test; and how, if no outward symptoms of tuberculosis exist, cattle could be notified as giving tuberculous milk in the absence of the proposed machinery of the Milk and Dairies Bill, whereby the presence of the disease in milk could, after bacteriological analysis, be traced from the retailer's premises to those of the cattle owner and the particular cow which yielded it. The President of the Board of Agriculture, in reply, said that no case of difficulty in making a differential diagnosis between tuberculosis with emaciation and Johne's disease had been brought to his notice, but he was advised that the following method might be used for distinguishing the two diseases, namely, by clinical examination, and, if necessary, microscopic examination of scrapings of the mucous membrane of the rectum, or by microscopic and biological examination of the faeces. With regard to the latter part of the question, whilst it was, of course, the case that owners of cows might not be able to notify cases of cows giving tuberculous milk from clinical symptoms, local Acts were already in existence under which cases might be found and dealt with even before the machinery was made generally applicable by the passing of the Milk and Dairies Bill. Mr. Bathurst asked if it were not a fact that the machinery of the Tuberculosis Order, so far as tuberculous milk was concerned, would break down almost entirely in the event of the Milk and Dairies Bill not passing into law. Mr. Runciman replied that he could not admit that. It was true that if the Milk and Dairies Bill were not passed into law the regulations would not be generally applicable, but would be applicable only in the most important cases. In reply to a question by Mr. Bathurst, who inquired as to the number of notifications of tuberculosis of the udder, emaciation from tuberculosis, or giving tuberculous milk, as the result of the Tuberculosis Order of 1913, during the month of May, and whether it was not a fact that the notifications were confined to the counties of Yorkshire, Lancashire, Derbyshire, Cumberland, Somersetshire, and Wiltshire, Mr. Runciman said that the number of notifications had been as follows: In England, 504; in Wales, 13; in Scotland, 51. He also gave a list showing a large number of counties from which no notifications had been received—more numerous in Scotland than in England and Wales. London was amongst the counties named in England. In conclusion, Mr. Runciman added that he was making inquiries with a view to ascertain whether in the counties named, or any of them, there had been unreasonable delay in enforcing the Order.

The Bee Disease Bill and the Milk and Dairies Bills.—In reply to Mr. Charles Bathurst, who indicated the need for legislation on these matters, and inquired as to whether the Government proposed to pass these bills this session, the Prime Minister said that the Government would be glad to carry the Bee Disease and the Milk and Dairies Bills through this session, but, unless they could proceed

as substantially uncontroversial measures, he was afraid there was little prospect of this in the time at their disposal.

The House-fly Pest. In reply to Mr. Charles Bathurst, the President of the Local Government Board said that, under the Public Health Acts, local authorities had powers with respect to the removal of refuse and for dealing with accumulations of manure and other offensive matters. They were also empowered to make by-laws relating to the deposit and removal of refuse matters, and by-laws of this kind were in force in many districts. The question of the relation between flies and disease had been frequently under the consideration of the Local Government Board, which had made and was continuing a series of investigations with regard to it. In the circular of August, 1911, to local authorities on the prevalence of epidemic diarrhoea amongst children, the Board emphasized the importance of prompt removal of stable and domestic refuse and the prevention of the accumulation of organic matters. He had reason to think that this circular led to much valuable work being done, and he was considering the question of issuing a further circular this summer.

Colonial Medical Officers.—Mr. Grant asked the Secretary of State for the Colonies how many district residents, assistant residents, and district doctors were married in the following comparatively unhealthy stations in British Central Africa: Port Herald, Chiromo, Limonde, Fort Johnston, Kotakota, Chintche, and Karongo; and how many district residents, assistant residents, and district doctors were unmarried in the following comparatively healthy stations: Zomba, Chirazulu, Blantyre, Neno, Neben, Dedza, Lilongar, Dowa, and Mzimba.—Mr. Harcourt replied that, according to the latest information, at the stations mentioned as unhealthy there were eight married and seven unmarried administrative and medical officers. At the stations mentioned as healthy there were ten unmarried and nine married officers of three classes. At two other healthy stations, Mlanje and Ngara, the two administrative officers and the medical officers were all married, and he was prepared without reserve to accept the classification of stations as healthy and unhealthy.

DR. W. GIBSON PARKER has published in *Public Health* (April, 1913) an interesting statistical inquiry into the relation between the "condition as to nutrition" of school children and the rate of infant mortality prevailing in the families from which they come. The children were classified with respect to nutrition as good, average, poor, and bad. After the children had been classified, the family record of births and deaths was obtained from each mother and the results analysed. It was found that the mortality per 1,000 under one was 56.1 in the class "good," 61.5 in the "average" class, and 97.5 in the "poor" and "bad" classes taken together. The author is careful to point out that these figures are not comparable with the rates of infant mortality generally employed since, *inter alia*, at least one child in each family must have survived to school age, but he holds that they support the belief that a high infant mortality is associated with a deterioration of health among the survivors. The facts here collected are worthy of attention, but the measurement of selective mortality, as has been pointed out by expert statisticians such as Yule and Snow, is a task of great difficulty. The problem is to study the after-history of two populations which have been subjected to different rates of infant mortality, keeping the environmental conditions constant. The words in italics reveal the source of the difficulty. Since in practice we are never likely to be provided with populations differing solely in respect of their infant mortality-rates, and the environmental conditions are constantly changing, it is necessary to have resort to statistical artifices of a very intricate kind, with the result that their interpretation is a matter of some uncertainty. We hope that Dr. Parker will return to this important point, he will find hints as to the pitfalls to be avoided in Yule's appendix to the Local Government Board Report (Supplement to the Report of the Board's Medical Officer, 1910, Cd. 5263), the memoirs of Snow (E. C. Snow, *The Intensity of Natural Selection in Man*, 1911 (Dulan), and *Biometrika*, 1913 (ix, 58 to 68), and Greenwood and Brown's study of infant mortality in Bavaria (Greenwood and Brown, *Journal of Hygiene*, 1912, xii, pp. 5 to 45).

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

LUNACY IN SCOTLAND.

THE fifty-fourth annual report of the General Board of Commissioners in Lunacy for Scotland was issued on June 10th. It states that exclusive of insane persons maintained at home by their natural guardians, there were on January 1st, 1913, in all 19,188 insane persons in Scotland. This number included the inmates of training schools for imbecile children and of the criminal lunatic department of Perth Prison. There was an increase of 154 in the total number of the insane, as compared with the previous year (1911). The Commissioners were in favour of a change in the law with regard to the admission of voluntary patients; it might take the form that a person could be received into and kept in an asylum for three days on his own written application to the superintendent, provided the sanction of the Board were at once applied for, and that no voluntary boarder were retained for a longer period than three days without such sanction. The recovery-rates from insanity were not quite so good as previous years, a fact which might be ascribed in part to the increased use of observation wards connected with the parochial hospitals of several large parishes which received persons suffering from passing attacks of mental disorder who would otherwise have been for short periods in asylums; but other causes were the accumulation of chronic cases, and the development of nursing and the improved means of hospital care in asylums which had led to their being more freely used for the reception of patients whose age and whose mental and physical condition were such as to preclude hope of recovery. The death-rate of both class of patients (private and parochial) was 9.8 per cent., and was, therefore, higher than it had been for many years; it was 8.7 in 1911. The escapes numbered 143; of these 65 were brought back within twenty-four hours, 35 within a week, and 21 after a week. This apparently leaves 22 unaccounted for. The total expenditure for the maintenance of pauper lunatics for 1911-12 was £427,495 as compared with £415,694 in the previous year, and the total average cost per patient was £26 4s. 8d.

OVERCROWDED HOUSES IN EDINBURGH.

Mr. David Rutherford, the chief sanitary inspector, in the annual report of the sanitary department of the City of Edinburgh for the year 1912, states that there are now within the city 7,354 ticketed houses which are regularly inspected; 108 were found overcrowded, 695 required to have walls and ceilings cleansed, and in 334 cases the floors and bedding were found to be in a dirty condition. Continued visits are paid to houses, especially in the poorer districts, in which cases of phthisis have been notified as existing.

EDINBURGH MEDICAL MISSIONARY SOCIETY.

The directors of the Edinburgh Medical Missionary Society gave a reception for the medical missionaries (former students of the society) now at home on furlough from the foreign field in the Green Café, Edinburgh, on the evening of June 13th. Emeritus Professor Crum Brown, the President of the Society, was in the chair for the first part of the evening, and Dr. J. W. Ballantyne, one of the vice-presidents, for the later part. There was a large gathering of the directors and of their friends, as well as of the present students of the society; and an attractive musical programme was carried through. Six of the medical missionaries present gave brief addresses. Dr. Leclaire Taylor, of the Church of Scotland Mission in the Punjab, spoke of medical work in the north of India; Dr. E. H. Edwards, formerly of the Baptist Missionary Society in Tai-yuen-fu, spoke of the calls China had made in the past thirteen years to the peoples of Europe; Dr. Nina Beath, of the English Presbyterian Church Mission in Swatow, spoke of the way in which medical work opened the hearts of the Chinese to western ideas; Dr. E. Mackenzie, of the Presbyterian Church of Victoria's mission in Santo, drew a picture of what medicine had done for the savages of the New Hebrides; Dr. J. W. Peil, of the Wesleyan Missionary Society's

station at Changsha in China, spoke of some of the different ways in which medicine opened up the path for Christian teaching; and Dr. J. Davidson, of the London Missionary Society's station at Neyoor, Travancore, told something of the native medical evangelists there. All the speakers referred very warmly to the benefit they had derived from the society during their college and university days in Edinburgh. Among the other medical missionaries present were Dr. S. Osborn, who is going to Rhodesia, and Dr. G. Ap Thomas, who is to join Dr. Davidson in Travancore. Dr. C. D. Walker had started for his station in Paraguay, South America, otherwise he also would have been among the guests of the evening.

EPILEPTIC COLONY OF THE GLASGOW PARISH COUNCIL.

The first epileptic home erected under Poor Law auspices in Scotland was opened last week. The question how best to deal with sane epileptics chargeable to the rates has for several years come up periodically before the Glasgow Parish Council, but owing chiefly to the cost no permanent steps were taken, and the epileptics were accommodated in existing parochial institutions and in part were kept at home. The unsatisfactory results of indoor treatment and the increasing number of indoor poor forced the question to the front. With the consent of the Local Government Board a deputation visited existing institutions in England, and afterwards drew up a scheme for the erection of a special home at East Muckerroft, near Chryston. This was adopted, and six villa blocks, each accommodating fifty patients, with the necessary administrative buildings, laundry, recreation-hall, and tradesmen's workshops, and houses for the medical superintendent, attendants, and workmen were provided at the cost of £45,000 (£150 a bed). If the cost of the villa blocks alone is taken, the cost is only £70 a bed, which is even cheaper than the cost of £80 a bed of the similar colony at Moughull, Birmingham. The Glasgow villas are one-storied brick buildings, containing day-rooms, dining-room, bathroom and lavatory accommodation, with kitchen and necessary offices. The dormitories are detached from the rest of the buildings. Each block has a separate heating boiler.

At the opening ceremony the Chairman of the Parish Council said it was intended to be more of the nature of a home than a hospital, and equipped with the view of relieving as much as possible the distressing accompaniments of the disease. It was proposed that the patients should lead as normal a life as possible, not the depressing, languid, wearisome drag so often seen in asylums. The colony was intended for those who were able to do something for themselves, and engage in work of some description which would in part at least help towards their maintenance. The colony had accommodation for 150 men and 150 women, and there were already 86 patients in residence. There were over 300 other epileptics of whom fully 200 were in mental institutions. Many of these reached a state of health which rendered them fitted for the greater freedom of the colony and as occasion offered they would be transferred to it.

ROYAL MEDICAL BENEVOLENT FUND.

THE annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held last week in the Royal College of Physicians, when the President of the College, Dr. Charles E. Fitzgerald, presided, and there was a large attendance. According to the report, the number of applicants was larger than usual last year, and the amount given in grants was greater than the average, yet to many of the recipients the aid given was far short of their urgent requirements. The total number of applications considered during the year was 106, and the total amount of grants recommended since the last distribution was £1,444 10s.; there was a decrease of £141 1s. 3d. on the income of the preceding year.

DENTAL CLINIC IN BELFAST.

Two months ago a dental clinic was opened in Belfast with the definite object of providing proper facilities for

treating the teeth of children in national schools; it was founded by a committee of the Children's Aid Society, and has been managed by it, but the scope and nature of the clinic's work have really been defined by the Commissioners of National Education, whose approval has been given. Local dentists have volunteered their services, which the Commissioners have consented to regard as equivalent to a fixed financial contribution, and have accordingly guaranteed an equal sum to help to cover working expenses. The local panel now contains eighteen dentists. During the first seven weeks one of the staff examined several hundred children of four schools, and of these 172 were sent to the clinic for dental treatment. Only children between 6 and 10 years of age have been dealt with; 129 permanent teeth have been filled; on alternate Mondays those cases requiring anaesthetics are treated; and a medical man has kindly offered to act as honorary anaesthetist. A trained nurse is in attendance. The local branch of the Dental Association has throughout given its approval and support; and the Secretary of the Children's Aid Society, Rev. W. G. Anderson, has made himself responsible for the registration of the cases and the general management of the clinic. Professor Powicke, Queen's University, Belfast, has brought the undertaking before the public, and contributed these details to the press. The preventive effect such work affords in disease should make a powerful appeal to all citizens, and enlist their help and sympathy.

HEALTH OF BELFAST.

The Medical Superintendent Officer of Health reported to the monthly meeting of the City Council on June 2nd that scarlatina was still very prevalent; 170 cases had been notified during the month; in one district many of the cases were traced to a dairy, and after the necessary precautions were taken, the numbers fell. He urged that medical advice should be sought, even in the mildest cases. The number of cases of typhoid fever notified was 21; a considerable number had previously eaten shellfish, gathered on the foreshores of the lough, a habit against which grave warnings had been issued from time to time.

The Children's Act Committee brought forward the question of school accommodation, and its chairman stated that, in face of the report of the inability of some 10,000 children to get admission to the elementary schools from lack of room, an effort must be made to remedy the evil. Most medical men will remember the revelations of the late Dr. A. McKeown in the matter. Belfast is justly proud of many of its institutions, but elementary school accommodation is popularly considered one of its disgraces, and there seems to be much truth in the accusation.

TREATMENT OF TUBERCULOSIS IN CORK.

At a meeting of the Committee of Management of the Cork Joint Hospital Board, on June 7th, it was proposed to recommend the county councils of the city and county of Cork to take over the management of the sanatorium at Heatherside from the Joint Hospital Board on receiving from the Local Government Board the sums of £8,621 16s. 7d. in respect of Cork County, £2,095 14s. 10d. for Cork Borough, or a total of £10,717 11s. 5d., with a subsequent recoupment of their share of the £25,000 deducted for other purposes from the total grant. By the Tuberculosis Act of 1913 the Conjoint Committee were enabled to do what was proposed and thus form a new body which would take over the management of the sanatorium. The further question, whether dispensaries should be established, was left open.

ANNUAL MEETING OF IRISH MEDICAL ASSOCIATION.

The annual general meeting of the members of the Irish Medical Association was held in the Royal College of Surgeons on Wednesday, June 11th, when Dr. J. B. Story, the newly-elected President, took the chair. The seventy-fourth annual report stated that the National Insurance Act, in its application to Ireland, had engaged the attention of the Council more than any previous legislation. At its annual meeting in Cork this Association arranged the general meeting of all medical practitioners, held on June 30th, 1911. At that meeting a Conjoint Committee of the British Medical Association and Irish Medical Association was formed. In June, 1911, a meeting of the

delegates was held, when the Conjoint Committee was reconstituted to consist of nineteen members of the Irish Medical Association and a corresponding number of the British Medical Association, with representatives from the licensing bodies, colleges, and four provinces. Numerous meetings of the Committee had been held, and important work had been done. While matters affecting the Act generally were referred to the Conjoint Committee, the Council of the Irish Medical Association, through its Committee, advised members on various questions arising from time to time.

Dr. R. Marlay Blake (Dundalk) moved:

That the representatives of the Irish Medical Association on the Conjoint Committee be called upon to resign their positions on that Committee.

He thought that the interests of the members of the Irish Medical Association had been betrayed by the Conjoint Committee when the latter advised the adoption of the panel system for certification as outlined by the Insurance Commissioners.

Dr. Callaghan (Galway), who seconded the motion, said that the Conjoint Committee had not the confidence of the profession. The Irish Medical Association had always represented the rural practitioners, and should dissociate itself entirely from the British Medical Association, which mostly represented the city practitioners.

Dr. Donnelly said the actual membership of the Irish Medical Association was 673, and on credible authority he learnt that there were in Ireland 800 members of the British Medical Association. There should, in his opinion, be no antagonism between the associations. When the Insurance Act was on the stocks it was the Irish Medical Association that banded the doctors together, and the Conjoint Committee was of no advantage to the doctors, but the contrary. Dr. Opherts stated that it was entirely incorrect to say that Down was a panel county.

The resolution was then put to the meeting and carried with almost complete unanimity. The president said that he would rule that this resolution would prohibit the Executive Council from allocating any further funds to the Conjoint Committee.

The following resolution was passed:

That all members of the Irish Medical Association who have gone on the panel in their areas, and outside their areas to certify for insured patients attended by non-panel doctors, be called upon to resign their membership of the Association.

A resolution expressing emphatic disapproval of doctors joining the panels, and calling on those who had joined to withdraw as soon as they could legally do so, was also passed.

The annual banquet was held in the Royal College of Surgeons in the evening, Dr. J. B. Story in the chair. On Friday afternoon the President and Mrs. Story entertained the members by an afternoon party in the Zoological Gardens.

England and Wales.

LONDON.

DISTRICT NURSING.

A CONFERENCE on the subject of district nursing in London was held at the offices of the Local Government Board on June 14th. In opening the conference, Mr. John Burns said that it was one of a series of efforts made by the Local Government Board to link up the different agents, public and private, working for the benefit of the poor. Hitherto the best possible results had not been obtained from district nursing, partly because of lack of co-ordination, while a further reason for holding a conference was the alteration in the problem introduced by recent legislation. For instance, one outcome of the medical inspection of school children was a need for the visiting of children in their own houses. Old Age Pensions Act and the National Insurance Act had also affected the problem. Neither the State nor the rates could do everything for the poor, nor was it desirable that they should. What was needed was the guidance and stimulation of the virtue the poor exhibited in helping

each other. Whatever was, or could be, officially done left plenty of room for the services of kindly people who were willing to devote their energies to district nursing. There were already, he was informed, 400 trained women engaged in work of this order, at a cost of not more than £30,000. It would be well if all public expenditure brought about an equally valuable return. The best work of nurses was not necessarily either medical or surgical; it was their human, sisterly, neighbourly qualities which were most valuable. They went into the homes of the poor and talked not at them, but to them, and by their kindly advice and persuasion brought about great changes for the better. Still, to get the best possible results, unification of aim and co-ordination of effort were necessary, though there should be no interference with the domestic management or independence of philanthropic associations. Some recent efforts at co-ordination in other directions proved their value. The drop in infant mortality from 145 to 90 deaths per 1,000 registered births was largely due to the Notification of Births Act having concentrated social and philanthropic agencies on the working-class mother and child at a very critical period, while the co-ordination of agencies for dealing with London vagrants had, besides removing the nightly blot on the Embankment, led to the closing of 33 per cent. of the casual wards in London, and to the reduction of casual pauperism from 1,300 to below 400. The discussion which followed this speech ended in the passage of three resolutions. The first asserted the desirability of all bodies concerned in district nursing in the metropolis being brought into closer co-ordination in order to meet the demand for nursing on systematic and co-operative lines; the second suggested the selection of ten persons to form a provisional committee to prepare and promote a scheme for carrying out the first resolution and to report further on the subject, and the third named the following persons as members of such committee: Mr. A. Ellis (Metropolitan Federation of Queen's Nursing Association), Miss Hughes (Queen Victoria's Jubilee Institute for Nurses), Miss Paxley (General Secretary of the Ranyard Nurses), Miss C. Gregory (Southwark, Newington, and Walworth District Nursing Association), Sir Arthur Downes, M.D. (Local Government Board), Mr. Warburg (London County Council), Mr. J. A. Dawes (London Insurance Committee), Canon Curtis (Wandsworth Board of Guardians), Mr. F. Briant (Lambeth Board of Guardians), and Mr. C. S. Loch (Charity Organization Society).

Australia.

[FROM OUR SPECIAL CORRESPONDENT.]

ROYAL PRINCE ALFRED HOSPITAL, SYDNEY.

At the annual meeting of the subscribers to the Royal Prince Alfred Hospital Professor Anderson Stuart, the Chairman of the Board of Directors, presented the annual report. It stated that the total number of in-patients during the year was 7,115. As the available number of beds in the hospital was 392, the daily average number of patients was 386, and the mean residence of patients in days was 21.06. The rate of mortality per cent. for all cases under treatment (excluding 96 deaths which occurred in patients within twenty-four hours after admission) was 5.07. The number of attendances in casualty and out-patient departments was 69,082. In the year 1883, when the hospital was first opened, the number of operations was 147, the percentage of the number of operations to admissions being 13.75. In 1912 the number of operations was 4,690, being 69.15 per cent. of the number of patients admitted. While there had been an all-round increase in the amount of work, the increase in the pathological, x-ray, and medical gymnastics departments was specially marked.

The question of providing increased accommodation for the treatment of gastro-enteritis amongst infants has been under consideration during the past year. At present comparatively few cases of this disease can be accepted into the wards, but it is believed that if there were suitable accommodation for open-air treatment the high rate of mortality now prevailing would be much reduced. A scheme for establishing an annexe to the children's ward

for the special treatment of these cases is now under consideration by the board. As the work of the pathological department has increased so much, the board, on the recommendation of the honorary medical staff, decided to appoint a chief resident pathologist, who, under the professor of pathology, would be a more or less permanent executive head of the department. Post-graduate work has also been under consideration for some time past. Recently a memorandum on the subject has been presented by Professor Anderson Stuart, Dean of the Faculty of Medicine, to the Senate of the University, and the matter is to be considered by a committee of representatives of the hospital board and the Senate.

During the year the number of students attending the Prince Alfred Hospital practice was again higher than during the previous year, and this showed that a large proportion of the students of the medical school desired to obtain their practical and clinical experience at this hospital. Considerable alterations have been made in the hospital buildings. The most important of these has been the erection of a large addition to the nurses' home. This consists of a brick building of three stories, and will provide over 200 bedrooms. The estimated cost of this building is £25,000, of which £8,000 was contributed by the board of directors and the balance by the Government. The net result of the year's operations was a deficiency of £1,412 2s. 7d. on the working account, while the Endowment Account showed a net gain of £538 3s. 8d. It was estimated that the ordinary expenditure of the hospital for the current year would be nearly £44,000, which should just be covered by the revenue to be expected from all sources.

MEDICAL FITNESS OF CADETS IN TRAINING.

The Minister for Defence has published some interesting information in regard to the work carried out in connexion with the universal training clauses of the Commonwealth Defence Act. Up to February 23rd, 1913, the total number of junior cadets examined (boys of from 12 to 14 years of age attending primary schools) was 45,248. The number found medically fit was 44,079; the percentage found fit was thus 97.4. The number found unfit or temporarily unfit was 1,169, or 2.6 per cent. The total registrations of senior cadets in training areas was 174,766. The total medically examined was 102,213; total medically fit, 93,483, or 91.5 per cent.; number temporarily unfit, 2,995, or 2.9 per cent.; number unfit, 5,737, or 5.6 per cent. The number of total exemptions granted in training areas was 53,582; number remaining to be medically examined or exempt, 22,701; number liable for training, 90,808; total number actually in training, 87,847. Exemption from training is given to all those who reside outside a training area, but they are nevertheless compelled to register. The total registrations of those cadets who reach the age of 18 years this year, and who on June 1st next will have to pass into the Citizens Forces, numbered 38,604; the total medically examined, 2,081; number medically fit, 1,521 (73.1 per cent.); number conditionally fit, 156 (7.5 per cent.); number temporarily unfit, 113 (5.4 per cent.); number unfit, 291 (14 per cent.); total exemptions granted in training areas, 16,481; number remaining to be medically examined or exempt, 20,446.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

FOOT AND MOUTH DISEASE.

THE small scientific commission, regarding the foot and mouth disease, which visited India during the cold weather, has now gone home, and the results of their mission will be communicated to the Board of Agriculture. It is feared that their experience will not be of much use in dealing with the disease at home, as the characters of the malady differ materially in the two countries. In Great Britain the disease is virulent and often fatal, but in India it is not so.

PLAGUE VACCINE.

With reference to the disinterment in a recent libel action of the alleged facts of the accident with plague vaccine in

1902, and the false argument unsuccessfully based thereon, it may be pointed out that from 1904 to the present date, 4,919,345 doses of vaccine have been issued in India, and although searching inquiries are always instituted regarding the action of the vaccine, there has not been a single verified case of any serious ill effects following its use.

BOMBAY MILK SUPPLY.

A scheme has been adopted for bringing milk into Bombay City from healthy dairy farms established in the surrounding country districts. The milk problem has long been a great difficulty to the Corporation. Milk-cattle stables are dumped down all over the town, and are often in most insanitary proximity to dwelling houses and other buildings which make undesirable close neighbours. The Corporation has recently maintained a steady effort to push these stables into more open localities on the outskirts of the city, and to ensure the observance of sanitary rules in each place, but there are obviously limitations in the power of compulsion in the matter.

PARIS.

Treatment of Appendicitis.—Operation of Pericardiolytic.

A DISCUSSION on the treatment of appendicitis, in which several leading French surgeons took part, was held at a recent meeting of the Surgical Society. M. Jacob, who said that he had had the opportunity of following many cases in soldiers from the very beginning of the attack, stated that during the past three years he had operated on 148 cases—30 in the acute stage, with 28 recoveries and 2 deaths. The two fatal cases were not operated upon till the fourth day. He held that the commencement of gangrene might be diagnosed from the intensity of the pain. When the pain was localized in the right iliac fossa and very acute, commencing perforation was to be dreaded, especially when the attack was not the first. M. Reynier said that if operation were delayed for forty-eight hours the prognosis became much less favourable. In cases presenting the peritoneal facies, black vomiting, and pulse of 140, temperature of about 101°, washing out of the stomach and bowel frequently ameliorated the general condition and bided over the attack. After four days the operation of appendectomy might be performed without undue risk. M. Lecomant reported a mortality of 30 per cent. in bad cases upon which operation was performed. If the operation were done within the first forty-eight hours the prognosis was good. He had had only 1 death in 20 cases. Among 15 cases in which the operation had taken place after forty-eight hours there were 5 deaths. M. Potherat advocated surgical intervention in all cases. Ice, he said, merely acted as an anodyne, and did not influence the inflammation existing in the appendix itself, and certainly could not affect gangrene. M. Hartmann's conclusions were summarized as follows: (1) If the case is acute, operate at once; (2) if subacute, wait twelve hours, and if after twelve hours the temperature has not fallen below 101°, operate. In 196 cases he had had 29 deaths (13 per cent.). The operation was performed within twelve hours in 12 cases, with no deaths; within thirty-six hours in 13 cases, with 2 deaths; and after fourteen days in 13 cases, with 10 deaths.

Dr. Delagènière has reported to the Academy of Medicine the results obtained by pericardiolytic or removal of the anterior portion of the pericardium in its totality: it was designed to give both the ventricles and the auricles and great vessels freer action. The operation had been performed thirty-eight times, with thirty-one recoveries and six bad results, all in adherent pericardium. He related a case of a woman, aged 28, complaining of palpitations, cyanosis, and oedema of the limbs. After operation all these symptoms disappeared, and the patient had been in good health for the past two years. The operation consisted in the removal of part of the sternum and ribs covering the pericardium, and the freeing of the pericardium in its entire extent anteriorly.

BERLIN.

Friedmann's Tuberculin.—The Serum Diagnosis of Pregnancy.—The Treatment of Carcinoma Uteri with X Rays and Mesothorium.

THE report by Westenhofer, Prosecutor at the Pathological Institute of the Charité Hospital, made to the last meeting of the Berlin Medical Society, of his *post-mortem* findings in a case that had died of hæmoptysis after a course of injections by Friedmann produced a considerable sensation. There were numerous pulmonary cavities, and a generalized miliary tuberculosis; but this is not the worst, for in the gluteal region, at the site of the infection, and in the musculature, where tuberculous deposits are exceedingly rare, there was a large focus containing giant cell systems and tubercle bacilli which could not be definitely classed either among the human or cold-blooded varieties. In the course of his remarks the speaker regretted that Dr. Friedmann had not as yet fulfilled his promise to the society to publish his culture methods in detail—a course, which he maintained, could only damage the high esteem in which German scientific research was held abroad. He was followed by Professor Schwalbe, who drew the society's attention to an official report of the Health Department at Washington, in which it was definitely stated that the patients treated by Friedmann in America had not been cured. The well-known bacteriologist—Frau Dr. Rabinowitsch—showed the society a pure culture of Friedmann's turtle tubercle bacillus recently sent to her from America. It had been obtained from an abscess produced by inoculation in a female patient in Rhode Island. Besides the tubercle bacillus there was cultivated from it a non-acid-fast bacterium which might possibly be designed to act in combination with the other. In her opinion the first named very closely resembled a bacillus isolated from the carp by Dubard fifteen years ago. Friedmann's bacillus grows best at room temperature and can be subcultivated on all the usual media, whilst microscopically and by staining methods it cannot be differentiated from the recognized "reptilian" tubercle bacillus. She reminded her hearers that Küster, Möller, and Edwin Klebs had fruitlessly tried to immunize animals some years ago with such bacilli, and mentioned that she herself had also failed. Piorkowski, a former assistant of Friedmann's, who had formerly cultivated turtle tubercle bacilli for him, has placed living cultures of this bacillus at the service of his colleagues in Berlin and elsewhere. At this meeting he stated that he had received favourable reports from certain sources, whilst other authorities had been unable to send him any positive observations. Friedmann found his only firm supporter in the person of Dr. Schleich, of local anaesthesia fame, who from the beginning has publicly stated his belief both in the man and the method. Schleich stated again that most amazing results had been obtained by Friedmann, and called upon the society to appoint a commission from among its members to examine into and report on his alleged cures.

At a Gynaecological Congress held at Halle recently, R. Freund and Brahm reported on 160 cases successfully tested by Aberhalden's method.* The practical value of the test was emphasized by Rübsamen, who in 7 cases of suspected tubal pregnancy obtained a positive indication four times and a negative thrice—results which were confirmed subsequently on the operating table. Rübsamen, after applying the test in 100 cases without a single failure, is of opinion that it is infallible. This speaker was followed by Schäfer (Berlin) and Lichtenstein (Leipzig), whose reports were likewise favourable to the method; whilst in an article in the *Münchener medic. Wochenschr.* (June 10th) Maccacruni reports correct results in 85 cases, among which were four doubtful tubal pregnancies, in which the diagnosis was made from the serum and afterwards confirmed by the operation. Schiff, of the Physiological Institute in Halle, writes in the same journal that he correctly diagnosed the presence or absence of pregnancy in every one of 49 cases whose serum reached his laboratory.

At a recent meeting of the Berliner medizinische Gesellschaft, Professor Bumm, the Director of the

* Some particulars of this method were given in a leading article on biological reactions in pregnancy published in the *JOURNAL* on March 29th, 1913, p. 577.

University Frauenklinik, opened a discussion, and related his experiences with x rays and mesothorium in the treatment of malignant disease of the uterus. His own results indicated a therapeutic advance. It had been clearly demonstrated that normal tissue (especially the uterine and vaginal mucous membrane) would tolerate much harder rays than had hitherto been used, and that larger doses, provided they were filtered, could be given without ill effects in uterine disease. Moreover mesothorium rendered it possible to utilize radio-activity in cavities inaccessible to x rays. Professor Bunm reported on 12 cases of carcinoma, among which were some implicating the ureter or the vagina. Several of these were apparently cured by the combined irradiation alone; others, previously classed as surgically hopeless, were brought into the operable category, and in every case where pain, suppuration, and haemorrhage had rendered the patient's life a misery to her, these distressing symptoms were relieved. The result was due, not only to the rapid vacuolization and subsequent destruction of the individual cancer cells, but also to the hyaline degeneration and sclerosis of the newly formed connective tissue cells. The depth of penetration of hard rays, and the question of their action, if any, on metastatic deposits in the vicinity, and in the lymph glands, was, Professor Bunm said, as yet undetermined, but he maintained his opinion that in rapidly growing cancer, especially in young people, complete surgical removal of the growth and the glands offered the best chance of cure, but he was moved to advocate after-treatment with x rays and mesothorium, a method he had now adopted in every case of carcinoma uteri operated on in his own clinic. In cancer of the vagina, the urethra, and the external genitalia, and in the slowly growing cervix cases in elderly women he now placed considerable reliance on radiotherapy alone, claiming for the method that the clinical and functional results were superior to the surgical, whilst in all inoperable and recurrent cases it was the method of choice. Professor Frauz, of the Charité Clinic, in discussing Bunm's paper, said that he could not accept the view that the use of mesothorium was the correct treatment for early carcinoma of the portio vaginalis. The records of operation on that condition showed a lasting cure of 50 per cent., whilst there were no means of determining, apart from operation, how deeply the growth might have extended from the visible ulcer. There was, he said, no doubt, on the other hand, that mesothorium was exceedingly useful in alleviating suppuration previous to operation, and sometimes in converting an inoperable into a comparatively easy case. The next speaker, Professor Rotter, said that during nine months he had in an inoperable case of carcinoma coli frequently injected, intravenously, $1\frac{1}{2}$ to 2 million mesothorium units in solution. The matted growth had completely disappeared locally, although cancer nodules had subsequently recurred in the artificial abdominal opening and round the anal canal. The results of Hirschfeld and Meidner, who are conducting experiments on men and animals with thorium X injections at the Cancer Research Institute at the Charité (*Zeitschrift für klin. Mediz.*, June 11th), do not, however, support Rotter's single success. In 10 cases so treated they could not find that thorium solutions, although they were well borne, had any effect whatever. In a case of sarcoma slight temporary benefit was noted.

BUDAPEST.

Death of Professor Korányi.—Election of the Hungarian Committee of the International Medical Congress.—International Prize for Essay on Trachoma.—Pensions for Hungarian Doctors.—A New Medical Periodical.

