necessary to say of what value to the practitioner will be the assurance of the non-existence of pectoriloquy in the one of these cases and its existence in the other. In the latter case, *the voice from the chest* may announce the speedy approach of suffering, and sorrow, and death, perhaps amid all the outward semblances of health; and in the former, its silence to all our questioning may not merely bid hope take the place of despair in the breast of friends, but may awaken the physician from the torpor of inactivity, and induce him to adopt such measures as may convert this hope into certainty.

**AUSCULTATION OF THE HEART.**—If we apply the ear, with or without the stethoscope, to the cardiac region of a person in health, we perceive, most distinctly, a series of sounds of a very marked and peculiar kind, subdivided into uniform parts by a brief interval of silence, after every second sound. Two sounds follow each other instantly, or within so short a space that the ear separates them rather by difference in their quality than from the intervention of any notable cessation of sound: then ensues a brief but well marked pause, which is again succeeded by the first of the twin sounds. This series of sounds may be perfectly well represented, as to rhythm, by musical notation. The relative duration of the sounds and pause is represented by Laennec to be nearly as follows: the whole being divided into four parts, two of these are occupied by the first sound, and one by the second sound and the pause respectively. The two sounds differ in kind as well as in duration. The first is nearly double the length of the second, of a graver and more subdued tone, rather louder at its commencement than at its termination, as if it was about to die away when suddenly interrupted by the second. The second is brief, smart, and clear, like a gentle tap with the pulp of the finger on a solid table, or, according to Laennec's comparisons, like the sharp sound produced by the falling back of a valve, the cracking of a whip, or the lapping of a dog. Exactly synchronous with the first sound, there is perceptible, in most cases, a well marked impulse or shock, communicated evidently by a body in motion within, to the walls of the chest. Every one acquainted with anatomy and physiology will at once conclude that the sounds and impulse just described are produced by the motions of the heart; and this conclusion will be justified and confirmed by an examination of the pulse in the extremities. It will be found, in all healthy subjects, that there is an invariable connexion between the sounds and the pulse, every stroke of the latter corresponding very accurately with every repetition of the twin sounds. As, under every variation of circumstances as to loudness, frequency, &c., the same exact relation is perceived, it cannot be doubted that there exists an essential physical connexion between the causes of the sounds and the pulse.

For a long time after the discovery of mediate auscultation, no doubt was entertained that the exposition of the motions and sounds

of the heart, given by Laennec, was the true one. He asserted that the first of the two sounds accompanied and was caused by the contraction of the ventricles; the second by the contraction of the auricles; and that the pause intervened between the auricular and the ventricular sounds. As a necessary consequence of this doctrine, he taught that in the natural rhythm of the heart, the ventricular systole comes first; is followed immediately by the auricular systole; and this, in its turn, by the interval of repose.

The accuracy of these statements of Laennec was first called in question by Mr. Turner, in a paper published in the third vol. of the *Edin. Med. and Chir. Transactions*; and the subject has been since more completely illustrated by the observations and experiments of Drs. Corrigan, Stokes, and Hope.\* The experiments of the last-named physician made on large animals (asses) are particularly deserving our attention and confidence. They are of such a kind, indeed, as, in our opinion, to set the question at rest; the results having been repeatedly witnessed by many most competent judges, and being in complete accordance with the pathological phenomena observed in the human subject, during life and in the dead body. Dr. Hope has recently repeated his experiments, with results precisely similar to those formerly obtained, and has been kind enough to favour us with a sketch of the natural movements of the heart and the relation of the sounds to them. This we shall here give almost in Dr. Hope's own words, being happy to avail ourselves of an authority so deservedly high, founded as it is on the most extensive observation particularly devoted to the subject.

*Rhythm of the heart.*—The first motion of the heart which interrupts the interval of repose, is the auricular systole. It is a very slight and brief contractile movement, more considerable in the auricular appendix than elsewhere, and propagated with a rapid vermicular motion towards the ventricle, in the systole of which it terminates rather by continuity of action than by the succession of a new movement. The ventricular systole commences suddenly, and is accompanied with a considerable diminution of the volume of the organ. Synchronous with the systole are the first sound, the impulse of the apex against the ribs, and the pulse in vessels near the heart: in the radials the pulse follows at a barely appreciable interval. The systole of the ventricles is followed by their diastole, during which they return, by an instantaneous expansive movement sensible to the touch and sight, to the same state (with respect to size, shape, position, &c.) as during the previous interval of repose. This movement, or diastole, is accompanied by the second sound, by an influx of blood from the auricle, by a retractile motion of this cavity most observable at its sinus, and by a retrocession of the apex of the heart from the walls of the chest. Next succeeds the interval of repose,

\* See the communications of these gentlemen in the *Lancet*, *Edinb. Journal*, and *Med. Gazette*.

during which the ventricles remain at rest, in a state of fulness, though not of distension, through the whole period intervening between the second and the first sounds; but the auricle remains at rest during the first portion only of that period, the remainder being occupied by its next contraction, with which recommences the series of actions described.

The duration of the several parts of a beat is the same as described by Laennec; namely,

1. The ventricular systole occupies half the time, or thereabouts, of a whole beat.

2. The ventricular diastole occupies one-fourth, or at most one-third.

3. The interval of ventricular repose occupies one-fourth, or rather less, during the latter half of which the auricular systole takes place.

*Causes of the motions.*—The auricles, which are always in a state of fulness, arrive, during the first half of the period of ventricular repose, at the state of distension, by which they are stimulated to contract. The object of the contraction at this moment is to propel a small additional quantity of blood into the ventricles, for the purpose of bringing them from the state of fulness to that of distension; an object which could not be accomplished without a contraction, as the blood could not otherwise force its way into the ventricles against the resistance offered by their elasticity. These cavities, then, being brought to the state of distension, are by this stimulated to contract: they expel a greater or less proportion of their contents: in small animals, frogs for instance, they expel the whole; which is proved by the ventricle becoming pale. In large animals they do not appear to expel the whole, but the fact does not admit of demonstration. During the act of expulsion, the apex is tilted up, in consequence of the retraction of the ventricles towards the base and upon the auricles, which, in a state of extreme distension, are placed like a fulcrum beneath them. The diastole appears to be occasioned by several concurrent causes, viz. 1. That power of the muscle by which it reverts from the state of contraction to that of relaxation, and in virtue of which it exercises a degree of motion. It may be called *elasticity* until its nature is more positively determined. 2. The distension of the auricles, which is greater at this moment than at any other, as they have been filling during a longer period; namely, that of the ventricular contraction, or half a whole beat. 3. The weight of the ventricles collapsing on the distended auricles underneath them. 4. The width of the auriculo-ventricular orifice, which allows the blood to shoot in instantaneously and with great facility. It is obvious that, as so many powerful causes conspire to promote the influx of the blood, an auricular contraction for this purpose, as imagined by Laennec, would be superfluous. The escape of blood from the auricles during the diastole, causes the slight retraction observable in them at the same moment. The expelled blood being instantly replaced from the *venæ cavæ*, distension of the auricles recommences, and the same series of actions is renewed.

*Causes of the sounds.*—The ventricular systole is the cause of the first sound, by the impulse which it communicates to the blood within it, thereby exciting sonorous vibrations of that fluid. If the sound of the muscular contraction contributes at all to the first sound, it can be only in a very slight degree. The ventricular diastole is the cause of the second sound, by the re-action of the walls on the blood, and the consequent production of sonorous vibrations, when its course is abruptly arrested by the completion of the diastole. Hence this sound is loud, brief, and clear. The auricles are not concerned in the production of the *two* sounds, as they take place when these cavities are motionless; nor do they appear to be productive of any sound, as no *third* sound is audible.

We now proceed to examine more minutely the phenomena produced by the actions of the heart, in health and disease, with the view to deduce therefrom such diagnostic signs as they are capable of affording. It is hardly necessary to premise that the auscultatory diagnostics of cardiac diseases are founded precisely on the same principles as those which apply to diseases of the lungs. We have certain natural sounds and movements, depending on the physical structure and natural action of the parts, and therefore of constant occurrence in the state of health. These sounds and movements are changed from their normal character by disease, in a certain determinate manner, in accordance with the known laws of physics. If we are acquainted with the movements and sounds of health, and with their various relations, we can have no difficulty in detecting their morbid deviations. And as these deviations depend on fixed physical changes of structure, just as the normal sounds depend on the normal structure, the study of the former sounds will enable us to ascertain the existence of the morbid causes, as in the other case, the sounds of health indicated the presence of the normal structure.

In strictness of language, auscultation can only take cognizance of *the sounds* which accompany the motions of the heart. As, however, these sounds are intimately connected with the shock or impulse communicated to the side, and as this important sign is appreciated by the same organ (the ear), though not by the same sense, it has been customary to consider it along with the phenomena of sound and rhythm, which are strictly referable to the sense of hearing. As this arrangement is extremely convenient, we shall adopt it in the present article; and shall, indeed, commence with the consideration of the phenomenon which, in a philosophical arrangement, could not be admitted at all.

I. *Impulse.*—This, as we have already said, is, in the state of health, always coincident with the first sound. It is not, however, exclusively confined to this period of time in the state of disease. The impulse may vary from the ordinary standard in different individuals in health, and in the same individual in disease: 1. in the period of its occurrence, or its re-

lation to the sounds; 2. in its individual character, particularly in its degree or intensity; 3. in its sphere, or the extent of chest over which it is perceptible.

1. Although the impulse is usually synchronous with the first sound, and with this only, it occasionally accompanies the second sound also. This, however, is of rare occurrence, and is only met with in a particular form of disease. It has also a very different character from the normal impulse which accompanies the first sound. It is perceived, according to Laennec, to have its origin much deeper within the chest than the other stroke, and, in giving it, the heart seems to be receding from the ear. Most commonly it consists merely of a sort of trembling felt deep within the mediastinum; and it is always very slight in degree when compared with the normal impulse. Dr. Hope terms this second impulse *the back stroke*, and considers it as in a great measure confined to cases of hypertrophy with dilatation; or, rather, that it is observed more particularly in this disease when existing in a great degree.

2. There is great difference among individuals in perfect health respecting the degree of impulse. In some no impulse can be detected either by the hand or stethoscope; in others it is imperceptible by the hand, and very perceptible by the stethoscope; and in some rare instances it appears on the application of the hand to be very great, at the same time that the instrument conveys only a slight impulse. These varieties depend on fixed physical causes, although they may not be readily explicable in every case. In lean subjects all movements as well as sounds are more perceptible from the greater susceptibility of the chests of such persons to vibrate, and their greater conducting power. In nervous flurry, the heart acts tumultuously and not powerfully, producing rather a general commotion than impulse; hence the effect is more distinct to the hand than to the stethoscope. In general, the impulse consists simply of the sensation of a slight blow or shock, communicated to the spot on which the hand or instrument rests, sometimes sufficiently strong to produce a perceptible elevation of the part, at other times only having sufficient power to occasion a sort of vibration without upward movement. Sometimes the body that gives the shock appears to be of large extent, sometimes quite small. The blows are sometimes quite distinct and abruptly defined; at other times they seem to run into each other. The causes of these differences are also well known. The brief, sharp impulse corresponds with a sudden abrupt blow, unaccompanied by any heaving of the heart, and indicates an organ with thin parietes. The prolonged impulse, with an extensive heaving movement, is the sign of thick walls, whether natural or from disease. In all cases the degree of impulse varies greatly according to the state of repose of the patient. Every kind of bodily exercise or mental excitement; in other words, every thing which stimulates the muscular action of the heart, or hurries the circulation, augments the impulse. When causes

of this kind act powerfully, they produce what may be considered as a factitious or temporary palpitation; and in such cases the impulse of a healthy heart is sometimes very great, being sufficient to elevate the ear as by a sudden blow. It is for this reason an invariable rule to depend only on such stethoscopic explorations of the heart as are made during a state of quietude both of body and mind. In this state, in healthy individuals having hearts well proportioned, the impulse is in general not very perceptible, and in a considerable proportion of cases it is quite imperceptible. When the respiration is frequent and laborious, we must be careful not to mistake the rise of the thoracic parietes, during inspiration, for the impulse of the heart.

It may be stated as a general rule, that, *ceteris paribus*, the degree of impulse is in proportion to the thickness of the walls of the ventricles, the impulse being greater, the thicker the walls. If, then, we find a degree of impulse beyond the ordinary standard, habitually present even during repose, we may be almost certain that there exists hypertrophy of one or both ventricles, more particularly if the pulse continues of moderate frequency. Increased impulse, as already stated, is a constant result of increased action of the heart, without any addition to its muscular substance. But in such cases the pulse (that is, the contraction of the heart) is always preternaturally frequent. Preternatural intensity of impulse with natural frequency of action—or with very slightly increased frequency—can hardly arise but from hypertrophy of the heart.

Many causes, particularly those of a depressing kind, greatly diminish the degree of impulse, and sometimes entirely destroy it, when previously existing in a preternatural degree. Of this kind are bloodletting, diarrhœa, whether natural or artificial, great abstinence, &c.; in such and similar states of the system, we must, therefore, be cautious in pronouncing against the existence of hypertrophy merely from the absence of impulse. Impulse also disappears, even when there exists considerable hypertrophy, upon the supervention of great dyspnoea, as in pleurisy, pneumonia, the asthmatic paroxysm, and likewise in the congested state of the lungs and heart which so generally precedes death.

In all these cases perhaps, certainly in the greater number, the disappearance or diminution of the impulse depends on the natural actions of the heart being impeded by the morbid accumulation of blood in its cavities. Cases certainly occur, also, in which, from some unknown causes, an hypertrophous heart does not give any preternatural impulse, as well as others in which an habitually great impulse accompanies a thin organ. But these are merely exceptions—rare exceptions—to a general rule, which is unquestionably as stated above. The rationale of increased impulse from hypertrophy of the heart is sufficiently clear. In the first place, the organ is larger, and its actions will necessarily bring it more closely in contact with the chest; secondly,

having a greater number of contractile fibres, its contractions must be more energetic; and, thirdly, the very condition of a hypertrophied muscle almost involves the fact of augmented irritability and activity.

It is well remarked by Andral, that, even if we were unable to account for the anomalies now referred to, both of increased and diminished impulse, we have no reason to doubt the truth of the general proposition. It is not to be wondered at, if, in a machine so complicated, and subject to such diversity of influences, as the human body, we should meet with anomalies beyond our power of apprehension. So long as they continue to be exceptions only, and do not militate against principles, medicine need have no fear to acknowledge their existence.

3. The impulse, in health, is in general felt only in the immediate region of the heart, that is, in the space occupied by the cartilages of the fourth, fifth, sixth, and seventh ribs, or, at most, over the lower half of the sternum. When this bone is very short, it is sometimes perceptible by the hand in the epigastric region. Generally speaking, the sphere of impulse is proportioned to the size of the heart, a small heart being felt over a small space, a large one over a large space. It is in some degree also proportioned to the degree of action of the organ, a heart that pulsates quietly having a less extensive sphere of impulse than one that is excited to quick and vehement action. When the heart is increased in mere muscular thickness without proportioned enlargement of its cavities, the sphere of impulse is scarcely extended beyond the space already mentioned; but in hypertrophy combined with dilatation, it is extended much beyond this, being sometimes felt very distinctly under the clavicles, on the right side of the sternum, and occasionally even on the back. The impulse may be extended beyond its natural sphere by displacement of the heart; although, perhaps, in this case it would be more correct to say that the impulse is altered in its situation than that it is extended beyond its natural sphere. Such alteration of the position of the heart may be either congenital, or the result of disease. (See DISPLACEMENT OF THE HEART.) In this last case, the causes of the displacement are generally of such a kind as are calculated to extend the sphere of sound also on other principles, namely, from disease of other organs. In the state of health, the heart is surrounded by parts very ill calculated to convey impulse, on account of their soft and yielding nature. But if the qualities which render the parts unsuited for the transmission of impulse have others of a different kind substituted in their place, the extension of the impulse will be altered with the change in their conducting powers. Every disease which renders the parts adjacent to the heart more solid or more coherent, will therefore augment the sphere of impulse. Of this kind are hepatization of the lungs from acute or chronic pneumonia; compression of the same parts by pleuritic and other effusions, or by tumors exterior to them;

the growth of foreign bodies within the pulmonary substance, particularly of a solid kind. If, in addition, the lungs are closely united to the walls of the chest, the conduction will be still more complete. Adhesion of the pericardium to the heart occasions an extension of impulse otherwise than by simple conduction. In this case every movement of the heart sets in motion all the parts to which the pericardium is naturally attached; and if these and the adjacent parts should chance to be condensed by any of the causes just mentioned, the impulse may be then very widely extended. An opposite condition of the pericardium gives rise to somewhat similar results. When this sac is greatly distended with fluid, as in chronic pericarditis, the heart floating loose, as it were, in its tumultuous movements, sometimes carries its impulse to a great distance beyond the cardiac region. Sometimes the impulse is even conveyed beyond the limits of the chest, as in the case of an enlarged liver encroaching on the thorax, and coming nearly in contact with the heart.\*

The cause of the impulse communicated to the walls of the chest by the action of the heart, was formerly and for a long time considered to be the reaction of the column of blood thrown into the curved aorta, tilting the loose apex of the heart forwards. This explanation has, however, been of late questioned; and it seems, indeed, quite inadequate to explain the fact. There seems little reason to doubt that the impulse is occasioned by the muscular action of the heart itself, although there may be various opinions as to the particular movements which produce it. All that is important in a practical point of view are the various relations which this phenomenon bears to the pathological condition of the heart and other organs within the chest.

II. *Sounds of the heart.*—These may be considered under two heads—*first*, the natural sounds; *second*, the adventitious sounds.

A. *Natural sounds.*—These may be considered according to—1. their individual character; 2. their relation to the impulse and to one another; in other words, their rhythm; and, 3. their sphere or the extent of chest over which they are perceptible.

1 and 2. The general characters of the sounds of the heart and also their rhythm have been already given. We shall only here observe that there is great variety in individuals in respect of these characters. In some the sounds are very loud and distinct; in others they are the reverse. They also vary in their tone or key, being sometimes grave or dull, and sometimes clear. The cause of these differences will presently be explained. Unlike the impulse, the sounds produced by the action of the heart are almost always, if not always, perceptible in the cardiac region in the state of health. They are generally very distinct as heard by the naked ear; but they are commonly perceived more accurately by means of the stethoscope. It is found that the intensity of

\* Med. & Phys. Journ. vol. xlix. p. 385.

impulse and sound depends on opposite conditions of the heart, and therefore they are never, in a state of health, present together in a great degree. The impulse, as we have already shown, is great in proportion as the walls of the ventricles are thick; the sound is greater in proportion as they are thinner. The sounds of the left cavities of the heart are chiefly perceptible near the junction of the cartilages of the fourth, fifth, sixth, and seventh ribs; those of the right more under the sternum.

3 In the state of health we find the impulse to be strictly confined to the region of the heart, or to its immediate vicinity. The sound, however, is much more erratic, being frequently perceived at a great distance. In certain persons indeed, the sound seems as strictly circumscribed as the impulse, appearing confined almost to the point on which the stethoscope rests. Such cases, are, however, rare; and it is usual, even in the healthiest individuals, to perceive the sounds over a certain proportion of the exterior aspect of the chest at least; as, for instance, the lower third of the sternum, or a little to the right of this, and midway between the nipple and left clavicle. There are many circumstances, still within the range of perfect health, which considerably augment the sphere of the heart's sounds. The range of sound is more extensive in infancy and childhood than in adult life. It seems, also, to bear a pretty accurate relation to the size of the thoracic cavity, the range being much greater, *ceteris paribus*, when this is small than when it is large. Hence in persons with very narrow or contracted chests, whether natural, or from the effects of disease, constrained posture, or improper modes of dress, the range of sound may be heard over the greater part of the chest, both before and behind, and certainly if the heart is naturally thin, or when the circulation is hurried by the least agitation. In women, even when well formed, the range of sound is greater than in the other sex; it is, therefore, in general very considerably greater in them, since the natural dimensions of the chest are diminished almost universally by the compression of stays. The thickness of the parietes of the chest has also a considerable effect in modifying the range of sound; this being very considerably increased by emaciation or leanness, whether natural or from disease. Perhaps the augmented range of sound in children and females is partly owing to the cavities of the heart being proportionally larger, and its walls proportionally thinner, than in adult males: in both the former classes of persons, the muscular system, as is well known, is less developed than in the latter. In all these cases the sound is frequently heard over the whole chest. It is highly necessary, therefore, before drawing any conclusions from the range of sound in individual cases, to ascertain the exact structure and conformation of the chest, as well as to procure a state of perfect quietude. We think it necessary to insist the more upon this point, because we believe it is one on which frequent mistakes are committed in practice; and as one or other of the various

causes of augmented range is of such constant occurrence, we would say that this is one of the indications which should be most distrusted by the young auscultator. The negative indications derived from a preternaturally confined range of sound, are much more trustworthy; since the number of accidental circumstances which can temporarily diminish the range in the case of persons in whom it is habitually great, is much smaller.

It is an important practical precept in studying the indications supplied by the range of sound, to take into consideration the frequency of the pulse. As every cause which augments the action of the heart augments also the range of sound, we shall be naturally much more distrustful of an extensive range in cases where the pulse is quick than where it is slow, inasmuch as quickness of pulse is a very common effect of mere temporary causes, and slowness a very rare one. An extensive range of sound with a quick pulse may be frequently neglected, as far as relates to the diagnosis of the cardiac affection; an extensive range of sound with a slow pulse always demands investigation, and will frequently be found to indicate disease.

Exclusively of their influence in hurrying the circulation, and thereby producing a louder sound, many diseases of the chest augment the range not only of impulse, as already stated, but also of sound, merely by conducting more widely the natural sound. All diseases will have this effect which render the organs more solid. Every form, therefore, of inflammation of the lungs will have more or less this effect, which will be the greater, the nearer the affection approaches to complete hepatization. Compression of the lung from pleuritic effusion will act in the same manner; and in this case, as in the preceding, the points on the surface of the chest on which the sounds will be most audible, will depend on the position of the indurated or compressed portions within. All solid depositions in the pulmonary substance will have a similar effect, proportioned, generally speaking, to the sum of their mass. The most common form under this head is phthisis; and if one had previously ascertained in health the range of sound, some idea might be formed of the amount of tubercular deposition from the range in the state of disease. Even when the tubercles have suppurated, and have left large empty cavities in the lungs, the transmission of sound continues to be greatly facilitated,—the solidity of the walls of the excavations, and the compressed state of the surrounding pulmonary substance, more than compensating the actual loss of substance from the disease. It is thus, as Laennec observes, that in the case of tuberculous excavations of the right lung, we hear the sound better under the right clavicle and in the axilla, than on the left side, and sometimes even better than in the region of the heart itself.

The sounds of the heart are always in some degree masked by the respiratory sounds, and in proportion to the loudness of these. In the cases of disease in which there is a very loud rhonchus, the sounds are completely obscured

on the anterior part of the chest; it becomes therefore proper, in such cases, in order to perceive the precise nature and extent of the sounds, to observe them in the intervals between inspiration and expiration; and these may be prolonged designedly by the patient, if it is found necessary.

In extending itself from the cardiac region over the rest of the chest, the sound of the heart almost always follows a fixed tract, being heard successively, according to Laennec, in the following places—the left side of the chest before; the right side before; the left side behind; the right side behind. “In these cases,” says Laennec, “the intensity is progressively less in the succession mentioned. For instance, it is less under the right clavicle than under the left: it is somewhat less on the lateral parts of the left side than under the clavicle; it is still less perceptible on the right side laterally; and much attention is commonly requisite to enable us to hear the pulsations at all in the back; particularly the right side. This succession has appeared to be almost constant, and may be taken as an index of the extent of pulsation. For instance, if this be perceptible on the right side, we may be assured that it will be equally so over the whole sternum, under both clavicles, and over the left side; but we are not sure that it will be so on the back. But if it be perceptible on the back on the right side, we may calculate on its being still more audible on every other part of the chest.” As this is the succession of health,—and almost invariably,—it is obvious that any deviation from it, at least any great deviation from it, may be considered as produced by disease, and may thus become a sign of some importance. For instance, if the sound is much more audible on the right back than on the left back, or even on the left side, we have great reason for believing disease to be the cause of this anomaly; and the circumstance may tend materially to elucidate the diagnosis in doubtful cases. If the heart retains its natural position, some change must have occurred in the contents of the right side of the chest, to occasion this increased power of conducting sound.

When the sounds of the heart are heard much beyond the usual sphere of health, in cases in which the chest seems pretty well formed, and in which none of the causes producing an extensive range can be detected, the individual rarely enjoys good health. Although he may not have any other of the more ordinary signs of disease of the heart, it will be found that his system is a feeble one, and obnoxious to many morbid impressions. “In examining him attentively,” says Laennec, “we shall discover indications of that cachexy peculiar to some diseases of the heart; and we shall find that, if he has not formal dyspnoea, his respiration is, at least, shorter than usual; that he is more easily put out of breath, and more subject to palpitation. This state, he adds, which is that of many asthmatics, may remain stationary many years, and does not always prevent the attainment of an advanced

age.” Our own experience would lead us to consider such a state of heart, which is generally congenital, if not the cause of many other morbid states of common occurrence, as, at least, a circumstance greatly predisposing to them, and aggravating others originating from different causes. It tends powerfully to the production of venous plethora and its numerous train of evils; it leads directly to a defective distribution of blood in the extremities and on the surface, and to a superfluous store in the head and larger viscera; it is a very common cause of head-aches, particularly such as are commonly termed nervous, and eventually leads to apoplexy and palsy. Such persons have almost always cold extremities. We are even of opinion that that complex disease, serofula, if not occasioned, is at least frequently hastened in its development, and is always aggravated, by the concomitance of a feeble heart.

*B. Adventitious sounds.*—Besides mere changes in the degree, extent, and relative succession of the sounds, their very character may be altered; new sounds may be superadded to the old, or may entirely take the place of these. The most common and most important of these changes is the conversion of the usual sound into one resembling the puff of a pair of bellows, or the rough, grating sound produced by the action of a file, rasp, or saw upon wood. The bellows-sound, termed by Laennec *bruit de soufflet*, most accurately resembles the puffing of a small pair of bellows, as employed to blow the fire. The new sound usually takes the place of the natural one; sometimes the two are conjoined; it may be present during the first and second sound, or only during one of these. The saw-sound, or rasp-sound, *bruit de scie*, *bruit de râpe*, of Laennec, is as happily named as the former variety, as nothing can be more precise, in many cases at least, than the resemblance between the sounds of the heart and those to which they are compared. The notion of smoothness is always conveyed by the bellows-sound, and that of roughness by the saw-sound. Yet they gradually pass into each other, from the slightest deviation from smoothness in the bellows-puff through all the intermediate gradations of roughness produced by a very fine-toothed saw, a wood-rasp, up to the harshest notes of a large-toothed saw. In many instances these abnormal sounds of the heart imitate, with singular accuracy, both in their individual qualities and in the regularity of their recurrence, the sounds produced by a carpenter sawing through a small piece of wood at a short distance from the hearer. The loudness of these sounds is frequently very great, as heard with the stethoscope, being sufficient almost to startle one on first applying the ear to the instrument. Like the bellows-sound, that just described may occupy the place either of the first or second sound; but it accompanies the former much more frequently than the latter. The sound of the saw or rasp is often heard at a great distance from its site, like the natural sounds of the heart; the

bellows-sound is for the most part confined to the place where it originates. Both of them, however, are occasionally perceived in the arteries, at some distance from the heart. The bellows-sound, in particular, is frequently observed at a considerable distance from the heart, and even when no such anormal sound can be detected in that organ. When the saw-sound exists in the heart, it may always be traced along the arch of the aorta to the carotids and subclavian arteries. Laennec has noticed a singular variety of the bellows-sound, in which the successive tones are modulated into regular musical notes. He therefore terms it the musical bellows-sound.

The causes of these morbid sounds have been investigated with much care by Laennec and his followers. At first Laennec considered them as exclusively the result of contraction of the valvular orifices from organic disease. Subsequent experience, however, led him to conclude that they may exist without any discoverable change in the orifices or valves, while such change may exist without their concomitance; and he at length adopted the opinion that all the varieties were owing to a spasmodic contraction of the parts in which they originated. As a general statement of the fact, this opinion is certainly erroneous. Indeed it now seems fully established that the immediate causes of all these sounds are certain anormal motions or currents produced in the column of blood, whereby this, which usually glides on smoothly and silently, is thrown into sonorous vibration. Whatever produces the movements in question may produce the sounds; and one of the causes may certainly be that which Laennec supposed. A much more frequent cause, however, is permanent alteration in the caliber of the canals through which the blood passes, by some organic change effected in them; and by much the most common cause is contraction of some of the orifices of the heart.

The bellows-sound appears to originate in much slighter causes than the sound of the rasp or saw, and is, therefore, of less value as a sign of disease. Laennec ascertained that pressure on an artery will reproduce the bellows-sound after it had ceased; and it is now known that the same pressure will frequently produce it in an artery where it had not before existed. It is very constantly present in cases of bronchocele of considerable size, and gradually disappears as the tumour is absorbed under the use of iodine. It is also present in the arteries of the impregnated uterus. It is frequently removed, when strongly marked in the heart, by venesection. It cannot, therefore, be admitted as a sign of organic disease, although it is by no means to be disregarded among the symptoms of diseases of the heart, more especially if it is permanently present.

The sound of the saw or rasp is of less frequent occurrence than the simple bellows-sound; although there is no reason to believe that their causes differ otherwise than in degree. Slighter causes suffice to produce the bellows-sound. The sound of the saw or rasp is occasionally perceived in the carotid and subclavian

arteries; it is also observed in the arteries of the enlarged thyroid gland, and in those of the impregnated uterus. It is, however, most constantly observed in the heart, in the case of a contracted state of the orifices.

In reference to these adventitious sounds, collectively and individually, we think the following conclusions may be deduced from the consideration of them:—

1. The source of the sounds is some impediment to the usual current of the blood, from some physical alteration in the channel through which it passes, whereby such vibrations are excited in the column of fluid as to give rise to audible sound.

2. The alteration in the channel may be merely temporary, and produced in parts possessing a healthy structure, from nervous causes, from want of the natural harmony of proportion between the size of the channel and its contents, and probably from other unknown causes. The more common cause, however, is some fixed physical alteration in the channels conveying the blood; either a contraction or enlargement of caliber, or some other deviation from the natural structure, whereby the current is more or less impeded or disturbed.

3. We are not justified, by the mere presence of any of these sounds, in concluding that organic disease of the valves or valvular orifices exists.

4. If the morbid sounds disappear after repose, bloodletting, or other form of depletion, or without any evident cause, we may suspect that they originate in mere functional disorder; and the probability of this opinion will be increased in proportion to the period of their absence.

5. If they are not removed by these or any other causes, or if they are removed for a very short period only, or are merely lessened in degree, we may conclude that they originate in disease of the valvular orifices; and this conclusion will be still further strengthened if there exist other symptoms of diseased heart.

6. The probability of organic disease is increased in proportion as the character of the sounds approaches that of the sound of the saw or rasp.

7. The sounds produced by valvular disease become much weaker when the contraction of the orifice is extreme than when it is moderate, a certain extent and force of current being requisite to produce them in the highest degree. Dr. Hope says that he has often found that when the orifice was reduced to a crevice of two or three lines in width, no sound whatever was produced.

8. The following is a brief sketch of the *rationale* of the morbid or anormal sounds resulting from valvular disease, for which we are indebted to the able physician just named.

- a. When the *aortic orifice* is contracted, an adventitious sound, or morbid murmur, accompanies the ventricular systole and first sound; and when the valves, not closing accurately, permit regurgitation from the aorta, a morbid murmur accompanies the diastole and second sound also; but this last, when it oc-

curs, is extremely slight and brief, as the influx of blood from the auricle, during the diastole, almost instantly puts an end to any regurgitation capable of producing sound.

b. When the *pulmonic orifice* is contracted, the effects are the same; but disease of the valves on this side of the heart, as will be shown in another place, is comparatively very rare.

c. When the *mitral orifice* is contracted, a morbid murmur accompanies and sometimes entirely supersedes the second sound, being occasioned by the passage of the blood from the auricle into the ventricle during the diastole of the latter. When the valve, not closing accurately, admits of regurgitation, a murmur accompanies the first sound, and this is sometimes excited by a degree of disease insufficient to produce it during the second.

d. When the *tricuspid orifice* is contracted, the results are the same as in the last case.

There is yet an adventitious sound, of a different kind, and originating in a totally different cause, which deserves to be noticed. This is the sound which Laennec compared to the creaking of the leather of a new saddle, and which he termed *cri du cuir*. At first he conceived this sound to be connected with pericarditis; but he afterwards gave up this opinion, and considered it as owing to accidental circumstances not of a morbid kind. Other observers, however, have been led to adopt Laennec's first opinion; and several cases have been published which render it extremely probable that this peculiar sound is produced by the friction of the heart against the pericardium, when one or both have lost their polish from the effusion of solid lymph with little or no serum. If this opinion be correct, the sound ought to present itself in most cases of pericarditis at some period of their course; and it should always be present when there is considerable albuminous exhalation with little or no serum.\* This sound, both in its character, causes, and its value as a sign, is precisely analogous to the *bruit de frottement*, noticed in a former part of this article.

The sounds of the rasp or saw are very frequently accompanied by a phenomenon which, like that of impulse, can only be brought under the head of auscultation on a principle of convenience, since, like impulse, it is appreciable by the sense of touch, not of hearing. This is the phenomenon termed by Corvisart *bruissement*, and by Laennec *frémissement cataire*, terms which it is not easy to render in English, nor yet to find good substitutes for. It is a peculiar vibration or thrill communicated to the finger laid upon the heart or artery where it exists, and which resembles pretty accurately the gentle tremor communicated to the hand of a person while stroking the head of a cat when purring.

When existing in the region of the heart, "the thrill" is identical with the sound of the saw, rasp, or bellows: the difference being in the sense which perceives, not in the thing perceived. If we could always say, from the character of the thrill, with which of the two sounds of the heart it is identical, it would be more valuable as a sign than it is. It is proper to observe that we do not always hear any of the sounds when we feel the vibration; nor, conversely, do we always feel the vibration when we hear the sound. This, however, is not any proof that both do not spring from the same physical cause. The cause may exist in a degree sufficient to excite one sensation and not the other; just as we may feel or see the vibration of a musical string after the ear has ceased to hear any sound from it. It is, therefore, we conceive, without good grounds, that Laennec considered the separate existence of these phenomena as proofs of their non-identity.\* Dr. Hope says that, although resulting from the same causes as the morbid sounds, the *purring tremor* or thrill requires, *ceteris paribus*, a stronger current for its production; for which reason it less frequently accompanies the passage of the blood from the auricles into the ventricles, than from the latter into their respective arteries, or into the auricles by a retrograde movement. Even in the latter cases, Dr. Hope adds, it is seldom strong unless the ventricle be hypertrophied, or the circulation hurried. Laennec says the thrill is almost always confined to the left side of the heart; although it is occasionally extended much beyond this. The hand must be pressed very firmly upon the heart, in order to feel it well. When existing in the arteries, a middling degree of pressure enables us to perceive it best; a very slight one does not attain it, a strong one abolishes it. It is sometimes continuous, sometimes renewed by the arterial pulse; sometimes it is confined within the caliber of the artery, sometimes it is perceived considerably beyond. In no case have we had occasion to observe the thrill more constantly and distinctly than in the thyroid arteries in cases of large bronchocele.

#### AUSCULTATION OF THE HEART IN THE FÆTUS.

##### DIAGNOSIS OF PREGNANCY.

M. Mayer, of Geneva, appears to have been the first who applied the tests afforded by auscultation to discover the existence of the fœtus in utero. In the *Bibliothèque Universelle* for November, 1818, it was stated that this gentleman had ascertained that the sounds of the fœtal heart are readily perceptible by applying the ear to the abdomen of the mother. The subject was afterwards prosecuted, with the aid of the stethoscope, by M. Kergardec, and with additional results indicative of its importance; and the following facts, verified by numerous auscultators in this country and on the continent, are now as well ascer-

\* Colin, *Exploration de la Poitrine*.—Thèses de la Faculté de Méd. No. 175.—De l'Auscult. Méd. 3<sup>e</sup> edit. tom. iii. pp. 66, 262. notes.

\* See Dr. Corrigan's Experiments in the *Lancet*.

tained as any detailed in former parts of this article.

There are two auscultatory signs of the presence of a living fœtus in the womb—1. the double sound of the heart; and, 2. the existence of the bellows-sound in the placental arteries, or rather, in the uterine arteries immediately connected with the placenta.

1. The pulsations of the fœtal heart may be perceived as early as the fifth month, or between that and the sixth. They are characterised by the double sound of the adult heart, and by the peculiar rhythm of this, which can never be mistaken for any other sound. The sounds, when compared with those of the adult heart, examined in the cardiac region, are extremely feeble; but they are, when at all perceptible, perfectly distinct. They are distinguished from all arterial pulsation of the mother by the duplex rhythm, and by the extreme frequency of their recurrence. The fœtal pulsations are generally more than double that of the mother. The sounds are found to be much more distinct at one time than another, in the same place, and in different places at different times. These variations no doubt result from the varying position of the fœtus, and from its relation to the uterine parietes.

The sounds will be much more distinct when the trunk of the fœtus is in direct contact with the uterus, and, most of all, when the anterior part of its chest is applied opposite to the spot on which the stethoscope rests. When the whole body of the child is removed from that side of the uterus over which the instrument rests, it is doubtful if the action of the heart can be at all perceived. The more copious is the liquor amnii, the less perceptible, *cæteris paribus*, will be the fœtal sounds. The space over which the sounds may be heard is generally pretty extensive, being, indeed, frequently the greater portion of the region occupied by the uterus. It is, however, in general, easy to discover the point which is nearest to the source of the sounds, by the decreasing and increasing intensity of these, as our examinations recede from or approach towards one particular spot. In general, the pulsations of the fœtal heart vary from 120 to 160 in a minute. In one case noticed by Dr. Ferguson,\* the relative frequency of the mother's and child's pulse was singularly reversed; the former being 100, while the latter was only 20. We have met with no similar instance on record.

2. The second auscultatory sign of the presence of the fœtus has been termed the *placental sound* or *placental bellows-sound*, likewise the *utero-placental soufflet*. It was first noticed by M. Kergaradee, and although a less absolutely certain indication of pregnancy than the sound of the fœtal heart, it is a sign of great importance. Although termed placental, there can be little doubt that the site of the sound is in the uterus, in the enlarged arteries which

supply the placenta.† The sound assumes, at different times, all the character of the bellows-sound of the heart. It becomes perceptible about the fourth month of gestation, and is then more distinct than at a later period. Dr. Ferguson says that he has not observed any variety of the sounds to be peculiar to particular stages of pregnancy. In the early stages, Laennec describes the sound as resembling that which is produced by discharging a blast from a pair of bellows into an empty bottle. At a later period, the sound is duller, more diffused, and no longer conveying the impression of being limited to the caliber of a single artery. It assumes all the varieties of the valvular sounds of the heart, from the simple bellows-sound to the sound of the rasp or saw. Dr. Ferguson says that the most constant variety "is a combination of the bellows or the sawing with the hissing sound, commencing with one of the former, and terminating with the latter." These sounds are confined to a much smaller space than those of the fœtal heart. The point where they are most audible is always fixed in the same person, but varies in each individual. In some, the sound can only be detected in a single spot a few inches square. There is no particular part of the uterine tumour in which the sound may not be found; but Dr. Ferguson says that he has found it most frequently in the iliac regions. The placental sound is always isochronous with the pulse of the mother, and is unaccompanied by any degree of impulse.

Whatever be the precise mode of production of this sound, there can be no doubt that it has its seat in the enlarged vessels of the uterus in that portion of it immediately connected with the placenta. This is proved by the following facts:—1. The sound, as already stated, is confined to a fixed space in each individual. 2. This spot is ascertained, by examination after delivery, to be always that to which the placenta had been attached. 3. That the sound is not seated, at least exclusively, in the placenta, is proved by the fact that the sound is still audible for a short period after the placenta is detached. 4. It ceases immediately upon the contraction of the utero-placental arteries, as is proved in cases of death of the fœtus without delivery, and by its instantaneous cessation on the contraction of the uterus after delivery. 5. It is in all cases synchronous with the mother's pulse. There seems little ground for believing, with Dr. Kennedy,‡ that the placental arteries themselves have a share in the production of the sound, any farther than by their action promoting that of the uterine arteries. The character of the sound is *changed* by the cessation of the fœtal circulation, as by the removal of the placenta, the death of the fœtus, or tying of the cord, (Dr. Kennedy denies

\* A striking analogical instance is afforded by the thyroid arteries in bronchocele, noticed in a former part of this article. *Query*, will the same result be obtained in active hypertrophies of other parts of the system?

† Dublin. Trans.

\* Dublin Trans. vol. i. New Series.

M. Ollivry's statement that it is immediately extinguished,) the sound becoming "abrupt, of short continuance, and wanting the lengthened terminating whiz observed in the perfect sound." This may easily be explained by the change necessarily produced in the uterine circulation by the removal of the fetal circulation, without supposing that the placental arteries had any direct share in its production.

Great care and attention are requisite on the part of the auscultator in investigating these phenomena. The sounds being very feeble, perfect silence is necessary during our explorations, and we must be very careful not to confound the sounds with others which may exist at the same time, such as the sound of the mother's heart (which is often distinctly audible in the region of the uterus), of the intestinal movements, and the sound of muscular contraction produced in compressing the abdomen with the stethoscope. As the phenomena are sometimes intermittent, or, at least, not always perceptible, we must not deny their existence because they are not discovered on the first examination.

The sounds may be heard almost as well by the naked ear as the stethoscope; but to all who are accustomed to use this instrument, there are numerous and very obvious reasons why it should be preferred. It is, however, well that practitioners should be aware that the phenomena may be detected by any one, whether a practised auscultator or not.

Different practitioners make the patients adopt different positions during exploration. In many cases the sounds are heard very distinctly while the patient is seated in a chair in her ordinary dress; but it is always preferable, when it can be done, for the patient to assume the horizontal posture, and remove her stays and thick petticoats. The presence of the solid stays is particularly objectionable, as they are apt to convey the sounds of the mother's heart from the chest downwards.

No one who is aware of the frequent and great difficulties experienced by practitioners in detecting pregnancy, and of the vast importance of doing so in some cases, will have any doubt of the great value of the signs now described. They are almost as certain as the perception of the fetal movements, and more certain than *the touch*; and they possess a very great superiority, in point of convenience and delicacy, over the latter. It is true, they have not been detected in some cases of pregnancy; it is probable that, owing to some peculiar idiosyncrasy, they may never manifest themselves in certain cases; but ample experience proves that their absence is a circumstance of extreme rarity. Their absence, therefore, must not be considered as an absolute test of the non-existence of pregnancy; although their presence may be looked upon as the reverse. Here, as in every other case in which auscultation is applied, we have all the other signs to guide our judgment in the instances where the fetal and placental sounds are not detected; while in the vast majority of cases, we have an additional sign, of almost infallible

accuracy. It cannot, therefore, be denied that this form of physical diagnosis has conferred even on puerperal medicine a boon of immense value.

This article has extended to so great a length as to prevent us from offering some general remarks on the actual and comparative value of auscultation as a diagnostic measure. We may probably have another opportunity of doing so. (See PHYSICAL DIAGNOSIS.)

(John Forbes.)

**BARBIERS.** This is a variety of paralysis, chiefly prevalent in India. Sauvages thus defines it: "Motus gradientium genu retrahens eum tremore, fornicationis sensu, vocis raucedine. India familiaris." Linnaeus defines it: "Partium tremor, genuum contractura, stupor, raucedo." Sagar adds to the definition of Sauvages, "Stupore dolorifico artuum." Dr. Aiken arranges the disease as synonymous with "contractura." Bontius describes barbiere well, but he gives it also the name of beriberi; and Dr. Mason Good has completely confounded the two diseases: it is of importance therefore that they should be discriminated.

The leading features of beriberi are uneasiness with partial loss of power of the lower extremities, obstructed respiration, and general oedematous intumescence. Beriberi is commonly an acute disease. Barbiere is characterized by pain, numbness, and partial paralysis of the inferior and superior extremities; sometimes the vocal organs are similarly affected. Barbiere is generally a chronic disease.

Bontius describes the disease as "a species of palsy, or rather a tremor; for at the same time that it impairs the sensation of the feet and hands, sometimes even of the whole body, it induces a trembling. It is more especially the product of a rainy season. In general the disease invades slowly; under particular circumstances it attacks suddenly. Among the chief symptoms of this disease is a lassitude of the whole body; the motion and sensation, especially of the feet and hands, are languid and depraved; and for the most part a titillation is felt in these parts, similar to what seizes them in cold countries in the winter, but with this difference, that the sensation in barbiere is more painful: the speech is sometimes so much obstructed that the patient can scarcely pronounce a syllable articulately."

The translator of Dr. Bontius's work states that barbiere "is most violent and frequent on the Malabar Coast, where (especially during the months of January, February, and March,) it attacks those who unwarily sleep exposed to the land winds which issue every morning about sunrise from the neighbouring mountains; suddenly seizing them with a painful sensation in the periosteum of the arms and legs. In some persons the pain abates as the day advances and the air becomes warm; but in others it continues for a considerable time, attended with a weakness of the knees and an uneasy sensation in the calves of the legs and soles of the feet, especially on any attempt to walk. It is scarcely ever cured by medicine

till after the shifting of the monsoon, unless the patient be removed to the coast of Coromandel, or to any place to the eastward of the Baligat mountains, where by the changes of the air they quickly recover."

Dr. Lind, in his account of the diseases incidental to strangers in different parts of the world, says, "Barbiers is a species of the palsy, a disease most frequent in India. It distresses chiefly the lower class of Europeans, who, when intoxicated with liquor, frequently sleep in the open air exposed to the land winds. Its attack is generally sudden, and entirely deprives the limbs of their motion; sometimes only part of them."

The following is Mr. Marshall's account of the disease:—"For the most part it commences with pain in the muscles of the thighs and legs, particularly of the bellies of the gastrocnemii. This uneasiness is usually attended by a general numbness of the extremity and an imperfect command of the powers of locomotion. Sometimes the patients describe their sensations to be as if hot water or sand was running over the affected parts; at other times they complain of a sense of formication accompanied with a pricking kind of pain. In some cases the hands and forearms become similarly affected. I never saw a case where the disease was confined to one extremity. In general there was but little difference in the degree of the affection of the extremity of one side from that of another. In one case the muscles situated on the back part of the neck became affected, and eventually the powers of articulation were much impaired. This last symptom admitted of partial alleviations. The appetite for food is seldom much impaired during the early stage of the disease.

"When the disease has made considerable progress, the patient is unable to walk steadily. Standing or walking in general greatly aggravates the uneasiness of the limbs. The patients have an infirm tottering gait, and those whose hands are affected lose the power of feeding themselves. They seldom enjoy sound sleep, although they seem to labour under a sluggish inactivity and an unwillingness to exert themselves.

"The progress of the disease is sometimes protracted to a period of several months. As the complaint advances, the patients express their sensations of the affected parts to be as if they were dry or dead, and almost entirely without feeling. Loss of appetite, indigestion, and emaciation soon follow; the extremities lose the natural temperature; the exterior muscles become paralytic, while the flexor muscles seem to have some force, by which means the joints (particularly the joints of the fingers) become contracted. The pulse is frequent, thready, and fluttering; the vital functions greatly impaired; and eventually death supervenes."

"The general remote causes of this disease appear to be cold and moisture applied to the body, intoxication, and the excesses and irregularities consequent on inebriety; violent ex-

ercise in the sun, lying down in the open air during the heat of the day; exposure to the cold chilling dews of the night, and particularly by going to sleep in this situation; suddenly obstructed perspiration, by exposing the body but partially covered to a current of cold air; long fasting, and perhaps every circumstance which exhausts the human frame."

Horses and dogs are sometimes liable to a similar paralytic affection of the extremities, in India, which is universally ascribed to the land wind: they rarely, if ever, completely recover.

The case of spasmodic disease described by Dr. Bostock in the Transactions of the Medico-Chirurgical Society, vol. ix. seems to have been an affection nearly allied to, if not the same, as the disease now under consideration. The patient, who was in the middle of life, was first attacked with aching in the lower limb on one side, accompanied with a difficulty and irregularity of motion which soon extended to the other side, and then gradually to the throat, so as to impede deglutition, except with great pain and severe exertion. The larynx next became affected so as to prevent speech, and afterwards the muscles on the back of the neck. The limbs were rigid, so that they were both bent and straightened with difficulty. The intellectual powers were at length affected and weakened; the failure of understanding gradually increasing, principally showing itself in paroxysms, during one of which the patient died. No cause of the disease could be traced before death, nor did dissection discover any organic change calculated to account for the symptoms. For the treatment of this affection, see PARALYSIS.

(J. Scott.)

**BATHING.** In its most comprehensive sense, the term *bathing* means the immersion, for special purposes, of the body, or a part of it, in a medium different from that in which it is commonly placed. Any substance which constitutes this medium, when considered only in relation to the special purpose, is, in medical language, termed a *bath*.

A great variety of materials has been employed to form baths, the enumeration of which in this place would be of little practical utility, however it might show literary research. In the present article we shall confine our observations almost entirely to baths composed of water, watery vapour, and air.

We shall commence with the fluid water bath, as being that in most general use, and by far the most generally useful. The most important circumstance respecting this bath, and indeed other baths also, is its temperature. To the consideration of this, therefore, we shall first direct our attention.

The range of temperature within which water in a liquid form has been employed for baths, includes about 80° or 90° of Fahrenheit's scale, viz. from 33° up to 112° or 120°. A lower degree, for obvious reasons, cannot be used; and as no therapeutical indication can ever require a higher, we need not extend the scale in this direction, although baths of

\* Notes on the Medical Topography of Ceylon.

even a higher temperature than 120° may occasionally have been had recourse to.

Various subdivisions of baths, according to their temperature, have been adopted by writers on this subject—all the subdivisions being founded on the presumed difference of effect of the bath at particular temperatures. It is obvious, however, that every classification of this kind must be, in some degree, arbitrary; it being utterly impossible precisely to limit the effects of any class of agents upon a subject like the living body, whose properties and susceptibilities are perpetually varying in the same individual at different times, and differ extremely in different individuals at the same time. In this respect bathing is precisely like every other therapeutical agent. We have the means of calculating with certainty the elements of one side of the equation only; the result, therefore, cannot be otherwise than uncertain. As, however, in the case of medicines, experience has enabled us to establish an approximation towards a medium standard of results, in calculating their effects on men in general, so, in like manner, we have obtained certain averages in the case of bathing. And although, as we have said, the conclusions can, at best, be viewed as mere approximations, still the knowledge of them is of great utility in practice. They must, at all events, be employed as convenient expressions of known facts by those who would communicate information to others.

The simplest and most natural division of baths is into *cold* and *hot*; the former comprehending all those which communicate the sensation of cold, the latter all which occasion the feeling of heat. Although, for reasons above stated, it is impossible to fix the degree which shall form the boundary between the two classes of sensations, we shall nevertheless, on the ground of practical convenience, assume such a precise limit. Generally speaking this boundary will be found between the 84th and 88th degree of Fahrenheit; and although well aware that this range is sufficiently small, we shall still further abridge it by naming the intermediate degree of 88 as the precise limit, denominating all baths of a temperature below this *cold*, and all above it *warm*.

In subdividing these two sections of baths according to temperature, we would propose the following arrangement to the practitioner, as one founded on practical indications, and therefore likely to be useful,—leaving it always to be understood that, in fixing the precise boundaries by individual degrees, we are influenced more by motives of convenience than from any belief that these are the exact and true limits of the different classes of baths:—

1. *The cold bath*, from 33° to 60°.
2. *The cool bath*, - - 60° to 75°.
3. *The temperate bath*, - 75° to 85°.
4. *The tepid bath*, - - 85° to 92°.
5. *The warm bath*, - - 92° to 98°.
6. *The hot bath*, - - 98° to 112°.

## OF COLD BATHING.

§ 1. *Of the phenomena and general operation of the cold bath.*

When a person in health first enters a bath of cold water, he experiences at the same time a sensation of cold proportioned to the lowness of the temperature, and a sudden impression on the nervous system, usually termed a shock, proportioned, *ceteris paribus*, partly to the degree of cold, and partly to the suddenness of the immersion. Frequent concomitants, if not universally constituent parts of the shock, are, a greater or less degree of shivering and convulsive anhelation, and a confused mental feeling of surprise and apprehension. If the temperature is very low, these sensations are proportionally vivid, but they are experienced in some degree at all temperatures below that conveying the feeling of warmth. Almost immediately after the shock, the feeling of cold vanishes and gives place to one of a different kind. This gradually increases and becomes speedily diffused over the whole frame, the unpleasant sensations being succeeded by others of a decidedly pleasurable kind. The water almost ceases to be felt, or is felt as communicating a sensation of warmth rather than of cold. If the immersion, however, is prolonged, this sense of warmth gradually decreases; but if the system is at all vigorous, and the temperature of the water not extremely low, the renewed sense of cold is, for a time, rather pleasant than otherwise, the individual feeling as if the external impression were more than counterbalanced by an active force within, of an opposite kind. After a time, however, longer or shorter according to the state of the system and the temperature of the water, the sense of agreeable coolness is succeeded by one of actual cold; more permanent tremors or shudderings come on; the extremities feel benumbed, and the whole body gradually becomes languid, exhausted, and powerless. No second glow ever succeeds this second chill; but the feeling of cold, numbness, general discomfort and debility increase with the continuance of the immersion. The face and whole surface of the body become pale and shrunk, and obviously reduced in size, as is familiarly evinced by the falling off of rings from fingers on which they had fitted tightly; the pulse becomes smaller and more feeble, and frequently slower than natural; there is a feeling of oppression on the chest, a disposition to pass urine, and the sense of chilliness gradually increases to a strong and general shivering.

If the individual leaves the bath before the supervention of the second access of shivering, or before this has continued long, he generally experiences, on dressing, a renewal of the reaction which had followed the shock of immersion, and this having now nothing to counteract it, becomes more vivid and permanent. The pulse becomes fuller and stronger than before immersion; the face, lips, and whole

skin not merely recover the colour and warmth and plumpness which they had lost, but are actually enlarged beyond their habitual state; the rings, which during the chill had dropped from the fingers, now fit tighter than before the bath; all sense of oppression in the chest and head, and of general languor vanishes, and to this succeed an exciting feeling of internal buoyancy, and an agreeable consciousness of animal power.

The above is a brief account of the principal phenomena usually produced by the bath of cold water as used for medical purposes. On proceeding to analyze them, they appear to admit of a ready division into two classes, according as they flow more or less *directly* from the action of the bath—the first comprehending the phenomena usually included under the term *shock*, the second those included under the term *reaction*; and it seems necessary, with a view to the practical application of the bath as a remedy, to enter somewhat more into detail respecting them, and also briefly to notice their physiological causes, and their therapeutic operation.

1. *The shock*.—Although it is impossible to separate entirely, either speculatively or in practice, all the phenomena included under the name of shock, we can still see that the system is affected by it in various ways.

1. The application of the cold water to the surface produces an immediate and very powerful influence on the economy through the medium of sensation. The whole nervous system seems suddenly impressed, and as if about to yield beneath some hurtful power; but, in general, before any of the important functions have become materially disturbed, the conservative energies are roused to successful resistance.

In certain states of the body, however, the impression is found to be too powerful for the nervous system; and there is either no reaction, or this is too feeble to produce any useful results. A complete and prolonged depression of the powers of life may be the consequence, or even life itself may be extinguished. Numerous instances are known of individuals being killed by the cold bath, in this way. Such persons have commonly entered it when they were exhausted by bodily exertion and long-continued perspiration.

2. Refrigeration, to a certain extent, must of necessity result immediately from immersion in the cold bath. This effect must always be conjoined with the former. *Cæteris paribus*, it is proportioned to the lowness of the temperature, and the duration of the immersion.

3. There is an immediate retrocession of the fluids from the surface of the body to the internal parts. The bath produces this effect partly through the nervous impression excited by it; partly by the contraction of the whole superficial capillaries from refrigeration, forcing their contents inwards; and partly through the mechanical compression produced by a denser medium.

4. The cold water produces, to a certain extent, a condensation of the tissues with which it comes immediately in contact, partly by the physical abstraction of heat, and partly through a vital impression on the organization. The contractions of the fingers, scrotum, &c. are obvious instances of this effect. Parts not in contact with the refrigerating medium also contract, in sympathy with those which are.

All the effects now mentioned are necessarily present in every case, but their relative intensity may vary infinitely, according to the condition of the subject, the mode of applying the agent, &c. The predominance of the one or the other class is of great consequence in a practical point of view; and it is important to know that the administration of the bath may be so regulated as to produce this particular effect.

II. *Re-action*.—The almost instantaneous result of the shock is the excitement of the nervous system to increased activity, in virtue, no doubt, of that general principle of self-conservation bestowed, in a greater or less degree, on all living organized beings. The retropulsion of the fluids from the surface upon the internal organs and large vascular trunks, producing mechanical distension, and probably also vitally stimulating the parts, unites its effects with those resulting from the direct conservative efforts of the nervous power. The centres of vital energy, the brain and heart, are roused; the latter organ re-acts with fresh vigour on its contents, and the blood is once more propelled through the whole capillary system, more particularly of the surface, carrying with it life, heat, and renovated action.

As the effects of the cold bath, considered as a medical agent, are greatly varied according to the mode in which it is applied and the condition of the individual at the time he employs it, it is no great wonder that considerable differences of opinion respecting its mode of action should have existed among physiologists and physicians. By some it has been deemed sedative, by others stimulant, by some debilitating, by others tonic. The truth is, that its operation varies with the circumstances of the case. Regarded abstractedly as a medium of communicating cold, there can be no doubt that the cold bath must be considered as debilitating in the highest degree, inasmuch as its continued application will eventually produce death, from exhaustion of the nervous energy and derangement of functions essential to life. But when we speak of the cold bath *medically*, we do not regard its absolute effects, but its effects when applied in a particular manner, and regulated according to certain views. Like many other remedies, it may be debilitating to the destruction of life in one dose, and yet salutary and tonic in another. Accordingly, when used in the proper case, at the proper time, and in the proper manner, the cold bath is unquestionably one of the most powerful tonics in the whole range of the *Materia Medica*, and it is chiefly as such that it is used in medicine.

§ 2. *Of the special effects of the cold bath as a medical agent, and of the mode of ensuring them.*

The cold bath is employed, in individual cases, chiefly with the view of producing one of the three following effects:—1. the shock on the nervous system, independently of the accompanying refrigeration or subsequent reaction; 2. the refrigeration, independently of the nervous shock, or vascular re-action; and, 3. the re-action independently of the shock or refrigeration. The two first of these objects are of inferior practical importance; the last comprehends nearly the whole doctrine of cold bathing.

I. *The nervous impression, or shock.*—When the cold bath is employed with the view of producing the shock, properly so called, or primary nervous impression, and if it is desired that this should be great, the water is used at a low temperature, and the application of it is sudden, forcible, and brief. To this end the patient is either plunged suddenly into the water and instantly withdrawn, or the water is dashed over him in the form of affusion. A familiar example of this use of the cold bath is the sprinkling the face and breast of a person disposed to swoon. On the same principle, a more copious affusion is used in certain convulsive diseases, more especially those of an hysterical or purely nervous kind. In such cases the application is often extremely serviceable. It has likewise been used in convulsive affections of a more permanent kind, as in chorea, tetanus, and epilepsy, but with less beneficial effect in general, and not always with safety. The same practice was formerly employed in mania; the mode of administering it being, in this case, to cause the unhappy maniacs to tumble unawares into a deep plunge-bath or pond. With a similar view the cold bath, chiefly in the form of a copious and forcible affusion, was much employed in fever, in the hope of breaking the train of morbid actions in which fever was imagined to consist.