THE death of Professor Frederic Korányi, the pride of the University of Budapest, is keenly regretted by the medical profession in Hungary. Korányi, who was a very energetic and hard-working man, and who had enjoyed excellent health during the whole of his long life, was in his 85th year at the time of his death, which occurred from heart failure on May 19th. Korányi had a very eventful career. Born in 1828 at Nagy-kállo in Hungary, he studied medicine at the University of Budapest, and at the age of 20 acted as military assistant-surgeon during the "War of Liberty"

in 1848. In 1851 he graduated as doctor of medicine, and in the same year became surgical clerk to Professor Schuh, in Vienna. In 1852 he settled in his birthplace, Nagy-kállo, as a general practitioner, and in 1863 was appointed chief physician to the county hospital. His name soon became known, and two years later he was appointed lecturer on nervous disorders in the University of Budapest. In 1865 he was also appointed physician-in-ordinary to the city typhoid hospital, and in the following year the wards at the City Hospital destined for patients suffering from diseases of the nerves were placed under his care. In 1866 he became chief physician to the cholera wards at the Ludoviceum (the cadet school) and also professor of clinical medicine in the university. Korányi's work was recognized by the King, who in 1876 conferred upon him the title of "Advisor to the King," whilst in 1881 he became a member of the Order of the Iron Crown. He received a patent of nobility in 1884, which enabled him to place the prefix "de" or "von" before his name, and in 1891 became a member of the Upper House. He had already been nominated Rector of the university in 1886; and in 1892 he was elected President of the National Public Hygiene Committee; in 1894 he was President of the Hygienic Section of the International Hygienic and Demographic Congress; and in 1898 President of the National Public Hygiene Committee. He was also a member of the Hungarian Academy of Sciences and of the London International Investigation Committee; and in 1909 the King conferred rank corresponding to a baronetcy upon him and his heirs. After forty-three years spent in incessant work and in active warfare against the spread of tuberculosis in Hungary, Korányi resigned his chair last year in order to devote his whole time and energy to the reform of public hygiene. His name will always be remembered in his own country as being that of the first Hungarian doctor who was ever asked to contribute to foreign medical journals; and it was largely due to his writings that Hungarian medicine, hitherto little known to the rest of Europe, received the recognition it deserved. Korányi was a contributor to the Billroth Pitha *Encyclopædia*, and compiled the five volumes of *Hungarian Clinical Medicine* besides writing scientific articles for Hungarian and foreign medical papers which aroused great interest. He also lectured constantly at the Academy of Sciences, whilst at the Wiesbaden Congress he was the head of the Pneumonia Section. His chief monographs deal with the position of the spleen; syphilis of the internal organs; nerve disease as observed in the Hospital of St. Roch; the diagnosis of diseases of the heart; combined infection from malaria and typhoid; the influenza epidemic of 1892; the arrangement and organization of a modern hospital. Korányi's funeral took place on May 21st. His body lay in state on its bier in the Great Hall of the University, and was followed to the grave by an immense crowd, in which almost every class of society was represented.

The Hungarian Committee of the International Medical Congress, whose members have just been elected, is working hard to promote the success of the congress by inducing as many Hungarian doctors as possible to take part in it. Prospectuses have been sent out containing full information as to travelling and accommodation in London, as well as details concerning excursions in various parts of England; and evening classes have been formed where intending members may take a course of lessons in the English language. The deputies sent to represent the Government at the congress have already been appointed, and Professor Emile de Grosz, who has thrown himself heart and soul into the work, has been nominated president of the committee, whose offices are at 39, Mária utca VIII, Budapest.

The offer made some time ago by the Minister of Public Hygiene of a prize for the best essay on trachoma has had very satisfactory results, for a large number of excellent monographs have been received from all parts of Europe and America. The merits of these essays are to be judged by a committee of three—namely, Emile de Grosz, professor of ophthalmology in the University of Budapest, Professor Nuttall of Cambridge, and Professor Kofle, of Berne.

The "Pension Bill," which provides pensions for doctors after they have been in practice for a certain number of years, has been before the Hungarian Parliament since

1907, and ought to have come into force on November 1st, 1909. The long delay is over at last, however, and the bill, which was passed last April, is to come into force this year, when it will doubtless bring relief to the widows and orphans of many medical men. The pensions being granted by the State, a small percentage will be deducted from doctors' salaries during their term of service. Five years' service will render a doctor eligible for a pension, which will increase by 10 per cent. for every additional five years, whilst after thirty-five years' service he is entitled to retire on full pay. An interesting discussion on the question of pensions for medical men was opened in the Hungarian House of Commons by Sándor János, who laid stress upon the fact that in spite of the increase in the salaries of parish doctors granted by a bill passed in 1908, there are still more than 400 parishes in Hungary where there is no doctor. Moreover, the conditions of life in some of these parishes are so intolerable that, although the Minister of Public Health has granted a still further increase of salary, no candidates can be found to apply for the posts. On the other hand, there are 1,600 doctors (25 per cent. of the total number of medical men in Hungary) in Budapest alone, because, as the speaker pointed out, doctors prefer to lead a precarious existence in the towns rather than apply for a post in a country place where the bad housing, bad roads, defective sanitation, and heavy work disable them before their time and cause them to leave their families in complete destitution. It is by no means an uncommon occurrence for a parish doctor to be buried at the expense of his colleagues, whilst his widow is forced to earn her living as a domestic servant or assistant in a shop, facts which do not redound to the credit of a country that spends millions on its army whilst leaving the pioneers of science and culture in want. At the time of writing, however, the bill has been passed, and in a short time the State pensions will be enjoyed by hundreds of medical men.

The first number of a new medical periodical, the *International Zeitschrift für aerztliche Psychoanalyse*, has just been issued under the joint editorship of Dr. Sandor Ferenczi of Budapest, a favourite pupil of Professor Freud of Vienna, and Dr. Otto Rank, the Vienna neurologist. The Hungarian editor is an ardent disciple of Freud, and has made many converts by his work on "Lélekelemzés" ("The Analysis of the Soul"). The list of contributors to the first number, which contains a large amount of very interesting matter, includes the names of men in almost every country in Europe. The periodical, which is written in German, is published in Vienna by Hugo Heller and Co., the cost of subscription being 21.60 kronen, or about £1 in English money.

A COMMISSION composed of Dr. R. P. Strong, Professor of Tropical Medicine, Dr. E. E. Tyzzer, Director of the Harvard Cancer Commission, and Dr. A. T. Brues, sailed from New York a short time ago for a five months' tour of investigation on behalf of the department of tropical medicine of Harvard. The main object of the expedition, according to the *Journal of the American Medical Association*, is to obtain material and specimens for the department of Tropical Medicine at Harvard, and Guayaquil, Ecuador, which is a hotbed of tropical diseases, has been selected as the scene of operation. The expedition will also study verruca peruviana.

A COMMITTEE of the American Institute of Homoeopathy has, according to the *Medical Record*, sent a communication to the American Medical Association asking on behalf of the homoeopathic physicians of the United States for a joint investigation of the scientific merits of the method of drug relation expressed by the formula *similia similibus curentur*. It is suggested that the American Medical Association shall appoint a committee of five to meet a like committee from the Institute of Homoeopathy to discuss this subject with a view of attempting a demonstration of the truth or falsity of the theory of similars. It is further suggested that the joint committee shall study the physiological action, in large and small doses, of a definite number of drugs in common use by the members of both societies, this investigation to be under the auspices of some research laboratory like the Rockefeller Institute in New York or the McCormick Institute in Chicago; and, finally, make a comparative trial of the therapeutic efficacy of these drugs, given according to the various methods of administration, in some of the large public hospitals.

Correspondence.

MENTAL HOSPITALS.

SIR.—In view of the increased attention now being paid to the hospital treatment of the insane, it is well to recognize that under that term there are several conceptions which have been proposed or actually carried into practice in varying ways. One sees that sometimes there is confusion in discussion in consequence of this fact not being considered fully. I am speaking by the book when I state that, during the debate in the Grand Committee on the Mental Deficiency Bill last year, one of the arguments or statements made by the very vigorous opposition was that there was great objection to the feeble-minded being sent to institutions for the doctors to make experiments on! Such a statement was, of course, due to the senseless suspicion felt by some more or less responsible people against any attempt to benefit mankind by research, and no doubt that suspicion will be shown by some of the public in regard to any hospital for the insane in which research work is carried out. But the majority of the institutions where the so-called hospital treatment is pursued do not carry on research work, and merely aim at individual treatment of those labouring under tangible disease. The different ideas which come under the general term can be catalogued in orderly series, but this would take up too much space. I can name a few of them.

First, there is the idea of lunacy wards in general hospitals. This idea was acted on at Edinburgh and, possibly, other towns. It was thus sought to bring lunacy within the scope of general medicine, an excellent idea in theory which the profession at large refutes in practice more and more each day by specializing.

I should place next the ideas of the London County Council, arrived at after an exhaustive inquiry instituted immediately after its constitution. The proposal (which has never been carried out) was to have a suitable establishment for the reception of cases of acute insanity, for treatment by general physicians, with the help, of course, of those specially skilled in psychiatry. I think I am right in saying that the leading idea was to give general medicine the chance of doing that which special medicine had failed to do. I am not aware how far this idea may be followed in the new hospital to be erected by the same body through the munificence of Dr. Maudsley.

Next I would place such an institution as the recently erected Mental Hospital at Cardiff, where, in addition to the care of the insane by alienists, assistance for research has been sought from the university, we hope with much ultimate success.

In all the foregoing it is to be observed that the advancement of general knowledge of the disease is an essential element. We turn from that to those places where the immediate care of the individual is the chief object.

Bethlem may be taken as an example of an institution which in principle aims at cure and not at detention. It has for many years been staffed by leaders in psychiatry, and its constitution aims at recovery or removal of the non-recovered, so that its machinery may be utilized for fresh cases which supply some hope of recovery. It is needless to say that its prime object has been supplemented by the offer of advanced teaching of a clinical nature. In fact, Bethlem, with other institutions, such as Morningside, have been veritable clinics.

After that may come the many places where a separate building has been erected for the reception of new cases in which inquiry, more or less scientific, can be, and often is, adopted, but in which the recovery of the individual is aimed at principally. This form was undoubtedly first provided in Scotland, where the example of the Fife Asylum has been followed in many newer asylums, such as Gartloch, Paisley, etc. But in these the population of the hospital portion has not been confined to the mental cases only. It is the asylum's general hospital in so far that other cases are lodged therein if they present signs of physical illness of any consequence.

Then followed in England the development of building within the asylum grounds separate establishments for the reception of recent mental cases only. As far back as 1889 I described my notions of such a place as an alternative to the more adventurous proposal of the

London County Council. Some years afterwards I had the pleasure of taking a leading part in the translation of these ideas into bricks and mortar in our County Asylum at Hellingly, though as a completed institution it was preceded by a few months by that built at Bexley under Dr. Stansfield. In addition to the concentration of medical attention on new cases I imagined, and not unwarrantably, that it would be a great thing to be able to say to those who entered the building, which is a few yards from the gate, "Thus far need you go and no further." The idea is also grateful to the relatives of the patients, many of whom are above the rate-paid class. Undoubtedly they are more ready to send in good time their invalids because they know that they will not be "herded," but specially treated as individuals.

Then come the arrangements made in existing asylums for the more or less segregated care of new cases. A shining example of this undoubtedly must be Morning-side, where, *me teste*, Sir Thomas Clouston succeeded in transforming wards, hitherto crowded with the violent and dangerous cases, into a nursing heaven. I am sure that I am right in backing him up in his claim to being the first to carry out the hospital idea with strenuous determination and to the full, in spite of the difficulties of the time and place. But good as the plan was it lacked the complete detachment from the main institution. Here, of course, the care of the individual was supplemented by much teaching for the general advancement of knowledge, the teaching at first being clinical, to be followed later by extended laboratory work, until the full conception of a clinic was established.

Then, again, we find now that in all asylums of any standing wards are put on one side for new cases, thus carrying out the general idea of concentration of treatment for the benefit of the individual. If I am not under a wrong impression, I think that Dr. Rayner at Hanwell, thirty years ago, kept all his new cases for a stated time in bed in a special ward for the purpose of careful inquiry as well as for treatment by continued rest.

To sum up, I suggest that it is necessary, when talking of the hospital idea, to determine whether it is sought to promote the welfare of the individual or the general advancement of knowledge, or a combination of the two elements. This issue is rather obscured by the practice, now becoming quite common, of adopting the name of mental hospital for what was formerly called county or borough asylum. This practice is highly laudable, in that it tends to promote in the mind of the public as well as of the staff the belief in the constant practice of the latest ideas of psychiatry; but, without special knowledge of the aims of each place, it is easy for the public to be misled as to the true significance of the term and the intentions of its users.

Perhaps I may be allowed to add a few words on a matter connected intimately with the contrast of the scientific general idea with that of the welfare of the individual. It must not be assumed, as it readily may be assumed, by the public that, in this very proper struggle for the scientific development of treatment, drugs, instruments of precision and the like shall replace that which is called moral treatment. We must always remember that insanity is the result of fault between two partners, the mind and the body. The fault may commence with either or both. Harmony may be re-established by the commencement of better things on the part of either, and, conversely, harmony can be indefinitely postponed by the misfortunes of either. A chance word or a new phrase of idea conveyed by a skilful nurse may be the beginning of recovery. I may say, without any fear of efficient contradiction, that the most scientific treatment in the world will be defeated by bad or careless nursing of the mind. There is a chance, slight it may be, that in the rush for physical care the need for the old-fashioned, but indispensable, guidance of mind may be lost to sight. Beyond this there is a chance that, under more liberal ideas connected with the scientific form of treatment, responsibility for the individual may be also forgotten. We know that an insane person is potentially dangerous to himself and others; therefore, means of supervision and safe custody cannot be dispensed with, even though they may obviously hinder progress. One can foresee that, while with those who know there will be no such danger, yet with the newer school

of thought and practice, science may sometimes outrun safety.—I am, etc.,

Titchurst, June 14th.

H. HAYES NEWINGTON.

INTRAVENOUS INJECTION OF IODOFORM IN PULMONARY TUBERCULOSIS.

SIR,—I have read with much interest the report of the discussion on this subject which took place at the Royal Academy of Medicine on April 4th and Dr. Dewar's reply to it which appears in the JOURNAL of June 7th.

Having used this method of treatment for phthisis ever since Dr. Dewar first made it known to the profession in the JOURNAL, I can, without the least hesitation, state that I can entirely bear out all that he has claimed for it.

The gentlemen who criticized Dr. Crofton's paper at Dublin had, with one exception, no practical experience of the treatment, and simply condemned the method from fear of disasters which seemed to have their foundations in their own imaginations.

I cannot lay claim to have given many thousands of injections, but I have given at least considerably over 3,000, and I can quite corroborate Dr. Dewar's statement that any thrombosis that may occur must be due to lack of skill on the part of the operator, as I have never seen any bad effects locally from an intravenous injection.

Sometimes a patient does get a paroxysm of coughing, but this can be completely controlled by making him take rapid sips of water, breathing out after each sip. This fact completely does away with the academic objection that the coughing is liable to produce pneumothorax and rapid dissemination of the disease in the lung.

Neither Dr. Dewar nor myself have seen the slightest bad effects from an intravenous injection, and those who have condemned the treatment or have hesitated to give it a trial have based their objections on purely theoretical grounds.

Dr. Dewar has never claimed that his discovery is a panacea for pulmonary tuberculosis, that intravenous injections will cure every case of phthisis. He, however, does claim—and I can fully bear out his contention—that iodoform injected intravenously will give as good results as any other form of treatment that is at present practised by the medical profession.

It has been my experience within the last few years that where iodoform failed to achieve success it was hopeless to expect to save the life of the patient by any other method of treatment, and this conclusion was only arrived at after a thorough trial had been given to other remedies.—I am, etc.,

South Shields, June 8th.

JOHN BAIN, M.B., C.M.

ADRENALIN IN CHLOROFORM ANAESTHESIA.

SIR,—It is to be hoped that the recent correspondence on the dangers of adrenalin in nasal surgery will put upon guard those surgeons who have up to the present found adrenalin satisfactory and safe. I am myself acquainted with two fatal cases, both following immediately the injection of adrenalin, and both under chloroform anaesthesia before the operation had commenced.

That there was danger was first brought home to me by the peculiar pallor, accompanied by cardiac distress and pain at the back of the neck and occiput, which followed an injection of a few drops of 1 in 1,000 solution. If this patient had been under chloroform anaesthesia it is possible that this would have been a fatal case. It is obvious that a solution of 1 in 1,000 is to many people a dangerous strength.

As Mr. Guthrie remarks, the nose must be packed with adrenalin for at least one hour for satisfactory ischaemia, and it is almost essential that the surgeon himself should do the packing; therefore, this will cause a difficult operation to occupy two to two and a half hours. Moreover, in a few cases it is physically impossible to introduce packing behind a deflexion on one side. The following technique will be found satisfactory in affording a bloodless operation field free from all danger:

1. An injection of morphine (grain $\frac{1}{4}$ to $\frac{1}{2}$) is made about twenty minutes before the surgeon's arrival.

2. A few gauze strips well pressed out after soaking in equal parts of adrenalin and 10 per cent. cocaine solution are inserted into each nostril.

3. The general anaesthetic should now be commenced, or if local analgesia is to be employed the syringe should be tested and charged with the infiltration solution. Pure chloroform should not be used for nasal operations if cocaine and adrenalin are also employed. A mixture of chloroform (1 part) and ether (2 parts) is quite satisfactory after the morphine injection. It should be noted that morphine overcomes some of the toxic action of cocaine.

4. When the patient is surgically anaesthetized an injection of $\frac{1}{2}$ per cent. cocaine solution should be made in two spots on each side of the septum; if the needle passes well under the perichondrium the pressure of the solution will render the mucous membrane pale and, more important than this, will give a characteristic sensation of resistance. The syringe should be very powerful, on the principle of the dental syringe but of larger capacity, and the needle should be fairly coarse.

No adrenalin should be injected, especially if a general anaesthetic is being employed. The tachycardia, dilated pupil, and greyish pallor are all signs of excessive stimulation of the sympathetic nervous system and are identical with the immediate signs of surgical shock, with the addition of the direct stimulating effect of adrenalin upon the heart itself, which, of course, with a 1 in 1,000 solution, only aids the onset of failure.—I am, etc.,

Manchester, May 11th.

WILLIAM WILSON, M.D.

A CONSTITUTIONAL POINT.

SIR,—In a letter appearing in your issue of June 14th Sir Victor Horsley comments on my action as President of the Royal College of Surgeons.

When he heard that the attention of the College had been called to his conduct by the Home Secretary, he wrote to me requesting that copies of all documents which had passed, or might in future pass, between me, or the College, and the Home Secretary should be forwarded to him. This letter I answered from the College of Surgeons the following day, and on returning to my house found a letter from his solicitor accusing me of the discourtesy of not replying. Sir Victor Horsley's statement that I did not reply until I had received a letter from his solicitor is therefore not in accordance with fact.

His comprehensive demand was one for consideration by the Council, not by me. When complaints are made to the Council with regard to the conduct of Fellows and Members, it is not the custom to communicate them to the parties involved, unless the Council decide to take the matter up. If any disciplinary procedure is contemplated, due notice is given, and ample time is allowed for explanation or defence. This, in my opinion, is the reasonable, fair, and prudent course to pursue. Complaints reach the College from time to time of the conduct of Fellows and Members which no useful purpose would be served by disclosing.

After mature consideration the Council decided that the evidence laid before them was so contradictory that they were not in a position to enter upon the ethical questions involved. They are, therefore, now under no obligation to disclose the precise form of the complaint, but, as a matter of courtesy, they have allowed Sir Victor Horsley access to all documents referring to himself, and have communicated to him the terms of their reply to the Secretary of State.

May I add that Sir Victor Horsley in numerous letters in the lay press shows that he is possessed by a fixed idea that I personally have been conspiring against him? I trust my professional brethren will believe that nothing is, or ever has been, further from my inclination or the fact.—I am, etc.,

RICKMAN J. GODLEE,
President.

Royal College of Surgeons of England,
Lincoln's Inn Fields, London, W.C.,
June 17th.

RHEUMATOID ARTHRITIS.

SIR,—When was Dr. Uhlhoff appointed Editor-in-Chief of the BRITISH MEDICAL JOURNAL? We have got a Journal Committee, an Editor, and two Assistant Editors. Now we have got a self-appointed individual to supervise the Editor. If I were Editor—which post I should like to

hold for about one week—I would not only not print this individual's letter, but I would tell him to mind his own business. Personally I attach no value to his opinion, except that I should feel that there was something wrong with my conduct if he approved of it. I may inform him that I would not attenuate, modify, or withdraw a single statement which I have made. On the contrary, many of the statements would have been very much stronger and more fitting for the occasion only for the supervised Editor.—I am, etc.,

Liverpool, June 14th.

JAMES BARR.

* * * Dr. James Craig (Llandudno) sends the following references in reply to the concluding paragraphs of Sir James Barr's letter published on June 14th, p. 1298: For the report of the Section of Balneology and Climatology of the Royal Society of Medicine to the *Proceedings* of the Society for April, 1913, p. 62, lines 22 and 23; for the statement attributed to Sir Robert Christison, his lectures for 1873 (February), in which the quotation about the salts of calcium will be found.

We cannot continue this correspondence.

SYPHILIS AND CANCER OF THE TONGUE.

SIR,—We have read with much interest the correspondence in the BRITISH MEDICAL JOURNAL concerning the interdependence of syphilis and cancer of the tongue. After all, this has a bearing on only part of a very important question.

In these laboratories an inquiry has been carried on during the last eighteen months upon a possible relationship between malignant disease and syphilis. Sixty cases of cancer have been investigated and a positive result with the Wassermann reaction obtained in 4 only. Carcinoma of the mucous membrane of the mouth provided 20 cases, with 1 markedly positive Wassermann reaction, while another was indefinite.

The suggestion put forward by Dr. Renshaw that the presence of malignant disease in a syphilitic patient may cause such an alteration in the blood as to negative the Wassermann reaction had occurred to us also.

We hope, at no distant date, to publish the result of our work on this subject.—We are, etc.,

HENRY MACCORMAC,
HECTOR COLWELL,
A. CLIFFORD MORSON.

Cancer Research Laboratories, Middlesex Hospital,
London, W., June 11th.

COST OF VACCINE TREATMENT.

SIR,—Would it not be a great convenience to your readers if your "vaccine" contributors would state in their articles what the cost of vaccine treatment is in any disease in which they advocate its use? At present it seems to me that the interest in this matter is chiefly commercial rather than scientific. Many of us might persuade our patients to make the experiment if only we could tell them what the cost is likely to be.—I am, etc.,

Leeds, June 16th.

A. G. BARRS, M.D.

DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

SIR,—May I appeal through your columns to all former residents at this hospital on the occasion of the retirement of the Secretary and Superintendent, Mr. J. Unsworth?

For the long period of forty-four years Mr. Unsworth has devoted his energies to the service of the hospital, and throughout that time he has maintained the most cordial relationships with the successive members of the resident staff, and in every way in his power has assisted them and endeavoured to make their term of office more agreeable.

I feel sure that all of them will welcome the opportunity of marking their appreciation of his valuable services, and shall be glad to receive their donations towards a presentation to him on his retirement.—I am, etc.,

GEORGE C. E. SIMPSON
(Honorary Secretary, the Medical Board).

21, Rodney Street, Liverpool, June 13th.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degrees have been conferred:

M.D.—L. S. T. Burrell, M. F. Grant, A. F. MacCallan, S. V. Pearson.
M.B., B.C.—J. H. Pendred, H. C. T. Longdon, S. H. Ronquette, C. Warner.
M.B.—W. C. Hodges.
B.C.—A. F. R. Wolloston.

Examinations.

The following candidates have been approved at the examinations indicated:

PRELIMINARY SCIENCE (*Part I, Chemistry*).—G. E. Birkett, R. C. S. Bowler, A. D. Coates, B. M. Coates, F. C. Cozens, H. T. Cubbon, R. W. M. Dandy, A. W. R. Don, F. N. V. Dyer, R. H. Emmett, C. W. S. Fernando, J. B. Foster, R. French, C. I. C. Gill, W. N. Goldschmidt, N. B. de M. Greenstreet, E. W. Hall, J. Harbord, L. B. Hartley, W. E. Heath, L. G. Higgins, C. R. Hind, N. Hoole, S. M. M. Jabir, R. W. Jackson, A. V. Johnson, J. S. La Fontaine, H. C. Langdale, F. G. Laurie, J. G. Lawn, E. E. Llewellyn, R. Lumsden, G. Lyon Smith, J. W. MacKenzie, J. H. Massey, T. H. McCall, C. S. Millard, H. J. T. Neilson, A. V. Pegge, A. S. Richardson, J. A. W. Robertson, G. M. Shackel, G. H. Shakespeare, H. F. Squire, H. J. R. Surrag, A. Swann, A. P. Thompson, G. D. Thomson, H. M. Tulloch, M. D. Vint, W. M. Wallace, Y. S. Wan, A. Winfield. (*Part II, Physics*).—H. R. Bickerton, C. L. P. Biggar, G. E. Birkett, A. D. Coates, C. T. Cobbold, H. T. Cubbon, R. W. M. Dandy, F. N. V. Dyer, R. H. Emmett, T. Fernandez, C. W. S. Fernando, J. B. Foster, R. French, W. N. Goldschmidt, E. F. S. Gordon, N. B. de M. Greenstreet, W. B. Hathorn, W. E. Heath, H. P. D. Helm, L. G. Higgins, N. Hoole, S. M. M. Jabir, R. W. Jackson, A. V. Johnson, F. G. Laurie, J. G. Lawn, P. C. Livingston, E. E. Llewellyn, A. G. F. McArthur, T. H. McCall, B. S. Martin, J. H. Massey, J. R. Mitchell, J. W. McK. Nicholl, J. Norman, C. E. V. Porter, E. A. Raines, A. S. Richardson, J. A. W. Robertson, G. H. Shakespeare, A. T. Spoor, H. F. Squire, H. J. R. Surrag, A. Swann, A. P. Thompson, G. D. Thomson, C. G. Tindall, N. J. Tuck, A. C. Walker, W. M. Wallace, W. T. Williams-Green, A. Winfield, J. M. McC. Wright. (*Part III, Elementary Biology*).—H. R. Bickerton, R. W. M. Dandy, R. H. Emmett, S. L. Higgs, S. M. M. Jabir, J. G. Lawn, T. H. McCall, Y. S. Wan, A. Winfield.

THIRD M.B. (*under old regulations*) (*Part I, Pharmacology and General Pathology*).—R. Hodson, G. H. Maw, J. H. Newmarch, M. W. Paterson, A. S. Seabrooke, J. L. M. Symms.

VICTORIA UNIVERSITY OF MANCHESTER.

DEGREES.

THE following candidates have been approved at the examination indicated:

M.D.—D. Dougall, *H. Heathcote, *C. B. Marshall, *A. B. Smallman, A. G. Bryce, F. M. Rodgers, A. Wharton.
† Awarded a gold medal. * With commendation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Thursday, June 12th, Sir Rickman J. Godlee, Bart., President, in the chair.

Diplomas.

Diplomas of Fellowship were granted to twenty-nine candidates found qualified at the recent examinations as follows:

H. H. Broome (Capt. I.M.S.), D. C. Taylor, A. E. Iles, H. G. Frean, H. C. R. Darling, R. H. Mawhood, C. E. Shattock, S. Hoyte, A. C. Palmer, C. D'O. Grange, H. Neame, D. D. Pinnock, A. H. Todd, J. E. P. Watts, C. V. Anderson, J. A. Davis, N. F. Lock, S. Ritson, M. E. T. D. Vlasto, G. C. Chubb, C. E. S. Jackson, W. M. Oakden, W. S. Perrin, R. Ferguson, W. Gemmill, J. Kennedy, C. F. M. Saint, F. G. N. Stephens, J. Thompson.

Diplomas for the Licence in Dental Surgery were granted to forty-nine candidates found qualified at the recent examinations.

Examiners.

Mr. William Thorburn was elected on the Court of Examiners for the period of five years, subject to the provisions of the Charter.

The President reported that the vacancy on the Board of Examiners in Dental Surgery, occasioned by the retirement of Mr. Sidney Spokes, would be filled at the next ordinary meeting of the Council.

The following were elected:

In Elementary Biology: G. P. Mudge, W. G. Ridewood. In Anatomy: J. Cameron, J. E. S. Fraser, A. M. Paterson. In Physiology: C. F. Myers-Ward, E. H. Stirling. In Anatomy for the Fellowship: C. H. Fagge, R. W. Reid, J. Sherren, G. Taylor. In Physiology for the Fellowship: E. W. W. Carher, J. S. Edkins, F. Gotch, H. W. Lyle. In Midwifery: H. R. Andrews, W. B. Bell, G. F. Blaeker, G. D. Robinson. For the Diploma of Public Health: R. T. Hewlett (*Part I*), R. D. Sweeting (*Part II*). For the Diploma in Tropical Medicine: J. W. H. Eyre (Bacteriology), C. L. Daniels (Diseases of Tropics).

Votes of Thanks.

The thanks of the Council were given to Sir Henry Morris as Visitor to the Examinations of the Egyptian Medical School at Cairo; and to Mr. Ernest J. Wilde, on his retirement as Solicitor to the College.

THE ROYAL COLLEGES IN IRELAND.

DEFICIENCY IN GENERAL EDUCATION.

A RESOLUTION was recently passed by the Royal Colleges of Physicians and Surgeons in Ireland: "That our Colleges instruct their examiners at all professional examinations to report all cases of deficient general education to the Committee of Management; and in any case where the deficiency is such as to reflect discredit on our Colleges, to reject the candidate in the professional subject in which he presents himself, and to enter the cause of his rejection, 'deficiency in general education,' on the result sheet."

THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

PORTRAIT OF DR. LOMBE ATHILL.

ON June 6th a meeting of the Royal College of Physicians of Ireland was held, at which the President received, on behalf of the College, a portrait of the late Dr. Athill. Dr. Little, Senior Fellow of the College, made the presentation on behalf of the Rev. William Athill and the Misses Athill, who were anxious that a picture of their father should be preserved in the College. Dr. Athill was admitted a Licentiate of the College on February 12th, 1857, and elected a Fellow on May 1st, 1861, and subsequently served in every office of the College, being elected President in 1888 and again in 1889. Dr. Little said that during his long connexion of 55 years with the College, Dr. Athill was its constant friend and wise adviser, and the high position which the College at present occupied was in no small measure due to the way he worked for the promotion of its interests. The portrait, which is the work of Miss Purser and an excellent likeness of the late Dr. Athill, was accepted by the President, who expressed the great pleasure with which the Fellows received the gift, and the assurance that it would be preserved as one of the greatest treasures of the College.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following officers have been elected for the ensuing year: President: Mr. Richard D. Purefoy. Vice-President: Mr. F. Conway Dwyer. Secretary: Sir Charles A. Cameron. Council: Mr. William Stoker, Sir Charles A. Cameron, Sir Lambert H. Ormsby, Mr. Henry Gregg Sherlock, Sir Charles B. Ball, Mr. John B. Story, Sir Thomas Myles, Sir John Lentaigue, Sir Arthur Chance, Mr. F. T. Porter Newell, Mr. Shepherd McC. Boyd, Mr. Robert H. Woods, Mr. Richard Lane Joynt, Mr. R. Bolton McCausland, Mr. Edward H. Taylor, Mr. William Taylor, Mr. R. Charles B. Maunsell, Mr. Trevor N. Smith, Mr. William Ireland Wheeler.

Medico-Legal.

IMMUNITY OF TRADE UNION FUNDS.

A CASE decided by Lord Cullen in the Court of Sessions, Edinburgh, on June 14th, possesses some interest for the medical profession in view of the disposition to establish medical unions registered under the Trade Union Acts. The earlier parts of the judgement are in accord with what has generally been understood, but the concluding sentences raise possibilities which have not been present in the mind of every one.

The action was brought by an ex-official of the National Sailors' and Firemen's Union of Great Britain and Ireland against the union and its officials and the trustees of the union for alleged slanders in the *Clyde Seamen's and Firemen's Gazette*. Damages (£1,000) were sought, and an interdict against the continued publication of alleged defamatory statements.

The Court dismissed the action with expenses. Lord Cullen, according to the report in the *Times*, said that the conclusion for damages was directed only against the trustees of the union. Under Section 4 (1) of the Trade Disputes Act, 1906, no action lay against a trade union in respect of any tortious act alleged to have been committed by or on behalf of the trade union. The pursuer, however, contended that the action, so far as it concluded for damages, might be brought against the trustees of the union, so that a decree might be got which would give recourse against the union's funds. Before the Trade Disputes Act, 1906, a trade union could be sued in respect of such tortious acts as were here alleged. The Act, however, gave trade unions an immunity from such suits. This immunity would be worthless if actions falling within it could be prosecuted against the trustees of a union and recourse had against its funds and property to the same extent as if the union itself had remained exposed to action. Therefore, the pursuer's case, so far as it concluded for damages against the trustees, was irrelevant. As to interdict, his lordship said it was not suggested that the alleged slanders were actually perpetrated by the trustees, and the reason given for combining them with the union in this conclusion was that the *Gazette* was the property of the union vested in them. He did not think that this presented any relevant ground for an interdict against the trustees. There remained the conclusion for interdict against the union itself. Reading Section 4 (1) of the Act of 1906, he did not see how the action could be said to be other than one brought in respect of tortious acts alleged to have been committed. The pursuer was not left without a remedy. He had his action for damages, if he had been defamed, against the individual officials of the union responsible for the publication of the defamatory matter, and similarly he might seek to have them interdicted from repetition of their acts.

Obituary.

NATHANIEL H. ALCOCK, M.D. DUB., D.Sc. LOND.,
PROFESSOR OF PHYSIOLOGY, MCGILL UNIVERSITY, MONTREAL.

It is with deep regret that we have to announce the death of Professor Alcock at Montreal, where he held the Chair of Physiology (Joseph Morley Drake Professorship) at McGill University.

Nathaniel Henry Alcock was born in 1871, and was a son of Dr. D. R. Alcock, staff surgeon in H.M. Navy, and nephew of the Rev. Dr. T. K. Abbott, D.D., Litt.D., Senior Fellow of Trinity College, Dublin. He received his medical education at Trinity College, Dublin, and Sir Patrick Dun's Hospital. He graduated B.A. in Dublin University in 1893, with the senior moderatorship and gold medal in natural science. He graduated M.D. in 1896, and was shortly afterwards appointed demonstrator of anatomy at Victoria University, Manchester. In the following year he was appointed assistant to the King's Professor of Institutes of Medicine (Physiology and Histology) in the School of Physic of Trinity College and the Royal College of Physicians, Dublin, a post which he held till 1902. In 1903 he was appointed demonstrator of physiology in London University, and in 1904 lecturer in physiology in St. Mary's Hospital Medical School, Paddington, being successor to Professor Augustus D. Waller in the latter post. In 1906 he was appointed Vice Dean of the Medical School, and in 1909 he was granted the degree of D.Sc. of London University for his researches on the influence of anaesthetics on nervous phenomena.

In 1911 he was appointed to the Chair of Physiology at McGill University, Montreal, the post which he held at his death. By it British science has lost one of its sons whose work was always of the highest merit. Those who were associated with him could not fail to be impressed by the thoroughness and accuracy with which all his experimental researches were carried out. Every control that could be applied was used, every possible source of error guarded against to secure the foundations upon which his inferences were based. Consequently all his published work bears the stamp of an accuracy which renders it all the more valuable as a contribution to modern physiology. His, too, were a breadth of scientific taste and a versatility which remind one of Helmholtz, and are becoming all too rare in our modern age of extreme specialization. One of his first published papers was a monograph on Irish Bats, which appeared in the *Irish Naturalist*, vol. viii, and is still quoted as the leading authority on the subject, and included unique photographs which have been reproduced many times in works on British natural history. Astronomy also was a favourite subject of his, and here, too, his practical knowledge and manipulative and mechanical skill were very evident. He not only observed the heavens, but constructed the silver-on-glass mirrors for the telescopes with which his observations were made; and their quality excelled in some cases that of the products of the workshops of the professional optician.

As a teacher most cordial relations always existed between him and his classes. He was always willing to descend to the level of the beginner, in order to appreciate his difficulties, and help him to understand the intricacies of physiology.

His administrative ability was of a high order, and was testified to by the numerous committees upon which he at different times served. His services to St. Mary's Hospital Medical School, at a serious crisis in its history, will long be gratefully remembered. In his capacity as Vice-Dean he originated the negotiations with the Board of Education which resulted in establishing the medical school on a much more secure financial basis. The example of St. Mary's was afterwards followed by several other schools.

In private life he had nothing of the dry scientist about him, but showed a charmingly agreeable and humorous personality, flavoured with a lurking satirical tendency which could not always be quite suppressed in his writings. His pluck and courage in suffering and danger were conspicuous features of his character. Quite recently, having had his hand badly crushed by a falling boulder while climbing a mountain, though fainting and weak from loss of blood

and in extreme pain, he trimmed up the crushed fingertips with his injured hand, and was afterwards found trying to staunch a secondary haemorrhage himself rather than arouse his wife who was sleeping, exhausted from constant attendance on her crippled husband.

To the present writer, who knew him as a fellow student and afterwards became his demonstrator, he was always more like a colleague and a brother than a chief, and a pleasanter colleague one could never meet.

His published contributions to scientific literature were very numerous, and included researches on the electromotive force of the negative variation of various nerves, especially the vagus, under the stimulus of respiration, published in *Pflüger's Archiv*; fatigue in nerve and the velocity of the nervous impulse in tall and short people, in the *Proceedings of the Royal Society* (vols. 73, 77, 78); numerous papers on the relation between the physical, chemical, and electrical properties of the nerves, in the *Journal of Physiology*. Among his other contributions were articles on: "Muscarine," "Carpain," "The Accurate Dosage of Chloroform by means of a Regulating Inhaler"—the latter constructed by himself. A *Textbook of Experimental Physiology* (in conjunction with Professor E. H. Starling and P. O'B. Ellison); chapters on the physiology of nerve in *Further Advances in Physiology*, and very many others.

He married, in 1905, Norah Lilian Leopard, daughter of the late Sir John Scott, K.C.M.G., D.C.L., and at the early age of 42 leaves his widow, one son, and three daughters to mourn his loss.

Sir WILLIAM OSLER writes:

The death of Dr. Alcock is a great loss to the Faculty of Medicine at McGill University. During the short time of his occupation of the chair his work was chiefly in connexion with the organization of his department. He was much appreciated both by his colleagues and by the students. The energy and enthusiasm he displayed, though suffering for nearly three years from medullary leucæmia, were remarkable. I saw him a few weeks ago with Dr. Martin, in Montreal, in the terminal infection with which these cases so often end. He had finished his session's work, and was struggling in vain with the weakness associated with the paroxysms of fever. He had made an exhaustive study of his own case, and I do not remember ever to have seen blood charts in the disease so extensive or so elaborate. Against an implacable enemy he put up a splendid fight, and literally died in harness.

OSCAR WILLIAM CLARK, M.A., M.B. OXON.,

SENIOR PHYSICIAN, GLOUCESTER GENERAL INFIRMARY.

We regret to record the death, on June 7th, of Dr. Oscar Clark, a medical man who for many years had played a prominent part in the professional and public life of the city of Gloucester. A few years ago he had had a somewhat serious illness, and it was known that his heart was affected, but he remained very active, and his death was quite unexpected; it occurred, indeed, quite suddenly while he was paying an official visit to the prison of which he was medical officer.

Dr. Clark, who at the time of his death was in his 59th year, joined St. Bartholomew's Hospital as a student in 1877, after a distinguished career at Oxford, where he took a first class in Natural Science. In 1881 he became M.R.C.S. Eng., and in the following year graduated M.A., M.B. of his old university. It was not very long afterwards that he established himself in Gloucester, but meantime he had successively filled the offices of house-physician and house-surgeon of St. Bartholomew's, and of resident clinical assistant of the City of London Hospital for Diseases of the Chest.

His early progress in Gloucester was rapid; in 1885 he was a successful candidate for a vacancy on the honorary staff of the General Infirmary, while in the same year he became medical officer of H.M.'s Prison, and little by little he began to play an increasingly active part in the general and professional life of the city. At the time of his death he was, in addition to being senior physician of the infirmary and senior medical officer of the provident dispensary, chairman of the District Nursing Association, governor of the United Endowed Schools, a valued member of the Public Library Committee, and a member

of the council of the Bristol and Gloucestershire Archaeological Association. He was a member of the British Medical Association, and a few years ago was president of the Gloucestershire Branch.

To the affairs of the District Nursing Society he devoted much energy, and this body shortly after his death held a special meeting for the purpose of recording its profound regret at its death and

Its lasting gratitude for the intense interest he had ever taken in the conduct of the business and in the efficiency of the society, in the general management of the home, and in all things pertaining to the comfort and welfare of the superintendent and her staff.

A man of wide culture, Dr. Clark was much interested in the Oxford Extension Lectures in Gloucester, and was the first chairman of the committee in charge of them. In private life he devoted much of his spare time to literary pursuits, the early English poets being his special study; he was also an enthusiastic and highly skilled photographer. Dr. Clark was married, and is survived by his wife and several daughters. His remains were cremated at Birmingham.

JOHN WILLIAM FAWEITT, L.R.C.P., L.R.C.S. EDIN.,
BROUGHTON-IN-FURNESS.

THE sudden death of Dr. Fawcitt, of Broughton-in-Furness, has robbed his patients of the services of one who was a notable example of the very best type of country doctor, and will be much missed by a large circle of friends; for to know John Fawcitt was to be his friend.

He was a Yorkshireman, and was brought up in Thirsk. His school days were passed in York, and he then went to the University of Edinburgh, where he qualified in 1884. After serving as assistant at Slough and Castleford, he settled in Broughton in 1887, and in that charming country he has lived and laboured for more than a quarter of a century, endearing himself to the whole countryside by his painstaking work and ready sympathy. There was no man, woman, or child in his district that he did not know personally and for whom he had not a kind word.

It is difficult to speak of his characteristics, so wide were his interests. Professionally he was very sound, keeping in touch with the latest developments of medicine. He joined the British Medical Association in 1903, on the formation of the North Lancashire and South Westmorland Branch, of which he became President in 1910.

He was a great admirer of the beautiful in Nature, and few knew the Lake District better than he. Whilst he was interested in all sport, and entered with zest into the amusements and pursuits of his neighbours, his chief pastime was fly-fishing, and he was an adept in this gentle art. All his too brief holidays were spent in the exercise of his favourite sport among the becks, tarns, and lakes of the north country, the burns of Galloway, the lochs of Ireland, the glacier-fed streams of Norway, or the great salmon rivers of Scotland. Whilst he enjoyed to the full a week or two of salmon fishing, he used to say that, after all, there was nothing to equal a day on a good trout stream with a little 11-ft. rod and the trout on the feed. He made a special study of the habits and life-history of the Salmonidae, and took a great interest in the work of the Duddon and Windermere Fishery Board, of which he was a member. He was a capital teller of stories, and had a full store of yarns, fishing and otherwise. He was a most interesting companion, and could talk well on a wide range of subjects, and was, moreover, a good listener. As becomes a Yorkshireman, he was a great lover and an excellent judge of a horse, and always prided himself on keeping at least two rattling good cobs and on having them turned out well. A touching sight at the funeral was to see his favourite old dun cob "Prince" led behind his dead master to the churchyard.

He was a good Churchman and a strong Conservative, and died beloved by his friends and respected by all.

We regret to have to record the death, on June 10th, of Dr. G. H. ROGÉ DABBS at his residence in Westminster. Dr. Dabbs had been for some years in failing health and had suffered from a distressing malady, which, however, he had not allowed to interfere with his professional avocations. More recently he had experienced several attacks of angina pectoris, and his death was no doubt due to the accidental inhalation of an overdose of chloro-

form taken to alleviate his sufferings. Dr. Dabbs, who was born in January, 1846, was the son of a staff surgeon in the Royal Navy and of a Basque lady. He was educated at the Royal Naval School, New Cross, and at King's College, London. In 1867 he took the diplomas of M.R.C.S. and L.S.A. and the degrees of M.B., C.M. at the University of Aberdeen. In the following year he graduated M.D. in the same university. After some years spent in visits to France and Spain, during one of which, we believe, he served as surgeon with the Spanish army, he settled in practice in the Isle of Wight. Dr. Dabbs had strong literary tastes, and it must have been a peculiar pleasure to him to have been the medical attendant of Tennyson when the poet resided, as was his custom for a part of every year, in the Isle of Wight. In the memoir of the poet by his son it is stated that according to Tennyson's manuscript notes *The First Quarrel* "was founded on an Isle of Wight story; Dr. Dabbs was the doctor." Dr. Dabbs attended Tennyson in his last illness, and wrote an account of the passing of the great poet beyond the bar. Dr. Dabbs wrote a good many books in prose and verse, among which *Ugly, a Hospital Dog*, was probably the most successful. He also composed several plays, and for some time edited, and we believe for the most part wrote, a small periodical which he called *My Journal*. In 1903 he left the Isle of Wight to become medical officer to the managers of the Stock Exchange. He had recently taken a partner, but retained the position until the time of his death.

DR. LOUIS ADOLPHUS DUHRING, of Philadelphia, whose authority on questions of dermatology was recognized throughout the medical world, died on May 8th in his 63th year. He took his degree at the University of Pennsylvania in 1867. After studying for two years in Paris, London, and Vienna, he returned to Philadelphia, where in 1870 he opened a dispensary for skin diseases. In 1871 he became a lecturer in the Faculty of the University of Pennsylvania, and in 1876 he was appointed professor. In 1911 he retired with the title of Emeritus Professor. He was one of the founders of the American Dermatological Association. Of his numerous works on dermatology, the principal are a *Practical Treatise on Diseases of the Skin*, which appeared in 1887, and was translated into French, Italian, and Russian. Of the others, his *Atlas of Skin Diseases* (1876) and his *Textbook of Cutaneous Medicine* (1898) may be mentioned.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the profession in foreign countries who have recently died are: Dr. Theophile Anger, formerly surgeon to the Paris hospitals; Dr. E. Bennecke, lecturer on surgery in the University of Jena; Dr. Cl. Bernoud, of Lyons, a well-known rhinologist and laryngologist, aged 43; Dr. A. A. Bliss, for more than twenty years laryngologist and otologist to the German Hospital and Mary Drexel Home, Philadelphia, a former president of the American Laryngological Association, aged 53; Dr. Bochenek, professor of anatomy in the University of Craeow; Dr. David Coggin, consulting ophthalmologist to the Salem Hospital, Massachusetts, aged 69; Professor Ernesto Ferrantini, of Rome, a well-known specialist in diseases of children; Dr. Frederick Forelheimer, professor of paediatrics and for some time Dean of the Medical College of Ohio, author of works on the prophylaxis and treatment of internal diseases, the therapeutics of internal diseases, president of the Association of American Physicians in 1910, aged 59; Dr. Edward Garceau, gynaecologist to the out-patient department of St. Elizabeth's Hospital, Boston, author of a textbook on tumours of the kidney, aged 40; Professor Raimondo Guaiata, founder of the Children's Hospital of Milan; Dr. Francis Parker Kinnient, professor of clinical medicine in the New York College of Physicians and Surgeons, and in 1907 president of the Congress of American Physicians and Surgeons; Dr. Charles Hunton Knight, of New York, for many years professor of laryngology in Cornell Medical College, in his 64th year; Professor Antonio Marro, Director of the Public Asylum, Turin; Dr. George H. Powers, of San Francisco, Emeritus Professor of ophthalmology in the University of California, aged 72; Dr. Ernest L. Shurly, one of the founders and Emeritus Professor of Laryngology and clinical medicine in the Detroit College of Medicine,

aged 67; Professor Willy Thorn, head of the gynaecological department of the Magdeburg Municipal Hospital, aged 56; Dr. Camillo Verdelli, lecturer on medicine in the Medical Faculty of Parma; Dr. P. Vergely, professor of histology and afterwards of pathology and general therapeutics in the University of Bordeaux, author of numerous medical monographs, just before completing his 74th year; Dr. Alcibiades Vicencio, extraordinary professor of obstetrics in the University of Santiago (Chile) and director of the School of Midwives in that city, a strenuous advocate of puericulture and initiator of a boycott movement in Chile; and Dr. Theodor Weyl, lecturer in the Technical High School of Charlottenburg, and well known as a hygienist, author of many writings on subjects connected with his speciality, aged 62.

The Services.

GLASGOW TERRITORIAL FORCE ASSOCIATION.

THE Army Council has approved of Colonel Donald J. Mackintosh, M.V.O., etc., Assistant Director of Medical Services, Lowland Division, being appointed to a seat as a military member of the Territorial Force Association for the city of Glasgow.

Medical News.

THE annual general meeting of the Research Defence Society will be held on Tuesday, June 24th, at 5 o'clock, at the Royal College of Physicians, Pall Mall. The chair will be taken by Sir David Gill, K.C.B., F.R.S., President of the Society. The report will be presented by the Hon. Sydney Holland, Chairman of Committee. Other speakers will be: Sir William Osler, Regius Professor of Medicine at Oxford; the Right Rev. Dr. Frodsham, sometime Bishop of North Queensland; and Mr. Waldorf Astor, M.P., and Sir Hugh Bell.

ON March 29th the Texas Senate rejected, by a vote of 14 to 11, a bill providing for the sterilization of defectives in the State institutions.

AMONG the members of King George's suite who received decorations on the occasion of His Majesty's recent visit to Berlin was Sir James Reid, on whom the German Emperor conferred the Order of the Red Eagle (First Class).

THE New York Academy of Medicine has issued an appeal to the public for funds to enable it to erect a new building. The Fellows of the Academy have promised £25,800.

SURGEON-GENERAL JOSEPH E. GODFREY, chairman of the Local Government Board of British Guiana, has been reappointed a member of the Executive Council of that colony.

THE Hamburg Cancer and Tuberculosis Research Institute has received from an anonymous benefactor a gift of £1,000 to be applied towards the erection of a department for investigation of fungi. Dr. H. C. Plaut has been appointed director of the new department.

AT the meeting of the Royal Society on Thursday next a paper on light sensations and the theory of forced vibrations will be read by Dr. G. J. Burch, and another on the luminosity curve of a colour-blind observer by Mr. W. Watson.

THE authorities of the institution known as the Caterham Sanatorium and Surrey Hills Hydropathic celebrated by a luncheon party, on May 30th, the tenth anniversary of its establishment. It is conducted, we are informed, on the same lines as the Battle Creek Sanatorium, Michigan, U.S.A.

THE annual prize distribution at the medical school of St. Thomas's Hospital is to take place next Tuesday, June 24th, at 3 p.m., the ceremony being performed by the Right Hon. Lord Amptill. A garden party on the terrace of the hospital will follow, and the various departments of the joint institutions be thrown open to inspection.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held on Wednesday and Thursday, July 16th and 17th, at the rooms of the Medical Society of London. The annual dinner of the association will take place at the Café Monaco on the evening of July 16th.

As announced in the advertisement pages, the next examination of candidates for the Royal Naval Medical

Service will be held at the Examination Hall, 8, Queen Square, Bloomsbury, W.C., on September 29th, and following days. Twenty-five appointments are offered for competition. Application forms and further particulars can be obtained from the Medical Director-General, Admiralty, S.W.

THE Royal Sanitary Institute has elected Mr. Waldorf Astor, M.P.; Mr. Lewis Haslam, M.P.; Major H. B. Paveus, R.A.M.C., assistant professor of hygiene, Royal Army Medical College; Lieutenant-Colonel Sir Joseph Payrer, R.A.M.C., superintendent of the Royal Infirmary, Edinburgh; Dr. W. H. Hamer, medical officer to the London County Council; Dr. F. St. George Mivart, medical inspector to the Local Government Board; and Professor H. A. Woodruff, M.R.C.S., L.R.C.P., M.R.C.V.S., of the University of Melbourne, to be Fellows of the institute.

AT the annual meeting of the Royal National Pension Fund for Nurses, on June 12th, the Chairman (Sir Everard Hambro) said that the invested funds stood at a book value of £1,720,475 at the end of last year, as against £1,632,725 at the end of 1911, and that any depreciation due to a fall in market values was well covered by the reserve fund. The sum now being paid to annuitants amounted to about £40,000 a year. The experience of the fund was that their annuitants lived long beyond the term of their assessed expectation of life at the time of their retirement. This, of course, was a disadvantage to the fund, but it showed what an advantage the fund was to nurses.

DR. JOHN JOHNSTON, of Bolton, who has taken a practical interest in ambulance work for the past twenty-five years, was the recipient on June 11th of a handsomely mounted umbrella from members of the Bolton ambulance class. The presentation was made at a meeting for the distribution of certificates and medallions secured by the Bolton ambulance division of the Lancashire and Yorkshire Railway during the past year. This division has for some years past held a conspicuous position among ambulance corps in the North of England; last year it won the shield offered by the company, and this year was awarded the Sir George Pilkington cup. In the course of the proceedings many allusions were made to the indebtedness of the corps to Dr. Johnston's tuition, and a comparison was supplied by the latter of ambulance work as it is to-day and as it was twenty-five years ago.

AT a meeting of the general court of governors of St. George's Hospital, on June 12th, it was decided by a majority of 17 on a total of 29 votes to take no action in the question at issue between the hospital and the King Edward's Hospital Fund for London until a report had been received from Lord Moulton and Sir George Hayter (Chubb, who, at the request of the president of the hospital, Princess Christian, have consented to hold an independent inquiry. This decision was reached as an amendment to a motion to the effect that the hospital should provide the difference between £1,000 and the sum expended on the bacteriological and pathological departments out of the discretionary fund, as suggested by the authorities of the King's Fund. An outline of the facts of this long-standing dispute between these two bodies and of the arguments on either side will be found at page 549 of the SUPPLEMENT to our issue for June 14th.

THE progress of practical medicine is to be dealt with in a series of lecture courses given in Berlin by the Lecturers' Association for Medical Vacation Courses from June 19th to 28th in collaboration with the Central Committee for Medical Post-graduate Education in Prussia. Lectures will be given on all special subjects of practical medicine. Among the subjects we note the new problems with which the practitioner is confronted, owing to the new Government insurance regulations. Foreign doctors are entitled to participate. All applications should be addressed to the Bureau of the Lecturers' Organization for Medical Vacation Courses (Herr H. Melzer, N. 24, Ziegelstr., 1011). Inquiries will be answered by the Bureau of the Lecturers' Organization and by the Medical Information Bureau of the Kaiserin Friedrich-Haus (Berlin N.W. 6, Luisenplatz 2-4).

AN excellent method for promoting friendly relations between England and Germany has been adopted by the managers of the Crystal Palace, where the great Anglo-German Exhibition was opened by the Lord Mayor on June 11th. Every effort has been made to render the exhibition as fully representative as possible of the arts and industries of both countries, and the result is an extremely interesting collection of exhibits, whose tasteful arrangement and attractive surroundings show them off to the best advantage. Paintings and statuary offer a good opportunity for studying the different methods of English and German artists, whilst the sections devoted

to music, printing, wood carvings, and brass and metal work enable the visitor to compare still further the artistic capacities of the two nations. Other sections contain naval and military appliances, machinery, and tools; textiles, furniture, chemicals, and surgical and optical instruments; whilst some of the prettiest stalls are given over to German toys, trinkets, and pottery, including a number of very beautiful specimens of Dresden china. A large variety of international musical and athletic competitions will be held during the course of the summer in the great hall and grounds of the Palace; and a repertory theatre has been instituted in which German plays will be acted nightly by a special company. The exhibition will remain open until October, and should fulfil a useful purpose in making better known to each other and fostering a more complete sympathy between the people of England and Germany.

In 1877 the Staffordshire Institution for Nurses was established at Hartshill, near Stoke-on-Trent, mainly through the exertions of the late Bishop Sir Lovelace Stamer and Mr. W. D. Spanton, then surgeon to the North Staffordshire Infirmary. The institution has done a great deal of good work, and recently it was arranged to establish in connexion with it a nursing home for paying patients. This home was opened a short time ago, and Mr. Spanton presided at the ceremony. He said that the home was intended solely for those who were unable to pay an adequate fee. The building, he said, was very simply constructed, the great objects being to secure an abundance of air, free ventilation, and plenty of light. The building was then declared open by Lady Stamer, the widow of the late bishop. The home has, owing to the slope of the site, three stories on the one side and two on the other. In the front are the kitchen, scullery, and other rooms. On the ground floor there are two large wards and a smaller one, with a preparation room, waiting room, and accommodation for the superintendent. On the floor above there are two large wards, bath room, maids' room, and store rooms. The floors are connected by a lift as well as by a wide staircase. The building is lighted by electricity, the corridors are heated by hot water, and each room has an open fireplace in addition to an electric radiator. The success of the nursing institution has been so great that it now employs over a hundred nurses, and its affairs have been so well managed that Mr. Spanton was able to state that the new home had been built from reserve funds.

THE annual report of the National Society for the Prevention of Cruelty to Children, presented to the Council on May 27th, states that the number of offenders against children in cases reported to the society in England, Ireland, and Wales in the year ending March 31st, 1913, was 74,687, being 899 more than in the previous year. The central fact of the whole report is that during the year the society acted as the protector of 159,407 children, a larger number than in any of the twenty-nine years of its existence, and 2,770 more than in 1911-12. The total number of complaints was 54,541, being 353 more than in 1911-12. The complaints are classified as follows: Neglect and starvation, 47,880; ill-treatment and assault, 3,886; indecent assault 194, criminal assault 163, immoral surroundings 485—making a total of 842 offences against morality; exposure for begging purposes, 575; exposure, 501; abandonment, 299; baby farming, 42; manslaughter, 1; other wrongs, 515. Of these 54,541 cases, 52,967, on a preliminary investigation, appeared to have substance in them; using the technical expression of the record, they were "found true." It is pointed out that this does not mean that the other 1,565 complaints made were not justified. "In the majority of these there was good reason for making them, but there was also an explanation that made it unnecessary for the investigator to proceed." Of the 54,541 complaints, 30,863 were made by members of the general public, 6,140 were reported by the police, 8,983 by school officials, 4,603 by other officials, while 3,952 were discovered by the society's inspectors. Stress is laid on the fact that prosecution is not the main object of the society's work. The cases brought to its notice during the year were dealt with as follows: Warned, 48,114; prosecuted, 2,456; otherwise dealt with, 2,397. The proportion of cases successfully dealt with by warning was larger than in any previous year, being 88.2 per cent. The report, though it bears witness to the splendid work done by the society, is sad reading, as showing the amount of suffering inflicted on helpless children. In view of the statistics set forth in the report there is comfort in the assurance, which is given with emphasis, that "neither cruelty nor neglect of children can be described as a characteristic of the people as a whole."

Letters, Notes, and Answers.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

SUGGESTIONS are invited by "C." as to the two following cases: (1) A boy who, although only 12 and of average height, weighs 8 st. 7 lb., and gets very readily tired. The urine shows phosphates and the blood an increased number of white corpuscles, but otherwise the boy appears healthy. Thymus extract is apparently of some utility. His stoutness began a few months after an operation for hypertrophied turbinates, adenoids, and tonsils. What is its pathogenesis? (2) A case of rheumatism in the shoulders. Ionization has not been tried, but all ordinary remedies for rheumatism, including hot ironing, have proved useless.

ANSWERS.

SOMNAMBULISM.

DR. ALEXANDER HAIG (London, W.) writes in reply to "Aber," JOURNAL, p. 1256: I would suggest that if he will measure the circulation by methods similar to those suggested in my paper, "Some Circulation Factors Admitting of Easy Measurement," JOURNAL, September 16th, 1911, he will find considerable defects due in part to impure blood and in part to heart weakness. If he can improve the circulation, the somnambulism will also improve or disappear. He will find a good deal bearing on the relation of the circulation to the kindred troubles, headache and epilepsy, in my book, *Uric Acid in the Clinic*, London, 1910, p. 32 and pp. 72 to 76.

LETTERS, NOTES, ETC.

ENQUIRER, who has recently sent us two letters, is informed that answers cannot be returned unless the enquirer authenticates his communications with his name and address.

PREMATURE CREMATION.

DR. G. ANGUS HUNT (London, N.) writes: With reference to the leader in the JOURNAL for June 14th, may I ask—and, like Rosa Dartle, "I only ask for information"—if the doom of a premature burial is possible, why not the doom of a premature cremation? Personally, I should prefer even a momentary return to consciousness in a coffin underground rather than in a casket in the midst of a burning fiery furnace. * * * We think that even Miss Rosa Dartle's thirst for information would for once have been satisfied had she witnessed a cremation. Moreover, with the stringent precautions as to the certification of death when cremation is proposed, the doom of a premature cremation is almost unthinkable.

DOGS AND DOG OWNERS.

MISS C. A. M. BAILEY, Honorary Secretary National Canine Defence League, has issued an appeal to dog owners not to chain their dogs. We quite appreciate the fine sentiment which has dictated this appeal, but is it not just a little sweeping? An unchained dog may have a taste for the calf of the human leg, but we agree that dogs are often treated by their masters with great carelessness. As Miss Bailey says: "A dog chained out in the sun in hot weather, unable to reach the shade, his kennel, which has been left to face the sunny quarter, baked through and through, probably with no water to quench his burning thirst, or only a drop of stale, filthy, hot liquid, suffers torments." But while condemning this inhumanity, we think that her unreserved demand, "Give dogs their freedom and do not chain them," fails to take sufficiently into account possible danger to human beings.

DIACHYLON OR DUTY: A CORRECTION.

In the sixth line of Dr. W. Wrangham's letter under this heading in last week's JOURNAL (p. 1297), for "blood" read "lead."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|----------------------|-----|-----|-----|
| Eightlines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posto restante* letters addressed either in initials or numbers.

An Address

ON

THE DIAGNOSIS AND TREATMENT OF DYSENTERY.

DELIVERED BEFORE THE SOUTH MIDLAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION

BY

SURG.-GENERAL SIR CHARLES PARDEY LUKIS,
K.H.S., K.C.S.I., M.D., F.R.C.S.,
DIRECTOR-GENERAL, I.M.S.

GENTLEMEN.—In the first place let me say how greatly I appreciate the honour which your President has conferred upon me by asking me to address you to-day. When I first received his invitation I was doubtful as to my ability to tell you anything in connexion with tropical diseases that would be of use to you in your practice; but when I remembered that a large Anglo-Indian colony exists in Bedford, it appeared to me that the choice of a subject lay between malaria and dysentery, and I finally decided upon the latter.

The term "dysentery" was first employed by Hippocrates to distinguish a disease of the bowels characterized by the presence of blood in the stools, but later on the disease was differentiated more clearly by emphasizing the fact that there must be mucus as well as blood in the stools, and that the symptoms of tormina and tenesmus must be present. This definition still held good when I went to India thirty-four years ago. We were taught that the association of frequent dejections and straining with blood and mucus in the stools was sufficient for the diagnosis of clinical dysentery, and any patient exhibiting this syndrome was at once placed upon enormous doses of ipecacuanha, elaborate precautions being taken to prevent it from acting as an emetic.

Here I wish to warn you against the danger of thinking that because a patient who comes to you for advice has resided for many years in the tropics, he is on that account necessarily a victim to some form of tropical disease. If, therefore, an Anglo-Indian comes to you complaining of the classical symptoms of dysentery, do not at once jump to the conclusion that he is really suffering from that disease. There are numerous "pseudo-dysenteries," and the symptoms in question may be merely manifestations of tuberculous or malignant ulceration of the bowel, of stricture or gumma of the rectum, of inflamed piles, of helminthic infections, or they may be a terminal condition of that very fatal disease, kala-azar. All these may, however, be excluded by careful examination of the thorax and abdomen, by digital exploration of the rectum, by microscopic examination of the faeces, and, in the case of kala-azar, by an exploratory puncture of the enlarged spleen and search for the Leishmania-Donovani parasite.

BACILLARY AND AMOEBIC DYSENTERY.

Having by these means satisfied yourselves that you are dealing with a true dysentery, the next point for consideration is "What type is it—is it bacillary or amoebic?" This is of paramount importance, because the treatment suitable in the one form of the disease is useless, or even harmful, in the other. We owe our knowledge of the etiology of bacillary dysentery to the investigations of Shiga in Japan and Kruse in Germany during the years 1898-1900. They proved that the causal organism of the disease is a short bacillus, belonging to the *typho-coli* group, which is Gram-negative, non-motile, and which does not either clot milk or produce gas in any sugar media. Further investigations by Flexner, Hiss and Russell, and Strong have shown that there are various strains of dysentery bacilli which resemble the original Shiga-Kruse bacillus, in that all of them have the common property of producing acid in the monosaccharides, glucose and galactose, whilst they do not ferment either lactose, dulcitol, or sorbitol. They differ from the Shiga-Kruse bacillus, however, in two important particulars—they all ferment mannitol and they produce indol. Considerable divergence of opinion exists as to the exact significance of bacilli belonging to the latter subgroup.

American writers regard all of them as being of equal etiological importance, whilst the German school hold that the Shiga-Kruse bacillus is the only true type, and this view receives some support from the results obtained by serum therapy. These various forms of *B. dysenteriae* are responsible for the production of three distinct types of disease—(1) epidemic dysentery, as seen in India; (2) asylum dysentery, as seen in England; and (3) certain types of infantile diarrhoea.

But there is another type of dysentery which is endemic or sporadic in its nature, which is most apt to run a chronic course, and which in a large proportion of cases is complicated by abscess of the liver. This type is associated with the constant presence of amoebae in the stools and in the lesions, especially in the walls of liver abscesses, and the pathological changes found in the bowel after death are entirely different from those of bacterial dysentery. As regards the relationship of the amoebae to this disease, there are three views: (1) That the presence of the amoebae is accidental, and they play no part in the causation of the disease; (2) that the ordinary *Amoeba coli* is a harmless saprophyte, but that there are two pathogenic amoebae—namely, *Entamoeba histolytica* and *E. tetragena*; (3) that, under certain conditions, all amoebae may become pathogenic. For reasons which I shall give later on we may, I think, reject the first view. The other two are subjects for academic discussion, and do not concern us as practical clinicians. It is sufficient for our purpose to remember that in one form of dysentery there is an absence from the stools of the various types of *B. dysenteriae*, and that their place is taken by certain forms of amoebae. Also that this disease differs from bacterial dysentery both in its pathology, symptomatology, prognosis, and its reaction to treatment.

As regards the symptomatology, the points of distinction between the two diseases are as follows:

1. Bacillary dysentery is always acute in onset, and it runs a rapid course in nearly all cases. Amoebic dysentery, on the other hand, even though it may begin with an acute attack, always runs a chronic course. It is therefore the form you are most likely to see in this country.

2. In bacillary dysentery pyrexia is common; in amoebic dysentery it is rare.

3. In bacillary dysentery toxæmia is a marked symptom; in amoebic dysentery it is absent except when a liver abscess is forming.

4. In bacillary dysentery the stools are muco-purulent, with large cellular exudate and small in bulk; in amoebic dysentery they are grungous, like those of serous colitis, they are copious, and they contain little or no cellular exudate.

5. Liver abscess never occurs in bacillary dysentery; it is a common complication in amoebic dysentery.

DIAGNOSIS OF ABSCESS OF THE LIVER.

Its onset is always insidious, but no difficulty occurs in a typical case in which you have the classical symptom of hectic temperature with night sweats, leucocytosis, diminished movement of the right side of the diaphragm, pain under the right shoulder blade, a dragging sensation on the right side associated with fullness and tenderness in the right hypochondrium, and rigidity of the right rectus. In many cases, however, all or many of these signs are wanting. You must remember (1) that the interior of the liver does not contain sensory nerves, and that quite a large abscess may form deep in the substance of that organ without causing any pain; (2) that a considerable portion of the liver is under the ribs, so that there may be no appreciable swelling, especially if the abscess is on the upper surface of the liver; and (3) that about 40 per cent. of liver abscesses are sterile, so that there may be a complete absence of fever or leucocytosis. Indeed, I have on several occasions diagnosed and evacuated abscesses of the liver in which all these signs and symptoms have been conspicuous by their absence.

How, then, is the diagnosis to be made in a case of this kind? The answer is simple—"By watching your patient." In amoebic dysentery there is an absence of toxæmia, except when a liver abscess is forming. If, therefore, a patient who has suffered from amoebic dysentery is obviously toxic and is losing flesh rapidly;

if his face is drawn and his expression listless, his complexion sallow, his conjunctivae dull, and his tongue thickly furred, lose no time in making an exploratory aspiration of his liver. The operation can do no harm even if you fail to find pus, and it may save you from the unpleasant experience of being sent for one day to find your patient coughing up pus from an unsuspected abscess of his liver which has burst into the lungs, or writhing in agony from its rupture into the peritoneum. Moreover, if when you aspirate the liver you find only a small abscess, and especially if the absence of fever leads you to think it is sterile, you may frequently cut short the disease and render subsequent operation unnecessary by repeated irrigation of the abscess cavity with a solution of bichloride of quinine (3 to 5 grains to 1 oz.) by means of the flexible sheathed aspiration cannula which has been designed by Major Rogers for that purpose.