In all these cases, although the object is to obtain the primary nervous shock through the sudden impression made on sensation; yet as there necessarily co-exist with this, refrigeration of the surface and repulsion of fluids to the internal parts, the secondary effect, termed re-action, is frequently an inevitable result of this application of the bath. In the cases, therefore, in which re-action is likely to prove injurious, the remedy should not be used, as it is hardly possible to avoid its occurrence; or when used, the application should be extremely short, and the body should be dried immediately. Before making trial, in any case, of a remedy so powerful, care will, of course, be taken to ascertain, as far as this is practicable, the powers of the system to sustain the shock.

II. *Refrigeration.*—When the object is to obtain the refrigeratory action of the cold bath, with as little as possible of the nervous shock or vascular re-action, it must be applied in

the way least likely to produce the two last. We shall see presently that the degree of reaction is, *ceteris paribus*, proportioned to the degree of cold, if this is only temporarily applied; we have just seen that the nervous impression is proportioned to the suddenness and vehemence of the application of the water, and also to its coldness; if, then, we wish to produce the refrigeratory effect alone, we must neither apply the water of a low temperature, nor suddenly, nor forcibly.

The only cases in which refrigeration is required as a remedy, are those in which the animal temperature is elevated above the natural standard; and this happens only in febrile diseases. In symptomatic fevers, the consequence of local inflammation of the viscera, this remedy is rarely applicable; being usually, when so employed, productive of an aggravation of the disease. In the class of fevers termed idiopathic, as in the common continued fever of this country, or typhus, cold water has been extensively used, and often with benefit. In the preceding paragraph we have already noticed one mode in which this remedy has been applied, not however with the view of refrigerating the surface, but of suddenly cutting short the disease. When this latter object is not attained, the result has commonly been an increase of the febrile heat and vascular excitement. To ensure refrigeration in this and other cases, the water should be applied at first only a little below the temperature of the skin, its heat being insensibly and gradually reduced, but never below that of tepid, or at most, cool. The gentlest mode of applying it is the best, as with a soft sponge; and the process should be persevered in without interruption until the desired effect is produced. The non-interruption of the application is the more essential in proportion as its temperature is low. In local affections of an inflammatory kind, in which very cold lotions are used as a refrigerant, as in cerebral inflammations and in phlegmon, the result is frequently different from what is intended, from neglect of the precaution just mentioned. The renewed application of the cold fluid, after a temporary suspension, frequently gives rise to a series of re-actions in the part, which are calculated much more to aggravate than to relieve the disease. In such cases, if the lotion is very cold, its application ought to be uninterrupted until the intended effect is produced. If the water is of a temperature little below that of the body, the interruption of its use will have no further injurious effect than the subtraction of the amount of good which its continued application is calculated to produce.

III. *Re-action, or glow.*—The cold bath may be used, in the third place, with the view of producing its secondary effects—re-action. As this is by far the most important end for which it is employed, and as, indeed, almost the whole practical doctrines relating to cold bathing are involved in the consideration of this subject, we shall devote a considerable portion

of the remainder of this part of our article to an examination of the circumstances which obstruct or favour its production.

1. The degree of re-action is, in general, *ceteris paribus*, proportioned to the coldness of the water. A very cold bath is followed by a speedy and powerful re-action; a cool bath by a slighter re-action, and after a longer interval; while a bath approaching the limits of tepid produces scarcely any re-action.

2. In general the re-action is proportioned, *ceteris paribus*, to the suddenness and also to the force with which the body is brought in contact with the bath. An instantaneous immersion produces a greater re-action than a gradual immersion; and a plunge from some height produces a greater re-action than a gentle dip, however rapidly performed. In like manner, water falling on the body from some height has a much greater effect than simple ablution with water of the same temperature.

3. Within certain limits, that is, short of the period at which healthy re-action ceases to be produced, the re-action is, in general, proportioned to the period of stay in the bath,—in other words, to the degree of refrigeration.

4. The re-action is commonly proportioned to the vigour of the circulation in general, and more particularly to that on the surface; it is likewise proportioned to the warmth of the skin and extremities previously to immersion. It is, therefore, a constant rule that persons with a feeble circulation and cold extremities must endeavour to invigorate the circulation, and increase their temperature previously to using the cold bath. To ensure the proper degree of power, it is even necessary, in some cases, to administer a warm beverage, or to take a glass of wine before entering the water; and were it always convenient, it would often be beneficial, in cases of this kind, to go into the warm bath for a few minutes before immersion in the cold.

5. Re-action is greater, *ceteris paribus*, if muscular motion is exerted in the bath, than if the patient remains in a state of repose. Swimming is therefore more tonic than simple immersion, and the large open bath admitting of motion more tonic than the common small bath. The increase of re-action from motion is partly owing to this producing a greater feeling of cold, by occasioning a quicker change of the particles in contact with the surface; but principally by the increased excitement resulting from muscular exertion. In the case of swimming, as in all others, it is always to be understood, when spoken of in relation to its power of increasing re-action, that the period of stay in the water is not prolonged beyond that suited for the production of all degree of re-action.

6. Whatever tends to prevent the temperature of the surface from falling below the proper degree, or directly stimulates the skin, or excites the action of the heart, will proportionally increase the power of re-action. On these grounds, the speedy drying of the body on leaving the bath, strong friction of the sur-

face or the application of heat to it, the drinking of warm fluids, or active bodily exercise, will ensure or increase re-action; while the omission of these measures, or measures of an opposite kind, will produce opposite effects.

§ 3. *Of the practical administration of the cold bath, and more particularly of the salt-water bath.*

Although it is certain that the most important of the effects produced by baths depend on their temperature, and on other circumstances having no relation to their chemical constitution, it will not be doubted by any practitioner of experience, who has had sufficient opportunities of comparing the effects of the bath of simple water with those of mineral waters or of the sea, that the chemical composition of the materials used in bathing is a matter of considerable importance. Without at all entering here upon the question of the powers of absorption possessed by the skin, whether of water simply applied to it or of substances dissolved in water, experience has satisfactorily proved that the effects of immersion in pure water, and in water containing salts in solution, are different. Sea-water and mineral waters, particularly such as contain sea-salt or iron in solution, are more tonic, stimulant, and bracing than simple water, and when used as a cold bath are productive of a greater re-action than the latter. When, therefore, the object is to produce re-action, and to brace the system, (and this is the object in a vast majority of the cases in which the cold bath is used,) sea-water is always to be preferred to fresh. If this cannot be procured, the water ought, when practicable, to be rendered artificially saline by the solution in it of common salt.

For these reasons, and because in the greater number of cases in which cold bathing is proper the summer temperature of the sea is exactly that most suitable,—and, moreover, because this is the form of the cold bath in most general use in this country,—we shall, in the present section, direct our attention particularly to *sea-bathing*.

1. The period of the year best adapted for sea-bathing is, of course, the summer and autumn, at which seasons the temperature of the sea on our shores varies from 55° to 70°. Bathing in the open sea may, however, be prolonged beyond the autumnal months, and even through the whole winter in particular cases. It will scarcely ever be proper to commence sea-bathing in the latter season; but many persons who have regularly used it in the summer and autumn may continue it through the severer season with great advantage. Such a recommendation presupposes the possession of a vigorous constitution, or, at least, great powers of re-action in the patient.

2. The time of the day for bathing in the open sea must depend, in many places, on the state of the tide. A slight deviation may be allowed on this account; but the particular time best adapted to the invalid must not yield

to reasons of mere convenience. By the majority of persons for whom the cold bath is prescribed, either as a measure of hygiene or as a remedy, the best time for using it will be about noon; that is, two or three hours after breakfast. At this time we may presume that the system is sufficiently recruited by the assimilation of the morning's meal; and we may yet farther be enabled to ensure re-action by such previous exercise as may be deemed proper. In very hot and calm weather, the sun is, however, often too powerful at noon for delicate persons, more particularly on those parts of our southern shores which are sheltered by high cliffs. In these cases an earlier hour must be chosen, or bathing in the open sea must be given up.

When the constitution is vigorous, and the temperature of the surface is uniformly high, and when the patient rises from his bed refreshed and active, the bath may be taken early in the morning, before breakfast. This is, in general, the best time for using the cold shower-bath; and the reason why it is found to suit better at this hour than the sea-bath, probably is, that the shower-bath is taken immediately on rising, while the surface still retains all the warmth of the bed. If one could plunge into the sea as easily, and before the surface is at all chilled by dressing, &c., there is no doubt that the practice would suit very well with many with whom it is found to disagree.

In using the open sea in summer, it may be of some consequence to recollect that the temperature of the water may be very different at different times, according to the circumstances of the locality, the hour of the day, and the period of high water. If the shore consists of level sand or shingle, the tide which flows in the afternoon, over a large expanse of surface heated by the noon-day sun, during the period of ebb, will often be a good many degrees higher than the morning tide in the same place.\*

3. In using exercise previously to the bath, with the view of rendering the circulation more vigorous, according to the principles formerly stated, the invalid must be careful not to induce fatigue or much perspiration. A slight moisture on the skin (which, however, should be wiped off previously to entering the bath,) forms no objection to its use, provided the surface still continues warm and the circulation vigorous; but if the body has been for some time losing its heat by copious perspiration, and the general powers of the system have been lowered by fatigue, the cold-bath cannot be used without danger, however warm the surface still may be.

\* The following memorandum shews the temperature of the sea at Bognor, on the coast of Sussex, in the summer and autumn of the year 1831.

On the 4th July, at mid-day, the temperature of the atmosphere being 72°, the sea was 69°.  
 July 12, 7 a. m. Atmosph. 63°, Sea 66°.  
 Aug. 3, 8 p. m. Atmosph. 65°, Sea 71°.  
 Aug. 11, 1 p. m. Atmosph. 70°, Sea 71°.  
 Sept. 5, 8 a. m. Atmosph. 64°, Sea 65°.  
 Oct. 29, 11 a. m. Atmosph. 60°, Sea 54°.

4. The mode of entering the bath, the length of time the patient remains in it, and other particulars, must be regulated according to circumstances. From what was formerly stated, the propriety of entering the bath suddenly will be seen, and likewise the necessity of leaving it while there still remains sufficient power of reaction. The advice commonly given to a patient to take at first only one or two dips to ascertain the power of reaction possessed by him, and gradually to prolong the period of stay in the water, is judicious. From five to ten minutes may be said to be a medium period for staying in. Moving the body and limbs while in the water, is highly advisable, and, of course, the exercise of swimming, if the patient possesses the requisite power and skill. The body should be speedily dried, and hastily but well rubbed with a somewhat coarse towel, and the clothes put on without any unnecessary delay. In ordinary cases no further precaution will be necessary to ensure the requisite degree of reaction; but in very feeble subjects the measures formerly mentioned in reference to such cases, must be put in practice.

5. The cold bath may be repeated daily or every other day, or twice a week, according to the nature of the case, the effects of the remedy, and the state of the weather. It may be continued indefinitely and uninterruptedly, or it may be taken for a short time, omitted for a space, and then resumed. Where it is found to agree with the patient, it ought to be continued at least one month, and may be very beneficially extended to three.

6. A common and often a most injurious error in the practice of sea-bathing is, that the patient remains so long in the water that the animal heat is lowered below the proper degree. This is an error, however, more commonly committed by persons using the bath as a luxury, than by invalids. In boys of a feeble constitution or strumous habit, we are convinced that great mischief is often produced in this way, when it is least expected. The principle on which such results are explained has been ably illustrated by Dr. Edwards, in his excellent work *On the Influence of Physical Agents on Life*. It was ascertained by him, in the course of his experiments on living animals, that the temporary elevation or depression of the animal temperature, above or below the natural standard, not merely added to or subducted from the system the amount of caloric necessary to produce the effect indicated by the thermometer at the time, but modified, for some time afterwards, the activity of the calorific process itself. Animals whose temperature had been raised by artificial heat, were invariably found, on the withdrawal of this, to continue for some time to generate more heat, in the same period, than before the experiment; and those whose temperature had been lowered, to generate less. Although Dr. Edwards's experiments were confined to the inferior animals, both analogical reasoning and observation leave no doubt that the principle is equally applicable to the

human subject. Every one must have had occasion to observe, and most people to experience in their own persons, the effects of a severe chill being felt long after the usual temperature has been restored. Subsequently to long exposure to cold, as in a carriage or church, when the clothing is insufficient, or when cold bathing has been improperly prolonged, a sense of chilliness often remains for days, although the body has been repeatedly and thoroughly warmed in the meantime. We have known such a state continue for two or three weeks, the individual daily expecting the invasion of some formal disease, and yet none such occurring.

The corollary from these premises is, that when the cold-bath is employed with the view of invigorating the system, it should never be so prolonged as materially to lower the animal temperature. In such cases the reaction will either be imperfect, or it will be succeeded by a sense of chilliness. In order to obtain the full degree of salutary reaction, and at the same time to avoid the risk of subsequent chilliness, immersion in the cold-bath should cease just before the animal temperature is sensibly diminished; and it may be deemed, for all practical purposes, a sufficient test that this point has not been passed, as long as the primary glow or reaction is felt to continue.

§ 4. *Of the temperate bath (75° to 85°).*

The effects of this bath on the system are precisely the same in kind as those of the cold bath, but they are much less in degree. This bath, therefore, is applicable in a different class of cases, and it is also applicable in the same cases in which the cold or cool bath may be of use, but cannot be applied without some hazard. The Buxton water, which is of the temperature of 82°, is the best natural example of this class of baths. The shock produced by water at this temperature is small, and the reaction proportionally slight. As this bath may, therefore, be safely prescribed in cases where danger might be apprehended either from the too powerful shock on the nervous system, or the too great and sudden repulsion of fluids on the internal organs, it will, for the same reason, be found much less efficacious in the cases in which the principal benefit results from a powerful reaction. It will also be frequently preferable in the case of delicate persons, and in persons of peculiar sensitiveness either of the whole system or of the skin only, in whom the shock of the very cold bath, or even the cool bath, cannot be borne; although if it could be borne, its effect in repelling the fluids could be productive of no evil. In such cases, and in others also of a somewhat different kind, a bath of this temperature will often be proper as a preparation for the use of the bath at a much lower temperature.

It is, indeed, a question often raised, whether the patient should at once commence with the bath of the full degree of coldness intended, or should at first use one of a higher temperature and gradually lower it. For instance, should a patient for whom the cool or cold

bath is prescribed, begin at once with it, or previously use that which we are now considering! This point can only be fixed in individual cases. Generally speaking, if there is any doubt of the system being able to bear the shock of the cold bath, the temperate should be used, and more particularly in the case of delicate persons and women and children, and in persons who have a dread of the effects of the bath.

It is always to be recollected, however, that if our object is to corroborate the system by producing reaction, the lower temperature is decidedly best, if it can be borne. And we are of opinion that among the vast number of cases in which the cold or cool bath is indicated, very few will be found in which it will not be borne at once. All that is necessary is, by proper management before and after the bath, and by making the immersion extremely brief, to ensure the salutary degree of reaction.

§ 5. *Of the different forms of the cold bath, and their particular effects.*

1. *Large and small baths—open and close baths.* The observations heretofore made may be considered as applying generally to every form of bath by immersion, whether the water is in the open sea, rivers, ponds, &c. or confined under a roof in large or small baths. It must not, however, be imagined that it is a matter of indifference to the patient under what circumstances the bath is administered. It may be stated in general terms that bathing in the open air is more advantageous than bathing under cover, and that a large bath is preferable to a small one. It is scarcely necessary to observe that when a tonic effect from the cold bath is the object, the open air, more particularly of the sea, will be much more bracing than that of a confined apartment. The size of the bath is of still greater consequence. In the common domestic bath, the patient can scarcely have the advantage of a complete and sudden immersion; and all effective motion, while in the water, is completely precluded. The importance of this deficiency will be understood from what was formerly stated on the subject of reaction: in the small bath, the degree of refrigeration is often not sufficiently balanced by a proportionate degree of this salutary process. For these and other reasons, the large baths at Matlock, Buxton, &c. are decidedly preferable to the small baths at the same places. Of all the substitutes for the open sea which we have seen, the *swimming bath* lately erected at Brighton is by far the best. From its great extent and airiness, and the constant renewal of the water, this bath certainly possesses many of the advantages of the open sea, and it has one superiority, that, namely, of being accessible in every kind of weather and at any time of the day.\*

2. *The shower-bath.*—The form and general character of the shower-bath are too well known to require description. Its effects are,

\* The swimming bath at Brighton is 53 feet in diameter; its depth from 3 feet 6 inches on one side to 5 feet 6 inches on the other.

on the whole, similar to those of the plunge-bath of the same degree of temperature: but there are some differences between them which deserve the notice of the practitioner.

The immediate shock from the shower-bath is, in general, felt to be greater than that from simple immersion; more particularly if the quantity of water is great, its temperature low, and the fall considerable. On the other hand, owing to the absence of permanent compression of the surface by a dense medium, and perhaps, also, owing to the access of air to the skin in the case of the shower-bath, the anhelation and præcordial distress are generally less in degree and certainly less permanent than in the plunge-bath. From these and various other circumstances, individuals constantly present themselves to the practitioner who will bear the one form of bath and not the other, or who will be more benefited by the one than the other.

In certain affections of the head, and in persons predisposed to such affections, the shower-bath possesses a very decided advantage over the plunge-bath, inasmuch as the shock and refrigeration are applied directly and in the first place to the head. And in these and many other cases also, it is a great advantage possessed by this bath, that the feet may be immersed in hot water during the process. This not only tends to prevent too great a repulsion of the fluids upon the internal organs in cases where this is to be apprehended, but in feeble and sensitive persons it tends at once to lessen the shock and to increase the re-action.

It is an important advantage possessed by the shower-bath, when properly constructed, that it can be increased or diminished in force, suspended, renewed, shortened, or prolonged, according to the feelings of the patient.\* The small quantity of water necessary to prepare a bath of this kind is another great advantage, as giving facility for having it at any degree of heat required.

3. *Affusion, aspersion, ablutio.*—These may be employed either as general or local baths. Water thrown over the naked body from a vessel is a rude form of the shower-bath, and has similar effects. By ablutio, we commonly understand the process of applying water to the surface by means of a sponge or towel. When general, it differs only from the shower-bath in being attended by a lesser shock, and consequently a feebler re-action. It is much more frequently used as a partial bath, more particularly to the head and trunk of the body, in which form we consider it as

\* A shower-bath should be so constructed as to contain a much greater quantity of water than is usually thought necessary, and to permit the shower to be suspended and renewed at the will of the bather. One of the most convenient forms is that which is erected over the common domestic warm bath, and which permits the patient to escape from under the stream, and to return to it at pleasure. The materials for enclosing the shower-bath ought to be of wood, as cloth or canvas, whether painted or not, retains moisture, and proves thereby injurious by occasioning dampness.

one of the most valuable applications both hygiènic and therapeutic. The daily ablution of the chest with cold water, containing vinegar or salt in solution, is one of the most effective tonics in a numerous class of diseases, and the easiest and surest remedy of that almost general and, we fear, increasing disease, a proclivity to catch cold. (See the article *ASTHMA*.) This form of bath is always to be used, by the delicate, in the morning, immediately on getting up, while the body still retains all the warmth of the bed, unless, indeed, there is perspiration present at this time.

The employment of cold ablution as a remedy in fever was formerly noticed. In this case, pure water should be used; in most other cases, salt water, or water rendered artificially saline, is preferable.

5. *The douse (dash, or douche).*—This form of bath is well known by its foreign name. It is of sufficient value to deserve an English appellation, and we venture to revive an old one, which has at least the negative advantage of being less discordant to our orthography and pronunciation than the French term.\* The douse consists of a small stream of water directed with considerable force from a tube upon some particular part of the body. It varies in its power according to the diameter of the stream, the temperature of the water, and the force with which it is projected on the body. It is an agent of great power; but it is more employed in the domain of surgery than medicine. This is, perhaps, the most effectual of all refrigerants, owing to the incessant and rapid change of the particles of the fluid applied to the part, and also to the compression on the capillaries produced by the mechanical impulse of the stream. A homely form of the douse is the placing the affected part under the stream from the nozzle of a pump, or the spout of a tea-kettle. The chief instances of a strictly medical kind in which this form of bath is used, are to the head in cerebral diseases, and to the loins in uterine affections. In inflammatory affections of the brain, whether idiopathic or originating in fever, it is a most potent remedy. It is also in frequent use, in some parts of the continent, in mania. In all these cases it requires to be used with discrimination and great circumspection, as it is capable of producing the most powerful effects.

6. *The hip-bath, foot-bath, &c.*—There is no limit to the number of partial baths but the number of parts of the body to which water can be locally applied. The most important are the two just named. They are both very valuable remedies, and their administration is well understood. The former is principally used in diseases of the pelvic viscera; the latter chiefly as a measure of hygiène. Children ought to be accustomed to the daily use of the cold foot-bath, as nothing tends more to prevent chilblains—a disease, however apparently

\* *The douse*, (pronounced like *house*,) from the old neuter verb, *TO DOUSE*, *to fall suddenly into the water*.

slight, of really serious consequence in delicate habits.

§ 6. *Of the diseases in which the cold bath is employed; and the contra-indications to its use.*

The applications of the cold bath, both as a measure of hygiene and as a curative agent, are numerous and important. It is, indeed, one of the most valuable remedies we possess. Like all valuable and powerful remedies, however, its employment requires great caution and discrimination, first, as to whether it should be used at all; and, secondly, as to the form and mode of using it. It must be confessed that in a vast number of cases no such discrimination is practised; and it will not be doubted by any physician resident in the vicinity of the sea, that in the case of no other remedy are greater mistakes committed and greater mischief produced than in the use of the cold bath. It is impossible, within the limits of the present article, to do more than give an outline of the numerous cases in which the cold bath is beneficial. This, however, is of the less consequence, as the practitioner who is acquainted with the mode of action of this remedy, and the general principles which ought to regulate its employment, (and we have endeavoured to explain these in the preceding pages,) will have little difficulty in applying it to individual cases.

Before entering upon the consideration of the diseases in which this remedy is proper, it will be well to give a brief statement of the particular conditions of the system, whether morbid or not, which either entirely forbid its use, or render great caution necessary in employing it.

1. The cold bath is less applicable in infancy and childhood than in youth and middle life.

2. It is not admissible during the menstrual period, and only with great caution during pregnancy.

3. It is inadmissible in great plethora; in cases where there exists a predisposition or tendency to active hemorrhage, to local congestions in the more important viscera, &c.; consequently in apoplectic subjects, in a tendency to hæmoptysis, &c.

4. It is improper in persons affected with disease of the heart, particularly with dilatation or valvular obstruction; and it must be used with great caution in those who, without any formal disease, have naturally a thin and feeble heart. This is often the case in strumous and phthisical habits.

5. It is generally inadmissible in indurations, obstructions, or chronic inflammations of the internal parts of the body, more particularly of the principal viscera; likewise in all acute inflammations of the same parts; and also in chronic inflammations of the mucous membranes of the bronchi and intestinal canal, except when these last are very slight.

6. It is improper in loaded states of the bowels, more particularly if these are combined with a gorged state of the venous system of the abdomen.

7. It is either inadmissible, or only to be

used with great caution, in most cutaneous diseases; particularly such as are apt, when suddenly removed, to be followed by internal affections.

8. It is inadmissible in great general debility, and where there does not exist sufficient power of re-action, more especially if there exists an habitually cold state of the surface. In cases of this kind, however, the cold bath may be often advantageously employed after the previous use of the warm water or vapour bath, provided the debility is not the result of some local organic disease.

One of the most important class of cases, short of formal disease, in which the cold bath is beneficial, consists of the various forms of general debility which show themselves in childhood and youth, either as congenital constitutional peculiarities, or as the consequences of previous disease. Of the first kind, the strumous habit constitutes the most important example. In cases of this kind, when properly selected, the cold sea-bath and a residence by the sea-side are frequently of very singular benefit. Everything, however, depends on the judicious selection of the cases, and on the proper administration of the remedy; since quite as much injury as benefit may result in this class of cases without the greatest care. In children of a strumous habit we have at the same time, in general, a feeble heart, and a very sensitive surface. Great caution is, therefore, necessary, in first administering the bath, lest the shock be too powerful for the energies of the system, and be not followed by the necessary degree of re-action. Every measure formerly mentioned as proper to ensure this result must be employed, as otherwise the bathing will be highly injurious. In most cases it will be found sufficient to take care that the circulation on the surface is as vigorous as possible previous to immersion; to make the immersion sudden and complete, and, at first, merely momentary; and to follow it up by strong general friction with flannels. In more delicate subjects it may be necessary to begin with the tepid or temperate bath, or to take some of the additional precautions formerly noticed. It is a matter of great consequence in bathing children, that they should not be terrified by the immersion, and every precaution should be taken to prevent this. A course of baths, gradually reduced from a high to a low temperature, is beneficial in this point of view, even if it were not often so likewise by improving the condition of the skin, and rendering it more susceptible of re-action. It is to be here understood that it is to the *strumous habit*, and not to the diseases of scrofulous persons, that the foregoing observations are intended to apply; as we are well convinced that there are few such diseases in which the cold bath is not injurious. Great care must therefore be taken by the practitioner, before prescribing this measure, to ascertain that there exists no local disease of consequence. We do not consider slight swelling of the external glands as a positive contra-indication of the cold bath, provided the internal organs are sound; but such appearances

are always suspicious, and impose greater caution in the use of the remedy than if they did not exist.

When, in strumous habits, the system is free from visceral disease, and sufficient energy exists to produce strong reaction, the frequent repetition of this exciting and tonic process may eventually establish a permanent degree of increased activity and power throughout the whole capillary system, with an habitual development of a higher degree of temperature on the surface. Such results may be considered equivalent to a change in the very temperament of the individual; and it is certain that they are occasionally attained by the use of the cold bath, aided by suitable regimen.

In children of a feeble and delicate habit, the result of previous disease, perhaps still greater caution is requisite in prescribing the bath, as such states of general debility frequently depend on organic affections of the viscera. In this last case, the remedy is altogether improper, and cannot be administered without danger. The same remark is equally applicable to persons in more advanced life. We may add, as a general observation, that there is scarcely a more common or more injurious practical error, than this of assuming debility to be general, when it is the result of some local affection. In all cases of this kind, at whatever period of life, cold bathing is seldom beneficial, and very generally injurious. Here, as in most cases, it is to be viewed in the same light as other tonics, which may be stated as generally contra-indicated in what may be termed symptomatic debility. In place of being strengthened, such persons are certainly debilitated by the treatment, and great risk is incurred, not only of increasing the primary disease, but of producing others. It is in such cases that we observe the occurrence of bilious and febrile attacks, headaches, and other disorders, so frequently noticed as results of indiscriminate sea-bathing. Permanent headaches have been produced under such circumstances.

In cases of a debilitated and relaxed habit, free from visceral disease, from whatever cause arising, the cold bath may be considered as useful, if sufficient power of reaction exist in the system. When the skin is relaxed and flabby, and there is a great tendency to warm perspiration on slight exertion, or to cold clammy perspiration in bed, the salt bath is especially indicated. In no class of persons is this measure more beneficial than in those who inhabit a low, relaxing, damp climate, in whom debility and nervousness in various forms, and relaxation of the skin and mucous membranes, are frequent and conspicuous ailments. When combined with a more bracing climate, and dry pure air, the benefit from this measure is often most speedy and remarkable. For persons of this class, no place on the southern coast affords such advantages as Brighton, and some other places in its vicinity, where the high, airy downs come close to the sea brink.

There is one case of debility frequently met

with in practice, which requires great caution in prescribing the cold bath, and where frequent mistakes are committed, for want of due discrimination: we allude to that state of debility which so often precedes the development of tubercles in the lungs, and which has been so well described by Dr. Clark, under the name of tubercular cachexy.\* If tubercles already exist in such cases, (and we know that they often do so without any external or local symptoms of their presence,) cold bathing will almost always be found to disagree, and will tend to accelerate the fatal disorder of the lungs. If only the predisposition exists, and the system still retains sufficient power of reaction, a cautious use of the cold bath may prove extremely beneficial; but in no case is more care requisite to ensure reaction, without which the measure cannot fail to be highly injurious.

As a preventive of the numerous diseases produced by cold; or rather by the variations of temperature, the cold bath, in one or other of its forms, excels all other measures. In the numerous family of catarrhal disorders, it is almost the only preventive of value; and frequently it is here of extreme value. It obviously acts in various ways in warding off these diseases. In the first place, it acts as a tonic to the whole system, thereby rendering it less easily affected by deleterious influences from without. Secondly, it strengthens, in a peculiar manner, the skin and the mucous membranes of the air passages, on which parts the morbid impressions producing catarrh are generally made. In the third place, by accustoming the surface to a frequent change of temperature, it renders it less liable to suffer from those which are unavoidable, and which are known to be the common causes of colds. The same observations apply, in a great measure, to rheumatism, chilblains, and other diseases produced by the same class of causes.

When used with the view of preventing these diseases, the bath, in some form, ought to be prolonged through the different seasons. In the summer sea-bathing will be best, and, afterwards, the shower-bath, or ablution. In most cases it will be found sufficient to employ the latter partially to the chest and trunk, after the weather has become cold; and it should be continued through the whole winter.

The cold bath may be said to be applicable to the whole class of nervous diseases, properly so called,—that is, diseases which manifest themselves chiefly by morbid mobility or excitability of the nervous function, and irregular action of the muscular system,—provided there exists no considerable physical change or obstruction, as it is commonly called, in any important viscus, and provided the first impression of the remedy is not found too powerful, either as an exciting or depressing agent. It is, however, more generally useful in those slighter, anomalous, nervous affections, so constantly met with in practice and under such varieties of form, than in the more formal and

\* *The Influence of Climate, &c.* Lond. 1830.

well-marked diseases which are alone treated of in our systems of medicine; although it is a valuable remedy in many of the latter class, when none of the contra-indications above noticed exist against its use, and when it is applied in the mode and form best suited to the individual case. Of this kind are chorea, hysteria, some cases of epilepsy, loss or deprivation of certain functions, as loss of voice, smell, taste, &c.; certain forms of hypochondriasis; local paralytic affections unconnected with cerebral disease, such as loss of power in the sphincters of the bladder or anus; certain cases of palsy of long standing, in which all active cerebral affection has been removed, &c. In some of these cases the remedy is frequently only of doubtful utility, and must therefore be administered with great caution. The chief circumstances which contra-indicate its employment in such cases, are the existence of organic disease in the brain or spinal marrow, or a disposition to cerebral congestion. In all such cases, and wherever any doubt exists as to the propriety of the remedy, the shower-bath is the preferable form; and this is the only form which should be used in any case of epilepsy.

The cold bath is beneficial in many chronic affections of the mucous membranes attended with discharges, such as leucorrhœa, gonorrhœa, &c.; also in certain cases of chronic catarrh, attended with little or no inflammation of the bronchial membrane, particularly in the dry catarrh, and in those forms which seem to depend rather on a relaxed than an irritated state of the bronchial membrane.

It is occasionally beneficial in cases of passive hemorrhage, particularly epistaxis and menorrhagia.

It is sometimes usefully employed in cases of nervous or functional dyspepsia, unaccompanied with inflammation of the gastro-intestinal membrane, more particularly after a course of warm bathing. Its employment in mania was formerly noticed.

For the use of the cold bath in febrile diseases, we refer to the article FEVER. We would only here repeat, what was said in a former section, that the tepid or cool ablution is the form most adapted to such cases.

The cold bath is useful in certain cases of amenorrhœa, particularly where there exists neither a very plethoric state of the habit, nor yet chlorotic debility. In chlorosis, properly so called, cold bathing is rarely admissible.

In no disease is the cold bath more beneficial than in the intervals of asthma, when the system is otherwise in a proper state for the remedy. In this case its principal action is, no doubt, as a preventive of catarrh or cold, which is by far the most frequent exciting cause of the disease. It also operates by giving tone to the nervous system, and rendering it the less susceptible of morbid impressions. (See ASTHMA.) On the same principles it is beneficial in the latter stages of hooping-cough. It is likewise useful in the intervals of ague, when the disease exists in a simple state, unaccompanied with any visceral affection.

#### OF WARM BATHING.

##### § 1. *Of the phenomena and operation of warm baths in general.*

The only forms of the warm bath which it is our intention to notice in the present article, are, the water, vapour, and air bath. As these are respectively productive of effects sufficiently different to entitle them to be regarded as distinct medical agents, we shall treat of them separately; but as they all agree in some important particulars, it will save repetition to notice these, in the first place, under one general head. This we shall do in the present section.

The immediate action of the warm bath on the system is, like the sensations excited by it, in many respects the reverse of that of the cold bath. In the latter, nature seems to encounter a hostile power, which she must overcome before she can make it minister to her comfort; the pleasurable feelings thence resulting being derived rather from the operations of the system itself, than from any impressions communicated to it from without. The warm bath, on the contrary, is directly gratifying to the feelings, and seems at once acknowledged as a power friendly to life. In the new medium, the surface and extreme parts seem to partake of that animating sense of heat which is, in general, confined to the trunk and central parts of the body.

The following are some of the principal modes in which the warm bath affects the animal body.

1. It acts directly, and in a way altogether incomprehensible to us, on the nervous system; partly, no doubt, by modifying sensation, but also by producing effects which seem unconnected with any such modification. Its effects vary considerably with the medium, but more particularly with the degree of heat communicated. When the temperature of the bath is confined within certain limits,—as for instance, when the water bath is of the temperature of 95°, 96°, or 97°, the whole nervous system is, in general, soothed, the feelings are gratified, and a gentle languor steals over the mind. Slight degrees of local irritation, pain, or spasm, that may be present, are frequently removed, and even, in some cases, great general irritability of the system is effectually subdued, at least during the continuance of the bath. At a temperature somewhat higher than this, the bodily and mental feelings are still gratified, but a very brief continuance of the remedy produces excitement in place of tranquillity. If the heat is considerably greater, the feelings are painfully excited, and the temporary stimulus is followed by a proportionate degree of exhaustion.

2. The warm bath influences the system by elevating the temperature either of the whole body or a part of it. If the parts which come in immediate contact with the heating medium are below the general temperature of the body, they will be gradually raised to this temperature, if the bath is continued. If the heating medium is of a temperature greatly above that

of the body, it will raise the superficial parts, and even the whole mass of blood, above their ordinary degree of heat. The extent of this elevation, however, as is well known, is confined within very narrow limits by that wonderful power of the living body which regulates its temperature, in a very considerable degree, independently of all external influence. While life remains, we can neither greatly elevate nor greatly depress the general temperature of the body by any degree of heat or cold applied to it. This conservative power, however, does not confer a complete immunity from the operation of the ordinary laws that regulate the distribution of caloric in inanimate matter. A great and long continued degree of cold sensibly depresses the animal temperature even of warm-blooded animals, at least in the external parts; and a great and long continued heat raises it in like manner.

The degree of heat which can be borne by the living body, as communicated by different media, varies extremely. The variation depends upon several circumstances in the nature of the heating medium, more particularly on its density, its capacity for caloric, its conducting power, the degree of fixedness or mobility of its particles, &c. Thus, the heating power of dry air is much less than that of moist air at the same temperature; this is much less than air loaded with vesicular vapour, as in the instance of the vapour bath; and this, in its turn, is greatly less than the common fluid or water bath.

3. The warm bath modifies very considerably the functions of the skin, as an exhalent and absorbent organ. We must refer to the writers on physiology, and more especially to the work of Dr. Edwards,\* for the full exposition of this important effect of the bath. We can only, in this place, refer to the principal points which seem to be established.

*a.* In the state of health, the skin appears both to exhale and to absorb fluids in the water bath. The relative amount of the two processes appears to vary considerably with the temperature. At very low temperatures, and up to about 50° Fahr., absorption by the skin exceeds transudation. From this point to about 70°, the two processes would seem to be pretty equally balanced. Above this degree the transudation exceeds absorption, and the excess progressively increases with the temperature.

*b.* The temperature of the bath, or rather the degree of heat communicated to the body, being the same, and other things being equal, the degree of absorption is proportioned to the density of the fluid in which the body is immersed. Much more fluid is, therefore, absorbed in the water bath than in the vapour bath. It is not ascertained that the amount of exhalation is in the inverse ratio of the density of the fluid; on the contrary, there are strong grounds for believing that this is not the case:

it is, however, ascertained that in the vapour bath the transudation exceeds the absorption.

*c.* In the warm-air bath the difference between the two processes is at the maximum, since the transudation is often extremely copious, while absorption is almost of necessity null from the absence of the material to be absorbed.

There is reason to believe that the absorbent and exhalent functions are modified in other ways by the chemical composition of the bath. But the whole subject stands in need of further investigation.

4. The warm bath modifies the texture of the skin; at least the bath of water and watery vapour. This effect arises partly from imbibition, and partly from a specific action on the animal fibre. It is greatly less on living bodies than on those which have become dead; but still it is conspicuously marked in them. The ultimate effect is to soften, to expand, and to relax the parts with which the fluid is in contact; and it would appear that its relaxant influence extends to parts with which it is only mediately in contact. After immersion in the warm bath for a considerable time, not merely the muscles of the limbs, but even the abdominal viscera appear to have lost a portion of their solidity and tension. Much of the relaxing property of the warm bath on the surface of the body is no doubt derived from the temperature; as we know that the cold bath has, in a considerable degree, the very reverse operation. Yet a good deal must be attributed to the effect of the water independently of the temperature, since we find, firstly, that even cold water, if long applied, produces a softened state of the skin; and secondly, that dry heat, or heat conveyed through the medium of air, does not produce similar effects.

5. The warm bath modifies the frequency and force of the action of the heart. This is sufficiently shown by its well known effects on the pulse. The precise effects of the bath in this way depend on many circumstances, some having reference to the patient, and some to the bath. In general it may be said that when the degree of heat communicated is moderate, and the sensibility and irritability of the subject are not excessive, the change produced in the frequency of the pulse is not remarkable. If the medium is water, and the temperature does not exceed 97°, although the pulse and respiration may be slightly quickened upon the patient first entering the bath, yet after a short time, when the surface and extremities have become moderately but thoroughly warmed, and the nervous system *accustomed*, as it were, to the new stimulus, the heart and lungs resume nearly their natural action. The pulse may be somewhat fuller, but, in general, is not increased in frequency. When the temperature is raised to the full heat of the blood (98°), it will, in most cases, slightly augment the power and frequency of the heart's action. At still higher temperatures, the pulse becomes considerably increased in frequency, and in a degree proportioned to the temperature; and if this is

\* De l'Influence des Agens Physiques sur la Vie. Paris, 1824.

carried to the highest point at which it can be sustained, the frequency becomes extreme.\* When so much excited, the pulse occasionally continues quick for several hours after the bath, and in some cases it does not regain its natural standard until after the patient has had a night's rest.

6. The warm bath modifies the relative distribution of blood throughout the system; more especially the relative proportion of this in the external and internal parts. When a disproportionate quantity exists in the internal organs, the warm bath recals it to the surface, and in various ways: 1stly, by exciting the superficial capillaries to increased action; 2dly, by relaxing and dilating the external tissues, so as to render them not merely capable of containing more fluid, but to force them, by a physical necessity, to draw an additional supply from other parts; 3dly, by directly relieving the local irritation on which the internal congestion may depend.

It is to be observed, however, that this equalizing power of the warm bath only exists when the temperature is of that moderate degree which does not excite the heart to preternatural action. If the stimulus of the heat augments the force and frequency of the heart's contractions considerably beyond the standard of health, although much more blood than before may be attracted to the surface, the internal parts are not unloaded in the same proportion. On the contrary, the whole vascular system being stimulated to increased action, and the contained fluids being in some degree dilated by the increase of the temperature, an increased quantity of blood is thrown into the capillaries (at least in the same space of time) in every part of the body.

7. The warm bath increases the volume of the superficial parts of the body and of the general mass of circulating fluids, in proportion to the degree of temperature communicated to the system. This effect is obvious on the surface generally, and is demonstrated in parts capable of admeasurement. Rings on the fingers, which we had occasion to notice as becoming loose in the cold bath, in the warm bath fit more tightly, the soft parts on both sides frequently swelling considerably beyond the diameter of the ring. The same thing is shown by the greater difficulty of putting on tight shoes after the warm bath. Some physiologists attribute the principal results observed in the application of the *hot bath* to the expansion of the fluids. No doubt it must have a certain effect, but by no means to the extent which has been supposed. The effect of heat as a stimulus exciting the heart to increased action, and thereby throwing the blood with greater force and rapidity through the whole

vascular system, is of much greater consequence than its physical dilatation. It must be recollected that the universal and intimate penetration by the blood of all the solid tissues will soon raise them to the same temperature as this fluid, and, expanding them proportionally, will remove the evils that might arise from an over-distension caused by a disproportion between the vessels and their contents.\*

§ 2. *Of the warm bath, strictly so called, (water from 92° to 98°.)*

The general effects of the warm bath have been mostly noticed in the last section; but we shall give a brief recapitulation of them here, for the convenience of practical reference. The warm bath possesses at once the somewhat opposite powers of exciting and soothing the nervous and vascular systems. Its power of soothing the nervous system is direct and obvious; its power of exciting is, in general, confined within the limits of natural or healthy action. It may be said rather to prompt to normal action than to excite. It acts as a direct but gentle stimulus to the skin, augmenting the quantity of its blood, and at the same time relaxing its texture. It produces a more general and equable distribution of blood throughout the whole system; and, in a more especial manner, *derives* it from the internal parts to the surface and extremities, without, at the same time, giving rise to undue action or irregular determinations to particular parts. By these various actions it universally promotes absorption and reaction. Its ultimate effects are to soothe and refresh the whole system, and, at the same time, to render all its functions freer and of more ready performance. When its operation is prolonged, the soothing and relaxing effects become progressively more and more predominant, while the gentle excitement proportionally decreases. By these various modes of influencing the system, it is capable of fulfilling various indications in the treatment of diseases, according to the mode of its application, and the particular state of the system at the time. By relieving pain and irritation, it acts as a sedative; by restoring deranged functions, and rendering them of more ready performance, it acts, like the cold bath, as an indirect tonic. By its soothing effect on the nervous system, and its general powers of relaxing, it is an antispasmodic. By modifying the circulation in the extreme parts, it is strongly derivative; by its action on the skin, it is directly diaphoretic; and by more or fewer of these modes of action combined, it becomes a powerful alterative. It acts in several other ways, to which it is not easy to give a formal designation, but which will be understood from what has been stated in the preceding section, and what we are now about to deliver.

*Medical uses of the warm bath.*—In treating of the employment of the warm bath, it has

\* See the experiments of Dr. Parr in his *Thesis de Balneo, Edin. 1773*, and in his *Medical Dict. Art. Balneum*; of Fordyce, Blagden, and Dobson in *Philos. Trans.* vol. lxx. p. 111, 463, 484; of Delaroché and Berger, *Journ. de Physique*, tomes 63, 71, 77; of Rostan, *Dict. de Méd.* t. ii. Art. *Bain*.

\* Is it probable that the impossibility of distension of the brain, within the solid cranium, is one reason why the effects of baths of very high temperature are particularly felt in the head?

been customary to consider it under two heads, as hygeiènic and therapeutic, or preventive and curative. As, however, the bath is never necessary in the state of perfect health, and as most of the conditions of the body in which it has been recommended, are, in fact, deviations from this standard, and therefore, in strictness of language, morbid, although perhaps not formally designated as diseases—it is obvious that this classification is not quite accurate. We shall, nevertheless, so far comply with the customary arrangement as to notice, in the first place, the milder forms of disorder; and, secondly, the more formal diseases.

I. The following are a few of the cases of milder disorder, in which the warm bath is highly beneficial:—

1. In fatigue after great muscular exertion, particularly if long continued, as from fencing, boxing, hard walking or riding, playing at any laborious game, as cricket, racket, &c. In these cases, the body should be allowed time to cool before the bath is taken, and the temperature of this should not be higher than is absolutely necessary to produce the desired effects. In general, 94°, 95°, or 96° will be sufficiently high.

2. After a long journey, more particularly in the case of persons of a delicate or feverish habit. Travelling for several successive days, even in the easiest carriage and on the best roads, produces, in almost every person, dryness of skin, irregular distribution of blood, defective secretion and excretion, general irritation of the nervous system, and a slight degree of feverish heat. In irritable subjects, and still more in persons affected with some chronic inflammation, or tendency to such, the excitement from travelling often leads to serious consequences if not speedily allayed. In such cases the warm bath is an invaluable remedy; and, when combined with repose and abstinence, and a gentle aperient, may be regarded as almost specific for safe travelling.

3. In sedentariness from any cause. Also after long-continued mental excitement and loss of sleep, whether accompanied by sedentariness and seclusion, and inactivity of the external senses, as in the labours of the study; or with bodily exertion and activity of the external senses, as in many departments of public and professional life, or in the no less laborious avocations of fashionable dissipation.

4. The warm bath is very beneficial in numerous other slight disorders of the system, from whatever cause arising, and whether of a chronic kind, or the harbingers of acute diseases. Of this sort are irregular determinations of blood, particularly congestions in the internal organs, and recession of it from the surface and extremities; nervous irritations of all kinds, and disposition to spasmodic affections; a dry and harsh state of the skin, either with a disposition to feverishness, or with coldness of the surface; the reverse state of relaxation of the skin, with a disposition to clamminess and cold perspiration, &c. &c.

II. The warm bath is beneficially employed in numerous diseases of a more formal and

serious kind, and of very different characters. We can only refer to some of those in which it is most useful:—

1. Chronic nervous diseases of a spasmodic kind, unaccompanied by a plethoric state of the system, or by fever, and not dependent on an inflammatory condition of the nervous centres. Of this kind are cramps, spasms, convulsions of various kinds, and, particularly the convulsive affections of infants, whether depending upon idiopathic or sympathetic irritation of the nervous system. The last-named qualifications must be strictly attended to, otherwise the bath may be productive of great mischief, as we have reason to know that it often is from such neglect. We shall have occasion to notice the cautions necessary in such cases hereafter.

2. Various painful affections, chiefly of a nervous or spasmodic nature, occurring in spare habits, and without inflammation, or with a degree extremely disproportioned to the severity of the pain. Of this kind are the numerous forms of neuralgia, including sciatica and lumbago, gastralgia, and colic; also gall-stone, nephralgia, stone in the ureter, bladder, urethra, &c.

3. Certain acute inflammations, more especially of the mucous membranes of the abdominal and pelvic viscera, when accompanied by great pain. Of this kind are certain forms of enteritis, gastritis, inflammations excited by and accompanying gall-stone and urinary calculi; some forms of dysentery, diarrhœa, cystitis, hysteritis, &c. In all these cases, or with very rare exceptions, previous loss of blood, both generally and locally, will be necessary to constitute the bath a useful, or even a safe remedy. With such preparation, however, and if not contra-indicated by the plethoric habit of the patient, or other circumstances, the bath, at a temperature not exceeding 97°, is often extremely beneficial.

In the class of cases now under consideration, a great mistake is frequently committed by the practitioner overlooking the inflammations which accompany the pain and spasm, and prescribing at once opium and the warm bath, without any attempt to lessen, previously, the violence of the local affection, or the general fever, by proper depletion. In instances of this sort, the bath, more especially if administered at a high temperature, as it often is, has a direct tendency to aggravate in place of relieving the disease.

4. Certain chronic inflammations, congestions, or irritations of several of the same parts, not essentially of a painful kind. Of this sort is that extensive class of diseases of the intestinal mucous membrane, commonly arranged by French writers under the general name of chronic *gastro-enteritis*, and indicated in different cases by the common symptoms of dyspepsia, constipation, diarrhœa, &c.; also chronic inflammations or irritations of the uterus, vagina, bladder, kidney;—*dysmenorrhœa*, *dysury*, *amenorrhœa*, *leucorrhœa*, &c. In most of these cases local bleeding will be proper previously to the administration of the bath; and in several

of the affections of the pelvic viscera, the hip-bath will frequently be preferable to the general bath.

In no class of cases is the warm bath more strikingly beneficial than in those affections of the stomach and bowels which are commonly ranged under the head of *dyspepsia*. This remark is more especially applicable to the forms of this affection in which there co-exist a fixed local irritation in some part of the bowel, an unhealthy state of the skin, and an irregular distribution of blood, more particularly on the surface and extremities. And we may add that there are few if any cases of dyspepsia, of long standing, in which one or more of these states do not exist. It is well known that the skin has a much more intimate sympathy with the mucous membranes than with the parenchymatous viscera; and this truth is in no case more strongly manifested than in the effect produced by the warm bath in affections of the gastro-intestinal membrane. Besides its direct effect in this way, through the medium of the nervous system, it acts at the same time locally on the skin as a powerful derivative, and as a means of equalizing the circulation in the central and extreme parts. A sensible remark, made by M. Rapou, in speaking of the effect of the vapour-bath in this disease, is equally applicable to the warm bath. He says, that chronic inflammations of the mucous membrane of the stomach and bowels are frequently confounded with diseases of a very different kind, such as nervous dyspepsia, gastralgia, &c. In cases of the last-mentioned kind, antispasmodics, bitters, tonics, &c., will often be beneficial; while they will be extremely injurious in the former,—the irritation of the membrane being thereby frequently excited to inflammation; or, if this already exists, it will be greatly aggravated. In both classes of cases the warm bath is at least a safe application; and, with very few exceptions, it is a most salutary one. Its administration is therefore not affected by error in diagnosis. We may add that it is in the very cases where internal remedies are most prejudicial, that the warm bath is most beneficial; namely, in irritated states of the mucous membrane, accompanied either with obstinate costiveness or a tendency to diarrhœa, or the one alternating with the other. From its action in such cases, the warm bath may be said to be at once laxative and astringent; and when its use is combined with proper diet and exercise, or, at most, with a few leeches to the præcordia or anus, cures will often be effected by it, in cases of long standing, with little or no aid from medicine. *Ceteris paribus*, the warm bath is the more indicated in dyspepsia the more the surface deviates from the healthy state, whether in regard to the distribution of the blood in it, or to its functions as a secreting and excreting organ.

5. The warm bath is beneficial in various chronic diseases of a general and cachectic kind, attended by great functional derangements of important organs, and generally by a depraved state of the blood, as well as an irregular distribution of it. Of this kind are gout, general

disorder of the system from long-protracted dyspepsia and loaded bowels, diabetes, chlorosis, &c. &c.

Few questions were formerly more agitated among medical men than the propriety of warm bathing in gout, and more particularly of the warm waters of Bath. The zeal with which the question was regarded has, however, greatly lessened in our time; partly because longer experience has tended to solve it more satisfactorily, and partly because some progress has been made in ascertaining the pathology of gout. Diseases in general, and this among the rest, are not now treated on principles so completely empirical as formerly.

In viewing gout in relation to its treatment by warm bathing, we may, in a great degree, although not entirely, dismiss from our minds its specific nature, and prescribe the bath on the same principles as in other diseases. In the great majority of cases, we consider it as totally inadmissible in the inflammatory stage of gout. In the intervals of the disease it is extremely applicable to many of the functional and other derangements that complicate it, or constitute an important part of it; but the propriety of its administration in individual cases must entirely depend on the particular state or degree of these derangements, or on other states of the system with which they may be combined. The great objection to the use of the warm bath in gout is the state of general plethora with which this disease is so constantly connected. It is chiefly the absence of plethora which permits the bath to exert its beneficial effects in many other diseases of a still more inflammatory nature than gout; and if we have removed this condition effectually in gout, the presence of some inflammation in the joints is not a necessary contra-indication to its use. In the general state of disorder in which gout originates, viewed abstractedly from the accompanying plethora, there is no single remedy more valuable than the warm bath; in the intervals of gout, therefore, after proper depletion, we recommend its use in the strongest manner.

6. The warm bath is useful in many chronic diseases of the external subcutaneous textures, with or without general disorder of the system. Of this kind are chronic rheumatism, the local sequelæ of gout, nodosity and other chronic affections of the joints, partial paralytic affections, muscular contractions, &c. In many of these cases the local bath, in the form of *douse* or vapour, is preferable to the general warm bath, more particularly when combined with the operations of friction, champooing, &c.\*

7. A great number as well as a great variety

\* In many cases of this kind the local bath invented by Dr. Blegborough, and termed by him the *air-pump vapour-bath*, is extremely useful. This apparatus combines the advantages of dry cupping with the stimulant or relaxing effects of the vapour bath. See Facts and Observations respecting the Air-pump Vapour-bath. By R. Blegborough, M.D. Lond. 1803.

of chronic diseases of the skin, both idiopathic and sympathetic, are greatly benefited by the warm bath in one or other of its forms. In such cases the bath acts directly as a topical remedy modifying the actual state of the skin, as well as a means of improving the general health and the internal disorders with which the cutaneous disease may be connected. This is the class of cases in which impregnation of the water with various saline or vegetable matters dissolved or diffused in it, is more especially useful, and in which the stay in the bath may be prolonged much beyond the usual period. When not otherwise contra-indicated, it may be extended to two or more hours.

9. The warm bath has been used, more particularly on the continent, in the cold stage of severe fevers, and in the retrocession or imperfect development of some acute exanthemata. In such cases, it is employed with the view of at once stimulating the skin topically, and deriving from the internal organs. The employment of the remedy, however, in such cases requires great discrimination, and we think it necessary to caution the young practitioner against its general use. In fevers of long standing, marked by much nervous irritation, harsh dry skin, &c. the warm bath of a low temperature—or the tepid bath,—is very beneficial.

Many other diseases might be mentioned in which the warm bath is occasionally found to be a very valuable remedy; but we cannot here take notice of all such cases. We trust that enough has been stated to guide the inexperienced practitioner to a safe application of the remedy in most instances that may present themselves.

*Cautions and contra-indications in the use of the warm bath.*—There are few remedies more frequently misapplied than the warm bath, or whose misapplication is of more serious ill-consequence. It cannot be expected that we should here enumerate all the cases in which it may be misapplied, or all the cautions that are requisite in prescribing it. These must, in a great measure, be derived from the general principles that regulate its administration; but every practical physician must be well aware how frequently the principles must be modified in their application to individual cases.

The warm bath is either altogether contra-indicated in the following cases, or is not to be employed without great caution or previous preparation:—

1. In very gross, full, habits; in plethora of all kinds, in great obesity.

2. In persons predisposed to apoplexy or determination of blood to the head, hæmorrhage, particularly hæmoptysis. It is equally improper in most organic diseases of the heart and great vessels; and, in general, in all cases, in which the excitement of the circulation or expansion of the fluids is likely to prove injurious. In these cases the risk, generally speaking, may be said to be proportioned to the heat of the bath; and we are far from

asserting that a bath of a moderate temperature may not be safely administered, under proper restrictions, in many of the diseases now alluded to. Previous depletion, as we had formerly occasion to observe, will often enable us to use the bath of a moderate temperature in inflammatory diseases, more particularly such as are accompanied with pain, or have their seat in the mucous membranes.

3. In great relaxation of the system, with a tendency to dropsy. In cases of this kind the tepid bath, however, will often be useful.

4. In extreme sensitiveness of the surface, and in persons in whom the pressure of the water occasions great preordial distress. In these cases the vapour bath is often well borne and is very beneficial. A little management will often get over the difficulties mentioned in this paragraph.

5. In all febrile diseases, whether accompanied with visceràl inflammations or not, where there is an active circulation and a hot dry skin.

6. During the presence of the catamenia, except in cases of great urgency. The warm bath may be used in pregnancy, more particularly in the early months, but not without considerable caution. The contra-indications to its use must be found in individual cases; but it may be stated generally that pregnancy, in relation to the warm bath, is to be viewed as a state of excitement, if not as an inflammatory disease.

Many other grounds for its cautious employment, and also for its total prohibition, have been noticed in the preceding pages; to these and to the principles on which the general administration of the remedy is founded, we refer the reader. We would here only add one important rule which should never be lost sight of in prescribing the warm bath, or, indeed, any other powerful remedy—and this is, never to recommend it in any disease without proper examination of the individual case. Much practical mischief is the consequence of neglecting this cardinal canon of therapeutics. Examples of this truth might be drawn from most diseases in which the warm bath is used. Thus we have stated that it is a most valuable remedy in chronic dyspepsia, gout, &c. &c. but it is so only provided there exists no active inflammation, general plethora, or other analogous complications. In many of these cases the bath will be found extremely beneficial after loss of blood, purging, or low diet; although before these were had recourse to, it might have been not merely useless but very injurious. Infantile convulsions occur to us as another case in point. Generally speaking, the warm bath is extremely beneficial in this class of diseases; but it is found to be sometimes no less prejudicial, when applied without due examination of the peculiarities of individual cases. In plethoric and gross children, a very considerable proportion, the local abstraction of blood from the head, and the complete unloading of the alimentary canal, are often necessary to render such a measure beneficial, or even free from danger.

*Practical administration of the warm bath.* Under this head we shall embody various important points which require particular attention in using the warm bath as a therapeutic agent, and with which, therefore, the practitioner ought to be well acquainted.

1. *Temperature of the water.* The exact degree of heat, between the limits 92° and 98°, that is to be prescribed, must be regulated by the peculiarities of individual cases. In certain states of disease and in particular constitutions, the same degree of temperature will be productive of very different effects on the feelings of the patient and on the system at large. It may be stated as a general rule, not however without many exceptions, that any degree of temperature may be selected between 93° and 97°, which is most agreeable to the feelings of the patient. Many persons will prefer a higher temperature than the last named degree, but few lower than the first. If the patient's feelings require it, and there is no particular contra-indication in the case, the temperature of 98° may be allowed; but we must on no account go above this, if our object is to refresh and soothe, not to stimulate and exhaust. The temperature of 95° or 96° is, on the whole, that which is most generally pleasant and beneficial at the same time; and if either of these is found sufficiently high to maintain the feelings of comfortable warmth, through the whole period of the bath, the temperature must not be raised. If a lower temperature, however, is found more agreeable, this may, in most cases, be allowed at the will of the patient.

Generally speaking, in the warm-water bath, the same degree of temperature must be kept up during the whole period of immersion; and this will easily be effected by the addition of a small quantity of hot water about a quarter of an hour after the patient has been in the bath.\* The temperature must always be ascertained by the thermometer in the first instance; and the subsequent additions of water are to be regulated by its indications, and not by the feelings of the patient. Great mistakes are often committed through neglect of this rule, the temperature being gradually and imperceptibly raised much above that of the warm bath, with the entire frustration of the objects with which the remedy is prescribed.

2. *Period of stay in the bath.*—The time of the immersion, like the temperature, must be determined by the practitioner in each case, according to the nature of the disease, the constitution of the patient, and the object for which the bath is prescribed. Speaking generally, a quarter of an hour may be said to be

\* Considerable difference is observed in the rapidity with which the warm bath cools; dependent on the materials and construction of the bath, its size, the circumstance of the same bath having been previously used or not, the temperature of the bather's body generally, the degree of motion kept up in the water, &c. &c. The only safe mode of regulating the temperature is by keeping a thermometer constantly in the water, to be observed from time to time by the patient or attendant.

the shortest period, an hour the longest, and twenty-five minutes to half an hour the medium. Periods greatly longer than these, however, are very common, more particularly on the continent, and are, no doubt, very proper and useful in certain cases. In the mineral water baths at different places in Germany and Switzerland, persons are accustomed to continue several hours consecutively in the bath, and even repeat the immersion after a short interval, so as to remain in the water eight, ten, and even twelve hours in the course of one day. The effects of the bath are, in all cases, greatly modified by the length of the immersion. It may be stated as a proposition generally true, that the bath, at the temperatures now under consideration, is more *relaxant* and *deobstinent* the longer it is continued. If at all approaching the temperature of the blood, it has always some stimulant effect at first; and it is only after this has completely subsided, that the relaxing effects are fully experienced. For this reason the same bath may be exciting if continued only ten or fifteen minutes, and soothing and relaxing if continued twice or thrice as long. It is not merely in cutaneous diseases, in which one of the principal objects is to produce a decided change in the affected parts by the local action of the fluid, that the immersion for several consecutive hours is recommended; the same practice is capable of producing very beneficial results in various chronic diseases of the internal organs. The least consideration of the subject, independently of experience, must lead to the conclusion, that an action of this kind, kept up for so long a time on the whole cutaneous surface, must have a powerful effect as a revulsive, and occasion important changes in the condition of the internal organs. We are of opinion that this mode of employing the warm bath is too little practised in this country. It can only be conveniently obtained at thermal springs, where alone large bodies of water of the proper temperature are always to be had, and where alone, consequently, the large or plunge bath of this temperature is to be found. So prolonged a stay in the common solitary bath would be altogether intolerable. Admirable opportunities for this kind of bathing are, however, afforded by the large mineral baths at Bath in this country, and at many places on the continent. The *Queen's Bath*, or the *Cross Bath*, at the former place, is exactly suited to the purposes now contemplated, being of the temperature best adapted to effect them, namely, from 94° to 96°.

3. *Time of using the bath.*—This, like the preceding circumstances, cannot be absolutely fixed. When prescribed in acute diseases, the bath must, of course, be employed at any time when needed. In chronic diseases, or when used as a measure of hygiene, the hour of bathing may be fixed. It is the practice at Bath, and some other mineral springs, to bathe early in the morning; but we apprehend this practice is adopted as much from motives of convenience as because this time is deemed preferable. On the contrary, we should say, as a general rule, that the best

time for bathing is between breakfast and dinner, either two or three hours after breakfast, or an hour and a half before dinner. The latter period has this advantage, that the patient is less tempted to expose himself to the open air after the bath.

4. *The conduct of the patient while in the bath*, as also previously to its use and afterwards, deserves some notice, although this is of less moment, perhaps, than in the case of the cold bath.

It is proper to enter the bath in as tranquil a state, both of body and mind, as possible. The patient, therefore, must not bathe while greatly heated with exercise or stimulated by a recent meal, more particularly after drinking much wine. A state of chilliness or coldness forms no objection to the bath.

While in the bath, the whole body should be covered with the water, or rather the parts that have been once immersed should not be left exposed to the air. Friction, with a coarse cloth or with the flesh-brush, is generally to be recommended. In the large baths which admit of locomotion, this will, as a matter of course, be used, and should be used.

After the bath, the patient should not unnecessarily expose himself to the open air for sometime, especially if the weather be cold; and it may be stated as a good rule for him to remain quietly in the house for an hour after the bath. It is not, however, intended to be asserted that there is, in general, much, or indeed any risk in the patient going abroad immediately on coming out of the bath: on the contrary, we believe that there is much less risk of catching cold immediately on coming out of the bath than afterwards; and, except in the case of very delicate or diseased persons, there is no objection to the patient walking from the bath to his own home, if at no great distance. We, however, consider it better that no unnecessary exposure or considerable bodily exercise should be taken for an hour or two after bathing, for the same reasons that we deem them improper after blood-letting or any other important therapeutic operation. When one of the objects of the bath is to excite much sensible perspiration, it will be proper for the patient to go to a warm bed after it, to place himself between blankets, and remain there as long as the perspiration continues. When the object is not to excite perspiration, the patient should not go to bed, but dress himself in his ordinary clothing. It is a slight circumstance, but one deserving notice in this place, because of some consequence, and often neglected, that the towels used for drying the body should be always warmed, and, of course, thoroughly dry.

5. *Repetition of the bath*.—The frequency of repetition of the bath, like the other circumstances connected with its exhibition, must be regulated by the exigencies of individual cases. One bath daily is the maximum of frequency, (except in certain cases formerly noticed;) once a week, the minimum. The most usual,

and upon the whole the best rule is—to take the bath every second day, or, at least, every third day. The length of time that a course of warm-bathing is to be continued cannot be at all fixed, except in individual cases; and then only by observing the effects of the remedy.

6. *Form of the bath*.—The special mode of applying the warm-bath is not a matter of indifference. It is true that, in a great majority of cases, the common small bath, in which the patient is immersed in the semi-recumbent posture, answers every purpose for which the bath is administered. In some cases, however, more particularly where the immersion is greatly prolonged, the constrained position in which this bath is taken cannot be borne. In such instances the large open bath, which admits of locomotion, is greatly to be preferred. Even, independently of the relief from the uneasiness of a constrained position, there are many cases in which the free movements permitted in the large bath are directly beneficial. Of this kind are local affections of the limbs and joints, in which the contemporaneous use of free motion and friction while in the water is of the greatest benefit. The advantage is no less evident in many cases of internal disease. We hold it therefore far from a matter of indifference in every case, which of the two forms of bath is used; and on this ground alone it will frequently be proper to give the preference to Bath as a place of resort for the invalid for whom warm bathing is recommended,—this being the only place in England where the warm-bath, with the full benefit of locomotion, can be obtained.

7. *Influence of saline impregnations in modifying the effects of the warm-bath*.—In the preceding observations, we have spoken of the water-bath, without regard to its impregnation with saline or other extraneous substances. It is, however, necessary to notice these in this place. This subject is, perhaps, less regarded in this country than it ought to be. Many persons seem to consider only the temperature, deeming it a matter of indifference whether the water is that in common use for domestic purposes, or is that of the sea or of mineral springs. This is a very great mistake, and can only arise from inexperience or want of observation. Two or three trials on delicate and relaxed subjects will suffice to convince any one that the two kinds of baths are productive of very different effects. In general it may be stated that water containing mineral and saline substances in solution, is less relaxing and consequently more tonic than pure water. Such compound baths can be borne for a longer period, and are followed by less exhaustion than baths of pure water. Patients are also less liable to take cold after the former. When, therefore, the object is to produce great relaxation and exhaustion, as in certain cases of acute inflammation, pain, or spasm, the pure water-bath is to be preferred; while, on the other hand, the saline or mineral water-bath is to be administered if the object

is not to exhaust but to refresh. In cutaneous diseases, sometimes one kind of bath will be preferable, sometimes another, according to the nature of the case. The compound bath is certainly more stimulant to the skin, consequently more derivative from the internal parts; and this circumstance will, no doubt, account for much of the difference observed between the two kinds of bathing. It would, however, be both unphilosophical and unjust to consider the chemical composition of the water as a matter of indifference, provided the same degree of stimulus were communicated by it to the skin. Without pausing to examine the question as to the absorbing powers of the skin, and the actual transference of the materials of the bath into the blood through this medium, it is a matter of simple observation and fact, that the effects of bathing vary with the nature of the chemical composition of the fluid. The warm-baths attached to the mineral springs of Bath, Buxton, Cheltenham or Leamington, Harrogate, Matlock, and Tunbridge-Wells, have each peculiar effects. The warm sea-water bath differs from all these: and, although the difference may not be often appreciable, there is no doubt a difference even in the action of river, rain, spring, and hard and soft pump-water respectively. In the cases in which the saline bath is considered preferable, an easy and in general an effectual substitute is afforded by the addition of common salt to plain water; and it will be found, in practice, that such addition is to be recommended in the majority of cases in which the warm-bath is prescribed medicinally. When used as a measure of hygiene, the saline bath is in almost all cases to be preferred.

§ 3. *Of the tepid-bath (temperature of the water from 86° to 92°.)*

The effects of the bath of a temperature considerably below that of the body, yet still communicating the sensation of warmth to the surface, are similar in kind to those of the warm-bath, but inferior in degree. Generally speaking, the tepid-bath is less pleasant, less animating, less soothing. It possesses neither the direct stimulus of the warm, nor the indirect stimulus of the cold bath. When prolonged, in place of the tranquillizing effects produced by the warm-bath, it gives rise to a gradually increasing sense of chilliness and discomfort. Caloric is carried off from the body faster than it is produced, while the unstimulating and relaxing medium has no power, like the cold-bath, to rouse the vital energies of the system to increased vascular action and augmentation of the processes that produce animal heat. In its medical effects, as well as in its thermometrical character, the tepid-bath may be said to occupy a middle position between the temperate and warm-baths. In all cases where we consider the warm-bath indicated, but are apprehensive that from particular circumstances it may prove too exciting, we must of course reduce the temperature to the degree that can be borne. We formerly had occasion to observe that only the

very lowest degrees of the warm-bath are found tolerable by some persons; and we may add that, in some rare cases, even a still lower temperature is necessary. In such individuals the tepid takes the place of the warm-bath as a matter of necessity. On the other hand, among the class of persons whose cases are commonly benefited by the temperate-bath, some will be found whose peculiarity of habit will require the temperature to be raised within the limits of the tepid-bath.

Besides these cases requiring the tepid-bath from the idiosyncrasy of the patient, there are others which require it from the peculiar character of the affection. Of this kind are various mild febrile diseases connected with much irritability and a dry harsh skin; morbid states of the skin itself, in which there exist, at the same time, a very irritable and a dry and heated state of it. There are many other cases in which the tepid-bath is beneficial, and which will readily suggest themselves to those who understand the principles on which the cold and warm baths are prescribed, and are practically conversant with their effects. Our limits oblige us to be contented with this general reference, and the very imperfect outline here given.

§ 4. *Of the hot-bath (temperature 99° and upwards.)*

This bath is a powerful but temporary stimulus to the skin and to the nervous and vascular system, and in a degree proportioned to its temperature. In the state of health, and in disease generally, it has no soothing effects; nor does it, like the warm-bath, gently solicit and encourage the natural actions of the system, but impels them suddenly, forcibly, and irregularly. It tends more to disturb than to equalize action. The heart being powerfully excited, the blood is forced with rapidity through the whole vascular system, the pulse being raised ten, twenty, and even fifty pulsations in the minute, and increased proportionally in strength. This preternatural force of the circulation is felt in a particular manner in the head. The carotids are seen and felt to beat powerfully, and headach, giddiness, and other cerebral symptoms are of frequent occurrence. The combined effect of the increased action of the heart and the direct stimulation of the skin by the local heat, occasion a great afflux of blood to the surface, which becomes universally red and swollen. This determination of blood to the surface does not, however, like that produced by the warm-bath, relieve the internal organs; on the contrary, it is very generally accompanied by great and irregular determination of blood to these parts. The great tension on the surface is, after a time, relieved by the breaking out of a general sweat on all parts not covered by the bath; and there is reason to believe that the same takes place on the parts that are immersed. The other secretions are, like the distribution of the blood, irregular and uncertain, some being increased and others diminished. If the bath is continued, although the pulse remains quick, the general excitement is spee-

lily followed by universal languor, lassitude, and debility; and torpor and somnolency supervene from exhaustion of the animal powers, as in the case of the warm-bath they had been induced by the tranquillizing influence of the remedy on the sensations and the nervous system generally.

In their action, both the warm and hot bath are stimulant to the nervous and vascular systems, but in very different degrees and with very different results. The primary effect of the former may be compared to that of a moderate meal of plain and wholesome nutriment; that of the latter to the potent and sudden stimulation of vinous or other strong drinks; and their ultimate effects may also be said to be analogous. The gentle stimulus of the warm bath remains some time after its application, beneficially prompting and aiding the healthy actions of the system, and gradually vanishing in the habitual conditions of health: the hot bath, on the contrary, excites beyond the limits of safety, disturbs the normal actions of the system, and then suddenly disappears, leaving behind it exhaustion and debility, and frequently disease.

The warm bath is in common use as a measure of hygiene and for luxury, as well as a curative agent. The hot bath is exclusively therapeutical, and its employment in this way is very circumscribed. We had occasion formerly to remark that there are certain peculiarities of constitution and states of disease wherein it is necessary to raise the temperature of the water above that of blood heat, before the ordinary effects of the warm bath are experienced. In ordinary cases, however, the bath at this high temperature produces the effects just described, and these are obviously of a kind which render it improper as a remedial measure in the great majority of instances in which the application of heat to the surface can be supposed to be indicated. The hot bath is, nevertheless, a valuable remedy in certain cases. Owing to its highly stimulating and exciting qualities, it is applicable to morbid states in which the warm bath, if not injurious, is at least of inadequate power; as, for instance, when we wish to produce a great and rapid excitement either of the general system, or only of the skin, or of both at the same time. It is therefore applicable in the following and other analogous cases:—

1. In extreme exhaustion, with a cold shrunk state of the skin and superficial parts of the body, and a concentration of the circulating fluids and the nervous energy in the internal organs. Examples of this morbid state are furnished by spasmodic cholera, certain forms of pernicious fever, ague, &c.

2. In sudden retrocessions of cutaneous diseases, both of an acute and chronic kind; scarlatina, measles, &c. &c. &c. In certain inflammatory affections of the internal organs, in which the circulation is equally concentrated in the interior of the system, and the pulse is too feeble and small to allow venesection to be performed: some forms of enteritis and gastritis, as from retrocedent gout, are of this

kind; but the utmost caution is requisite in applying the remedy in all such cases.

3. In chronic diseases of the skin. In this case the bath is used chiefly as a topical remedy in some of the most obstinate and indolent forms, with the view of exciting the skin, and altering its physical and vital condition. Its application in cases of this kind requires great discrimination and caution; but with the proper care it is capable of being made a very powerful remedy.

4. In certain cases of paralysis of long standing, when there are no grounds for apprehending that the stimulating effects of the bath may induce fresh disease within the head. The very existence of the paralytic state frequently renders the system less susceptible of the stimulus of heat; and when this is the case, there is no doubt that an application so powerful and extensive as the hot bath must in many cases be productive of excellent effects. This remedy is in great use at Bath in such cases; the patients being accustomed to remain in water, of the temperature of 104°, upwards of an hour without suffering any inconvenience, and frequently with much advantage.

In most of the cases above mentioned, the object is to obtain the stimulating and not the debilitating effects of the bath; it ought, therefore, to be used at the highest temperature that is deemed proper, and continued only for a very short period.

All the cautions and contra-indications formerly delivered, respecting the use of the warm bath, are still more necessary in the case of the hot bath.

##### § 5. *Of the vapour-bath.*

*Forms of the vapour-bath and modes of using it.*—In treating of the warm bath it was almost unnecessary to notice the particular forms in which it is administered, as these differ very little from each other, either in their nature or effects on the system. The case is different with the vapour-bath; there being several modes of applying this, which are productive of results respectively different.

There are two principal forms of this bath:—

1. The free or public vapour-bath, steam-chamber or humid stove, bagnio, Russian or Oriental bath. 2. The confined or solitary vapour-bath, such as is commonly used in this country.

1. The free or Russian bath consists of a close room filled with vapour, in which the patient may move about at pleasure, and where many persons may bathe in concert. The chamber is commonly of considerable dimensions, and is arranged somewhat in the manner of a theatre, with benches rising one above another. In the Russian and German baths the vapour is produced within the apartment by throwing water from time to time upon red-hot stones, heated by a furnace underneath. By this process the whole room is soon filled with vapour, heated to a temperature varying from 112° to 160° or 180°, the heat, owing to the diminished gravity of the air, being progressively greater with the elevation of the benches. In the best arranged establishments there are various other apartments connected

with the bathing-chamber. The bathers first enter an ante-room, not containing any vapour, but heated to the temperature of from  $75^{\circ}$  to  $80^{\circ}$ , where they take off their ordinary clothing, put on a proper dress, and then enter the bath. On first commencing the use of the bath, the patient commonly remains on the lower benches, where the temperature varies from  $112^{\circ}$  to  $120^{\circ}$ . At the successive visits he progressively ascends the benches until the temperature is  $130^{\circ}$  to  $140^{\circ}$ . During the bath it is customary to rub the body with soap-suds, wheaten-bran, &c., or to have it gently beaten with small leafy twigs. It is also common to apply a cloth, dipped in cold water, to the head or face, or to have cold water thrown on the head or some part of the body, from time to time, by means of a douche-tube, the water being applied either in an undivided stream, or in the form of a small partial shower-bath. Having remained the requisite time, the bather descends from the upper benches, and after a short stay in this lower temperature he retires to another room heated with warm air, where, after being dried, he puts on a flannel dress, and lies down on a couch for some time. Frequently, previously to lying down, the patient drinks some warm fluid, and takes other steps to encourage perspiration. He then returns to the ante-room, where it is customary to remain a short time after being dressed, in order that he may be somewhat cooled before going into the open air.\*

2. The confined or solitary vapour-bath is that in general use in this country. The distinctive character of this is that the patient is restrained from locomotion, being confined in a small close cell or tent of cloth, containing the vapour.

This form of bath admits of three modifications: *a.* the head of the patient being included in the apparatus, so that respiration is restricted to the air in which the vapour is suspended; *b.* the head, or at least the mouth, not being included in the apparatus, so that the patient breathes the common air of the apartment; *c.* the apparatus being so arranged as to admit of the patient breathing either the vapour of the bath or the external air at pleasure.

The vapour-bath, as generally used in this country, scarcely requires description. It consists essentially of a small frame of wood surrounded by a woollen or other cloth impervious to vapour, enclosing a space little more than sufficient to contain the body of the patient seated on a stool in the centre of it. The vapour is admitted at the lower part of the apparatus by means of a tube connected with a vessel of boiling water. The more common modification of the bath used in this country is that which permits the patient to breathe the air or vapour at pleasure, by excluding or including the head through an opening in the side of the covering. Fixed baths of this kind are now common at all our watering-places, and in most of the large towns in the kingdom; and

there are several varieties of the apparatus of a portable kind equally effective. The best of these are the modifications introduced by Captain Jekyll, Mr. Green, and Dr. Gibney of Brighton.\*

*General effects of the vapour-bath.*—As the principal effects produced by both the vapour and warm-water bath depend, in a great measure, on the same cause, namely, the application of heat and moisture to the surface of the body, it is obviously unnecessary to enter on a detail of all the consequences resulting from the use of the vapour-bath, as this would be to repeat, in a considerable degree, what has been already described. Our object will be sufficiently gained by stating, in this place, the chief differences which exist between the operation of the vapour-bath and the warm-water bath. These have chiefly reference to the bath as a medium of communicating heat, and as influencing the functions of the skin and lungs.

The difference in the heating power of different media was formerly referred to when treating of the water-bath as a means of increasing the temperature of the body. It was there stated that the heating power was greatly influenced by the density of the medium, its capacity for caloric, its conducting powers, the relative fixedness of its particles, &c. *Ceteris paribus*, the more intense the degree in which these qualities exist in the medium, the greater is its heating power. The following are the highest temperatures at which the respective liquids could be borne by the hand of the same individual: spirits,  $130^{\circ}$ ; oil,  $129^{\circ}$ ; water,  $123^{\circ}$ ; mercury,  $117^{\circ}$ .† As a general bath, water can hardly be borne at the temperature of  $120^{\circ}$ ; Rostan bore it with great inconvenience for half an hour, of the temperature of  $115^{\circ}$ . In the form of vapour, however, this fluid can be employed as a bath at much higher temperatures. The ordinary heat of the Russian or Oriental bagnio is from  $120^{\circ}$  to  $140^{\circ}$ ; and it is occasionally raised as high as  $180^{\circ}$  or  $190^{\circ}$ . The same difference of results, as to the relative heating power of water and watery vapour, was observed by Dr. Edwards, in his experiments

\* *Osann*, in *Encyclopädisches Woerterbuch der Med. Wissensch. Art. Bad* Band. iv. *Berlin*, 1830.

\* Many substitutes for these more elaborate contrivances have been suggested, and may beemporaneously employed with sufficient effect when such are not at hand. A thick blanket or two thrown round a drying-screen, or other frame of wood, and placed over a steam-tube connected with a common kettle, answers the purpose very well. The common slipper-bath may also be used for the same purpose, the patient being guarded from the sides of the bath by a covering of flannel, and the mouth of the bath being closed by a blanket placed round the patient's neck; the steam being admitted through an opening in the lower part of the apparatus. Perhaps one of the simplest, least expensive, and most convenient forms of the portable vapour-bath consists of a large open wicker basket, like that used by woolstaplers, reversed over the patient and covered with blankets, the patient being previously seated on a small stool or chair placed upon a piece of floor-cloth, near the chimney of the apartment. The tube from a small portable steam-boiler, placed on the common fire, is introduced along the floor. The basket is so constructed, with a sort of open door at one side, as to admit of the exclusion of the patient's head at pleasure.

† *Phil. Trans.* vol. lxx. p. 111.

on animals. He could never get frogs to remain alive more than two minutes in water of the temperature of 104°, although the head was not immersed; while they survived the same degree of heat in vapour (and breathing it) upwards of five hours.\* When conveyed by the still rarer medium of air, it is well known that heat can be sustained, without inconvenience, at degrees greatly exceeding the highest now mentioned. In the experiments performed in heated rooms by Drs. Fordyce, Blagden, and Dobson, air of a temperature varying from 200° to 260° was borne for a considerable time with perfect impunity. A still higher temperature, viz. 270°, had been previously borne by some young women in France, as recorded by Tillet and Duhamel; and yet greater heat has been sustained by others since that time.

In respect of the heating power of watery vapour, an important difference results from the circumstance of its being breathed or not by

the patient. The application of the vapour to the lungs tends to increase the animal temperature, not merely by reason of the additional surface thus exposed to the influence of the heating medium, but because such application puts a stop to the cooling process of evaporation constantly going on from the lungs in a dry air. It is extremely difficult to ascertain the exact ratio of the heating powers of water and of vapour in its two different forms of application. Judging, however, from the results of common practice in the different kinds of bathing, and from a pretty extensive examination of the observations and opinions of practical writers, we are disposed to place reliance on the following comparative view as containing as near an approximation to the truth as can be obtained on such a subject. For reasons of practical convenience we retain the ordinary divisions and titles of the warm-water bath.

|                      | WATER.     | VAPOUR.       |             |
|----------------------|------------|---------------|-------------|
|                      |            | Not breathed. | Breathed.   |
| Tepid Bath . . . . . | 85° — 92°  | 96° — 106°    | 90° — 100°  |
| Warm Bath . . . . .  | 92° — 98°  | 106° — 120°   | 100° — 110° |
| Hot Bath . . . . .   | 98° — 106° | 120° — 160°   | 110° — 130° |

Independently of its greater power of communicating heat to the body, when extended to the pulmonary surface, the vapour bath, when so applied, will necessarily exert a very different local influence than when its action is confined to the skin. This difference of effect must always be kept in view in prescribing the remedy in affections of the chest, or in persons predisposed to these.

There is little doubt that at the corresponding degrees of temperature, the vapour-bath occasions a greater degree of cutaneous transudation than the water-bath, a circumstance easily explained by the difference of the two media as physiological agents. We would, however, make one remark here in reference to this point, as it is of practical importance, and this is, that a part of the additional perspiration experienced in the vapour-bath often arises from the disproportionate degree of temperature employed. Much greater latitude is commonly permitted in regulating the heat of the vapour-bath than of the water-bath; and we know that the former is often used at temperatures corresponding with those of the hot-bath, when it is intended to be used—and ought to be used—as a warm-bath. One of the causes of increased transudation in the vapour-bath arises from the greater accumulation of fluids in the cutaneous and superficial tissues, a necessary physical result of the greater rarity of the medium; and this circumstance, moreover, constitutes the vapour-

bath a more powerful derivative, *ceteris paribus*, than the water-bath.\*

It is particularly necessary in using the vapour-bath to attend to the actual temperature as indicated by the thermometer; even more so than in the case of the water-bath; the gradual increase being less felt owing to the greater rarity of the medium. And the caution is still more requisite because, in using the vapour-bath, the temperature is gradually raised to the proper degree, after the patient is in the bath.

*Medical uses of the vapour-bath.*—Generally speaking, the solitary vapour-bath in which the head is not included may be said to be applicable in the same cases as the warm-water bath, and to be productive of similar results. An attentive consideration of the peculiarities of action of the two kinds above noticed will point out the particular cases in which the one is to be preferred to the other. The vapour-bath at the *corresponding* (*not the same*) degree of temperature must be considered as upon the whole more derivative to the surface,

\* It is, probably, in this circumstance of the relative amount of superficial compression in the two cases, that we are to find an explanation of a phenomenon frequently experienced in the water-bath, and very rarely in the vapour-bath. We allude to that feeling of præcordial oppression on first entering the bath, which is so distressing to many persons, and which, indeed, occasionally renders this form of bathing impracticable; the sudden retropulsion of the blood from the whole surface of the body upon the heart and lungs giving rise to the feelings of distress alluded to.

\* Loc. Cit. p. 374.

more diaphoretic, and probably less stimulating generally. It seems, however, to have a less soothing effect on the nervous system. This result, in some cases at least, is partly owing to the more constrained and to the upright position in which it is usually taken. The reclining posture used in the solitary water-bath, where no muscular effort is required to keep the body in its position, gives it a decided superiority over the common vapour-bath or large water-baths, in cases of great debility or severe disease. In such cases, however, by a particular contrivance, the vapour may be applied to the patient in bed.

Most of the cases formerly noticed under the head of the warm-bath are equally benefited by the vapour-bath, and some seem more benefited by the latter. We shall only here refer to one of these, namely, the well-known condition of the system which precedes many acute diseases, and which is familiarly known by the name of *a chill*, because it is usually produced by the application of cold. This state often exists for several days before the reaction of disease and fever supervene. It is the usual precursor of acute catarrh or bronchitis, asthma, pneumonia, rheumatism, diarrhoea, or dysentery, &c.; in a word, of the numerous class of inflammatory diseases which derive their origin from cold. In most of these cases the vapour-bath is a very effective remedy if administered at the proper time and in the proper manner. The most proper time is the earliest possible after the application of the morbid cause; but the remedy may still be applied with benefit, although with much less effect, at any time previously to the actual establishment of the local inflammation. After this has taken place, or is about to take place, the application of the bath will, in most cases, be more injurious than beneficial. In cases of the kind now under consideration, the vapour-bath, particularly if the vapour is breathed, appears to possess decided advantages over the common warm-water bath. But although fully convinced of the admirable effects likely to result from this mode of treatment, we cannot consider it as a practice to be had recourse to at the discretion of patients, without medical sanction, as, like all powerful remedies, it is capable of doing harm as well as good. Under proper regulation, we have little doubt that it will in many cases effectually check the morbid process, which, if left to nature, must end in formal disease. The temperature in cases of this kind should not be high. The object being to derive to the surface without exciting the circulation, the application of the vapour should be commenced at the lowest degree which is felt to be agreeable, as about 95°, and the temperature should be gradually and slowly raised, and should rarely exceed 106°. The more copious the perspiration that can be excited at a moderate degree of heat, the more likely is the result to prove beneficial.

§ 6. *Of the warm air-bath.*

The temporary exposure of the naked body

to the air of a common chamber has been termed the *air-bath*; and although it has not often been formally prescribed in disease, it has frequently been had recourse to as a means of relieving slight degrees of feverish restlessness. It was practised and recommended for this purpose by Franklin. The immersion of the body in air of which the temperature has been artificially raised, is a therapeutical mean of much greater power, and has been extensively used as such. This is what is termed the *warm air-bath*. Like the vapour-bath, it is of two kinds, according as the air is breathed or not breathed. Warm-air chambers have been employed on a great scale, as luxuries, by persons in health, and especially by the ancient Romans. They are still occasionally used for medical purposes, but more frequently as appendages to vapour-baths than as distinct baths. The heated air-chamber has, however, formed a frequent medium for experimenters to ascertain the effects of high degrees of heat on the animal body. The experiments of Drs. Fordyce, Blagden, and Dobson, in England, of Delaroche and Berger, in France, and of many others, undertaken with this view, were formerly noticed and are well known. We allude to them here only for the purpose of again remarking, that owing to the great rarity of the medium and to the cooling effects of the evaporation produced by the dry air, a very high degree of temperature can be sustained in air with little inconvenience. Much lower temperatures, however, than were borne in these experiments, suffice to produce all the stimulating effects of the ordinary hot-bath, whether of vapour or water. In the experiments of M. Berger and Delaroche in air of a temperature varying from 150° to 190°, the following effects are noticed:— A considerable degree of smarting was perceived in different parts of the surface, particularly in the eyes, nose, and nipples; the superficial veins became universally dilated; the surface, at first burning hot, was soon covered with general and very copious perspiration. The temperature of the body was raised several degrees; the pulse rose to 160; the respiration became anxious; and headach, vertigo, and other symptoms of cerebral disorder took place. The above temperatures represent those which correspond with the higher degrees of the hot-water bath. Much lower, therefore, are employed when we wish to produce effects corresponding to those of the warm-water bath.

The warm air-bath is now most commonly used as a solitary bath, the patient not breathing the heated air. By much the most convenient form of the apparatus is that introduced a good many years since by Dr. Gower, under the name of the *sudatorium*.\* This consists merely of a semi-cylindrical frame-work of wicker, laid over the patient in bed, and covered with blankets. By means of a metallic tube

\* See his little work entitled "Auxiliaries to Medicine." Lond. 1819.

communicating with the end of the frame, a stream of air, heated by a lamp placed at the extremity of the tube, is directed into the hollow space formed round the patient. The speedy and almost certain effect of this bath is to produce copious general perspiration. It may be used at different temperatures, and be so regulated as to correspond with the divisions adopted in the case of the water and vapour baths. Although, as we have stated, a much greater degree of heat is required in air than in vapour to produce either the elevation of the animal temperature, or the stimulating effects on the system, still it is found, by experience, that a moderate degree of heat is alone necessary to excite copious perspiration. No doubt the sudatory effect is greatly promoted by the rarity of the medium applied to the surface. Dr. Gower informs us that he found the most profuse sweating take place when the air was only of the temperature of 85°, and he adds that he "had reason to believe that at a much higher degree the effect would be rather frustrated than increased, owing to the ardent heat which the patient feels and complains of, without obtaining the relief which sweating invariably produces." Our own experience with this apparatus does not quite correspond with this statement of Dr. Gower. We have, however, found that very copious perspiration may be excited by a temperature not greatly above this, viz, from 90° to 100°; and we are of opinion that even when we use this bath more with the view to stimulate the surface than to excite perspiration, it will seldom be requisite to elevate the temperature beyond 120°, or at most 130°.\*

The warm air-bath is most analagous in its operation to the vapour-bath; yet it is considerably different from it. It seems to possess all its stimulating qualities without its relaxing and soothing effects. It is, therefore, a much more exciting application at the corresponding temperatures. It appears to be more powerfully derivative to the skin than any other bath, and more certainly productive of perspiration within a short period.

There are three classes of cases in which the warm air-bath seems to be particularly indicated:—1. in chronic rheumatism and other pains and stiffness, as of the joints; 2. in morbid states of the skin, more particularly in dry scaly eruptions; 3. in acute diseases marked by great exhaustion and retrocession of blood from the superficial parts of the body, as in certain forms of fever, and in the malignant or spasmodic cholera. In the last-mentioned diseases,

\* The warm air-bath, and its great power in inducing perspiration, were well known to the older practitioners. "Aliud genus balnearum est (says Hoffmann) quæ audiunt vaporosa sive Laconica. In his vapores, sive sicci calidi ex accenso vini spiritu halantes, sive calidi humidi ex decoctis herbarum cum viuo vel aqua surgentes, immediate ad universum corpus vel ad certas duntaxat ipsius partes, admiuntur. Est autem calidorum ejusmodi habituum maxima vis ad eliciendum sudorem, tubulos subcutaneos aperiendos," &c. *F. Hoffmann, Op. Om.* tom. i. p. 465.

(which alone we shall notice in this place,) and in others of the same class, the warm air-bath, employed on Dr. Gower's plan, has great advantages over all other kinds of baths, inasmuch as its effects on the system are as powerful, while its application can be made without trouble or inconvenience, and without any risk of yet farther exhausting the patient.

This bath was occasionally used by the late Dr. Armstrong in that form of fever which he termed *congestive*. The following brief extract from his lectures will point out the cases in which he recommended it, and the fortunate results which he obtained from its employment. "The whole surface is chilly; the blood has retreated from the surface, and has been accumulated in some internal organ, where it undergoes almost a complete stagnation, or at least produces a complete interruption of the venous circulation. A derangement of the functions of that part is the result, and, if that part be important, of the functions of the whole body. The use of the hot air-bath is to rouse the energies of the system; and in some of these cases the patient is raised, as by the touch of a magic wand, from weakness to strength by its application."\*

We have much pleasure in laying before our readers the following notice on the same subject, with which we have been favoured by Dr. Tweedie:—

"It sometimes happens that the febrile poison is so intense, and the living power so depressed by it, that, the subsequent efforts of the system to bring on re-action being ineffectual, the patient is suddenly placed in great danger, and often dies in a few hours after the first appearance of the symptoms. Under these circumstances the surface feels cold and damp, more especially on those parts which are at a distance from the centre of the circulation; the pulse is feeble and compressible; the functions of the brain are disturbed; the breathing is anxious and hurried, and the lips are livid. All these symptoms depend on the peculiar operation of the febrile poison on the nervous system, and on the irregular distribution of blood consequent to this. This fluid, probably changed also in its properties, recedes from the surface, and accumulates in the internal organs. In other instances, sudden collapse supervenes in the more advanced stages of fever, and similar symptoms make their appearance. In such embarrassing circumstances, much judgment is requisite to rescue the individual from the danger in which he is plunged. Some writers have recommended blood-letting with the view of relieving the congestion which is supposed to have taken place in the internal organs. This treatment may, in some instances, have been beneficial, though it appears to me that it can only be adopted when the circulation, though oppressed, is still carried on with some degree of vigour; because, should blood be abstracted when the heart's action is weak, fatal syncope may be

\* Dr. Armstrong's Lectures. *Lancet*, vol. v. p. 74.

induced. It should be remembered that, though the heart's action is, in such cases, oppressed by the accumulation of blood which it is unable to propel, this want of power in the heart is primarily induced by the peculiar action of the febrile poison on the whole nervous system. In this debility the heart, of course, participates. In this state of things, more benefit certainly results from the exhibition of diffusible stimulants, while at the same time efforts are made to determine the blood to the surface by the application of the warm air-bath. In cases of collapse coming on in the later stages of fever, bleeding is out of the question: the patient, already exhausted, is thrown into a species of continued syncope; and from this he is to be roused by the cautious administration of stimulants, and the application of the hot air-bath. The exhibition of stimulants is only to be continued while the pulse continues feeble and soft; they are to be immediately withdrawn, or given at more distant intervals, when re-action has taken place."

The pathological state in the early stage of malignant or Indian cholera is very analogous to that in congestive fever; and the indications of treatment seem precisely similar. In such cases the warm air-bath, speedily raised to a high temperature, offers one of the best means of fulfilling these indications; and we are happy to observe that very general preparations are making to give it a trial in the disease that has just (Oct. 1831) broken out at Sunderland.

This would be the proper place to notice the other forms of baths in which the heated air is combined with sulphureous and other dry vapours; but the consideration of these, as also of the medicated humid vapour-baths, particularly the chlorine bath, must be postponed to another occasion. At present we must content ourselves with referring to the works of MM. Gales and Rapou, and to the publications of Mr. Wallace, of Dublin.

(John Forbes.)

**BERIBERI.** The disease usually denominated beriberi, was, we believe, first scientifically described by Dr. Rogers, who published a thesis on the subject in 1808, at Edinburgh. He denominates it *hydrops asthmaticus*, a term which conveys an imperfect notion of the pathology of the disease, a paralytic affection of the lower extremities being, perhaps, a more constant symptom of beriberi than dyspnoea and dropsical effusion. Dr. Mason Good calls it *synclomes beriberia*, and gives the following definition:—"Spasmodic rigidity of the lower limbs, impeding locomotion; often shooting to the chest, and obstructing the perspiration and the voice; trembling and painful stupors of the extremities; general œdematous intumescence." This definition is tolerably accurate; but in his description he confounds a chronic paralytic affection (*barbiers*) with the acute disease now under consideration.

The word *beri* is stated by Staff-Surgeon Marshall, in his Notes on Ceylon, to imply, in the Singhalese language, *weakness* or *inability*;

in fact, we may consider it as a generic name, agreeing with our word *disease*. The repetition of the term *beri* conveys an idea of the greater intensity or degree of debility. Beriberi is characterized by oppressed breathing, general œdema, paralytic weakness, and numbness of the lower extremities. The attack is sometimes very sudden, but more commonly the patient complains for some days previously of languor, weakness and inability, or unwillingness for motion. The first appearances are numbness and stiffness of the extremities, with œdematous swelling of the feet and legs. These symptoms often show themselves simultaneously. The patient experiences great weakness and breathlessness, especially on motion; the anasarca extends upwards over the body, accompanied with a peculiar feeling of numbness, with fulness, and a sense of weight and oppression in the serobiculus cordis; the face becomes swollen and bloated, and the lips are pale; in the advanced stage they are blue and livid: dyspnoea is always present in a greater or less degree, and is much increased by exertion; the pulse is usually quick, small, and hard, sometimes little affected, but as the disease advances, becoming irregular and intermittent; the stomach is often very irritable, especially in the advanced stages of the disease; the bowels are constipated, the urine is high-coloured and scanty, and sometimes suppressed. As the disease advances, the dyspnoea and anxiety become most distressing; the sleep is unsound and interrupted; the patient complains of violent palpitation, and experiences great uneasiness, especially in a recumbent position; the feeling of weight at the præcordia increases, and spasms of the muscles of the chest and abdomen take place: vomiting becomes incessant, the pulse sinks, the lips and countenance assume a livid hue, and the patient is carried off in a state of suffocation. In cases where debility, oppression, anxiety, and dyspnoea are extremely severe from the beginning, the patient sometimes dies in a space of time varying from six to thirty hours. When the symptoms are less violent, the disease may continue for three weeks or a month, or, as frequently happens, the patient experiences a number of relapses, and is at last carried off suddenly, sometimes after the dropsical symptoms have subsided, and he seems to be convalescent. Mr. Holloway had two patients, who died without appearing to awaken from a state of sleep. In general, however, death is immediately preceded by great agony.

The writer of this article had an opportunity of witnessing the phenomena attending this disease at Trincomalee, in the Island of Ceylon, where it prevailed in 1815. In some of the cases that came under his notice, the external or anasarcaous symptoms were apparently unimportant, although death was the result. Some of the patients expired who appeared to be recovering, and who stated, shortly before death, that they were better than they had been for several days. The dropsical effusion did not by any means appear to be the immediate cause of death, and Dr. Christie states that some of

his patients died who had no decided anasarous symptoms; the face was, however, bloated and leucophlegmatic.

Beriberi was very prevalent in various parts of Ceylon from 1795 to 1803. In the former year two hundred Europeans died in Trincomalee, chiefly from this disease.\* It also prevailed at Colombo, both among European and native troops. During the Kandyan war in 1808, its ravages were severely felt. Among Europeans, those engaged in certain occupations, such as tailors, smiths, &c., were especially liable to beriberi; while commissioned officers, women, and children, were generally exempted from it.

This disease appeared in a comparatively mild form in Kandy, in 1820-1, and ever since it has been little known in Ceylon. Beriberi prevailed among the troops in the Carnatic in 1782-3.† Mr. Hamilton says, "it is principally, if not entirely confined to Ceylon, to the Malabar Coast, and to that tract of country reaching from Madras as far north as Ganjam, in no part extending inland more than 40 miles. It is most prevalent during the decline of one monsoon and setting-in of another, when the atmosphere is loaded with damp, raw, cold vapours, and the vicissitudes of temperature are greater than at any other season of the year; and the instances are comparatively rare where it has been found to occur at a distance from the sea exceeding sixty or seventy miles." It may be remarked, however, that Kandy, where the disease was particularly severe, is at a much greater distance from the sea. At Trincomalee it was observed that the most severe cases occurred during the change from wet to dry weather, where a strong and hot land-wind prevailed; whereas at Palitoopane it appeared in 1814, while the weather was remarkably dry.‡

Dr. Christie has remarked, that a residence of some months at a station where the disease prevails seems essential to its production. Dr. Rogers never saw it attack an individual who had been less than six months in Ceylon. Beriberi occasionally occurs at sea, especially among Lascars (Indian seamen) on the outward-bound voyage. Dr. Hunter has given a particular account of the probable causes, and of the treatment employed in several of the East India Company's stations where it prevailed.

The remote as well as the proximate causes of this disease are extremely obscure. Drs. Christie and Rogers, and several other medical gentlemen who observed it in Ceylon, considered it a disease of debility, arising from a want of stimulating and nourishing diet, impure air, and exposure to a moist and marshy atmosphere while the frame is debilitated by residence in an unhealthy station. How far

these circumstances contributed to predispose the system to beriberi, it is difficult to say.

Mr. Marshall\* remarks that "during the insurrection in Kandy (1815), the troops and public followers were greatly exposed to variable weather, privation in regard to food, and other causes of physical and mental exhaustion. Fortunately, however, beriberi did not supervene."

Mr. Colquhoun and others who adopted every available precaution with respect to food and clothing, were mortified to find that the disease did not seem to be materially checked by their prophylactic measures. No particular cause could be assigned for its appearance in the 19th regiment, at Trincomalee, in 1815.

There is extremely little accurate information before the public in regard to the organic changes which occur in this disease. The skin is usually pale and colourless; and Dr. Christie observes that a remarkable degree of obesity exists, even after a long continuance of the disease. The cellular membrane in general is found infiltrated with serum; and Dr. Rogers states that he discovered a small quantity of fluid effused between the brain and its membranes, as also in the cerebral cavities. Mr. Hamilton says, that he observed general vascularity in the brain, effusion of fluid into the ventricles, with appearances of congestion in the medulla spinalis.

A greater or less quantity of serous fluid is usually found in the cavities of the pleura and pericardium. Dr. Rogers states that it varied from a few ounces to two pounds in the former, and in the latter from two to twelve ounces.

In a case related by Mr. Marshall, the fluid in the pericardium amounted to four ounces. Mr. Hamilton describes a case where "a large quantity of fluid was effused into the cavities of the pleura, but none into the pericardium, though on this membrane, both externally and internally, there existed evident marks of inflammation." The lungs are gorged with blood and watery fluid.

In the abdomen a quantity of fluid, varying from two to three pounds, is commonly found. The liver is invariably described as being unusually large and very dark-coloured. Mr. Marshall states that in his case, on removing it from the body, a great quantity of dark-coloured blood flowed from the large vessels, and that it then became reduced in size and natural in colour. The whole substance of this viscus is commonly gorged with blood.

Several other traces of disease, such as inflammation of the diaphragm, intestines, &c. are mentioned by authors, but so loosely, that little reliance can be placed on their description.

*Diagnosis.*—It is scarcely necessary to enter much into the diagnosis of this disease. The paralytic symptoms, together with the dyspnoea and dropsical effusion, would appear sufficient to distinguish it from other diseases. The *mal d'estomac* and *cachexia Africana*, which have

\* *Rogers de Hydrope Asthmatico.*

† *Med. Commentaries*, vol. x. and *Trans. of the Medico-Chirurgical Society of Edinburgh*, vol. ii. 1826.

‡ *Ridley, Account of an Endemic Disease of Ceylon. Dublin Hos. Reports*, vol. ii. p. 227, and *Essay on the Diseases incident to Indian Seamen on long Voyages*, by *W. Hunter*, Calcutta, 1804.

\* *Notes on the Med. Topography of the Interior of Ceylon.*

often been confounded with beriberi, are totally different diseases.

The real nature or pathology of this disease is as obscure as its origin. We know nothing satisfactory respecting the origin of the paralytic symptoms, nor regarding the immediate cause of death, where there is little or no dropsical effusion. Accurate observation and more extensive experience are wanting, to enable us to arrive at any thing like a satisfactory conclusion on the subject. From what we have seen of beriberi, and from our subsequent experience in other diseases, we are strongly inclined to consider the dropsical affection as the result of inflammation. In fact, it seems to be one of the numerous modifications of acute dropsy that affect the cellular membrane generally, but more particularly the cellular texture of the lungs, whereby a condition similar to that described by Laennec, under the name of œdema of the lungs, is produced. We have often been struck with the resemblance in the countenance and general appearance in patients affected with beriberi, and in the suffocative disease, with œdematous effusion, which attacks children after measles or hooping-cough.

In no disease with which we are acquainted, is internal congestion so strongly marked as in beriberi. How far this congestion may be the origin of the paralytic symptoms is a difficult question. Mr. Hamilton attributes them to congestion of blood in the brain and spinal marrow.

*Treatment.*—The method of treatment pursued by Dr. Christie, and recommended by him to the medical officers in Ceylon during the prevalence of beriberi in that island, was in correspondence with the views then entertained of the nature of the disease. The patients were at once put on a course of calomel and squills; saline and antimonial medicines were also given, and the strength supported by cordial liquors, generally gin-punch: the sheet-anchor, however, as Dr. C. forcibly expresses it, was mercury, given so as to induce ptyalism. He adds that, “by these medicines the symptoms in the milder cases are very often removed in the course of a few days, except the numbness of the extremities, which generally remains longer than the rest.” The pediluvium and stimulant liniments to the extremities were then ordered, and the patients were put upon a tonic plan of bark and wine, or porter, which was continued for some time after all the symptoms had disappeared. In the more severe cases, where the dyspnœa, vomiting, spasms, or other symptoms were violent, it was necessary to apply blisters to the breast, to make use of fomentations and the hot-bath, and to exhibit the strongest cordials and antispasmodics, such as brandy, and particularly laudanum and vitriolic ether. “By these means I have,” says Dr. Christie, “in most instances been enabled to relieve the dyspnœa and other urgent symptoms, and procure time for the exhibition of the medicines mentioned above, which it is sometimes necessary to use for several weeks.” Digitalis was tried, but without any decided effect.

Mr. Colquhoun also trusted to mercury in this disease; but he remarks that salivation did not avert the fatal termination, for the patients who died in hospital were frequently in a state of ptyalism.

During the period in which the writer of this article had an opportunity of witnessing beriberi at Trincomalee, the method of treatment laid down by Dr. Christie was strictly pursued, but with little cause of congratulation as to its success. The patients frequently sank while under the influence of mercury; and he has often regretted that the dyspnœa, discoloration of the countenance, &c., did not lead to a different mode of treatment.

Mr. Hamilton treated the first two cases which came under his charge according to Dr. Christie's plan, and both proved fatal. Dr. Hunter says that in one of the outward-bound ships venesection was had recourse to, but without any effect, either of accelerating or retarding the disease. Dr. Rogers, in his Dissertation already referred to, has the following words: “*Quin et ad phlebotomiam tandem cursum ejus funestum celerius absolvit.*” Increased experience appears to have induced Dr. R. to alter his plan of treatment, for we find from Mr. Hamilton's statement, that in 1822 he approved of bloodletting, and successfully employed it in two cases.

Mr. Marshall remarks that in 1820 many cases of anasæra occurred among the European troops in Kandy: the first cases were comparatively mild, and a considerable period elapsed before the well-marked and pathognomonic symptoms of beriberi appeared. Brisk cathartics and confinement to bed generally reduced the swellings and relieved the numbness in a few days. In a case where the chest was severely affected, great and speedy relief was obtained by copious and repeated bleeding. The depleting method of treatment was followed by Dr. Paterson, in the hospital of the 45th regiment, then under the superintendence of Mr. Marshall, with decided advantage. Mr. Hamilton, as has been already stated, having treated two cases unsuccessfully, was led, from the morbid appearances, to adopt other remedial means. In the next patient who came under his care, thirty ounces of blood were drawn, *pleno rivo*, from the arm. The blood was buffed, and the operation was attended with great relief; but as the symptoms returned, venesection was repeated to the amount of thirty-five ounces, with good effect. Mercury was then had recourse to, with laudanum, the vapour-bath, inunctions of mercurial ointment, with purgative doses of calomel and gamboge till the cure was completed. A similar mode of treatment was pursued in two other cases, in one of which blood was drawn, to the extent of sixty-five ounces, at three different times in the course of thirty hours.

According to the views supported in the former part of this paper, it will be seen that our mode of treatment would be in accordance with that pursued by Mr. Marshall and Mr. Hamilton. The quantity of blood to be drawn must of course depend on the

state of the disease, and the constitution of the patient; but we should scarcely feel inclined to recommend the large and successive bleedings employed by Mr. Hamilton. If the patient be placed in an upright position, and the blood be drawn in a full stream, a smaller quantity will produce a more decided effect on the system, with less risk of producing subsequent debility. Free purging by ealomel and gamboge, while the secretions of the mucous membrane and kidneys are stimulated by cream-of-tartar, squills, &c., with the use of the vapour or warm bath, and stimulating liniments to the limbs and spine, and blisters to the chest when the symptoms require it, will prove useful assistants in the treatment of beriberi. We may conclude with Mr. Marshall's remark, that a more extended clinical experience is still necessary, before a due estimate can be made of the true efficacy of the depletory means of cure.

(J. Scott.)

**BLISTERING.** See COUNTER-IRRITATION and DERIVATION.

**BLOOD, MORBID STATES OF.** The term *blood* needs no definition. Every one knows that the blood is that fluid which is circulated chiefly by the powers of the heart and arteries, over the whole animal frame, of every part of which it constitutes an essential ingredient. The blood must be first viewed as arterial and venous. The former, of a florid red hue, flows from the extreme parts of the lungs to the extreme parts of the system; the latter returns from the system to the lungs. The blood itself is only one degree more essential to life than its arterial character. In all the high orders of animals of adult age, life ceases in a few minutes after the blood is prevented from assuming the arterial character in the lungs, by cutting off the contact of the atmospheric air. In proportion as the individual is younger, however, it bears the exclusion of the atmospheric air better, and the detraction of blood worse. The blood, as it flows along or from the large vessels, has the appearance of a homogeneous fluid, of a red colour, of a rather viscid consistency, having a peculiar flesh-like odour, and an unctuous feel. Seen flowing along the capillary vessels, or placed upon a portion of glass, by the aid of the microscope, the blood presents the appearance of globules floating in a serous fluid. Stagnant, or removed from its vessels, the blood soon loses its homogeneous character, and divides into two portions, of which one is more solid, and termed the *cruur* or *crassamentum*, the other more fluid, yellowish, and transparent, and denominated the *serum*.

We purpose dividing the subsequent remarks, to which we shall endeavour to give a practical character, into two sections: the first will treat of the natural, the second of the morbid state of the blood.

There are several modes of analysis of the blood: the first is chemical, and consists in determining the secondary and ultimate elements into which the blood may be divided; the second may be designated the physiological, and would consist in determining the elements

of the blood as it exists in the different parts of the arterial and venous systems, under various circumstances; the last, which will alone occupy us in this place, may be viewed as the *clinical*, and consists of observations on the blood and its several parts, as it undergoes its spontaneous changes on being drawn from an artery or vein. We have designated this kind of analysis *clinical*, because it is principally this which daily becomes an object of greater interest and importance. We, however, by no means wish to exclude the other modes of analysis from clinical inquiry.

The first part of this clinical analysis of the blood is, as we have stated, into *cruur* and *serum*. On a minuter examination, it is found that the *cruur* consists of two different matters, very easily separable from each other, by immersion or washing in water. The more solid part of the *cruur* is, by this simple process, deprived of its colouring principle, becomes whitish, and appears fibrous: it is designated *fibrine*. The colouring matter is more or less dissolved in the water: it has been denominated *hæmatosine*, (from *αἷμα*, *αἷματος*, blood,) to denote its constituting a peculiar and essential part of the circulating fluid. *Hæmatosine* is not a simple substance. It is composed, according to Berzelius, of .500 of oxide of iron, .750 of subsulphate of iron, .200 of magnesia, .200 of chalk, and .165 of carbonic acid. The *serum* is, in its turn, susceptible of a simple analysis. Heat, or alcohol, induces the coagulation and deposit of one of its principal constituent parts: this is termed *albumen*.

One of the first occupations of the medical student should be, to become familiar by actual experiment with these different substances. The experiment itself is one of the simplest and most instructive. We learn by it at once the partial solubility of *hæmatosine*, the insolubility of *fibrine*, the solubility of *albumen* in cold water, and its insolubility in hot.

The texture of the *cruur*, the quantity, apparent and real, of the *serum*, vary; the *serum* is sometimes slightly opaque; the *hæmatosine* is occasionally partly precipitated to the bottom of the vessel in which the blood is received. But these are probably morbid conditions, and will be considered in the ensuing section.

Besides the *albumen*, the *serum* contains various substances, of which the following are the enumeration and proportions according to Berzelius: water .905, *albumen* .080, chloruret of potassium and sodium .006, lactate of soda united to an animal matter .004, carbonate of soda, phosphate of soda, with animal matter, .004. Doubtless each of these substances has an important influence in the animal economy. The little we know of their influence should only excite us to further inquiry in regard to these substances.

Besides these matters, according to the analysis of Berzelius, other substances have been discovered in the blood: as carbonic acid, substances severally resembling *mucus*, *oil*, *brain*, the colouring matter of *bile*, and of the *urine* and *urica*.

For more minute details we must refer to the

various systems of chemistry. The clinical analysis of the blood must almost inevitably be confined to the more obvious results of observation, although we dare not exclude experiment altogether.

Arterial blood is less abundant than venous. It separates more promptly into crur and serum. It contains less albumen, and is at once less viscous and less serous. Dr. J. Davy found that it possesses less specific gravity. It is said to have less capacity for heat. It has more of the peculiar odour of blood.

One of the most interesting questions in this enquiry is that which relates to the differences in the blood in the first and later periods of life. It is a singular fact that the globules of the blood in the fetus are larger than those of its mother. According to Prevost and Dumas, they are of double the magnitude of those of a man of adult age. According to Fourcroy and Dr. Davy, the albumen is more abundant, and the fibrine less firm in infants than in adult age.

It is said that differences are perceptible in the blood of youth and old age, and of the two sexes. M. Barmel has recently occupied himself with the latter subject.

§ 1. It may be safely alleged that there is no external agent which may not, under extraordinary circumstances, become the cause of disease: it may also be alleged that there is no internal part, whether it be solid or fluid, in which the seeds of disease may not be sown.

The blood, of all the fluid parts of the animal economy, seems, from its complicated formation (may we not say structure!) to be most liable to morbid changes. The older physicians observed the dissolved state of the blood, as it was termed, in some cases of fever and in scorbutus, and the singular appearance called buff upon the crassamentum in certain cases of inflammation. Had they not unfortunately deviated from the course of pure observation, we should now have possessed a series of facts of extreme value. But from the moment that certain unfounded chemical and humoral notions began to prevail, and physicians to speak of the acidity, the alkalinity, the acrid, the putrescent state of the blood, and of chyle, of milk, of pus, of bile in the blood, from mere hypothesis, observation was at an end. The error being detected, the whole humoral pathology fell into disgrace, and physicians, passing from one extreme of opinion to another, became pure solidists, as they were termed, whilst obvious and well ascertained facts became neglected.

But now that all exclusive views in physic have ceased, and that every organ, every texture, every fluid is subjected to careful observation, there is no doubt that many morbid changes will be discovered, not only in the blood, but in the other animal fluids, whether such as are provided for the nutrition, or such as are separated for the purification of the system. Indeed if any of these be morbidly affected, the blood itself must suffer by the addition of what is imperfect, or by the retention of what should be discharged. It is in this

manner that impure air, and impure diet, and defective excretions of the faces, urine, or perspirable matter, act in impairing the condition of the blood.

The first of the morbid changes which take place in the blood, relates to its quantity. This may be excessive or deficient: the former state is denominated plethora, and will be treated of under that head; the latter condition constitutes the state of anæmia, of which an account has already been given. (See PLETHORA, ANÆMIA.)

The next changes in the blood relate to excess or deficiency in one or more of its constituent parts. The crur, the serum, the colouring matter or hæmatosine, may each be too abundant or deficient. The same observation may be made in regard to the constituent parts of the blood viewed under a different aspect: the fibrine, the albumen, the saline ingredients may severally be augmented or diminished.

Other changes consist in the different manner in which the spontaneous separation of the crur and serum takes place: sometimes this separation is very distinct; the crur is firm and cupped, whilst the serum is fully pressed out and appears copious: in other cases the crur is large and loose in its texture, involving a considerable quantity of serum, the portion pressed out being small: in a third case, in which the albumen appears to be in excess, this substance is separated, mingled with fibrine, and attached to the upper surface of the firm and cupped crur, forming what is designated the buffy coat: in a fourth case the crur is small, distinct in form, yet neither firm nor cupped, and floats in a serum of greater viscosity than usual.

A further series of changes consists in the defective coagulation of the blood, which remains more or less sanious, and is of various colours.

In other instances the blood appears to be deficient in hæmatosine as well as in fibrine and albumen. It is more or less deprived of colour and viscosity. Its crur is of a salmon colour. Dropped upon white linen, it scarcely affords a tinge. This occurs especially in cases of protracted hemorrhage, and in chlorosis.

Besides the changes in the proportion of its different constituent parts, the blood frequently contains matter foreign to its healthy constitution, as pus, the encephaloid substance, entozon, calculi. At other times the blood itself undergoes other changes, becoming grumous, sanious, &c.

That other changes still are induced in the blood, is proved by experiment. The morbid blood injected into the veins or cellular membrane of a healthy animal, immediately induces morbid or fatal effects. M. Gendrin introduced an ounce of the blood of a man affected with fever with gangrenous pustules, into the cellular membrane of the groin of a cat. Various symptoms followed, and the animal died in little more than six hours. The same effect was produced on injecting blood of the same patient into the crural vein of a dog. Similar results followed the similar injection of the blood of a patient affected with variola.

From these and similar facts it becomes quite obvious that the blood itself is morbidly affected in various diseases, as the worst forms of fever, variola, &c.

The blood may become morbid, not only from a deficient freshness of the air, and a deficient quantity of food, but from deleterious matters incorporated with the air or food. Contagious miasmata, malaria, may float in the atmosphere and corrupt the blood. Poisonous substances may be conveyed into the circulating system, more or less promptly, by means of the diet: many interesting facts of this kind are on record; but none is more so than the well-known influence of salt provisions in inducing scorbutus, and of the ergot in inducing a tendency to gangrene of the extremities.

The nervous system has also a direct influence upon the blood. In experiments in which the eighth pair of nerves has been divided, it is said that the venous blood is prevented from being changed into arterial (Dupuytren); that the blood even coagulates, and the fibrine and hæmatosine separate in the larger pulmonary arteries and veins (Mager); and that arterial blood drawn from the carotid was deprived of a portion of its fibrine (Dupuy).

The same experiment, performed by M. Dupuy upon a horse, is said to have led to a dissolved state of the blood. Being injected into the veins of another horse, this blood is said to have induced gangrene.

Who, after reading these facts, will doubt that the humoral pathology has a solid basis in nature? It can, however, only be erected by observation and experiment, conducted with extensive views. Every inroad, every egress, every source of modification, physical or physiological, must be carefully taken into consideration in such an investigation.

§ 2. We shall now proceed to enumerate the various diseases in which changes in the blood are obvious enough to be placed beyond a doubt, yielding facts which may be added to science.

The first disease we shall mention is fever. There can be no doubt that the blood is variously affected in various kinds of fever. There can be little doubt that this affection of the blood is sometimes the *primary* affection. If this fact be established, the dispute, whether fever be ever idiopathic, that is, independent of local disease, will be at an end.

Much information respecting the condition of blood in *fever* may be acquired from some of the more ancient authors, especially of what may be termed the observant sect, as Sydenham, Huxham, &c. The latter author describes the appearances of the blood of malignant fever thus: "The crasis of the blood is not sufficiently firm, too attenuated; the serum blackish or tintured with red." (On the Air and Epidemics, vol. ii. p. 68.) In speaking of what he designates peripneumonic fevers, or in modern language, of fever complicated with pulmonary affection, he says, "The blood of such persons is always found too dissolved, although it is generally florid and specious, and for a long time preserves its

serum; examine it at another time, and you will find the crassamentum livid and exceedingly dissolved, and swimming in a great deal of tawny, turbid, greenish, or reddish serum; again, at another time it is almost black and sanious, and not having the least cohesion." (Ibid. p. 202.) This appearance is contrasted with that of blood in pleuro-pneumony, in which it "was very thick and viscid, and on growing cold was covered over with a whitish, and as it were leather-like pellicle:" (p. 203.)

Such are still the appearances of the blood in various fevers, simple and complicated. But an entirely new series of observations is required, in order that the subject may be raised to the level of science in the other branches of medicine.