From the description I have given of the symptoms you will see that in the majority of cases no great difficulty arises in the diagnosis of amoebic dysentery from the bacillary form of the disease, but it is not always plain sailing, and in any doubtful case a complete microscopic and bacteriological examination of the faeces is advisable. The identification of the various forms of *B. dysenteriae* takes up more time than the busy practitioner can afford to give to it, and shreds of mucus should be put up in sterile tubes and sent to a pathological laboratory. But it is quite easy to detect the amoebae; for this purpose all that is necessary is to take a small piece of a freshly-passed stool and place it on a slide, adding to it one or two drops of a 1 in 10,000 solution of neutral red in normal saline. A cover-glass is then placed on top, gently pressed down and "ringed" with vaseline, and the preparation is examined under a $\frac{1}{2}$ objective and a 1 or 2 in. eyepiece. With this magnification the amoebae are easily detected, and it will be found that they have taken up the neutral red, all the other constituents of the faeces, even the leucocytes, remaining uncoloured.

TREATMENT.

It is impossible to deal with this very important subject fully in the short time at my disposal. I shall confine myself, therefore, to the specific treatment of the causal organisms.

Bacillary Dysentery.

In bacillary dysentery we may adopt either the saline or the bacteriological methods of treatment; but in the amoebic form of the disease we must rely upon ipecacuanha or emetine.

There are two methods of treating bacteriologically a case of bacillary dysentery: (1) The use of a vaccine, thus producing an active immunity; (2) the use of an antitoxic serum, thus raising passively the immunity of the patient.

1. *Vaccines.*—Much work on this subject has been done in India by Major Forster, Professor of Pathology in the Lahore Medical College. His vaccine is prepared with the Shiga-Kruse bacillus, which he uses for all types of bacillary dysentery. He uses it in both acute and chronic cases, but in acute cases it is contraindicated from the fourth to the twenty-first day. After this period inoculation may be commenced with an interval of ten days between each dose. In both acute and chronic cases the dose recommended for an adult male is: First dose, 0.1 c.c.m.; second dose, 0.2 c.c.m.; third dose, 0.3 c.c.m.; fourth dose, 0.4 c.c.m. Females and children are given proportionately smaller doses. According to Forster these doses produce little or no negative phase, and in fourteen days the immunity is considerably raised, whilst a course of four doses usually suffices to get rid of all bacilli and to prevent the patient from becoming a chronic "carrier." Most authorities consider that on account of the severity of the local reaction and the risk of producing a negative phase the vaccine method is best reserved for chronic cases, and that in acute cases it is inferior to the serum and saline treatments. Certain experiments, however, are now being made with "sensitized vaccines," which, as you are doubtless aware, consist of bacilli which have become coated with specific antibodies (lysins, agglutinins, etc.) as the result of exposure to the action of an immune serum. Such bacilli are now "sensitized" and do not lose this property when killed by heat. As

the result of this sensitization, they are more easily dealt with by the leucocytes, and the toxicity of the vaccine is decreased, whilst its immunizing power remains unaltered. For these reasons I am disposed to think that there is a great future before these sensitized vaccines, and that it may be necessary ere long to modify our views as regards the unsuitability of vaccine treatment in the acute stages of disease.

2. *Antidysenteric Serums.*—These may be either mono-valent or polyvalent, but the highest degree of immunity is conferred when the Shiga-Kruse bacillus is used in their preparation. These serums are of the greatest value in the acute stages of the disease, especially if there be profound and prolonged toxæmia unaffected by other forms of treatment. The dosage depends upon the strength of the serum used, and is, as a rule, marked on the phial, but it is necessary to give it in large doses, the injections being made with the usual antiseptic precautions under the skin of the abdomen or flank. Thus the serum from the Lister Institute should be given in 20 c.c.m. doses twice, or even, in severe cases, four times daily. The interval between the injections should be six hours. They need not, as a rule, be continued after the second or third day, and the only untoward effects likely to follow are urticarial rashes and other anaphylactic phenomena such as pain in the joints, etc. Textbooks tell us that these complications may be avoided by the administration of calcium chloride or lactate. Experience does not support this statement, but it may be taken as granted that grave anaphylactic phenomena only occur when the interval between the doses is long or irregular. The remedy, therefore, is regular and systematic administration of the serum.

Salines.—When the serum treatment cannot be carried out, or when you get the patient in the first day of the disease, the saline treatment is, in my experience, the most useful. Indeed in many early cases it suffices for a complete cure. Two drachms each of magnesium sulphate and sodium sulphate dissolved in 1 oz. of water should be administered and then half doses of a similar mixture should be given every hour or every two hours until the motions became faeculent, after which it is given every three or four hours for another twenty-four hours and then discontinued; but do not stop it too soon, otherwise the patient will still suffer from faecal retention, even though he be passing a large number of stools containing only blood and mucus.

Amoebic Dysentery.

Up till recently our only method of treatment of this disease was by the administration of huge doses of ipecacuanha. This treatment, if persevered in, was undoubtedly efficacious, but the nausea caused by the drug was so severe that it was extremely difficult to persuade patients to take it. To remedy this a de-emetized ipecacuanha was put on the market some years ago, but this proved to be useless, and we were reluctantly compelled to return to our old methods. Recently, however, the treatment of amoebic dysentery has been revolutionized by the researches of Vedder in 1911 and by the brilliant discovery of Major Rogers that the amoebae can be quickly killed by the hypodermic injection of emetine, and that, when given in this way, the patient experiences no nausea or discomfort of any kind. Both the hydrochloride and the hydrobromide of emetine are equally useful, but the former is more soluble, the latter requiring 2 c.c.m. of sterile water or saline for the solution of one dose. Rogers began with $\frac{1}{2}$ grain, which is equal to 30 grains of ipecacuanha, but he now gives 1 grain of emetine each day, in two hypodermic doses of $\frac{1}{2}$ grain each, and he claims that by this method all the amoebae in the body can be killed in from two to four days, the average for a number of cases being 2.35 days. He has also shown that one or two $\frac{1}{2}$ grain tablets may be given by the mouth on an empty stomach without exciting any great nausea, especially if they are keratine-coated. This method of administration does not effect a cure as speedily as when the drug is given hypodermically, but it may be useful when for any reason there are difficulties in connexion with the giving of the injections.

The hypodermic injection of emetine is also a valuable aid to diagnosis. If you have a case which you suspect to be amoebic dysentery, but which does not react to emetine within three days, you may be sure that your diagnosis is

wrong, and you need waste no further time in treating it as such. Moreover, the powerful effect of emetine on amoebic cases, compared with its uselessness in bacillary cases, may, I think, be taken as strong proof that amoebic dysentery is really a separate entity. That is why, in the earlier part of this address, I said that we might reject the view that intestinal amoebae play no part in the causation of this disease.

A Lecture ON MINERS' NYSTAGMUS.*

BY
T. LISTER LLEWELLYN, M.D., B.S.LOND.,
TYNDALL RESEARCH STUDENT OF THE ROYAL SOCIETY.

MINERS' nystagmus is an occupational disease of the nervous system, and is only found among workers in coal mines. The first case was described in Belgium, by Decondé, in 1861; and among the earliest observers were C. Bell Taylor, Nieden, Gräfe, and Snell. Romée pointed out that the earliest recorded case was described in Belgium ten years after the safety lamp had been recommended for use in that country, and that it was only after the compulsory introduction of the Mueseler lamp in 1876 that he noticed an increase in the number of cases of the disease.

There have been two chief views as to the causation of the disease—the one that it is due to the position assumed by the miner at his work, and the other that it is due to deficient illumination. The first view was very ably and strongly advocated by Dransart, Nieden, and Snell, and the last named had several discussions with Dr. Court, who has the honour to be the first English observer to call attention to the importance of the light factor. Most English observers now hold that the chief factor is deficient light, but on the Continent there is still diversity of opinion.

SYMPTOMS.

The first symptom is failure of sight, especially at night time, or when the sufferer is called upon to perform the more skilled portion of his work. The man next complains that the lamps dazzle his eyes, and sooner or later that the lamps and all surrounding objects dance before him. Headache, varying from slight pain between the temples to attacks of extreme severity, giddiness on exertion and stooping, inability to see at night time, and dread of a bright light, are often present.

There are two distinct varieties of the disease. In the first the symptoms are absent or latent, and the man, suffering no disability, is unaware that he has nystagmus; in the second the disease is manifest, and the man is more or less incapacitated and aware that his eyes are affected. Among 750 consecutive cases 150 latent cases were observed.

The table shows the frequency of the various symptoms in the remaining 600 manifest cases.

TABLE I.—Symptoms in 600 Manifest Cases.

| | Number. | Percentage. | Symptom Marked. | Very Marked. |
|--------------------------|---------|-------------|-----------------|--------------|
| Movements of objects ... | 566 | 94.3 | — | — |
| Headache | 507 | 84.5 | 51 | 16 |
| Giddiness | 490 | 81.6 | 52 | 8 |
| Night blindness | 459 | 76.5 | 4 | — |
| Dread of light | 284 | 47.3 | 10 | — |

PHYSICAL SIGNS.

The signs of the disease are: Involuntary and irregular movements of the eyeballs, chiefly of a rotatory character, tremor of the eyelids, eyebrows, head, and, in some cases, even of the neck and shoulders. A backward inclination

* Delivered at the Mining Machinery Exhibition, London, on May 31st.

of the head with drooping eyelids is characteristic and common. An attempt has been made lately to describe a condition in which the disease miners' nystagmus exists without the presence of the nystagmus proper, and in which the oscillation of the eyeballs is replaced by blinking of the eyelids. The question is at present under consideration by a Departmental Committee, and there is no time this afternoon to discuss the matter.

THE CAUSE OF NYSTAGMUS.

Owing to the deficient light in a coal mine, the images formed in the eyes are indefinite and inexact; this leads to indecision on the part of the controlling mechanism in the brain, with the result that irregular inco-ordinate movements of the eyeballs ensue. These irregular movements of the eyeballs are known as nystagmus.

FREQUENCY OF THE DISEASE.

Foreign authors estimate the frequency of the disease as being from 5 to 25 per cent. of all workmen employed underground. The following table will show the number of men disabled by the disease in this country. The figures are taken from the Blue Books on statistics of compensation.

TABLE II.—Frequency of Disablement.

| Year. | Number of Certified Cases. | Percentage to Underground Workers. | Cost of All Industrial Diseases. |
|-------|----------------------------|------------------------------------|----------------------------------|
| 1908 | 460 | 0.057 | £13,82 |
| 1909 | 1,011 | 0.23 | £26,759 |
| 1910 | 1,618 | 0.19 | £42,507 |
| 1911 | 2,539 | 0.29 | £68,017 |

I have estimated the cost of the disease to the country in 1910 to have been over £100,000, and on the same basis to have been over £155,000 in 1911.

INCAPACITY.

With regard to the incapacity caused by the disease, I hold the following views: Slight cases can soon return to work underground; ordinary cases can return after an interval of surface work of three to twelve months. Although one attack of nystagmus predisposes to another, I think it only fair to allow a man to try to regain his income by working underground again if possible. The exceptional cases should not return to work underground, and by exceptional cases I mean the following: Men who have failed to work several times before; very young lads; old men with commencing cataract; men with high degree of refractive error, and those cases which have been of exceptional severity. The following table was taken from returns, extending over four years, from five large colliery companies employing over 28,000 men:

TABLE III.—Late Results.

| | |
|--------------------------------|-------------|
| Back at old work | 152 or 45 % |
| Left employ or commuted | 9 |
| At surface work | 105 |
| Idle | 73 |

It is at the present time much more difficult to persuade men to attempt to work underground.

A further question may be asked: Is it dangerous to employ a man underground who has once suffered from nystagmus? In the first place, is the man more liable to accident? It is very difficult to answer this question. Men are often sent out of the pits by managers from fear of this danger, but this is when they are about to fail on account of the disease. I think it probable that many slight accidents are due to nystagmus, but I have only once had a complaint from a man that his accident was directly due to his nystagmus. There is, however, the possibility of a greater danger—namely, that a catastrophe may result from the failure of a fireman or collier suffering from the disease to detect the presence of gas. The table given below shows the results of tests made on all the firemen of five large collieries. The tests were made on the surface with the help of an Oldham gas-testing chamber. The men were first examined for the presence of nystagmus and then tested independently for their ability to detect the cap given in the presence of gas.

TABLE IV.—*Examination for Ability to see Gas Cap.*

| | Number Tested. | Correct. | Trace. Failed. | Cap Shown. | | | | 3 Per Cent. |
|-----------------|----------------|----------|-------------------|-------------|------------------|-------------|------------------|--|
| | | | | 1 Per Cent. | | 2 Per Cent. | | |
| | | | | Failed. | Under-estimated. | Failed. | Under-estimated. | |
| Normal men | 49 | 28 | 14 | 4 | 9 | 0 | 14 | Seen by all, but frequently under-estimated. |
| Nystagmic cases | 41 | 4 | 19 | 10 | 13 | 6 | 12 | |

It will be seen that all the men were able to detect the presence of gas when 3 per cent. was in the chamber. The nystagmic cases, however, certainly made more mistakes than the other men.

FACTORS DETERMINING THE OCCURRENCE OF THE DISEASE.

Age.

The mean age was 39.84 years and the mean years of underground life was 25.58 years.

Occupation.

The occupation of 685 cases is given; the remaining cases were all among under-officials who had been specially examined for the disease, and it was felt unfair to include them in the table. It will be seen that, although all classes of workmen are affected, the great majority of cases come from the coal face.

TABLE V.—*Occupation in 685 Cases.*

| | | |
|--|---------|--------------------|
| Colliers | 525 | } = 557, or 81.3 % |
| Collier lads (fillers or loaders) ... | 32 | |
| Timbermen and repairers ... | 52 | = 7.5 % |
| Hauliers and haulage men ... | 40 | = 5.8 % |
| Rippers | 8 | |
| Labourers | 6 | |
| Contractors | 5 | |
| Under officials | 3 | |
| Hitcher, engine driver, ostler, and mason | 1 each. | |

Method of Work.

The method of coal getting known as holing (under-cutting of the coal) is said by many authors to be the chief factor in the production of the disease. The following table was based on answers given by 580 nystagmus cases, who either were or had been colliers:

| | | |
|----------------------|-----|------------------|
| Much holing | 177 | } = 348, or 60 % |
| Some holing | 171 | |
| Little holing | 40 | |
| No holing | 192 | } = 232, or 40 % |

Taking all the cases, 362, or nearly 50 per cent., had done no holing. Colliers in Somerset, Forest of Dean, and in the house coal pits of South Wales all get their coal by bottom-holing, yet nystagmus is very rare in these pits. The collier when holing is supposed to direct his eyes obliquely upwards, and the advocates of the old school say that nystagmus results from the strain produced by this unnatural position of the eyes, but does a collier look obliquely upwards when he holes? A collier looks upwards when engaged in top-holing, but not when he holes in the bottom. The eyes are then either directed straight-forward or a little downwards. A little consideration will show that the swing of the pick will be more powerful and complete when the blow is ended below the level of the eyes. The photographs handed round will show the position of the men at work.

Seams.

The thickness of the seams does not appear to be of very great importance, as shown by the following table:

TABLE VI.—*Thickness of Seams.*

| | |
|-------------------------|-----|
| Less than 2 feet | 1 |
| 2 to 3 feet | 47 |
| 3 to 4 feet | 133 |
| 4 to 5 feet | 148 |
| 5 to 6 feet | 115 |
| 6 feet and over | 141 |

Illumination.

In metalliferous mines candles or open lamps are used, while in a coal mine safety lamps are often necessary. The naked light coal mine comes midway between the safety-lamp coal pit and the metalliferous mine, having the general blackness of the former and the good light of the latter. Manifest nystagmus is common in the safety-lamp coal pit, rare in the open light coal pit, and unknown in the metalliferous mine. Nystagmus is practically unknown in the purely naked light districts of Somerset and the Forest of Dean, and is rare in the open light pits of South Wales. In South Wales most of the men had worked at one time or another with lamps, and it is common for the men to continue working in an open light pit after they have failed to work with lamps. Taking into consideration the number of men employed, England and Wales, using safety lamps three times more frequently than Scotland, had four times the number of cases of nystagmus in 1910.

In the present series 741 men had used safety lamps, 723 almost entirely, and only 9 had worked with candles alone. As a result of an investigation in South Wales the following figures were obtained. The number of men working in both classes of mines was known and the illumination at the coal face had been tested.

TABLE VII.—*Number of Cases and Average Illumination.*

| | Relative Number of Certified Cases of Nystagmus to Men Employed. | Average Illumination at Coal Face in Foot-Candles. |
|---------------------|--|--|
| Safety-lamp pits... | 6.3 | 0.008, or 1 |
| Candle pits ... | 1 | 0.09, or 5 |

In the same district the incidence of nystagmus was found to vary inversely with the candle power of the lamps used.

TABLE VIII.—*Number of Cases and Candle Power.*

| Pit. | Men. | Nystagmus. | Candle Power of Lamps. |
|------|-------|------------|------------------------|
| A | 450 | 9 | 0.235 |
| B | 1,400 | 22 | 0.27 |
| C | 1,500 | 10 | 0.33 |
| D | 2,000 | 14 | 0.4 |
| E | 1,900 | 8 | 0.42 |

The illumination at the coal face depends mainly on four factors: (1) The candle power of the source of light used; (2) the distance at which this light has to be placed from the coal face; (3) the character of the surroundings; (4) the composition of the air at the coal face.

1. The candle power of the wax candles used in mines is generally equal to one standard candle, but the tallow candle may be equal to two. The oil safety lamp rarely gives more than one-third of a candle power at the coal face when clean and much less when dirty. Some dirty lamps have only given one-tenth of a candle power.

2. The candle can be placed close to the coal face, but the lamp must be placed out of danger, and is always much further from the coal face. As the intensity of illumination varies inversely with the square of the distance the advantage of the candle is very great.

3. In the coal mine practically all the incident light is absorbed and the advantage of reflected light is lost. We do not realize how much of the lighting of interiors is due to this reflected light, but the difference between a room papered with light paper and one with a dark red paper is very obvious.

4. The light of a safety lamp diminishes rapidly when the oxygen percentage of the air falls and the presence of moisture has the same effect. The presence of gas up to 4 per cent. increases the luminosity of the flame. So accurately does the safety lamp answer to the various changes in the atmosphere that a rough estimate of the oxygen percentage might be calculated by taking photometric readings of a standard oil lamp first under normal conditions, and then in the different districts of the mine,

The actual amount of light falling on the coal face was measured in several collieries, and the average of a large number of observations is given below.

In five open light collieries the average illumination at the coal face was 0.09 of a foot-candle. In eight safety lamp collieries the average illumination was 0.018 of a foot-candle, or only one-fifth of that obtaining in an open light mine.

The questions of the influence of holing and illumination have been discussed separately, and the following table has been drawn up to show the relation they bear to one another.

TABLE IX.—Holing and Illumination.

| District. | Holing. | Position at Work. | Thickness of Seam. | Light. | Incidence of Nystagmus. |
|-------------------------------|---------|-------------------|--------------------|--------------|-------------------------|
| Somerset ... | Much | On side | Feet. 1½-3½ | Candles | Unknown |
| Forest of Dean ... | Much | On side | 2-4 | Candles | Unknown |
| Open light pits, South Wales | Much | Side or knees | 2½-5 | Candles | Rare |
| Safety lamp pits, South Wales | None | Knees or standing | 3½-6 | Safety lamps | Common |
| Midlands ... | Much | Side ... | 5-7 | Lamps | Common |

The Personal Factor.

The personal factor remains to be considered, and it is now recognized by a large number of surgeons that ocular defects play an important part in determining whether a man should have nystagmus or not. The result of my investigations is given below:

| | | | | | |
|--------------------------------|-----|-----|-----|-----|------|
| Not examined | } | ... | ... | ... | 175 |
| Latent | | ... | ... | ... | 49 |
| Too bad to test | | ... | ... | ... | —225 |
| Normal | ... | ... | ... | ... | 95 |
| Error of refraction present... | ... | ... | ... | ... | 430* |
| Kind of error present— | | | | | |
| Hypermetropia | ... | ... | ... | ... | 170 |
| Myopia | ... | ... | ... | ... | 57 |
| Astigmatism | ... | ... | ... | ... | 203 |

* = 81.9 per cent. of cases examined.

It must be remembered that a small error of refraction is common in normal people.

Accident and ill health are also determining factors. In 146 cases there was a history of an accident—in 73 cases to the eye, in 43 cases to the head, and in 30 cases the injury was general. In North Staffordshire accidents to the eye occur very frequently before the onset of nystagmus. In the first 600 cases seen there was a history of accident to the eyes in 36 cases; in the last 150 cases, all from North Stafford, there has been injury to the eyes in 37 cases.

PREVENTIVE TREATMENT.

It is in the first place necessary to improve the miners' lamp, and the mining engineer must no longer be content with an average illumination of one-fiftieth of a foot-candle at the coal face. The introduction of electric lamps into general use is probable, as it seems unlikely sufficient light can be obtained in any other way. The elimination of unfit workmen by medical examination before employment would also be of the greatest service. Efficient ventilation and any hygienic measures will also help.

AMINO-ACIDS AND SUGARS IN RECTAL FEEDING.*

(From the Physiological Laboratory of the University of Bristol.)

In spite of its great drawbacks, "feeding" by nutrient enemata is in almost universal use at the present time. During the past few years, however, the advance in our knowledge of the ordinary processes of absorption from the bowel makes it necessary to review the experimental

* Part of the expenses of this research has been defrayed by a grant from the Colston Research Fund.

and clinical evidence on which the practice of rectal feeding is based. We hope to demonstrate that, as at present practised, it is nearly useless, but that it is possible considerably to enhance its value in most cases.

HISTORY OF RECTAL FEEDING.

An excellent summary of the older history is given by Gros. Galen and Celsus both practised it, and it was in fairly frequent use during the Middle Ages. Ramazini, in the seventeenth century, claims to have kept a girl alive by its means for seventy days.

The classical researches on the subject, on which the modern practice is based, are those of Ewald and Leube. In 1872 Leube kept a dog alive for months on injections of chopped meat and pancreas, claiming an absorption equivalent to 500 calories daily. Ewald in 1887 published tables purporting to show the results of administering egg and peptone enemata, which appear to demonstrate great absorption, but his experimental methods were unsatisfactory (for example, he used phenolphthalein as an indicator for ammonia) and the data inadequate. Later workers (Huber, Bial, Sharkey, Plantenga, Edsall and Miller, Mutch and Ryffel) all report a small but variable absorption of albumen and peptone.

All the above observations were made by the "wash-out" method, the enemata given one day being washed out next morning by rectal lavage, and it being assumed that what could not be recovered from the washing must have been absorbed.

Boyd and Robertson, whose tables we shall presently examine, appeared to have reposed confidence in the "wash-out" method, but they also analysed the nitrogen excretion in the urine. Langdon Brown criticized the "wash-out" method and trusted to the urinary analysis. He found practically no absorption of peptone.

The data for the absorption of sugar and fat will be discussed later.

THE ABSORPTION OF PROTEINS.

We have seen that many observers, trusting to the "wash-out" method, have reported a small, variable degree of absorption of albumen and peptone, the latter giving the better results. As a type of these observations we may examine the careful and detailed figures supplied by Boyd and Robertson, who also made urinary analyses for nitrogen by Kjeldahl's method. Seven young women suffering from gastric ulcer were fed entirely on nutrient enemata for six or seven days. They were kept in bed, and weighed before and after. All did well clinically. The enemata were given six-hourly, and consisted of two eggs or 200 c.cm. of milk and egg, dextrose, normal saline, and in one case cod-liver oil. The whole was pancreatized for twenty minutes. Every day the bowel was washed out, and the contents analysed.

Results of Analyses.

| | Loss or Gain of Weight in Kilos. | Total N Disappeared from Bowel. | Total N in Urine. |
|-----------------------|----------------------------------|---------------------------------|-------------------|
| Case I (6 days) ... | - 2.27 | Grams. 9.26 | Grams. 19.66 |
| Case II (6 days) ... | - 1.475 | 6.59 | 33.04 |
| Case III (7 days) ... | - 2.837 | 11.93 | 18.81 |
| Case IV (7 days) ... | - 3.632 | 4.33 | 44.21 |
| Case V (7 days) ... | - 4.086 | 9.70 | 48.13 |
| Case VI (7 days) ... | - 5.448 | 15.60 | 56.87 |
| Case VII (6 days) ... | + 0.227 | - 0.17 | 42.19 |

It will be observed that in every case the amount of nitrogen absorbed from the bowel could not possibly account for that lost by the urine, even if we admit that disappearance from the bowel means absorption by the patient. As Langdon Brown has pointed out, this is very improbable. Patients who are having daily rectal washes may pass a huge putrid stool, which presumably came from the caecum and was not touched by the lavage. The physiological antiperistalsis of the colon may carry the remains of the nutrient enema up beyond the reach of the wash, and so it will disappear from the rectum and yet not be absorbed, but putrefy.

Boyd and Robertson's own figures demonstrate this forcibly. If disappearance of nitrogen from the rectum means absorption, then the nitrogen excretion in the urine will run parallel. It does not. In Case III, where the urinary nitrogen is lowest, the apparent absorption was best but one. In Case VII, though the absorption was nil, the urinary output is above the average.

If it is accepted that the wash-out method is totally unreliable, as we maintain, the whole question of the value of rectal feeding with proteins requires fresh consideration. It emerges very badly from the examination; it is not going too far to say that the quantity absorbed is quite insignificant.

It may be argued that as patients can be kept alive for weeks on nutrient enemata, and the loss of weight is often very small, therefore the clinical evidence of their value is conclusive, and cannot be upset by physiological experimentation. This reasoning is quite fallacious. Men have lived as long as sixty-four days with no food at all, and if a patient is kept warm in bed, supplied with plenty of fluid, and given absorbable sugars by the rectum, it is not surprising that he may live for weeks on perfectly useless nitrogenous enemata. All clinicians know, however, that it is impossible to restore patients to strength or vigour by rectal feeding, and they are liable to sudden collapse, and even death.

It is certainly remarkable that so little weight is lost. Gros shows that even after a month the average loss is only about 4 kilos. Boyd and Robertson's cases, during a week of abstinence from food by mouth, lost weight varying from 1.475 to 5.448 kilos. More remarkable still are the cases in which there is an actual gain in weight. This, however, by no means proves that nitrogen is absorbed. In the only patient of the Scottish observers who gained a trifle, they admit that absolutely no nitrogen disappeared from the rectal washings; in fact, more was recovered than they injected. Langdon Brown has shown that a gain of weight is possible when nothing is given but normal saline per rectum.

The patients on whom observations have been made were almost all young women who had suffered from severe hæmatemesis and were exsanguinated in consequence. The gain of weight is, in our opinion, probably due to absorption of water to replace the blood lost. In Boyd and Robertson's series it was the patient who had lost most blood who gained in weight.

Again, it may be argued that even if the rectum is not able to absorb protein, antiperistalsis will carry the enema through the ileo-caecal valve into the small intestine. Gros quotes Gilles de la Tourette's famous cases, in which hysterical persons have vomited enemata. These occurrences are, however, highly exceptional. We now know from the employment of skiagraphy after bismuth enemata that in the great majority of cases the injection gets no further than the colon or caecum.

We believe that very little, if any, nitrogen is absorbed from nutrient enemata as ordinarily prepared, on the following grounds:

1. The nitrogen output in the urine of persons "fed" on peptonized proteins is little, if any, higher than that in the urine of professional fasting men or of patients receiving only normal saline per rectum.

2. Analyses of the differences in the amount of nitrogen in the alimentary contents—(a) at the ileo-caecal valve, (b) in the faeces passed per anum—show little or no absorption by the rectum (Groves and Walker Hall). These observations were made on patients with a right-sided colostomy.

3. We know that patients lose strength instead of gaining it on rectal feeding. It can never be relied on, for instance, to build up a patient with oesophageal cancer and make him more fit for a gastrostomy.

4. It has recently been established that the older teaching on the absorption of proteins is incorrect. We used to be taught that they were absorbed principally as peptones. Now we believe they are absorbed principally as amino-acids. Peptonization therefore does not go far enough to render protein absorbable by the bowel.

The second and third of these arguments need not be elaborated further.

Analyses of the urine of patients "fed" on peptonized milk or peptonized egg albumen have been made by many workers, and are now sufficiently numerous to lead to

some definite conclusions. Laidlaw and Ryffel found that the nitrogen output corresponded pretty closely to that of professional fasting men. Langdon Brown found no difference in the urinary nitrogen output (Kjeldahl's method), whether the patients were given normal saline or the following enema pancreatized for twenty minutes:

Milk, 4 oz.
Plasmon, 1 to 2 drachms.
Dextrose, 1 to 2 drachms.
Sod. bicarbonate, 20 grains.
Liq. pancreatius, 1 drachm.
Tinct. opii, η v.

Boyd and Robertson have published daily urinary analyses in seven cases fed on pancreatized milk or eggs. They found, as we have, that the output of nitrogen varies much in different patients; in our cases it appeared to depend on whether the patient had been dieting and starving before the attack of hæmatemesis. In the Edinburgh cases sufficient clinical data to determine this are not given. Taking these seven cases together, the average daily excretion of nitrogen during the week of rectal feeding was 5.7 grams. During their first week of starvation, Succi and Cetti, the professional fasting men, passed a daily average of 12.6 grams. No doubt they were fortified for the ordeal by previous good living, but it is evident that the rectal "feeding" was practical starvation for the women with gastric ulcer.

The writers have made daily urinary analyses in eight cases of gastric ulcer fed by nutrients of varying composition.

Two patients were given raw milk nutrients. In one of these the average daily output of nitrogen from the second to the ninth day was 7 grams, as against the Succi and Cetti average of 11 grams. In the other case, the Bristol case showed a daily nitrogenous output from the eighth to the thirteenth day of 7.6 grams, as against the Succi average for the same period of 6.8 grams. A man was given nutrients of peptonized milk and somatose; his daily average output was 10 grams as against the Succi-Cetti average of 12.6 grams. In several of our cases the patients were given nothing but saline for a day or two, and then ordinary peptonized enemata, but these never stopped the starvation fall in the nitrogen output.

It is proved, therefore, that little if any nutriment is absorbed from a rectal injection containing albumen or peptone. This may be due to one of two causes: (a) That the colon is unable to absorb proteins or the products of their digestion; or (b) that the colon lacks the power to convert peptone, which is not absorbable, into amino-acids.

Modern physiological research has revolutionized our conceptions of protein absorption. It is now believed that peptones are scarcely at all absorbed, but that the products of protein digestion pass through the epithelial lining of the small intestine in the form of amino-acids as leucine, tyrosine, tryptophane, lysine, arginine, etc. Trypsin of pancreatic juice converts albumens into these amino-acids, and the ferment erepsin, in the succus entericus, can finish the work of the gastric juice and convert peptones (also caseinogen) into amino-acids. The ordinary nutrient enema is pancreatized for twenty minutes. In this time no amino-acids are split off. If we hope that the mixture of caseinogen, albumen, and peptone will be absorbed from the patient's rectum, we are assuming the presence of erepsin or trypsin in that particular person's rectum without evidence. If there is none there, absorption is impossible. Now it is true that the faeces may contain trypsin, but there is no evidence that the colon of patients who are receiving no food by mouth contains either trypsin or erepsin.

It might be thought advisable to use Leube's method, and to introduce into the bowel a mixture of chopped pancreas and meat. In practice, however, this leads to grave putrefaction and toxæmia.

It occurred to us that before abandoning rectal feeding as useless it would be wise to try the effect of giving prolonged pancreatic digests containing amino-acids.

Rectal Feeding with Amino-Acids.

All our patients were suffering from gastric ulcer, and were treated by cutting off all food by the mouth, though water was allowed. The nutrients were varied in each case. The plan was to give either normal saline or milk

peptonized for twenty minutes during the first three or four days, and then to change to milk pancreatized for twenty-four hours to see if it would interrupt the steady starvation fall in the output of nitrogen. In two cases we gave mixed amino-acids prepared by Merck by the action of strong sulphuric acid on proteins. This was, however, expensive, and only suitable for experimental purposes.

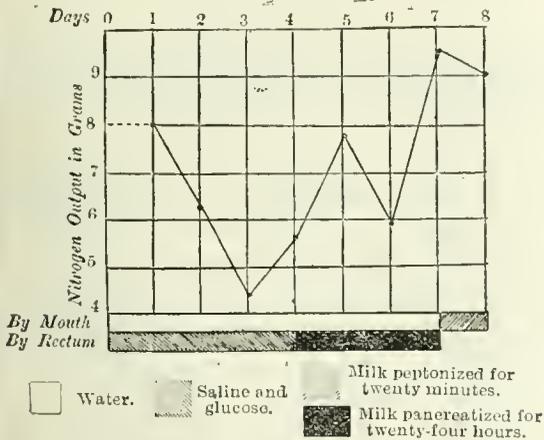

The enema we used most was prepared by boiling a pint of milk in a flask, adding two to four drachms of some reliable pancreatic preparation (some that we used were subsequently found to be inert), and keeping in the incubator for twenty-four hours, then boiling. From five to eight fluid ounces were given every six hours. A daily rectal wash-out was employed, but we did not analyse the washings. Instead, the nitrogen in the urine was estimated by Kjeldahl's method. The ammonia nitrogen was estimated by the formalin method by Dr. P. A. Opie.

CASE I.

Female, aged 25, suffering from gastric ulcer. Had been on peptonized milk by mouth for several days.