The morbid appearances of the blood in typhus fever have been particularly noticed by Dr. Tweedie, in his "Clinical Illustrations of Fever." He states, that in this class of fevers the crassamentum of the blood, instead of forming a firm coagulum, is loose, small in proportion to the quantity of serum, and so soft that it breaks readily on attempting to raise it, resembling in consistence half-boiled currant jelly; and that in some instances, when abstracted late in the disease, it scarcely coagulated at all.

The state of the blood in yellow fever has been lately particularly and ably brought before the profession by Dr. Stevens. (See Observations on the Blood: read at the College of Physicians, May 3, 1830.) Dr. Stevens observes—"On examining, soon after death, the black and dissolved blood that had been taken from the heart of those who had died of the yellow fever, it was very evident, even at first sight, that several great changes had taken place.

"1st. The blood was more fluid than natural, partly from an excess of serum, probably produced by a stoppage of the secretions and the retention of those fluids in the system, which ought to have been thrown out by the secreting organs; but independently of this, in these violent continued fevers, as little nourishment is used, the fibrine or solid part does not appear to be formed in its usual quantity, and perhaps, also, it is exhausted faster than in health, in supporting the high and continued excessive heat, that is so great in the commencement of the inflammatory form of that fever. In the first stage of the disease, the structure of the red globules is frequently deranged, which is evident from the fact, that in those fevers the colouring matter is often detached from the globules, and dissolved in the serum, giving to that part of the blood, when it separates from the fibrine, a bright scarlet colour, and this colouring matter cannot be separated from the serum, either by filtration or any other mechanical means; but as the disease advances, this red colour is lost, and the whole circulating current becomes black, and so thin that it has no longer any resemblance to the blood of health.

"2d. The colour of the whole mass of

blood, both in the arteries and veins, was changed from its natural scarlet, or modena red, to a dark black. I have frequently filled one glass with the black fluid taken from the heart, and another with the black vomit taken from the stomach. They were both so unlike the blood of health, and resembled each other so completely, that it was almost impossible to distinguish the one from the other; and from its appearance it was very evident that such diseased blood could no more stimulate the heart or support life in the solids, than putrid water can nourish vegetables, or carbonic acid gas support respiration.

“ 3d. In violent continued fevers, the saline matter, like the fibrine, appears to be exhausted faster than it enters the circulation; the blood soon loses a great proportion of its saline impregnation; it loses entirely its saline taste; and we shall afterwards see that the black colour is a certain proof of the entire loss, or at least of the great diminution of the saline matter.

“ 4th. The blood, though dissolved, was yet not putrid; for the blood is so essential to life, that putrefaction of this fluid cannot exist in a living body. But dissolution is the first step towards putrefaction; and when this to a certain degree takes place, death of all the solids must follow. I may here add, that this dissolved state of the vital fluid was the cause, and not the effect of death; for I have sometimes seen the blood, even previously to death, both black, and so thin that it could scarcely be retained within the vessels; and occasionally it has been observed oozing from the tongue, the eyes, the skin, and other surfaces, where there was not even the slightest lesion.

“ The dissolved state of the blood is the effect and not the cause of fever. But as it was evident in many of the fatal cases, that this dissolution was the sole cause of death, it then became an object of importance to find out some agent capable of preventing this fatal change in the whole circulating current.”

“ In the Asiatic cholera, on the other hand, the blood becomes of an unnaturally dark colour and thick consistence.”

Considerable changes are induced in the blood in *inflammation*. It is well known that the blood drawn in inflammation of the serous membranes is apt to be cupped and buffed; that is, the cruor is firm and contracted, and its edges are much raised above the central part of its surface; and its upper portion consists in a substance nearly deprived of colouring matter. This buff consists of fibrine and albumen; the serum contains more albumen than natural; and the crassamentum is exceedingly firm.

Is this modification of the blood the effect, or a cause, of the inflammatory process? That the blood may be cupped and buffed independently of inflammation, is proved by the facts of the occurrence of these phenomena in cases of pregnancy.

It is true, on the other hand, that the buffed and cupped state of the blood is not so obvious on the first day as on subsequent days, in cases of inflammatory disease. It must therefore be

concluded that inflammation, and the state of pregnancy, and other sources of excitement, and even bloodletting itself, when so conducted as to lead to reaction, induce the cupped and buffy state of the blood.

It is an interesting fact to note, that the layers and adhesions formed upon or from the surfaces of inflamed serous membranes, are of the same chemical and physical constitution as that of the buff of the blood itself.

It is important to remark that it is not every kind of inflammation which induces the cupped form and buffy coat in the blood. Inflammation of the serous membranes and parenchymatous substance has chiefly this effect. Inflammation of the mucous membranes, as bronchitis, and dysentery, frequently occurs without any disposition to a cupped or buffed condition of the blood. Indeed, there is a greater difference between these two classes of disease than their names would lead us to suspect.

Dr. Tweedie has observed, in two instances of acute disease, the buffy coat on arterial blood. The only reason why this appearance is not so familiar to us is, probably, the less frequent performance of arteriotomy than of venesection.

But besides the marked morbid appearances of the blood in fever and in inflammation, very peculiar changes take place in *chlorosis*. In this disease there is a general state of bloodlessness; the crassamentum is small, the proportionate quantity of serum large; a drop of the blood observed upon white linen is seen to be extremely pale. It still remains to ascertain the exact proportions of fibrine, albumen, hamatosine, &c. in chlorotic blood, and to observe its appearance under the microscope. It still remains to compare it with the blood of persons blanched by hemorrhagy. The morbid character of the blood in chlorosis must be ranked amongst the most unequivocal proofs of the truth of a humoral pathology.

The next disease to be noticed in connection with the pathology of the blood is *scorbutus*, the stronghold of the humoral pathologists,—the pons asinorum of the solidists. The defective cohesion and separation of the cruor, the “dissolved” state of the blood in scorbutus, could never be forgotten by either party; it was continually reproduced by the former, and pertinaciously neglected by the latter.

Dr. Mead gives a vivid description of the state of the blood in scorbutus. “ In the beginning,” he observes, (Medical Works, Dublin, 1767, p. 332,) “ as it flowed out of the orifice of the wound, it might be seen to run in different shades of light and dark streaks. When the malady was increased, it ran thin, and seemingly very black; and after standing some time in the porringer, turned thick, of a dark muddy colour, the surface in many places of a greenish hue, without any regular separation of its parts. In the third degree of the disease it came out as black as ink; and though kept stirring in the vessel many hours, its fibrous parts had only the appearance of wool or hair floating in a muddy substance.

“ In dissected bodies the blood in the veins was so entirely broken, that by cutting any

considerable branch you might empty the part to which it belonged of its black and yellow liquor. When found extravasated, it was of the same kind. And lastly, as all other kinds of hemorrhage are frequent at the latter end of the calamity, the fluid had the same appearance as to colour and consistence, whether it was discharged from the mouth, nose, stomach, intestines, or any other part."

There is no point in pathology more instructive than this of scorbutus. The morbid influence of salt meat, and the curative influence of acids; the baneful effects of impure air and impure diet, and the beneficial effect of a change of atmosphere and regimen; are shewn more clearly in this disease than in any other. And as subsequent links of the chain, the influence of a "dissolved" state of the blood in inducing a "dissolved" state of the solids, to use the ancient phraseology, is equally remarkable in this disease.

Nearly allied to scorbutus is *purpura*. Some singular appearances have been observed in the blood in this disease. The crassamentum has been found separated without being firm, or contracted; and buffed without being cupped; its upper surface covered to a considerable depth by a straw-coloured substance resembling ordinary jelly. This, as well as the other parts of this interesting subject, still needs further investigation.

As an improper kind of diet produces a baneful influence upon the composition of the blood, so does a disordered and *loaded state of the bowels*. This is apparent from the condition of the secretions: the saliva, the perspiration, the urine, are alike deranged in their obvious qualities, but especially in odour; and there is more or less of the bloodless appearance seen in chlorosis.

*Icterus* is another disease in which the blood is known to suffer. The colouring principle, at least, of the bile is retained in the blood. It appears to act as a narcotic upon the brain, inducing drowsiness. The serum of the blood and the secretions from the skin and kidney are in some cases alike tinged with the yellow colouring matter of the bile.

Every one knows the baneful influence of a suppressed state of another secretion—the *urine*. It cannot be doubted that some of the principles of this secretion are retained in the blood. Prévost and Dumas found urea in the blood of an animal in which the ureters had been tied. In the human subject, suppression of the urine, or the presence of some of its principles in the blood, produces coma and death.

M. Dance has recently renewed the idea of a former day, that the suppression of the secretion of milk may, like that of the bile or urine, affect the blood and the secretions. In one such case it is said that caseum was found in the fluid of ascites, evacuated from the abdomen.

But if the secretions become sometimes suppressed, and produce a reflex alteration in the blood, there is a case in which the blood becomes morbidly affected, together with an

excessive secretion, as in diabetes. The blood in this disease is more serous, and contains less fibrine than usual. It would be interesting to examine the effect upon the blood of excessive perspiration, undue lactation, and profuse or protracted menorrhagia or leucorrhæa.

The facts which result from this inquiry are these:—1. In many diseases, as fever, inflammation, chlorosis, scorbutus, there are undoubted morbid changes induced in the blood itself; 2. that other morbid changes are induced by impure atmosphere and an unwholesome diet; 3. that various miasmata in the atmosphere, and various poisonous qualities in food, produce morbid changes in the blood; 4. that suppressed secretions induce morbid changes in the blood; 5. that excessive secretions induce other morbid changes in this fluid; and, 6. that an affection of the innervation, or of the nervous system, may, as is observed on a division of the eighth pair of nerves, produce its peculiar changes in the circulating mass.

The practical indications resulting from these and other morbid states of the blood will be noticed under the head of diseases in which they chiefly are found. We consider their statement in this place as highly important in a practical point of view.

(Marshall Hall.)

**BLOODLETTING.** The detraction of blood is either *general* or *topical*: the first consists of phlebotomy or venesection, and of arteriotomy; the second, of leeching, cupping, and scarification.

As general bloodletting is, of all our remedies, the most powerful, its employment requires the utmost consideration and precaution. If we neglect this remedy in cases in which its use is required, we allow the disease to make a dangerous progress; on the other hand, if we employ it inadvertently and inappropriately, we induce a dangerous state of debility or exhaustion. It will, therefore, require much care to lay down such rules as may guide, or, at least, assist the young practitioner in the due and efficient, but appropriate and cautious, use of bloodletting.

Of the circumstances which require consideration in the prescription or performance of bloodletting, the principal are, 1. the nature and stage of the disease; 2. the velocity and the force of the action of the heart; 3. the condition of the pulse at the wrist; 4. the appearance of the blood; and, 5. the effect upon the patient, in arresting the symptoms, subduing the disease, or in inducing syncope. In regard to the repetition of the bloodletting, the same circumstances must be considered, in conjunction with the actual state of the symptoms, the appearances of the blood previously drawn, &c.

The diseases which require bloodletting are chiefly inflammation, diseases of the head, and some forms of fever. Of the first class it is remarked, that inflammations of the serous membranes and of the substance of

organs require bloodletting much more than inflammations of the mucous membranes: arachnitis, pleuritis, peritonitis, pneumonia, hepatitis, require general bloodletting far more than bronchitis or dysentery. The second class, or affections of the head, consist either of inflammatory, congestive, or organic disease, as arachnitis, apoplexy, tumours; or of what may be termed affections of nervous irritability, such as are observed from intestinal derangement, exhaustion, &c. and in delirium tremens, the delirium traumaticum described by M. Dupuytren, &c. Now the diseases of the former of these subdivisions require bloodletting proportioned to their severity; whereas in those of the latter the detraction of blood requires great caution.

Laennec assures us that the force of the beat of the heart under the stethoscope is an excellent criterion and guide for the use of the lancet. As this point does not appear to have excited further attention, it will be especially proper to introduce the remarks of that eminent pathologist in this place: "In all cases in which the pulsations of the heart are, proportionately, more energetic than those of the arteries, we may bleed fearlessly and be certain of an improvement in the state of the pulse. But if the heart and the pulse be alike feeble, bloodletting will almost always precipitate the patient into a state of complete prostration."\* Laennec adds,† "the certainty and facility with which the stethoscope affords or excludes the indications for bloodletting, appears one of the greatest advantages conferred by this instrument."

It must be confessed, however, that as the pulse may be "*fictitie debilis*," or apparently, not really, a mark of weakness, so the beat of the heart may be apparently, rather than really, strong; this occurs in cases of mere nervousness, and in one stage of exhaustion. But in the instances from which such sources of error are excluded, it is plain that an attention to the force of the beat of the heart may be of the utmost advantage.

The condition of the pulse is also one of those circumstances which greatly assist us in the administration of bloodletting. But that we may derive all the advantage possible from the state of the pulse, it must always be considered in connexion with the disease. Thus in enteritis, although an inflammatory disease, the pulse is small and feeble, and would not to the inexperienced suggest the propriety of the essential remedy, bloodletting; in a certain stage of exhaustion from loss of blood, on the other hand, the pulse is bounding and strong, and the ignorant or incautious practitioner might be led by it to an improper and unsafe detraction of blood.

Still the pulse, taken in this connexion, is an important guide to us for the use of the lancet; its strength indicating, its feebleness contra-indicating, the detraction of blood.

During the flow of blood itself, great atten-

tion must be paid to the state of the pulse; if it grow larger, fuller, stronger, the propriety of taking more blood is distinctly determined; if, on the contrary, it becomes feebler, the further flow of blood must be arrested.

In some cases the blood flows well, and displays only a proper degree of the venous hue; in other cases it flows tardily or scarcely at all, and is of an unusually deep livid hue. The former state of things affords an indication of the propriety of proceeding with the detraction of blood; the latter warns us of the necessity for the greatest caution in regard to this measure. This distinction has been recently particularly insisted on in regard to fever by Dr. Tweedie, in his work on that subject.

It sometimes occurs, however, that the blood flows ill at first, and better shortly afterwards. This is particularly observed in those cases which are attended by a small pulse, and a cold, livid surface, as enteritis. This improvement in the flow of the blood from the vein must be viewed as an indication of the propriety of allowing the blood to flow on.

A change in the appearance of the blood, as it flows, from the more livid to the less livid hue, must also be considered as indicating the propriety of the still further detraction of blood.

The effect of the flow of blood upon the patient is also to be strictly adhered to. If pain for instance, or any other symptom of an inflammatory disease, remain unsubdued, it is frequently right to continue the abstraction of blood. If, whilst the strength is good, stupor in apoplexy, or pain in pleuritis, remains unmitigated, the blood must be allowed to flow. When, on the contrary, the disease or the symptom is alleviated or removed, we are frequently to arrest the flow of blood, and to wait and watch the subsequent state of the patient and of the symptoms; to repeat the bloodletting if the symptoms return and the strength of the patient remain good, and vice versa.

But of all the criteria for the regulation of general bloodletting, the effect of the detraction of blood upon the patient, in inducing syncope, is, in our opinion, the most important. The principle of this criterion is only applicable in cases in which it has been previously judged right to recommend the full effect of bloodletting; but in such cases it appears to afford the precise measure to which that bloodletting should be carried.

The principle alluded to may be stated thus:—1. *ceteris paribus*, some diseases enable the system to bear a greater loss of blood than in health: 2. other diseases, on the contrary, induce an unnatural susceptibility to the effects of loss of blood: 3. these two points are severally established by placing the patient *perfectly* upright, and letting blood from a moderate-sized orifice until *incipient* syncope be induced, the quantities of blood which flow denoting the power or the susceptibility of the patient in regard to the loss of blood: 4. this effect is also accurately indicative of

\* De l'Auscultation, t. i. p. 486-7.

† T. ii. p. 481.

the quantity of blood which should be abstracted in order to subdue the disease.

It is found, for instance, that in arachnitis and apoplexy much blood flows before there is any symptom of approaching syncope: it is also well known that it is necessary to abstract much blood in these diseases before the chain of morbid actions can be broken. It is probably not so well known that these two facts are precisely commensurate with each other: so that to bleed to incipient syncope is to bleed precisely according to the exigencies of the case.

Pleuritis and pneumonia not only require, but enable the patient to bear the abstraction of a large quantity of blood: bronchitis, on the other hand, neither bears nor requires much loss of blood. In any case, if we place the patient upright and bleed to incipient syncope, we abstract precisely the quantity of blood which the patient will bear to lose, and which the disease requires to be withdrawn.

Similar remarks apply to peritonitis, and what has been termed muco-enteritis.

In other cases there is a difficulty in the diagnosis, and there may be symptoms resembling arachnitis, pleuritis, peritonitis, without inflammation: such symptoms are apt to arise merely from a loaded and deranged state of the stomach or of the bowels; some indigestible substance taken under circumstances of susceptibility, as in the puerperal state; the presence of scybala, or unhealthy secretions. The intestines, under similar circumstances, induce pain and affections of the head or abdomen so similar to inflammation as not easily to be distinguished from it. In such cases we may, however, safely place the patient erect, and bleed to incipient syncope. Whereas in arachnitis we frequently abstract thirty, forty, or fifty ounces of blood, or even a still greater quantity,—in these cases the loss of ten, twelve, or fourteen ounces will frequently induce the most decided syncope.

We are thus furnished at once with the due measure of the remedy and the diagnosis of the disease.

The same rule applies in the early stage of fever, in which, if there be great constitutional power and excitement, or inflammation, much blood must and will be drawn; whereas, in cases of an opposite kind, there will be early syncope—our safeguard against withdrawing an undue quantity of blood.

Having stated and explained the general principle, it only remains to add that several precautions are required in carrying it into practice. We must not be deceived by that kind of fainting which occurs from timidity in regard to the mere operation. We must not be misled by the state of things very early and very late in the disease. In the former case the disease has not induced its influence upon the system; in the second it has led to sad devastation of its powers, as well as of the structure of the organ affected.

Chlorosis and every form of dyspepsia are amongst the diseases which neither bear nor require bloodletting.

There are diseases which may be benefited by the detraction of a small quantity of blood, but in which full bloodletting would not be proper. Such are, some cases of hæmoptysis, diabetes, and probably the cholera. In regard to these, experience of the past alone can guide us in the future. The principle just adverted to is only applicable in cases in which the full effects of bloodletting are required, not exceeding the limits of efficiency on one hand, and of safety on the other.

The next point to be determined is the repetition of the bloodletting. The strength of the patient, the force of the symptoms, the beat of the heart and of the pulse, must again aid us in our decision. But it is important to remark, that if at the first bloodletting much blood should flow before syncope is induced, it must be received as a criterion that the disease may require, as the patient will bear, the early and efficient repetition of the remedy:

Much importance has been attached to the appearance of buff upon the blood, as an indication for further bloodletting. This appearance, however, if trusted to alone as a guide, is very apt to mislead the practitioner. It occurs in many other cases besides inflammation, and especially in almost all puerperal diseases. A patient has been daily bled in puerperal mania, on account of the constant appearance of buff on the blood, and bled to death! Dr. Willan makes an excellent remark on this subject. "Some practitioners," he observes, "continue to let blood in most cases of acute rheumatism, thinking themselves justified in their mode of practice by the size appearance of the blood. The same principle would lead them to empty the whole sanguiferous system; for every time bloodletting is repeated, the blood becomes more and more dense or sizey." (*Diseases of London*, 1821, p. 261.) Not only is buff induced by other causes besides inflammation, but in some cases of inflammation it does not exist. Much, too, depends upon the mode in which the blood flows from the vein, and other circumstances. So that the light cast upon the treatment of diseases by this circumstance is feeble, if not actually deceptive.

The "dissolved" state of the blood, and the small quantity of crassamentum compared with the serum, form a more certain contraindication of blood-letting, generally speaking; and yet even this is probably not absolute.

The different modes of general bloodletting are venesection, performed in the arm or foot, or in the neck; and arteriotomy.

It is almost needless to mention that the arm is generally preferred. The jugular vein, however, should be opened when the head is affected. But it is principally useful to have recourse to the incision of the jugular vein in children, in whom it is readily opened, and in whom the veins of the arms are small.

Arteriotomy is preferred principally in cases of disease of the head or of the eye, or in

cases in which blood cannot be obtained from the veins.

Local bloodletting is chiefly applicable as an auxiliary to general bloodletting, and in local diseases in which general bloodletting is not required. In cases of inflammation within the head, chest, or abdomen, after the due abstraction of blood generally, the local abstraction of blood is very often employed most opportunely. The second remedy secures the benefit, which the first had conferred. In regard to the application of a large number of leeches in such cases, a few words of caution are, however, necessary. The loss of the blood so withdrawn is not always well borne when the lancet has been used efficiently just before; and if applied late at night, the flow of blood is apt to continue unheeded, until an undue quantity of blood has been poured out. Both these events have occurred, and led to unavailing regret.

Cupping is, generally speaking, a more efficient remedy than leeching. It is most appropriately applied to the nape of the neck, behind the ears, to the temples, to the various parts of the chest, over the region of the liver, the kidney, &c. To the softer parts of the abdomen, leeches must be applied.

Both these remedies are peculiarly efficacious in cases in which the powers of the whole system have been duly subdued by general bloodletting, without the removal of the symptoms of the local disease. Only the quantity so withdrawn after the general bloodletting must not be too great.

In some chronic local affections, in which general bloodletting would be inadmissible, the local abstraction of blood by leeches or cupping becomes our chief remedy. Such cases are chronic inflammation within the head, thorax, or abdomen; especially when this is fixed chiefly to one part or organ. Inflammatory pain long confined to one part of the head or chest, chronic inflammation of the liver, kidney, uterus, &c. are cases in which local bloodletting is the appropriate remedy.

It should not be omitted, perhaps, that the application of leeches near the anus has been much recommended in France, in order to effect what is supposed to be effected by hemorrhoidal discharges, viz. to unload the vena portæ, and to relieve the head or the liver. This mode of local bloodletting is also very beneficial in diarrhœa and dysentery. Leeches have also been applied by means of an appropriate metallic tube to the vagina or to the os uteri, in cases of inflammation of those parts.

These appear to be appropriate cases for the use of local bloodletting by cupping and leeches. Scarification is a mode of taking blood in a few cases of local disease, as in inflammation of the eye, of the tonsils, and in inflamed hemorrhoids.

*Morbid effects of loss of blood.*—The morbid effects of loss of blood may be divided into the *immediate* and the *more remote*: the former occur at the moment of the excessive detraction of blood or of profuse hemorrhage; the latter, at a more remote period, or during

the course of a continued drain from the sanguiferous system. The immediate morbid effects of loss of blood are, syncope, convulsion, delirium, coma, sudden dissolution; the more remote are, excessive reaction, mania, coma, anaurosis, sinking.

In ordinary syncope from loss of blood, the patient first experiences a degree of vertigo, to which loss of consciousness succeeds; the respiration is affected in proportion to the degree of insensibility, being suspended until the painful sensation produced rouses the patient to draw deep and repeated sighs, and then suspended as before; the beat of the heart and of the pulse is slow and weak; the face and general surface become pale, cool, and bedewed with perspiration; the stomach is apt to be affected with eructation or sickness. On recovery there is perhaps a momentary delirium, yawning, and a return of consciousness; irregular sighing breathing, and a gradual return of the pulse.

In cases of profuse hemorrhage the state of the patient varies: there is at one moment a greater or less degree of syncope, then a degree of recovery. During the syncope the countenance is extremely pallid; there is more or less insensibility; the respiratory movements of the thorax are at one period imperceptible, and then there are irregular sighs; the pulse is slow, feeble, or not to be distinguished; the extremities are apt to be cold; the stomach is frequently affected with sickness. There are several phenomena observed in this state particularly worthy of attention. We have remarked that, when the movements of the chest have been imperceptible or nearly so, in the interval between the sighs, the respiration has still been carried on by means of the diaphragm. It may also be observed that the state of syncope is often relieved, for a time, by an attack of sickness and vomiting, immediately after which the patient expresses herself as feeling better; and the countenance is somewhat improved, the breathing more natural, and the pulse stronger and more frequent. It may be a question, in this case, whether the state of syncope increases until it induces sickness; or whether the stomach be nauseated by the ingesta usually administered, and the syncope be, in part, an effect of this state of the stomach. In any case, the efforts to vomit are succeeded for a time by an ameliorated state of the patient.

In cases of fatal hemorrhage there are none of these ameliorations. The symptoms gradually and progressively assume a more and more frightful aspect: the countenance does not improve, but becomes more and more pale and sunk; the consciousness sometimes remains, until at last there is some delirium; but every thing denotes an impaired state of the energies of the brain; the breathing becomes stertorous, and at length affected by terrible gasping; there may be no efforts to vomit; the pulse is extremely feeble or imperceptible; the animal heat fails, and the extremities become colder and colder in spite of every kind of external warmth; the voice may

be strong, and there are constant restlessness and jactitation; at length the strength fails, and the patient sinks, gasps, and expires.

Convulsion, as an immediate effect of loss of blood, occurs when bloodletting has been inappropriately or unduly employed, or from excessive hemorrhage. It is apt to occur in cases in which the patient has been bled in a more or less recumbent position, in which the blood has flowed slowly, or in which time has been lost during the operation. In such cases much blood flows before syncope is induced—too much to be safe. When the blood flows slowly, we should be cautious how we bleed to deliquium even in the erect posture; in the recumbent posture it will always be attended with danger.

The more usual occurrence of convulsions is from hemorrhagy. In this manner such convulsions occur after parturition, and constitute one form of puerperal convulsions. A more frightful and formidable disease it is impossible to witness. The countenance and the limbs are variously contorted, the respiration is laborious and stertorous, and foam issues from the mouth; the colour of the face is deepened, and may be designated as being of a palish lividity. Such a case calls for the utmost presence of mind. The alarm of the by-standers must be quieted. No hasty measures must be adopted. The recumbent posture, the sprinkling of cold water upon the face, a cold lotion applied to the head, and frictions to the feet, are the immediate remedies; stimuli and opiates, with nourishment, are to be administered during the intervals of convulsion.

Sometimes, instead of convulsions, a fit of delirium occurs; in other, rarer, cases, we may have both delirium and convulsions. This delirium is generally of short duration; it has, in other instances, continued so long as to deserve to be considered as mania. A state of coma is another form of the morbid effects of loss of blood. Convulsion frequently terminates in coma, but the latter symptom may arise without the former.

Of these effects of loss of blood, delirium chiefly occurs in adult age; convulsions frequently occur both in adults and in infants; the state of coma is most frequent in infancy. The last case constitutes one of those affections which are apt to be mistaken for hydrocephalus. It will be particularly described under the head of the HYDROCEPHALOID DISEASE.

Amongst the immediate effects of loss of blood must be mentioned that of sudden and unexpected dissolution. The patient does not recover from a state of syncope; or, without syncope, he may gradually sink after bloodletting. This event is particularly apt to occur if the patient be bled in the recumbent position. It has taken the most able and experienced practitioners by surprise.

At various periods after the profuse loss of blood, whether by bloodletting or hemorrhagy, that state which has been termed reaction occurs. This state of excessive reaction is formed gradually, and consists, at first, in for-

cible beating of the pulse, of the carotids, and of the heart, accompanied by a sense of throbbing in the head, of palpitation of the heart, and eventually perhaps of heating or throbbing in the scrobiculus cordis, and in the course of the aorta. This state of reaction is augmented occasionally by a turbulent dream, mental agitation, or bodily exertion. At other times it is modified by a temporary faintness or syncope. There is also sometimes irregularity of the beat of the heart and of the pulse.

In the more exquisite cases of excessive reaction, the symptoms are still more strongly marked, and demand a fuller description.

The beating of the temples is at length accompanied by a throbbing pain of the head, and the energies and sensibilities of the brain are morbidly augmented; sometimes there is intolerance of light, but still more frequently intolerance of noise, and of disturbance of any kind, requiring stillness to be strictly enjoined, the knockers to be tied, and straw to be strewed along the pavement; the sleep is agitated and disturbed by fearful dreams, and the patient is liable to awake, or to be awake, in a state of great hurry of mind, sometimes almost approaching to delirium; sometimes there is slight delirium, and occasionally even continued delirium; more frequently there are great noises in the head, as of singing, of crackers, of a storm, or of a cataract; in some instances there are flashes of light; sometimes there is a sense of great pressure or tightness in one part or round the head, as if the skull were pressed by an iron nail, or bound by an iron hoop.

The action of the heart and arteries is morbidly increased, and there are great palpitation, and visible throbbings of the carotids, and sometimes even of the abdominal aorta, augmented to a still greater degree by every cause of hurry of mind or exertion of the body, by sudden noises or hurried dreams or wakings; the patient is often greatly alarmed and impressed with the feeling of approaching dissolution; the state of palpitation and throbbing is apt to be changed, at different times, to a feeling of syncope. The effect of sleep is in some instances very extraordinary, sometimes palpitation, at other times a degree of syncope, or an overwhelming feeling of dissolution. The pulse varies from 100 to 120 or 130, and is attended with a forcible jerk or bounding of the artery.

The respiration is apt to be frequent and hurried, and attended with alternate panting and sighing; the movement of expiration is sometimes obviously and singularly blended with a movement communicated by the beat of the heart; the patient requires the smelling-bottle, the fan, and the fresh air.

The skin is sometimes hot; and there are frequently general hurry and restlessness.

In this state of exhaustion, sudden dissolution has sometimes been the immediate consequence of muscular effort on the part of the patient, or of his being too suddenly raised from the recumbent into the erect position.

The state of reaction may gradually subside and leave the patient feeble, but with returning health; or it may yield to the state of sinking. This term is adopted not to express a state of negative weakness merely, which may continue long and issue in eventual recovery, but to denote a state of positive and progressive failure of the vital powers, attended by its peculiar effects, and by a set of phenomena very different from those of exhaustion with reaction. In the latter the energies of the system were augmented; in the former the functions of the brain, the lungs, and the heart are singularly impaired. The sensibilities of the brain subside, and the patient is no longer affected by noises as before; there is, on the contrary, a tendency to dozing, and gradually some of those effects on the muscular system supervene which denote a diminished sensibility of the brain, as snoring, stertor, blowing up of the cheeks in breathing, &c. Instead of the hurry and alarm on awaking observed in the case of excessive reaction, the patient in the state of sinking requires a moment to recollect himself and recover his consciousness, is perhaps affected with slight delirium, and is apt to forget the circumstances of his situation, and, inattentive to the objects around him, to fall again into a state of dozing.

Not less remarkable is the effect of the state of exhaustion with sinking on the function of the lungs; indeed, the very first indication of this state is to be found in the supervention of a crepitus in the respiration, only to be heard at first on the most attentive listening; this crepitus gradually becomes more audible, and passes into slight rattling, heard in the situation of the bronchi and trachea; there is also a degree of labour or oppression, sighing, hurry, blowing, in the breathing, inducing acuteness in the nostrils, which are dilated below, and drawn in above the lobes at each inspiration; in some cases there is, besides, a peculiar catching laryngeal cough, which is especially apt to come on during sleep, and awakes, or imperfectly awakes, the patient. The heart has, at the same time, lost its violent beat and palpitation, and the pulse and arteries have lost their bounding or throbbing. The stomach and bowels become disordered and flatulent, and tympanitic, and the command over the sphincters is impaired.

The last stage of sinking is denoted by a pale and sunk countenance, inquietude, jactitation, delirium, and coldness of the extremities.

It has already been observed that delirium occurs as an immediate effect of loss of blood: mania, or delirium in a more or less continued form, is not an unfrequent occurrence, as a more remote effect of the same cause. That form of this disease termed *puerperal mania*, generally arises from the loss of blood in the predisposed. A form of mania, not to be distinguished, except by the history of the case, from *puerperal mania*, occurs from loss of blood, independently of the circumstance of parturition.

Coma, amaurosis, deafness, and paralysis

are other forms of the effects of loss of blood. Cases of the first kind are detailed by Dr. Abercrombie as well as by the writer of this article. Mr. Travers describes a form of amaurosis from depletion. Deafness from exhaustion is by no means unfrequent; and it occasionally remains for a considerable length of time. Paralysis, more or less permanent, occurs occasionally in extreme cases of exhaustion.

Various circumstances exert an influence in diminishing or augmenting the disposition to present the phenomena of loss of blood. Inflammation of the serous membranes and of the parenchymatous substance of organs protects the system from the effects of loss of blood; gastric and intestinal derangements have a precisely contrary effect. It is probable that the mode in which these circumstances operate is that of inducing different states of the blood itself: inflammation is known to increase the quantity of albumen in blood, and in general to induce the disposition to buff; chylipoietic derangements, on the contrary, induce an opposite condition of the blood. In the former case the arterial system is probably more firmly contracted upon its contents, even when a part of these is subtracted; and in this manner the disposition to syncope and to the other effects of loss of blood may be obviated.

Besides the affections described, there are some organic effects from loss of blood. There is a disposition to effusion within the head, so that actual apoplexy as well as serous effusion has occurred in the last stage of exhaustion. Another effect of exhaustion is effusion into the air-cells and bronchi, giving origin to a peculiar rattle heard with the stethoscope, and generally of fatal omen. Tympanitis is another effect of loss of blood; and a general disposition to dropsy, internal and external, is amongst the most frequent of the effects of this condition of the system.

The treatment of the effects of loss of blood must be resolved into that which is general or constitutional, and that which is local; and it must vary according to the peculiar state or stage of these effects. Syncope, reaction, and sinking require their appropriate treatment. The constitutional treatment must be stimulant in syncope, sedative and soothing in the state of reaction, and restorative in that of sinking. The local treatment must vary with the organ chiefly affected, and with the mode in which it is affected.

When syncope assumes a dangerous form, the principal remedies are, an attention to the posture of the patient, stimulants, and chiefly brandy, and the transfusion of blood.

The effect of posture is not, even now, fully known. It would be easy to allow the patient to lie over the edge of the bed, the head low upon the floor, and the feet gently raised. In this manner such pressure would be restored to the encephalon as would in many cases support life, until, other remedies being administered, the patient might be placed out of immediate danger. We need not in this place notice the importance of a regulated mode of giving brandy and nourishment. We think it is

frequently given in such quantities as actually to induce sickness and its own rejection from the stomach, and so as to frustrate the object of the physician completely. The effect should be carefully watched. The physician ought not, of course, in such a case, to leave the patient for a moment.

The next remedy is transfusion. Unfortunately it has too frequently happened that the proper period of adopting this measure has been allowed to pass by. Not only the vascular system is exhausted, but, after a time, the functions of the nervous system have begun to fail. It might be a question, therefore, whether galvanism might not be usefully conjoined with transfusion.

It is an important point to determine how large a quantity of blood the system will bear to receive under various circumstances of exhaustion. Too much may overwhelm; too little may be inadequate to the accomplishment of the object in view. It is also an important question whether the operation should be done at once, or at twice, or thrice, and with what intervals. As the system cannot bear a sudden reduction of the quantity of blood, so it may not be enabled to bear its too sudden restoration. It is almost needless to add that a due attention must be constantly paid to assist the arterialization of the blood by the admission of fresh air; and to sustain the animal heat by proper clothing, and especially warm applications to the feet.

If there should be convulsions, delirium, or coma, it may be necessary to apply a sinapism to the nape of the neck; and in the two former cases some mild sedative, as the *tinctura hyoscyami*, may be of advantage.

In the case of excessive reaction, the remedies appear to be, first, 'extreme quiet of body and of the mind; then, the mildest sedatives, especially the *hyoscyamus*; thirdly, the mildest nutriment; and lastly, and above all, time.

The pain and throbbings in the head, the intolerance of noises, the general susceptibility to disturbance, the palpitations of the heart, alike demand the utmost quiet, to which every thing soothing in the manner and treatment must be added. The *tinctura hyoscyami* is, we think, the kindest anodyne and sedative in these cases. The cause and other circumstances of the case point out the necessity for mild nutriment, to which perhaps the minutest quantities of brandy may be added.

It may be necessary to subdue the throbbing action of the head even by local bloodletting; and it is most remarkable how small a quantity of blood being taken will relieve. Two or three leeches are frequently quite sufficient.

But the most unequivocal remedy is a cold spirituous lotion, applied all over the head by means of a cap consisting of one fold of stocking.

In exhaustion with delirium, the *tinctura hyoscyami* should be conjoined, in full doses, with the other remedies. The morbid susceptibility, not only of the brain but of the heart, is greatly assuaged by this remedy.

In cases of exhaustion with sinking, stimulants must be administered abundantly. Cataplasms of mustard may be applied to the nape of the neck and to the feet. It is difficult to imagine what would be the effect of a transfusion of blood; we have no doubt that galvanism would prolong life; and we should think the two remedies might be conjoined with advantage.

In all cases of exhaustion the functions of the bowels suffer. Constipation and flatulency are the usual consequences. These are best relieved by the warm-water enema, which must, however, of course, be administered with due precaution, so as to prevent further exhaustion.

It is interesting to observe the blunted sensibilities in syncope and in sinking, and to compare them with the morbidly acute sensibilities of the state of reaction. Sinapisms to rouse, and the *tinctura hyoscyami* to lull them, are, in their respective places, remedies of the greatest value.

(*Marshall Hall.*)

#### BLUE DISEASE. See CYANOSIS.

**BRAIN, INFLAMMATION OF.**—Under this term we propose to include the pathology, symptoms, and treatment of the inflammatory affections of the brain and of its membranes. We adopt this plan, not merely because of the intimate relation subsisting between these structures, but because, when we trace the history of a number of acute affections of the encephalon, and examine the lesions of structure presented after death, we shall frequently find that the substance of the organ as well as the investing membranes has been involved in the disease. Hence arises the difficulty of establishing the diagnosis between inflammation of the parenchyma of the brain and that of its membranes. Both forms of disease have been classed by the majority of nosologists, ancient as well as modern, under the same head as *phrenitis*, in consequence of their inability to draw any distinct line of demarcation between their symptoms.

Several modern pathologists, however, (Lallemand, Rostan, Bouillaud, Jendrin, &c.) having devoted much time and attention to the study of cerebral diseases, and collected a large body of well-observed clinical cases, conceive that they have succeeded in establishing correct rules of diagnosis between several of the inflammatory affections of the brain and of its membranes; and they affirm, moreover, that it is quite possible, in many cases, to ascertain the different degrees, stages, and even seats of cerebral inflammation. The rapid advances made of late years in the knowledge of the physiology and morbid anatomy of the brain, have no doubt greatly assisted modern observers in discriminating the characters of its various diseases. It is not, in the mean time, improbable that they may, in some instances, have been led, by their zeal in a new field of discovery, to overstep the exact boundaries of fact. We think there is, however, an equal probability that many of our failures in diagno-

sis, in a class of diseases hitherto so little studied in this country, are to be imputed to a deficiency in our own powers of observation; the old adage that it is possible to *look* at an object without *seeing* it, which is not the less true for being trite, being, we apprehend, often verified in the study of the symptoms of disease.

The result of our own experience leads us to the conclusion that there are extreme cases in cerebral affections which can never be mistaken one for another; that there are cases not so well marked, in which the attainment of an accurate diagnosis is attended with greater difficulty; that there are also mixed cases, in which one form of disease, which may have existed separately for a time, gives rise to another, or in which a disease, at first local, becomes general. All these circumstances must necessarily tend to complicate the diagnosis. We should reflect, however, that the study of the pathology of the brain is only in its commencement; that the surest method of acquiring greater power of discrimination is to avail ourselves cautiously of the information and experience of those who have already been labouring in the field, and to bring to the further investigation of this intricate subject a spirit of careful observation and strict induction. We may thus reasonably hope to be enabled in time to rectify their errors, extend the sphere of our knowledge, and establish this important branch of pathology on a more practical foundation. The utmost that can be expected from precise rules of diagnosis, in any class of diseases, is that they should guide us accurately in the great majority of cases; and although it may occasionally happen that they do not accomplish this, they are not on that account to be laid aside as of no value. There is indeed no class of diseases in which the symptoms may not at times prove deceitful; we thus have latent affections of the lungs and alimentary canal without any or with only very slight symptoms; and very decided symptoms of inflammatory or other diseases of these organs without any or at least with only very insignificant disease.

When either the arachnoid or pia mater, which closely invest the brain, are extensively inflamed, the functions of this organ become inevitably disturbed by sympathetic irritation, without its parenchyma necessarily partaking of the inflammation; or if the inflammation extends to the parenchyma, it is mostly confined to the superficial layer of cortical substance. This is exactly the manner in which the functions of the lungs or intestines are disturbed in pleurisy or peritonitis. Hence in arachnitis or meningitis, besides head-ach and intense fever, we have an increase of the general sensibility, preternatural acuteness of the external senses, violent delirium and convulsions, and, finally, collapse, coma, and death. Extensive and acute inflammation of the hemisphere of the brain will be characterized by a nearly similar train of symptoms. In the great majority of cases the two diseases give rise to each other, and are thus combined;

it is then extremely difficult, if not impossible, to discriminate between them. There are, however, other forms of cerebral inflammation more circumscribed in their seat, and chronic in their progress, respecting the diagnosis of which it cannot, we think, be any longer asserted that the practitioner is altogether left in doubt.

We shall now proceed to consider inflammation of the encephalon under two divisions, viz. 1. inflammation of the membranes of the brain (meningitis): 2. inflammation of the substance of the brain (cerebritis).

I. INFLAMMATION OF THE MEMBRANES OF THE BRAIN (MENINGITIS).—When we look into systematic works on medicine, we are at once struck with the confusion which exists in the nomenclature of cerebral diseases. Thus the term phrenitis, which has been so long and so generally known that it has passed into popular use, was employed by some of the earlier physicians to designate that delirium which so frequently arises in the course or towards the termination of different diseases; whilst amongst the moderns it is applied to inflammation of the brain or of its membranes. The group of symptoms which Frank names encephalitis, is called *phrenis* by Vogel, *meningitis* by Herpin, *cephalitis* by Linnaeus, *arachnitis*, or, more properly, *arachnoïditis* by Martinet; and in different essays and detached publications by various authors, cases strictly analogous are collected together under the denomination hydrocephalus, hydrocephalic fever, or hydrencephalus. All this has arisen from a difference of opinion as to the seat of the disease, one person considering it as located in the cerebral substance; a second in the investing membranes, viz. the arachnoid membrane, the pia mater, or in both; whilst a third is altogether taken up with the consideration of the effused fluid and of the means of removing it; not knowing perhaps that it is a mere consequence or result of inflammatory action, and not at all an element or a constituent of the original disease. Cullen was decidedly of opinion that we could not, by any reference to the symptoms during life, or the appearances presented after death, assign exactly the seat of the different acute affections within the head; and therefore he included, under the term phrenitis, the inflammations of the different structures contained in the cranium, no matter whether seated in the substance of the organ or in its investments. Mason Good gives what may be considered a qualified assent to this view of the subject. He observes that “the disease may commence in the membranes or in the substance of the brain; and if it were to confine itself strictly to the part first affected, instead of spreading from one to the other, there would perhaps be no great difficulty in determining from the symptoms before us its actual seat; for whilst membranous inflammation is accompanied by acute and rousing pain, great heat, and a pulse permanently and considerably quickened, parenchymatous inflammation is distinguished by a heavy and often

stupifying pain, slight increase of heat, pulse irregularly quickened, or sometimes, on the contrary, below the natural standard." As each of these conditions is occasionally presented to us in different cases of cephalitis, we may, says the same writer, infer that in the one instance the disease is seated in the membranes, [inflammatio meningica—phrensy—brain-fever,] whilst in the other it is situated in the cerebral substance itself, [inflammatio profunda—acute dropsy of the head.]

Nothing has contributed more to the diffusion of error in medicine than the disposition so constantly manifested to consider symptoms as if they were diseases, and diseases—entities, endowed with individuality or a uniform mode of existence. It also but too frequently happens that effects are taken for causes, and, under the influence of a hasty disposition to generalize, conclusions are drawn from partial observations, confined perhaps to a few detached instances. The opinions entertained, and the doctrines taught with regard to inflammation, generally, as a morbid condition, furnish a full illustration of these errors. Are there not many who think and act as if the effusion in hydrocephalus were the essence of the disease, and not a result or effect of inflammatory action? It is with many a fundamental axiom that inflammation softens all textures; hence "ramollissement" or softening comes to constitute the anatomical character of the substance of the brain when inflamed. In point of fact softening is only a single step or stage in the progress of change, the first departure from the healthy condition being a turgid and tense state of the part affected, which subsequently becomes softened; but instead of passing on to suppuration, in some instances the process of disorganization is arrested, and then the part becomes indurated. Pinel was so fully impressed with these views, that instead of following the usual routine of commencing with a definition of inflammation, he considered under so many distinct heads the inflammations of the different primary textures of which the body is composed, indicating the anatomical characters and the peculiar symptoms of each. The arachnoid membrane, for instance, belonging as it does to the class of serous tissues, resembles them in its lesions when diseased, as it does in its character and properties in the healthy condition. Like all the individuals of its class it becomes, when the subject of different degrees and modes of irritation, the seat of serous and purulent effusions, as well as of exudations of coagulable lymph: and as acute inflammation of the pericardium, the pleura, or the peritoneum, are considered as distinguishable by a special train of symptoms, it would be natural to infer that the like lesion of the arachnoid must be attended by its appropriate characteristics.

These general views, which are confessedly applicable to inflammation in other parts of the system, would have induced the learned author of the "Nosographie Philosophique," when treating of the cerebral inflammations, to divide them into separate groups, according as they

are seated in the membranes or in the substance of the organ. But he was too discriminating an observer to be biassed by *à priori* views, or led away by the spirit of system: he admits, that in order to keep up the unity of his plan, it would be necessary to describe separately cerebritis and meningitis, and to cite cases in which the existence of each could be distinguished by a special train of symptoms. This he found to be impracticable, and consequently felt himself obliged to include under one head, *encephalitis*, the general history and the complex and varying symptoms of inflammation, whether seated in the membranes or in the substance of the brain. The majority of our practical men subscribe to the correctness of these views; for they learn by experience that it is much easier to indicate a diagnosis in a nosological table than to support it at the bed-side of a patient.

An examination of the structure of the brain, and of the peculiarities of the circulation in it and upon it, would also lead to the inference, that if the meninges be the seat of inflammation, the contiguous cerebral substance must participate in some degree in the irritative influence. In other organs the vessels, after entering them by trunks and branches of various sizes, branch out and ramify in their interior until they become capillary in their spongy and areolar tissue. But in the brain a different arrangement takes place: the vessels, after entering at the base of the skull, communicate freely with one another, and then branch out upon the surface of the brain, ramifying in an extended web of cellular tissue [pia mater]; in this way they become reduced to so great a degree of tenuity before they enter the substance of the organ, that it may be said to be surrounded by a vascular atmosphere from which its supplies are derived. Hence it is, that as the meninges and the contiguous cerebral substance are supplied from the same source, each will more or less become affected by any inflammatory action set up in the other. M. Bayle, in his thesis, gives six cases of what he considers chronic arachnitis, as in all of them the arachnoid membrane was thickened, opaque, and resisting, and there was found some serous effusion; but in five of these cases portions of the cerebral substance were adherent to the membranes, and so much softened as to be brought away with the latter when an effort was made to detach them: in five of them also the pia mater was injected, thickened, and infiltrated with serous fluid. MM. Martinet and Parent, in their elaborate monograph on arachnitis, give the results of their examination of one-hundred and sixteen cases, published with the expressed design of establishing the diagnosis and pathology of arachnitis. But though these cases are classed as inflammations of a serous membrane, we find that in a considerable number of them the inflammation had extended to the cerebral substance, the vessels of the pia mater being at the same time injected, and its substance thickened and covered with a serous or sero-purulent effusion; so that, judging from the post mortem appearances, they were in fact mixed

cases; and in strictness we must refer the symptoms or physiological indications presented during life, to the lesion of the cerebral substance rather than to that of the meninges.

The brain confessedly presides over all the phenomena which are attended with consciousness, and over every act which is influenced by the will; it is the organ of intellect, and the centre of sensation and of voluntary motion. Moreover, through the pneumo-gastric nerve, it influences directly the functions of digestion and respiration, and indirectly (through the respiratory apparatus) that of the circulation. Experiment also demonstrates its intimate connexion with the regulation of animal temperature. Now if we note the symptoms attributed to inflammation of the arachnoid membrane, or look over the catalogue of them as enumerated by different writers, we shall find that they are but so many lesions or disturbances of one or more of the cerebral functions, and as such they must arise from an affection of the organ itself which holds these functions in dependence, and not of the investing membranes, which cannot exert on these functions any direct controul. Thus, when in a summary of the symptoms of arachnitis we find delirium, spasm, and rigidity of the muscles, convulsions, vomiting, stupor, coma, contraction or dilatation of the pupils, with strabismus, we must refer them to an alteration in the function or structure of some part of the cerebro-spinal mass, and not of its investments merely. The arachnoid and pia mater are so simple in their structure and function that we can scarcely assign to inflammatory action when set up in them any other indication except pain or head-ach.

Dr. Abercrombie expressly gives it as his opinion, "that our knowledge is not sufficiently matured to enable us to say *with confidence* what symptoms indicate inflammation of the substance of the brain, as distinguished from that of its membranes." The difficulty of establishing this point of diagnosis has been felt by all those who have treated of the subject. There are circumstances, however, in which we can indicate with sufficient precision the symptoms of cerebritis, as distinguished from any that can in strictness be referred to meningitis; for instance, when the inflammation is isolated, and does not reach the membranes, as where it is seated in the thalamus or corpus striatum. If in such a case the attack does not proceed with unusual violence or rapidity, the pathognomonic symptoms can be traced readily enough, and no attentive observer would mistake the disease for arachnitis. But if the inflammation occurs at the circumference of the organ, where the membranes and the cerebral substance are in contact, and both are supplied by the same vessels, then, though the inflammatory action may at the outset be seated in the meninges, it will speedily extend more or less to the cerebral substance, and by complicating the lesion, will confuse the diagnosis. We have examined many cases which, on a superficial inspection or hasty examination, would be set down as cases of acute meningitis; but by carefully elevating the membranes, we could

distinctly observe vessels, enlarged and distended, passing into the cerebral substance; and on examining the latter texture attentively, we could also recognise an increase of its vascularity, and occasionally some degree of change in its colour and consistence. In the great majority of superficial inflammations there is a mixed lesion, and all that discrepancy which their progress and symptoms present is explicable not merely by the extent and degree of the inflammation, or by peculiar idiosyncrasy, but by the fact that in some of them the inflammatory action is for the most part expended on the membranes, the brain receiving but slightly the irritative influence; that in others the reverse obtains; whilst in a third group it seems as if concentrated upon the vessels of the pia mater, the arachnoid on the one hand and the brain on the other being but slightly affected. By viewing the subject in this way, (and we are induced to do so from an attentive consideration of it, as well as from numerous post mortem examinations,) we shall clearly perceive that the diagnosis of the membranous and parenchymatous inflammation in the encephalon has been considered obscure because in very many cases they occur simultaneously. From this mode of considering the subject, it will be obvious that in a practical point of view it is of much more importance to be able to determine what may be considered a previous question, namely, what are the symptoms which indicate inflammation within the encephalon, than nicely to mark its exact location.

Cerebral irritations are divisible into two great classes, symptomatic and idiopathic; the former being by far the more numerous. Broussais goes so far as to say that "the brain is of all organs the one which is the least liable to inflammation, inasmuch as it is seldom if ever affected directly, being almost always acted on through its sympathetic connexions with other viscera." Symptomatic irritation is for the most part connected with and dependent on a morbid condition of the chylopoietic viscera. We frequently observe that for weeks previously to the occurrence of pain or any disturbance in the head, the digestive functions have been impaired, the bowels confined or irregular, and the stools unnatural. In many of these cases, when the head-ach, retching, irregular fever, and even coma, have set in, speedy and permanent relief has followed the use of purgatives, and the other means usually resorted to for correcting disordered functions. An irritative influence is in such cases propagated from the digestive organs to the brain by reason of the close sympathetic connexion which subsists between them in health and in disease; and that irritation, if kept up for a while, will pass into positive inflammation, marked by its usual consequences. The irritation of worms and of teething may also induce similar results, more particularly in those constitutionally predisposed. We frequently observe these cerebral affections to spring up during the course of other diseases, of which they may be considered as complications; namely, continued fever, scarlatina, measles, whooping-cough; and they not unfre-

quently follow accidents or injuries. Hence, says Dr. Abercrombie, it becomes necessary to keep in view those symptoms which set in in the course of these diseases, or follow such accidents, and indicate the existence of a dangerous affection of the head. Referring these to their respective seats, they are as follows:—*In the head*—head-ach, with throbbing and giddiness, tinnitus, sense of weight and fulness, stupor, and propensity to sleep. In many obscure and insidious cases a constant feeling of giddiness is the only remarkable symptom. *In the eye*—impatience of light, unusual contraction or dilatation of the pupil, double vision, blindness, distortion of the eyes outwards, paralysis of the lids, causing the shut eye, or the gaping eye. *In the ear*—unusual acuteness of hearing, great noise in the ears, transient deafness. *In the speech*—indistinct or difficult articulation, unusual quickness or unusual slowness of speech. *In the pulse*—slowness, remarkable variations in its frequency. *In the mind*—transient fits of incoherence, confusion of thought, forgetfulness, high delirium. *In the muscles*—convulsion or partial paralysis. Whilst examining complex cases of this sort, attention should be directed, not merely to ascertain the existence of a particular symptom, but rather to determine whether there is a correspondence and harmony between the symptoms;—thus “the peculiar oppression which accompanies a high degree of fever is not considered dangerous, or perhaps unfavourable; but the same degree of oppression without fever, or with a very slight fever, would indicate a head-affection of a dangerous character.” This remark is applicable also to head-ach and delirium.

*Acute meningitis.*—Under this term we shall include all those cases in which the inflammatory action has its principal seat in the membranes, but in which it is a legitimate matter of inference that an irritative influence is propagated to the contiguous cerebral substance.

This affection presents a train of symptoms which varies in different ages and in different temperaments. Its most marked and ordinary character at its outset is an increased sensibility to all sorts of impressions, the ordinary external influences producing inordinate effects. Thus a child is restless and sleepless, seldom even dozing, or if he does doze, from time to time starting and waking up; he attends to every sound, the eyes are suffused, the retina is so sensitive to light that he winks or turns away if his face is directed to a window or to a candle; the pupil is generally contracted, but not invariably so. The head is often moved about, or from side to side, so are the limbs; the temper is peevish, and nothing seems to soothe this irritable condition but motion up and down the room in the arms of the nurse or attendant. The state of the bowels varies much in different instances: they may be confined or relaxed, but the stools do not present any unnatural appearance. There is a minor degree of this state which is marked by increased animation and liveliness, which with ordinary observers may pass for an increase of health and vigour, though an atten-

tive observer will readily perceive that the countenance wants that disengaged air which exists in health; and on making a closer examination he will find that the eyes frequently close and wink, and the countenance assumes an expression as of frowning: the hand, too, is frequently raised towards the head, and the fingers are fixedly closed. We occasionally observe in children a state the very opposite of this—a state characterised by a want of animation, accompanied by plaintive moaning at times, and an indifference to surrounding objects. Though the child does not sleep, yet his state is not that of waking; and if roused, he betrays fretfulness and peevishness. These may be considered as so many indications of an incipient irritation, which in some constitutions may arise independently of any assignable agency, but which in many cases is referable to an irritation propagated to the brain from the peripheral extremities of the nerves during dentition, or by worms in the alimentary canal, or by vitiated secretions, or a torpid liver. The symptoms here indicated are by some persons denominated *fièvre*, some epithet being usually added for the purpose of indicating its source or its nature; hence the terms gastric, irritative, and hydrocephalic fever. The most expressive term that can be employed is that devised by Dr. Nicholl, “sensitive erethism.” It is distinct from inflammation of the brain, of which it is frequently the precursor; and according to individual peculiarities or other modifying circumstances, it may end in cerebritis, meningitis, or that modification of the latter called hydrocephalus: and this termination is but too often unexpected by the practitioner, whose attention has perhaps been directed to secondary indications and minor effects, whilst the erethismal state of the brain has crept on unheeded. The condition here indicated cannot be supposed to exist unaccompanied by an increased flow of blood through the cerebral vessels, or in other words, an increase in their degree of tension; and as the tension may vary from a slight degree of fulness to the greatest of which the vessels are susceptible, such a state of local determination of blood will soon end in inflammation if not subdued by proper means. The actual inflammatory attack is generally ushered in by head-ach more or less violent, (the pain being referred to the temples, the vertex or forehead, sometimes to the occiput and base of the skull,) by intolerance of light: heavy and suffused eye, with quick pulse, are also attendants; so, in many instances, is vomiting. In adults, particularly those who have suffered much from mental disquiet, spasmodic twitchings are sometimes perceived, not unlike those which arise from slight electric shocks. In children and very young persons it frequently commences with a sudden and long-continued convulsion without any previous warning. After a while the convulsive movements cease, a remission takes place, and the patient appears free from complaint for one or more days, when a second attack occurs, which may terminate in coma and death. Some instances have been cited in which no remission occurred,

insensibility supervening on the convulsion, and death in thirty-six or forty-eight hours. Martinet indicates three stages of the disease, each accompanied by a distinct group of symptoms. The first comprises the period of cerebral excitement and increased sensibility above noticed; the second is the stage of reaction, or more properly that in which the cerebral irritation is propagated to the muscular system, and other systems in immediate dependence on the brain; hence it is characterised by restlessness and convulsions, delirium, oscillations or commencing dilatations of the pupils: its duration varies from two or three days to a week, or perhaps two weeks. It is not undeserving of notice, that when the arachnitis is seated on the convex surface of the cerebral hemispheres, delirium sets in very early, and becomes the prominent and characteristic symptom; whilst if it occurs at the under surface and base of the brain, coma is the more usual attendant, and sets in early. The third stage is that of collapse; being marked by loss of sense and motion, by paralysis, local or general, and coma; its duration varies from a few hours to three or four days. A considerable number of cases do in fact exhibit these regular steps and gradations of change during their progress; but we frequently observe the state of collapse and of excitement to co-exist; each of course being partial in its extent. Thus one arm may lie motionless by the side, whilst the other is convulsively agitated; and the muscles of the eye-lids may be paralysed, whilst those about the mouth are convulsed. Again, the first stage of the disease is not in all cases ushered in either by pain or convulsions, by vomiting or fever. A state the very opposite to this sometimes presents itself. Thus Cruveilhier details the case of an elderly medical man, who, after some fatiguing employment, suddenly became oblivious, looked stupid, could not answer questions, and seemed apoplectic: he was treated accordingly, but without relief; he still remained comatose, passed urine involuntarily, but retained the power of moving his limbs, though the left side seemed weakened. After death, serous effusion was found beneath the arachnoid membrane, extensively diffused over the brain and cerebellum, mixed with albuminous flocculi or flakes of false membrane. This would be considered as a case of serous apoplexy were it not for the effusion of lymph and false membrane. Another case was considered a feigned disease, so few indications of ill health, much less of cerebral inflammation, did it present. It was that of a youth at school, who was frequently accused of feigning illness. His countenance was natural, pulse not at all excited, nor did he complain of pain. The medical attendant ordered him to get out of bed and dress himself. This he submitted to very reluctantly; he went towards the fire-place, tottering as he walked, and sat down resting his head against the chimney-piece. So convinced were all present that he but feigned illness, that he was chastised. He died soon after, when the reality of his illness was ascertained by examination;

a considerable degree of effusion of serum and coagulable lymph being found beneath the arachnoid membrane. This form of disease Cruveilhier calls "*meningite sous-arachnoïdienne comateuse*;" and as he has met with several instances of it, he is disposed to come to a conclusion the very opposite to that which other pathologists have adopted, inasmuch as when the meninges over the convexity of the hemispheres is inflamed, it is, according to his experience, characterised by stupor gradually increasing to coma; whilst head-ach, with increase of sensibility, delirium, and convulsions, are strangers to it.

*Morbid anatomy.*—After having been the subject of inflammation, the membranes present various changes dependent either on the duration and intensity of the attack, or on the frequency of its recurrence; but all of them are referable to the following heads, namely, simple redness of the arachnoid; thickening and opacity, with increased firmness; serous effusion beneath or upon it, or into the ventricles; puriform, or sero-purulent exudations; false membranes; increased vascularity and thickening of the pia mater. The redness of the arachnoid varies in extent and degree, and is usually confined to a few points on the convexity of one or both hemispheres, or at the base of the brain. It requires much care to distinguish this state of the membrane from one that closely resembles it, and in which the pia mater is minutely injected, and at the same time adherent to the arachnoid. To determine whether the redness exists in the arachnoid or only in the vessels of the pia mater, a part of it should be cautiously raised from the surface of the convolutions, and gently scraped with a scalpel, or exposed for a few minutes to a slight current of water; if the membrane is really inflamed, the colour will be found persisting, as if it were dyed into it; if the membrane is not inflamed, its natural transparency will be restored. The alteration most commonly observed in the arachnoid is that it becomes opaque and whitish. In proportion as its transparency is diminished, its density and tenacity increase; so that it is easy to detach it from the surface of the brain. These changes are seldom, if ever, general; they are usually confined to some parts on the upper surface of the hemispheres, or at the base. In most cases there is no appreciable increase of thickness, the membrane being merely a little opaque, and of a milky hue. This condition of the arachnoid is almost invariably accompanied by an effusion of serous fluid, either upon its free surface, beneath it, or into the cavity of the ventricles. The effusion varies in quantity, being sometimes not more than a few drachms, and in other instances amounting to several ounces. It is usually limpid, particularly when contained in the ventricles; but occasionally opaque or milky, and mixed with albuminous flocculi or shreds of lymph if an exudation of false membrane exist at the same time. When the effusion is beneath the membrane, this is elevated along the sulci which separate the

convulsions, and presents a gelatinous appearance, as if it had suffered a change of structure; but if an incision is made along the surface, the fluid can be made to exude, and then the membrane subsides to its original position, and exhibits no other change except that of being a little opaque and thickened.

Dr. Abercrombie notices a modification of this disease, remarkable from its rapidity and from simulating hysteria, or even mania; although on examination it presents merely a highly vascular and injected state of the pia mater, complicated in some instances with slight subserous effusion. It commences with depression of spirits, to which cheerfulness soon succeeds, but finally passes on to delirium. The patient's manner is hurried; he talks rapidly, wandering from one subject to another. Obstinate watchfulness exists throughout; the pulse is small and rapid; the countenance pale and expressive of exhaustion. The treatment is founded on these circumstances. Stimulants cautiously given afford relief, while depletion aggravates the evil, or produces but a temporary alleviation.

*Chronic meningitis.*—Meningitis is in many instances so slow in its progress as to assume the chronic form. The disease is then characterised by a different train of symptoms. According to Bayle, delirium and progressive paralysis are the constant attendants of chronic meningitis. The delirium is at first partial; it is a monomania with weakness of intellect; but, after a time, it passes on to maniacal excitement, and finally subsides into confirmed idiocy. The paralysis in those cases does not exhibit a total privation of sensation and motion in any particular part of the body; it is at first slight, but gradually increases, and extends to the whole muscular system, rendering the gait feeble and vacillating, and ultimately destroying the power of motion. It is remarkable that the diminution of sensation is not proportioned to that of motion. Spasmodic movements, with contraction and rigidity of the limbs, sooner or later set in; and, finally, epileptic attacks, which terminate in fatal apoplexy.

Besides the injection and thickening of the membranes, and the serous and albuminous effusions presented by the more rapid cases, the free surface of the arachnoid is found studded with minute conical granulations, or flocculi, so as to lose its smooth and polished appearance. Contiguous parts of the membrane are also occasionally found connected by bands of false membrane; this most frequently occurs at some point of the inner flat surface of the hemisphere, where it is in contact with the falx major. The investing and reflected parts of the membrane are also found closely adherent along the angle formed by the inner and upper sides of the hemisphere, where the superficial veins enter the longitudinal sinus. In this situation the surface of the arachnoid is found rough, and studded with small rounded or irregular masses of a greyish white colour, which are sometimes called glandulæ Pacchioni. These productions do not exist in early infancy, or in the healthy condition of the organ; they

appear to be an albuminous exudation, the result of chronic inflammation. In many cases the membranes are adherent to the subjacent cerebral substance, which is found altered both in colour and consistence.

*Causes.*—Meningitis is a frequent consequence of injuries of the head, of fractures, concussion, or even wounds, of the scalp. It not unfrequently happens that a wound of the head heals rapidly, and that the patient returns to his usual occupations, thinking himself quite well; but after ten or fourteen days he begins to feel pain in the situation of the wound, which gradually increases in intensity; and in a very short time all the symptoms of cerebral inflammation become manifest. A child may suffer serious injury from a fall, and as all mention of the accident is suppressed by his immediate attendant, it escapes the notice of others, and no ill effects follow perhaps for a week or two: the child then, however, loses appetite, becomes restless and irritable; febrile excitement, delirium, and convulsions succeed, and too often are the precursors of a fatal termination. In such cases, the real cause of the disease not being suspected, it is generally attributed to the irritation arising from dentition or worms; but examination after death shews that it is not merely a sympathetic disturbance, there being abundant evidence of active meningitis.

In the list of causes should also be included depressing passions; sudden fright, or unexpected disappointment; violent emotions; immoderate indulgence of any sort, particularly in the use of spirituous liquors; the suppression of cutaneous eruptions, and habitual evacuations or discharges; insolation (*coup de soleil*) in warm climates; deposition of bone in the dura mater; tubercle developed in the cerebral substance, and extending to the circumference of the hemisphere, so as to become a mechanical irritant to the membranes.

Such are the exciting causes of meningitis; but there are predisposing circumstances which confessedly render some persons more liable to it than others. One class of persons consists of those who possess what is termed the apoplectic constitution, indicated by a large head, short neck, and sanguineous temperament; the other class exhibits evidences of the lymphatic temperament, together with considerable cerebral development, indicated by precocious talent. Such persons in early life are very liable to attacks of meningitis, which terminate in serous effusion. Sex also seems to be a predisposing cause, or rather the peculiar pursuits and habits of the sexes; for males are more liable than females, according to Martinet, in the proportion of three to one. All ages are liable to this affection, but not equally so; of one hundred and sixteen cases recorded by the author just cited, twenty-nine were under fifteen years, forty-four from fifteen to thirty, thirty-eight from thirty to sixty, and five from sixty to eighty. These results, it should be remembered, are taken from hospital practice, in which the great majority of patients are adults. In private practice the proportion

of cases under puberty is much greater than that here stated. The ordinary duration of acute meningitis is from seven to ten days, but death may occur on the third or fourth; few cases are prolonged beyond the twenty-fifth or thirtieth.

The treatment of meningitis will be included in the subsequent article, on inflammation of the substance of the brain.

(J. Quain.)

II. INFLAMMATION OF THE SUBSTANCE OF THE BRAIN (ENCEPHALITIS).—We find very little information on the subject of inflammation of the substance of the brain, as a distinct and separate disease, in the early records of medicine. It has scarcely obtained a separate place in any of the nosological arrangements; every variety of inflammation, both of the brain and its membranes, being generally classed under the head of *phrenitis*. Bonetus and Morgagni are among the first writers who make any mention of the morbid alterations of the brain arising from inflammation; but they give no very distinct history of the symptoms, being satisfied, in general, with naming the diseases: many of their observations, indeed, are evidently taken from casual examination of bodies in the dissecting-room, and therefore afford very little satisfactory information. Sauvages sets down loss of sleep, headach, subsultus tendinum, and convulsions, as symptoms of arachnitis, and low delirium as that of encephalitis. Cullen includes all the inflammatory affections of the brain and its membranes under the head of *phrenitis*, stating his inability to distinguish them from each other; and the same course is followed by Frank. Pinel, in his *Nosographie Philosophique*, endeavours to draw a line of demarcation between inflammation of the membranes and that of the brain itself, but this attempt is altogether hypothetical; he, however, states that after ataxic fevers he has found injection, inflammation, and suppuration in the brain and its membranes, and therefore considers them as the seat of the disease. Several other French writers have alluded to inflammation of the substance of the brain as a concomitant of ataxic fevers. Dr. Mason Good, in his *Study of Medicine*, ranges inflammation of the brain under one species, which he terms *empresma cephalitis*; and he makes out two varieties, one superficial inflammation, called *meningea*, *phrensy* or brain fever, and the other *profunda*, affecting the substance of the brain and lining membranes of the ventricles, to which he refers *hydrocephalus acutus*; but he merely follows other nosologists in his description of symptoms and causes. The first distinct account given of that peculiar alteration of the brain called *softening*, and of its characteristic symptoms, was by M. Recamier, physician to the Hôtel Dieu, in Paris; who considered it as one of the terminations of nervous fevers. Several of his pupils, and more especially Lallemand, Rostan, Parent, and Martinet, have since pursued the investigation of this interesting branch of pathology with considerable success, and have published valuable works on

cerebral diseases. Nearly about the same period the attention of the profession in Great Britain was directed to this subject by Dr. Abercrombie, whose pathological researches on diseases of the brain are held in high estimation on the continent, as well as in his own country. Some separate cases of inflammation and suppuration of the brain are to be found in Dr. Baillie's excellent manual of *Morbid Anatomy*. He refers to Dr. John Hunter's account of softening of the brain in the *Gulstonian Lectures*, read before the College of Physicians in 1796, describing two forms of softening; that which occurs in old age, and that which is combined with apoplectic effusion. A valuable addition has been lately made to our medical literature in this branch of pathology by the medical reports of Dr. Bright, whose splendid plates of the diseased structure of the brain are admirably illustrated by a history of well selected cases. It will be seen by this brief sketch of the information afforded in medical writings on inflammatory affections of the brain, that it is only within our own times that our knowledge of these diseases has begun to assume a practical and systematic character.

Inflammation of the substance of the brain may be divided into *general* and *partial*, *acute* and *chronic*. The general inflammation is always acute. The partial inflammation may be acute or chronic. Inflammation of the brain sometimes commences suddenly; this is not, however, the most ordinary case. It is generally preceded by a variety of premonitory symptoms; and as the disease, when once fully developed, is very formidable, it is of the highest importance that the practitioner should be well acquainted with these symptoms.

The most usual *premonitory* symptoms are, a general uneasiness and restlessness, with a tendency to congestion in the head; a sense of weight and fulness; occasional attacks of pain in the head, or of temporary apoplexy or epilepsy; flushing of the face and increased heat of the head; drowsiness and vertigo; preternatural acuteness of the external senses; intolerance of light and optical illusions; contraction of the pupils, strabismus, or imperfection of sight; tinnitus aurium, or various other noises in the ear; confusion of thought; failure of the memory; mental excitement or depression, or some striking alteration in the habitual character and pursuits of the individual. In some cases there is little appearance of indisposition throughout the day, but the symptoms are aggravated at night: the sleep is uneasy or disturbed by alarming dreams, and in children there is often grinding of the teeth. Pains in the limbs and frequent cramps, general lassitude and muscular debility, are often felt, alternating with fits of shivering and feverishness; the digestive functions are disordered; there is in general loss of appetite; often obstinate vomiting; the bowels are either irritable or torpid, the secretions being always unhealthy.

The above symptoms precede either general or partial inflammation of the brain. Those which follow indicate more especially the inva-

vasion of partial and chronic inflammation. A long-continued, fixed, and deep-seated pain in one part of the head; pain, numbness, weakness, a sensation of creeping and tingling in one extremity or in one half the body; or confined to one portion of the extremity: there may be numbness and loss of power in one finger only, or in one set of muscles. Sometimes the speech is affected so as to produce a degree of hesitation, stuttering, or indistinctness of pronunciation. Drowsiness, languor, depression of spirits, are observed also more particularly in the chronic form of cerebritis. Some of these premonitory symptoms may have been present for weeks, for months, or even for a year, or for a longer period. The practitioner cannot be too deeply impressed with the importance of the discovery and due appreciation of the foregoing train of symptoms: many of them may be overlooked by the patient, unless his attention be called to them; he attributes his ailments to nervousness, debility, rheumatism, gout, and any but the real cause. He is allowed, perhaps, to live well; his stomach is strengthened and his nerves are soothed; whilst the disease in the brain, which will certainly end in death, is suffered to pursue its course.

1. *General cerebritis*.—General cerebritis is always acute. Its symptoms have been divided into two periods: 1. the period of irritation or excitement; 2. the period of collapse.

The symptoms which characterize the period of excitement are, intense pain extending over the greater part of the head; great excitement of the cerebral functions; violent delirium; preternatural acuteness of both the external and internal senses; intolerance of light; brightness, redness, wildness, or protrusion of the eyes; contraction of the pupils; tinnitus aurium; flushing of the face; throbbing of the temporal arteries; paroxysms of general convulsion; rigidity of some of the muscles on one or both sides of the body in the interval of the paroxysms. There are also severe shooting pains in the extremities, greatly increased by extending them; twitchings of the muscles of the face; rolling of the eyes; quick, suspirious, and irregular breathing; rapid, full, and hard pulse; subsultus tendinum; red and dry tongue, either tremulous when protruded, or in violent motion, pushing out the cheek, or forcibly thrust out of the mouth; great thirst; occasionally severe vomiting, especially in children; scanty and high-coloured urine. The paroxysms of convulsion are always attended with an exacerbation of the symptoms. The respiration is hurried, and the pulse rises suddenly forty or fifty beats in a minute. When the convulsions subside, the pulse and respiration become comparatively slow and feeble.

The symptoms just enumerated may last from twelve to forty-eight hours, or more, when they are succeeded by others of an opposite character, which constitute the second period, or that of collapse. The headach is now no longer complained of; the delirium gradually passes into stupor and coma; the preternatural

acuteness of the senses is succeeded by obtuseness and insensibility; the convulsions subside into general muscular relaxation, and more or less complete paralysis succeeds. The pupils become dilated and motionless; the eyes sunk, pale, and dim; there is sometimes strabismus, or deafness; the pulse is rapid, small, unequal, or intermittent; there are frequent rigors, the skin afterwards feeling cold and covered with a clammy sweat; the face is pale, sunk, and cadaverous; the respiration is slow, or irregular and stertorous. When the patient lies senseless on his back, and swallows with difficulty, the fatal issue is not far distant. There may be several alternate paroxysms of excitement and collapse, until the patient finally sinks into a state of coma, which soon ends in death.

A great resemblance is apparent between the preceding delineation of general cerebritis and that of arachnitis. A more strongly marked and permanent degree of rigidity in the muscles on one side of the body is, however, believed more particularly to indicate cerebritis. The disease may have been preceded by some of the premonitory symptoms, and have set in with headach and delirium, terminating in coma; or the invasion may have been sudden, and attended by a violent paroxysm of convulsions. In the former case, it is probable the inflammation had its origin and principal seat in the brain; in the latter, that it was confined to the membranes. The diagnosis between the two cases is, however, extremely difficult; the one generally giving rise to or terminating in the other.

The symptoms are of course variously modified, according to the extent and intensity of the inflammation, which may occupy one half of the brain and extend in depth, or may be spread over the surface, or affect several isolated portions in both hemispheres.

General cerebritis in most instances proves speedily fatal; the inflammation of a large portion of the brain being incompatible with the prolongation of life. In the majority of cases on record, death occurred within a week; in some within twenty-four or even twelve hours, the inflammation scarcely ever going beyond the first stage.

This form of inflammation of the brain may exist in combination with inflammatory affections of other organs, and occasion modifications in their symptoms demanding close attention. The intense pain arising from inflammation in the abdominal and thoracic viscera may, when such a combination exists, not be felt by the patient, although the inflammation is pursuing its course unabated. This has sometimes led to the dangerous mistake of believing a disease removed which was only masked. Hippocrates was acquainted with this source of delusion, for he says that whenever a patient suffers and does not complain, *mens agrotat*, the mind is diseased. We have seen serious consequences follow this deception in cases of continued fever with head symptoms. In such cases, therefore, the practitioner cannot be too much on his guard;

and the very circumstance of the denial of pain, without amendment in other respects, should induce him to ascertain, by manual examination and every other means, the true condition of the principal viscera. Particular attention should be paid to the region of the bladder; as, from insensibility, the bladder gets over-distended and partially paralysed; the resistance of the sphincter vesicæ is overcome; the urine dribbles out by drops, and the patient is supposed to suffer from incontinence, whilst he is, in reality, affected with retention of urine. The same insensibility is the cause of the great difficulty sometimes experienced in exciting vomiting in cerebral affections.

II. *Partial cerebritis*.—Partial inflammation of the substance of the brain may be acute or chronic; the disease assuming a variety of forms according to the severity, extent, and seat of the inflammation. Its invasion is generally slow, and preceded by some of the premonitory symptoms, which are, in fact, the mere signs of that state of local congestion and irritation which immediately precede inflammation. We shall first give a description of the principal forms of the disease, and then take a general review of the symptoms.

1. In partial cerebritis, the individual is attacked with fixed, deep-seated pain in the head, vertigo, dimness of sight, hesitation of speech, sensation of tingling, pain, cramps or weakness in one or other of the extremities; one of the limbs suddenly giving way during exercise, so as to occasion stumbling; or the walk is unsteady, like that of a drunkard. The general health is, at the same time, more or less impaired. These symptoms may have gone on for a certain time without fever or affection of the intellect; so that no serious alarm has been excited till the patient is suddenly seized with an attack of coma and insensibility. He may recover from this in a few minutes or hours, when one arm or leg, or even one half the body is found paralysed. The paralysed limbs are almost always first in a state of permanent rigidity, and more or less bent, in consequence of the flexor muscles having greater power than the extensors. Lancing pains are also felt in the muscles, and much increased by extension. From all these symptoms the individual may so far recover as to be able to leave his bed, the limbs continuing paralysed; in other cases, some degree of stupor and mental weakness remains, with a peculiar frowning or vacant expression of countenance; the patient still, however, shewing some signs of intelligence when roused. Several of the external senses may be affected; the sight of one eye, for instance, may be impaired or destroyed: or there may be dilatation and insensibility of one pupil, and contraction of the other, or strabismus. In like manner, the sense of hearing may be imperfect, or wholly lost. There may be symptoms of low fever, with delirium; but there is seldom any violent re-action. The assemblage of symptoms just described constitutes the *first period* of the disease, or that of cerebral irritation.

After various intervals, a second or even a

third attack of coma is experienced, and the patient either dies suddenly or sinks under gradual exhaustion. As the disease advances, a change takes place in the state of the paralysed limbs; the rigidity, gradually subsiding, is succeeded by relaxation, flaccidity, and complete paralysis. This marks the *second period* of the disease, or that of softening and complete disorganization of the portion of brain affected.

2. In many cases the paralysis of the limbs is at first only partial; a certain degree of motion is preserved, but there are convulsive spasms, generally of short duration; and after alternate attacks of this description, the paralysis gradually becomes complete. This order of the symptoms generally corresponds with the progress of the inflammation from the first stage, or that of excitement, to the second, or that of softening and suppuration.

When the inflammation spreads from the brain to the meninges, constituting the combination of partial cerebritis and arachnitis, the side of the body not paralysed is generally affected with paroxysms of convulsion, in which sometimes the paralysed parts themselves participate. These diversities in the affections of voluntary motion will be more particularly considered in the general review of the symptoms.

3. The order in the progress towards complete paralysis just described is sometimes reversed; there being at first sudden and complete resolution of the muscles; and the spasmodic rigidity with convulsions only appearing some time after. It not unfrequently happens that, if the congestion be violent and sudden, and the blood-vessels weak or diseased, extravasation of blood takes place in the brain, either by rupture of a blood-vessel or exudation, before the inflammation has had time to set in. Instead of a gradual loss of voluntary motion, with spasmodic irritation of the muscles, there is then a sudden and complete abolition of muscular power in some regions of the body, and a state of perfect paralysis, in consequence of the sudden destruction of a portion of cerebral substance, and of the pressure exercised by the clot of blood. This difference in the mode of attack forms a good line of distinction between sanguineous apoplexy and cerebritis in the great majority of cases. After a certain time, however, the clot of blood irritates the surrounding cerebral substance, and excites inflammation: pains, cramps, and convulsions are then experienced in the relaxed and paralysed muscles, so that they sometimes become perfectly rigid: this constitutes the form of disease known as *consecutive cerebritis*. Apoplexy and cerebritis are diseases which frequently have a common origin, viz. cerebral irritation and congestion, and are only modified in their progress by accidental circumstances; though in apoplexy it is too often the custom to consider only the extravasated blood, which is a mere effect, and to overlook the previous morbid condition of the brain which was the cause of the hemorrhage. The invasion of cerebritis is gene-

rally slow, and characterised by premonitory symptoms; the course of the disease is marked by great irregularity, by frequent exacerbations of some of the symptoms, and by deceitful remissions. Apoplexy, on the contrary, takes place more suddenly, and often without any very decided premonitory symptoms; the paralysis is more complete from the beginning, and the progress of the disease less variable. Apoplectic extravasation of blood sometimes takes place in the advanced stages of cerebritis, by the bursting of a vessel in the centre of the softened mass of brain: a sudden attack of coma is generally the consequence. The pre-existence of the symptoms of cerebritis will afford a sufficient distinction of such a case from common apoplexy.

4. Partial cerebritis is sometimes *acute*, and the inflammation passes rapidly through its different stages, as may easily be conceived in an organ so vascular and highly organized as the brain. The patient may in that case sink under the first attack of coma, and the disease will be generally found to occupy a considerable portion of the brain.

Even when the disease is limited to a small extent, it may prove rapidly fatal, in consequence of the portion of the brain it affects; as, for instance, when its seat is in the medulla oblongata, or contiguous to the arachnoid and pia mater. It is proper also to remark that the extent of the injury arising from disease of the brain is very much in proportion to the rapidity of its development: a very slight degree of pressure, if suddenly applied, is capable of creating violent constitutional disturbance: this will account for the disproportion sometimes observed between the severity of the symptoms and the extent of the disease. When it commences by an attack of paralysis, without coma, delirium, or any serious affection of the head, the inflammation is commonly at first slight, and seated near the origin of the spinal cord.

5. There is another form of cerebritis, in which the inflammation is of a more *chronic* character; the disease more slow, obscure, and variable in its progress, and the paralysis of the muscles neither preceded nor attended by symptoms of irritation. The disease may commence with a slow and gradual loss of power, at first limited to a single region of one of the extremities, or to a single set of muscles, and without pain, cramps, or rigidity; the tongue may be affected, or the sight of one eye; or there may be slight distortion of one side of the face: the paralysis gradually creeps on, until it has invaded successively the upper and then the lower extremity, on one and sometimes on both sides of the body. The disease is not attended in its progress with any general reaction, the only appearances of disturbed health, for a length of time, being symptoms of debility and decay, both bodily and mental; until, at the end of several months, or perhaps longer, the patient is suddenly seized with coma and convulsions, or else sinks under

gradual exhaustion. There are sometimes however, deviations from this uniform course, and the progress of the disease, although slow, is marked by occasional affections of the head and symptoms of general irritation. This is the form of disease which has appropriately enough received the appellation of *creeping palsy*. It usually proceeds from a low state of inflammation of the brain, commencing in a small portion, and gradually extending to a larger one; the inflammation generally continues for a considerable time in the first stage; it may prove fatal in that stage, with symptoms of coma and convulsion; or pass on to softening and abscess, with their usual consequences. This is the form of disease which usually attends that variety of white softening called *simple softening*, in which the arteries are frequently found diseased. The disease also sometimes terminates in permanent *induration* of the portion of the brain affected.

A good many cases of partial *induration* of the brain have been related by Morgagni, Baader, Abercrombie, &c. &c.; they were all of a protracted nature, and characterized by a degree of irregularity and intermittence in their symptoms, which closely resembled those of organic disease. The disease in some cases assumed so completely an intermittent form as to mislead with regard to its real character. This tendency to periodicity is of frequent occurrence in all the chronic forms of cerebral inflammation.

There is a variety of chronic cerebritis peculiar to lunatics, who, after being affected for a considerable time with acute mania, have gradually sunk into imbecility and idiocy. The paralysis is not confined to one region, but extends to the whole muscular system; it is at first slight, and only indicated by a general tremor and debility; a sluggishness and vacillation in all the motions; fatuity, and sometimes low delirium: these symptoms gradually increase; the sensibility becomes obtuse, and the disease generally terminates in paralysis with spasmodic rigidity, or in apoplexy. The appearances after death are—redness, softening, sometimes atrophy, and a granulated appearance of the cortical substance on the whole surface of the hemispheres; chronic inflammation of the membranes, which adhere firmly to the surface of the brain; serous effusions; an indurated state of the medullary substance, sometimes with partial softening.

6. Partial cerebritis is sometimes connected with disease of the *cranial bones*. Desault, Abercrombie, and others, have recorded some interesting cases of a disease of the inner table of these bones, the outer table remaining perfectly sound, so that there was no external indication of the disease. The symptoms were characterized by fixed, intense, and deep-seated pain in the head: a disturbed state of health; violent delirium; drowsiness, double vision, and coma. The disease seems to have been the result of a very slow inflammatory action, lasting in some cases for many years, and gradually destroying the bone by caries.

On dissection, the inner table of the bone has been found destroyed; the rough cancellated structure covered with lymph, or adhering to the inflamed and thickened dura mater; the membranes adhering to the brain, which was inflamed and softened. In some cases the bone has been reduced by absorption to a transparent thinness; the dura mater being also partly absorbed, and the brain livid and indurated. In others, after a blow on the head, a small portion of the cranium has been completely absorbed without any ulcerating process, leaving the brain covered only by the healthy skin. Two instances of this kind are related by Mr. Howship and Mr. Wilmar; in one of them there was hemiplegia; both patients survived, but the deficiency of bone was not supplied. More generally, however, both plates of the bone and the intervening diploë are affected with chronic inflammation, which brings on a variety of morbid changes; such as the formation of bony tumours, or ridges, caries, exfoliations, or excessive thickening of the integuments: these finally lead to inflammation of the brain and its membranes. Saviard mentions the case of a woman in the Hôtel Dieu, in whom, in consequence of an injury of the head from a fall, successive exfoliations of both tables of the cranium took place to such an extent that the pieces, when put together, resembled the scull-cap as it is sawn off in dissection: this process occupied two years, at the end of which she was dismissed in good health, but with the upper part of the brain covered only by integuments.

There is a variety of the disease beginning in the periosteum, which is often accompanied by very urgent symptoms; it is a chronic inflammation of the periosteum, with thickening, induration, and sometimes suffusion of pus. The corresponding portion of dura mater is inflamed, and thickened, and the disease extends to the brain; the intervening bone in some cases remains healthy, in others it is also diseased. It is attended with intense, fixed pain, and there is sometimes such exquisite tenderness in the part, that the slightest pressure brings on syncope and convulsions: there may be also various affections of the sight, hearing, speech, and intellect, and various forms of paralysis or convulsions. Relief has generally been afforded by deep incisions down to the bone, and by exciting and keeping up suppuration. It may be necessary in some cases to repeat the incisions. In some instances related by Mr. Crampton, the disease appeared as a circumscribed tumour: in one, the swelling spread considerably, and was accompanied by erysipelas; more generally, however, there is no visible tumefaction.

One of the distinguishing features of these various forms of disease is, their very slow progress, owing to the low state of inflammation of the parts affected; they have been known to last for years, and even during a great part of a patient's life; and an apparently very slight degree of inflammation has in some cases given rise, for a considerable length of

time, to the most urgent symptoms. The inflammation has been excited in some instances by an injury so trivial as to escape the patient's attention; though it should be kept in view that it is not always confined to the part which was the seat of the injury, but has sometimes a tendency to spread over the cranium. It may also occur spontaneously, in which case it is occasionally connected with a syphilitic taint, or scrofulous diathesis.

In chronic otitis there is a great tendency in the inflammation to spread from the inner ear to the brain: suppuration of the brain has also, in some cases, made its way out by the ear; and it is generally remarked, that when the suppuration from the ear is checked or suppressed, this is almost immediately followed by symptoms of acute cerebritis; and again, that as soon as the suppuration of the ear is restored, the symptoms of cerebral inflammation disappear. This affords a striking proof of the effects of pressure, and points out the great caution which is required in the treatment of otitis, to prevent the extension of the disease to the brain.

7. We shall conclude this account of the different forms of cerebritis with some general remarks on the progress of the disease. It sometimes pursues its course without intermission, either to a favourable or fatal termination, with only occasional exacerbations of the symptoms. At other times there are well-marked remissions, with an apparent amendment. When cerebritis passes from the first stage of inflammation, or that of excitement, into the second or that of softening, there may be such a remission of the febrile symptoms, although the paralysis remains, as to excite hopes of recovery. This should not however deceive the practitioner, as the improvement is often merely delusive, and soon followed by repeated relapses. There are occasional instances of the symptoms assuming a remarkable *periodical* course, and returning at regular intervals. In one case, after a wound in the head, the patient was seized every evening with a paroxysm of delirium, succeeded by stupor; he died in the course of the fifth paroxysm; and on dissection there was found extensive inflammation of the membranes, and suppuration of the brain. In another case, in which the paroxysm set in at the same hour, lasted exactly the same time, and recurred every second day, the symptoms were those of well marked cerebritis, and there was complete apyrexia during the intermissions; the arachnoid and pia mater were found inflamed, and there was a large undefined abscess in the middle lobe of the right hemisphere. These cases had been mistaken for pernicious intermittent fever, and treated by bark. It is not easy to explain satisfactorily the cause of these regular exacerbations and intermissions; they are probably the effect of some sudden congestion in the brain, aggravating the symptoms. There is a well known tendency to periodicity in all affections of the cerebral and nervous system; the formation of pus in every vital part is also known to be

attended with occasional rigors and paroxysms of hectic fever. This tendency to intermittence and periodicity is most frequent in chronic cerebritis.

A number of interesting observations on cerebritis in horses have been made by M. Dupuy, professor in the Veterinary College of Alfort, near Paris. The spinal marrow was found more frequently affected than the brain; which is easily accounted for by its being much larger in these animals, in proportion to the brain, than in man; and by its being also much more exposed to suffer from violent muscular exertion. The morbid alterations after inflammation corresponded in every respect with those observed in the human subject: the symptoms attending the disease were—tremor of the extremities, weakness, convulsions, tetanic stiffness of the muscles of the neck, jaws, and more especially of the hind quarters, which were the first to be affected with paralysis. One remarkable symptom was, a disposition in the horses thus affected to place the head against the wall and to push forward with all their force, so as even to break through or overthrow partitions. They were observed to continue in this attitude, with a kind of tetanic stiffness, for above an hour, until the paroxysm of spasm subsided, when they dropped down from exhaustion. The disease always ended in paralysis, coma, and convulsions. It is one of the forms of disease known in this country by the name of staggers.

*General review of the symptoms.*—We shall complete the history of the different forms of cerebritis by taking a general review of the leading symptoms, pointing out at the same time the different pathological conditions of the brain with which they seem to be connected; so far at least as is practicable in the present state of our knowledge.

When the inflammation occupies at the outset a large portion of the brain, we have seen that it is generally complicated with meningitis, and characterized by disturbance in all the vital functions; that we may recognise in the symptoms a period of high excitement, and one of corresponding depression; and that it runs its course speedily, either to a favourable or fatal termination.

When, however, a smaller portion of the brain is engaged in inflammation, as in *partial cerebritis*, the course of the disease is seldom so rapid; its invasion is more gradual, and preceded by symptoms of irritation in some of the organs of voluntary motion, sensation, or intelligence; and in the more advanced periods of the disease the functions of some of these organs become considerably impaired, or completely abolished.

We have stated that, when partial cerebritis is fully established, one of the most constant symptoms of the first period is paralysis of voluntary motion, with spasmodic rigidity of the muscles, producing permanent flexion of the affected limb. The limb is sometimes considerably bent, and its extension is attended with severe muscular pains; this spasmodic action generally shews itself first in the arm,

in which it is always greatest, and then extends to the inferior extremity. When the muscles of the face partake of the spasm, the mouth is drawn towards the paralyzed side; the eyelids are closed by the contraction of the orbicular muscle, so that some stiffness is felt in attempting to open them. But in the more advanced stages, when the paralysis becomes complete, and the muscles are relaxed, the mouth is drawn by the healthy muscles to the side opposite that paralyzed. The eye continues closed, but it is from the dropping of the eyelid, in consequence of the paralysis of the levator palpebræ superioris.

Convulsive rigidity and retraction of the muscles are sometimes observed in connection with meningitis; but it may be generally distinguished from spasmodic paralysis by several well marked signs. There is no actual paralysis; and when the convulsive retraction intermits, the patient fully recovers the power of voluntary motion in the same manner as after the paroxysms of spasmodic rigidity in tetanus. This convulsive rigidity is scarcely ever limited to one region or to one side of the body, as in partial cerebritis, but affects a variety of parts at the same time on both sides. Another ground of distinction is, that the sensibility remains unimpaired. In spasmodic paralysis the rigidity and loss of voluntary motion are permanent, and the sensibility of the affected parts is more or less obtuse.

The accuracy of these rules of distinction has been considered by some as still rather doubtful, and this is a point in the pathology of these diseases requiring perhaps further investigation. We are of opinion, however, that they are not without foundation. It is true that spasmodic paralysis is a very common symptom of chronic meningitis; but it is equally certain that, if the brain be carefully examined, chronic inflammation of the membranes will almost always be found combined with inflammation and softening of the surface of the brain. These views are supported by the authority of Bayle, Laennec, Lallemand, Gendrin, and several other eminent pathologists. Spasmodic paralysis, with pain and other signs of irritation, is generally characteristic of the *first stage* of cerebral inflammation, or that of excitement: the disease sometimes terminates fatally at this period.

When the inflammation, however, advances towards the *second stage*, or that of softening and suppuration, the rigidity and muscular contraction gradually lessen, until at last there is complete paralysis. This condition of the muscles has generally been found in connexion with softening and disorganization of some part of the brain. An important difference exists, therefore, between the spasmodic and the complete paralysis: the first, being the effect merely of the compression and irritation of the cerebral substance occasioned by the great influx of blood in the first stage of inflammation, is capable of being removed, if we can only succeed in subduing the inflammatory action at an early period; the second, arising from the complete destruction of a portion of

cerebral substance, is beyond hope of recovery, since there is yet no instance on record of the reproduction of brain.

When the paralysis is at first partial, and increases only gradually, the paralyzed muscles are sometimes affected with convulsive motions, generally of short duration. This usually happens when the progress of the inflammation is slow, and the diseased portion of brain is partly in the first and partly in the second stage of inflammation. When arachnitis supervenes on partial cerebritis, both sides of the body may be convulsed; but in this case, when the paroxysms of convulsion intermit, one side only remains paralyzed. Convulsions affecting both sides of the body at the same time, may generally be considered symptomatic of inflammation of the membranes, rousing into inordinate activity the functions of the healthy brain, and thus exciting violent irregular action of the voluntary muscles. But, when the substance of the brain itself is extensively diseased, the power of voluntary motion is partially impaired or altogether destroyed. General convulsions may also be the effect of simple pressure or of nervous irritation; but in these cases the fever which attends arachnitis is altogether absent. In some instances one-half of the body has been violently convulsed, whilst the other has remained perfectly motionless, as if dead: this has been observed to arise from the combination of arachnitis with very extensive softening and destruction of one side only of the brain. In other cases both sides of the body have been affected with paralysis in succession; this generally indicates the extension of the inflammation from one hemisphere to the other, but these cases of double cerebritis are not common. In chronic cerebritis we have seen that the paralysis assumes a different character; its invasion and progress being very slow and gradual, and not usually attended with any muscular pain or spasmodic irritation. Inflammation and softening of some of the central parts of the brain (the corpus callosum, fornix, and septum lucidum) do not occasion any paralysis.

The paralysis in the latter stages of cerebritis frequently affects the organs of speech. In some cases there is great volubility of speech; this principally happens on the approach of delirium; but more generally the utterance is slow and drawling: at first there may be only a slight defect or hesitation in pronouncing one letter or certain words; at other times the patient is affected with an entire loss of speech, either suddenly or by slow degrees. The loss of speech may proceed from loss of memory alone, the tongue remaining free; or the tongue and memory may be simultaneously affected.

Paraplegia, which had generally been considered as always the result of disease of the spine, has been observed by several writers to depend sometimes on inflammatory or organic affections of the brain alone, especially in adults. A paper will be found on this subject, by Dr. Baillie, in the Transactions of the College of Physicians, vol. vi., and one by Mr. Earle, in the Medico-Chirurgical Transactions

for 1828. This subject will be more fully considered in the article PARALYSIS.

The explanation of paralysis and convulsions affecting the side of the body opposite to the diseased hemisphere of the brain, is to be found in the decussation of the nervous fibres in the anterior portion of the medulla oblongata. It takes place so invariably that it may be almost considered as a general rule; there are, however, several well-authenticated cases on record, of paralysis having occurred on the same side of the body as that occupied by the disease of the brain. M. Bayle, in the *Révue Médicale* for January 1826, states that he had seen two unequivocal cases of this description in his own practice, and relates eight similar cases taken from former writers; three of them from Morgagni. A case in support of the same fact has been published by Dr. James Johnson, in the first volume of the Transactions of the Associated Apothecaries. Dr. Gall and other modern anatomists have distinctly shown that the decussation of the nervous filaments in the anterior portions of the medulla (corpora pyramidalia) is not always complete, and that several of these filaments are sometimes continued from each crus cerebri along the medulla spinalis on the same side: this may afford some explanation of the cases in question, although it is not perhaps altogether satisfactory. It has been supposed by some that the decussation takes place in the corpus callosum; but this appears without the least foundation. This subject has been discussed by Dr. Yelloly at considerable length, in a paper published in the first volume of the *Medico-Chirurgical Transactions*.

Next to the affections of voluntary motion, loss of sensibility is one of the most prominent symptoms of cerebral inflammation: the two classes of symptoms are generally combined, but seldom manifest themselves exactly at the same time. The paralysis of the skin usually appears later than that of the muscles, so that an extremity may have lost the power of motion, while it still preserves some degree of feeling. The sensibility, however, gradually decreases, until at last it becomes very feeble or totally abolished. The arm is generally deprived of motion before the leg; and the loss of feeling follows in the same order. The loss of voluntary motion alone indicates a less complete degree of paralysis than when combined with loss of feeling. There are some interesting facts connected with the loss of feeling as well as with diminution of temperature, which we shall have occasion to consider more in detail in the article PARALYSIS.

This account of the symptoms derived from the affections of voluntary motion and sensation has been deduced from a careful examination of a large body of well observed facts collected by others, as well as from our own experience. It is necessary, however, to keep in mind that the accurate study of the symptoms in cerebral diseases is too often surrounded with many difficulties and sources of error. The patient is sometimes in the situation of a child, unable to explain his sensations, either past or present;

the obtuseness or total loss of consciousness, preventing the free and full development of the symptoms, alters or completely conceals the true character of the disease; the absence, therefore, of any of the leading symptoms, in one case, under such circumstances, is not to be taken as a proof of their fallacy in every other. Several of the symptoms, spasms and convulsions for instance, may be so evanescent as to escape superficial observation. An accurate knowledge of the comparative state of the different regions of the body with respect to sensation and motion is sometimes attended with great difficulty, and requires the most careful examination. We cannot always see the patient in motion so as to judge of the exact degree of power he possesses over the different muscles; we must then make him grasp or lift a body. The state of feeling and of heat in each region should likewise be accurately noted. We feel strongly convinced that numerous mistakes are committed in all these respects by a hurried and superficial observation; and we need no better proof of the truth of this assertion than the very imperfect manner in which many of the cases on record are reported, some of the most important facts being frequently altogether omitted. It is always of considerable importance to obtain, if possible, a correct account of the history of the case from the earliest appearance of the symptoms; for it is chiefly from the mode of invasion that the different forms of cerebral inflammation derive their distinctive character, as they assume a greater resemblance to each other in their latter stages.

We have noticed, among the symptoms of acute cerebritis, paroxysms of increased activity of the external senses and intellectual faculties, such as intolerance of light, tinnitus aurium, violent delirium. The pupils are contracted during the period of excitement, but resume their natural size when it subsides; this distinguishes cerebritis from sanguineous apoplexy, in which the pupils are almost always dilated. Sometimes there is dilatation of one pupil and contraction of the other; the pupil, whether contracted or dilated, may be immovable, which is always an unfavourable symptom. Acute delirium and intense headach are more common attendants on the combined inflammation of the brain and its membranes than on that of the brain alone. Inflammation of the membranes, extending only to the surface of the brain, excites a considerable degree of sympathetic irritation and general disturbance in the cerebral functions, which, however, continue unimpaired so long as the organ remains healthy; but when the substance of the brain itself is deeply or extensively inflamed, its functions are rather oppressed and impeded, in proportion to the extent of the disease, than highly excited.

Partial and chronic cerebritis is scarcely ever attended, in its first stage, with general excitement of the cerebral functions. When the sight or hearing is affected, it is on one side only; the intelligence is rather partially weakened than excited. Cephalalgia is not so con-

stant in cerebritis as in affections of the arachnoid and dura mater. There may, however, be a local fixed headach, sometimes intermitting; but the pain subsides as the disease advances and the brain becomes more deeply affected; headach, therefore, is a less unfavourable symptom than stupor. In some cases the pain has been felt on the side opposite to the disease, an anomaly not easily explained. In the latter stages of partial cerebritis the senses and intellect become more seriously impaired, the patient falling either suddenly or gradually into a state of coma, or being cut off by an attack of meningitis.

It has been generally remarked that inflammation of the brain alone does not occasion much disturbance of the circulation, as large portions of brain have been destroyed by supuration, in injuries of the head, without any disturbance of the pulse or general re-action. This has been accounted for by the heart receiving its nerves chiefly from the great sympathetic, and being only indirectly influenced by the brain. The high fever accompanying some cases of cerebritis is to be ascribed generally to the complication of the disease with arachnitis, or with inflammation of some other organ. Great and sudden variations have been noted in the frequency of the pulse in very acute cases; it sometimes suddenly rises from 100 to 160; at another time it may be irregular or intermitting, or so feeble and slow as scarcely to be felt; and again quickly recovering its strength and frequency. These changes in the pulse correspond with the alternate paroxysms of excitement and collapse, and are connected, as will be seen presently, with similar changes in the respiration.

The respiration is not in the least disturbed in the great majority of cases of simple cerebral inflammation. This is satisfactorily accounted for by Sir Charles Bell's interesting discoveries respecting the origin and functions of the respiratory system of nerves: large portions of the brain may be destroyed, and extensive regions of the body deprived of sense and motion; but as long as that portion of the medulla which gives origin to the nerves of respiration continues free from irritation, inflammation, or pressure, the functions both of the respiratory and circulating systems proceed without interruption, and life is sustained. When, however, the inflammation or general irritation extends to the medulla, as happens in the paroxysms of convulsions which sometimes occur in cerebritis, the respiration then becomes extremely hurried; the violence of the convulsions forces also the blood towards the heart, which is excited by these two causes to redoubled action, in order to relieve itself of the congestion by which it is oppressed; hence the rapidity and sudden rising of the pulse: as soon, however, as the paroxysm subsides, the respiration and the pulse become comparatively tranquil. When the medulla is exposed to pressure, the respiration is slow, laboured, and stertorous.

Difficulty of breathing is on many occasions the effect of mere cerebral irritation, and there

is in reality a *cerebral dyspnea*, which we have no doubt has sometimes been mistaken for disease of the lungs. This difficulty of breathing is distinguished by its frequency, its irregularity, and a kind of hysterical sighing; or it is slow, laboured, and stertorous, as in coma. Auscultation will be found an invaluable resource in all cases of doubt; an accurate diagnosis, especially in the latter stages of continued fever.

The functions of the digestive system are so much under the influence of the brain that they must obviously sympathize with its diseases; the sensations of hunger and thirst, for instance, being greatly modified by the various conditions of that organ. Thus, in cerebritis the appetite is in general deficient, and the digestion slow and imperfect, especially in the more chronic forms; there is also a great disposition to sluggishness and constipation of the bowels; and the stomach itself is sometimes so torpid, that the strongest emetics are insufficient to excite vomiting. In other cases, however, there is considerable irritability both of the stomach and bowels, with vomiting or diarrhoea, and a very unhealthy state of the secretions; this chiefly happens in children. We have already sufficiently pointed out the influence of cerebral affections on the urinary organs, and the necessity of great attention to the state of those organs when the functions of the brain are much disturbed.

The convulsions, paralysis, and other pathognomic symptoms of cerebral inflammation, may be referred to the more immediate action of three causes:—1st, *inflammation* affecting either the membranes or a portion of the substance of the brain: 2d, *nervous irritation* extending from the diseased to the healthy parts of the brain, and stimulating its functions: 3d, *pressure*. The difficulty in ascertaining from which of these causes the various symptoms arise, constitutes the chief obstacle to our always forming an accurate diagnosis in cerebral diseases. Convulsions, spasmodic paralysis, increased activity of the intellectual faculties and external senses, delirium, and all symptoms of excitement, may generally be considered to indicate either commencing inflammation or nervous irritation in the substance of the brain or its membranes. Convulsions may also arise from pressure alone, although paralysis is its most frequent effect; but the absence of all fever and other symptoms of general irritation, will distinguish these convulsions from those of arachnitis and cerebritis: the same distinction applies to the convulsions of a purely nervous character, observed in hysteria, and after the use of certain poisons, &c.

The effects of pressure have often been examined by experiments on animals. If the cranium of a dog is trepanned and pressure performed on the dura mater to a certain extent, the animal shews signs of great uneasiness, and is affected with general convulsions; if the pressure is increased, the convulsions cease, the breathing becomes stertorous, the animal torpid and comatose; if the pressure

is diminished, the breathing becomes more free and the convulsions return; and if it is entirely removed, the animal soon completely recovers. The principal causes of pressure are congestion; effusion of blood, pus, or serosity into the ventricles, between the membranes, or in the substance of the brain; organic diseases of the brain or cranium. The obscurity in which all these interesting questions is still involved, is capable, we think, of being considerably lessened by further investigation; and nothing would be more likely to contribute to so desirable an end, than pathological observations made with care and impartiality. A valuable collection of cases illustrating the consequence of pressure on the brain, will be found in Dr. Bright's Reports of Medical Cases.

Some important information is afforded on the modifications produced by pressure in cerebral diseases, by the results observed to follow injuries of the head. Many interesting cases of this description are recorded in medical and surgical writings.

It is a matter of general observation in injuries of the head, that when there is an external opening forming an outlet for the pus, extensive inflammation and suppuration of the brain may take place, with only very slight paralytic and other symptoms, compared with those which arise from spontaneous inflammation of a much more limited extent. In confirmation of this we shall adduce the extraordinary case mentioned by Mr. O'Halloran.—A man, after an injury of the head, lost a considerable part of the frontal bone on the *right* side; a great opening was formed, and extensive suppuration having taken place, there were discharged through it at each dressing immense quantities of purulent matter, mixed with large pieces of cerebral substance, emitting a horrid smell, and making, after some time, “a frightful cavern” in the very substance of the brain. On the *eighth day* of this affection, the *left* hand and arm became paralytic, and the *left* thigh and leg on the *tenth day*: the man lived to the seventeenth, retaining his faculties to the very moment of dissolution, and having continued through the whole course of the disease perfectly composed and intelligent, and with a pulse quite natural. Mr. O'Halloran says he could affirm that no less than three ounces of the brain followed every dressing after the eighth day. These facts clearly prove the great share which pressure has in the production of the fatal consequences attending inflammatory affections of the brain. They enable us to understand how the swelling of one portion of brain, in the progress of inflammation, may be sufficient to exercise considerable pressure on the whole organ; hence the occurrence of complete hemiplegia with disease only of a small portion of brain; and that likewise of convulsions, paralysis, affections of the external senses on both sides of the body, and coma, with disease on one side only of the brain. That there is a considerable tendency in the cerebral texture to expand and swell

under inflammation, is made evident by the great protrusion of the brain through the openings in the skull which sometimes takes place after injuries of the head. The effects of pressure are local or general, according to its degree: when slight, it may excite convulsions; when great, it suspends consciousness and paralyzes motion; if long continued, it destroys life by interrupting the circulation in the brain.

*Morbid anatomy.*—Before proceeding to the description of the different morbid conditions of the brain, it may be useful to state that there are several appearances depending on accidental circumstances, which it is important not to mistake for the effects of disease. In persons who have died of acute disease, the brain is more injected than in those who have died of chronic; the injection is much greater also in cases of death from asphyxia or after violent convulsions. In chronic diseases the brain is often very soft and flaccid, whilst in acute diseases, where death has taken place rapidly, its density is rather increased.

After removing the membranes from the surface of the brain and cutting it in slices, a long exposure to the air is followed by a considerable increase of redness. If, as frequently happens, the head of the subject has been placed in a dependent position, a considerable degree of injection and of uniform redness may be the result, in consequence of the gravitation of the blood, and of its oozing through the pores of the vessels; the brain has then an appearance as if stained or washed with blood: the same takes place when the post-mortem examination is delayed until a considerable time after death, and putrefaction has already commenced: it occurs also more readily in hot weather and after malignant diseases. But this kind of accidental injection and redness of the brain differs so greatly from that which is the result of disease, that it is scarcely possible to mistake the one for the other; in the former case the blood will be much more easily removed by ablution in water, than in the latter.

It is important also to notice that a very great difference is produced in the vascular turgescence and redness of the cerebral substance, according to the order in which the cavities of the head or thorax are opened. When the thorax is first opened, it is evident that the vessels of the head and brain must be drained of some of their blood, in consequence of the large vessels of the lungs and heart being emptied. The brain will therefore always appear more loaded with blood, when the head is opened before the other great cavities. Finally, when the hammer is used to open the cranium, a certain degree of redness and ecchymosis is always produced round the line of fracture by the concussion, which might, through inattention, be mistaken for disease.

There can be no difference of opinion respecting the appearances which indicate inflammation of the brain in its advanced and confirmed stages; but the case is very different as regards incipient inflammation. Pathologists are not yet perfectly agreed upon the exact

appearances which constitute the commencement of inflammation in the brain, or any other organ: this has at all times been a fertile source of error in the history of diseases, cases of mere congestion having often been erroneously described as inflammation. The celebrated Laennec was perhaps justified in his opinion that, as a general rule, the deposition of a new product in any texture, such as pus or coagulated lymph, was the only genuine and incontestible proof of the previous existence of inflammation. Inflammation is, however, always necessarily preceded by an increased flow of blood to the part; and, by a timely removal of the exciting cause, this congestion may subside without passing into inflammation; but it is obvious that there must always be considerable difficulty in drawing the exact line at which congestion ceases and inflammation begins, or the physiological condition of the brain becomes pathological; nor is this indeed at all necessary for practical purposes. These observations will shew the importance of guarding against the too common practice of setting down as decided inflammation every appearance of redness and increased vascularity. We have no doubt that mere cerebral congestion has often thus been mistaken for inflammation.

*Congestion.*—In cerebral congestion all the vessels on the surface of the brain are more injected than usual, and it is easy to trace their minute ramifications. The substance of the brain, when cut through, presents a greater number of red dots, especially in the cineritious substance; but between these red dots the brain preserves its natural colour: its texture is not in the least altered, and this increased vascularity is general.

Cerebral congestion assumes sometimes another appearance, that of uniform redness, which, however, is never general. The white substance presents a light rose colour, sometimes a deep red tint not unlike mahogany; the grey substance, in which it is more frequent, assumes a reddish or scarlet tinge; the shades of red vary however, being described as purple, violet, chocolate, &c. M. Billard observed a slate-coloured tint in the cortical substance of the hemispheres in two individuals who had presented signs of chronic irritation of the brain. This uniform discoloration is only found in patches in different parts of the brain: it might not inaptly be compared to that condition of the lung which leads to pulmonary apoplexy, and it may likewise lead to cerebral hemorrhage, either by the exudation of blood or rupture of vessels. An uniform blush of a rose-coloured tint or of a deeper red, frequently surrounds apoplectic clots of blood, or softened portions of brain.

Cerebral congestion almost always accompanies inflammation of its membranes, and this affords an explanation of several of the symptoms. In some instances there is an effusion of a turbid or limpid serum into the ventricles, or between the arachnoid and pia mater; in others the arachnoid is, on the contrary, remarkably dry.

The character of congestion varies according as the arterial or venous system is most involved in the morbid action. A loaded condition of the venous system is common in old people, in persons affected with disease of the heart, or any other complaint preventing the free return of blood from the head; in those also who die of asphyxia, or whose last moments are attended with violent and long continued struggle. Venous congestion is not so frequent an attendant upon inflammation as the arterial; they are distinguished from each other by the darker colour of the venous blood, and the evident greater distension of the veins and their sinuses. The quantity of venous blood poured out is sometimes very considerable.

A high state of congestion, either general or local, precedes inflammation. General congestion may cause death, either by compression or the extravasation of blood, before there has been sufficient time for the development of inflammation. Local congestion is seldom so rapidly fatal, and time is afforded for the inflammatory process to go through its different stages.

*Inflammation.*—The first and most simple stage of cerebral inflammation is characterized by a high degree of vascularity and a red florid injection of the cerebral substance. When cut through it presents a considerable number of red dots out of which oozes blood, the naturally colourless capillaries being filled with blood. Besides these red dots, there are other small spots, in which, owing to the rupture of the capillaries, the pulp is infiltrated with blood; these spots or stains are striated, resembling ecchymosis: when numerous, they give the cerebral substance a marbled appearance, with various tints of red,—the cineritious substance of a deep red, the white substance of a marbled violet. The intensity of the redness generally decreases from the centre to the circumference of the inflamed portion. Several of these spots of ecchymosis sometimes unite, and form a small coagulum of blood; the diseased portion of brain is rather firmer than usual, owing to the turgescence of its vessels, and has less tenacity. All the preceding appearances will be more or less strongly marked according to the intensity of the inflammation. They may occupy a considerable portion of one of the hemispheres, or a number of circumscribed spots in different parts of the brain, extending more or less in depth. If the inflammation be extensive, and combined with arachnitis, it may prove fatal in this stage. When more limited, its progress is not so rapid, and it generally passes into the second stage or that of softening.

*Softening.*—In the second stage of inflammation, the substance of the brain becomes completely infiltrated with either blood or pus, or both; its delicate texture is broken down, softened, and more or less diffuent. When blood predominates, this constitutes the *red softening*. The colour of the broken down pulp varies from a bright red to a wine-lee tint,

with intermediate shades of claret, brown or ash. In the cineritious substance it is of a reddish-grey or brown, from the mixture of grey substance with the blood; all traces of fibrous texture disappear. The pulp in the centre of the diseased portion is diffuent, and contains sometimes loose turgid vessels; whilst towards the circumference it is firmer, deeply injected, and presents the character of the first stage of inflammation. There may be several softened down spots, and small clots of blood may be found in the softened mass; the surrounding brain presenting sometimes a serous infiltration or a kind of œdema.

When purulent softening takes place, globules of pus are seen mixed up with the deeply-injected pulp, giving it a greyish or yellow colour. As the disease advances, the purulent infiltration becomes general, and presents a softened mass, consisting of pus mixed up with brain. This constitutes the *yellow softening*. The same diseased portion may shew the different stages of inflammation; the red and hardened state at the circumference; that of semi-purulent infiltration next; and the diffuent purulent softening in the centre. The infiltration of pus may take place very irregularly throughout the same inflamed portion: it may be of various degrees of consistence; semi-concrete, in a state of jelly, or that of a thick fluid. The pus has sometimes fused from the diseased into the healthy brain, forming for itself a new cavity. The red and purulent softening are frequently combined, one portion of the inflamed part presenting a sanguineous infiltration, and another a purulent; or else there is a general mixture of blood, pus, and brain, of a dirty grey or reddish colour. It is evident that the colour of the inflamed brain must depend on the nature of the fluids, whether blood or pus, with which it is injected, and on the proportion in which these fluids are mixed.

The cineritious substance is the most frequent seat of the red softening; its great vascularity strongly predisposing it to inflammation. Thus, of forty-six cases of cerebritis collected by Lallemand, the grey substance was the principal seat of the inflammation in thirty-three, and the medullary in only eight. The surface of the convolutions, which consists entirely of cortical substance, was affected in sixteen cases; the corpora striata and optic thalami, in which the grey predominates over the white substance, in thirteen; and the tuber annulare, which contains less of grey substance, only in four. Some influence must be allowed to the greater extent of surface of the cortical substance, and to its connection with the arachnoid.

The softening in some cases is of a uniform yellow or greenish colour, with only a blush of red at its circumference, and the appearances of a less acute degree of inflammation. This is the form in which it is most generally found in the medullary substance, which is much less vascular, as already stated, than the cortical.

There is a variety of cerebral softening very distinct from the preceding, and which is

called the *white softening*; it affects more particularly the medullary substance. The pulp seems broken down by a kind of serous infiltration, and presents the appearance of whipped cream, with a few drops of pure serosity sometimes intermixed. The colour is generally of the purest white, at times however inclining to grey or yellow, especially when seated in the cortical substance; it is not surrounded by increased vascularity or redness, but rather by a state of œdema of the adjacent brain. This is the simplest form of softening of the brain, and that most common to old people; it is generally attended with serous effusions in other parts of the brain, and also with disease of the arteries, which is supposed to be one of its principal causes. The coats of the arteries are either ossified or affected with earthy brittleness; their tubes sometimes very much narrowed or obliterated, or else having a succession of small bony rings; the inner coat is in some cases thickened, soft, and easily separated. The basilar arteries are the most subject to these changes of structure. The veins have also been found diseased. Dr. Cheyne has seen a case\* in which there was a deposition of a firm yellowish white substance between the two coats of the veins, and this extended to all the veins of the brain; there was a turbid effusion between the arachnoid and pia mater; the whole brain was bloodshot; there was a portion of softened brain on the side of the left ventricle, an inch in length, with a cavity in its centre; the patient had long suffered from headach, and died apoplectic. The white softening must not be confounded with that softness and flaccidity of the entire brain which occurs after cachectic diseases, or those attended with great prostration of strength and symptoms of putridity.

Softening of the brain sometimes occurs round a clot of extravasated blood: this may take place consecutive to the extravasation, as the effect of inflammation excited around it; or else the softening may have existed previously, and the extravasation have been occasioned by the ulceration and rupture of blood-vessels in the centre of the broken down brain: we shall consider this more fully hereafter. Softening of the brain is frequently observed round organic tumours, as the result also of secondary inflammation.

With regard to the seats of softening, the surface of the convolutions, the optic thalami, corpora striata, and medullary centres of the hemispheres, are the most ordinary seats of cerebritis. It is less frequently met with in the corpora quadrigemina, crura cerebri, cerebellum, medulla oblongata, and spinal cord; it is in fact most frequent in those parts of the brain which have the largest share of cortical or cineritious substance, because that substance, as observed before, is considerably more vascular than the medullary. The cortical substance of the convolutions is some-

times extensively softened, whilst the white substance beneath remains untouched; this may happen in arachnitis. The white softening of the brain, which is less decidedly inflammatory, is most frequently found in the medullary substance.

Some of the central parts of the brain, such as the corpus callosum, septum lucidum, and fornix, are often affected with softening in hydrocephalus. In one of Dr. Abercrombie's cases there was a ragged irregular opening in the septum lucidum, and the opening was surrounded by a ring of inflammation; the inner surface of the ventricles was in a state of high vascularity; they were distended with colourless fluid, and the substance bounding them was in some places considerably softened. The softening is sometimes confined to the corpus callosum. It is evidently the result of a serous infiltration of the medullary matter, whether the serum be poured out as the consequence of inflammation or the reverse. This form of softening is repeatedly alluded to by Morgagni, and by most authors who have written on hydrocephalus. Dr. Abercrombie divides hydrocephalus into two species; one depending on simple inflammation of the lining membrane of the ventricles; the other attended with inflammatory softening of the corpus callosum, fornix, and septum lucidum, and also of the cerebral substance forming the walls of the ventricles: the latter species he believes much the most frequent, and he is decidedly of opinion that hydrocephalus is an inflammatory affection of the central parts of the brain. He maintains, also, that the effusion, which was hitherto considered as the cause of the disease, is merely one of its terminations, contributing, however, by the increased pressure it occasions, to aggravate the symptoms.