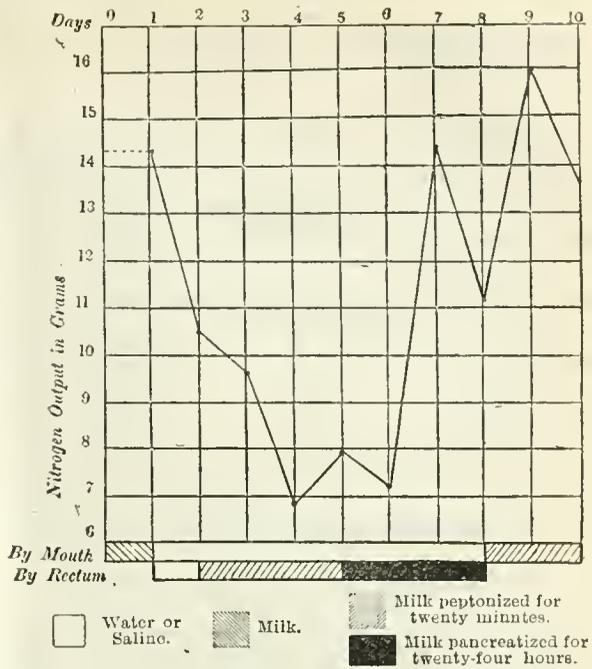

| Day. | By Mouth. | By Rectum. | Urine. | Ammonia per Cent. of total N. | Daily N Output in Grams |
|------|-----------------|--|--------|-------------------------------|-------------------------|
| 1st | Water | Saline and glucose | oz. 29 | — | 8.03 |
| 2nd | Water | " " " | 22 | 3.2 | 6.28 |
| 3rd | Water | " " " | 26 | 0.8 | 4.36 |
| 4th | Water | " " " | 26 | 12.3 | 5.56 |
| 5th | Water | Peptonized milk 24 hrs. (6 oz. 4 hourly) | 16 | 12.7 | 7.66 |
| 6th | Water | " " " | 22 | 12.5 | 5.91 |
| 7th | Water | " " " | 32 | 9.3 | 9.53 |
| 8th | Peptonized milk | — | 31 | 0.5 | 9.02 |

* Glucose not well retained.

CASE II.
Man with gastric ulcer. Had been taking full diet up to day of haematemesis.

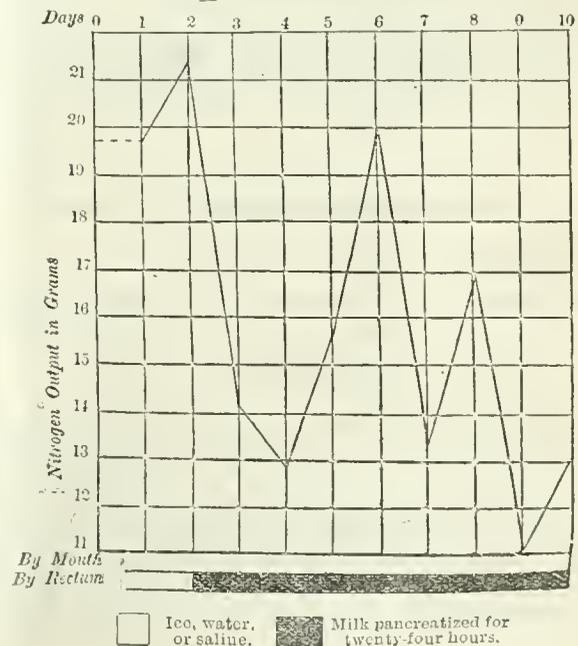

| Day. | By Mouth. | By Rectum. | Urine. | Ammonia per Cent. of total N. | Daily N Output in Grams |
|------|-----------------|--|--------|-------------------------------|-------------------------|
| 1st | Milk | — | oz. 21 | 1.4 | 14.3 |
| 2nd | Water | Saline | 19 | 2.9 | 10.7 |
| 3rd | Water | Peptonized milk 20 min. (5 oz. 6 hourly) | 21 | 3.5 | 9.6 |
| 4th | Water | " " " | 20 | 4.8 | 6.8 |
| 5th | Water | " " " | 16 | 2.9 | 7.9 |
| 6th | Water | Peptonized milk 24 hrs. (5 1/2 glucose 5 oz. 6 hourly) | 10 | 2.9 | 7.2 |
| 7th | Water | " " " | 21 | 3.0 | 14.4 |
| 8th | Water | " " " | 15 | 3.7 | 11.2 |
| 9th | Peptonized milk | — | 23 | 2.8 | 16.1 |
| 10th | Peptonized milk | — | 54 | 0.9 | 13.7 |

CASE III.

Man with haematemesis. Had been taking full diet up to that time.

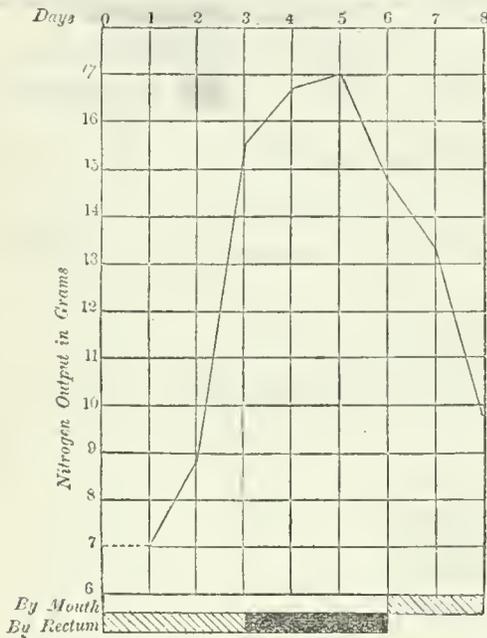

| Day. | By Mouth. | By Rectum. | Urine. | Daily N Output in Grams. |
|------|------------|---|--------|--------------------------|
| 1st | Ice, water | Saline | oz. 38 | 19.7 |
| 2nd | Ice, water | " | 50 | 21.4 |
| 3rd | Ice, water | Milk peptonized 24 hours (3 oz. 6 hourly) | 32 | 14.1 |
| 4th | Ice, water | " " " | 26 | 12.8 |
| 5th | Ice, water | " " " | 31 | 15.6 |
| 6th | Ice, water | " " " | 36 | 19.9 |
| 7th | Ice, water | " " " | 24 | 13.3 |
| 8th | Ice, water | " " " | 30 | 16.9 |
| 9th | Ice, water | " " " | 21 | 11.1 |
| 10th | Ice, water | " " " | 24 | 13.0 |

CASE IV.

Man with haematemesis. On very scanty diet for three days before admission.

| Day. | By Mouth. | By Rectum. | Urine. | Daily N Output in Grams. |
|------|--------------------------------|--|--------|--------------------------|
| 1st | Water | Milk peptonized 20 minutes (6 oz. 6 hourly) | oz. 20 | 7.0 |
| 2nd | Water | " " " | 28 | 8.8 |
| 3rd | Water | " " " | 41 | 15.5 |
| 4th | Water | Amino-acids (Merck) (25 grams in 6 oz. saline, 6 hourly) | 40 | 16.7 |
| 5th | Water | " " " | 37 | 17.0 |
| 6th | Water | " " " | 30 | 14.8 |
| 7th | Peptonized milk (1 oz. hourly) | Nil | 24 | 13.3 |
| 8th | " | Nil | 17 | 9.8 |

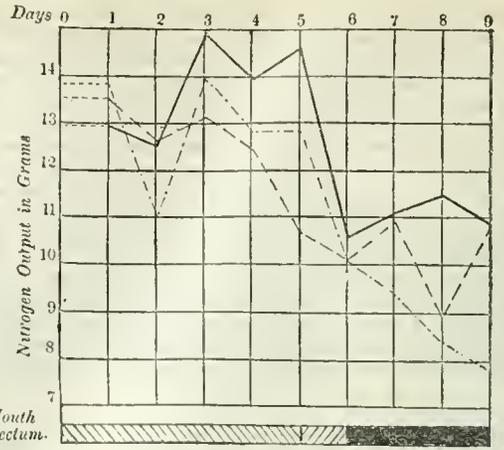

Water. Milk peptonized for twenty minutes. Amino-acids in saline.

CASE V.

Man, aged 24, admitted for haematemesis. On full diet up to that time.

| Day. | By Mouth. | By Rectum. | Urine. | Daily N Output in Grams. |
|------|-----------|---|--------|--------------------------|
| 1st | Water | Milk peptonized 20 minutes (5 oz. 4 hourly) | oz. 19 | 12.9 |
| 2nd | Water | " " " | 18 | 12.5 |
| 3rd | Water | " " " | 20 | 14.8 |
| 4th | Water | " " " | 19 | 13.9 |
| 5th | Water | " " " | 20 | 14.6 |
| 6th | Water | Peptonized milk 24 hours | 15 | 10.6 |
| 7th | Water | Amino-acids 4 per cent., glucose 3 per cent. (5 oz. 4 hourly) | 16 | 11.1 |
| 8th | Water | " " " | 16 | 11.5 |
| 9th | Water | " " " | 15 | 10.9 |

Water. Milk peptonized for twenty minutes. Amino-acids + glucose. Milk pancreaticized for twenty-four hours. Cetti's fasting figures indicated thus: - - - - - Succ'i's fasting figures indicated thus: - - - - -

In none of the above cases was any rectal irritation produced, either by the long-peptonized milk or by the amino-acids.

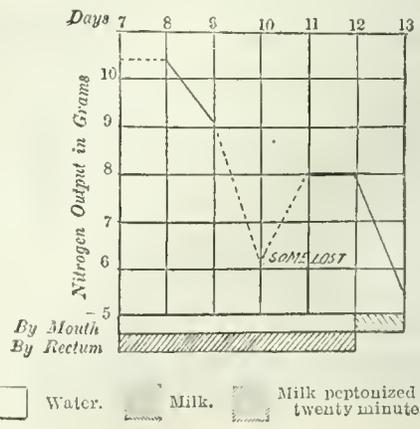

The three following cases serve for purposes of comparison. In two of them it was intended that they should be repetitions of the method used for Case II, but it was found afterwards that the preparation of pancreas used was absolutely inert.

CASE VI.

Female, aged 24, admitted for haematemesis. Well fed up to date of admission. Menstruating for first seven days; no observations. During this time she had nutrients of un-peptonized milk.

| Day. | By Mouth. | By Rectum. | Urine. | Daily N Output in Grams. |
|------|-----------------|-------------------------|--------|--------------------------|
| 8th | Water | Raw milk (1 pint a day) | oz. 26 | 10.4 |
| 9th | Water | " " " | 24 | 9.1 |
| 10th | Water | " " " | 26* | 6.1 |
| 11th | Water | " " " | 18 | 8.0 |
| 12th | Water | " " " | 18 | 8.0 |
| 13th | Peptonized milk | Nil | 16 | 5.5 |

* A few ounces lost.

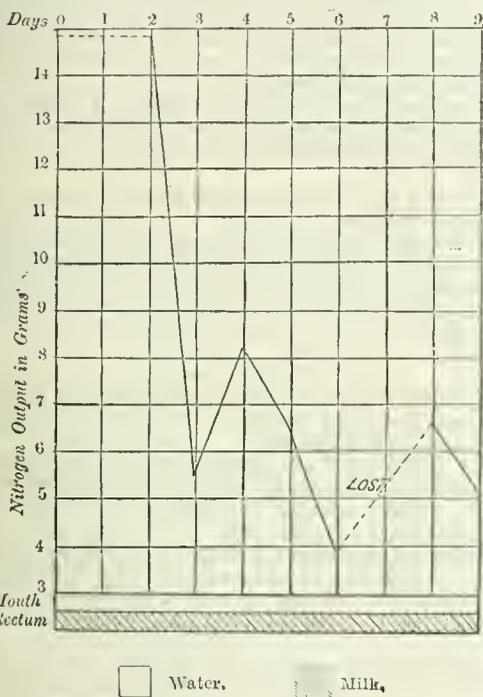

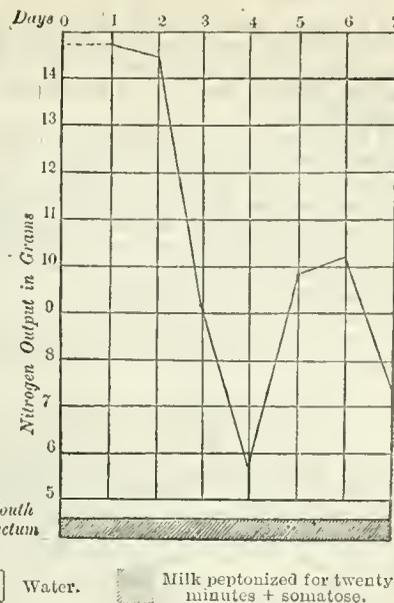

Water. Milk. Milk peptonized for twenty minutes.

CASE VII.

Female, aged 27, with haematemesis. Had been well fed till then.

| Day. | By Mouth. | By Rectum. | Urine. | Daily N Output in Grams. |
|------|-----------|---------------------------|--------|--------------------------|
| 1st | Water | Raw milk (5 oz. 4 hourly) | oz. 16 | — |
| 2nd | Water | " " " | 28 | 14.8 |
| 3rd | Water | " " " | 15 | 5.5 |
| 4th | Water | " " " | 16 | 8.2 |
| 5th | Water | " " " | 14 | 6.5 |
| 6th | Water | " " " | 18 | 3.9 |
| 7th | Water | " " " | (Lost) | — |
| 8th | Water | " " " | 19 | 6.6 |
| 9th | Water | " " " | 27 | 5.2 |

CASE VIII.

Man with gastric ulcer. Had been well fed up to time of admission.

| Day. | By Mouth. | By Rectum. | Urine. | Daily N Output in Grams. |
|------|-----------|---|--------|--------------------------|
| 1st | Water | Milk peptonized 20 minutes; somatose (4 oz. 6 hourly) | oz. 24 | 14.7 |
| 2nd | Water | " " " | 40 | 14.4 |
| 3rd | Water | " " " | 28 | 9.1 |
| 4th | Water | " " " | 21 | 5.7 |
| 5th | Water | " " " | 40 | 9.8 |
| 6th | Water | " " " | 35 | 10.2 |
| 7th | Water | " " " | 21 | 7.4 |

On studying the records of these cases, it is to be observed first that it takes about twenty-four hours for the urine to show any response to improvement in the feeding in most cases. We have observed in these and other unpublished observations that the rise in the nitrogen output when sufficient mouth-feeding is resumed usually takes that time to develop. We notice, secondly, in Cases I, II, and IV, a very striking rise in the nitrogen output as soon as the patient is put on amino-acid nutrients, whether given as milk long peptonized or as artificial mixed amino-acids. This rise takes place at the time when there is usually a fall if no nourishment is being absorbed. Again, we observe in Case III, fed after the first two days on milk peptonized for twenty-four hours, that the nitrogen output maintains an extraordinarily high level, far higher than Succi's, Cetti's, our Cases VII and VIII, or Boyd and Robertson's seven cases. We are bound to conclude, therefore, that in these four patients amino-acids were undoubtedly absorbed from the large bowel in very considerable quantity. Clinically all the cases did most satisfactorily. They kept very fit and had little or no rectal trouble.

Our Case V demands a few words of special reference. It was in a different hospital, and the amino-acids were not keeping very well when they were brought into use. Apparently he did not absorb as much nutriment as the other patients. It is possible that this may have been due to some fault in the mode of administration. Although this case does not show the rise in the output of urinary nitrogen which is so striking in Cases I, II, and IV, it will be observed that the figures for the later days are higher than those of Succi and Cetti, although they were prepared for their fast:

| Day. | Patient given Amino-acids. | Succi. | Cetti. |
|------------|----------------------------|-------------|-------------|
| 6th | Grams. 10.6 | Grams. 10.1 | Grams. 10.1 |
| 7th | 11.1 | 9.4 | 10.9 |
| 8th | 11.5 | 8.4 | 8.9 |
| 9th | 10.9 | 7.8 | 10.8 |

A criticism has been brought against the results, that perchance the amino-acids were so broken down by putrefaction that they could not be assimilated by the tissues after absorption, but simply ran to waste in the urine. The milk, however, if boiled before the twenty-four hours' pancreatization, kept perfectly sweet. If comparatively simple putrefactive bodies were absorbed and excreted, the ammonia nitrogen in the urine must have shown a rise; but it will be observed in Case I that the ammonia nitrogen was only a fraction higher on the three amino-acid days than on the fourth. In Case II the

evidence is yet more convincing, as the ammonia nitrogen was lower on the three amino-acid days than on the three days preceding. Free amino-acids, of course, would appear in the urinary analysis by the formalin method as ammonia nitrogen.

It might be argued that the products of protein digestion absorbed were converted into urea by the liver and not assimilated by the tissues, and thus it appears impossible to refute; but there is no reason to suppose, if amino-acids are absorbed at all, that they should not be any less nourishing to the tissues when they enter by the rectum than when they enter by the small intestine. The rectal washings were not putrefactive.

We did not weigh our patients, partly because it was difficult in view of their ailment, and also because we believe that any loss of weight is masked by the absorption of water.

THE ABSORPTION OF SUGARS.

The two sugars with which most experimenters have worked are lactose and dextrose, the former in milk and the latter in pure solution. It is important to use it chemically pure, or it will probably be irritating.

There are two reliable means of estimating the amount of sugar absorbed into the blood. One is to determine the ammonia nitrogen in the urine, which only rises to a high figure when the sugar is very deficient. The other is to measure the respiratory quotient by analysing the expired air. The quotient is raised by carbohydrate feeding.

Reach found that a small inconstant rise in the respiratory quotient takes place after giving dextrose or lactose by the rectum, but much less than after giving the same quantity by the mouth.

One of us* has published determinations of the ammonia nitrogen on two patients "fed" on nutrient enemata containing lactose in milk. The ammonia nitrogen soon rose to a very high figure (15 to 17 per cent.). This would appear to indicate that lactose is badly absorbed.

Dextrose undoubtedly controls the acidosis causing the rise of ammonia nitrogen very effectually. In our Cases 1 and 11, so long as the glucose was well retained the ammonia nitrogen kept very low. This has been abundantly proved by other workers.

Although we attach no importance to the analysis of rectal washings in calculating the absorption of nitrogen, we are prepared to admit that Boyd and Robertson's arguments derived from this method of experimentation in favour of dextrose absorption are valid. The bulk of the protein they administered could always be recovered from the rectal washings, but the sugar had almost entirely, in two cases entirely, disappeared. They show conclusively that this cannot be accounted for by putrefactive changes. Deucher, Plantenga, and Zelmisch all obtained absorption of the great bulk of the sugar given per rectum.

Mutch and Ryffel have recently confirmed these results. Scarcely any sugar could be recovered in the rectal washings after 6 per cent. glucose enemata had been given.

Dextrose is, of course, a very valuable food, and the demonstration that it can be absorbed by the rectum opens up an important means of feeding patients who cannot take anything by the mouth.

THE ABSORPTION OF FAT.

We have made no special observations on the absorption of fat, but a brief summary of our knowledge on this subject is included.

Deucher and other workers found a small absorption, but in their cases fat was being taken by mouth as well as by the rectum.

Boyd and Robertson used the unsatisfactory "wash-out" method, and felt justified in concluding that the fat which they failed to recover must have been absorbed. How little reliable this is one of their cases showed, in which more fat was found in the washings than was given in the enemata. In three of their patients they considered that a good deal of fat was absorbed (as much as 7 grams a day in one case), and they believed that the more they gave the more was retained.

The most reliable observations are those in which it has been possible to estimate the fat in the chyle from the thoracic duct. Munk and Rosenstein used a case in which the chyle could be collected from a lymphatic fistula. On a fat-poor diet an enema of 15 grams of lipanin was given; the lymph showed a rise in fat contents from 0.18 per cent. to 0.45 per cent., about 3.7 per cent. of the oil being absorbed. In another experiment 5.5 per cent. was absorbed. Even when fat is given by the mouth, only about half of it can be recovered from the thoracic duct, so that these figures might probably be doubled to represent the actual absorption.

Langdon Brown mentions a case of filarial chyluria in which nutrients of olive oil and of milk failed to get absorbed sufficiently to appear as fatty droplets in the urine.

We must conclude, then, that the power of fat absorption by the rectum is only slight. If it is intended to take advantage of it, cod-liver oil should be given. Boyd and Robertson, as well as Langdon Brown, show that the quantity absorbed from milk is negligible.

GENERAL CONSIDERATIONS.

In using rectal injections as a means of treatment for gastric ulcer, or after operations on the stomach, it must not be imagined that that organ is given complete rest. Umber has shown on a patient with a gastrostomy that there is a copious gastric secretion after a nutrient enema, the total acidity being 30 and the HCl 20. Probably this accounts for the dyspeptic pain suffered by patients with gastric ulcer after each enema.

Eggs are not desirable constituents of a rectal feed. The sulphuretted hydrogen liberated from them is unpleasant for the attendants, and probably harmful to the patient.

We consider that the best form of nutrient enema should be prepared as follows:

To a pint and a half of milk, boiled and cooled, add $\frac{1}{2}$ oz. of some reliable pancreatic fluid, or four pancreatic tablets. Keep in the incubator twenty-four hours. Add $1\frac{1}{2}$ oz. of pure dextrose. Give 5 oz. every four hours, or, if the patient can retain it, 10 oz. every eight hours.

CONCLUSIONS.

1. The older observations on the absorption of foodstuffs from rectal enemata, based on the analysis of rectal "wash-outs," are unreliable.
2. The daily output of nitrogen in the urine of patients given nutrient enemata of milk or eggs peptonized for twenty or thirty minutes demonstrates that almost no nitrogenous matter is absorbed.
3. Modern physiological opinion holds that proteins are absorbed principally as amino-acids. The failure of the rectum to absorb ordinary nutrient enemata is largely due to the fact that peptones are given instead of amino-acids.
4. Chemically prepared amino-acids, or milk pancreaticized for twenty-four hours so that amino-acids are separated, allows of a much better absorption of nitrogenous foodstuffs from the rectum, as demonstrated in five cases by the high nitrogen output in the urine.
5. The low output of ammonia nitrogen shows that this high output was not due to the absorption of putrefactive bodies. The rectal washings were not offensive.
6. Dextrose is much better absorbed than lactose, and relieves the acidosis of starvation.
7. Fat is not well absorbed. Scarcely any of the fat of ordinary milk enemata is retained.
8. The best nutrient enema consists of milk pancreaticized for twenty-four hours, with 5 per cent. pure dextrose.

We are greatly indebted to Dr. P. A. Opie and Dr. W. A. Reynolds for help in obtaining clinical material.

THE EXPERIENCES OF A MEDICAL ADVISER UNDER THE INSURANCE ACT.

BY
 BERTRAM M. H. ROGERS, B.A., M.D., B.Ch. Oxon.,
 BRISTOL.

It may be of interest to Insurance Committees who are considering the advisability of appointing a medical adviser, and to the profession generally, if I give a short account of my experiences in that capacity, based on the first hundred cases sent to me for my opinion. The duties that have been imposed upon me are to see and examine any insured person sent either by a medical man or by one of the friendly societies, and to report to the Insurance Committee my opinion as to whether the person sent is fit or not to work; perhaps it may be put thus—to decide whether a person complaining of certain symptoms and alleging that he or she is unfit to return to work, is fit. On my decision depends the payment of or refusal to pay sickness benefits, as far as regard the friendly societies, while it relieves the doctor of the unpleasant duty of refusing to sign any more sick certificates, an act which often makes him very unpopular in his district, as the matter is soon spread abroad.

My appointment dates from February 12th, but the doctors and the societies did not at first seem to appreciate the post, or perhaps to understand in what manner I might be made use of, for in the first few weeks no cases were sent to me. When they did, there was no mistaking the fact, as the cases came rolling in, so that by May 15th one hundred had been told off to come to me. The exact figures are: From March 5th, the day of my first case, to the end of the month, 22; in April, 50; while the remaining 28 came in the first fifteen days of May. Since then I have had 64 more, so that the number for the last four weeks is greater than any preceding four.

It must be remembered that there is nothing in the Act to compel any one to come; an insured person receiving a letter telling him or her to come to my house for examination can ignore it. No doubt they think it part of the Act, and fear some penalty if they neglect the order. Of course, they run the risk of having further payments refused by their society, and a few do abstain from coming or giving any reason for not appearing. On the other hand, many express their wish to be examined and seem to look on a visit to me as a sort of consultation on their ease. So far I have not had any difficulty with any one. I have had an abusive letter from one alcoholic person whom I reported as fit to work, but that is the only case, though no doubt several have not been best pleased with my decision. I am confident if one treats these people with courtesy and does not charge each and every one with being a malingerer that unpleasantness will be the exception; they may not like my report, but I hope they recognize that my opinion was come to fairly and after duly weighing the facts they gave me. This want of power to compel an examination by a doctor specially appointed should be altered, in my opinion, and the Act made uniform with the Workmen's Compensation Act. My duty is not to act as a consultant, as is generally understood by that term, but merely to decide whether or not a person is fit to work.

The method is as follows: All references, whether from a doctor or a friendly society, for a person to come to me, are sent to the office of the Insurance Committee. The doctors have a printed form something like that used for the notification of infectious diseases; the societies write a letter to the clerk. All these references are telephoned to me and I give instructions on what day the person is to be told to come to see me and the hour. Generally I fix the next day, for I look on all cases as urgent, and I see

them all at my house. I have had a little grumbling about this, as it often involves a long tram journey and the expenditure of some pence, which I fear some can ill afford; but as long as the post is a part-time one, my convenience must be considered both as regards time and place, though I am willing to make such arrangements as are possible for the insured persons. The question whether this post should be a whole-time one has been considered, and at present we in Bristol are not in favour of it being so, and for the following reasons: First, we are not too fond of the official doctor; secondly, we prefer to have one of ourselves in the position of adviser, and (though I say it of myself) one who is acceptable to the local profession; thirdly, the salary must be sufficiently large to make it worth the while of a medical man of some position and standing to give up his private work, for it is no light matter to ask a doctor to throw over his friends and patients after many years of attendance; there must, too, be some fixity of tenure, for the holder of the post cannot render himself liable to be turned out at the caprice of the Insurance Committee to pick up what shreds of practice he can gather after being for some years out of private work; and, lastly, there is the question of a pension. My salary is at present paid out of the local funds, but this may be altered if the Commissioners will take it over.

On the receipt of a note giving the name, address, and detail of the insured person, and the name of the doctor in attendance, I write to the latter and ask if he wishes to communicate anything to me about his patient. I generally get a letter or message giving me much useful information, which is of very material help to me. When the case has been referred by a doctor, this is not necessary, as a few notes are made on the notification paper. This, of course, involves a great deal of letter writing, for I always write to the doctor again after seeing the insured person to tell him what decision I have come to. There is, further, the report to the Committee. This latter body sends my report to the society the insured person was in.

Coming now to my figures, my hundred consisted of 43 males and 57 females, on whom the following reports were sent:

| Males. | | | | |
|--|-----|-----|-----|----|
| Reported as fit... | ... | ... | ... | 23 |
| Reported as unfit | ... | ... | ... | 7 |
| Reported as not coming for examination | ... | ... | ... | 6 |
| Reported as Workmen's Compensation cases | ... | ... | ... | 6 |
| Reported as too ill to come and wrong address... | ... | ... | ... | 1 |
| | | | | 43 |
| Females. | | | | |
| Reported as fit... | ... | ... | ... | 20 |
| Reported as unfit | ... | ... | ... | 25 |
| Reported as not coming for examination | ... | ... | ... | 9 |
| Reported as unclassified | ... | ... | ... | 3 |
| | | | | 57 |

One or two remarks may be made on these tables. I find that some doctors do not recognize that I have, in my capacity as medical adviser, nothing to do with Workmen's Compensation cases. The distinction is easily made, for if a workman is in receipt of pay from his employer for an accident received in the course of his work, then the Insurance Act does not come in, though the man may be in receipt of pay from his club. The unclassified cases are as follows:

1. The woman received an accident between the time of reporting her to me and the time she was told to come.
2. The officious action of a health visitor.
3. A case in which I had some correspondence about the action of a doctor in refusing to give a certificate for more than one day.

So far the friendly societies have made more use of me than the doctors, as they have sent me 59 and the latter 41. In my second hundred, as far as I have gone, this proportion is more marked, for out of 64 the doctors have only sent me 6. Some societies are very active, partly, no doubt, because they have a much larger number on their books than others, but in the first hundred two societies sent me 15 each. Sufficient care is not exercised yet in referring the cases to me, for I have had several who were obviously too ill to work, but as I found 43 fit out of 100 and only 32 unfit, there is not much to complain of.

The number of malingerers is very small; all have had

some ailment, and many for various reasons are disinclined to go back to work, or in some cases, having lost their job from sickness, to find another. From every person I inquire what wages they were receiving when at work, and one can see without much trouble how little inducement there is to go back and work hard for perhaps 6d. or 1s. a week more; one youth told me he only got 6d. more when at work, and with many women the difference is only 2s. 6d. a week. I will quote one case of this kind, but the young man gave himself away. His work was to take pastry round on a cycle with a side car to houses in the vicinity of his master's shop. He had an attack of influenza some weeks before he came to me, and his complaint was that he could not ride the cycle as it caused pain in his side. His chest revealed nothing at all, but he had unfortunately forgotten to take the clips off his trousers when he came into my consulting room, and on my charging him with having cycled from his home about four miles off, he admitted it, excusing himself by saying he walked up all the hills. Those who know Bristol will see that he must have walked nearly all the way, if he was truthful. He was reported as "fit for work." The difference between his receipts in work and out was only 6d.

THE "CONTROLLED" USE OF NEW TUBERCULIN IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

By ARTHUR C. WATKIN, M.R.C.S., L.R.C.P., D.P.H.,
TUBERCULOSIS OFFICER TO THE COUNTY OF SALOP; LATE HOUSE-
PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND
DISEASES OF THE CHEST, BROMPTON.

In a recent issue of this JOURNAL¹ Dr. E. E. A. T. Rigg published the results of his observations on the effects of new tuberculin on the physical signs of pulmonary tuberculosis. His cases were free from fever except when they reacted to tuberculin. My observations at the Brompton Hospital were carried out not only on cases which were afebrile, but also on cases which were intermittently febrile—that is, they sometimes had fever and sometimes were free from it—and also on some cases where there was spontaneous fever throughout. A further point of difference was the limitation of the dose of tuberculin to just those quantities which fell short of producing any febrile reaction, the object being to preserve complete parallelism between the tuberculin-treated cases and those not treated with tuberculin which were used as controls. As Dr. Rigg cogently remarked, his cases treated with tuberculin, by reason of the doses used and the reactions following them, were put at a disadvantage, as they were kept in bed, whereas the control cases were, throughout their stay in the hospital, able to be up all day and to take exercise in the grounds of the hospital.

I have had under observation in all 22 cases. These, whether controls or not, were watched for three months, with the exception of one or two which were under supervision for a fortnight or so less than that period. As in Dr. Rigg's report, no final decision can be said to have been arrived at, because both his and my own cases were limited in number, and the period of observation was only three months. I have, however, published my results, because notwithstanding these drawbacks the report has this advantage, that it concerns individuals who have been under close observation; and, further, it may encourage others who have access to cases for more considerable periods to carry out similar investigations. By this means a larger number of cases may be tested, sufficient to afford a reasonable conclusion as to whether tuberculin favourably influences the local manifestations of pulmonary tuberculosis as judged by physical signs.

My 22 cases include:

| | |
|-------------------------------|----|
| Afebrile cases | 5 |
| Intermittently febrile | 12 |
| Continuously febrile | 5 |

It is unfortunate that the number of afebrile cases is so small. This is accounted for by the fact that the class of case now admitted to the hospital is different from that when Dr. Rigg held office, and also that the opportunity

of sending afebrile cases to the Brompton Hospital Sanatorium at Frimley was greater. It is also unfortunate that the cases which were afebrile and those which were continuously febrile are represented by odd numbers. This can be explained by the fact that cases which at the beginning of my observations fell into one or other of the above categories had to be transferred to another because of spontaneous changes in temperature.

Another difficulty with which I have had to contend is that the dosage had to be very small, and the advances in the doses very tentative, lest fever—that is, reaction—should be produced. Indeed, in some cases, a rise of temperature did follow some doses. Whenever the rise persisted in afebrile cases, these were referred to one or other of the remaining categories, but when a rise of temperature was of short duration (twenty-four to thirty-six hours only) I retained them in the afebrile list, and, profiting by the experience, did not increase the dose, or repeated it after a longer interval than the usual two days.

Dosage.

In the afebrile cases the minimum dose was 0.00001 mg. of T.R. and the maximum 0.03 mg. In the intermittently febrile and the continuously febrile the minimum was 0.000005 mg. and the maximum 0.005 mg. (reckoning on the basis that 1 c.cm. T.R. contains the insoluble bacterial matter of 10 mg. of tubercle bacilli). Not every case received the above maximum. Something less was given as a maximum in cases in which it was not advisable to push the dose.

Criterion.

All cases had tubercle bacilli in the sputum, and had definite physical signs at the commencement of observation. They were all examined by Dr. Batty Shaw at the beginning and at the end of the period, and sometimes also between these limits of time. I also examined the cases at these times, but in addition made examinations once a fortnight. By this means it was possible to reduce to a minimum of error those spontaneous changes in rales which occur in the chests of tuberculous and non-tuberculous subjects alike, because when it could be seen that the signs of the final examination were not, as it were, the finale of a crescendo or decrescendo movement of the rales, re-examination and adjustment were made.

No reference was made to the notes of the previous examination, until the present physical signs had been estimated. Differences between the results as obtained by Dr. Batty Shaw and by myself, when they occurred, were met by re-examination and agreement.

The Controls.

These were chosen by lot from among the 22 cases at the commencement, as was done by Dr. Rigg. The patients were aware of the nature of the investigation and its purpose.

Results.

The results were as follows:

| | Improved. | <i>In statu quo.</i> | Worse. |
|--|-----------|----------------------|--------|
| 1. <i>Afebrile Cases</i> (5 in all) | | | |
| Treated with tuberculin ... | 1 | 1 | 0 |
| Without tuberculin | 0 | 2 | 1 |
| 2. <i>Intermittently Febrile Cases</i> (12 in all) | | | |
| Treated with tuberculin ... | 2 | 4 | 0 |
| Without tuberculin | 3 | 3 | 0 |
| 3. <i>Always Febrile</i> (5 in all) | | | |
| Treated with tuberculin ... | 0 | 0 | 3 |
| Without tuberculin | 0 | 0 | 2 |

Putting these 22 results in a different form:

- Of 6 cases which improved, 3 had been treated with tuberculin, 3 had not.
- Of 11 cases which remained *in statu quo*, 5 had been treated with tuberculin, 6 had not.
- Of 5 cases which were worse, 3 had been treated with tuberculin, 2 had not.

Comment.

As already mentioned, the cases are too few to allow of a final deduction being made, nor is this intended in the

publication of these observations. One result, however, is brought out, and that is the crying need for similar and more extended investigation at the hands of other workers. There cannot be the least doubt that the system of instituting "control" cases is sound, and I would add that the "controls" should be simultaneous ones and chosen by lot, so that there may be no possibility of unconscious bias in the selection.