The softening of the central parts of the brain appears to be sometimes connected with diseases of debility, as likewise the serous effusion which accompanies it: this is found to be the case principally in old paralytic people, and in those labouring under dropsy and other lingering diseases. It is ascertained by numerous observations that these central parts of the brain may be affected with softening, even to a considerable extent, without occasioning paralysis in any region of the trunk: these parts seem chiefly intended to connect together the hemispheres, and have very little communication with the medulla oblongata. There are a few cases on record in which this variety of disease has proved fatal without any serous effusion or other morbid alteration, although the actual symptoms of effusion were present. This is, however, of such rare occurrence, that no practical conclusion can reasonably be deduced from it.

General softening of the brain is stated by Andral to be exceedingly rare in adults, but to occur sometimes in new-born infants. In thirty cases of pultaceous softening of the brain, observed by M. Billard, there were ten in which the affection extended also to the whole of the spinal cord; and in each of these ten cases the odour of sulphuretted hydrogen was

\* Abercrombie, Pathological Researches on the Brain.

perceptible. The infants in whom this alteration was observed lived for some days after birth, but their respiration was laborious and imperfect, their limbs were flaccid and motionless, and the pulsations of the heart scarcely perceptible. It appears also, from the labours of M. Billard, that softening of the brain is most frequent in old people, and next to them in adults. It is rather uncommon between the ages of fifteen and twenty, but becomes less so between two and fifteen; it may occur immediately after birth, and is then more considerable and extensive than at any other period of life: it is probable indeed that in some cases it begins even before birth.

Having thus far described the morbid alterations of the brain arising from inflammation, it seems desirable to inquire briefly into the nature of these changes, and into the various opinions entertained respecting them by medical writers.

It is not a little remarkable that the peculiar morbid condition of the brain termed softening, which has, with a few exceptions, been overlooked by pathologists in both ancient and modern times, should not have escaped the attention of the great founder of the medical art. Hippocrates (lib. iii. de morbis, tom. ii. p. 96, edit. of Vander. Linden), gives an exact, although short, description of cerebritis, under the name of œdema of the brain: this wonderfully acute observer seems to have justly appreciated its true character, for he states that this tumefaction of the brain is an inflammatory disease, for which he recommends bloodletting. Morgagni, Bonetus, Lieutaud, Jemima, in their accounts of softening of the brain, describe it as a broken down putrilage—corroded—consumed—and consider it analogous to gangrene in other tissues. Dr. Baillie concurred in this opinion, which has also been adopted by Dr. Abercrombie. The latter considers softening of the brain as the death of the affected portion, and that, like gangrene, it may arise from two opposite causes—from excessive action, which includes the cases with appearances of vascular injection, suppuration, &c. and from deficiency of action, owing to a failure of the circulation, which includes the cases of white softening with disease of the blood-vessels. Among the French writers, M. Recamier considers softening of the brain as a change of structure *sui generis*, distinct from any other, analogous to softening of the spleen, and the primary cause of certain forms of nervous fever. Lallemand conceives it to be always an inflammatory affection, passing through the different stages of tumefaction and suppuration, like phlegmon. Rostan adopts quite an opposite opinion, that it is a real gangrene of the brain, (*gangrena senilis*,) depending on a diseased state of the blood-vessels: this opinion may partly be accounted for by the circumstance of his observations being chiefly collected in the wards of the Salpêtrière, which is an asylum exclusively for old people. Laënnec, who had paid great attention to this subject, was of opinion that softening of the brain was of two kinds—the one inflammatory, in which

pus, either fluid or concrete, was deposited in the cerebral substance, constituting the yellow or reddish softening; the other (the white softening) depending on an infiltration of the cerebral substance with destruction of its cohesion by serous fluid, forming an œdema of the brain. He observed another species of œdema, without destruction of substance, surrounding sometimes inflamed portions of brain, resembling the œdema so common in the neighbourhood of phlegmonous tumours.

If we turn from these opinions to an attentive consideration of what is exhibited by dissection, we shall find that in all the forms of disease which have been described, the substance of the brain is infiltrated either with blood, pus, or serum, or with various combinations of these fluids. The cerebral pulp being provided with only a very small proportion of cellular tissue, and that of extreme delicacy, it is easy to conceive that it should soon become lacerated by the deposit of any considerable quantity of fluid between its fibres and laminae; the pulp is then broken down and mixed up with the interposed fluid. The most rational explanation of cerebral softening would seem therefore to be, to consider it not as a specific disease, but as the result of changes of structure following certain morbid conditions of the brain, nearly similar to those which occur, under similar circumstances, in other organs; and with only such modifications as are satisfactorily accounted for by the natural difference in its texture. In the phlegmonous inflammation of other organs, the parts affected are to a certain extent lacerated, broken down, and destroyed, previous to the formation of an abscess, although this may not take place so rapidly as in the brain, the parts offering a greater degree of resistance.

One of the effects of inflammatory action is ultimately to destroy the cohesion of tissues, although in some of them their firmness may at first, in consequence of the distension of vessels or deposition of concrete lymph, appear increased. Some pathologists having erroneously considered hardness and cohesion as always synonymous, have asserted that it is the property of inflammation to soften hard tissues and harden soft ones. This is a complete fallacy. A portion of inflamed lung in the second stage appears firmer to the touch than healthy lung, and yet by a slight pressure of the fingers its texture immediately breaks down; it is found brittle; the cohesion of its parts is greatly weakened; and it has lost its tenacity. The cohesion of tissues is equally lessened by cachectic diseases and watery effusion. But it may be asked, since the organization of the brain is broken down and destroyed, is not this gangrene? It has just been stated that in the process which leads to the termination of phlegmon in healthy suppuration, the central parts of the tumour are broken down and disorganized; a large cavity is formed with loss of substance; and yet this is not looked upon as gangrene, and differs very widely from the termination of the same tumour in gangrene:

in fact, the term gangrene cannot, strictly speaking, be applied to every case of disorganization and loss of substance. There is in parts affected with gangrene a tendency to rapid decomposition; a putrescence, exhaling a specific fœtor, known by the appellation of gangrenous, which does not belong to suppuration, and has only occasionally been observed in spontaneous softening of the brain. Genuine gangrene of the brain is stated by most medical writers to be a rare termination of inflammation of this organ. Laennec\* says he has very seldom met with it; Bayle gives an account of *one* case of white softening with apoplexy and gangrene; Dr. Abercrombie, in two or three of his cases, speaks of the softened brain mixed with pus having an intolerable fœtor, and these were probably cases of true gangrene. In a case mentioned by Sauré, after acute cerebritis occasioned by a blow on the head, the membranes of the brain were of a livid colour for an extent of several inches, and the brain beneath was very black and gangrenous to the depth of several inches. The most numerous accounts of undoubted gangrene of the brain are those found in surgical works treating of wounds of the head with protrusion of the brain, and also of polypous excrescences of the brain protruding through the skull, and terminating in gangrene: in these cases the cerebral substance has been found of a purple red or blackish grey, considerably softened, and exhaling an ammoniacal fœtid odour.

*Suppuration and abscess.*—The next variety of morbid change in the brain incidental to inflammation, and which generally follows the preceding, is the passage of the inflamed portion of the brain to complete suppuration and abscess. The globules of pus contained in the softened brain gradually unite and form homogeneous purulent collections: these are either recent and undefined, or of long standing and encysted. In the undefined abscess the pus is only circumscribed by the cerebral substance, which is partially softened down, and forms a cavity with irregular walls. The pus is generally mixed with shreds of softened cerebral substance; it varies in colour and fluidity: it is either yellow, greenish, or brown; sometimes, as Laennec states, partially concrete, like coagulable lymph, and floating in a thinner fluid; at others nearly homogeneous. Its smell is usually that of genuine pus, at times, however, emitting a peculiar fœtor.

The formation of a cyst takes place in the brain by nearly the same process as in phlegmon; the ragged sides of the cavity are lined with successive layers of coagulable organised lymph, whose delicate vessels form a union with those of the brain, and become thus connected with its circulation. The first layers are thin and delicate, but others are superadded as in the adventitious membranes of serous tissues, until the walls of the cyst become firm and perfectly organised; the internal surface

is smooth and somewhat analogous to the structure of mucous membranes. Sometimes, however, the sides of the cyst are fibrous, cartilaginous, or incrustated with a calcareous deposit. It would appear from numerous observations that the rudiments of the cyst have been found as early as the end of the first week; it gradually acquires its completion, and is perfectly organised between the third and fourth week. It sometimes continues increasing in thickness for years; and some estimate may be formed of the length of time the abscess has existed, by the number of layers in its cyst. These facts have led to some important practical conclusions in cases of medical jurisprudence. An instance of this kind is related by Lallemand (Lett. IV. p. 87) in which the physicians, consulted by a court of justice, were enabled to decide that the death of a man, which was supposed to have been occasioned by the beating he received from another who was on his trial for the murder, was distinctly to be attributed to chronic inflammation of the brain combined with otitis. Encysted abscesses are sometimes the consequence of acute, and at others of the more slow and insidious forms of cerebritis: the pus, being once circumscribed, is prevented from extending its ravages; and the life of the patient may be prolonged for years, exactly as in the case of an organic tumour. When the cyst finally becomes the cause of death, it is by exciting fresh inflammation in the surrounding cerebral substance; or it may give rise to arachnitis and serous effusions, or to sanguineous apoplexy. The symptoms which attend chronic encysted abscesses sometimes resemble those of organic disease.

Our attention is directed here to a rather interesting question—Do abscesses of the brain ever heal, like those of other parts? There are sometimes found in the brain appearances of large cicatrices: they have in general been attributed to the closing up of cavities which contained apoplectic clots of blood. Lallemand and other writers are of opinion that a similar healing process may take place in encysted abscesses, after the absorption of their pus; and that these are not always to be considered as incurable. This appears by no means improbable, and is rather confirmed by the circumstance of the walls of encysted abscesses being sometimes united by transverse organic bands, which give them a cellular appearance.

Suppuration may take place very rapidly in the brain; Laennec says he has known pus to form in less than twenty-four hours; and Dr. Abercrombie mentions two remarkable cases, in one of which three well-formed encysted abscesses were found in the brain, after an illness of twelve days; and in the other several small undefined abscesses at the end of four days' illness. Cerebral abscess being one of the terminations of inflammation in that organ, is attended with the same symptoms as those belonging to the periods of excitement and softening already described; they vary only according to the

\* The writer of this article has heard Laennec state that he and Bayle had made together five thousand post-mortem examinations.

character, more or less acute or chronic, and the seat of the inflammation. There are a great many interesting cases of abscess recorded in the writings of Lallemand, Abercrombie, Rostan, and of some of the ancients.

There are a few cases on record of extensive suppuration having taken place in the brain without the manifestation of any symptoms indicating such a disease, until immediately before death. Objections have been raised from this occurrence against the value of any rules of diagnosis: it should be observed, however, that such cases are rare, and that some of them are so superficially described, as greatly to invalidate the weight of their evidence. The best authenticated is one by Dr. Broussais, of a man in whose brain an extensive abscess was found in the centre of each hemisphere, and in whom no other symptoms had been observed during life than a peculiar dulness of manner and taciturnity, which terminated in coma after thirty-seven days' illness. A solution might be given of these cases by conceiving a portion of brain to have been for a considerable time in the first stage of low inflammation, which may exist without giving rise to any well-marked symptoms, until, from the sudden influence of some strongly-exciting cause, it is made to pass rapidly into the stage of softening and suppuration. The great rapidity of the formation of pus in the brain has already been alluded to. But after all, why should not latent diseases occur in the brain as well as in other organs?

Abscesses have also been found in the cerebellum, but not so frequently as in other parts of the brain. Abercrombie gives the remarkable case of a young girl in whom the left lobe of the cerebellum was entirely converted into a bag of purulent matter of a greenish colour and intolerable fetor; it was contained in a soft and organised sac. The symptoms were intense headach for several days; a sudden rising of the pulse to 160; dilated pupil and strabismus; great debility and loss of the power of swallowing; she was nearly suffocated each time she attempted to drink. She died of exhaustion on the fifteenth day. Inflammation and softening are not, however, so frequently observed in the cerebellum as in other parts of the brain. The diagnostic symptoms are in general very obscure: the intellectual faculties are generally less affected than when the disease is situated in the cerebrum.

*Ulceration.*—This state of the brain has been described by several writers, although it is uncommon. It has been found on the surface of the convolutions, on the optic thalami, and the corpora striata. The ulcers present an irregular surface, covered partially with either a bloody or albuminous exudation, and having jagged edges. In some cases it is hard and dry; in others there are fistulous communications between the ulcer and deep-seated collections of pus; and in others the ulcer forms the bed of a coagulum of blood: the ulcers vary in depth and dimensions. Some writers consider these ulcerations as affecting

more particularly the arachnoid and pia mater, and not belonging to the cerebral substance. This may be true in some cases, but not in all. Morgagni speaks, in one of his cases, of an erosion of the corpus striatum, and in another of an ulcerous cavity at the base of the left ventricle. Two cases of the same nature are recorded by Scontetten.

There are also ulcerations occasioned by the penetration of foreign bodies, of which many cases are given by Morgagni and other surgical writers, but these are foreign to our present purpose.

*Induration.*—This is mentioned by Abercrombie, Andral, Bouillaud, Lallemand, and others, as an occasional termination of cerebritis. The induration may be general or partial, and of different degrees of density from that of wax to that of fibro-cartilage.

General induration has been observed in persons affected with ataxic fever, and in some who have died in a state of general convulsion from the poisonous effects of lead: it is not uncommon also in lunatics. The brain contains little or no blood, is of a bright whiteness, and the medullary substance more condensed than the grey: the exact nature of this form of induration is yet but imperfectly known.

Partial induration is of more frequent occurrence. The simple chronic inflammation may, in some instances, terminate in induration of the portion of the brain affected. The fluids contained in the vessels, or exuded between the fibres and laminae, whether blood, lymph, or pus, become concrete, and continue so for a longer or shorter time. The part, when cut into, is as firm as flesh or kidney; either of a bright or dark red, or yellow; or else a slow process is carried on which leads to a conversion of the diseased portion into a species of fibro-cartilage. The induration may, after lasting a considerable time, pass into suppuration. It either effects a considerable portion of the brain in depth, or extends superficially over the surface; or there are several small circumscribed indurated spots.

A curious case is related by Baader of a man aged 40, who became suddenly epileptic, with fixed local pain on the left side of the head, and such exquisite sensibility of the surface of the left hand and arm, that the slightest breath of cold air upon them brought on convulsions. He died rather suddenly after an illness of five years. There was a superficial induration of the brain corresponding to the seat of the pain, and under the indurated part there was an abscess of the size of an egg.

*Organic diseases.*—It is the opinion of several writers, among whom is Dr. Abercrombie, that the state of simple induration of the brain just described, may be considered as the origin or first stage of the organic tumours sometimes found in the brain; that these tumours are the result of chronic inflammation; and that the various forms of scrofula, carcinoma, melanosis, fibro-cartilage, or hydatids, which they assume, depend on peculiarities of constitution or other accidental circumstances with which we are unacquainted.

Dr. Abercrombie mentions that in some cases the portion of indurated brain has been found surrounded by a cyst, so as to form a complete tumour. He thinks it probable that this is only a part of the cerebral substance in a state of low scrofulous inflammation; that in its early stage it is a disease which may be cured; and that the formation around it of a cyst by the deposition of coagulable lymph, or its termination by an induration of the part, are the points in its progress which give it the character of organic or hopeless disease. Accordingly, this might be considered as the intermediate step between chronic inflammation and the development of organic disease. This is an ingenious view of the subject; but it does not rest upon sufficient evidence to be received yet as an established truth: the whole question involving the origin and nature of organic tumours, and also of tubercles, is one of considerable interest and importance, and respecting which there exists much diversity of opinion.

The principal organic diseases are, bony tumours of the internal surface of the cranium; thickening or excrescences of the dura mater; a variety of tumours in the brain, some consisting chiefly of a whitish mass, having the properties of albumen; others more organised, reddish, and resembling the substance of the kidney; others carcinomatous, fatty, or tubercular: the latter are by far the most frequent, particularly in children. Ossification and long spiculae in the dura mater, falx, or tentorium, and serous cysts and hydatids are also sometimes found. There are others of more rare occurrence, such as stony and bloody tumours, fungus hæmatodes, melanosis, fungous excrescences of the brain or of its membranes, protruding sometimes through the cranium. There are several instances of a clot of blood becoming organised and forming a tumour. It is next to impossible to distinguish these organic diseases from each other during life. When there is any well-marked specific diathesis, such as the scrofulous or the cancerous, some plausible conjecture may perhaps be formed respecting their nature. In a few of the recorded cases of cancer in the brain, there were severe lancinating pains through the head; but this is not a point of much consequence, as they are hopeless diseases.

The existence of organic disease in the brain is manifested by various lesions of the intelligence, voluntary motion, and sensation: the effects either of pressure on the brain or of inflammation. These diseases bear, therefore, a strong resemblance in their symptoms to some of the forms of cerebritis. Acute cerebritis is not very likely to be mistaken for organic disease, as the symptoms of the former run their course with a degree of rapidity and violence which never belong to the latter. The diagnosis, however, between the more chronic forms of cerebritis and organic disease may sometimes be attended with greater difficulty; and it is necessary to pay great attention to the mode of invasion, progress, and duration of the symptoms in each class of diseases, in order to distinguish them from each other. The

progress of the symptoms in organic diseases is very slow, irregular, and intermittent; very trivial circumstances are sometimes sufficient to bring on attacks of cephalalgia, vertigo, temporary apoplexy, or convulsion; such as quick exercise, hot rooms, sudden emotions, prolonged attention in reading or writing, a low position of the head; in fact, every thing calculated to disturb and hurry the circulation in the brain. When this organ is already suffering from pressure, a very slight change in its circulation may suffice to give rise to the most alarming symptoms; but these subside as soon as the momentary congestion is removed, and the patient then recovers every appearance of his usual health. In some cases the symptoms entirely disappear for a considerable time, and then return with increased violence. The disease does not in general assume a decidedly active and regular character until the surrounding brain becomes inflamed; and the two forms of disease being then combined, the ordinary symptoms of cerebritis make their appearance.\* In chronic cerebritis, although in some instances the symptoms may be slow and irregular, they do not in general exhibit such sudden exacerbations or complete and protracted intermissions, nor are they aggravated by the same trivial causes. Cases, however, attended with much doubt and difficulty, may sometimes present themselves, especially when chronic cerebritis terminates in induration; but it may be laid down as a general rule, which will materially assist in forming the diagnosis, that the very large majority of cases of primary cerebritis run their course in less than six months from the time of the full development of the disease; whilst the great majority of organic diseases last beyond that time, and some even as long as several years. The tubercular diseases are those the course of which is most rapid, particularly when there is active tubercular inflammation in other parts of the body.

*Hypertrophy.*—Several pathologists, and amongst others Laennec and Jadelot, have described an alteration of the brain connected with its acute diseases, which they term *hypertrophy*: this alteration appears to have been known also to Morgagni. Laennec observed it in persons who had previously been supposed to be affected with hydrocephalus in-

\* The late Dr. Wollaston died of an organic disease of the brain, which there is good reason to suppose originated in slow chronic inflammation: we find it stated, in the post-mortem examination, that the optic thalamus of the right side was found converted into a tumour as large as a middle-sized hen's egg; towards the circumference, it was of a greyish colour, harder than the brain, and somewhat of a caseous consistence, but in the centre, of a brown colour, soft, and in a half-dissolved state. We learn from Dr. James Somerville, who attended him, that he had suffered more or less for several years from a train of symptoms corresponding to those above described, and that he ultimately died paralytic. Four years previous to his death (in 1828) he read before the Royal Society an ingenious paper on a peculiar defect of vision to which he was subject, and which, it is highly probable, was a symptom of the incipient disease of the brain.

ternus; also in epileptic children, and in others who had died of convulsions. The following are its distinctive characters:—the convolutions of the brain are crowded together and flattened; the intervals between them disappear; and it seems as if the membranes of the brain were too tight for it. After the upper part of the cranium has been removed, it is found difficult to make it fit on again, the brain appearing too large for the cavity of the skull; the substance of the organ is firm, contains but little blood, and appears remarkably dry when cut into; the ventricles are, as it were, effaced, and the various surfaces of the brain deprived of their ordinary moisture: in other respects the texture remains unaltered. The affection is most frequently general. Andral has however seen a case, in which the left thalamus was one-fourth larger than the right, which was of the natural size; there had not been any particular symptom observed during life, that could lead to a suspicion of such a state of the parts. No instance of hypertrophy of the cerebellum has hitherto been published. In a few rare cases the enlargement of the brain has been carried to such an extent as to occasion an enlargement of the skull. A remarkable case is recorded in the *Archives de Médecine*, 7th volume, of a child of five years of age, who had a head as large as that of a stout man; the parietes of the cranium varied from a line and a half to two lines in thickness; it was chiefly the hemispheres that were enlarged; there had not been any peculiarity in the intellectual faculties;—the death was owing to another accidental cause. The brain appears sometimes as if generally enlarged, when its vessels are over-distended with blood, in inflammatory fever, &c. This state must not be mistaken for the hypertrophy just described.

We shall briefly notice another class of morbid alterations of the brain, as being connected with its acute affections; we mean those observed in lunatics. After acute mania, the cortical substance on the whole surface of both hemispheres has been found deeply injected, and of an intense red, similar to that of erysipelas. In other cases of longer standing the membranes had contracted close adhesions to the brain; the cortical substance was red and so much softened, that the membranes could not be removed without tearing it away with them; it had also a granulated appearance. In very old cases the convolutions have been found remarkably diminished in size; and this has seemed to arise from the atrophy of the cortical substance, which was reduced to a very thin layer, and of a pale dirty colour; there has been generally in such cases a serous effusion, as if to fill up the vacuum. The medullary substance has also been found to have undergone remarkable changes: it was in some cases highly injected, and of a marbled red colour; in others it had experienced a surprising increase of density, being as tough and difficult to cut through as caoutchouc, and of a smooth shining white colour; and, lastly, it has been found softer than in health, and flaccid. A great quantity of serous fluid is some-

times found in the brain of old lunatics. We only notice these morbid appearances very briefly, in order to give a general view of every variety of change of structure produced in the brain by inflammation: they will be described more in detail in the article LUNACY.

The different morbid appearances of which a description has been given may be summed up as follows:—

1. Increased vascularity; redness either dotted or uniform, no change of consistence or structure, no exudation of fluid or rupture of vessels.—*Congestion.*

2. Great increase of vascularity, intense dotted redness, spots of ecchymosis, with a striated appearance and effusion of drops of blood, increased firmness.—*First stage of inflammation.*

3. Infiltration of blood, and softening of the cerebral pulp towards the centre of the inflamed portion.—*Red softening.* Infiltration of pus mixed up with the disorganized pulp.—*Yellow softening.* The red and yellow softening combined.

4. Serous infiltration of the cerebral pulp; softening of a milk white colour, without vascularity.—*White softening.*

5. Increased formation of pus of various colours, the walls of the cavity lined with a membrane.—*Undefined abscess; encysted ditto.*

6. Loss of substance on the surface of the brain or that of the ventricles.—*Ulceration.*

7. Infiltration of the pulp or its vessels with permanently concrete fluids; conversion into a more or less dense mass.—*Induration.*

*Diagnosis.*—The diagnosis between arachnitis, apoplexy, and cerebritis, having been already fully considered in the general history of the disease, a brief recapitulation is all that will now be required. We have seen that the leading features of arachnitis were the absence of premonitory symptoms; spasmodic and convulsive symptoms on both sides of the body; febrile excitement, without decided paralysis, followed by collapse.

Those of apoplexy, sudden and complete paralysis, without spasmodic symptoms at the beginning; sudden invasion and rapid progress.

Those of cerebritis, symptoms of irritation, followed by spasmodic paralysis, only partial at first; the paralysis becoming complete as the disease advances; irregular exacerbations and remissions; well marked premonitory symptoms.

In laying down these general rules, it is fully admitted that, in the present state of our knowledge, cases may occur, in which the diagnosis will be involved in doubt and obscurity.

The distinction between cerebritis and acute hydrocephalus may sometimes be obscure, especially in adults. We have seen that hydrocephalus is often attended with inflammation and softening of the central parts of the brain. It may, however, be stated, in general, that in acute hydrocephalus there is seldom slow, partial, spasmodic paralysis of the extremities; the sight and the speech are much more frequently affected. It is also characterized by high fever, general convulsions,

irritability of stomach, ending in a state of collapse and coma; symptoms much more resembling those of arachnitis than of partial cerebritis. When hemiplegia or other forms of paralysis have occurred during its progress, inflammation and softening of the brain have generally been found, in addition to the ordinary morbid appearances of hydrocephalus.

It is of importance to attend to the circumstance that, in children, diseases of the brain often come on very insidiously, and may have existed for some time previous to the appearance of any very decided symptom. The case of a child affected with fever, restlessness, headach, slight convulsions, irritability of stomach and vomiting, a foul tongue and disordered bowels, is looked upon as one of gastric remittent fever, or as the effect of dentition, whilst there is inflammation going on in the brain or in its membranes, which, however, is not suspected until delirium, strabismus, or convulsions, point out an advanced stage of cerebral disease. The condition of the brain, in the febrile and inflammatory affections of children, should always therefore be attentively watched.

Some of the premonitory symptoms of cerebritis, such as pains in a limb, numbness, weakness, or stiffness, have been mistaken for rheumatism, and treated by local applications, while these symptoms were produced by disease of the brain. The absence of all local swelling, redness, or tenderness on pressure, will assist in sufficiently distinguishing the muscular pains in cerebritis. In the same manner vertigo, cephalalgia, irritability of temper, disturbed sleep, loss of appetite, and impaired digestion, indicating the approach of cerebritis, have sometimes been treated as nervous or bilious headach, connected with dyspepsia; and the true character of the complaint has been overlooked, until the brain has sustained some material injury. The importance of diligently watching all those premonitory symptoms which indicate a threatened attack of cerebral disease, cannot be too strongly enforced.

Epilepsy, chorea, nervous and hysterical convulsions, and several other nervous affections, bear some resemblance in many of their symptoms to those of cerebritis. We must refer, however, to the history of these diseases, for a more particular account of their diagnosis. We shall only observe in general, that the greatest attention is often required to discriminate cephalalgia, vertigo, confusion of sight, and other symptoms of affection of the brain, connected with vascular excitement, from purely nervous irritation. It must be remembered, in forming our diagnosis, that both causes sometimes react on each other.

The absence of all tendency to permanent paralytic affections in the purely nervous cases, will be a good general rule of distinction. Much useful information is moreover to be obtained by attending carefully to the predominant character of the temperament, and of the prevailing diathesis, whether sanguineous or nervous. The great irregularity and mutability of purely nervous symptoms form

a striking contrast with the comparatively uniform and durable nature of those which originate in disorder of the vascular system. We must not, however, be led to imagine that pallid, thin, and apparently nervous people, are exempt from inflammatory affections of the brain, or that others of a full habit and florid complexion are not subject to purely neuralgic complaints.

There are some conditions of the system in which a distinction between the genuine and spurious symptoms of inflammation and compression of the brain, is of great importance. A patient in a state of exhaustion after long illness, intense pain, copious bleeding, and other evacuations, is suddenly seized with violent headach, restlessness, hurried pulse, convulsions, coma, and apparently all the symptoms of acute cerebral inflammation. This is a common affection in children, and has often been mistaken for acute hydrocephalus. In other cases, after great anxiety and depression of spirits, a person is affected with delirium, incoherence, maniacal excitement, a hurried manner, great volubility, and hallucinations; the pulse is hurried, rising suddenly to perhaps 160: these symptoms pass rapidly into fatal collapse and coma. No morbid alteration is found in the brain in these cases, except, perhaps, slight vascular injection. This affection has been mistaken for arachnitis, mania, hysteria, and its true nature overlooked, until the patient has rapidly sunk. The use of evacuations in such cases is sure to hasten death; whilst under the timely administration of cordials, stimulants, and opiates, the symptoms are often speedily relieved. Towards the close of low fevers, when a decided amendment has taken place, a series of symptoms sometimes occur, simulating a dangerous affection of the brain. The patient becomes restless, complains of headach, and does not sleep, and at length lapses into muttering delirium. These symptoms are, however, purely nervous, and relieved by mild opiates and a moderate allowance of wine.

Cerebritis may exist in combination with a variety of other diseases, such as hypertrophy of the heart, chronic inflammation of the lungs, the liver, stomach, and bowels; with continued fever, measles, scarlatina, erysipelas, mania, &c. The diagnosis in such cases is not in general attended with much difficulty, although one disease sometimes lessens the violence of the other. We have already directed attention to the important fact of severe cerebral inflammation completely concealing for a time the existence of other diseases with which it may be combined.

There are partial paralytic affections of the face, neck, and extremities, depending on inflammation and compression in the course of the nerves, or on diseases of the vessels, which may be referred by mistake to disease of the brain. We are indebted to Sir Charles Bell for a most interesting and satisfactory description of some of these affections. The absence of any cerebral symptoms capable of accounting for the paralysis, will direct the attention of the

practitioner to its real causes. The same may be said of the diagnosis between cerebritis and paraplegia arising from spinal disease, and the paralysis also occasioned by mineral or other poisons.

Before concluding the subject of diagnosis, we shall briefly allude to the interesting inquiries of some French pathologists, who have endeavoured to point out the parts of the brain affected in cerebritis, by the various modifications of the paralytic symptoms. We have seen that paralysis may affect one extremity, or both; one entire side of the body, or the eyes, face, and tongue, either singly, or in a variety of combinations; that there are the same diversities in the state of the sensibility and intellectual faculties. How are these modifications to be accounted for? Several of the older writers had conjectured that, if the nervous filaments could be traced up to their remote origin in the brain, it would be found that each part of the body receives regularly its nerves from a determined part of the brain, so that any lesion of that part must necessarily affect the functions of the organ to which it sends nerves. The following are the results of numerous pathological observations made on this subject, by MM. Foville, Serres, Pinel Grandchamp, and Bouillaud. They are, of course, to be received with a good deal of reserve; but we still think them deserving of notice, if it were only to direct others in the path of inquiry.

1. The paralysis of the organs of speech depends on diseases of one or both anterior lobes of the brain. There are seventeen cases reported in the works of Lallemand, Rostan, and Bouillaud, with paralysis of the tongue, in which the anterior lobes of the brain were found affected with various degrees of inflammation and softening; on the other hand an examination of about fifty cases, in the same authors, without loss of speech or paralysis of the tongue, does not afford a single instance of inflammation or softening in the anterior lobes. It should be noted that there may be loss of speech without paralysis of the tongue, from mere loss of memory; and M. Bouillaud's observations lead him to think that the anterior lobes of the brain preside over the memory of words, as well as over the organs of speech. The above statement, if the facts on which it is founded can be relied on, is certainly very remarkable, and deserving of further investigation.

We remember an interesting case under the care of Dr. Cuming, of Armagh, in which there was disease in the anterior part of the brain from a blow received on the forehead just above the nose: it was found necessary to remove a portion of bone with the trephine; and after a variety of remarkable and untoward symptoms, the gentleman perfectly recovered: one of the prominent symptoms was a loss of the memory of language.

2. The paralysis of the inferior extremities depends on disease of the middle lobes of the brain, and of the corpora striata. This con-

clusion is not supported by the same number of facts as the former.

3. The paralysis of the upper extremities depends on disease of the posterior lobes of the brain, and of the optic thalami. This is likewise stated as yet resting only on a small number of facts. The paralysis of one arm only has been observed in a good many cases, in connection with inflammation at the junction of the posterior and middle lobes. When several parts are paralysed at the same time, the morbid alterations of the brain are supposed to be more extensive, or seated near the medulla oblongata. Paralysis of the arm and leg on the same side, or hemiplegia, is supposed to follow the combined affection of the corpus striatum and thalamus, or else disease of the crus cerebri, from which these two bodies derive their origin.

The last speculation on this subject which we shall refer to, is one relating to the respective uses of the cortical and medullary substances of the brain. We have seen that the cortical substance has been found, in a great many lunatics, highly injected, and often inflamed, whilst the medullary substance remained healthy. M. Foville and Pinel Grandchamp have conjectured from this and some other circumstances, that the cortical substance was the seat of intelligence, whilst the medullary was intended to preside over motion. The principal other grounds of this hypothesis are, the apparent decrease of the cortical substance, which has been found reduced to a very thin layer, in cases of imbecility; the small size of the convolutions and small quantity of cortical substance observed in the brains of idiots, compared with those of intelligent beings.

In the article *Encéphale*, of the volume of the *Dictionnaire de Médecine et de Chirurgie Pratique*, just published, M. Foville, whose recent discoveries on some points of the minute anatomy of the brain have deservedly attracted much attention, enters at considerable length into the examination of the preceding considerations. He has adduced a number of striking facts and arguments in their support, and lays down the following general propositions.

1. The joint lesion of the corpus striatum and thalamus of one side, gives rise to the same paralytic symptoms as the lesion of the whole fibrous substance of the corresponding hemisphere, of which they are in some manner the centres or nuclei.

2. The lesion of the crus cerebri is followed by the same paralytic symptoms as that of the corpus striatum and thalamus, which are themselves in a great measure formed by the expansion of the fibres of the crus.

3. A lesion of the medulla oblongata produces all the symptoms which arise from the joint affection of the crura cerebri and cerebelli; and if we ascend still higher in the brain, from that also of the corpora striata, thalami, and hemispheres.

4. If we direct our attention to the portion of the nervous system below this great centre of the nervous action of the brain, we shall find the cerebral influence continue unimpaired in all

parts superior to any lesion of the spinal marrow, whilst it is completely intercepted in parts inferior to that lesion.

*Prognosis.*—Cerebritis is a disease always attended with considerable danger. When once fully developed, it had hitherto been generally considered as incurable; but since we have been enabled, by a better knowledge of its true nature, to apply with promptitude more appropriate remedies, the treatment is often successful, even under the most unpromising circumstances. The extremely delicate structure, however, of the brain, its situation in a bony unyielding case, without room for expansion, or any opening for the exit of effused fluids, and the great importance of the integrity of its functions to the preservation of life, are circumstances which must always connect a considerable degree of danger with its inflammatory affections.

It may be said in general that so long as the inflammation is only in the first stage, and the texture of the brain not broken down by the infiltration of blood, pus, or serum, resolution is still possible. The following circumstances may lead us to hope for this favourable termination: the paralysis being only partial; the muscles firm, not flaccid, and retaining some degree of motion; the sensibility being little impaired; after an attack of coma, a gradual return to consciousness, without affection of the intellect; sound sleep; the tongue cleaning, and motion progressively returning in the paralysed parts. It must not be forgotten, however, that there are frequently exacerbations and remissions in the symptoms; intervals of apparent recovery and a great tendency to relapse. It has been already stated that a delusive amendment often attends the passage of the inflammation from the first stage into that of softening or suppuration. Such an amendment, therefore, at a late period is more to be suspected than in an earlier stage of the disease. The continuance of headach, uneasy sleep, shiverings, and languor are unfavourable symptoms, whatever may have been the amelioration in other respects. Headach and delirium are less unfavourable than stupor and coma. When profound coma is succeeded by headach and delirium, this is rather a favourable occurrence, as it indicates a return of the previously paralysed action of the brain; when, on the contrary, they are followed by coma, it is a bad omen. The danger is of course in proportion to the extent of the paralysis, and greater in complete hemiplegia, than when the paralysis is confined to one limb. When the paralysis extends to the side of the body which was at first free, the danger is imminent, since both hemispheres are then affected; and when both sides are simultaneously paralysed, a speedily fatal termination may be predicted. Embarrassed breathing is always a bad symptom.

When the inflammation has reached the second stage, and the diseased portion of brain has become softened and infiltrated with pus, the danger is great and the recovery very doubtful. Paralysis of the bladder and retention of urine are generally fatal symptoms.

The chronic form of cerebritis, accompanied by very slow and creeping palsy, is always an unpromising disease. The circumstance of the symptoms at first being slight, and confined to an apparently trifling numbness or weakness in a few muscles, must not throw the practitioner off his guard. This form of disease is almost always attended with a considerable degree of failure of the powers of the constitution; and sooner or later, in the majority of cases, comes to an unfavourable termination. The more acute cases afford a better prospect of recovery, there being sufficient strength to admit of the use of active remedies.

The coma and paralysis following a sudden attack of sanguineous apoplexy are attended with less danger than the coma and complete paralysis of the latter stage of cerebritis; for there are numerous instances of the resorption of a clot of blood, whilst those of the resorption of pus and healing of an abscess are extremely rare. The inflammation of the brain consecutive to sanguineous apoplexy is always dangerous, and greatly lessens the chances of recovery. Cerebritis following concussion is generally severe, and attended with greater danger than that consequent upon an injury of the head with opening in the skull.

The duration of cerebritis varies according to its form. Acute cerebritis generally runs a rapid course; it may prove fatal the first, second, or third day, and seldom lasts more than from ten to twelve days. Chronic cerebritis is very variable in its duration, being often attended with intermissions and relapses; the disease may thus be prolonged for several months, and some cases have been described as lasting even several years; but it is more than probable that when symptoms resembling those of cerebritis continue beyond five or six months, they do not arise from genuine cerebral inflammation, but are to be attributed either to an organic tumour, or to some neuralgic affection simulating chronic cerebritis. In a collection of thirty-four cases, nine died in the course of the first week, six in the second, six in the third, two in the fourth, and eight in the course of from two to six months.

With respect to age, it appears that old age and childhood are the two periods of life the most exposed to cerebral inflammation. The examination of a large number of cases shews that more than two-thirds were persons above forty-five, and a majority of these between fifty-five and seventy. It is a disease, however, which may affect all ages. The frequency of falls and blows on the head in children, the irritation of dentition, the pressure of the head during parturition, predispose them to cerebritis, although there is perhaps a greater tendency at that period of life to membranous inflammation. Traces of cerebritis have been found in still-born children. Men are more subject to cerebritis than women, in the proportion of about two-thirds, owing probably to their being more exposed to the influence of exciting causes. The disease, also, is more

common in hot than cold climates, and in summer than winter.

*Causes.*—The causes are predisposing and exciting. The only difference, however, between these often consists in their degree of activity; since a predisposing cause may become exciting if its activity be sufficiently increased. Every circumstance capable of causing congestion, or of disturbing the balance between the arterial and venous circulation in the brain, becomes a predisposing cause. These circumstances are a plethoric habit, particularly in individuals who have short necks and are subject to habitual constipation, the diathesis justly termed apoplectic. Persons, however, of a thin habit and slender make, with long neck and pallid countenance, and especially if such individuals are intelligent, are also under certain circumstances predisposed to cerebral affections, particularly when labouring under disease of the heart. An hereditary tendency to fulness in the head and diseases of the brain may be reckoned among the predisposing causes. Hypertrophy of the heart, particularly of the left ventricle, is a very common predisposing and sometimes exciting cause. The celebrated Malpighi died of an inflammatory affection of the brain, attributed to hypertrophy of the heart, from which he had long suffered. Disease of the heart acts either by impeding the regular return of the blood from the head, or causing the blood to be propelled with excessive impetus towards the brain; the latter takes place more particularly when the hypertrophy is produced by obstruction in the aorta beyond the origin of the carotid arteries. Inflammation of the lungs, phthisis, and asthma act in the same manner in producing cerebritis, though these diseases are less powerful exciting causes than those of the heart. There is a great predisposition in phthisis to sudden attacks of inflammation of the brain or its membranes; the patient is all at once seized with intense headach and violent delirium, ending sometimes in confirmed mania, and it is very remarkable that the pulmonic symptoms, howsoever severe, have often in such cases suddenly disappeared, and have not returned until the attack in the head had subsided, the two affections thus alternating the one with the other. It cannot be said in every case that the cough and other pectoral symptoms are merely obscured, for we have seen cases of perfect recovery from an advanced stage of phthisis, by the supervention of an attack of mania. These are striking examples of the actual translation of disease. Dr. Abercrombie very justly observes that there may be in serofulous constitutions a tendency to serofulous inflammation of the brain, and that the disease of the lungs is not properly to be always considered as the cause of the head affection; that in the same manner disease in the brain may appear in connection with the disease of any other organ, and that diseased liver has often been thus improperly stated to be the cause of hydrocephalus.

The mutual influence of the functions of the brain and digestive organs on each other

is so obvious as not to require any explanation; and thus the headach, drowsiness, and other signs of cerebral congestion, which follow overdistension of the stomach, or the abuse of spirituous liquors, are easily accounted for. Habitual drunkenness is perhaps one of the most powerful causes of cerebritis or arachnitis. The striking similarity between the symptoms of the last stage of intoxication and those of apoplectic coma has been frequently noticed. The sub-acute inflammation of the mucous membrane of the stomach and bowels, the gastro-enterite of Broussais, is often accompanied by great cerebral irritation. This complaint, in young children from two to four years old, frequently terminates in coma. A vitiated state of the secretions of the alimentary canal is a very active and frequent cause of cerebral irritation; it accompanies that fretfulness and irritability of temper which so commonly precedes attacks of inflammation in the brain: the convulsions produced by intestinal worms are also the effect of sympathetic irritation.

There is a disease of the urinary organs, known as ischuria renalis, of rather uncommon occurrence, which predisposes sometimes to dangerous affections of the brain. Sir Henry Hallford has published an interesting paper on this subject.\* In many of the cases, after the patient has suffered for two or three days from dull pain and sense of weight in the iliac regions, these symptoms are succeeded by great anxiety, nausea, vomiting, hiccup, cramps, slow pulse, delirium; and he gradually falls into a state of lethargy and coma. The ventricles of the brain are found on dissection distended with serum.

The suppression of urine is sometimes not complete; if there be perspiration, it may have a urinous smell. Suppression of urine is sometimes not attended with any marked inconvenience. Dr. Parr, in his dictionary, mentions the case of a person who had suppression of urine for six weeks and yet recovered. Dr. Abercrombie gives a case in which the suppression was occasioned by obstruction of both ureters; the patient died on the thirteenth day, of a cerebral affection.

Ischuria renalis has in some instances been supposed to originate in a disease of the brain, causing paralysis of the kidneys. The persons most subject to this affection are fat corpulent men, between fifty and sixty years of age, of a gouty habit, and naturally predisposed to cerebral congestion, though it is sometimes also met with in children.

We have already said that inflammation of the brain may occur in the course of a variety of febrile diseases, such as continued fever, scarlatina, measles, &c. It has often been observed as one of the sequelæ of scarlatina; and when accompanied with anasarca, its inflammatory character has been entirely overlooked, and attributed to mere serous effusion in the brain. There is a great tendency to cerebral congestion in the continued fevers of

\* Transactions of the College of Physicians, vol. vi. p. 398.

this country; thus of eight hundred and sixty-four cases treated in a large fever hospital, six hundred and two presented head symptoms. Suppuration of the brain may sometimes occur in the course of fever, but is not very common; of fifty cases of fever with well marked cerebral symptoms, pus and blood occurred in only three. Sub-acute inflammation of the membranes is of much more frequent occurrence. The injury, however, sustained by this organ during an attack of fever with violent head symptoms, often gives a predisposition to future cerebral inflammation.

Among the predisposing causes are to be ranged suppressed evacuations. That of the catamenia, especially in young women, is often followed by dangerous affections of the brain. A similar result may attend the suppression of artificial discharges and of cutaneous eruptions, the healing of chronic ulcers, erysipelas, gouty or rheumatic affections of the joints, &c. Over-exertion of mind, depressing passions, such as grief, fear, &c. great bodily fatigue, long continued nervous headaches, and all neuralgic affections of the brain, epilepsy, and mania, operate as predisposing and sometimes exciting causes. The brain cannot long suffer from nervous irritation without a reaction taking place in its vascular system.

External injuries are among the most direct exciting causes; and this is much more frequently the case than is imagined, particularly in children. A considerable interval, sometimes two or three weeks, may intervene between the injury and the appearance of alarming symptoms; and a very trifling fall or blow, which is often the cause of serious disease, may have been altogether overlooked or forgotten.

Exposure to the intense heat of the sun is a powerful exciting cause. It may bring on either arachnitis, cerebritis, apoplexy, or mania. The same results may follow a sudden transition from heat to cold. Long exposure to intense cold acts also in a remarkable manner on the brain, bringing on inflammation, and sometimes the most violent maniacal delirium: there were many remarkable examples of this during Napoleon's campaign in Russia.

Inflammation and suppuration of the internal ear has a great tendency to extend to the brain, and it is in this manner it often proves fatal. Tedious and painful dentition is a great source of cerebral irritation; intense and long-continued pain from any cause often brings on delirium and coma. The ligature of large branches of nerves in the neighbourhood of the head has had this effect; of which the following case, related by Lallemand, is a remarkable instance. The subclavian artery was tied above the clavicle for an aneurism in the axilla on the *right* side; several branches of the brachial plexus, supplied by the third cervical, were included in the ligature; intense pain was immediately felt in the neck; this went on increasing notwithstanding the most active treatment; coma, convulsions, and a strong retraction of the head appeared the seventh day; the patient died on the eighth. The posterior portion of the *left* hemisphere of the brain presented a large

undefined abscess, containing softened diffuent brain, and in the centre greenish pus; the sides of the abscess were deeply injected; the arachnoid was healthy. Such a case is interesting both to the pathologist and physiologist.

The internal use of certain narcotic and irritating poisons may become a cause of cerebral inflammation. This is the special property of *nux vomica*; and we have seen its unguarded administration in hemiplegia bring on a fresh attack of inflammation of the brain. The inhalation of putrid effluvia and contagious miasmata, particularly in very hot climates, and when the system is in a state of depression, has been quickly followed by cerebral inflammation. We had experience of this ourselves some years ago, while attending a fever hospital. After inhaling a horrid fœtor which emanated from a patient in an advanced stage of typhus gravior, we were instantly seized with sickness and headach, as if struck by a blow, and, in less than forty-eight hours after, a dangerous attack of typhus fever supervened, attended by strong cerebral symptoms. The action of these numerous causes is very variable; sometimes sudden and rapid, at others slow and imperceptible.

*Treatment.*—The inflammatory nature of the more acute forms of cerebritis and arachnitis is so obvious, that their treatment has always been conducted on correct principles. Until very lately, however, the inflammatory character of partial and chronic cerebritis was either entirely overlooked, or so imperfectly understood, that though active treatment was sometimes adopted at the beginning of the disease, it was soon laid aside, and remedies of an opposite description substituted. These affections were in fact generally set down as nervous; mistaken for rheumatism, neuralgia, nervous dyspepsia, and debility, or nervous palsy, and treated by tonics, electricity, and stimulants; the fatal termination of the disease being thus accelerated.

Cerebritis and arachnitis are so formidable, that their prevention is of no less, if not of greater importance, than their treatment. It is extremely important to have recourse to active measures on the very first appearance of any of the premonitory symptoms, however trifling: as we may thus succeed in effectually removing that state of congestion and irritation of the brain, which is the precursor of inflammation. The means of accomplishing this are, the careful and timely removal of all the exciting causes; of every source of irritation, both bodily and mental; regulation of the diet; avoiding all excesses; relaxation from study, change of air, general and local bloodletting, counter-irritation, with occasional purgatives. Great vigilance is particularly required in the cerebral affections of infants and children, who frequently suffer without complaining. A predisposition to affection of the brain may often be suspected by some slight cast or rolling of the eyes; by dilatation of the pupils; or occasional startings, and attacks of spasmodic croupy breathing during sleep: there may be every other appearance of perfect health

with these symptoms, which are often only evanescent; but they will not escape the attention of the experienced observer, and will be sufficient to put him on his guard.

When it is necessary to relieve the brain from habitual congestion by occasional topical bleeding, the method of taking blood from parts as remote from the disease as possible, seems to us preferable to that of abstracting blood from the head itself. When the vessels of a part are partially emptied of their blood, if they have been much weakened by long continued over-distension or previous disease, so as to have lost their elasticity, there will be an immediate flow of fresh blood to the part; this will take place on mere hydrostatic principles. We have thus seen in an eye long exposed to injection and low inflammation, the redness and suffusion much greater the day after an application of leeches than it was before; and we have likewise known headach considerably increased in plethoric and bloated people, after leeches had been applied to the temples. On the other hand, no fact is better established than that the loss of an exceedingly small quantity of blood from certain parts of the body, is sufficient to relieve distressing symptoms of congestion and oppression in others most remote from them; as for instance, a very slight discharge of blood (one or two ounces) from the hemorrhoidal veins being sufficient instantly to remove vertigo, flushing, headach, or oppressed breathing: the same is the case in a still more striking manner with the catamenia, although some account must be taken of the influence of uterine irritation over the system. We prefer, therefore, in cases of habitual congestion in the brain, taking blood occasionally from the feet or legs, by opening a vein, or applying leeches and letting them bleed in a foot-bath; or the application of leeches to the anus, whenever practicable. We have found this the surest method of affording permanent relief; and by repeating it at certain intervals, the tendency to cerebral congestion may be completely overcome. We have pursued this plan in lunatics with the very best results. It was a practice of the ancients, which has, in our opinion, been too much laid aside. When, however, there is active inflammation in a part, as it is most material to unload the vessels freely and quickly, the blood had better, in such a case, be drawn from the immediate neighbourhood of the organ affected.

The insertion of an issue is often advisable, as a preventative, in people of a plethoric habit. The head should be kept cool by the frequent use of cold ablutions; the hair cut short; the head and shoulders raised at night; tight bandages round the neck must be avoided; the daily use of the cold shower-bath is often very beneficial; but a reaction takes place in the head unless it be used with the feet immersed in hot water. The feet, legs, and lower parts of the body ought to be carefully kept warm and dry.

In the treatment of cerebritis, when fully developed, attention must be paid to its two

periods of *excitement* and *collapse*. The remedies chiefly to be relied upon are, bloodletting general and topical, purgatives, cold applications to the head, and counter-irritation.

In the more acute cases the patient must be freely bled from a large orifice to the amount of from twenty to forty ounces: one copious bleeding has more effect in bringing about the speedy resolution of the inflammation than several small bleedings. If the symptoms continue unabated, the bleeding must, however, be repeated several times, at intervals of a few hours; and this practice must be carried, during the first period of the disease, to the utmost limit of the patient's strength. It often happens that very little impression is made on the disease by the first bleeding, and no amendment takes place until after the second. The symptoms often abate after bleeding; but a fresh exacerbation may take place in the course of a few hours. Topical bleeding, by cupping or leeches, is, under such circumstances, highly beneficial.

The head must be shaved, and pounded ice mixed with cold water and vinegar may be applied to the scalp. A very effectual method of applying cold is by making the patient hold his head over a basin, and pouring a stream of cold water on it from a certain height: this often removes the heat and flushing, and calms the excitement: it should be repeated as often as the heat and flushing return. The application of cold to the body is always followed by a re-action, and the temporary relief refrigerants afford will be succeeded by an increase of the inflammatory symptoms, and their use become decidedly injurious unless their depressing action be kept up by a steady and repeated application. Some practitioners have, on this account, given the preference to the use of a mixture of alcohol or ether with liquor ammoniac acetatis and water, applied not quite cold, in order to produce rapid evaporation. An excellent practice is that of keeping the patient's feet and legs immersed in hot water during the application of cold to the head.

The remedies next to bleeding and cold, and often not less efficacious, are active purgatives, which must be administered at short intervals until copious evacuations be procured. Free purging sometimes makes a greater impression on the disease than even bleeding. In some cases no marked amendment has taken place until the bowels have been freely moved: they are sometimes exceedingly torpid, for reasons which have been already assigned, and large doses of cathartics may be required. Combinations of calomel, jalap, scammony, and cathartic extract, followed by an infusion of senna with salts, are the purgatives on which the most reliance can be placed. Croton oil is also in these cases a valuable remedy, from the facility of its administration and certainty of its effects. Mercury may be given freely as a purgative, but no particular advantage has appeared to follow its use with a view to affect the constitution; it is, indeed, found very difficult in acute diseases to produce ptyalism.

We have sometimes found tartar emetic of great service when there was no irritability of stomach to prevent its being tolerated; the power of tartar emetic in controlling the action of the heart, and subduing the inflammatory diathesis, is now fully established: a solution in the proportion of one grain to the ounce, and two table-spoonsful given every two, three, or four hours, suspending it should vomiting occur, has often been attended with great benefit. The remedy is in general well tolerated, owing to the torpor of the stomach: violent vomiting should, however, be prevented, as it would obviously be extremely injurious.

In the second stage of acute cerebritis, that of collapse and coma, general bloodletting is to be used more sparingly; decided advantage, however, has resulted from a moderate bleeding even at a late period. In this stage, topical bleeding is more generally indicated. There are periods of exacerbation in the symptoms which should be watched and overcome by these means; which may be persevered in as long as there is any hardness and resistance in the pulse. We have seen a patient instantly recover from a state of profound coma by the abstraction of a very small quantity of blood with the cupping-glass. When bleeding is no longer advisable, moderate purging may still be of use. In this stage, we may have recourse to counter-irritation with advantage: blisters may be applied between the shoulders, to the occiput, or to the neck or legs. There is an objection to their being applied to the whole head, that it prevents the subsequent application of cold. We have, however, in desperate cases, seen a decided amendment follow the application of a large cap blister. Particular attention should be paid to the abdominal region, and especially that of the bladder, which ought to be examined morning and evening, in order to detect retention of urine; and we must take care not to be led into error by an incontinence of urine from the over-distension of the bladder: this must be obviated by drawing off the urine with the catheter twice a day.

In the more chronic forms of cerebritis, unattended with fever or much general excitement, the same activity of treatment is of course not admissible. We must still, however, pursue the antiphlogistic plan, modifying it according to the urgency of the symptoms. During the period of irritation, with cephalalgia, vertigo, or rigid spasm of the extremities, moderate bleeding, general and topical, purgatives and counter-irritation, are the only remedies from which any advantage is to be expected: they must be repeated at longer or shorter intervals, according as the strength of the patient and the continuance of the symptoms may seem to indicate. A great deal is to be accomplished in all chronic inflammations by persevering in a moderate course of antiphlogistic treatment. We must watch carefully any signs of amendment, remembering that there is a great tendency to relapse, and that the natural course of the complaint is characterised by irregular remissions and exacerbations.

When the period of irritation is over, and is followed by a remission of all signs of excitement, by a complete paralysis of the muscles, and by the other evident signs belonging to the period of softening and suppuration, the strength of the patient must no longer be reduced by active treatment. In all inflammatory diseases, when the stage of excitement and disorganization is over, a process of reparation commences, which requires for its completion a certain degree of power in the constitution. If at this period we persevere in lowering the general strength, we deprive the constitution of its natural resources, and interfere with its healing operations. It becomes, therefore, an object of considerable importance to watch the moment when the tide of excitement is on the turn, and when the powers of the constitution are verging to a state of collapse, in order that we may abstain from an injurious interference, husband the patient's strength, and even support it if required. This precaution is particularly necessary in old people and young children. We think it necessary to lay some stress on this rule of practice, as there is perhaps a tendency in the present day to overlook it; and we have seen considerable harm from carrying the antiphlogistic treatment beyond its safe limitation. We have already alluded to the pseudo-symptoms of cerebral congestion and inflammation which are sometimes the consequence, especially in children, of extreme exhaustion, and require the use of cordials.

After convalescence has been established, the patient will still require to be closely watched for some time, before his recovery can be considered fully confirmed: he must be kept perfectly quiet, free from every species of excitement, and the regimen duly regulated. When the brain has once suffered from inflammation, it is slow in recovering its tone, and the most trifling cause, such as a slight mental exertion or emotion, a full meal, &c. has been, in many cases, sufficient to occasion a relapse.

When cerebritis has occurred after suppressed evacuations or the metastasis of other diseases, we should endeavour to procure their return. If menstruation be suppressed, leeches should be applied to the pubis or inguinal regions, and the frequent use of hot pediluvia with flour of mustard recommended. If cutaneous eruptions or rheumatic gouty pains in the joints previously existed, blisters or rubefacients are to be applied to the parts originally affected.

M. Bland has published in the *Bibliothèque Médicale*, vol. lxii. several cases in which he says that he speedily overcame the symptoms of cerebritis by the mere compression of both carotids for several seconds; stopping thus the flow of blood to the head. Laennec considered this an unsafe proceeding, and not easy to perform without the risk of suffocation. This plan has often been proposed as a means of checking inflammation, and also of preventing the accession of the paroxysm of ague. We have, however, never seen it tried, and should

think its general application scarcely practicable.

The following summary gives a connected view of the various morbid conditions of the brain, which are the effects of congestion and inflammation, together with their symptoms.

1. Cerebral congestion, over-distension of vessels:—vertigo, tinnitus aurium, confusion of sight, cephalalgia; if the pressure on the vessels be carried to a sufficient extent to intercept the circulation,—*simple apoplexy*; seldom fatal; recovery rapid.

2. If the cerebral congestion be permanent, or returns frequently; drowsiness, oppressed intellect; the vessels become weakened, and on a sudden increase of congestion are ruptured; extravasation of blood,—*sanguineous apoplexy*; destruction of cerebral substance and compression; loss of consciousness, permanent or temporary; sudden and complete paralysis, without spasmodic affection of the muscles.

3. General congestion, followed by inflammation of a considerable portion of the brain; deep injection; partial sanguineous infiltration; dotted and ecchymosed striated appearance of the cerebral substance;—*general cerebritis*, (combined usually with arachnitis.) Period of high excitement of all the cerebral functions, with general convulsions, followed by a period of collapse and coma.

4. Partial congestion and inflammation of the brain: *1st period*, the same deep injection and sanguineous infiltration, more circumscribed;—*partial cerebritis*. Partial symptoms of irritation in the organs of motion and sense; weakness, pain, numbness, spasmodic paralysis, confined to one side or a few regions of the body: *2d period*, infiltration of pus in the cerebral substance; softening, abscess; complete paralysis; relaxation and flaccidity of the muscles; loss of feeling; abolition of some of the external senses or intellectual faculties; death, either gradual or sudden, by the extension of the inflammation, or by pressure.

5. After sanguineous apoplexy and sudden and complete paralysis, inflammation of the cerebral substance surrounding the coagulum; *consecutive cerebritis*; the paralysed limbs affected with pains, convulsive motions, spasmodic rigidity.

6. Slow and gradual congestion, with very slight irritation; long continued state of low inflammation, ending sometimes in *softening*, sometimes in *induration*, or else in an infiltration of serous fluids and *white softening*;—various forms of *chronic cerebritis*; sense and motion very gradually weakened and impaired, without pains or spasmodic rigidity in the muscles.

(*Adair Crawford.*)

BRONCHI, DILATATION OF. See BRONCHITIS, CHRONIC.

BRONCHITIS. This term is applied to inflammation of the mucous lining of the bronchi or air-passages of the lungs. There are few disorders of more common occurrence; and few, perhaps none, so varied in impor-

ance. In its slighter forms it is scarcely deemed an interruption to health; but when severe, it becomes a dangerous and fatal disease. The pathology explains this diversity, and refers the danger, which attends bad cases, to interruption of the due performance of the function of respiration. It does not seem correct, therefore, to describe these different degrees under the different names, *catarrh*, *bronchitis*, *peripneumonia notha*, &c. as some authors have done. The term *catarrh* implies only the flux or secretion which accompanies the inflammation. We shall therefore include under the present head all affections of the bronchial membrane, which exhibit the characters of inflammation, and reserve the term *catarrh* for those changes in the secretion of the same membrane that do not appear to originate in inflammation.

Bronchitis presents itself under two forms, the *acute* and the *chronic*; the one differing from the other in the greater intensity of the inflammation, and in the more rapid progress of the disease. We shall therefore consider each form separately, as this method will enable us to point out the circumstances which characterize each variety.

I. ACUTE BRONCHITIS.—The commoner cases of acute bronchitis generally succeed to coryza, or inflammatory affection of the mucous membrane lining the nose and its contiguous cavities the frontal sinuses. Sometimes the inflammation first attacks the tonsils and fauces, from thence is transferred to the lining of the larynx, and gradually extends downwards to the trachea and bronchi. In other instances the inflammation begins in the bronchi themselves; and this mostly occurs in those whose lungs are susceptible.

The first symptom which characterizes bronchitis is a feeling of roughness in the trachea, which occasions frequent attempts to clear the throat, and is much increased by exertions of the voice, or of the organs of respiration. It soon amounts to such a degree of titillation as to excite cough, which is at first hard and dry. At this time there is generally more or less hoarseness, with a tight feeling across the chest, which often amounts to pain, especially on coughing, and occasions considerable uneasiness in breathing. Some signs of fever are usually felt at this period, such as lassitude, cold shiverings, pain in the limbs, and some acceleration of the pulse. A feeling of chilliness is hardly ever entirely absent, even in the slightest cases. The cough, which at first seems to be caused by an increased sensibility of the inflamed membrane, is very soon accompanied with expectoration of a thin fluid, having a saline taste. This secretion rather increases than otherwise the frequency of the cough; and, like the fluid of coryza, when thin it seems to possess a peculiarly irritating quality; for, although the fits of coughing are not so prolonged as they afterwards become, they are more frequent and more irresistible than at any stage of the disease. It is during the continuance of this form of secretion, likewise, that in the common cases of bronchitis.

the dyspnœa and pain in the chest first appear; and as the expectoration becomes thicker and more abundant, these are proportionately relieved. It is this change in the character of the cough and expectoration, that in common cases proves the signal for a general amelioration of the symptoms. The constriction of the chest is diminished or removed; the pulse loses its frequency; the skin, which was hot, becomes cooled by free perspiration; the urine, which was scanty and high-coloured, becomes more copious, and deposits an abundant sediment; and the degree and rate of the decline of all the troublesome symptoms very generally correspond with the change of the expectoration. This seems now to have lost its acrid irritating quality, and has less of the saline taste which at first characterized it. In its appearance it changes from a glairy colourless liquid to a pearly tenacious phlegm, increasing in consistence and opacity as it diminishes in quantity, until at length each fit of coughing easily brings up a pellet of opaque white, or greenish white mucus, to which the soot and smoke of the air in large towns often give a grey tinge. This change, or *ripening* of the expectoration, is first observed in the mornings only, and gradually extends, as the disease declines, throughout the day and night. Towards its termination, the cough and expectoration are chiefly observed in the morning and evening.

Such is the ordinary course of the slighter cases of acute bronchitis, for which the nature of their usual cause has obtained the name of "a common cold." But the same disease, differing from these only in the extent of membrane affected, presents a much more formidable character. In such severe cases, rigors and symptoms of general fever usually attend at the onset of the disease. The patient suffers from headach, particularly over the eyes, sickness and loss of appetite, lassitude and great prostration of strength, with occasional pains in the limbs. The tongue is foul, and the urine scanty and high-coloured. The dyspnœa is often urgent from the beginning, particularly in the night; and this symptom, as well as the tightness and pain in the chest, is much aggravated by the fits of coughing. The pain in the chest is most frequently referred to the sternum, and is more obtuse than the pain of pleurisy; it is often accompanied with a sense of weight to which the dyspnœa is ascribed. The pulse is hard and quick, but presents considerable variety as to the degree of frequency and fulness. The matter expectorated is usually scanty at first, and afterwards becomes copious; it is glairy, frothy, sometimes streaked with blood, and its evacuation affords but little relief to the cough or breathing: it has been compared to the white of egg in different degrees of dilution: it is generally most frothy when moderately viscid and in great abundance: its quantity increases, and there is a general aggravation of all the symptoms in the evening. It is at this time that the fever increases, the dys-

pnœa is most oppressive, and the cough most distressing.

Between the fourth and the eighth days the disease declines in favourable cases; the dyspnœa is diminished, and is confined chiefly to the evening, when there is almost always a tendency to exacerbation. The expectoration now becomes pearly and less abundant, and affords relief to the dyspnœa. The symptoms of fever subside, and the disease either entirely disappears or passes into the chronic form. In certain cases, however, if the therapeutic means have not been seasonably resorted to, or have been insufficient to subdue the acute symptoms of the disease within a few days, a state of collapse very rapidly takes place; the pulse becomes very weak, frequent, and often irregular; the countenance pallid and expressive of great anxiety, and often covered with a cold sweat; the strength is wasted by efforts to relieve the lungs of the accumulating mucus; but the cough becomes less and less effectual to remove it, whilst the wheezing and audible rattle in the large air-tubes increase. Lividity, delirium, and other symptoms of the circulation of black blood in the system, frequently succeed, and the patient dies suffocated. A remarkable feature in the character of the worst form of bronchitis is, the rapidity with which the collapse and symptoms of extreme prostration and debility succeed to high fever and well-marked local excitement; and this circumstance indicates the serious nature of the attack on the vital functions. The whole course of these fatal cases is sometimes wonderfully rapid; death ensuing within two days from the commencement of the attack. They are commonly confounded with pneumonic inflammation, and are scarcely to be distinguished from it during life but by the physical signs. The severest form of bronchitis is, however, more formidable and rapid in its course than pneumonia itself.

In the extremes of age, and in persons of weakly and phlegmatic habit, acute bronchitis frequently presents a form so different from what has been just described, that it is necessary to advert a little to these varieties. In young children a very fatal kind of bronchitis not unfrequently comes on in a most insidious manner. It may present at first the aspect of a common catarrh with coryza, without pain, much fever, or derangement of the general health. Attentive observation, however, discovers a frequency and wheezing in the breathing, which is uncommon, particularly before and after the fits of coughing; and the pallidity of the countenance, and heavy state of the child's spirits indicate something more than a common cold. The cough is not always present, so that this symptom does not indicate the extent of the disease; and as children do not expectorate, the disorder in the chest may escape remark, until the dyspnœa suddenly comes on, and renders the danger imminent. Then the pulse becomes extremely quick, and the severity of the attack is evinced by the manner in which the respiration is op-

pressed, and the circulation disturbed. This aggravation of symptoms often goes off for a time, leaving the child in a somnolent state without much cough or quickness of pulse; but if the breathing still continues quick, the dyspnœa returns after a while with increased severity, the frequency of the pulse is increased, stupor comes on, the lips become livid, and in this, or in some succeeding similar exacerbation, the child dies suffocated.

The disease which resembles this more than the case before described, is that form of bronchitis which attacks old people and those of lax phlegmatic habit, and which bears the name of *peripneumonia notha*, or spurious inflammation of the lungs. Oppression of the breathing is here one of the earliest symptoms, and it is accompanied with a peculiar wheezing; but all the symptoms of inflammation are less acute than in the intense bronchitis before described; and the fever that attends is of a lower and less phlogistic type. There is perhaps a greater loss of appetite, and more disturbance of the gastric function; the tongue is loaded, and there is much thirst. The pulse is quick and wiry; the skin not much raised in temperature except in the evening. The dyspnœa is liable to temporary exacerbations, which are often so severe as to prevent the patient from lying down, and are accompanied by extinction of the voice. The expectoration is scanty at first, but afterwards becomes very copious and frothy. The terminations of this form of bronchitis, which Dr. Badham appropriately denominates *asthenic*, are much of the same kind as those of the more violent inflammation; but its duration is commonly longer, and it has a great disposition to pass into a chronic form. Persons liable to pituitous catarrh, or who have habitually a cough with copious thin expectoration, when attacked by bronchitis, generally suffer from this form.

*Exciting causes.*—The usual cause of bronchitis is cold, particularly when conjoined with moisture, applied locally or generally, as for instance, by wearing damp clothing, or exposure to a cold, moist, variable atmosphere, especially after the body has been heated by exercise, crowded rooms, &c. But it appears that all sudden alterations of temperature from cold to heat, and certain epidemic states of the atmosphere also, are capable of giving rise to bronchitic affections. Irritating gases and vapours may excite inflammation of the bronchial membrane; but it is of the slighter kind, and soon passes away, unless the cause be again applied. A much more severe bronchitis accompanies some of the acute eruptive diseases, and frequently causes the chief danger that attends them. In some cases the eruption fades or is diminished, to the great increase of the bronchial affection, which is then announced by oppressive and dangerous dyspnœa. The inflammation of gout is sometimes translated in a similar manner in those predisposed to bronchial inflammation, and the suddenness of the attack renders these cases the more dangerous.

*Physical signs.*—In investigating the pathology of acute bronchitis, we shall find that a much more accurate knowledge of the nature and extent of the disease may be obtained by a study of the physical signs than by any attention to the general symptoms alone.

Inflammation of the mucous membrane of the bronchi at first causes tumefaction, and consequently a diminution of the caliber of the tubes. This, occurring in individual points, so modifies the passage of the air through them, that, as in a musical instrument, a sound is produced. This sound varies according to the form of the constriction and size of the tube; but the general effect is, that on applying the ear to the chest we find the ordinary respiratory murmur accompanied by various whistling and wheezing sounds. These occasionally present a graver tone, like the prolonged note of a violoncello or the cooing of a dove, and then indicate that some of the large bronchi are the seat of disease. To such modifications of the respiratory sound, M. Laennec gave the names the *sibilant rhonchus* and the *sonorous rhonchus*. They are the symptoms of the earliest stage of bronchitis, and are often perceptible before the patient is aware of any suffering in the chest. They prove moreover the fact, supposed by Dr. Badham and doubted by Dr. Hastings, that the dyspnœa of the early stage of bronchitis is caused rather by the state of the mucous membrane than by the redundancy of its secretion. Both the co-actation of the tubes by which air is scantily admitted, and the general thickening of the membrane by which the oxygenation of the blood is intercepted, appear to be the physical or pathological causes of the symptom in question. Percussion on the chest does not detect any loss of resonance.

In the progress of the disease, the auscultator soon discovers the presence of a liquid secretion, by the huddling sound occasioned by the passage of the air in the bronchi. This is the *mucous rhonchus*, and its presence announces the second, the catarrhal or secreting stage of the inflammation. By practice the ear soon becomes enabled to distinguish the several sounds that are produced in tubes of different sizes; from these a pretty accurate estimate may be made of the situation and extent of the inflammation; and these circumstances bear a relation to the severity of the case. When the inflammation occupies only the large tubes, as is the case in common colds, the bubbles of the mucous rhonchus are large and uneven, and the sound of respiration may still be heard. But if the rhonchus is fine, and accompanies the whole of the respiratory act, it may be concluded that the disease is in the smaller bronchi; and if extensive, the function must seriously suffer. In this case there is sometimes a slight diminution of the resonance on percussion of the affected part. The passage of the secretion from a thin to a consistent state, commonly called the *ripening of the cold*, has likewise its distinctive symptom. The bubbles

of the mucous rhonchus first become more interrupted, and gradually give place to a clicking, or a sibilant sound, occasioned by portions of the inspissated mucus partially obstructing the bronchi. Sometimes the respiration of a portion of lung is entirely obstructed by a pellet of this mucus in its principal bronchus; and thus the dyspnœa occurring at this stage of the disease is explained. These several symptoms are liable to frequent change from the removal or altered position of the mucus consequent on coughing or expectoration; and it is useful to avail ourselves of this in our examination; for we may thus prevent the mistake of ascribing absence of respiration to peripneumony or any other cause.

The varieties that we have before described as occurring in the progress and termination of acute bronchitis, depend on the character as well as on the extent of the inflammation. In the plethoric and sanguine temperament the inflammation is intense, and remains for a while dry; and the congested and thickened state of the membrane preventing the effectual arterialization of the blood, may in this stage cause dyspnœa. The copious secretion, however, that soon succeeds, and which appears to take place earlier in the dyspnœa of children, soon becomes an additional interruption to the function, and unless removed by expectoration or re-absorption, may soon amount to suffocation. The suddenness, as well as the abundance of its effusion, increases the danger of its effects; and this is the reason why cases of bronchitis suddenly supervening on a suppressed exanthema are amongst the most formidable. In old people, again, and those of a relaxed habit, there seems to be a serous infiltration accompanying the inflammation, which causes a greater straitening of the tubes in the first stage, than is usual in the other forms; and which is only relieved by a free secretion from their mucous coats.

*Morbid anatomy.*—The anatomy of fatal cases of bronchitis, as far as it goes, is in perfect accordance with what we learn from the physical signs. The lungs do not in general collapse on opening the thorax; the escape of air being prevented by the obstructions in the bronchi. These in most instances contain a quantity of frothy liquid, of the quality of the matter expectorated before death. Not unfrequently it is mixed with bloody serum; but this, as it is not perceived in the matter expectorated, has probably exuded from the surcharged blood-vessels at the moment of and after death. Purulent matter is also sometimes observed, and mostly in very acute cases, which have proved fatal within four or five days. The mucous coat presents an appearance of red injection, diffused, or in patches, of various shades from a bright crimson to a brown red. It is sometimes thickened, but rarely softened; and never to the degree in which the gastrointestinal mucous membrane is frequently found.

*Diagnosis.*—The diagnosis of acute bronchitis is to be deduced from the leading symptoms which we have given of the disease; and if we

avail ourselves of the physical as well as the general signs, its character will be quite distinctively defined. It is distinguished from pneumonia by the nature of the expectoration, which, although in severe cases often viscid, is less so than in pneumonia, and wants altogether that rusty tinge so characteristic of the latter disease: it is also distinguished by the clear sound on percussion of the chest, and the absence of the crepitant rhonchus or bronchophony. (See PNEUMONIA.) From pleuritis, the clear sound on percussion is sufficient to separate it. Both these diseases may, in some cases, be confounded with bronchitis without reference to these tests, but these never fail to decide its character.

*Prognosis.*—The prognosis in acute bronchitis must depend on the extent of the disease. When the inflammation is partial, affecting a few bronchi only, as in common cases, and without much dyspnœa or fever, it may terminate in from six days to three or four weeks; and its disposition to pass off is always indicated by the expectoration becoming opaque and more consistent, and gradually diminishing in quantity. This change is always first observable in the mornings; the evening exacerbation restoring the thin glairy character to the sputa, even in cases tending towards convalescence. A relapse is marked by the expectorated matter becoming again transparent and glairy, and this is always accompanied by an aggravation of the cough and other symptoms.

In the more extensive attacks of inflammation, where the dyspnœa is great and unremitting, and particularly where the fever was high in the beginning, the prognosis may be very unfavourable; and if the acute symptoms have already yielded to the state of collapse, it is to be feared that the power of the system is insufficient to restore a function on which the disease has made a serious inroad. The extreme anxiety of the pallid countenance, and a slight appearance of lividity, announce the asphyxiating effects of this stage of the disease; and the universal mucous rhonchus, with little or no respiratory murmur heard on the application of the ear or stethoscope to the chest, gives direct evidence of impending dissolution.

There is sometimes accompanying continued fever a severe bronchial affection, which this examination alone can detect. There is little cough, and the general symptoms so mask the dyspnœa that it may proceed to a fatal termination without being distinguished from the symptoms of general weakness and oppression that severe cases of continued fever commonly present. (See FEVER.)

In the severe bronchitis of children, likewise, the real amount of the danger can seldom be appreciated by the general symptoms in time for the effectual application of remedies; but where auscultation discovers, from a universal mucous rhonchus, that the inflammation is extensive, and occupies both lungs at once, great danger may be apprehended, whatever be the amount of dyspnœa and other symptoms at the time; for these frequently come on in paroxysms only, or are scarcely marked in the

somnolent state in which the child lies during the remissions.

The danger in asthenic bronchitis, or peripneumonia notha, arises from the weakness and age of the patient: if these are great, there will be a great risk of the strength proving unequal to clear the lungs of the secretion that is so copiously poured out. The respiration of old people bears ill any sudden abridgment; for the more rigid texture of their lungs does not, as in younger subjects, admit of additional or supplementary respiration in the healthy parts. (See *DYSPNOEA*.) One of the most fatal forms of bronchitis is that supervening on a suppressed eruption.

*Treatment of acute bronchitis.*—1. The slighter cases of acute bronchitis are more frequently objects of domestic than of formal medical treatment. When neglected, however, a common cold may give rise to the most serious complaints; and we are far from subscribing to a prevalent opinion to which even Laennec seems to lean, that it must always run its course. By antiphlogistic diet, and a few simple means calculated to restore the secretions, and, if required, to cause revulsion from the inflamed part, a cold may often be checked in a few days, which if left to itself might run on for weeks, entailing on some subjects other and worse evils. The means which we have found most effectual are as follow:—At the first feeling of the cold, let a purgative be given, with two or three grains of ipecacuanha or James's powder. Let a hot pediluvium be used, the patient getting into a warm and well covered bed immediately after, and promoting any disposition to perspiration by a warm draught of thin gruel, barley water, or any other mild diluent. If perspiration comes on and the purgative operates well, the cold is sometimes already cured; and it is only necessary to remain at home, and to abstain from animal food and wine next day to prevent a return.

If, however, perspiration do not follow, or if the cough has already come on, the disease generally proceeds, and we must then endeavour to mitigate its severity, and bring it quickly through its course. If the patient cannot, or thinks it not worth while to remain in bed for a day or two, he should clothe more warmly than usual; for the susceptibility of the body is such as to render a very slight exposure enough to keep up the disease, and abstinence from meat and all fermented liquors or spirits is at this period equally necessary. To loosen the cough and lead the bronchial inflammation to the stage of free secretion, small doses of ipecacuanha or tartarized antimony are often most effectual; and, although called a stimulant expectorant, squills, when combined with these, have always appeared to us to exert a beneficial effect: ten minims of the tincture with thirty of the vinum ipecacuanhæ, and six or eight of liquor potassæ, given three or four times a day, seldom fail to facilitate expectoration and relieve the cough. Whether the alkali act by facilitating the absorption of the medicine, or by any specific ac-

tion on the vessels of the bronchial membrane, we cannot determine; but its effect in increasing the action of expectorants we have proved in a variety of examples. Should nausea be produced, the dose of the medicines may be diminished; and if the cough is still troublesome at night, a little extract or tincture of hyoseyamus may with advantage be added.

This treatment is generally sufficient to relieve the tightness across the chest, which yields as the cough becomes loose; but if the case is obstinate, it may be necessary to resort to a blister, or some of the means which we shall presently recommend for the more severe forms of the disease.

The inhalation of the vapour of warm water may be sometimes useful; but we have seen it in some instances increase the oppression; and from its effect of determining blood to the part, we do not deem it so universally safe a measure in recent bronchitis as it has been represented to be.

With still more force would we object to the cure by spirits or wine, as recommended by Laennec; not that we doubt its occasional efficacy, but from the experience that where it does not cure, it greatly aggravates the inflammation. Towards the termination, when the matter expectorated has become thick and loose, and all febrile symptoms are dissipated, animal food and wine may be indulged in with impunity, and even with advantage. At this period, too, if the disease shows a disposition to linger, much good may often be obtained by using some of the stimulant expectorants, as myrrh, copaiba, &c.; and if necessary, the cough may be allayed by opium. This treatment will be noticed under the head of chronic bronchitis.

There are very many remedies which are in common use for coughs, which it is impossible here to advert to. The safest are those which are simply demulcent; many are stimulant and narcotic, and often do mischief. Ipecacuanha lozenges is a remedy worthy to be named, as the convenience of its form recommends it when more formal medicines are objected to; and although it is apt to cloy the stomach before sufficient quantity can be taken, it often proves as serviceable as the less agreeable compounds of the medicine.

2. The danger attending severe acute bronchitis renders far more energetic measures necessary; and these, although generally of the same class as those usually directed against acute inflammations, must be exercised with more than usual discretion and caution.

As long as the phlogistic state continues, with high fever, hard pulse, and great feeling of straitness and oppression in the chest, there can be no doubt of the propriety of bleeding more or less freely, according to the intensity of the symptoms, and the strength of the patient; but it is not prudent, as in pleurisy or peripneumony, to bleed to syncope, or to push the measure with an expectation of very marked relief. From sixteen to twenty-four ounces may be taken at first in severe cases; and the repetition of general bloodletting must depend on the state of the pulse rather than on other

symptoms. If it is weak, or if the patient is advanced in life, we must endeavour to subdue the symptoms by less violent means, such as local bleeding and medicines, rather than run the risk of destroying strength that is absolutely required for the act of expectoration.

Cupping is generally to be preferred to leeches, as its effect is more speedy and more within controul; and it is of considerable advantage to apply it to the part in which auscultation has discovered the greatest obstruction to the passage of the air.

There is an objection which obtains so against blisters, as to exclude their use in many cases of the early stage of acute bronchitis; namely, that before they rise, they always produce an irritating effect on the whole system, which is very apt to aggravate for the time the inflammation for which they are applied. This effect, however, varies much in different individuals, and in those whose skin easily vesicates under a blister, it is obviated by the serous discharge that immediately succeeds.

In other instances, it is advisable to resort to other counter-irritants, and we give the preference to the tartar emetic. To make it available in an acute disease, we have found it necessary to excite the skin previously to its application, by means of a brush or coarse flannel, by applying a warm hand wetted with ether or camphorated spirit, or by a short application of a mustard poultice. The tartar emetic should then be immediately rubbed in, either in the form of a warm saturated solution, or an ointment composed of one part tartar emetic to two of spermaceti ointment. With these precautions we have rarely failed to excite a full pustular inflammation in as short a time as that required for the rising of a blister, with far less irritation to the system, and with decided relief to the pectoral symptoms. We have reason to believe that a minute quantity of the tartar emetic is absorbed into the system, as we have sometimes observed nausea succeed its use; and this, instead of being injurious, as in the case of cantharides, is a part of the treatment which has been found most serviceable. This brings us to the subject of internal remedies.

At the onset of the disease, the earlier the better, a brisk purgative should be given. Where the inflammation is high, calomel, with a grain or two of ipecacuanha, combined with jalap, scammony, or any of the active cathartics, is to be preferred, and followed by repeated doses of a saline aperient, containing a small quantity of tartarized antimony. This medicine proves useful not only as an evacuant, but as a sedative and diaphoretic, and the nausea, which it sometimes produces, is generally beneficial by modifying the secretion of the bronchial lining, and facilitating expectoration. For the same reason, a full emetic has been generally recommended, and is often decidedly useful; but it is better adapted to children, and to cases in which the bronchial secretion is profuse, than to the more inflammatory forms of the disease.

For the relief of the dyspnœa and cough,

those medicines are to be preferred which act on the vascular system. The sensation of dyspnœa is not to be looked on as one merely of discomfort, to be relieved by means which deaden sensibility, but as an indication of the inroad made on a vital function, which, if not restrained, must terminate in its destruction. To aid, therefore, the antiphlogistic measures that we have already recommended, it is proper to administer such medicines as are likely to moderate the action of the vessels and relieve the congested lungs. Tartar emetic, digitalis, and colchicum best answer this indication, and we generally prefer the two former. The tincture of digitalis, in the dose of eight or ten minims, with thirty or forty of the liquor antimon. tartar., three or four times a day, is the form which we usually adopt. Of course it will be necessary to watch the effects of these medicines, and to diminish or discontinue the digitalis if the pulse become intermittent. It will be of considerable advantage to increase the dose of tartar emetic; and if the dyspnœa continue, and the mucous rhonchus in the chest is undiminished, to persist in its use even should it excite vomiting; for its beneficial effects in peripneumony, to which bronchitis, in its severe form, really approaches, very nearly, are sufficient to prove its power to restrain effusion and promote absorption. Dr. Badham strongly recommends this medicine in doses "frequently repeated, and increased till the maximum which the stomach can bear without vomiting is attained."

Calomel and opium combined, and given in frequently repeated doses, as in other acute inflammations, are likewise sometimes highly beneficial; and we consider that their use is especially indicated, where, as is not unfrequently the case, the bronchitis is complicated with gastro-hepatic disease. The opium should be in smaller proportion than usual, and is, perhaps, most safely given in the form of Dover's powder.

Should the collapsed stage have come on, and the symptoms of debility shew that the function of respiration has been already so much injured as to reduce the excitability of the system, it is necessary to resort to expectorants of the stimulating kind. Of these the best is carbonate of ammonia, which often enables a patient to expectorate what in his weakness might be sufficient to suffocate him. We are disposed to think that this remedy is more than an ordinary stimulant, and acts in an especial manner on the bronchial membrane.

The attenuating or solvent power of alkalies may with advantage be resorted to in the latter stage of bronchitis, when the matter of expectoration is very consistent, and, lodging in the bronchi, occasions local absence of the sound of respiration, and, if copious, dyspnœa. The liquor potassæ, in doses of ten minims given with the vinum ipecacuanhæ, is productive of obvious benefit.

From what we know of the effects of the lobelia inflata in suffocative catarrh of the chronic kind, we should judge it to be worthy of a trial in the collapsed stage of acute bronchitis.

Besides attempts to relieve the lungs of the load which prevents the penetration of air into them, another indication presents itself in this stage, which is to obviate the bad effects of black blood in the system; for this it is, unquestionably, that gives that peculiarly depressed and adynamic type which precedes the fatal termination. Here, unfortunately, our experience fails us; and we feel the necessity of appealing to further researches of experimental physiology.

3. It remains for us to notice the modifications of treatment which the several varieties before described require.

In the bronchitis of young children emetics are peculiarly serviceable; for besides the beneficial effect they produce on the inflamed membrane itself, the muscular action of vomiting greatly assists expectoration, which can scarcely be effected at this age. Purgatives, too, are generally of more marked utility than in adults, and, if repeated, may frequently prevent the necessity for general bleeding. Dr. Hastings, however, highly recommends bleeding from the jugular vein; and in imminent cases this is probably the means most to be relied on. Dr. Badham suggests opening a vein in the foot, and immersing it for a few seconds in warm water, which causes blood to flow in sufficient abundance. In these cases, especially, we never can proceed confidently in the treatment without frequently appealing to the physical signs. The disease is so deceitful, (as Dr. Hastings remarks,) that except the universal mucous rhonchus, which nearly or entirely obliterates the respiratory murmur, no indication of the imminent danger can be discovered.

In the asthenic form of the disease in adults, bloodletting is rarely admissible, and never to a great extent. To restrain the secretion in the bronchi, and to rid them of it by means which do not greatly impair the strength, are here the obvious indications. Nauseating doses of tartar-emetic, or even larger, continued as in pneumonia until *tolerance* is established, purgatives, and derivatives, better fulfil these intentions. Blisters answer better here than in the more inflammatory disease, but to be effectual, they should be ample; and it is useful to give squill and digitalis (ten or fifteen minims of the tincture of each, three or four times a day,) during their operation; for the secretion of urine is thus kept free, and there is less chance of irritation of the system by the cantharides. Dr. Badham recommends assafœtida in the occasional aggravations of the dyspnoea, which he supposes to arise from a temporary spasm in the bronchi. The asthenic form of bronchitis leaves a greater weakness than the more inflammatory; or rather, we should say, the weakness is the consequence of the habit of body which causes the disease to assume the asthenic form. It is therefore generally necessary to use tonics after it to restore the strength; and if an irritable cough remains, without any excitement, opium may be resorted to to allay it. Change of air may sometimes effectually answer both these purposes,

and will generally be found a beneficial adjunct.

It is generally necessary to be peculiarly energetic in the treatment of bronchitis supervening on suppressed discharges and eruptions. Extensive counter-irritation, as recommended above, with tartar-emetic, would seem here to be especially indicated. In case of repulsed gout, means should be taken to bring the gouty inflammation back to the limb by mustard poultices and hot water; but these measures are not solely to be depended on.

II. CHRONIC BRONCHITIS.—Chronic bronchitis presents as great a variety of form as the acute disease; and from the complications into which it very frequently enters, it is less tractable in its nature. It is not an easy matter to define distinctly the character which entitles a case of bronchitis to the specific term *chronic*. The duration of the acute disease is very varied; and it is frequently renewed for such a length of time as might truly gain it the name of chronic. The distinction which Andral gives, although by no means perfectly exact, is perhaps the best, inasmuch as it is founded on the pathology of the mucous membrane itself. As long as the expectorated matter remains glairy and viscid, uniting in mass, and without opacity, the inflammation is acute. Towards the termination of an attack of this kind, the sputa become opaque, and are expectorated in distinct masses, which, although consistent, are not very adhesive or glutinous. Sometimes, instead of diminishing and becoming more consistent, as when the disease is about to terminate, they remain in this state, or increase and become diffused and heterogeneous in quality, without sensible increase of fever; and they then indicate inflammation of the chronic kind.

Chronic bronchitis in its slightest form manifests itself only by habitual cough and expectoration, which are increased by certain changes of weather, and generally prevail most in winter and spring. It is most common in advanced life; and in fact very few old people are perfectly free from it. In its severer forms it is accompanied with dyspnoea, occasional pain in the chest and about the præcordia, and some febrile symptoms, especially towards evening, palpitation, and disorder of the digestive functions. The cough is sometimes very severe, especially at night, and the expectoration copious; and if these persist long, they seldom fail to waste the body and reduce the strength.

The character of the expectoration is various. Generally it consists of a greenish-white mucus, or it may assume a muco-purulent appearance, and is often mixed with little thin pituita. Sometimes the pituita are abundant, as in pituitous catarrh, and a few masses of brownish or ash-coloured mucus float in it. Sometimes it is purulent, and streaked with blood; and in some cases it is real pus, presenting all the varieties that are seen in pus from other sources. In such instances there are generally a quick pulse and signs of hectic; and the disease tends to a fatal termination, with night sweats, emaciation, diarrhoea, and all the common sym-

ptoms of pulmonary consumption. The worst cases are usually those which succeed to repeated or severe attacks of acute bronchitis, whether of the intense or asthenic form.

*Exciting causes.*—When occurring in early life, chronic bronchitis generally follows whooping-cough, measles, small pox, or some cutaneous eruption, and does not often succeed to an acute attack. A very distinct form of chronic bronchitis is excited by the habitual inhalation of air loaded with dust. Needle-pointers, stone-cutters, those who powder and sift the materials for making china, and leather-dressers, are particularly liable to this affection. In these cases it usually begins with dyspnoea, which may continue for a considerable time before the disease declares itself. In the course of a few months, however, the dyspnoea is increased, and accompanied by severe cough and a copious expectoration, sometimes mixed with pus and blood. Not unfrequently the cough brings on a profuse hæmoptysis. At this time the constitution generally suffers much; the pulse becomes quick; thirst and fever attend; the tongue is loaded; and the aggravations of dyspnoea occasion lividity of the countenance. Unless these symptoms are relieved by remedies, and a total abandonment of the unhealthy occupation, they become worse; the expectoration increases to a great extent and becomes more purulent; hectic, with night-sweats, succeeds; and the patient dies with most of the symptoms of tubercular phthisis. (See DISEASES OF ARTISANS.)

*Physical signs and pathology.*—The physical signs of chronic bronchitis do not materially differ from those of the acute disease. The resonance of the chest on percussion is scarcely if at all impaired. The respiration is varied in its distinctness, being often louder than usual, but occasionally obscure, and accompanied with mucous rhonchus. This rhonchus is not universal over the chest, and seldom accompanies the whole of the respiratory act. It very rarely happens, as in the latter stage of acute bronchitis, that the respiration is completely interrupted in a part of the lungs; and this proves that the mucus is in a more diffuent state, and yields to the air passing through the bronchi. Occasional sonorous and sibilant rhonchi prove the partial obstruction of the air-passages; and this may be either by a thickening of the mucous membrane, or by portions of thick mucus; but these symptoms are not so common in chronic bronchitis as in the dry and pituitous catarrhs.

A remarkable feature in chronic bronchitis is, that dyspnoea is not unfrequently present to a considerable degree, when from the sound heard in the chest it is plain that the air enters the lungs as well as or better than usual; the respiration being distinct or even puerile. For a complete consideration of these apparently contradictory phenomena we must refer to the article DYSPNOEA, and shall merely remark here, that the nature rather than the quantity of the bronchial mucus is probably the cause of the symptom in question.

The continuance of inflammation has the effect, ultimately, of altering the texture in the mucous membrane of the bronchi as in other parts. Its greater tenuity and simplicity of structure exempt it from a number of the changes which are incident on the gastric and intestinal mucous membranes; but it is nevertheless subject to softening, ulceration, induration, and thickening; and the effects that these produce on the caliber of the bronchi are worthy of our attention.

*Morbid anatomy.*—The mucous membrane is frequently found, on dissection, of a deep red colour, the redness being diffused or in patches. It is of a more livid or violet tint than in the acute disease, where it is usually brighter and more verging on brown. Not unfrequently, however, the membrane is quite free from this; it is sometimes even whiter than usual, and this in cases where there has been copious purulent expectoration. Softening does not occur to the extent to which it goes in inflammation of the gastric mucous membrane, and the simpler nature of the membrane explains this. (See SOFTENING OF ORGANS.) Ulceration is also rare, particularly in the smaller branches of the bronchi, except in those cases which arise from the inhalation of dust, in which the mucous membrane is generally ulcerated, often to a considerable extent; and the thickening and general alteration of structure are greater than in the ordinary cases of chronic bronchitis. The ulcers are usually small, clean, and do not extend below the mucous and sub-mucous coats. Thickening of the membrane is a more common effect, and it sometimes occurs to a very notable extent, nearly obliterating the cavity of the tube. It is rarely uniform, but generally affects several points, particularly at the bifurcation of the tubes.

Another and very remarkable state, produced by chronic bronchitis, is a *dilatation of the bronchi*. It is not of very unusual occurrence, and presents itself to the anatomist in different forms. Sometimes a single tube is dilated at one or more points into a sac of various sizes, in some examples capable of containing a walnut. In other instances the dilatation is uniform, and extends to several tubes, which enlarge, instead of diminishing, as they divide. Thus a bronchus of the size of a straw is seen to dilate to that of a goose-quill. Sometimes several branches from the same tube are affected in this manner. The mucous membrane can always be distinctly traced from the undilated portions of the tubes, and usually with some difference in its texture. It is sometimes thickened; in other instances so extremely thin as to give the dilated portions the appearance of shining vesicles amongst the pulmonary tissue. Occasionally either the mucous membrane or the circumjacent coat becomes considerably indurated, so that the dilatations are rigid, and scarcely susceptible of compression or dilatation; but the mucous membrane is more frequently softened, so that it can be scraped off by the nail.

These dilatations, as the diseased bronchi in

general, are frequently found full of pus, mucus, or whatever kind of matter has been expectorated before death.

Lacméc considers these organic changes to be produced simply by the thick mucus accumulating and gradually causing a mechanical distention of the tubes. But in this case we should discover more frequently an absence of the respiratory sound in the part: such a sign, although common in the latter stage of acute bronchitis, scarcely ever occurs in the chronic disease. We are more disposed to ascribe them, with Andral, to the altered texture of the membrane; but even this is only the predisposing cause. The physical cause of dilatation of the bronchi, we apprehend, is to be found in acts of respiration and cough exerting a degree of pressure on the softened membrane, greater than its elasticity can resist. Thus the forcible inspiration which succeeds each fit of coughing acts with greater effect on these weaker parts; and again, the violent expiration of coughing brings an undue pressure on the same tubes, which, distended in one part, and partially obstructed by the thickening of their membrane in another are perpetually exposed to a straining influence. Induration, the effect of another degree of the inflammatory process, sometimes succeeds, giving the dilated portions that rigidity that is occasionally noticed in them. The effect of these dilatations must be to obliterate the neighbouring cells, and to abridge the function of the lung. Accordingly the adjacent tissue is found, on dissection, to be dense, and deprived of its cellular structure; and when extensive, the disease thus causes habitual dyspnoea.

*Diagnosis.*—The characters of chronic bronchitis are such as easily to distinguish it from all diseases except pulmonary consumption. The severer forms sometimes so closely resemble this disease, that it is impossible to distinguish them by the general symptoms; and even with the aid of auscultation and percussion the distinction is often very difficult. The presence of pus in the expectoration, which was formerly considered characteristic of phthisis, is, we have already seen, very common in chronic bronchitis; and in fact, that which occurs in the course of phthisis, proceeds more from the inflamed bronchial tubes, than from the tubercular excavations themselves. So likewise, hectic, night-sweats, emaciation, and diarrhoea, frequently accompany both diseases.

When unattended with dilatation of the bronchi, an attentive examination of the physical signs will, however, enable us to form a pretty sure diagnosis. It is in the absence of the signs of phthisis that we recognise the character of chronic catarrh; and as this negative test is weaker than positive proof, so it is necessary that it should be often repeated to produce certainty. If, after having repeatedly examined the patient, at different hours, during several weeks, there are found no gurgling cavernous rhonchus, no cavernous respiration, no pectoriloquy, and no constant absence of the respiratory murmur, and of the sound on per-

ussion, we may, with tolerable certitude, pronounce the disease to be simply pulmonary catarrh; and a still further multiplication of examinations will remove all doubt.

But if there be considerable dilatation of the bronchi, the same signs which are produced by tubercular excavations in phthisis, may likewise occur in chronic bronchitis. If the dilatation is produced at one part of the tube, and is of a rounded shape, it may be the seat of pectoriloquy and cavernous rhonchus, in the same manner as a tubercular cavity of the same size: but if, as is the more common case, the tubes are more uniformly and generally dilated, the vocal resonance in the tubes scarcely amounts to pectoriloquy, but is rather a loud bronchophony; and the breathing is accompanied with a *whiffing* sound, more distinct than the bronchial respiration of peripneumony. It is only by attention to the progress of such cases that they can be discovered not to be phthisical. A tubercular excavation rarely remains stationary as these do, but enlarges and gives a pectoriloquy of a greater extent; whilst other excavations are usually formed in other parts. Dilated bronchi rarely affect the sonority of the chest on percussion to the degree that the engorgement and infiltration about tubercular excavations do; nor can they produce the other physical signs of large cavities. The most common situations of dilated bronchi are in the scapular, mammary, and lateral regions: the subclavian and acromion are the more usual seats of phthisical signs.

The only instance in which the sputa can assist in the diagnosis is, when they declare themselves phthisical by the presence of tubercle, or portions of the pulmonary tissue; in other respects they may be exactly the same. A remarkable fœtor has been repeatedly observed in the sputa where the bronchi were dilated.

It must be confessed that cases do occur, although rarely, which leave the most experienced auscultator in uncertainty; but these are exceptions of comparatively little practical importance, and hardly detracting from the utility of auscultation. For it need scarcely be remarked that dilatation of the bronchi is quite incurable; and it is often connected with such extensive lesion of the bronchial membrane as would leave the prognosis the same as in phthisis.

*Prognosis.*—The prognosis in chronic bronchitis depends very much on its origin, and on its simplicity or complication with other disorders. When succeeding to an acute attack, and when unattended with much derangement of the general functions, it does not tend to a fatal termination. Even should there be some purulent expectoration and hectic, favourable circumstances will sometimes bring about a cure; and slighter forms, though obstinate and lasting for years, seem scarcely to have any effect in abridging life. But in its worst character, with constant dyspnoea, copious purulent expectoration, hectic, and emaciation, and especially if attended with symptoms of confirmed

disease in the abdominal mucous membrane, or in the liver, it is nearly as fatal as phthisis itself. In these cases of complication, the bronchitis is frequently secondary; and there are abundant examples which prove that it may disappear entirely, if the abdominal disease is of a tractable nature, and yields to treatment.

In many cases the prognosis must depend on the nature of the physical signs: the disease is itself an attendant on phthisis; and if these do not establish with certainty that tubercles are not present, the case must always be considered of doubtful prospect. In the first stage of phthisis an extensive bronchial inflammation frequently attends, when the tubercles are very numerous and generally dispersed, before the stage of softening has come on. In all cases, therefore, which the history and constitution would indicate to be phthisical, the presence of a general mucous rhonchus, with partial dulness on percussion, must be considered a sign of the worst import, for a tubercular disease of this description generally runs a speedy and fatal course.

The cases of simple bronchitis that prove fatal are those in which the mucous membrane has become so altered in its structure and function, that it permanently impedes the oxygenation of the blood, and wastes the body by its secretion, and the wearing efforts to evacuate it. These generally occur in old persons, and those already reduced by fever or a severe attack of acute disease. One effect of the constantly imperfect oxygenation of the blood which attends bronchitis, is a stagnation and congestion of blood in the lungs and heart; hence organic diseases of the heart, and effusion of blood and serum, not unfrequently supervene to its long continuance.

*Treatment of chronic bronchitis.*—In the treatment of chronic bronchitis, as of all chronic diseases, regard must be paid to the time required for the cure, and the strength economised accordingly. Unless in case of a temporary increase of pulmonary congestion, or aggravation of inflammation, bloodletting is not admissible; for besides its bad effect in adding to the weakness, which is one of the worst characters of the disease, it has but little power to controul the action of vessels under the influence of chronic inflammation. Those remedies are to be preferred which act on the extreme vessels, whether directly, in the diseased part, or by establishing a new action in another part of the system.

The objection which we urged against blisters in the acute disease, does not apply here; and they are often in a high degree serviceable. It is generally necessary to repeat them several times; for few cases yield to a single application. In some constitutions they produce a great prostration of strength, and in others their beneficial effects do not continue: in such cases an effective substitute will be found in tartarized antimony, as recommended in the acute disease. The suppurative inflammation that this excites is often more efficacious in removing inflammation from a deep seated part, than the irritation of a blister, the effects of which

usually cease with the serous discharge. When it happens that a blister suppurates, a more permanent benefit is obtained; but keeping up the irritation by means of cantharides or savine ointment has not the same effect, and is more painful than salutary. Counter-irritation by tartar-*emetic* may, by attention, be regulated to any degree; and by slight reapplication a constant succession of pustular eruptions may be continued for months, if required. From this measure, conjoined with internal medicines, we have seen the happiest results in cases of the most formidable aspect; and we have scarcely ever known it fail to give some relief. It seems to moderate the irritation and secretion of the bronchial membrane, which often changes from purulent to mucous during its use; and it enables the system to bear a tonic and nutritive regimen without aggravation of the bronchial disease. It is by the success of a measure of this kind that a well known modern empiric has gained a name famous enough to blind many to the gross ignorance with which he has applied it.

The utility of expectorants in the chronic form of bronchitis has been called in doubt by the question—on what principle can they be prescribed, when the secretion is already redundant? But let it be remembered that the power of expectorants is not confined to increasing the bronchial secretion; they tend also to modify it. Thus, in acute catarrh, under the same expectorant that at first tends to *moisten* the cough, the mucous secretion becomes consistent, diminishes, and gradually returns to its healthy state. *Ipecacuanha* is certainly capable of producing this effect, and is perhaps the most generally useful expectorant that we possess. In some cases it may be given with great advantage in emetic doses, repeated every two or three days. In some obstinate examples of the milder form of the disease attacking persons of robust habit, this practice has effected a cure. As an expectorant, it may be given in the dose of a grain or two of the powder, or twenty minims to 3℥ of the wine, repeated several times in the day, according to its effects, and combined with squill, colchicum, digitalis, and opium, as the case may require. It is a useful adjunct to any expectorant medicine, and is only contra-indicated in case of profuse night-sweats.

Squill is of decided utility in some instances of chronic coughs, but rather in cases which are slighter and unattended with purulent expectoration. It is generally useful to combine it with an alkali; and a small quantity of opium may be added to prevent it from passing off too rapidly by the kidneys.

Wherever the circulation is much accelerated, and the dyspnœa is distressing, the tincture of digitalis is very likely to afford relief; and those cases which simulate phthisis are frequently fit subjects for its use; but it is necessary to watch its operations, both on account of its effects on the circulation, and its tendency to disorder the stomach and digestive organs. The same thing may be said of colchicum, which is highly spoken of by

Dr. Hastings, who recommends the tincture in the dose of twenty drops three times a day, increased or diminished according to the effects.

The *lobelia inflata* is a medicine less known in this country than it deserves. Its action seems to be of the same class as colchicum and squill, but it is more decided in its effects, and therefore likewise requires greater care in its exhibition. It may be tried first in the dose of ten minims of the tincture three times a day; in many cases this may be increased to forty or fifty; but in others not more than five minims are borne without nausea, vertigo, and a feeling of faintness. From the manner in which it relieves the dyspnœa, it is probable that it operates as a sorbificient as well as an expectorant. It is especially serviceable in those aggravations of chronic catarrh, which Laennec designates by the title of *suffocative*, and which do, in fact, sometimes produce suffocation.

In such cases, likewise, ammonia becomes a valuable remedy; and the one, in extreme cases, when suffocation is threatened, on which we must principally depend. From five to ten grains of the carbonate may be given in camphor mixture, and repeated, if necessary, every hour, or half hour, according to its effects. In the weak and atonic cases, without profuse expectoration, it is a useful adjunct to squill, ipecacuanha, and other medicines, instead of the fixed alkalis; and, conjoined with assa-fœtida or musk, it is well suited to diminish the convulsive character of some habitual coughs, which are very apt to wear down the patient, and deprive him of his nightly rest.

It would be endless to go through all the remedies that have been extolled as effectual expectorants in chronic bronchitis. All the balsams and gum-resins have enjoyed this reputation, and fallen again into disrepute: some, as copaiba and myrrh, have been resumed by some practitioners, and not without reason; but their utility is limited to cases of the atonic kind. Myrrh we have found really serviceable, particularly after a course of the other expectorants, when its grateful and tonic effects on the stomach give it an additional recommendation. Copaiba frequently disagrees with the stomach; but when it is well supported, it often restrains and modifies the bronchial secretion. Neither of these medicines is eligible when fever or vascular irritability is present; and it may be considered a matter of doubt whether they do not act rather as general stimulants than peculiarly on the bronchial membrane.

There is a class of remedies from which, if they were better known, much good might be expected; those, namely, directly applied to the diseased membrane itself by inhalation. The vapour of water does not seem to possess any property to recommend it in chronic bronchitis, unless it be in those rare cases of deficient or very viscid secretion, where it may be of some use in relaxing the vessels and facilitating expectoration. Whether combining it with chlorine or with the vapour of iodine,

as lately practised in Paris in consumptive cases, may be of any avail in this affection, we want data to determine. It is probable that they can scarcely be exhibited for a sufficient length of time to be effectual in a very diluted form; and when stronger, they decidedly irritate and prove injurious.

The diffusion of the vapour in the air of the apartment, as has been done with tar, is a preferable method, as it ensures the constant application of the remedy without extra fatigue to the patient. The inhalation of tar-vapour has had repeated and extensive trials since Sir A. Crichton directed the attention of British practitioners to it; and although its utility in phthisis has not been confirmed, many have testified to its beneficial effects in certain cases of chronic bronchitis. As it is of a stimulating nature, it proves useful only in cases free from irritability or from tendency to active inflammation; and it is important to watch its effects when first employed, and to diminish or withdraw it altogether, if it decidedly aggravates the cough, and quickens the circulation.

Another class of remedies may in many instances of chronic catarrh be judiciously conjoined with those already noticed; those, namely, that deaden sensibility, and allay that mobility of the muscular system which greatly increases the length and frequency of the fits of coughing. The most powerful of these narcotics, of course, is opium; but on account of its tendency to check secretions and increase local congestions, it cannot with propriety be given alone, unless occasionally, for the sake of obtaining a night's rest. In this case the acetate or sulphate of morphia, or any of the acid preparations of opium, such as Battley's liquor opii sedativus, is to be preferred; and these will generally be found to be safer medicines for habitual use, in combination with squill and ipecacuanha or other expectorants, than the tincture or solid form of opium. The tinctura camphoræ composita is also a very useful narcotic in chronic coughs of the less inflammatory kind.

There are other narcotics of very high utility, and which are free from the disadvantageous properties that opium sometimes manifests. At the head of these may be placed conium, the extract of which, in the dose of four or five grains three or four times a day, very signally relieves cough and irritation of the chest. Dr. Paris, who greatly extols this remedy, recommends the dose to be increased until it produce some giddiness, tremor, and nausea, or a heavy sensation and tightness in the forehead; unless some of these sensations are produced, he considers that the remedy has not had a fair trial. It is always advantageous to combine it with ipecacuanha; and the extract of hyoscyamus is indicated where an additional narcotic power is desired. The extract or leaves of belladonna, in the dose of a grain or two, we have found a useful adjunct where dyspnœa is present. The tincture of digitalis may be used with the same view; and either of these medicines is to be pre-

ferred to the hydrocyanic acid, which, notwithstanding the praises lavished on it, must be considered at least a very uncertain remedy.

Besides these means, directed against the local disease, it is of the greatest importance to attend to the state of the functions in general. Whenever any fever attends, the daily exhibition of a saline purgative is advisable. In the more atonic cases, if aperient medicine be required, a compound colocynth or aloetic pill is to be preferred; and where the cough shews a convulsive character, we have seen the greatest advantage result from the daily use of the pil. aloës et assafœtidæ combined with ipecacuanha.

Should there be, as there very often is, any complication with abdominal disease, it is of the first consequence that this be not neglected. Thus, when pain of the right side and shoulder, with fulness and tenderness in the right hypochondrium, stools of unnatural colour, a foul tongue and turbid urine, discover disordered function of the liver and alimentary canal, it will be proper to put the patient under such an alterative course of blue pill and the like medicines, as may be best calculated to bring back the healthy action of these important viscera.

Again, where a florid tongue, tender epigastrium, frequent thirst, dry skin, and nightly accession of fever, indicate that the disease extends to the mucous membrane of the stomach and bowels, it is quite apparent that many of the remedies directed against the bronchial disease will not be borne or will prove injurious, until the gastritic disease be relieved by leeches and blisters to the epigastrium, castor oil, the mildest alterative aperients, and warm-baths, with the most rigid regulation of diet. For more ample directions on this head we must refer to the several articles GASTRITIS, DYSPEPSIA, &c. Whether these diseases be primary or secondary is a consideration of less consequence than that, as long as they continue, the action of all remedies on the bronchial disease must be uncertain or prejudicial. Thus it is that even digitalis and colchicum may prove stimulant until the gastritic disease be subdued.

If due attention be paid to the removal of such complications, and if the disease do not present a decidedly inflammatory character, the weakness of the system may be combated by tonics, especially the sulphate of quinine. In case of profuse perspirations, these are scarcely to be dispensed with, and may properly be combined with sulphuric acid.

The diet in all cases of chronic bronchitis should be mild and simple in its nature. Farinaceous and milky food is that best adapted to the plurality of cases, particularly when accompanied by gastritic disorder; but in those cases that require nutrition in a smaller bulk, simple animal food is not to be withheld. Notwithstanding the encomy bestowed by Laënnec on the spirituous treatment of chronic mucous catarrh, we consider spirits and all fermented liquors in themselves as decidedly

injurious; and they are only to be admitted in a very few cases, where their assistance in the digestive process is absolutely required.

It is scarcely necessary to insist on the importance of avoiding extremes and sudden transitions of temperature, improper clothing, and all those circumstances that are in themselves frequent exciting causes of the disease: when re-applied, they must necessarily prolong it; and not a few instances are met with where, owing to the nature of our climate, it is impossible sufficiently to avoid them. In these cases, in spite of the most careful administration of remedies, the disease persists; but a perfect cure is effected by simple removal to a more genial climate. This is, perhaps, the most effective remedy that can be resorted to; and where the circumstances of the patient do not permit him to adopt it to its full extent, a change of air to the distance of a few miles may often be productive of good. The careful regulation of the air in his apartments must be his resource in the winter months.—(See CLIMATE and PHTHISIS.) It is of importance to attend not merely to the temperature, but also to the hygrometric state of the air; and it may be useful in some cases to follow Dr. Paris's plan of diffusing the vapour of water through the room during the prevalence of those dry easterly winds which irritate the mucous membranes, and aggravate the cough.

Of the means which may be called prophylactic against bronchitis, that of sponging the chest daily with salt water, or vinegar and water, deserves warmly to be recommended. If this, which may be practised by the most delicate, and the cold plunge or shower-bath for those stronger, were more commonly resorted to, the number of pulmonary invalids would be greatly diminished.

(C. J. B. Williams.)

BRONCHOCELE means, literally, a swelling of the throat, from βρόγχος, *guttur*, and ἄλζη, *tumor*; and, in fact, every indolent tumour on the fore-part of the neck, until recent times, passed under that denomination. Modern physicians, however, have confined the term to a chronic enlargement of the thyroid gland, sometimes complicated with a morbid growth in the surrounding structure. There is no precise name for the disease in this country; but, from being more common in Derbyshire than other parts, it has sometimes been called the "Derbyshire neck." In Switzerland, where in many parts it is endemic, it is called goitre, probably a corruption of *guttur*, and is generally an attendant on that humiliating state of body and mind known by the name of *cretinism*. There is, however, by no means an invariable fellowship between the two diseases, although Professor Foderé has ascribed the mental imbecility to the state of the gland,\* and Dr. Rush, of Philadelphia, has even deduced a theory respecting its uses

\* *Traité sur le Goitre et le Crétinisme*, 8vo. Paris, an. 8.

from this supposed causation among other things.\*

The tumour, as we have stated, is of a chronic or indolent nature, increasing gradually, and often continuing for many years, or even a whole life-time, without affecting the general health. It usually appears in early life, and is much more common among women, especially those of a lax fibre, than among men; insomuch, that in this country it is very rarely met with in the male sex. In all the cases admitted at the Hampshire County Hospital during the last ten years, amounting to forty-nine, the patients have, with only one exception, been women. We are informed by Dr. Forbes, that out of seventy patients treated at the Chichester Dispensary and Infirmary during the last nine years, only two have been males. It is also worthy of notice, that both the latter cases occurred in boys of a very feeble and feminine habit of body, and very backward for their years. The disease has, in some instances, been observed to make its first appearance during parturition, and, in other cases, to have made rapid progress during gestation or suppression of the menses.† The swelling generally embraces the whole gland, but is sometimes confined to the lateral lobes, or the middle lobe, separately. It is usually soft and rather flabby to the touch, though somewhat unequal in that respect, and is for the most part free from pain and of a natural colour. It varies in shape, at first presenting but little outline, and, while of moderate dimensions, possessing a more rounded and compact appearance than it afterwards preserves. When of considerable size it has a pendulous form, not unlike the dewlap of a turkey-cock, the bottom being the largest part. In point of magnitude it varies still more remarkably; often remaining through life of no very conspicuous size; in other cases increasing to a degree of hideous deformity: sometimes it rises as high as the ears. Alibert mentions one instance in which it descended to the middle of the sternum; and another in which it was of a tapering cylindrical shape, and reached to the middle of the thigh.‡ In cases of great enlargement it impedes respiration, deglutition, and the return of the blood from the head, by its pressure; thus occasioning hoarseness, wheezing, flushings of the face, headach, giddiness, and, in some instances, even death. In these extreme cases there are occasional pains in the tumour, and the skin becomes of a livid appearance, with the veins on its surface much swollen. The late Dr. Parry, of Bath, often observed bronchocele to follow diseases of the heart, epilepsy, and other maladies in which the blood is propelled with excessive momentum to the head.§ Flajani has seen it accompanied with palpita-

tions and irregular and intermitting pulse; and he believes that fatal disease of the lungs has been induced by the consequent disorder in the pulmonary circulation.\*

On dissecting the tumour, Hunter and Baillie found it to contain cells with a fluid more or less viscid; and Mr. Benjamin Bell states this to be frequently the nature of the disease. "These cells," says Baillie, "vary in their size in different parts of the same gland, and in different swellings of the same kind in different individuals. Some of them are so large as to be able to contain a small pea, but most of them are of a smaller size. The viscid fluid, when the gland has been preserved some time in spirits, is changed into a transparent jelly. From this account of the morbid change of structure which takes place in bronchocele, it seems not unreasonable to suppose that the swelling depends upon a vitiated and increased secretion in the gland. The secretion, being in large quantity, gradually distends the cells, increasing thereby their capacity, and this enlargement of the cells forms the general swelling of the gland."† The tumour is sometimes steatomatous. It is rarely found to contain purulent matter. Occasionally it has been in part converted into cartilage or bone. Dr. Hedenus, of Dresden, states that he has almost uniformly found this to be the case.‡ Sometimes the enlargement of the gland is a true sarcoma. Dr. Mason Good names it *sarcoma cellulorum*, or cystose tumour, and states that it generally consists of "oval cells, currant-sized or grape-sized, containing a serous fluid, sometimes caseous."§ Celsus has briefly and accurately described the appearances on dissection in these words: "Modo caro hebes, modo humor aliquis, melli aquæve similis, includitur; interdum etiam minutis ossibus pili immisti."|| There have been instances in which the tumour has exhibited a complication of almost every diversity of structure. De Haen relates a striking example of this, in a person who died of dropsy from visceral tumours. "In cadavere horrendam mole thyroidæam glandulam nactus, publice dissecui. Mecum auditores mirabantur nullum ferè genus tumorum dari, quin in hac sola thyroidæa inveniretur. Hic enim steatoma, ibi atheroma, alio in loco purulentus tumor, in alio hydratrius, in alio erat coagulatus sanguis, fluidus fere in alio, imo hinc glutine locus plenus erat, alibi calce cum sebo mista," &c.¶ These circumstances countenance the opinion that the same causes may produce most of the different kinds of tumour, the modifications depending upon the difference of site, habit of body, idiosyncrasy, &c.

There are some other diseases with which bronchocele might be confounded, and which have, indeed, at times been included under

the same name. Thus, the thyroid gland is occasionally attacked with acute inflammation, though, perhaps, less liable to it than most other glands of the body. In such cases, however, the swelling is more rapid in its progress than in bronchocele, but does not attain so large a size: it is firmer to the touch, painful on pressure, and the disease is much more liable to terminate in suppuration. Again, scirrhus of the gland may be distinguished from goitre by its great hardness, by occasional darting pains in the part, and by its generally occurring in advanced age, and seldom attaining to any great size. Alibert, however, states that he has seen an instance of true goitre terminating in cancer.\* Aneurisms, though they do not frequently occur in that situation, might possibly be mistaken for bronchocele; but they may be distinguished by their sudden appearance after violent exertion, particularly in coughing or laughing, by their being soft and compressible, by their situation directly in the course of the carotid arteries, and by their strong pulsation. The lymphatic glands are sometimes so enlarged, in scrofulous cases, as to form tumours of considerable size in the course of the trachea; they may, however, be distinguished from this disease by their greater tenderness on pressure, sometimes by an evident sense of fluctuation, by their being accompanied with swellings in other parts, and by the state of the general health. In some instances, indeed, the thyroid gland has, on dissection, been found in a natural state, the whole of the tumour consisting of a diseased state of the lymphatic glands and cellular membrane surrounding it. Instances have occurred of tumours arising in consequence of the lining membrane of the trachea being forced out between the cartilages in violent fits of coughing, sneezing, laughing, or other exertions of the lungs. Cases of this kind are styled the *real bronchocele* by M. Larrey. They might, perhaps, with more propriety, be called *hernia gutturis* or *hernia bronchialis*, names which have been sometimes given to the common bronchocele. Certainly, however, this is not the disease which has been usually known by the name of bronchocele, and to which the term is now almost universally confined; and as we are not at present considering the nosological propriety of the designation, we would include such cases among the spurious goitres. Their most characteristic symptom is the complete disappearance of the tumour when compressed. The voice, too, is almost entirely lost, and the respiration performed with the mouth wide open. Larrey observed it most frequently among the blind people who are employed by the priests to chaunt at the tops of the minarets in Egypt; and he met with two cases of it in subaltern officers, who had for a considerable time been employed as military instructors.† Dr. Barton, in his Memoir on Goitre as it prevails in America, states, on the authority of Foderé, that air has sometimes been forced, in like

manner, into the substance of the thyroid gland and the surrounding cellular membrane.\* Whether this be so or not, it appears certain, from the statements of various authors, that the tumour is often increased on exertion of the lungs. Goitre may also be confounded with encysted tumours situated in the course of the trachea. The latter, however, are generally rounder, more moveable, more elastic, and more equal to the touch: they are sometimes diaphanous, and fluctuation may often be perceived on pressure. The period of life, too, may at times assist in the diagnosis. In addition to these spurious or complicated cases of bronchocele, there are other instances in which the gland itself is healthy, and the tumour consists of condensed cellular membrane, sometimes interspersed with cysts. Sometimes a cyst, filled with matter of a pul-taceous or purulent nature, has been formed around the gland; and there have been cases in which the enlarged gland was surrounded by a yellow fatty mass.