To the objection that has been raised abroad that a period of three months is not sufficient to allow of judgement being formed upon the effect of tuberculin on the physical signs, heed must be paid, and it is to be hoped that others who have favourable opportunities for such extended observations will help to settle the question on the lines of this and Dr. Riggs's investigation.

Addendum.

One of the above continuously febrile cases not treated with tuberculin showed at the end of three months an increase of rales, although there were unmistakable signs of development of fibrosis in the affected lung.

One of the intermittently febrile cases treated with tuberculin showed no change in the extent of rales, but fibrosis was observed to be developing.

A child of the intermittently febrile class who was treated with tuberculin showed a reduction of rales, but a patch of lupus on the arm was not apparently diminished in severity or extent by the treatment.

In conclusion, I must record my thanks to Dr. Batty Shaw for the kind way in which he has supervised the work and assisted me in carrying it through.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN UNUSUAL CASE OF AMENTIA.

A FEMALE child, aged about 5 years, well grown, and healthy to all appearance, presents a complete absence of the faculty of interpreting the visual and auditory sensations which Charcot described as internal representation. Her eyesight and hearing seem to be sharp enough. She can pick up the smallest article without effort, but when she takes anything in her hands she lets it hang down and strikes the lower part of it as if she were trying to make it vibrate; but all interest in it seems to end here. When she wants anything she will catch her mother's hand and lead her to it, when she wants the door opened she will drag her mother's hand to the handle and place it on it. To words addressed to her she pays no attention, but sounds she can hear. The power of speech is totally undeveloped; within the last week or two she has been able to pronounce something like the word "ma." She hums a note or two. She is restless and constantly on the move; if caught firmly by the arm she does not struggle to get free, but immediately arrests her movements and assumes a thoughtful appearance, as if she were trying to interpret the meaning of the grasp or the external impression conveyed in this way to her brain. She seems to recognize her relations by the sense of smell; she will go round a roomful of people smelling at each one till she comes to her parents, when she will assume a fondling attitude, and smiles most pleasantly. It is most remarkable to see her rubbing her nose along her mother's arm and smiling all the while. I must confess I have never seen anything like this case before.

Bolton.

A. W. CRAWFORD, M.B., C.M.

OBSERVATIONS ON OSTEOMALACIA.

SEEING in the BRITISH MEDICAL JOURNAL of February 8th, 1913, on page 24 of the Epitome of Current Medical Literature under the heading "Treatment of Rickets," that "a number of observers have come to the conclusion that rickets and osteomalacia are manifestations of one and the same disease," I wish to state that my five years' experience in India supports the view that osteomalacia and rickets are entirely distinct from one another. Of these five years I passed four on the staff of the Dufferin

Hospital at Agra. This is in the United Provinces, where among Indian women osteomalacia was very common. It was of typical form, characterized by bowing of the long bones, settling down of the spine with forward displacement of the sacral promontory and exaggeration of the sacral curve, beaking of the pubes, approximation of the acetabula, and indrawing of the thoracic frame, causing great diminution of the capacity of the thorax. Accompanying these skeletal changes were spinal pressure symptoms, especially spasticity of the lower limbs, dwarfing of stature, rheumatoid pains, and tenderness to pressure of the affected bones.

In my experience the condition is much more common among Hindu than Mohammedan women, and the majority of the cases seen by me have belonged to the *Bunya* caste. The members of this caste are usually possessed of sufficient means and religious prejudice to prompt strict observance of the Hindu custom of child-marriage, which is often actually consummated at an incredibly early age. Miserable little girls of apparently 9 years or thereabouts, who had been subjected to sexual intercourse (as evidenced by ruptured hymen, etc.), have been brought to me by their mother-in-law; and if I remonstrated against this practice, the reply that the husband was a "young boy" was evidently thought complete justification. Mohammedan girls, on the other hand, are not married until puberty, and their diet includes flesh food. Probably both, and certainly the former, are reasons for the lesser incidence of osteomalacia among Mohammedans, despite the fact that their seclusion inside the houses is more strict. Of the 23 Caesarean sections (all for osteomalacic pelvic contraction) performed during these four years in the Dufferin Maternity Hospital, Agra, where the total number of Hindu and Mohammedan women admitted is about equal, 20 were on Hindu women and only 3 on Mohammedans. Among domiciled Anglo-Indians I have not seen any case.

Unlike osteomalacia, rickets in Agra is rare among Indian children, who are practically all breast-fed. If an infant has to be fed by hand in an Indian home, it usually soon succumbs. Nevertheless the disease is fairly common among the bottle-fed children of the mission orphanages, and among poorer class Anglo-Indians and Europeans, and this has strengthened my conviction that breast-feeding is the great prophylactic against the disease.

Osteomalacia I associate with overstrain of the sexual functions. It may begin prior to the occurrence of pregnancy, but I do not remember having seen a single case in an unmarried girl. Our Caesarean section patients, whom we invariably sterilized by ligaturing and dividing the Fallopian tubes, used to improve in health and find relief of pains with increased functional use of their bones and joints after the operation. This simple division of both the tubes between ligatures was followed by amenorrhoea (menopause) in all cases which I have been able to trace.

THE ADMINISTRATION OF EMETINE BY THE MOUTH IN AMOEBIC DYSENTERY.

RECENTLY having had the opportunity of treating a case of relapsing amoebic dysentery, I thought it might be interesting to see what effect emetine administered by the mouth might have upon it. The results were very satisfactory. The patient acquired his dysentery abroad in August, 1912, and from that date had suffered from frequent relapses. I saw him on his return to England on June 9th, 1913, and found blood and mucus still present in his stools with many amoebae having the characteristics of *E. histolytica*. He had to leave town again the same afternoon, so I did not inject him with emetine, but told him to get Burroughs and Wellcome's keratin-coated tabloids of emetine hydrochloride (grain $\frac{1}{2}$), and to take one of these on going to bed that evening. If no bad effects followed I advised him to go on taking one each evening, to rest as much as possible, and to go on a milk diet.

I heard from the patient five days later. In his letter he stated that the effect of the drug was immediate, and that it did not cause sickness or upset him in any way. On the day following the first dose he noticed a distinct amelioration of all his symptoms, and by the second day

they had completely disappeared. Up to the time of writing this satisfactory condition had continued, and the patient's own words were "that after battling with the disease for ten months it seemed almost like a miracle to get rid of it so quickly."

The valuable effect of emetine when given by injection on amoebic dysentery is now of course well known. It may at times be inconvenient to give it by this method, and, if it acts as well by the mouth, then there is no special necessity for doing so. In administering it by the mouth, as far as one can judge at present, it will be best to employ keratin-coated tablets, so as to prevent the drug getting into solution until past the stomach, and if, in addition, the patient rests quietly in bed the risk of vomiting would seem to be slight.

Since writing this I have seen another patient just returned from India, who brought a supply of keratin-coated tablets of emetine from there with him. He was taking one of these at nights with no special precautions, and they did not excite emesis in him either. There is always, of course, the danger of a keratin-coated tablet not dissolving and being passed unchanged; if the symptoms do not improve rapidly this should be borne in mind.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

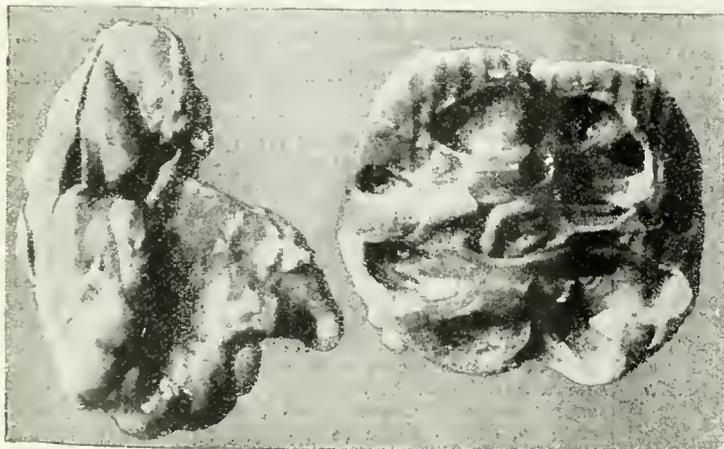

SHOREDITCH INFIRMARY.

A CASE OF CONGENITAL CYSTIC DISEASE OF THE KIDNEYS.

(By HARMAN GRAVES, M.R.C.S., L.R.C.P., Senior Assistant Medical Officer.)

A boy aged 5 years was admitted on June 21st, 1912, suffering from symptoms believed to be due to ptomaine poisoning. The mother stated that both she and her son partook of some fried fish on June 19th. She noticed it was tainted, but thought it would be "all right"; the following day she felt queer, and had a "red blush" all over her body; her son was feverish and had diarrhoea. He was seen by a doctor on June 21st, and was sent to the Infirmary. His temperature on admission was 104° F., and he was extremely ill. He died the following day.

A *post-mortem* examination was made. The gastrointestinal tract showed the usual signs of "acute enteritis,"

but the point of greatest interest was as follows. The kidneys presented marked congenital cystic disease. The right kidney weighed 1½ oz., the left 1 oz. Both pelves were dilated. The remaining parts of the ureteric tracts were not beyond the ordinary calibre. The bladder was enlarged and sacculated; this, I take it, was due to the extreme degree of phimosis present.

The interest of this case appears to me that the patient,

up to the date of his illness, had been a healthy boy, and the degree of structural changes present (as demonstrated by the accompanying photograph) would seem to contradict this fact.

LONDON HOSPITAL.

RECTAL SEPTUM PRODUCING CHRONIC INTESTINAL OBSTRUCTION.

(By H. S. SOUTTAR, F.R.C.S., Surgical Registrar to the Hospital.)

A MARRIED woman, aged 54, with eight children, was admitted on January 20th, 1912, with signs of chronic intestinal obstruction becoming acute.

For many years she had been troubled with wind and abdominal distension, but her bowels had acted normally till four months ago. For four months she had suffered from marked distension of the abdomen and from a bearing-down pain on walking, while the bowels had been somewhat relaxed. For one month there had been constant slight diarrhoea. Six days before admission she had an attack of vomiting. She had never had any severe illness, and her confinements had all been easy.

The patient was thin, but looked in the best of health. The abdominal wall was thin, and beneath it could be seen huge coils of hypertrophied bowel in violent peristalsis. In the centre of the lower abdomen was a vertical cylinder of bowel, in which the contractions passed from above downwards. To such a degree was the intestinal wall hypertrophied that this portion might easily have been mistaken for a solid tumour. The rectum appeared to be ballooned, but no obstruction could be reached.

A diagnosis of increasing chronic intestinal obstruction at the lower end of the pelvic colon was made.

Under stevaine spinal anaesthesia the abdomen was opened in the middle line below the umbilicus. The vertical portion of the intestine above referred to presented in the wound and proved to be the upper end of the rectum. It was about 6 in. in diameter. It was traced upwards to the right lobe of the liver, and from that point across the abdomen and down the left side to the left iliac fossa, where it became continuous with the descending colon. On passing my hand downwards I found that there was no pelvic peritoneal cavity whatever, the peritoneum being reflected directly from the rectum on to the brim of the true pelvis. The small uterus and appendages lay immediately behind the abdominal wall and entirely above the pelvis. The caecum, appendix, and colon were somewhat distended, but otherwise normal. The pelvic colon and rectum were enormously hypertrophied and distended.

Being unable to find any cause of obstruction on the abdominal side, I inserted the forefinger of my left hand into the rectum by the anus, when I found that my right hand in the abdomen could press down within its reach a septum stretched across the rectum with a small aperture in its centre.

The abdominal wound was protected and the patient placed in the lithotomy position. On stretching the sphincter a large cavity was displayed occupying the whole pelvic outlet and roofed in by the septum above mentioned. In the centre of the septum was a small aperture through which a minute stream of liquid faeces oozed. Its margins were thickened, and it would admit a No. 8 English bougie. The aperture was enlarged to admit a finger, and it was then found that the septum was a thin fibrous sheet. It was widely divided transversely with scissors, with practically no haemorrhage. A stream of liquid faeces at once

began to flow with great force, and more than three quarts were removed. The patient made an uninterrupted recovery, and left the hospital eighteen days later perfectly well.

On the whole, it appears to me probable that the condition was congenital and due to persistence of the septum which, in the fetus, separates the proctodeum from the hindgut. The enormous hypertrophy of the bowel and

its entirely abnormal peritoneal relations indicate that the obstruction must have been present for many years, and, in the entire absence of symptoms, it may well have been present since birth. It is exceedingly difficult on any other hypothesis to account for a thin fibrous septum 4 in. in diameter. Malignant disease can be absolutely excluded, and there was no evidence of syphilis. There was no thickening or ulceration to suggest a chronic inflammatory process.

I have been unable to find in the literature any record of a similar case.

I am indebted to the kindness of Mr. F. S. Kidd, Assistant Surgeon to the London Hospital, for permission to publish the case.

Reviews.

THE CONTROL AND ERADICATION OF TUBERCULOSIS.

At a time when an opportunity is open to the nation of grappling with the problem of tuberculosis as a whole, from an imperial rather than from a parochial or political point of view, any serious contribution to the discussion should meet with a cordial welcome. A noteworthy addition to the literature of the subject was made by the publication of a volume on *The Control and Eradication of Tuberculosis*,¹ edited by Dr. HALLIDAY G. SUTHERLAND, which for various reasons we have hitherto been unable to notice. A title so comprehensive as this might seem to imply that the book was intended to be *primarily* a study of the campaign against tuberculosis. It is, however, really, as the dedication frankly states, written in the first place as an appreciation of the work carried on by Dr. (now Sir R. W.) Philip in connexion with the Royal Victoria Hospital, Edinburgh, and in support of those measures which, in his opinion, need to be co-ordinated if a successful attempt is to be made to combat the disease. It is, in fact, an exposition of the principles of what is called the "dispensary system," founded by Sir R. W. Philip in Edinburgh.

The editor has received assistance from many contributors who are able to speak with authority on the conditions which exist in the various countries with which they are acquainted. Some of these writers have been Sir R. W. Philip's pupils, and most of them fully and generously acknowledge the debt which they owe to him for the inspiration they have received in their work.

The contributions are written from many different points of view, and come from widely separate parts of the world. Amongst them may be mentioned those of Adami, Hermann Biggs, and Vincent Bowditch from the continent of North America, of Béranek from Switzerland, of (the late) Professor G. and Dr. F. Arloing from France, and of Dr. W. L. Mackenzie from Scotland, whilst there are others from Norway, Sweden, Denmark, the Netherlands, Russia, Italy, India, and New Zealand.

Such a variety of opinion has its disadvantages as well as its advantages. In the first place, there is a good deal of unavoidable repetition; and secondly, some of the articles, such as that on India, are too brief to be considered serious contributions to the subject. At the same time, much useful information may be gathered as to the progress of the antituberculosis campaign which has been made in various countries, and as to the success which has followed the adoption of those means which have been utilized to meet the widely different conditions which have had to be faced. It is obvious that identically the same methods cannot be applicable to Norway, to India, and to Russia.

As a general principle it cannot be questioned that Sir R. W. Philip's contention is a sound one. Any scheme for successfully dealing with tuberculosis should have at its centre an organization for locating cases when they occur, and for dealing with them when they have been found. It is obvious that more would be done to relieve the suffering of individuals, and to lessen the risk of contagion from hopeless and incurable cases, if all the agencies

established for this purpose (whether voluntary or state, parochial or county) could be thoroughly co-ordinated into one harmonious scheme.

This is ideal. In the centre there would be a dispensary, working in touch with the medical officer of health, and endowed with powers and the necessary funds to draft off suitable cases to sanatoriums for the treatment of early cases; to asylums for the segregation of those who are incurable or dying; to labour colonies those who are able to work, though unable to return to their ordinary vocations; and, lastly, with means for treating such cases as may be rightly dealt with, without removing them from the surroundings of "home." The details of such a scheme were very clearly outlined in Dr. Philip's address at the Annual Meeting of the British Medical Association in 1909, which is reprinted at the end of the volume.

The book is divided into thirty-one chapters, of which four are devoted to the consideration of tuberculosis dispensaries and sanatoriums, and two to tuberculin and its uses. Others deal with such subjects as hospitals for advanced cases, the administrative control of open air schools, farm colonies, biological problems (with an excellent bibliography by A. E. Porter), and the antituberculosis movement in various countries. The volume closes with an appreciation of Sir R. W. Philip's work, and includes a selection from his writings, such as those to which allusion has already been made: On the Public Aspects of the Prevention of Consumption (1906), on Progressive Medicine and the Outlook on Tuberculosis (1909); and to these are appended a list of his writings on similar subjects—forty-four in number—dating from 1886 to 1911.

Such is the general scheme of the work under review. Its scope is almost too comprehensive to permit of each subject being dealt with in adequate detail. Some of the articles are, in consequence, little more than sketches of the matters with which they deal. The purpose of the book is, however, fully accomplished, since it brings generous recognition of Dr. Philip's work from many quarters of the globe, and so fulfils the special object with which it has been written.

If it has a defect it seems to be that it fails to recognize much of the work which has been done in similar directions by other workers in the same field; neither does it give any adequate account of the varieties, uses, and dangers of tuberculin in treatment, nor is any notice taken of the possible causes of the decline in the death-rate from tuberculosis as a result of agencies other than sanitation or treatment.

The first "antituberculosis dispensary" was instituted in Edinburgh by Dr. Philip in 1887. It was designed to be the one link in a co-ordinated system of defence against, and of attack on, the disease. It is defined as a clearing-house for tuberculous cases, from which they could either receive the treatment required or be passed on to such other institutions as their especial needs might indicate. The scheme is excellent, and that the hopes to which it gave birth are enthusiastically supported is well shown by the following statement in the introduction by Professor Béranek (p. 3):

Unquestionably if the measures existing in Edinburgh were applied universally, the extension of the disease would be prevented, and within a measurable time this scourge would become extinct.

It may be objected that such an outlook is too narrow, since it leaves out of account many factors which may exert a very powerful influence on the result, not the least important of which are those tending towards the development of a racial immunity, as has been so strongly urged by Karl Pearson, Sanarelli, and more recently by Metchnikoff. In this regard Professor Béranek's glowing tribute to Dr. Philip's work may well be compared to the more guarded statement made by Dr. Hermann Biggs (p. 287), who, after describing the details of the far-reaching schemes for combating tuberculosis in New York, concludes by saying:

Where such a comprehensive scheme as has been outlined in part above can be made effective, in my judgement there is every reason to look forward to a steady and continuous reduction in the morbidity and mortality-rate from this disease, but the extinction of tuberculosis will only be achieved when many, as yet, unsolved social and economic problems have also been satisfactorily met. (The italics are ours.)

¹*The Control and Eradication of Tuberculosis: A Series of International Studies by Many Authors.* Edited by Halliday G. Sutherland, M.D., Medical Officer to the St. Marylebone Anti-Tuberculosis Dispensary. Edinburgh and London: Wm. Green and Sons. (Price 15s. net.)

In Chapter VII Dr. Sutherland gives an interesting account of the methods of treatment adopted in a sanatorium, including that by graduated exercise. No acknowledgement, however, is given to the splendid pioneer work inaugurated by Dr. Paterson at Frimley in 1904, nor is any allusion made to the fact that, even before work was started at Frimley, Grunat at the Lyster Sanatorium in Norway had instituted manual labour as a therapeutic agent for the stronger patients in 1902. Some of the methods suggested seem hardly necessary for the ordinary hospital patient, such as sponging with tepid water to which eau de Cologne is added, the giving of a glass of rum and milk at 4.15 p.m., and the addition of raw meat to the dietary. These, although doubtless sometimes permissible, must be looked on rather as luxuries than necessities for the ordinary patient, and in many cases would certainly be undesirable.

Professor Béraneck writes on the theoretical and practical basis of tuberculin in treatment, but his article is of necessity by so much incomplete as it is merely an exposition of his personal views, and not in any way a critical study of the subject. It is impossible not to regret that no attempt has been made to correlate and compare the various and often conflicting opinions which are held on this important subject, or to give the arguments for and against the diverse methods of treatment by the many preparations of tuberculin which have been from time to time brought into use. Such a critical review might well find a place in any work which professes to deal with the treatment of tuberculosis as well as with its administrative control and prevention.

In writing of the public health aspects of the Edinburgh system, Dr. Hewat truly says that the "notification of cases can do no material good unless it be combined with measures for helping the patients and for preventing the spread of the disease." Much may be hoped for if those who are responsible for the administration of measures framed for dealing with the problem from a national point of view realize to the full the importance of this fact. As it is at present, neither the Insurance Committee for the County of London, nor the Metropolitan Asylums Board, nor any other single executive body, is able to extend sanatorium treatment to all tuberculous cases whether insured or no, so that a large number of necessitous cases, whose poverty renders them peculiarly liable to disease, and whose lack of employment leads them to be uninsured, are for the present inadequately provided for, and there is little doubt that they constitute a serious menace to the whole community by spreading the disease to those with whom they come into contact.

The administrative control of pulmonary tuberculosis is dealt with in an able and practical article by Dr. Leslie Mackenzie, of the Scottish Local Government Board. He rightly includes in the plan of campaign such questions as the prevention of overcrowding, the supervision of dairies, improved milk supply, sanitation and housing, the maintenance of paupers, etc. Without attention to these, the mere carrying out of any scheme of treatment must be of quite secondary importance. Further, he discusses the meaning of "sanatorium benefit" and the effect which may be expected to result from it in actual practice. The conclusion at which he arrives is that,

With a disease so various, so widely diffused, so treacherous, the only road to success is patient study of individual cases, patient study of individual environments, and patient correlation of all administrative methods to the purpose of treating each individual patient according to his needs, and each individual's environment according to its condition.

It cannot be doubted that this is true, and in proportion as no provision is made for dealing with the great mass of those who are uninsured, by so much will the result fall short of what might be done if all tuberculous persons alike, whether insured or uninsured, are dealt with on the same lines, and are given the same opportunities of such treatment as may be possible, or, if in too advanced a stage of the disease, of being given an asylum in which to end their days.

It would be impossible within our limits to study in detail each of the articles which follow, but they show well the progress which has been made in some countries, notably in America, Norway, and South Australia, and the inefficiency of the measures adopted or perhaps even possible in others, such as India, Russia, Italy, or South

Africa. Amongst the individual articles, attention may be directed to that of the late Professor G. Arloing, in which he enunciated clearly and emphatically the belief that in spite of the differences between human and bovine tubercle bacilli, they are merely variations of one species induced by long residence in one or other host. We are reminded that the infectious nature of pulmonary tuberculosis was recognized in Italy as long ago as 1754, and that, in spite of the fact that dread of the disease amounts almost to a panic, little effective effort is made to combat it in that country. Among other articles, one of special importance is that on the administrative measures for the control of tuberculosis in New York City, which bears strong testimony to the practical methods of our cousins across the Atlantic in any matter which they take energetically in hand.

The general get-up and typography of the book are excellent, and reflect much credit on the printer. Many of the illustrations do not seem to add much force to the text—a man "sweeping a lawn" or "securing the potato crop" looks much the same in a photograph whether he is on a farm colony or on any other farm. There are, too, some curious misprints which it would be well to correct in a second edition, such as "Arloing, Professor S." for "Professor G.," "mitigate" for "militate" (p. 20), "tetanus" for "tetanus" (p. 105), "Bericht. Über die Taugkeit der . . . Schultartze" for "Bericht über die Tätigkeit der . . . Schultartze" (p. 150), "bacilla" for "bacilli" (p. 371), whilst on p. 375 appears a statement, which seems to need verification, to the effect that in Sweden the "May-flower" collection proved so successful that it brought in £186,608 2s. 5d., though we are told five pages previously that it had actually brought in £7,184 15s. 11d. in 1909. Is it possible that in the larger figure "pounds" are put instead of "kroner" (kr. 18.15=£1)?

Lastly, it is unkind to readers to publish a book without an index.

In spite of these minor defects, this volume does credit to its editor, and is a notable testimony to the warm appreciation in which Sir R. W. Philip is held by his pupils, and to the value of his unwearied effort to coordinate and systematize all the weapons which are needed and which should be available in prosecuting the arduous campaign against tuberculosis.

COOKING FOR VOLUNTARY AID DETACHMENTS.

We have received a copy of *Cooking Notes for V. A. Cooks*,² by B. H. DAVY, Staff Officer, Exeter Division, Voluntary Aid Organization. The book was written for the use of voluntary aid cooks belonging to the Exeter Division, and has been published in the hope, which we have no doubt will be fulfilled, that it will prove useful to the V. A. cooks in other divisions. Miss Buller, Assistant County Director, Exeter Division, Devon V.A.O., in a preface states that it would probably be fair to say of most Voluntary Aid Detachments that the level of efficiency amongst the nurses is superior to that found amongst the cooks. This she attributes to uncertainty as to the lines on which the cook's training should be conducted. While the official instructions lay it down that each woman's detachment must include four qualified cooks, there is no prescribed standard of efficiency, so that the word "qualified" may be variously interpreted. In consequence, she states, the post of cook is filled by persons of very different capacities—from the fully-trained professional to the amateur, who, given time and a recipe book, may be relied upon to produce a sufficiently good imitation of beef tea—but in very few cases are detachment cooks competent to perform the highly responsible duty which might be theirs in the event of mobilization. It is to remedy this defect that Miss Davy has written her handbook, and the method of instruction she advocates has been tested in the Exeter Division and found to work most satisfactorily.

The first three sections of the book deal with the

²*Cooking Notes for V. A. Cooks.* By B. H. Davy, Staff Officer, Exeter Division, Voluntary Aid Organization. With introductory preface by Miss Buller, Assistant County Director, Exeter Division, V.A.O. Exeter: M. A. Rudd and Son, 180, Fore Street, 1913. (Demy 8vo, pp. 90. Price 1s.; single copies, post free, 1s. 2d.)

general organization and lay down a scheme of instruction for ordinary cooks, the War Office requirements being in all cases noted. The fourth section deals with experts' classes, a matter of great practical importance, since a good domestic cook has much to learn of the methods of providing food for a large number of people in a short space of time with a scarcity of utensils and no convenient accommodation. In the following sections dealing with stoves, cooking utensils, and field kitchen arrangements, Miss Davy, writing from practical experience, mentions the difficulties likely to be encountered, and sufficiently shows that to surmount them requires knowledge and resource such as the ordinary domestic cook, however expert, has little opportunity of cultivating. There are some general observations on methods of cooking, the time and temperature required, and the percentage loss, and these are followed by a series of sections enumerating the various articles of diet and indicating the times of the year in which they are in season. There is a section on the stock pot—an institution little understood in this country—and others giving tables of weights and measures, diets for military hospitals, and an explanation of army farms. The last thirty-four pages of the book contain a classified list of recipes for cooking all kinds of food, from fish and meat to arrowroot and turnips; this section will appeal not only to V. A. cooks but to all persons whose acquaintance with cooking is more theoretical than practical, for Miss Davy gives the inexperienced just these definite details about the preparation of the raw food and the length of time for which it should be boiled or roasted or stewed which are so often missing from the ordinary cookery book; the handbook, therefore, will be found most helpful by the caravaner, the yachtsman, and the camper-out, although its direct appeal is to members of voluntary aid detachments. In appendices brief notes are given on the principles of food and feeding, on reasons for cooking, and of the quantities of food required daily when at work.

The handbook is to be very highly commended as a thoroughly practical production, and we are not surprised to learn that already voluntary aid detachments in other parts of the country have subscribed for copies of it. Any profit resulting will be given to the Voluntary Aid Fund in Devonshire.

A HANDBOOK FOR INSURANCE COMMITTEES.
As indicated in the title, *Knight's Handbook for the Use of Health Insurance Committees*³ hardly pretends to be a full guide to the working of the Insurance Act, as, except incidentally, it deals only with those parts of the Act which specially concern Insurance Committees. The full text of the Act is printed; but while a detailed description is given of the administration of medical and sanatorium benefits, which are wholly in the hands of the Insurance Committees, sickness, disablement, and maternity benefits are only dealt with as they apply to deposit contributors, for whom the Insurance Committees are responsible, and little or no guidance is given to approved societies in the multitudinous matters that concern their members in connexion with the three last-named benefits. A careful and in the main accurate description is given in three chapters of the composition, powers and duties, and general proceedings of Insurance Committees. A special chapter is devoted to the finances of the committees and the prescribed methods of keeping their accounts, and while no one can fail to be struck with the extreme complexity of this subject, the chapter would be none the worse for a mere concise digest of the numerous Orders and Memorandums which have been issued by the Commissioners. Little is attempted in way of criticism of the Act or Regulations, the object being evidently to paraphrase or explain in simpler language the various provisions that concern Insurance Committees, and to present them in something like a connected form. Several statements, however, are made which appear to need some modification, or at least amplification, such as that on page 35 to the effect that the Local Medical Committee "is in no way a

statutory body." It would be more correct to say that though there is no statutory necessity that a Local Medical Committee should be formed, if one is formed and is recognized by the Commissioners it then has certain statutory rights. Again, on page 1 it is stated that two members of the Insurance Committee shall be elected in manner provided by Regulations by "any association of duly qualified medical practitioners resident in the county," etc., but an important qualification of this which occurs in the Act, clause 59 (2) (a), is omitted—namely, that such association must have been "formed for that purpose under the Regulations." It was clearly not intended that "any" association formed primarily for other purposes should be entitled to elect two members of the Insurance Committee. It must have been formed specifically for the purpose of the election, and special stress has been laid, particularly in Wales, on the necessity that any association formed for this purpose shall cover all the practitioners resident in the county or county borough. As a matter of fact, several months ago when the elections took place of two members representing the profession to hold office till July, 1914, few, if any, such associations had been formed, and provisional Regulations were issued on January 31st by the Commissioners prescribing the procedure of election by all the practitioners resident in the areas. Thus the bare statement of the book needs considerable modification, even though the provisional Regulations referred to are given in an appendix. Again, on p. 63 we read: "Where the panel is not such as to secure adequate medical service, that gives to the Committee and the Commissioners jointly or to the Committee themselves alone, the right to make any other arrangements they think fit or to suspend medical benefit and hand back to each insured person his own 6s." The words here printed in italics are surely hardly correct, for the Insurance Committees cannot "themselves alone" suspend medical benefit, and can only "make such other arrangements as the Commissioners may approve" (clause 15, (2)). The right of a Committee to allow insured persons to make their own arrangements when there is an adequate panel is, of course, a very different thing. The sum of 6s. here mentioned is corrected in other parts of the book, but this is not the only place where the amount mentioned as available for medical benefit needs correcting in view of the last Government grant. Again, in several places, and particularly on p. 67, referring to the Harmsworth subsection 15 (4), the author speaks of the "expressions used in the Act—namely, 'scheme' or 'institution,'" whereas the word used in the Act is not "scheme" but "system," which was chosen deliberately and after the most careful consideration after rejection of the word "scheme." It is well to be accurate in this, though, after all, the word "system" is left without precise definition. Every care appears to have been taken that all the Orders and Regulations issued up to January 31st should be either included verbatim or summarized, but already since that date the Commissioners have issued numerous other proclamations; and, as the author suggests in the preface, no apology is needed for the fact that the book is already in some particulars not completely up to date. Within the limitations imposed by the book itself it ought to be a useful handbook for members of Insurance Committees.

NOTES ON BOOKS.

LITTLE more than two years have passed since we reviewed the fifth edition of Professor von NOORDEN'S work on diabetes,⁴ and we have now the sixth edition before us. In spite of the introduction of much new matter, the volume is no larger. The author has given special attention to what he calls the useful but dangerous and two-edged weapon of carbohydrate cures. He tells us that he has amplified the literary references and simplified and revised the index. Quite recently (see BRITISH MEDICAL JOURNAL, April 12th, 1913, p. 772) we reviewed Professor von Noorden's lectures on *New Aspects of Diabetes*, delivered in the New York Post-Graduate Medical School last October, which are actually more up

³ *Knight's Handbook for the Use of Health Insurance Committees and all Other Local Authorities, Approved Societies, and Medical Practitioners Affected by the National Insurance Act, 1911.* London: Charles Knight and Co., Ltd. 1913. (Demy 8vo, pp. 390. Price 6s. net.)

⁴ *Die Zuckerkrankheit und ihre Behandlung.* Von Professor Dr. Carl von Noorden. Sechste vermehrte und veränderte Auflage. Berlin: A. Hirschwald. 1912. (Roy. 8vo, pp. 450. Mk. 10.)

to date than this volume, the preface to which was written on February 20th, 1912. As a textbook Professor von Noorden's work has become a classic and has passed beyond the range of criticism.

We have received a second edition of the book on gony and rheumatic disorders by KLEINE,⁵ which was reviewed two years ago (see BRITISH MEDICAL JOURNAL, May 6th, 1911, p. 1058). We feel indisposed to add anything to what was said then. As was stated on that occasion, the book purports to be written by a patient who has been under the care of Dr. Kittel, of Franzensbad, and is designed to draw the attention of the public to the method of treatment pursued by that physician.

We have received a volume on *Mechanical Vibration: Its Physiological Application in Therapeutics*,⁶ by Dr. M. L. H. ARNOLD SNOW (New York, 1912). It is largely made up of quotations from the works of other authors, and gives a full but quite uncritical account of the wonders that may be expected from the methods it advocates. It is dedicated "To one who lives that the world may be better for his having lived," a sentence that should serve as a model to any grammarian in search of an example of amphibology.

One hardly expects to see the term "treatise" applied to a small crown octavo volume, but the word is not ill used, perhaps, as part of the title of Dr. CHARLES COTAR's book on *Mineral Waters of Vichy*.⁷ He certainly deals with the subject comprehensively, as also in clear terms, and betrays throughout his writing wide reading and knowledge of the views of other medical authorities. Among other things he reviews the alleged physiological actions of Vichy waters, and endeavours to deduce therefrom the indications and contraindications for their use, corroborating these by observations derived from the work of his colleagues in Vichy and his own long personal experience at that health resort. A chapter is devoted to the diseases of children in this connexion, and the work concludes with some consideration of how far Carlsbad and Vichy are comparable. There is an excellent index. In a foreword Professor Harley refers to the scientific fashion in which Dr. Cotar has dealt with the subject, and expresses an opinion that the work will be found useful to medical men as giving them a complete summary of the whole treatment of diseases by Vichy waters, in particular, as well as by mineral waters in general.

The beginnings of disease in childhood are often so insidious that irreparable harm may be done before the condition of the patient is recognized to be sufficiently serious to justify a visit from the family doctor. Moreover, the same ignorance that has caused the delay in summoning him frequently handicaps the doctor in another way in his dealings with the case, since it is difficult, if not impossible, to obtain any satisfactory or coherent statement from an inexperienced or unobservant mother. Most practitioners, at one time or another, have occasion to deplore the lamentable want of knowledge displayed by even the most careful and devoted of parents; and it is for the guidance and assistance of these latter that Dr. C. WILLET CUNNINGTON has written his *Nursery Notes for Mothers*,⁸ in which he describes, in the simplest possible language, the ordinary ailments of childhood, and the signs by which their coming is usually heralded. His book is not intended as a manual of first aid for the nursery, or even as a handbook of domestic medicine, but rather as a practical book of reference wherein the young mother may learn how to recognize the early symptoms of childish maladies and how to avoid the mistakes arising from a hasty amateur diagnosis. Mr. Cunningham's work may be highly praised, and should prove a friend in need to many an anxious mother whose education in child lore has hitherto been mainly left to chance.

⁸ *Nursery Notes for Mothers*. By C. Willet Cunningham, M.B., B.C. London: Baillière, Tindall, and Cox. 1913. (Cr. 8vo, pp. 144. 2s. 6d. net.)

The seventh volume of the *Transactions of the American Association of Genito-Urinary Surgeons*⁹ relates to the proceedings of this body at its twenty-sixth annual meeting, just a year ago, when some eighteen papers, all coming strictly within the scope of the society's work, were read and duly discussed. Of special interest, perhaps, were two discussions in regard to the complement fixation test as a guide in the treatment of cases either known to be of gonorrhoeal origin, or open to the suspicion of having gonorrhoea as a factor in their causation. The facts put forward suggested that this test must often be of practical utility, especially in dealing with female patients. There is a carefully recorded case in which both chronic incontinence and retention of urine persisted despite the absence of any mechanical obstruction or any demonstrable nervous lesion. The volume also includes three theses presented by candidates for admission to the association.

This is an age of faith-healing and what the sergeant in *Punch* irreverently termed "fancy religions," and there is nothing overdrawn or exaggerated in Mr. PAUL NEUMANN'S account of the Church of the Gifts, whose rapid rise and equally rapid decay form the subject of his novel *Open Sesame*.¹⁰ Its founder, Will Porteous, the son of an old-fashioned Nonconformist clergyman, and himself destined for the ministry, is an interesting study of a charlatan whose power over the minds of his fellow-men is discovered through an incident that launches him on his career as a fashionable preacher and faith-healer. But the Church of the Gifts is another house built upon sand, and suffers the same fate. The failure of its founder to cure a lame child leads to a gradual loss of prestige and popularity, and when Porteous is finally struck down with general paralysis the whole edifice collapses like a house of cards. Mr. Neumann has never done anything better than this moral dissection of the distorted mind of a quack. The man's whole mental attitude is revealed to us with pitiless fidelity, whilst his struggles to avert the inevitable catastrophe, and the misery of his last days, are described in a manner both powerful and convincing. The author has placed the unfortunate thanaturlist and his willing dupes under the microscope, and the result, if not precisely pleasant, is at least a brilliant exposition of the unplumbed depths of human folly and credulity.

A notice of the first part of the fourth volume of the *Proceedings of the Canal Zone Medical Association*¹¹ appeared at page 776 of our issue for April 12th. We have now received the second part, which brings up what, as we pointed out on the previous occasion, is a somewhat belated record to the end of March, 1912. This part contains some twenty-four papers, most of which relate, as did their predecessors, to subjects of tropical medicine. Specially worth noting among them, perhaps, are two on the subject of the amoebae and entamoebae found in the area of the canal. Two others deal with some cases which were brought forward in support of two theories maintained by their exhibitors in regard to pellagra: the one being to the effect that there is a possible relationship between pellagra and the bacilli of the colon group, the other that this disease is an example of a disorder due to an autointoxication, resulting in this instance from imperfect assimilation of sugars and starches.

The author of *In the Grip of Destiny*,¹² when writing his latest novel, appears to have been animated with the same desire that led the fat boy in *Pickwick* to divulge the clandestine courtship of Mr. Tupman in order to make his mistress's flesh creep, for he has made "on horror's head horrors accumulate" in the course of his sensational story. The Russian conspirator is a stock character in fiction, and in Mr. STERREY'S novel he appears once more in the midst of plots and counter-plots, in which a mysterious pebble seems to play the part of the fiery cross of the ancient Highlanders. The story develops on somewhat conventional lines, but the secret society of the Equalisers is a romantic band of criminals, and Mr. Sterrey has unraveled the tangled threads of their

bewildering machinations with no little skill and ingenuity. His book can be safely recommended to that large body of readers who prefer incident to character; whilst those who enjoy a good detective story cannot do better than follow the famous Tanquerville step by step in his search for the clue that will enable him to lay his hands upon Professor Frayling's murderer, and discover the secret of his death.

MEDICAL AND SURGICAL APPLIANCES.

Blood Examinations in General Practice.

DR. P. G. HARVEY (Monmouth) writes: I do a good deal of blood work and bacteriological examination, but being in general practice in the country, naturally at very irregular intervals. I have experienced considerable trouble with my reagents, especially with Jenner's and Leishman's stains, Lugol's fluid and Toison's fluid. Tablets of stains and reagents are of course very handy, but they require preparation, and some of them some time before they are fit for use; whilst those requiring methyl alcohol for their preparation, owing to the trouble of getting a reliable sample, are especially troublesome. At my suggestion Messrs. Phillip Harris and Co., Edmund Street, Birmingham, have prepared sealed ampoules of various stains and reagents.

Jenner's stain.
Leishman's stain, $\frac{1}{2}$ c.cm.
Distilled water, 1 c.cm.
Lugol's solution for Gram's stain.
Toison's fluid.
Acetic acid 0.3 per cent., with methyl green, for white corpuscles in blood counts.

I have tested several of these at intervals, comparing the results with films, etc., stained from similar reagents taken from $\frac{1}{2}$ oz. and 1 oz. bottles obtained at the same time, and the results are far superior. I venture to think that many men situated as I am, who like to do such work occasionally, will find these ampoules extremely convenient. Messrs. Harris are prepared to put up any other reagents in the same way if the demand is large enough. I have to thank Mr. T. Elliott, of Messrs. Harris's laboratory, for the trouble he has taken in carrying out my suggestion. The prices run from 1s. to 1s. 6d. a dozen.

A Bed Support.

Messrs. H. Aitken and Co. of York have recently brought out under the name of the Captain Edwyn Walker's Bedstop a very simple device for preventing patients slipping towards the foot of the bed when in a semi-recumbent position. It consists of a cylinder of wood encased in a coating of stout cloth or other resilient material, which is covered in its turn by waterproof, so that the appliance when complete forms a kind of round cushion some 16 in. long, with a circumference of about 9 in. It is brought into use by placing it just below the patient's buttocks. The outer covering is detachable for cleansing and is supplied in flannel as well as in waterproof material.

It is announced that a gift of £200,000 has been made to the district of California by Mrs. George William Hooper of San Francisco, to be devoted to the establishment of an Institute for Medical Research. The gift is intended as a memorial to her husband.

It is reported, according to the *New York Medical Journal*, that the clergy of the various denominations in the Oranges, New Jersey, will in future require that persons intending to marry, brides as well as bridegrooms, shall furnish certificates of health along with the marriage licence before the ceremony is performed.

THE fourth Congress of the International Surgical Society will take place in New York in April, 1914 (14th to 18th). The following subjects are proposed for discussion: Ulcer of the stomach and duodenum, to be introduced by Drs. de Quervain, Hartmann, Mayo, Sir Berkeley Moynihan, and Dr. Payr; grafting in plastic surgery, M. Morestin; grafting of blood vessels, M. Villard; grafting and transplantation, Drs. Ulmann and Lexer; transplantation of organs, Dr. Alexis Carrel; technique of amputations in general, Dr. Witzel; amputation of the arm and forearm, Dr. Ceci; amputation of the hand and upper part of the thigh, Dr. Kuzmik; amputation of the leg and foot, Drs. Binnie, Durand, and Ranzi. Arrangements have been made for a visit to the chief cities of the United States by the congressists.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (LONDON, 1913).

SECTION OF OPHTHALMOLOGY.

THE lamented death of Sir Henry Swanzy on April 12th deprived the Section of a president who had devoted much time and attention to its affairs for more than two years. Sir Anderson Critchett, a former vice-president of the section, has consented to fill the vacancy so created, although recognizing the difficulties inseparable from so late an assumption of office.

The meetings of the section will be held in the Mechanics Laboratory, Royal School of Science, Exhibition Road, South Kensington. The following is an outline of the arrangements:

On Wednesday, August 6th, the Section will meet at 3 p.m., when a brief address of welcome will be given by the President. The arrangements for the meetings will be announced, and the reading of independent papers will then be begun. On the succeeding days the meetings will begin at 9.30 a.m. and 3 p.m., except on Saturday, on which day there will be no afternoon session.

The morning session on Thursday, Friday, Monday, and Tuesday will be devoted to discussions, although, if time permit, independent communications may be taken after the discussion. The subjects which have been chosen, the names of the openers, and the day selected for each discussion are as follows:

Thursday, August 7th.—The pathogenesis of chronic uveitis, excluding the syphilitic, tuberculous, and sympathetic varieties. Professor Fuchs (Vienna), Professor de Schweinitz (Philadelphia).

Friday, August 8th.—Glaucoma operations, with special reference to the comparative results obtained by iridectomy and its recent substitutes. Professor Lagrange (Bordeaux), Professor Priestley Smith (Birmingham), Lieutenant-Colonel Elliott (I.M.S.).

Monday, August 11th.—Affections of the eye produced by undue exposure to light. Professor C. von Hess (Munich), Mr. J. Herbert Parsons (London).

Tuesday, August 12th.—Anaphylaxis in its relation to ophthalmology. Dr. Morax (Paris), Dr. von Szily (Freiburg).

The afternoon sessions of the four above-mentioned days will be reserved for the reading and discussion of independent communications. Saturday morning, August 9th, has been set apart for demonstrations.

The sectional dinner will be held at the Connaught Rooms, Great Queen Street, on Thursday, August 7th, at 7.15 for 7.30 p.m., the president of the Section in the chair. Tickets, price £1 ls. inclusive, may be obtained from Mr. W. H. Jessop, 73, Harley Street, after July 1st. The President hopes to entertain members of the Section at luncheons at the De Vere Hotel, Kensington, at the termination of the morning sessions. The secretaries of the Section have also arranged to invite members to luncheons at the Rembrandt Hotel, Cromwell Road. A Ladies' Committee has been formed in order that suitable provision may be made for the entertainment of the wives and daughters of members of congress coming from abroad.

The honorary secretaries of the Section are: For London, Mr. J. B. Lawford, 99, Harley Street, W.; Mr. E. Treacher Collins, 17, Queen Anne Street, W. For Scotland, Dr. Geo. Mackay, 20, Drumsheugh Gardens, Edinburgh. For Ireland, Dr. L. Werner, 31, Merrion Square, Dublin.

SECTION OF NEUROPATHOLOGY.

The President is Sir David Ferrier, F.R.S., and the Secretaries Henry Head, F.R.S., and Dr. Fred. E. Batten. The meetings will take place in the Plant Physiology Laboratory of the Imperial College of Science and Technology, South Kensington.

The work of the Section will begin on Thursday, August 7th, at 9.30 a.m., when Dr. J. Babinski of Paris and Professor D. Rothmann of Berlin will open a discussion on the symptoms of cerebellar disease and their significance; and MM. André Thomas, M. Mendelssohn, Dr. R. Bárány, and others have signified their intention of taking part in the discussion. At 2.15 p.m. Dr. Bárány will give a demonstration of his method of investigating cases of cerebellar disease.

At the afternoon session, beginning at 3 p.m., a series of papers will be read.

On Friday, August 8th, Professor Déjerine of Paris and Professor Liepmann of Berlin will open a discussion on motor aphasia, anarthria, and apraxia. The discussion will be continued by Drs. Henri Claude, Ernest Dupré, Félix Rose, J. S. Collier, S. A. K. Wilson, V. Monokov, H. Gutzmann, and Heveroch.

At 3 p.m. a meeting will take place at the National Hospital, Queen Square, at which will be exhibited patients illustrating various forms of family and hereditary diseases of the nervous system. There will also be an exhibition of pathological specimens. Tea will be provided in the quadrangle of the hospital at 5 p.m., when it is hoped that ladies will be present.

The sectional dinner will be held at Princes Restaurant, Piccadilly, in the evening at 8 p.m. (Tickets, £1 ls.)

On Saturday, August 9th, Professor Oppenheim, of Berlin, and Professor Spiller, of Philadelphia, will open a discussion on the relations of the myopathies; it will be continued by Drs. Huet, Félix Rose, G. Etienne, Mendelssohn, Batten, Madame Long-Landry, and others. At 2 p.m. papers will be read.

On Monday, August 11th, a joint discussion will be held with the Surgical Section in the Jehangir Hall, University of London, South Kensington, on the treatment of tumours of the brain and the indications for operation. It will be opened by Professor Bruns (Hanover), Professor Cushing (Harvard), Professor v. Eiselsberg (Vienna), and Dr. Tooth. They will be followed by Drs. Babinski, Henri Claude, J. Sicard, Jumentié, de Martel, and others. At 3 p.m. papers will be read.

On Tuesday, August 12th, Dr. F. W. Mott and Professor Nomme (Hamburg) will open a discussion on the nature of the condition termed parasyphilis. The discussion will be continued by Drs. Déjerine, Babinski, J. Sicard, A. Léri, de Massary, Charpentier, Sézary, J. Tinel, G. Etienne, Head, McIntosh, and others. At 2 p.m. papers will be read.

RESEARCH DEFENCE SOCIETY.

Annual Meeting.

THE annual meeting of the Research Defence Society was held at the Royal College of Physicians on June 24th, Sir DAVID GILL, K.C.B., F.R.S. (President), in the chair. Among those present were Sir Thomas Barlow, Lord Cromer, Sir Hugh Bell, Mr. Waldorf Astor, M.P., Bishop Frodsham, sometime of North Queensland, Mr. Sydney Holland (Chairman of the Committee), Dr. F. M. Sandwith (Honorary Treasurer), Mr. Stephen Paget (the Honorary Secretary). Sir William Osler, who was to have spoken, was unable to be present, and expressions of regret for unavoidable absence were sent by Sir Clifford Allbutt, Mr. Otto Beit, Lord Blyth, Lord Robert Cecil, Lord Cheylesmore, Sir James Dewar, Sir Arthur Conan Doyle, Mr. McAdam Eccles, Lord Faber, Mr. Walter Guinness, Lord Claude Hamilton, Sir Norman Lockyer, Mr. Spencer Lyttelton, Lord Northbrook, Sir Gilbert Parker, Mr. W. F. D. Smith, Sir Edgar Speyer, the Bishop of Stepney, and Mr. Henry S. Wellcome.

Testimony of a Bishop.

Bishop FRODSHAM, who was allowed to speak before the regular proceedings began in order that he might fulfil an engagement elsewhere, said the society had justified its existence. Since its foundation in 1908 it had increased from a small handful to more than 5,000 members and associates. When he accepted the office of Vice-President he anticipated that he would receive a share in the abuse which fell upon the members of the medical profession, and he was not allowed to be disappointed in his anticipation. But he was surprised to receive a little four-paged tract entitled *An Atheistical Bishop*, and to find that he was considered to be that person! The root of his offending was that he was a member of the Research Defence Society, which was guilty of gross cruelty to animals, and therefore unfaithful to Christianity. He instanced that egregious pamphlet because it represented the unfair attacks against scientific research which were constantly being made, and which the society had done so much to refute. In the first place, the society confined its operations to the publication of facts, and only by considerable rhetorical licence could be said to be involved in any charges of cruelty. Then scientific research in this country did not connote cruelty. Lastly, it would be

difficult for objectors to construct a definite case in justification of the statement that research as it was carried on in this country was opposed to Christian teaching. He could with due modesty claim to have had more to do with obscure diseases than the majority of clergymen. There was nothing of which he was more proud in his life than of being instrumental in the formation of the Australian School of Tropical Medicine, where research work was being carried on. He humbly believed that it was an act of service to Him who said, "Inasmuch as ye do it unto one of the least of these My brethren ye do it unto Me." But he had done nothing in comparison with those members of the medical profession who were every day being held up to contumely and abuse. There were stages where the experiments upon animals ceased to be informative; then men experimented upon themselves. What could be said against the Christianity of those young American medical students who allowed themselves to be bitten by the *Stegomyia* mosquito in order to test how long the mosquito could be the host of the yellow fever germ? And yet these men were directly associated with medical research which involved experiments upon animals! He wondered how men who had never faced the horrors of unknown diseases, whose own lives were sheltered by the discoveries of science, dared raise their voice against the Christianity of those who showed over and over again their readiness to make the supreme act of applied Christianity: "Greater love hath no man than this, that a man lay down his life for his friends." During the past week a correspondent had at much trouble to himself copied out the opinions of ten "notable persons" on what he calls vivisection. The Bishop noted with interest that the oldest of these opinions was given in 1876—the last in 1884—thirty years ago! He believed that many people who were most conscientious in their opposition to medical research were condemning things which might have existed thirty years ago, but which did not exist now. His friend, Dr. Sandwith, asked him to give this society a "mundane benediction." He did not exactly know what he meant. But with grave deliberation and an earnest realization of his own responsibility as a minister of Christ, he declared from a Christian standpoint that he believed research was not only justifiable, but that it was an act of service to Him of whom no higher panegyric could have been written than that simple phrase, "Jesus of Nazareth who went about doing good."

Report of Committee.

The report of the Committee stated that during the past year they had gained more than 400 new members and associates, but they had lost by death many members and associates and eight vice-presidents. The following members of the society had accepted the office of vice-president:—Sir Hugh Bell, Sir John Rose Bradford, Sir Arthur Branfoot, Sir John Brunner, Sir Lauder Brunton, the Dean of Ely, Lord Harlech, Sir William Mather, and Sir John Tweedy. After giving an account of the work of the society in the past year, the report went on to state that during its course several bills had been before the House of Commons for the further restriction or total abolition of experiments on animals, and one of them had reached a second reading. The Home Office had appointed its new Advisory Committee in place of the Association for the Advancement of Medicine by Research. At the annual meeting on May 21st of the Royal Society for the Prevention of Cruelty to Animals, the re-election of Lord Cheylesmore to the council of that society was defeated on the ground that he was one of their Vice-Presidents. The number of those who belonged to both societies was about fifty. A strong protest was signed by them against this action of the older society. This protest was drawn up and sent out by their committee. The Council of the Royal Society for the Prevention of Cruelty to Animals, at a special meeting last week, decided to take a poll of all the members, so as to ascertain the general feeling of the society on this important matter. It was hoped that the answers to this referendum would have a good result.

Honorary Treasurer's Report.

Dr. F. M. SANDWITH, in presenting this report, said that the subscriptions received by the parent society in 1911 showed

an excess of £113, while the contributions from branches were also £100 in excess of the previous year. On the present occasion the subscriptions to the parent society showed a diminution of £106, while the contributions from the branches only slightly exceeded the amount paid during 1911. It was hoped that this was not due to any loss of interest in the society, but rather to the fact that many of their supporters considered it unnecessary to continue their subscriptions after the issue of the report of the Royal Commission on Vivisection. On the other hand, friends had nobly rallied round them again and had swelled the list of donations by responding to special appeals for funds towards the checkmating of the influence of temporary antivivisection shops.

Lord CROMER said he thought the vote by which Lord Chylesmore failed to secure re-election as a vice-president of the Society for the Protection of Animals did not represent the real opinion of the majority of the members of that society. If it were not rescinded he would withdraw from its membership.

Sir THOMAS BARLOW said the College of Physicians and the medical profession were deeply grateful to the society, not only because of the good work it had done in educating the public mind, but especially for the manner in which it had defended the men engaged in research. A few years ago such men were overwhelmed with abuse against which there was no organized system of defence. The Research Defence Society had changed that state of things, and had carried the war into the enemy's country. Sir Thomas Barlow paid a high tribute to the work of Mr. Stephen Paget, who had always carried on the controversy on behalf of research in a manner befitting an English gentleman. Those engaged in the actual practice of medicine and surgery were glad that their brethren who forged weapons for them by means of research should be defended against calumny by the society. "Their cause," he declared emphatically, "is our cause."

President's Address.

After some introductory remarks Sir DAVID GILL said the society was founded in January, 1908,

To make generally known the facts as to experiments on animals in this country, and the regulations under which they are conducted; the immense importance of such experiments to the welfare of mankind; and the great saving of human and animal life and health which is already due to them.

The need of such a society was due to the fact that efforts were being persistently made to bring about legislation which would have disastrous effects on the progress of medical science. As the result of these efforts there were at the present moment no less than four bills before Parliament:

1. The Hon. Stephen Coleridge's bill.
2. Sir Frederick Banbury's bill "To prohibit Experiments upon Dogs."
3. Mr. George Greenwood's bill, entitled "Cruelty to Animals Bill," its object being to carry out the minority reservations of the Royal Commission on Vivisection.
4. Mr. Chancellor's bill to provide for the total abolition of vivisection.

One of these bills—that of Sir Frederick Banbury to prohibit experiments on dogs—slipped through its second reading on Friday, January 6th, without opposition, because a bill dealing with the hours of polling, introduced by Mr. Pearce, the member for Limehouse, instead of occupying the whole day for discussion as had been anticipated, was suddenly withdrawn at 2 o'clock as the result of a compromise. The Dogs Bill was the second order of the day; and, as the House had emptied, an expert parliamentarian like Sir Frederick Banbury seized the opportunity, and got his second reading in a few moments without opposition. The bill had been sent to Grand Committee A, to which, in accordance with the usual practice, fifteen members have been added. It would then still have to pass the report and third reading stages in the House of Commons, and the chances of its so doing for a private member's bill were very slight. But no precautions to prevent its passing can be neglected, for Professor Starling's paper on The Use of Dogs in Scientific Experiments shows how essential such use was. This paper had been sent to every member of the Committee on the bill.

Sir David Gill proceeded: The bills above referred to have their origin chiefly in the efforts of the antivivisection societies to instil into the public mind the belief that

experiments on animals are needless to humanity, and that they involve cruelty to animals. Unfortunately these erroneous views have been accepted by many people as the result of reading misleading literature like *The Shambles of Science*, and by witnessing the disgusting and delusive objects exhibited by some of the antivivisection societies in their shop windows. The recent libel action—Miss Lind-af-Hageby v. Dr. Saleeby and the *Pall Mall Gazette*—proved, after a long and exhaustive trial, that the language published in the *Pall Mall Gazette* in condemnation of that class of literature and these exhibits was amply justified, and it is to be hoped that all respectable people will now withdraw their names from societies that employ such methods. The fact, however, remains that certain societies still continue to issue literature of the same misleading kind and to make disgusting exhibitions of a like character. In a shop in Kensington High Street there is exhibited a stuffed dog mounted in an apparatus of a formidable kind which has the following description:

"Vivisection Apparatus."

For firmly securing a live dog in a position for experimentation, supplied by Scientific Instrument Makers June 1910, consisting of a fixed board and NEW MUZZLE GAG according to Dr. W. Cowl (described in the Transactions of the Physiological Society).

This model is copied from a photograph of an animal taken whilst the instrument was in use.

The gag is made so as to be applied to the living animal without the use of an anaesthetic. It is furnished with adjustable nuts so that the mouth of the animal may be opened to any extent, and the tongue drawn out and fixed so as to expose the whole cavity of the throat.

I entered the shop, drew attention to the exhibit in question, and asked the person in charge whether it was intended to imply that, in this country, animals were thus vivisected without anaesthetics. The reply was:

Most certainly I do; look at that inscription, which is copied word for word from the catalogue of the maker of that machine.

This is an example of one of the methods by which public opinion on the subject of experiments on animals has been misled, for not only was the exhibit in itself delusive in character, but the statement made to me in defence of the suggestion was absolutely false; for, as we all know, no vivisection is allowed in this country without the use of anaesthetics. Other societies make like displays in other places, for apparently the law has no power to put a stop to such exhibitions, and doubtless the societies that continue to make them trust to the shortness of the memories of the persons to whom they appeal, and believe that the results of the Lind-af-Hageby action will be soon forgotten. It is refreshing to relate that Mr. Henry C. Sharpe, the owner of the shop above referred to, is so angry at the use to which his premises have been put, without his authority, that he caused the house agents on June 12th to hand over to the Research Defence Society the sum of £30, being the rent for the month of their tenancy paid by the antivivisectionists; he added that he will not take their money because it is "not clean." I am sure that this meeting will cordially render its heartiest thanks to Mr. Sharpe for this manly and generous action.

We cannot expect always to arrive at so satisfactory a solution of our difficulties as this, and therefore, for the reason above stated, it is necessary that our society should take active steps to counteract the misleading effects of such displays upon public opinion. On these grounds I most cordially concur in the view of the Committee—namely, that our society ought to have for the next few years a place of its own in London on the ground floor, with a window facing a good thoroughfare, where the true facts of our case can be quietly put before all passers-by—every day, and all day long.

For this object the Committee is making an appeal for a special fund, and I would urgently beg of all who are interested in our cause to aid this good work. A total sum of £600 is required, of which £240 has been already received. To-day I am informed that Mr. Henry S. Wellcome has made a gift of £100 to this special fund.

I am bound to say that there are some antivivisection

societies which do not make such exhibitions, but in too many cases their publications are hardly less reprehensible. Since most of these societies are mainly supported by worthy, well-meaning, and kind-hearted people, how comes it that such methods and such writings are tolerated by them? The fact is that these good people, as a rule, have neither read the original literature nor studied the results of experimental research on animals. They have probably, in the first place, been induced to join some antivivisection society by the delusive literature it has published, and such literature continues to be their only information.

There is an admirable leaflet recently published by our society, entitled "A School for Scandal," which attributes much of this misleading literature to the abuse of the practice of press-cutting. The point is there so well put that I quote it verbatim:

When rightly used, the Press Cutting Agency is a valuable means whereby a busy man may keep himself up to date in the literature of any subject in which he is interested, and qualify the impressions of his own experience by constant reference to those of others.

But when press-cutting is employed to prove some narrow point, and is applied to the purposes of special pleading, it is capable of the gravest misuse. By the aid of press-cutting agencies the employees of the antivivisection societies are enabled to ransack the whole of literature—books and periodicals, medical and lay, old and new, for cuttings consisting of illustrations, paragraphs, sentences, or in some cases single words, which, isolated from the context that is needed to show their real meaning, can be used to support one or both of these two ideas—namely, that experiments are useless, and that they involve cruelty. And the people who are engaged in the production of this concentrated extract of scissors and paste are the very last who are likely ever to realize how very misleading a product it is, both to producer and consumer.

The mistake is that the kindhearted enthusiasts who start antivivisection societies expect too much of human nature. They employ men and women as secretaries, keep them year in and year out at this sort of work, and they apparently expect them not to develop the instincts of the scandalmonger.

Does the habit of scandalmongering not grow fast enough upon men and women who indulge in it, without it being made a means of livelihood?

One is saying nothing against the moral character of those who compose the staffs of the antivivisection societies when one points out that the advent of the professional antivivisectionists destroyed the last hope that the societies they serve would ever be induced to look at the other side of the matter from their own, and that it is their presence more than anything else that keeps up that competition between the rival antivivisection societies, which would make it so difficult for any one of them, at this time of day, to lower its voice and moderate its tone.

There is besides the unconscious vanity of their individual leaders, each of whom enjoys a certain distinction in his or her present capacity, which would have to be sacrificed in a general merging of the societies into one. And there is the fact that among people who hold forth, as antivivisectionists do, upon a subject they do not understand, there is room for a confusion of ideas and for a tendency to work at cross-purposes, which do not affect the defenders of research, who only need one society to represent them, and who know that they can trust it.

If people before joining antivivisection societies would read the final report of the Royal Commission on Vivisection, and study its conclusions, they would learn the real truth of the matter. That Commission held more than seventy sittings, examined a very large number of witnesses, and published its report last year; and we read on p. 20 of the final report as follows:

We desire to state that the harrowing descriptions and illustrations of operations inflicted on animals, which are freely circulated by post, advertisement, or otherwise, are in many cases calculated to mislead the public, so far as they suggest that the animals in question were not under an anaesthetic. To represent that animals subjected to experiments in this country are wantonly tortured would, in our opinion, be absolutely false.

With reference to the administration of the law, the Commission makes certain unanimous recommendations in regard to the inspectorate and other matters which, on the whole, we as a society regard as perfectly right and reasonable, and to which few if any of the men I know who are engaged on research would object. On the contrary, they feel that if an increase of the inspectorate will lead to diminished misconception on the part of the public they will welcome the proposed increase. Formerly, there were three inspectors who also held other appointments. Now, in accordance with the recommendations of

the Royal Commission, there are to be four inspectors who will devote their whole time to the work. I see no reason why that number should not be increased if it is found to be really necessary for proper and legitimate inspection. The law of the land regards all men as honest and law-abiding unless they are proved to be otherwise—and proper and legitimate inspection provides means for detecting those who are not honest and law-abiding. But the proposal inserted in Mr. Greenwood's bill now before Parliament is that an inspector shall be present throughout the whole course of each experiment; in other words, it is assumed that every experimenter is wanting in honour and cruel of disposition.

The proposal is impracticable on the face of it, for no Government would agree to provide the number of inspectors that would be necessary; and, worst of all, it is an insult to a class of men who, so far as I know them, are conspicuous for their humane and honourable character. To impose conditions that are only applicable to "law breakers" or "ticket-of-leave" men is an indignity which we have no right to inflict on any honest class of men, least of all on those who are labouring earnestly for the good of humanity. Wanton cruelty is in every case reprehensible and wicked, and our society sternly sets its face against it, but the most terrible and far-reaching class of wanton cruelty to man and to the lower domestic animals is that which would result from the abolition or undue restriction of research, and thereby withhold from them benefits which in the past have been the means of saving many thousands of lives; and which, with increasing knowledge derived from such further research, must bring added health and length of life to many millions in the future.

Vote of Thanks.

SIR HUGH BELL, in proposing a vote of thanks to the President, expressed his agreement with Lord Cromer in regard to the vote of the Society for the Prevention of Cruelty to Animals, and said if the resolution were adhered to he also would withdraw from that body.

MR. WALDORF ASTOR, in seconding, made a strong appeal to the public for support. If they only could be made to realize the amount of preventable suffering and death that existed they would not wait, as he thought many now did, till they had lost some one dear to them before subscribing to the society and to hospitals.

MR. SYDNEY HOLLAND congratulated the members on the progress made by the society during last year. Referring to the bill for the prevention of the vivisection of dogs which had passed its second reading, he spoke of the gratitude all real lovers of dogs, like himself, owed to research on the diseases of these animals, especially distemper and malignant jaundice. He added that they had been jeered at for the small attendance at their meetings, but if those who came were not very many they were all in earnest, and it was their keen interest in the subject that brought them there. Mr. Stephen Coleridge had, he said, spoken of the annual meeting of the National Antivivisection Society as a packed meeting. He would not deny the appropriateness of the word "packed," for he had heard that the bulk of the audience had been increased by persons who had been brought to the Queen's Hall in brakes; each of these, he had been told, had received ninepence for coming. Another criticism that had been made was that they were really a vivisection defence society. Vivisection happened to be at present the only form of research attacked; if other forms were subjected to the same opposition they were prepared to defend them. He concluded with an earnest appeal for funds.

SIR DAVID GILL, in acknowledging the vote of thanks, said the society owed everything to Mr. Stephen Paget, who inspired and directed the work.

A NEW pathological institute was opened at Jena on May 31st. The building cost £25,000.

ACCORDING to the *Medical Record* of June 14th, the United States Senate on June 6th unanimously adopted the following resolution, which was introduced by Senator Bristow, of Kansas: "That the Secretary of the Treasury be and he is hereby directed, if not incompatible with the public interest, to transmit to the Senate such reports as have been made by officers of the United States Bureau of the Public Health and such documentary information as he may have upon the so-called tuberculosis cures."

HISTORICAL MEDICAL MUSEUM.

THE Historical Medical Museum at 54A, Wigmore Street, organized by Mr. Henry S. Wellcome, was formally opened by Dr. Norman Moore on June 24th. Among those present were Sir Thomas Barlow, Sir Rickman Godlee, Sir Frederick Treves, Sir F. Champneys, Sir George Savage, Dr. Dudley Buxton, and Mr. D'Arcy Power.

Address by Dr. Norman Moore.

DR. NORMAN MOORE said: I have been asked, as President of the Section of the History of Medicine in the International Congress of Medicine to be held in August, to preside over the opening of this museum. It will be a most important addition to the studies of the congress and will interest a great many of the 7,000 medical persons who are expected to attend. Museums are now so common that we forget what recent creations they are; they are a development from libraries. In the reign of Elizabeth, John Dee had a collection of mathematical and astronomical instruments and of various curiosities in his library at Mortlake, but the first considerable museum in England was that of John Tradescant, father and son, at Lambeth. The catalogue of the Tradescantian Museum was printed in 1656 and shows that it had fifteen sections, among which were birds, beasts, reptiles, weapons, and many dried plants and fruits, for the Tradescants were primarily gardeners and collectors of herbs. Their museum went to Elias Ashmole and was rearranged at Oxford, where most of us have seen one unique but dilapidated specimen—the head and foot of the dodo—the body having been destroyed in one of those periods of darkness to which all universities are liable.

Another great museum was found in London by James Petiver, an apothecary of the Charterhouse who was educated at Rugby School and at St. Bartholemew's Hospital. He was a botanist and entomologist, but the many sea captains whom he came to know brought him every kind of curiosity from all over the world. Sir Hans Sloane bought his collection and others, and made a great one of his own, and, as every one knows, bequeathed the whole under certain conditions to the nation. All these early museums were allied to libraries, and contained every kind of specimen, and this form the British Museum still retains. The museum of Francis Calceolari of Verona is described in a folio of 800 pages printed in 1622, and the picture of the museum shows the original form, which has developed into such a collection as is the British Museum. The specimens are in a well-proportioned room paved with variegated marble and surrounded by an ornate sort of dresser with drawers and shelves. At one end are books and on the shelves all round are specimens, some dried, some in jars. On one side is a statue of Atlas bearing the world, showing the regions whence the specimens have come, and on the other Minerva showing that all learning is included in the collection. On the cornice and hanging from the ceiling are stuffed animals of all kinds. Whatever the earth possesses, whatever had been hidden in the depths of the sea, the toil and skill of Calceolari had collected, says a Latin poem prefixed to the catalogue. The gift of Dr. William Hunter to the University of Glasgow was another museum of this type. It contains pathological, anatomical, and natural history specimens, manuscripts, pictures, early printed books, Greek and other coins.

A more limited kind of museum succeeded these vast collections. When Sir Edward Browne (son of Sir Thomas), having just taken his M.B. degree at Cambridge, came to London in 1664, he visited Edmund King, Surgeon to St. Bartholemew's, who showed him a collection of anatomical preparations. Woodward soon after made a small museum of geological specimens. Of these specialized museums the greatest was that of John Hunter, which is now under the care of the Royal College of Surgeons in Lincoln's Inn Fields.

The museum which we are here to open to-day has been formed by Mr. Wellcome, and is the first established in England to illustrate the history of medicine. A lectureship in the subject was founded at the Royal College of Physicians in 1901, and is at present the only one in England, though occasional lectures are given at Glasgow, and a professorship has been instituted at Edinburgh. This museum may justly be regarded as a further step in the establishment of the history of medicine as a regular study.

The origins of medicine may be studied in two directions. You can see in this hall two figures which typify these. There is Ixtilton, the Mexican god of healing, his head covered by a grotesque mask, a necklace of the teeth of the sperm whale round his neck, a curious instrument of enchantment in his right hand, seeming to have uttered some strange and terrifying ejaculation as he extended his left hand. Near him is the Apollo Belvidere, the most perfect of the sculptured representations of men, in his face showing the highest flights of thought and powers of observation. The figure of Ixtilton brings charms, amulets, and magical ceremonies before us at once. The figures of Apollo and of his son Asklepios suggest observation and experiment and reasoning, the clinical instincts of Hippocrates and Galen and Avicenna—a way of thought not disconnected from our own times, the true precursors of Harvey and Glisson, and Sydenham and Matthew Baillie, and Lister. It is this part of the history of medicine which interests me most, but other men prefer the study of incantations and of folklore. In the entrance hall these will find a fine collection of fetishes, of masks, and of strangely attired medicine men. The room in which we are meeting contains Egyptian, Chaldean, and other gods, a fine series of ancient models of morbid structures left as *ex-voto* offerings in temples, and collections of ancient dentistry, and of numerous instruments for operations. In the gallery are many drawings enlarged from illuminations illustrating medicine and surgery, and many cases of amulets. The next room contains portraits, busts, and medals, and beyond it is a room with medical pictures on its walls, and in its cases manuscripts—Latin, Arabic, and Persian—and early printed books on medicine and surgery. The basement has a series of scenes in the medical life of the past, beginning with a pharmacist's shop of the eighteenth century containing a fine collection of medicine pots and jars. Near this, on the ceiling, is painted the prescription for the Theriaca containing seventy-five ingredients, which, in a slightly modified form, remained in the London *Pharmacopoeia* till 1788. Next is an apothecary's shop in the Old Bailey in 1662. This was a contemporary of Francis Bernard, apothecary to St. Bartholemew's, who stayed in London throughout the plague of 1665. He was a most learned man and had a vast library of valuable books. Later in life he received a degree at Cambridge and became a physician. The Master of the Society of Apothecaries, who is here to-day, will support my statement that there were many apothecaries of similar learning. The laboratory of an alchemist stands next, and on the opposite wall are pictures relating to the plague, so that Ben Jonson's play comes into the mind and the pranks of *Subtle the Alchemist* in the house of a citizen who had left town because the plague was prevalent.

An early Italian pharmacy full of beautiful jars and vases shows us an apothecary who had thriven better than the Mantuan who had sold poison to Remco. The workshop of a Tudor barber-surgeon is also presented, and, last of the series, a Pompeian surgeon in his gaily painted house. The silver skeleton with turning joints and backbone mentioned by Petronius Arbiter shows how far a knowledge of anatomy had extended in the provincial Roman towns, and makes us hope that the surgeon was well informed in proportion.

Such are a few of the features of this remarkable museum. It is due to the munificence and the labours during several years of Mr. Henry S. Wellcome, while its arrangement has been admirably carried out by Mr. C. J. S. Thomson and Dr. L. W. Sambon. That the museum is due to the exertions of a private individual like those founded in past years by the Tradescants, Petiver, Sir Hans Sloane, William Hunter, Woodward, and John Hunter is a proper ground of pride for him and for the nation.

Votes of Thanks.

SIR THOMAS BARLOW, who is President of the International Medical Congress, proposed a vote of thanks to Dr. Norman Moore for his interesting and fascinating address. In connexion with museums the name of Sir Jonathan Hutchinsen, whom they had just lost, should be mentioned, for he had formed collections of all kinds for educational as well as scientific purposes. Sir Thomas Barlow made special mention of his tables and charts intended for the chronological study of the principal

events in human history. He paid a warm tribute to Mr. Wellcome, who had made, regardless of cost, a collection which gave unrivalled opportunities for the study of the history of medicine—a study most useful to doctors and interesting to all educated people.

Sir FREDERICK TREVES, in seconding, said the profession owed a debt of gratitude to Dr. Norman Moore for the immense services which he had rendered to the study of medical history. It would be hard to exaggerate the utility of such a museum as was opened that day. Progress in medical science was so rapid that it was well sometimes to pause and look back so as to see the steps by which the present state of knowledge had been reached. In regard to surgery, it was remarkable to note the narrow lines along which advance had been made. The study of the evolution of surgery made it to a certain extent possible to forecast its future development. Looking at the instruments there exhibited, the most striking feature was the steady advance from highly complicated to simple forms.

Sir RICKMAN GODLEE, in proposing a vote of thanks to Mr. Wellcome, congratulated him on a hobby which was at once delightful and useful. He had spent his time and wealth in the pursuit of a favourite study which now, after twelve years, had resulted in the formation of the splendid museum in which they were met. He understood that the collection was ultimately to be handed over to the nation. He did not know the locality that might be finally chosen for the housing of the museum, but he mentioned there was a fitting place in Lincoln's Inn Fields.

Sir FRANCIS CHAMPNEYS, who seconded, said he envied those who at the outset of their career had the opportunity offered by that museum of starting with a knowledge of how the foundations of the profession to which they were to devote themselves had been laid. Such a museum as they had there before them could not fail to excite the imagination of the medical student, and would enable him to begin with his mind set in the right direction.

Mr. WELLCOME, in acknowledging the vote that had been passed, made graceful reference to the advice he had received from Dr. Norman Moore, Mr. D'Arcy Power, Dr. Dudley Buxton, and other leading men in the medical profession, and to the invaluable assistance given by Mr. C. J. S. Thompson, Dr. L. Westerman Sambon, and other members of his staff. He also expressed his gratitude to the numerous persons who had lent or given objects for exhibition, and to the institutions which had contributed to the collection. The fact that the museum was connected with the International Medical Congress greatly enhanced its utility. Mr. Wellcome went on to announce his intention of forming a bureau of medical research in London. Of that bureau the head would be Dr. Andrew Balfour, whose brilliant work carried on for twelve years at Khartoum was known to all. The museum might form a fitting adjunct to the bureau. He said that the more he studied the older medicine the more he became convinced that it was not so bad as it was sometimes painted.

The visitors were then conducted by Mr. Wellcome round the museum. It is impossible to describe the exhibits in detail here. The collection is unique of its kind, and as nearly complete as well-directed knowledge and enthusiasm, reinforced by lavish expenditure on the part of Mr. Wellcome, can make it. It is intended to represent the evolution of the healing art in all its branches from its earliest beginnings. There is a magnificent show of fetishes, amulets, and charms of every age; numerous specimens of the "make up" of the medicine man of savage tribes; Roman votive offerings excavated chiefly at the Temple of Aesculapius on the Tiberine Island, and at the Temple of Maternity in Capua, and modern *ex votos* from Italy, Portugal, and other countries. Surgical instruments of all ages and nations, arranged as far as possible in the order of their development, make a most interesting display. There is a whole library of early printed books on medicine, and an interesting collection of old diplomas, some of which are real works of art. There are also numbers of personal relics, such as medicine chests that belonged to Nelson and Wellington, and a letter containing a prescription written by the victor of Waterloo to his apothecary; the first toothbrush used in this country, made for George III; letters and relics of Edward Jenner; the pocket surgical cases of Mungo Park and Livingstone; personal relics of

Guy, the founder of Guy's Hospital; illustrated books relating to touching for the king's evil; instruments of torture and apparatus for restraining lunatics; reproductions of ancient hospital wards, old apothecaries' shops, with numerous portraits of eminent medical men and paintings relating to the history of medicine. The history and present knowledge of plague, malaria, yellow fever, sleeping sickness, pellagra, and other tropical diseases, are illustrated by charts, maps, and diagrams prepared under the direction of Dr. L. W. Sambon, whose experiment in association with Dr. Low in the Campagna was the crucial test of the mosquito theory of malaria, and whose researches into the etiology of pellagra have already revolutionized the notions on the subject which previously held the field. The whole collection is tastefully and conveniently arranged. The museum, which will remain open till September, is not intended for the general public, but members of the medical profession, chemists, scientists and nurses in uniform will be admitted.

LITERARY NOTES.

In the April number of *Aesculape* Dr. Félix Régnault gives an account of modern anatomical *ex votos*. Ancient specimens are common in most museums. A fine collection of such *donaria* from ancient Rome may be seen in the Historical Medical Museum, of which a brief account appears on this page, and there are numbers of similar offerings belonging to the Gallo-Roman period in French museums. The use of *ex votos* is still common in Italy, Portugal, and elsewhere, but it may not be so generally known that such testimonies from gratified patients are found in South Germany and Tyrol. Dr. Régnault has visited as a scientific pilgrim the churches in these regions, and has found not only votive tablets recording cures like those in the ancient Greek Asclepieia, but representations in wax and in wood of parts which have been the seat of diseases believed to have been miraculously cured— hearts, ears, eyes, legs, feet, hands, busts, heads—even the penis and testicle. In Italy, Spain, and Greece the organs, though rudely modelled, are all normal; Dr. Régnault has sought almost in vain in those countries for an *ex voto* portraying disease. He has only found some specimens of eyes which appear to be intended to represent squint at Portici, near Naples, in the chapel of Saint Rita, who enjoys a reputation as a spiritual specialist in diseases of the eye. Sometimes, as in a church at Naples, there are voluminous bellies with large breasts suggestive of pregnancy; and occasionally a clubfoot may be seen, but this appearance may be due to the rudeness of the workmanship. In Bavaria and in Tyrol, on the other hand, pathological *ex votos* are common, and there are numerous specimens in the ethnographical museums of Berlin and Vienna. A very complete work on the subject, written by Richard André, was published at Brunswick in 1904. Many of the representations of organs are copied, as was the case in antiquity, from the corresponding parts of animals. Therefore Dr. Régnault holds that it is a mistake to suppose that the state of anatomical knowledge among the ancients may be inferred from these votive offerings. A noteworthy point is the symbolical representation of diseases of the uterus, which was looked upon by the old physicians as an animal having the power of independent motion. This belief still survived in the sixteenth century; the womb was conceived as a toad which bit the woman; the disease was healed by presenting an image of the offending animal to the divinity, and the cure was signalized by cramps and loss of blood. The cramps were represented by the image of a hedgehog or sea urchin. Males might also be attacked by the malevolent beast; hence arose the curious notion that, as shown by *ex votos*, men might suffer from disease of the womb. While in Italy and the East the *donaria* are usually fashioned of metal, in Germany they are mostly made of wood. Sometimes the patients buy a wax candle at the door of the church, and mould it themselves very roughly into the likeness of the affected part, as is told in Heine's pathetic ballad, "The Pilgrimage to Kevlar," where the mother is said to have taken a candle and made it into a heart, telling her lovesick son to offer it to the Mother of God, who would soothe his suffering.

British Medical Journal.

SATURDAY, JUNE 28TH, 1913.

ORGANIZATION OF MEDICAL RESEARCH.

THE official statement of the Chancellor of the Exchequer as to the organization of the work of medical research, for which provision was made in the Insurance Act, is printed in full in the SUPPLEMENT (page 585). An executive committee, styled the Medical Research Committee, and an Advisory Council are set up and their functions defined. The intention is to give the organization a wide scope, for the suggestion made in some quarters that the researches to be undertaken are to be confined to tuberculosis is incorrect. Section 16 (2) of the Insurance Act provides that one penny for each insured person (or about £58,000 a year in all) out of the moneys provided by Parliament may be applied, in accordance with regulations made by the Commissioners, for the purposes of research, and we understand that the decision of the law officers of the Crown is that the research may be undertaken in connexion with any disease to which insured persons are liable. It would manifestly have been very undesirable that the work of the Committee should be limited by any such restriction as has been suggested, and we are glad to find that such is not to be the case. The Committee will have a free hand to survey the field both from the point of view of the researches that may be necessary and of the social, statistical, or other inquiries which it may desire to institute. Owing to the nature of the case and to the conditions under which the Committee is appointed, a great deal of its work in the earlier stages will doubtless be in respect of the different problems associated with tuberculosis, but it is free, as it may be able or may find it necessary, to prosecute inquiries on collateral or other issues.

Various considerations have doubtless had weight in the decision to institute an Advisory Council of a large and representative character. Foremost amongst these is the fact that in the proposed scheme the moneys available for the four countries have been pooled in a common fund. This is a wise and statesmanlike proceeding, and we are heartily glad that it has been adopted. In connexion with this, however, it is manifest that the representatives of the four countries will be anxious to secure that their own peculiar problems or needs are not overlooked, owing to an undue or precipitate centralization of effort. The Advisory Council, as indicated in the statement issued by the Chancellor of the Exchequer, has been constituted after receiving advice from the various colleges and universities in the different kingdoms, and is intended to secure, amongst other things, that the Minister, before consenting to the plan proposed by the Research Committee, should be fully informed as to the criticisms put forward by a body of a widely representative character. It was doubtless felt that it would be a mistake to constitute a body such as the

Research Committee, whose sole purpose should be research and inquiry, on a strictly representative basis; that is to say, on a basis which should necessarily involve representation in due proportions upon it of the different parts of the United Kingdom.

Entirely apart from the problems which immediately need investigation, it will be a very important branch of the Committee's work to secure that a body of trained researchers shall be forthcoming in the future. One of the chief drawbacks which we have suffered in this country has been the fact that many men, who had both the disposition and the ability to prosecute useful research, have been deterred from following it because it afforded little or no prospect of providing them with a sufficient livelihood, and often they have had to dissipate their best energies by undertaking routine, "coaching," or other work in order to obtain an income, or to abandon their research altogether in order to take up practice. One of the most difficult tasks in front of the Committee will be to find and train men; but it will operate with this great and important advantage—that when it has found them it will be able to secure to them a sufficient livelihood.

We welcome also the arrangements which have been made to secure that the members of the Committee shall have sufficient length of office to secure continuity of plan and effort, while making provision for changes in its personnel at regular periods, so as to prevent its work becoming stereotyped or directed in too narrow a groove.

We have already discussed this great new departure in the relations of the Government to scientific work when the report of the Committee appointed to advise on the matter was issued. We pointed out the temptation which existed to embark on insufficiently considered schemes, and we insisted that the initial procedure should be the utilization to the full of the existing resources of the medical schools of the United Kingdom. We are glad to believe that what has now been done opens the way to such a policy. The task before the two administrative bodies instituted—the Medical Research Committee and the Advisory Council for Medical Research—is of the most arduous nature, and will call for constructive and administrative qualities of a very high order on the part of the members. It is no other than the creation of a machinery which shall organize and co-ordinate all the research workers in the United Kingdom who may be capable of furthering knowledge regarding the diseases of insured persons. The Chancellor of the Exchequer is to be congratulated on securing the services as the Chairman of both committees of Lord Moulton, for his pre-eminent qualities as a judge and his intimate acquaintance with the conditions of scientific work will appeal to all concerned. It is a further asset of the executive committee that it will have the services of Sir Clifford Allbutt, whose broad-minded views as to the equipment of the scientific physician are well known. All the proposals of the Committee must come under the review and criticism of the Advisory Council. This is a body on which all the interests concerned are represented, and the list of names of those who have consented to act on it will inspire general confidence. The considered opinion of its members, or even of a majority of them, on any question will be difficult to resist.

The situation which will develop during the next few months as the result of the deliberations of these two bodies will be of great interest, and we trust will ensure the full utilization of the great

opportunities which the research scheme presents for investigating tuberculosis and the other diseases which exact so heavy a toll from the industrial classes. The results of these investigations will, it cannot be doubted, place in our hands new and more effective means of combating these diseases—of preventing their occurrence, and of treating the sufferers to their own greater benefit and to the welfare of the community to-day and our successors in the future.

THE COMFORTS AND DISCOMFORTS OF OLD AGE.

THE attainment of healthy old age is probably the secret desire of every one, but only a few are privileged to achieve it. To some, even in perfect health, the later years may be attended with "labour and sorrow," but, as a rule, it may be noted that aged persons cling to the hope of extended life with as much tenacity as at any other period of their career. To what extent our days may be prolonged by "taking thought" has afforded a theme for many writers in times past, and the subject is once more brought into prominence by the appearance of a work on the subject by Dr. Saundby.¹ A physician of long experience and wide acquaintance with families of varying longevity cannot fail to have observed the practical bearing for good or evil of habits and peculiarities of living in the earlier stages of life. He must also have had constant opportunity of watching the gradual onset of disease in old persons, and of the conditions which have been operative in producing it.

The obituary columns of the daily papers lead every one to assume that a much larger proportion of the population reach old age than was formerly the case. This may not be entirely accurate, but some reasons why longevity should increase are obvious, and may be attributed primarily to the wider spread of education and common sense. It is no longer considered contemptible for a man to drink only when he is thirsty, nor does any glory attach to his ability to swallow more alcoholic liquor than another without getting intoxicated. It is no longer considered effeminate to take reasonable precautions against cold and wet; but, at the same time, it has been abundantly proved by armies in the field that hardships can be endured with as much stoicism as in the "good old days" before the umbrella had become an institution.

Middle-aged readers will doubtless remember the effort made some twenty-five years ago by Professor Humphry to ascertain by the process of collective investigation whether any common rules of life could be traced amongst octogenarians and other still more aged persons. The returns made by a very large number of contributors proved that in the majority of instances of life extended beyond the normal span there was a consistent history of sound physical health from birth upwards, and that in many cases a high standard of structural perfection and outward comeliness was manifest. Thus it was evident that such persons owed more to heredity than to their own observance of hygienic rules, but in most of the cases the records told of constant activity, moderation in diet, and powers of abundant sleep. Proof, however, was not lacking that, even without the advantages of inherited

physical perfection, a very considerable number of persons lived to fourscore years by simple attention to the ordinary rules of health after they had passed the age at which the downward grade is supposed to begin.

In the discussion of the manifestations of old age and the precautions that must be observed if health is to be maintained, Dr. Saundby is able to draw upon the writings of distinguished octogenarians who have put their own experiences on record. From them we may extract two cardinal points which deserve most careful consideration from all who are, or would be, in the full enjoyment of old age. The first of these is exercise, a point upon which there is almost complete unanimity. The old man cannot take violent exercise, and games are not for him. No form of activity suits him so well as walking, but he must do it regularly and graduate the time and the distance by his reserve of physical power, always taking care to stop short of actual fatigue. The neglect of such exercise has led in countless cases to premature failure of health directly traceable to retention of effete substances, which might have been effectively prevented from accumulating by the very simple expedient of an hour's daily walk. The second cardinal point to be observed by the would-be octogenarian is in relation to diet. Not so much the quality as the quantity of food which he takes may influence his chances of longevity. As a man gets older he must no longer persist in his custom of eating more than is actually necessary to supply the wastage of the day's work. As he approaches the period of old age he may even take less than is actually required, and may suffer no greater harm than loss of superfluous fat; and this in the long run may prove to be a gain. Neglect of this rule is responsible for much disappointment as age advances. Indigestion and goutiness not only undermine the vigour of the individual, but they cause him a vast deal of suffering which might have been avoided had the rules of dietetic prudence been followed out.

But in spite of all care and precaution, it must happen that disease will come, and old age is prone to a very large number of ailments which may materially interfere with the enjoyment of later years. While all the organs are liable to functional disorder of some kind as their blood supply becomes modified by defective blood vessels, it is the nervous system which is chiefly prone to undergo damaging changes, having far-reaching though not necessarily fatal results. The curious loss of memory by which almost all elderly persons are affected was aptly described by Sir George Humphry when he said that old men were fond of telling tales of long ago—but they were apt to forget that they had just told them. Lapses of memory, slight attacks of vertigo, tremors, and general loss of enthusiasm and emulation are common symptoms as years advance. The graver forms of cerebral disturbance are too often productive of a form of living death which, as Dr. Saundby observes, is more to be dreaded than a sudden passing away in the midst of life.

Treatment claims a large place in the book, and a great deal of useful information will be found as to dieting and the general management of the disorders of advanced life, conveyed in an interesting form and interspersed with accounts of much personal experience which make the book at once readable and instructive. Although able to look back upon a fairly long series of years, the writer betrays no sign of senility in his own work, and the most recent theories and methods find their due expression.

¹ *Old Age: Its Care and Treatment in Health and Disease.* By Robert Saundby, M.D., Edin., F.R.C.P. London: Edward Arnold, 1913. (Cr. 8vo, pp. 320. Price 7s. 6d. net.)

CHARGES AGAINST DOCTORS IN CONNEXION WITH THE INSURANCE ACT.

THERE has been quite an epidemic in the daily papers recently of charges made by officials of friendly societies against doctors with respect to certificates given under the Insurance Act. It is, for instance, reported that at the biennial assembly of the United Order of Ancient Druids a Mr. Ward of London said that the doctors in his district were paralysing the efforts of the Order, and that he knew of a case where a doctor had given a man six certificates in advance, to be used as required. At the same meeting a Mr. W. J. Luff of Portsmouth is reported to have said that when the doctors of his district were rushed on the panel they said, "We will take it out of you for this," and other similar statements were made. The assembly passed a resolution calling upon the Commissioners to take a strong course in respect of excessive sickness rates with a view to bringing about a more efficient medical supervision. At the Scottish National Conference of Affiliated Friendly Societies in Edinburgh on June 21st the President referred regretfully to the removal of the administration of medical benefits from friendly societies, and "to the consequent wholesale malingering which that has led to." The Grand Master of the Manchester Unity is reported to have told an interviewer that "the excessive drain on the sick funds of my society is due to unsatisfactory administration of the medical benefit. The doctors are in part overworked, in part slack, and in part vindictive." Mr. Rockliffe, Secretary to the Joint Committee of Approved Societies, alleged that certificates were given by panel doctors in many districts without regard to the capacity or otherwise of the individual to work, and the Treasurer of the Royal Liver Friendly Society that in some cases doctors were helping members to malingering. It may be said, and said, we do not doubt, with a good deal of truth, that charges such as these are merely evidence of an organized campaign to induce politicians to believe that the only remedy for the evil painted in these lurid colours is to hand over the administration of medical benefit, "the control of the doctors" it is called, to the friendly societies. But the charges have been publicly made, and the honour and interests of the medical profession as a whole, which the British Medical Association exists to maintain, demand that they should be sifted, and, if substantiated, that the offenders should be punished. The charge seems to be that medical practitioners cannot be trusted to give certificates to their insurance patients, either because they are desirous of making things easy for themselves, or, as it is maliciously insinuated, because they desire to damage the Insurance Act. But if there is anything in the charge of giving certificates out of mere slackness, it would apply with equal force to the private practitioner dealing with his private patients, because the contention apparently is that the doctor is afraid to act according to his convictions, and gives the certificate merely to please his patient. The profession of medicine, like other professions, no doubt contains some members who do not come up to its highest ethical standard, but its record will show that these loose charges of general dishonesty and want of backbone are absurd. Charges of slackness in certification are, it is true, not altogether new. The friendly societies often enough complained of their club doctors on this ground, and it is possible that if asked to certify in the case of one of the influential members of a club the practitioner did not always take a very stern view of the case when he knew that such a course might lead to much trouble and vexation, ending, perhaps, in the loss of the club. The situation of a practitioner under the Insurance Act is in this respect more favourable. If he takes a strong line and declines to give a certificate in any particular case,

his loss at the worst will be restricted to the patient offended, and perhaps a few of his friends, and even they, by the time they are at liberty to take their names off his list, may have come to the conclusion that their health will be safer in the hands of a man who knows his business and is not afraid to take a strong line than in those of some one who might be more complacent. Whatever the views of individual medical men may be in regard to the Insurance Act, the members of the profession, we feel sure, must universally recognize the honourable obligation to act with absolute fairness and impartiality if they, for any reason, have undertaken to do work under the Act at all. The charges so publicly made seriously affect the honour and good name of the profession, and we trust that those officials of the approved societies who have attacked the profession will take early steps either to substantiate the charges or to apologize for having made them. There is one other aspect of the matter to which it seems desirable to make reference. As has already been hinted, it is certain that increased calls on the funds of the approved societies will lead to a demand by them for control over the doctors and greater supervision of their work. Practitioners who do not use the greatest discretion in the matter of certification are doing a great disservice to the profession, not only to its reputation, but because they may unconsciously help on the demand, as an alternative, for a national whole-time medical service, which we believe the bulk of the profession is far from wishing to see established. In making these remarks we wish it to be clearly understood that in our opinion much of the trouble which the approved societies are now experiencing has been brought upon themselves by their anxiety to enrol in their ranks as many insured persons as possible without any reference to their physical condition. The inevitable result is that they are now suffering from the claims made by a class of life which is quite different from the average some of them were previously accustomed to deal with. Many of the complaints are in respect of women, and there is no doubt that most of the friendly societies had very little experience of the insurance of women against sickness, and are now realizing that they and the State have been to a certain extent gambling with a comparatively unknown factor. The State will have to meet its own difficulties, but the profession must boldly face those which threaten its reputation for honesty and self-respect. While our anxiety is for the good name of the profession, we would suggest that it is the duty of the Commissioners, who are responsible for the protection of the insured person and to whom the information in the press is available equally with ourselves, to insist that the charges we have mentioned shall be probed to the bottom.

MALINGERING UNDER THE INSURANCE ACT.

IN a recent number of the *National Insurance Gazette* Mr. J. Redman Ormerod strongly urged that, instead of medical examiners appointed by approved societies, "a more effective, reliable, and generally acceptable plan would be for the State to appoint in each district an expert medical examiner, especially one with a knowledge of working class conditions, habits, etc., who should be employed and remunerated by the State and entirely independent." Mr. Ormerod is vice-chairman of the Lancashire County Insurance Committee and also a member of the managing board of the National Amalgamated Approved Society, and is thus in a good position to know how great a strain is at present being placed on the sickness funds of the societies. He points out that in practically all cases the rules of approved societies provide that disputes between members and societies shall be decided by

arbitration, and Section 67 of the National Insurance Act gives leave to any party to such dispute to appeal from such decision to the Insurance Commissioners, but he holds that in practice it would be more costly to a society to conduct an inquiry by arbitration with the risk of further inquiry by the Commissioners than to continue to pay the malingerer. Mr. Ormerod evidently realizes the difficulties which doctors on the panel at present experience in dealing with malingering, and, while urging that medical referees should be doctors acquainted with the conditions of practice among the insured, he says "few panel doctors would care to take the possible risk to the patient and to the doctor's own interests by refusing to certify the insured person to be sick if that insured person declared he suffered the pains, etc., of sickness. It is necessary to relieve the panel doctor of having to exercise any judicial powers in respect of any of his patients, and the only way in which that can be done is to have medical examiners who are not panel doctors, and who are entirely independent." He therefore suggests that in the proposed amending Act, Section 67 should be altered so as to remove disputes regarding sickness benefits, etc., from the jurisdiction of the Insurance Commissioners, and to place them under the absolute jurisdiction of a State medical officer, or of a medical examining board in each district. The editor of the *National Insurance Gazette* considers that Mr. Ormerod's scheme goes to the root of the matter more completely than any other scheme, and may have to be adopted in the end; but he sees a difficulty, because it is understood that the Government will refuse to find any more money. In any case, he thinks that, even if the State will not pay, any amending bill should include a clause giving official medical referees final powers of decision, as "this would be at least a valuable alternative to the clumsy examination, arbitration, appeal proceedings imposed by the rules." While the discussion was still going on as to the advisability of appointing medical referees, the Bristol Insurance Committee so long ago as the beginning of February last appointed Dr. Bertram Rogers as part time medical referee, and in our present issue, page 1367, he relates his experience down to a recent date. Out of 100 suspected cases receiving sickness benefit, Dr. Rogers had to report 43 as really fit for work. He says that the number of actual malingerers, meaning by this apparently persons who falsely pretended to be ill when they were not, was small. The funds of the approved societies according to his experience suffer far more from valetudinarianism than from actual malingering. Most doctors on the panel will make short work with the gross forms of malingering, but they frequently find great difficulty in dealing with valetudinarianism. When a doctor has attended a patient during a long and perhaps dangerous illness, it is often a very fine question to decide when to sign the patient off as fit for work, and he properly gets the benefit of the least doubt especially if he has lost a situation through the illness, even though the sickness funds may have to suffer in consequence. In these cases, more than in cases of fraudulent malingering, an independent medical referee may be of great service to the panel doctors, always provided that the referee is a man of wide practical experience in dealing with the special difficulties of the working classes and refrains from all unwarranted interference with the practitioners in attendance.

THE DISABILITIES OF MEDICAL OFFICERS OF HEALTH.

ΑΙΤΙΟΤΗΤΗ, owing to the rules of the House of Commons, and in consequence of the factious opposition of a small group of members, there is little possibility of any progress being made this session with the Medical Officers of Health (Superannuation) Bill, Sir Philip Magnus, who has charge of the bill, has succeeded in another way in giving prominence to some of the disabilities under which

a considerable number of medical officers of health are carrying on their work. In a very comprehensive and withal concise question, addressed to the Prime Minister on June 18th, he suggested the appointment of a committee to inquire generally into the conditions of service of medical officers of health. He apparently had in mind the insecurity of tenure of office of district and borough medical officers of health and the absence of any form of superannuation for, practically, all these officials. He included also in his question the important implication that many officers have to pay out of their salaries the expenses connected with the discharge of their duties. The full meaning of this last can best be appreciated when it is stated that the additional duties under the Housing (Inspection of Districts) Regulations, 1910, and under the last Tuberculosis Order of the Local Government Board have increased the travelling expenses of many medical officers of health by two or three hundred pounds annually, and, although the Board has intimated that it is quite prepared to sanction a corresponding increase in salary, such increase can be granted only with the acquiescence of the electing authorities, many of whom are not at all eager to increase the local rates for the purpose of carrying out more efficiently legislation with which they may not be altogether in accord. The present President of the Local Government Board has been credited in some quarters with a lack of sympathy with medical officers of health and with their work; it is therefore gratifying to find from his reply to Sir Philip Magnus, on behalf of the Prime Minister, that he is considering the question of the extension of the principle of fixity of tenure of whole-time officials and other aspects of the matter in the light of changes introduced by recent legislation. He also promised to give careful consideration to the suggestion of appointing a committee of inquiry. It could hardly have been expected that any more definite reply would be given, and medical officers of health must be satisfied with knowing that the reforms in the public health service which they have been demanding for years are at any rate being considered. This means a great deal in the light of the *non possumus* attitude hitherto adopted by the Board.

JOHN LOCKE AS A PHYSICIAN.

It was mentioned recently in the *JOURNAL* that John Locke, the philosopher, was originally a physician. According to the *Encyclopaedia Britannica*, he did not take a medical degree, though his friends called him "doctor." In the *Nugae Chirurgicae* of William Wadd, Surgeon Extraordinary to George IV, however, it is stated that Locke took the degree of Bachelor of Medicine at Oxford, where he was practising when he became acquainted with Lord Ashley, afterwards Earl of Shaftesbury and Lord Chancellor. The history of Locke's connexion with him is interesting as showing how much a man's destiny is determined by accident. Ashley had been advised to drink the mineral waters at Acton for an abscess in his breast, and he wrote to Dr. Thomas, a physician at Oxford, to procure a quantity of those waters to be ready against his going there. Thomas was called away by other business and asked Locke to see to the matter for him. Locke, having entrusted the business to a person who failed him, was obliged himself to wait upon the noble patient and apologize for the disappointment. Lord Ashley received him with great civility, and being much pleased with his conversation detained him to supper and engaged him to dinner the next day. He even pushed his courtesy to an extent that might be inconvenient to physicians, if it became a general custom, by asking Locke to drink the waters with him. This was with the object of having the doctor's company both that and the following summer of 1667. Afterwards Lord Ashley invited Locke to his house and followed his advice as to having the abscess in his breast opened; the operation saved his life though the

would never closed. The success of the treatment gave Lord Ashley a great opinion of Locke's skill in physic; yet upon a further acquaintance he regarded this as the least of his qualifications. He therefore advised Locke to turn his thoughts another way, and would not suffer him to practise physic out of his house except among some of his particular friends. He urged him to apply himself to the study of political subjects, both ecclesiastical and civil. This advice proved very agreeable to Locke's mental temper, and he quickly made so considerable a progress in the study of these matters that he was consulted by his patron upon all occasions. Ashley likewise introduced him to the Duke of Buckingham, the Earl of Halifax, and others of the most eminent persons of that time. About 1669 Locke accompanied the Countess of Northumberland to France with her husband, but the Earl dying at Turin in May, 1670, he returned with the Countess to England. He afterwards lived as before in the house of Lord Ashley, then Chancellor of the Exchequer. Ashley having, jointly with some other lords, obtained a grant of Carolina, employed Locke to draw up the fundamental constitutions of that province. Locke still retained his studentship at Christchurch, and he went occasionally to reside there for the sake of books and study, as well as the air, that of London aggravating an asthma from which he suffered. His connexion with Shaftesbury enabled him to see political actions from their origin to their result. The larger sphere of London life gave scope for his great faculties. He was intimate with Sydenham, and became a Fellow of the Royal Society, on the Council of which he served. After the fall of Shaftesbury in 1675 Locke went to France, where he spent three years, partly at Montpellier and partly in Paris. He always retained his interest in medicine, and he gives an amusing account of the elaborate ritual with which the degree of doctor of medicine was conferred at Montpellier. With Locke as a philosopher, or even a politician, it is not within our province to deal.

A PLACENTAL CAUSE FOR THE OVER-WEIGHT FETUS.