We are so completely unacquainted with the uses of the thyroid gland, and consequently with the peculiar causes of disease in it, that it is not wonderful, perhaps, that there should have been so much conjecture and discordance of opinion with respect to the origin of bronchocele. Whatever may be the primary source of the disease, there is much reason for supposing that, once established, it is often continued in families by inheritance;‡ or, at least, that a strong predisposition to it is in this manner acquired. Thus we have known a woman with goitre, whose grandmother, father, paternal aunt, and cousins, also had it; although they did not all live in the same place, and no other person in their neighbourhood was affected with the disease. Similar instances have presented themselves to others;‡ and it is well known that where cretinism prevails, infants are often born with goitre. In such places, therefore, the effect of intermarriage among the inhabitants is not to be overlooked, as tending to spread and perpetuate it. The disease has sometimes been attributed to a scrofulous taint in the constitution; but as it is only met with in particular districts, as it is not always accompanied with swelled lymphatic glands or disordered general health, and as the tumour in bronchocele is scarcely known to suppurate spontaneously, while, on dissection, it has mostly been found of a totally different nature from strumous swellings, the conjecture must be abandoned. It has been held by some that bronchocele arises from a deficiency of nutritive food; and Dr. Mason Good countenances this opinion. He states, that on a visit to Derbyshire "he found a much larger number of the poor affected with this disease than he had ever seen before, while the rich escaped; and he found, also, that by far the greater part of those who were labouring

under it were not only exposed to all the ordinary evils of poverty, but derived their chief diet from that indigestible and innutritive substance the Derbyshire *oaten cake*, which," he adds, "is probably the chief cause of all the glandular and parathyroid enlargements which are so common in that quarter."\* That insufficient nutriment may concur with other causes in producing the disease, is probable enough; but that this is its principal origin is an untenable idea; since, in countries where the malady prevails endemically, the rich are by no means exempt from it. There are other circumstances besides diet, too, capable, it may be, of producing it, and to which the poor are more exposed than the rich, as we shall presently shew. And lastly, the oaten diet, to which Dr. Good attributes the disease in Derbyshire, is still more exclusively used in Scotland, where the disease is of rare occurrence.

It was long supposed, from goitre prevailing so generally in mountainous countries, that it arose from the habitual drinking of snow water. This notion seems to have been derived from Pliny,† and copied by succeeding writers, because it tallied with their doctrines of cold and crude matters. When it is considered, however, that no such cause exists where the disease prevails in this country; that it is rare in Scotland, though common in many parts of the south of England; that the Swiss, who live contiguous to the glaciers, and drink no other water but what flows from the melting of ice and snow, are free from the disorder; and that it is never met with in Greenland, where snow-water is the common drink; while in Sumatra, where snow is never seen, it is of frequent occurrence;—it is evident that we must look for some other cause. Dr. Richardson, indeed, in his journey with Capt. Franklin to the shores of the Polar Sea, ascertained that at Edmonstone, where, it seems, a residence of a single year is sufficient to render a family bronchocelous, the disease is seldom met with in those who drink melted snow, but is almost exclusively confined to those who use the river water.‡ This circumstance, on the other hand, countenances the opinion that goitre arises from certain calcareous or other impregnations of the water in common drink. The same view is strongly favoured by Dr. Bally, a native of a goitrous district in Switzerland. He says, "Bronchocele appears to me to be produced by certain waters which issue from the hollows of rocks, trickle along the cliffs of mountains, or spring from the bowels of the earth. That this is the case I may instance some fountains in my own country, (Département du Léman au Hameau de Thuet,) the use of whose waters will, in eight or ten days, produce or augment goitrous swellings. Such of the inhabitants of the above village as avoid these waters are free from goitre and cretinism."§

Dr. Coindet states that the use of hard

water, or the pump water of the lower streets of Geneva, brings on the goitre very speedily:\* and Dr. Manson attributes the prevalence of the disease in Nottingham to the same cause.† The frequency, also, of its occurrence in the valleys of the chalky districts in Hants and Sussex is certainly in favour of these views. In the central parts of Hampshire, however, we have almost uniformly met with it in the valleys only; and even there its frequency is by no means so great as, in our opinion, to justify the conclusion that it arises solely from the nature of the waters. That it should prevail to a far greater extent in these vales than in many much more confined valleys in the more northern parts of the island, may possibly arise from the greater moisture of the soil where the substratum is chalk; and partly, perhaps, from the greater degree of miasmatic evaporation occurring under a more southern sun.

Whether or not the disease be necessarily connected with the impregnations of the water in those places where it prevails, every circumstance in its history tends to prove, almost beyond a doubt, that it is induced by the agency of some one or more physical causes upon the constitution. Larrey observed that almost all the inhabitants in the valley of Maurienne were affected with goitres;‡ and Postiglione remarks that, in Savoy, Switzerland, the Tyrol, and Carinthia, there are villages in which all the inhabitants, without exception, have these swellings; the form and position of which are considered as indications of beauty.§ Professor Foderé, in his journey to the maritime Alps, made numerous observations in proof of its being a disease of low and moist regions. In the chief village of the valley La Roja, which is situated on high ground, there is not a goitre to be seen, though it is very prevalent in the immediate neighbourhood, which is comparatively low. He found, indeed, that all elevated regions, and all dry situations, whether warm or cold, were exempt from the disease; and he conceives that, throughout all climates, it takes its rise from the same cause—the humidity of the valleys. Dr. Clark, in his "Notes on Climate, Diseases, &c. in France, Italy, and Switzerland," states that he agrees in most respects with Foderé as to the origin of goitre, and expresses his opinion, that it is probable, if the villages situated in the low, close, marshy situations of the Vallais, were destroyed, and the inhabitants removed to elevated, dry situations, cretinism and goitre, which he believes to arise from different degrees of the same cause, would disappear. Dr. Gibson, also, in the first number of the Philadelphia Journal for the Medical and Physical Sciences, has collected a great number of facts leading to the same conclusion. It appears from his statement, that bronchocele

may be found as an endemic disease in all mountainous and marshy districts of the United States; that it generally prevails in valleys at the bottom of the highest mountains, in the neighbourhood of rivers, falls, lakes, or of the sea, and where the soil is rich and sheltered. Dr. James Johnson, in his *Excursion through France, Switzerland, and Italy*, recently published, has some excellent remarks on the physical causes of bronchocele and cretinism in the valley of the Rhone, drawn from his own personal observation. "Were this valley beneath a tropical sun," says he, "it would be the seat of pestilence and death. As it is, the air must necessarily be bad; for the high ridges of mountains, which rise like walls on the north and south sides, prevent a free ventilation; while in summer a powerful sun beats down into the valley, rendering it a complete focus of heat, and extricating from vegetation and humidity a prodigious quantity of malaria. In winter, the high southern ridge shuts out the rays of a feeble sun, except for a few hours in the middle of the day; so that the atmosphere is not sufficiently agitated at any season of the year. To this must be added the badness of the waters, which, along the banks of the Upper Rhone, are superlatively disgusting." In farther allusion to the same subject, he states that "it is remarked that cretinism is bounded to certain altitudes above the level of the sea. The Vallais itself, and the ravines or gorges of the mountains by which it is enclosed, are the chief seats of this deformity. All, or almost all, those who inhabit the higher ranges of the mountains overlooking the valleys, are exempt from the malady. This single fact proves that cretinism is owing to a physical rather than a moral cause, or series of causes. There can be no material difference in the moral habits of peasants residing at the base and on the brow of the same mountain. If the former be more subject to goitre and cretinism than the latter, it must be owing to something in the air they breathe, the water they drink, or the emanations from the soil on which they reside. Saussure, Ferrus, Georget, and all those who have personal knowledge on the subject, acknowledge that at a certain height (five or six hundred toises) among the Alps, goitre and cretinism disappear."—"In short, we find in the Vallais, and in the lower gorges or ravines that open on its sides, both cretinism and bronchocele in the most intense degrees; and as we ascend the neighbouring mountains, cretinism disappears, and goitre only is observed; and when we get to a certain altitude, both maladies vanish." (pp. 56 to 58.) We believe that careful observation of the circumstances under which bronchocele is found to prevail in certain districts of our own country would lead to similar views respecting its origin; and in this manner may be explained the fact, that with us it almost exclusively affects the lower orders, who are of necessity the most exposed to such causes, and to those concurrent circumstances which poverty and ignorance entail upon them. Dr. Reeve, who visited the Vallais in 1805, for the purpose of

making personal observations on the causes of goitre and cretinism, remarks that "all the cretins he saw were in adjoining houses in the little village called La Batia, situated in a narrow corner of the valley; the houses being built up under ledges of the rocks, and all of them very filthy, very close, very hot, and miserable habitations. In villages situated higher up the mountains, no cretins are to be seen."\* It would be wrong, however, to pass over the observations of the celebrated Humboldt, which certainly tend to throw some doubt upon these views. He observes that, in South America, bronchocele is met with both in the upper and the lower course of the Magdalen river, and on the flat high country of Bogota, 6000 feet above the bed of the river. The first of these regions is a thick forest, while the second and third present a soil destitute of vegetation. The first and third are exceedingly damp, the second peculiarly dry. In the first the air is stagnant, in the second and third the winds are impetuous. In the two first the thermometer keeps up all the year between 22° and 23° of the centigrade scale; in the third it ranges between 4° and 17°. The waters drunk by the inhabitants of Mariquita, where goitres are the most hideous, are not those of snow, but of springs which flow over granite. He states, also, that the disease is progressively extending itself from the lower provinces to the flat elevated regions of the Cordilleras.†

Ramond, likewise, in his observations on the Pyrenées, informs us that cretinism and goitre exist among these mountains even in greater extent and degree than in the Vallais, and under circumstances of locality very different; namely, in open, well-watered, and well-ventilated valleys. Upon the whole, therefore, we are scarcely warranted by facts in considering that bronchocele has its origin in any one exclusive source; though, as we have already stated, we think it probable that most frequently it is the offspring of a close, stagnant atmosphere, impregnated with moisture and the effluvia of the subjacent soil.

As bronchocele arises without our being able to trace with certainty its cause, so does it often unexpectedly disappear without any assignable reason, even after resisting all the approved remedies. This has frequently occurred under a change of residence, a circumstance which favours the view that we have considered the most probable respecting the origin of the disease. Alibert states that he has known many ladies in whom the tumour has subsided after a residence of some time in Paris.‡

*Treatment.*—A variety of means have been employed for its cure, both of a local and general nature. The former used to consist of dry rubbing the part; bathing it with cold water; friction with stimulating lotions, liniments, or ointments; mercurial applications, leeches, and

\* *Edin. Med. and Surg. Journ.* vol. v. p. 33.

† *Journ. de Physiologie*, par F. Majendie, t. iii. p. 116.

‡ *Nosologie Naturelle*, t. i. p. 473.

blisters, kept open or repeated. Electricity also has been employed, and latterly galvanism, it is said, with some success.

Of the internal remedies, till within these few years, the most celebrated was burnt sponge. This was generally exhibited in doses of ten grains to half a drachm, three times a day, in the form of an electuary, infused in wine, or made into a lozenge, which was kept under the tongue till dissolved, from an idea that, in this manner, its influence was more direct and speedy. It was usual, however, to accompany this remedy with alterative medicines and purgatives, chiefly mercurial; and although we believe the efficacy of burnt sponge, when unadulterated,\* to be undeniable, it might not perhaps be easy to assign its exact share as a remedy when combined with others. That mercurial preparations, internally administered, have in some cases cured the disease, even when burnt sponge has failed, there can be little doubt. There is an instance related by Mr. Davies, of Alresford, in the 13th vol. of the Medical and Physical Journal, in which two pounds of sponge had been taken without any effect, and yet the tumour entirely disappeared in the course of ten days, while the patient was taking mercury internally for some other ailment. Preparations of soda, potass, and iron; the muriates of barytes and lime; egg-shells, burnt hartshorn, and even burnt toads, have likewise been recommended. Courses of sea-water, or mineral springs, and the use of distilled water, which has appeared to Professor Odier, of Geneva, (who ascribes the disease to the qualities of the water,) to prevent the increase of the swelling, and even to lessen its bulk, have also been advised.

Of all the medicines, however, which have been administered for bronchocele, the substance called iodine is unquestionably the most efficacious, though it may not deserve the name of a specific, which some of its advocates have been inclined to claim for it. Of one hundred and twenty cases, treated by Dr. Manson, of Nottingham, where the disease appears to be endemic, seventy-nine were cured, eleven greatly relieved, and only two derived no relief.† It is now considered certain, that on the presence of iodine in burnt sponge depend the virtues of the latter in the cure of goitre. The discovery of this fact is disputed between Dr. Coindet of Geneva, and his countryman Dr. Straub of Hofwyl. There is no reason, however, to suspect that either was aware of the other's researches while prosecuting his own. Dr. Straub appears to have been led principally by the similarity of smell between iodine, burnt sponge,

and other marine productions, to suspect the existence of the former in these substances. Dr. Coindet, whilst making researches for other purposes, found that the *fucus vesiculosus*, or bladder-wrack, had been recommended by Russell for the cure of goitre; and as it is from this plant, and other species of the same family, that the soda, with which iodine is generally found combined, is extracted, he was led to suspect that the virtues of sponge, likewise a marine production, might depend upon the same active principle; a conjecture which was soon after confirmed by the discovery made by Dr. Fyfe, of Edinburgh, that iodine existed in the ashes of burnt sponge. M. Roulin has found, likewise, that the *uceyte de sal*, a South American remedy for the disease, contains iodine.\* In whatever manner the question of originality may be decided, it must be admitted that to Dr. Coindet's exertions we are principally indebted for the speedy and extensive adoption of this new medicine. In goitre its effects may be obtained either by local application to the tumour, or by administering it internally. Where the former is sufficient, it is preferable to the latter. The formula recommended by Coindet, and by Professor Brera of Padua, is that of an ointment, composed of half a drachm of hydriodate of potass mixed with an ounce and a half of lard, of which a drachm should be rubbed in over the surface of the swelling, morning and night. Brera, also, uses an ointment consisting of a drachm of pure iodine and an ounce of lard. Of this, the quantity to be rubbed in is a scruple at a time. Dr. Manson uses a liniment, composed of a drachm of the tincture of iodine mixed with an ounce of the liniment sapon. comp., which may be kept in a phial, and the evaporation of the iodine, that takes place in the ointment, be thus, he says, prevented. For internal administration, the preparation in most common use in this country is the tincture. Coindet directs this to be made, by dissolving forty-eight Genevese grains of iodine (forty grains troy weight) in one ounce of alcohol. As, however, the strength of the spirit varies, and it is liable to evaporate, a weaker tincture is preferable, from which the iodine is less likely to be deposited, and thus the deleterious action on the bowels, which has appeared to Dr. Gairdner to be more marked in proportion to the free iodine in the preparation, avoided. Dr. Manson directs the tincture to be made in the proportion of twenty-four grains of iodine to an ounce of rectified spirit; and the dose of this may be from fifteen to thirty drops, three times a-day, taken in some distilled water. The dose of Coindet's tincture is from ten to twenty drops; but Dr. Gairdner, who has had considerable experience in the use of iodine, and has given us an excellent description of its occasional mischievous effects, conceives this to be the most objectionable form in which it is used; and in this Dr. Kolley of Breslau seems to agree with him.† Iodine

\* It is stated by Dr. W. Gairdner, that chemists are in the habit of substituting charcoal for burnt sponge, of which an undeniable proof is the fact that it is sold at a less price than unburnt sponge can be bought for. In this manner Dr. Gairdner explains the inefficacy of this medicine in the hands of British practitioners, whilst its virtues are so palpable and evident at Geneva that not only physicians, but also the inhabitants, in general, are convinced of their reality.—*Essay on the Effects of Iodine*, p. 2, 8vo. London, 1824.

† *Medical Researches on the Effects of Iodine*.

\* *Majendie's Journ. de Physiologie*, T. v. p. 273.  
† *Reflexions, &c. sur l'emploi de l'iode. Journ. Comp.* Fevrier, 1824.

may also be given in the form of pills, containing each half a grain, made, as Brera directs, with elder-rob and liquorice-root. Dr. Gairdner prefers the solution of the hydriodate of potass to any other preparation, for internal use. He directs it to be made by dissolving half a drachm of the hydriodate in one ounce of distilled water; the dose is from ten to twenty drops. Dr. Manson prepares it with twenty-four grains only to an ounce—Coindet with thirty-six. By adding ten grains of iodine to this last, the solution of ioduretted hydriodate of potass is formed, which Coindet considers the safest preparation for internal use. The dose of this should not exceed five drops, three times a day, on its first exhibition. There is an alcoholic, or ethereal tincture also, used by Coindet, which, next to the last, he prefers. Dr. Gairdner states that he has seen reason to believe that bleeding from the arm in plethoric patients accelerates the effects of the medicine, when absorption is slow. Goitrous tumours are subject to sudden augmentation of size during catarrh, or in febrile states of the body, and the efficacy of the local application of iodine seems to be increased in such circumstances by a preliminary application of leeches. Dr. Coster relates a case, in the *Archives Générales de Médecine*, for July 1823, in which galvanism and friction with iodine completely removed a bronchocele, although neither of them was successful by itself. And there can be no doubt that, when required, it is necessary to improve the general health, in order to afford the remedy a fair chance of success.

When iodine is administered internally, it is necessary to avoid combining it with substances which may decompose it; it should be taken when the stomach is empty, and its effects carefully watched, as it has sometimes produced the most serious and even fatal consequences; though, under proper caution, it may be given with perfect safety. Dr. Kolley, who was himself cured of goitre by means of iodine, after all other remedies had failed, and who has both taken and prescribed it largely, gives us some instructions with respect to the circumstances which have appeared to him to contra-indicate its use. He states that it is improper when there is a disposition to congestion in the head or other internal parts; when febrile or inflammatory symptoms are present; in cases where there is diarrhœa, dyspepsia, or other gastric affection, or hepatic disorder; when there is a disposition to hydrocephalus; and in phthisis pulmonalis, for which it has been extolled as a remedy by some others.\* Dr. Gairdner informs us, that so great had been the ravage committed by the imprudent use of this medicine in the Pays de Vaud, that the government of that canton issued an injunction against its sale, excepting under the signature and responsibility of a physician. The mischievous effects which follow its use are generally insidious in their approach. The patient becomes affected with a sense of faintness, tremor, and sinking; dimness of vision, palpi-

tation, and other symptoms of a nervous kind. The degree of tremor, Dr. Gairdner informs us, is sometimes so great, as to present some resemblance to chorea, though the limbs can always be kept steady, when not called on for exertion. More violent effects than these occur at times; symptoms apparently proceeding from the direct and acrid effects of iodine on the alimentary canal, and strongly resembling the Indian cholera:—violent and incessant vomiting, strong spasms of the back and legs, extremely frequent, small, and oppressed pulse, urgent thirst, and excruciating pain of the stomach and bowels; the latter being sometimes violently purged, at other times obstinately confined. For the prevention of all bad effects from the use of iodine, it is an excellent rule to begin with small doses, and increase them gradually, so as never to exceed the minimum quantity required.\* The muscular spasms and the disturbance of the nervous system appear to be more benefited by attention to diet, air, and exercise, than by medicines. Of the latter, all that is required are mild aperient medicines, which, combined with gentle exercise in the open air, a mild, sparing, and nutritious diet, abstinence from wine and other stimulants, and the use of the warm bath, soon restore the patient to health. In the choleric affection, the remedies of much the greatest use are opiates, henbane, or hemlock, together with the warm bath, and mucilaginous drinks. Purgatives and bitters are decidedly injurious. In the second stage, when there appears to be an actual ulceration of the mucous membrane of the bowels, the pulse, instead of being small and oscillating, becoming firm and bounding, the treatment requires much more discrimination. The diarrhœa, which assumes a dysenteric form, is best treated by the union of opium and aperients. The emaciation which follows the improper use of iodine is rapid and extreme. On some parts of the continent, a wasting of the mamma has occasionally been observed, during its use, even when cautiously administered; and we have ourselves witnessed this effect. Dr. Manson found it, in one case, to excite ptyalism. The external use of the remedy seldom produces any unpleasant effects on the general system; but it sometimes stimulates the arterial vessels of the tumour so powerfully as to produce pain and inflammation. In such cases, it may occasionally be necessary to bleed the patient from the arm, lest the inflammation should extend to the trachea; but, in general, the discontinuance of the medicine, together with fomentations, poultices, and leeches, is all that is required.

When both external and internal remedies fail in discussing the tumour, surgical measures have been adopted to destroy or remove it. Of the former, the application of caustics, as recommended by Celsus, is the oldest. This, however, is a dangerous as well as a painful and tedious mode of cure. Hemorrhagy, all but fatal, has sometimes occurred from it; and

\* *Op. cit.*—or *Medico-Chirurg. Review*, Vol. vi. p. 229.

\* *Dr. E. Barlow. Edin. Med. and Surg. Journ.* Vol. xxi. p. 337.

Dr. A. T. Thomson relates an interesting case, in the eleventh volume of the *Medico-Chirurgical Transactions*, in which, from empirical application of quick-lime to an enormous goitre, the most dreadful inflammation, delirium, and sloughing ensued. The tumour has sometimes been punctured with a trochar when it contained cysts, or cut into with the scalpel. The latter, it appears, is a very common practice in Denmark; but unless a drain be in this manner instituted in the part, no very permanent benefit can be expected from it; and when suppuration does ensue, dangerous and even fatal symptoms have occurred from the formation of sinuses and sloughing.\* Issues, also, have been established in the part, sometimes with success. Their operation apparently consists in breaking down the tumour by the suppurative process, but they may also act by communicating a stimulus to the absorbents. Goitres have been cured by spontaneous suppuration, or by the inflammation and suppuration arising from accidental blows or wounds. It is reasonable enough, therefore, to expect that similar processes artificially excited should be followed by like good effects. When circumstances have rendered such means advisable, the introduction of one or more setons in the tumour is the most effectual mode of accomplishing it, and attended with the least risk of forming sinuses. Several writers of the last century recommended this mode of treatment for goitre, but the attention of practitioners in this country has been principally attracted to it by the *Memoir* of Dr. Quadri, of Naples, published in the 10th volume of the *Medico-Chirurgical Transactions*; and the operation has since been frequently performed in England. Some cases are published in the 11th volume of the *Medico-Chirurgical Transactions*, and in the 90th number of the *London Medical Repository*; from which it will appear that the operation is not so uniformly successful and free from danger as Dr. Quadri found it to be. Alibert mentions a case in which a seton produced a partial diminution of the swelling; but two years after it was withdrawn the tumour became painful, suppurated, fifteen pints of matter were discharged, and six ounces daily for three months after; yet, notwithstanding, the disease was only partially removed.† That the success or failure of this remedy is in some measure dependent upon the nature of the swelling is extremely probable, but from what specific difference in that respect the difference of effect may arise we are as yet entirely ignorant. Dr. Quadri states that he has passed a seton sixteen times in as many different directions through the tumour without any untoward accident. In one instance, endeavouring to perforate it pretty deeply, an unusual quantity of blood flowed from the wound, perhaps more than an ounce; and the tumour seemed to swell, as if injected with

blood; but the bleeding ceased spontaneously, and he states his conviction, that unless the needle were pushed deep enough almost to touch the scutiform cartilage, the principal trunks of the thyroid arteries would not be injured. He states, also, that the consecutive inflammation is of trifling consequence. When we consider, however, that the blood-vessels of the tumours are frequently very much enlarged, there may, without doubt, be occasional risk of hemorrhage. In two out of the four cases in the 11th volume of the *Medico-Chirurgical Transactions*, hemorrhage did occur, though not to an alarming extent; and Mr. Samuel Cooper states that fatal hemorrhages have sometimes followed the operation.\* It must be admitted, also, that active inflammation excited so near to the trachea may often induce dangerous consequences, especially when the tumour is attached to that part. In one of the cases related in the *Medico-Chirurgical Transactions*, a patient of Mr. Gunning's, in St. George's Hospital, the operation was followed by fatal sloughing, and there was some appearance of inflammation on the lining membrane of the trachea. In another case, related by Mr. James, of Exeter, which, however, was ultimately cured, there occurred expectoration of purulent matter and lymph, a great degree of orthopnoea, suppressed voice, as in laryngitis, and threatening death, until the seton was removed. Dr. Hedenus, of Dresden, informs us that he has seen a patient die of tetanus after the operation. From our own experience, indeed, as well as that of others in this country, we should say that it ought only to be attempted when symptoms urgently demand it. We have, it is true, seen it at times produce but few unpleasant symptoms, though we have witnessed at other times serious consequences from it; so, also, we have seen both successful and unsuccessful cases with regard to the ultimate cure. Of the former, a case has been reported in the *Medico-Chirurgical Review*, vol. vii. 1827, treated by Mr. Henry Lyford, of the Hants County Hospital. The tumour, which was of four or five years' growth, and easily moveable, but unusually hard, almost entirely disappeared in less than two months. Dr. Quadri states that it is expedient to retain the seton in the tumour for a considerable length of time, in order to keep up the suppuration, until a cure is accomplished, as well as to prevent the formation of sinuses. When the suppuration ceases, and the wounds are perfectly healed, he has observed the curative process to go on in some cases until the goitre is entirely dissipated. The skin which covered the swelling remains corrugated a short time after the cure, but soon resumes its natural appearance; and the cicatrices left by the seton in a few months present hardly any deformity.

With the view of cutting off the supply of blood by which the tumour is fed, the thyroidal arteries have been tied, and the disease,

\* *Flajani*, *Colezzione d'Osservazioni*, &c. t. iii. p. 283.

† *Nosologic Naturelle*, t. i. p. 466.

\* *Good's Study of Medicine*, vol. v. p. 322.—*Note*.

in some instances, removed by thus destroying the balance between absorption and deposition. Dr. Quadri, indeed, suggests that the effect may have been obtained simply from the increase of absorption, occasioned by the irritation of the ligature, and from the inflammation and suppuration consequent upon the operation.\* But we cannot conceive that such causes are sufficient to account for so disproportioned an effect. The experiment, we believe, was first attempted by Sir William Blizard, and he succeeded in reducing the size of the swelling one-third in the course of a week; but the ligatures having then sloughed off, repeated bleedings took place from the arteries, hospital-gangrene ensued, and the patient was lost. From the circumstances of the case, however, the same event was by no means to be necessarily expected from the operation. Accordingly, in 1814, Professor Walther of Landschut repeated the operation in a case of that particular species of bronchocele which he calls the aneurismal. The patient was a young man, in whom the respiration was much impeded by the swelling, and the upper thyroid arteries were large and pulsated strongly. The left thyroid artery being tied, on the third day after the part of the tumour on that side became less tense, and the throbbing soon ceased. It continued to diminish gradually, becoming at the same time harder, and, as it were, cartilaginous. No febrile symptoms followed the operation, and the wound was completely healed on the twenty-third day. At the end of a fortnight, the left side of the swelling having diminished one-third, the Professor tied the right superior thyroid artery, with a like freedom from any unpleasant consequences. The right portion of the tumour also began to diminish; but, though originally smaller than the left, it did not waste away so completely as the latter, which at last was only one-third of its original size. Two years after, the remains of the tumour produced no inconvenience.† Another operation of the same kind was performed by Walther in 1820, and with still more complete success. In this patient, also, the tumour was tense, hard towards its centre, and pulsated strongly. The face was pale and tumefied, the respiration obstructed, and deglutition extremely impeded. On exposing the left superior thyroideal artery, it was found dilated so much as to surpass the diameter of a common quill. After it was tied, it became considerably contracted below the ligature, and ceased to pulsate. At the end of seven weeks the wound was entirely cicatrised; deglutition and respiration were performed without any difficulty; the tumefaction of the face had disappeared; the left half of the tumour, originally much larger than the right, was reduced to its natural size; and the patient left the hospital cured.‡ The first apparently successful case of the operation in

this country that we are acquainted with, was that of Mr. H. Coates, of Salisbury, published in the 10th volume of the *Medico-Chirurgical Transactions*. The patient was a young woman, in whom the tumour was so large as to render respiration and deglutition extremely difficult, and causing a noise in breathing, which might be heard at a considerable distance. The superior thyroideal arteries were large and pulsated strongly. The left of these vessels was taken up. On the next day there was headach, and some swelling of the neck and side of the head; but these gave way to the abstraction of blood, and in three days all unpleasant symptoms vanished. The wound was completely healed on the fourteenth day. The patient's breathing was much improved, the size of the tumour being reduced nearly one half; and in less than seven weeks from the operation she was discharged from the hospital quite well. - In consequence, however, of an application we made to Mr. Coates for information as to the *final* result of the operation, we are authorized to state that, though the case proceeded extremely well for some time after the patient was discharged and lost sight of, yet the tumour subsequently, he understands, enlarged, and in the end destroyed her by suffocation. Mr. Coates states that he has not repeated the operation in any other case, nor should he be disposed to do so from the result in this instance. Mr. W. J. Wickham, of Winchester, has furnished us with the following notes of a case, in which one of the thyroid arteries was tied, in the Hampshire County Hospital, the operation being followed in like manner by apparent success at first, and failure in the end. He says, "It was the largest bronchocele I ever witnessed, but of the exact measurement I have no memorandum. After the ligature of the artery, the swelling gradually diminished for about six weeks, after which it as gradually regained its former size. It seemed that the decrease of the tumour continued so long as the part of the gland, which had been supplied by the vessel, remained without nourishment; but as soon as the supply was restored by the anastomosing branches from the opposite superior and the two inferior thyroideal arteries, the swelling returned to its former dimensions. Such, I should conceive, would be the case, unless all the thyroideal arteries were obliterated, which it would be a very difficult task to accomplish, if not altogether impracticable, from the depth of the lower vessels. In this case, after the foregoing operation, I introduced a seton through the gland, which was succeeded, at first, by great tumefaction of the part and alarming difficulty of breathing, but produced afterwards a slight diminution of the swelling. After a few weeks, however, it was necessary to withdraw the seton in consequence of its having occasioned great constitutional disturbance, and ultimately no benefit at all was derived from it. The result of the case, indeed, does not give me much encouragement to attempt a repetition of either plan of treatment on another occasion." Mr. Samuel Cooper mentions,

\* *Medico-Chirurg. Transact.* vol. x. p. 26.

† *Neue Heilart des Kropfes, &c.* 8vo. Sulzbach, 1817.

‡ *London Medical Repository.* October, 1822.

in his Surgical Dictionary, that Mr. Brodie performed the operation in one case without producing any material diminution of the tumour. Mr. H. Earle, however, has been more successful. He has published the result of a case, in which he tied both the superior thyroideal arteries, with great advantage, though not with the effect of completely dissipating the tumour. The patient was a girl of seventeen, in whom the gland was very painful, and so large as greatly to impede respiration and deglutition. Her general health was bad; she suffered much from pain in the head and drowsiness, and complained of pain in her chest, and cough, with foul tongue, and rapid pulse. As the disease did not yield to the usual remedies, she was sent back into the country on account of her general health, but returned some months afterwards with the goitre increased, so as to produce extreme dyspnoea, and totally prevent her from swallowing solid food. The pulmonary affection continued; there was constant head-ach and drowsiness, and the pulse was 120. As the disease still resisted medicine, and threatened fatal consequences, the operation was determined upon. The right superior thyroid artery was found to be enlarged to the size of the carotid. On tying it, there succeeded intense head-ach and increased drowsiness, which were subdued by a full bleeding from the arm, leeches to the temples, purgatives, and digitalis. In a few days the tumour was found to be diminished, respiration and deglutition were much less impeded, and the cough had nearly left her. Within a month she was sent home; the circumference of the swelling being diminished three inches and a half. A fortnight afterwards, the tumour remaining stationary, she returned, to have the artery on the left side tied. This was found of the size of the radial artery. No urgent symptoms followed from its being taken up; but the diminution of the tumour was not nearly so great or so rapid as after the former operation. In a month the patient finally left the hospital, with no impediment in swallowing or respiration, and free from cough, the tumour being much softer and smaller. Three months after the operation it was continuing slowly to decrease.\* From all that we yet know of this operation, we may conclude that it may be performed, perhaps in most cases, with safety; but that it is advisable in all instances of bronchocele is much more than doubtful. It appears not to have been uniformly successful even in reducing the tumour; still less in the complete removal of it. When it is considered, indeed, how largely the thyroid gland is supplied with blood, having four considerable arteries assigned to it; and how soon the place of obliterated trunks is supplied by the collateral branches; the occasional failure of the operation is not surprising, and the permanency of its benefit, even in apparently successful cases, may sometimes, as we have seen, be questionable. When the

urgency of symptoms, however, demands it, and more particularly when the tumour is of a pulsating nature, a dexterous surgeon may probably adopt this with as much safety and prospect of success as any other surgical means of relief.

In some instances the goitrous tumour has been removed, at once, by excision. This, however, will appear to be a most hazardous undertaking, when we consider the number and magnitude of the blood-vessels, and the important nerves adjacent to the tumour, with which it is generally involved; the impossibility of using much pressure in such a situation for restraining hemorrhage; and the risk of wounding the trachea and œsophagus, to which the diseased mass is often adherent. Possibly the removal of the tumour at an early stage of its progress might not be attended with very serious danger. Mr. J. Baillie Fraser tells us, he was informed in his tour through the Himala mountains, that goitre, which prevails in the valleys there, was sometimes cured when early means were taken, and that these consisted in extirpation of the part by the knife. He adds that he saw some persons with the scars from the operation on their throats, and that, in these instances, the cure was complete.\* In 1791, Dessault extirpated a tumour of the right portion of the thyroid gland, which was five inches in circumference, and proved to be similar in all respects to scirrhus glands, except that in the centre there was a cartilaginous nucleus. In this case there were no very untoward circumstances, and the patient was dismissed cured on the thirty-fourth day after the operation.† The difficulties and danger, however, attending the operation, when the tumour is large, of long standing, and has formed extensive adhesions, are very great. Mr. Gooch relates two cases in which he attempted this mode of cure. In the first he was compelled to desist, before the operation was half completed, in consequence of profuse hemorrhage, which no means were able to stop; and the patient died in less than a week. The second had nearly ended fatally, also, from loss of blood, this dexterous operator being completely foiled in his attempts to stop the hemorrhage by ligatures. The patient's life was only saved by having a succession of persons to keep up a constant pressure upon the bleeding vessels, by means of their fingers, or proper compresses, day and night, for nearly a week.‡ The operation has been fatal, also, apparently from injury to some of the important nerves in the vicinity of the disease. A woman on whom Dupuytren operated, without losing more than a few ounces of blood, was seized with hurried respiration, sickness, coldness of skin, &c., and died soon after the excision. The operation, however, has accomplished a cure, in some instances even of the most aggravated description. Vogel and Theden performed it with success.

\* *Med. and Physic. Journ.* vol. lvi. p. 201 & seq.

Professor Græfe, of Berlin, succeeded in a case where the tumour was so large that he thought it advisable to perform the operation by instalments, cutting off one side of the gland first, and, after waiting till the wound was healed, removing the other. In the course of the operation he took up fifty arteries.\* But, of all who have attempted excision in bronchocele, Dr. Hedenus, of Dresden, has been the most fortunate. It appears that he has performed it six times with success. In one instance the circumference of the tumour was fourteen inches. The operation lasted an hour and a half. Some hours after, there commenced a considerable oozing of blood from all the wounded surface, which it required assiduous care to suppress. After the separation of the ligatures, on the eighth day, there was a considerable hemorrhagy, and on the eighteenth day a more serious one occurred in consequence of a convulsive cough. The patient lost two pounds of blood; there was a deadly paleness over his whole body, dimness of sight, loss of speech and hearing, and extreme faintness. By judicious treatment, however, his life was preserved, and he was, at last, dismissed cured.† A case was published some years ago, in which Klein removed a very large bronchocele, but the patient died upon the operating table.‡ In short, judging from the results of the operation, even in the hands of the most judicious and highly skilful surgeons, we may venture to state that it ought scarcely to be attempted when the tumour is of great magnitude, and adheres firmly to the neighbouring structures, and certainly, in no case, until all other means have failed.

Dr. Clark states that Mr. Major informed him of a case in which the tumour was successfully removed by ligature. In another, in which Mr. Major himself adopted that plan, the patient was lost in consequence of hemorrhagy, from neglect of the attendant; or rather, he sank under the low fever which ensued from it.§

It should be kept in mind by the practitioner, that the removal or sudden subsidence of a bronchocele is sometimes followed by irregular action of the heart, or some other functional disturbance.

(Andrew Crawford.)

BULLÆ, *blains*, an order of cutaneous diseases characterized by an eruption of large thin vesicles, containing a serous or sero-purulent fluid, and succeeded by yellowish or blackish scabs, sometimes by ulcerations.

Συν. Φλύκταιναι, ἰλκῶδεις, φλυκταινίδες, φλύκτιδες, (*Hippoc. et vet. Grec.*); Πομφόλυγες (*rec. Grec.*); Phlyctænæ, Ampullæ (*Auct. var.*); Bullæ (*Plenck*); Dartre ptyetenoïde (*Alibert*); Bulles, Ampoules, Cloches (F.); Blasen (Germ.) *Blebs*.

† Græfe's Journ. der Chir. B. ii. p. 237. Berlin, 1822; or Quarterly Journal of Foreign Medicine. No. 19, p. 317.

‡ Journ. der Chir. B. i. p. 120.—Journ. of Foreign Medicine, Vol. ii. p. 380.

§ Op. cit. p. 111.

Plenck was the first to found a class upon this form of eruption, for before his time the diseases distinguished by bullæ were comprehended, together with all vesicular affections, under the more general term of phlyctænæ; but not being rigorous in the definition of his class, he included in it phyma, a superficial collection of pus, a species of paronychia, approaching nearly to the nature of furunculus. Willan had returned to the ancient classification which placed vesicles and bullæ in the same order, from which he was only induced to depart in deference to the well-founded criticism of Professor Tilesius, of Leipsic; and they who have seen much of vesicular eruptions will allow that the learned professor might have found reasons for his distinctions not less in the different nature of the constitutional affections than in their external appearances. But in correcting this error, Dr. Willan did not remove all the objections which might have been made to his arrangement; for, whilst on the one hand he retained, in the order of bullæ, erysipelas, of which vesications are only incidental phenomena, he excluded rupia, of which disease they form the proper elementary eruption. It is therefore our intention to follow M. Bielt, in part of his reform of this classification, leaving pemphigus, pompholyx, and rupia to constitute the order of bullæ.

This elementary form of cutaneous eruption may be produced by external as well as internal causes; and hence bullæ are the ordinary effects of blisters, as of cantharides, ammonia, and many other acrid or rubefacient substances; hence they are caused by burns, scalds, and frost-bites, and are common consequences of friction, pressure, and of distention, as occurs in œdema. The poisons of some serpents are also said to give rise to eruption. But the bullæ arising from the foregoing causes, generally denominated vesications, we leave to our surgical brethren, reserving to ourselves those of spontaneous origin, which observe also a very different progress.

The formation of these last is generally preceded by an elevated erythematous spot, more or less of a bright colour, which, in a certain time, seldom exceeding forty-eight hours, is followed by a small vesicle, which gradually enlarges to a blain. The humour contained in the bulla is in general serous and transparent, but is sometimes sero-purulent, rarely sanguineous. At first the bulla is tense, and the humour may remain a long time accumulated under the epidermis; but it becomes afterwards flaccid, whilst the humour thickens, and often dries into solid scabs, more or less considerable. Or, if situated in a part where the epidermis is thin, the bulla bursts after a few days, and is followed by a thin scab, unless the surface be defended from the air by a portion of the detached cuticle, or any other covering, when it presents a white flocculent secreting covering. In either case the skin gradually provides itself with a new epidermis, or becomes the seat of an ulceration more or less deep.

Though the diseases of this order may exist as acute, they generally present themselves as chronic disorders, eruptions of bullæ following each other in regular succession. As chronic diseases they are never contagious, but generally connected with some disorder of the constitution or the internal organs; hence bullæ are symptomatic of a state of cachexy, of inflammation or irritation of the mucous membrane of the bronchi or the alimentary canal, or of dérangements of the function of the liver. They are also observed incidentally in small-pox, the bulla *variolosa* of Plenck.

The pathological condition giving rise to this form of eruption consists, as far as has been ascertained, in an inflammation of the *rete mucosum*, or upper surface of the cutis, by which a more copious secretion of serous fluid takes place than can be transmitted by the cuticle, thus causing its separation and elevation. In proof of this we may mention that the *rete mucosum* remains adherent to the cutis, and is not detached with the cuticle, as happens when this latter is forcibly torn off. The inflammation which gives rise to the formation of bullæ may be also considered to exist in a higher degree than in erythema, for a higher degree of irritation converts erythema into bullæ.

As bullæ may be dependent upon such different states of body, it is obvious that their treatment must be various; and therefore we may understand how, in some diseases of this order, the antiphlogistic regimen may be required, whilst, in others, alteratives or tonics may be most advisable, and how, in all the forms, great attention to regimen is always essential.

(T. J. Todd.)

**CALCULUS, (CHEMICAL COMPOSITION).**  
—The term calculus is applied to any solid or unorganized concretions found in the human body. Such concretions have been found in almost all the mucous cavities and canals; in the lachrymal passages; in the mouth, for the tartar in the teeth is certainly of this nature; in the tonsils; in the salivary and pancreatic ducts; in the stomach; in the intestines; in the gall-bladder and biliary passages; in the ramifications of the bronchi; between the prepuce and glans; in the ducts of the mamma; in the vesiculæ seminales; in the ducts of the prostate gland, and in the urinary canals and bladder. Earthy concretions have also been found imbedded in the substance of the brain and other soft parts; within serofulous abscesses; in cancerous cavities, and in hydatid cysts. The deposition of this earthy matter seems to take place around foreign bodies introduced into the animal frame, as the effect of the irritation which they cause, and probably as the means of rendering them less obnoxious to the living textures. Thus where an extra uterine fœtus has been long retained, it is usually found more or less encrusted with earthy matter; and when musket-bullets or other projectiles have remained in the human body, their surfaces become covered with a coating of what appears to be phosphate of

lime. Even the vascular system is not free from calculous concretions; and small indurated masses have been found within the cavities of veins, which have thence obtained the name of phlebolithes.

**CHEMICAL COMPOSITION OF CALCULI.**—Calculous concretions were noticed by the ancients, and named, obviously from a notion that they were of a stony nature, *λιθία* by the Greeks, and *calculi* by the Romans. Hippocrates describes the symptoms of calculus in the kidney and urinary bladder with his usual precision. Pliny enumerates a great number of remedies for this dreadful disease, and Celsus describes a method of extracting calculi from the bladder, which Heister praises as excellent. But we look in vain into the writings of the ancients for any description of calculi, or any examination of their nature.

The first person who attempted to speculate respecting them was Paracelsus, though it is somewhat difficult to form an accurate idea of the notions which he entertained on the subject. He seems to have thought that the calculus separates from the liquids of the living body in the same way that tartar is deposited from wine upon the sides and bottom of the wine-cask. This seems to have been the reason that induced him to give the name of tartar to calculi. This tartar, which is apt to be generated in the living body, was in Paracelsus's opinion the origin of most diseases. It differed in its qualities according to the nature of the liquid from which it was generated. He gave it the name of tartar, because it burns the patient like *hell-fire* in severe diseases. It is deposited when the archeus acts with too much impetuosity and irregularity, and when it separates the nutritive principle with too much activity. Then the *saline* spirit unites with the *earthy principle*, which always exists in the liquids, but in the state of *materia prima*; and this union occasions the formation of *tartar* or *calculus*.

The subject of *calculus* was taken up by Van Helmont, in his treatise *De lithiasi*, which constitutes perhaps the most important and valuable part of all his works. He subjected various urinary calculi to a chemical investigation, and showed that they differed entirely in their nature from the *stony* bodies which occur in the mineral kingdom; from which he drew, as a consequence, that they did not originate from matter contained in food and drink. Tartar, he observed, was deposited from wine, not as an *earth*, but as a crystallized salt; and in the same way the natural salt of urine is precipitated to give origin to a calculus. This precipitation may be initiated by mixing spirit of urine (*solution of carbonate of ammonia*) with rectified spirit of wine. A white precipitate immediately falls, to which he gave the name of *ossa alba*. This view of the subject, which was to a certain extent just, induced Van Helmont to lay aside the name tartar, which had been employed by Paracelsus; and to avoid ambiguity, he employed the term *duellech*, to denote the state in which the spirit of urine is precipitated when it gives origin to

calculous concretions. These views he endeavoured to confirm by an analysis of urine, which was as perfect as could be expected when the experiments were made, and certainly enabled him to approach much nearer the truth than any of his predecessors had done.

No attempt (so far as we know) was made to determine the nature of calculi, or to discover remedies capable of dissolving them in the bladder without injuring that organ, till the publication of the second volume of *Hales' Vegetable Statics*, in the year 1733. He exposed different calculi to a red heat in a gun-barrel, and found that they yielded a quantity of air amounting to above five hundred times their bulk—a greater quantity of air than most other animal or vegetable substances could be made to yield. This was a decisive proof (if any had been wanting after the experiments of Van Helmont) that urinary calculi are quite different in their nature from the stony bodies belonging to the mineral kingdom. Dr. Hales made several attempts to discover a solvent of urinary calculi, but it is unnecessary to relate them as they were not attended with success.

In the year 1743 Dr. Whytt published an essay to show that *lime-water* was a remedy for the stone. This essay first appeared in the *Edinburgh Medical Essays*, and was reprinted with them in 1747, and finally published separately in 1752. Soon afterwards Dr. Alston published *A Dissertation on Quicklime*, in which he deduces from his experience that lime-water may have a tendency to prevent the formation of calculi; but that it is incapable of dissolving them when once formed. As neither of these gentlemen made any experiments on the calculi themselves, their observations contributed very little towards improving our knowledge of the nature of these concretions. The analysis of calculi by Stare contributed but little to explain their nature.\* Boyle had subjected them to distillation, and had obtained an oil and a great quantity of carbonate of ammonia.

Such was the state of the chemical knowledge of calculi, when, in the year 1776, Scheele published a set of experiments upon urinary calculi in the *Memoirs of the Stockholm Academy*.† He found all the calculi that he examined of the same nature. He could discover in them no sulphuric acid and no lime; but they consisted of a peculiar substance possessing acid properties, and characterized by dissolving with effervescence in nitric acid, and assuming a beautiful pink colour when the solution is evaporated to dryness without the application of too much heat. To this acid the name *lithic acid* was afterwards applied, which by Fourcroy was changed into *uric acid*, in consequence of a remark of Dr. Pearson. Scheele showed that all urine contains this acid. Hence the origin of urinary calculi came to be understood. Whatever has

a tendency to throw down uric acid from urine may give origin to a calculus.

To this paper of Scheele an appendix was added by Bergman, in which he stated the result of his own experiments. He detected the uric acid which Scheele had discovered, but found also some lime in all the calculi which he examined. This important paper of Scheele constituted the first step, and it was a very material one, towards a full investigation of the nature of urinary calculi.

Hardly any addition was made to the facts ascertained by Scheele and Bergman till the year 1797, when Dr. Wollaston published a paper on *gouty and urinary concretions*, in the *Philosophical Transactions*. In this paper he gave an account of three species of urinary calculi, quite different in their composition from those described by Scheele. The concretions which appear in the joints of gouty persons, and which had been known to medical men by the name of *chalk stones*, he ascertained to be a combination of *uric acid* and *soda*. To the three new species of calculi he gave the names of *fusible calculus*, *mulberry calculus*, and *bone-earth calculus*.

The *fusible calculi* had been first noticed by Mr. Smithson Tennant, who found, that when urged by the blow-pipe, instead of being nearly consumed, as happens to the uric acid calculi of Scheele and Bergman, they left a large proportion which fused into an opaque glass. This he conjectured to be phosphate of lime mixed with other phosphoric salts of urine. Dr. Wollaston found that this kind of calculus was white, and that it consisted partly of sparkling crystals composed of ammonia-phosphate of magnesia. These crystals had the form of short triangular prisms, having one angle a right one and the other two equal, and terminated by a pyramid of three or six sides. The other constituents of this calculus are phosphate of lime, and a very small quantity of uric acid.

The *mulberry calculus* had been noticed and named before by medical men; but no attempt had been made to determine its nature. The surface is irregular and knotted, bearing a distant resemblance to the mulberry. Dr. Wollaston shewed that it is composed of oxalate of lime, mixed with a little blood and other animal matter. Calculi of the same nature are sometimes met with, smooth on the surface, and much lighter coloured. These, from their appearance, were called *hemp-seed calculi*, and were not suspected to be of the same nature with the mulberry, till Dr. Wollaston ascertained their composition.

The *bone-earth calculi* are of a brown colour, and so smooth as to appear polished; they consist of regular laminæ, easily separated from each other. Dr. Wollaston shewed that they are composed of phosphate of lime: hence the name by which he distinguished them. Before the blow-pipe this calculus is slightly charred: it then becomes white; and when urged with the utmost heat from a common blow-pipe, it is at length fused. As this cannot be done with the earth of bones, Dr. Wol-

\* Phil. Trans. vol. xvi. 140.

† *Undersökning om Blöse Stenen*, p. 327.

Wollaston infers that the bone-earth calculi are composed of neutral phosphate of lime; whereas the earth of bones is known to be a subsesquiphosphate of lime, or a compound of—

|                                  |      |
|----------------------------------|------|
| 1 atom phosphoric acid . . . . . | 4.5  |
| 1½ atom lime . . . . .           | 5.25 |
|                                  | 9.75 |

Dr. Wollaston, in this important paper, also examined the calculi from the prostate gland, and found them composed of neutral phosphate of lime tinged with the secretion of the prostate gland.

Some years after, a set of experiments on urinary calculi was published by Fourcroy and Vanquelin. They examined no fewer than five hundred different calculi, and were thus enabled to add a little to the important discoveries of Dr. Wollaston, to which, however, they make no allusion in their paper. They found calculi composed of urate of ammonia; and in two different calculi they found a small quantity of silica. The animal matter which serves as a cement to the constituents of the calculus, they consider as sometimes consisting of albumen, and sometimes of urea; but it is evident from the way they speak of it that they had not subjected it to a rigid examination.

The next addition to the chemical knowledge of the nature of calculi was made by Dr. Wollaston in 1810;\* by the discovery of a urinary calculus composed entirely of a peculiar substance capable of combining equally with acids and alkalis, and which he distinguished by the name of *cystic oxide*. It is of rare occurrence; only about six or seven such calculi having been hitherto met with.

The labours of Austen, Walther, Brugnatelli, Pearson, Brande, &c. have not added many new facts to those already known; but Dr. Marcet, in his *Essay on the Chemical History and Medical Treatment of Calculous Disorders*, published in 1817, gives an account of two new species of calculi which he had observed. The first, which he received from Dr. Babington, weighed eight grains, and was composed of a substance to which Dr. Marcet gave the name of *xanthic oxide*, from the lemon yellow colour which it forms when acted upon by nitric acid. The other calculus was about the size of a pea, and the substance of which it was composed possessed the characters of *fibrin*. On that account Dr. Marcet gave it the name of *fibrinous calculus*.

In the year 1821, Dr. Prout published *An Inquiry into the Nature and Treatment of Gravel, Calculus, and other Diseases connected with a deranged Operation of the Urinary Organs*; a new and improved edition of which appeared in the year 1825. In this work he treats at large on urinary calculi, and the states of the urine connected with their formation; and has thrown more light upon the subject than any preceding writer.

\* On a new species of Urinary Calculus, Phil. Trans. 1810, p. 223.

Such is a short history of the principal discoveries respecting calculi, chiefly of the urinary organs. We shall now take a view of the different calculi which are apt to form in living animals, and point out their nature, and the causes of their formation, so far as the subject has been investigated.

The calculi formed in living bodies are distinguished according to the organs in which they appear. We shall notice them in alphabetical order, dwelling principally on their chemical composition.

1. *Biliary calculi*, formed in the gall-bladder.

2. *Gouty concretions*, formed in the joints of gouty individuals.

3. *Intestinal concretions*, formed in the stomach and intestinal canal of man and the inferior animals.

4. *Ossifications or concretions* which occasionally form in the pineal gland, the salivary glands, the pancreas, the liver, the spleen, the lungs, &c.

5. Calculi formed in the prostate gland.

6. *Urinary calculi*, formed in the kidney or urinary bladder.

I. **BILIARY CALCULI.**—Hard bodies occasionally form in the gall-bladder, which, making their way into the duct through which the bile passes into the intestinal canal, prevent the bile from passing, and thus occasion the well-known disease called *jaundice*. These concretions have received the name of biliary calculi, or gall-stones. Though their existence was known to the ancients, and though they had been imperfectly described by medical men, scarcely any thing was known respecting their nature till they were examined by Poulletier de la Salle, about the year 1784, who found that they were partly dissolved by boiling alcohol, and that the alcohol on cooling deposited a number of brilliant white plates, bearing some resemblance to spermaceti. The subject was taken up by Fourcroy in 1785, who compared the matter of gall-stones to the fatty matter into which human bodies had been converted when left in great numbers, piled on each other, to spontaneous decomposition. To this substance he gave the name of *adipocire*; and the same name was applied by him to the chief constituent of gall-stone. In 1814, Chevreul shewed that these notions of Fourcroy were inaccurate; that the substance discovered by Poulletier de la Salle in gall-stones was quite different from Fourcroy's adipocire. Chevreul gave it the name of *cholesterine (solid bile)*, and shewed that it existed as a constituent in bile. The biliary calculi hitherto described may be divided into three species, namely, *cholesterine calculi*, *mellitic calculi*, and calculi composed of *in-pissated bile*.

1. *Cholesterine calculi.*—These calculi are not by any means so abundant as those belonging to the second species, if we are to judge from the number which we have ourselves seen. They have a white colour, and a crystallized, shining, lamellated structure. Pretty frequently they have a slight shade of brown, sometimes

indeed a decided brown colour, owing doubtless to the matter of bile interspersed through them, but in too small quantity to be visible to the eye, except by affecting the colour of the calculus. These calculi are composed of cholesterine, nearly in a state of purity. The largest we have seen was about the size of a hazel-nut, and very nearly spherical. It is exceedingly light, owing to the low specific gravity of cholesterine.

Cholesterine, when pure, has a white colour, and a silky or pearly lustre. It is lighter than water; it is tasteless and insoluble in water, and possesses little or no smell. Boiling alcohol dissolves about the fifth part of its weight of it, but deposits it on cooling in small brilliant plates. When heated to about 279° it melts, and in a vacuum it may be sublimed without decomposition. It does not combine with potash, nor can it be converted into a soap. According to the analysis of Chevreul it is composed of—

|                           |         |
|---------------------------|---------|
| 1 atom oxygen .....       | 1       |
| 37.5 atoms carbon .....   | 28.125  |
| 31.5 atoms hydrogen ..... | 3.9375  |
|                           | 33.0625 |

But as it possesses neither acid nor alkaline characters, and is not known to combine in definite proportions with other bodies, we have no means of determining whether these numbers or some multiple of them constitute the true compositions of it.

2. *Mellitic calculi*.—We have given this name to by far the most common species of biliary calculi; and we have named them from the colour, which bears a considerable resemblance to honey, only it is browner. These calculi have always a polygonal shape, occasioned by mutual pressure; for a number of them always exist in the gall-bladder together. We have taken six out of a gall-bladder after death, and the gall-bladder in that case was almost filled. Most commonly they have three blunt edges, and have some resemblance to two low tetrahedrons applied base to base, with their edges and angles rounded off. The mean specific gravity is about 1.061. Their outer surface is smooth, and has a soft feel. When broken, they exhibit a thin outer crust, composed of concentric layers crystallized in small rays inclining towards the centre. These crystals consist of cholesterine. The nucleus has usually the appearance of granulated honey, and consists of inspissated bile.

In the calculi of this species which we have subjected to analysis, very nearly 19-20ths of the whole was cholesterine. The rest was a mixture of picromel and some other animal matter, which was too small in quantity to admit of a rigid examination.

3. *Inspissated bile calculi*.—This species has a yellow colour, contains little or no cholesterine, but is entirely composed of inspissated bile. So far as our observations go, it is much more uncommon than either of the other two. That it exists, however, there can be no doubt, as Thenard examined several biliary calculi be-

longing to this species. The gall-stones of oxen are usually of a yellow colour, and consist of the yellow matter of bile mixed with minute traces of bile, which may be separated by water. When thus washed, they are tasteless and insoluble in water and in alcohol. They are used by painters, though their colour is not permanent, but soon changes to a brown.

As all the constituents of biliary calculi exist in the bile, there is no difficulty in understanding how they may be deposited when the proportion of the constituents of that liquid undergoes alteration.

Cholesterine has been rarely found in biliary calculi of the inferior animals; but that it exists in them also is certain; for Lassaigue found the constituents of a biliary calculus from a sow which he examined, as follows:—

|                    |         |
|--------------------|---------|
| Cholesterine ..... | 6       |
| White resin.....   | 44.95   |
| Bile.....          | 3.60    |
| Animal matter..... | 45.45   |
|                    | 100.00* |

II. *GOUTY CALCULI*.—It is well known that concretions occasionally make their appearance in joints long subject to gout. These concretions, from their colour and softness, have received the name of *chalk-stones*. They are usually small, though they have been observed of the size of an egg. Their nature was first discovered by Dr. Wollaston in 1797, who proved that they were combinations of uric acid and soda, or composed of *urate of soda*.

Gouty concretions are soft and friable. Cold water has little effect upon them; but boiling water dissolves a small portion. If an acid be added to this solution, crystals of uric acid are deposited on the sides of the vessel. They are completely soluble in caustic potash when the action of the alkali is assisted by heat. When they are treated with dilute sulphuric or muriatic acids, the soda is separated, while the uric acid remains, and may be obtained in a pure state by filtration and washing. When the liquid is evaporated, it yields crystals of sulphate of soda or of common salt, according to the acid used. When the uric acid thus obtained is distilled, it yields ammonia, prussic acid, and the acid sublimate of Scheele (*pyruvic acid*). When dissolved in a little nitric acid, it tinges the skin of a rose colour, and, when evaporated, leaves a rose-coloured deliquescent residuum.

III. *INTESTINAL CALCULI*.—Concretions of very considerable size are sometimes found lodged in the stomach and intestines; not so frequently in the human body, but very often in some of the inferior animals.

The only intestinal concretions from the human body which we have seen are in the collection of the late Dr. Monro, of Edinburgh, and may still be seen among the preparations belonging to the anatomical class in the University of Edinburgh. They amount to forty-one, and are all very nearly of the same.

\* Ann. de Chim. et de Phys. 31. 220.

nature, though they differ in size. There are fifteen calculi exactly similar in the collection of calculi made by Dr. Hunter, and now belonging to the University of Glasgow. The largest of these weighs 1057 grains, and as some parts of it are wanting, there can be little doubt that its weight, when entire, was at least 1100 grains. These calculi have a brown colour, and are composed of fibres interwoven together after the manner of felt. They have altogether a certain resemblance to sponge. They feel soft, but are too hard to be much compressed. The specific gravity is about 1.4. One of those in Dr. Hunter's collection has a fruit-stone for a nucleus. In most of those in Dr. Monro's collection no nucleus whatever can be observed. Dr. Monro used to mention, in his lectures, that these concretions had been found in the colon, and that they had all proved fatal. The principal constituent in these concretions is the felted fibrous matter, which was naturally supposed to have been derived from the food. Mr. Clift, of the College of Surgeons, London, conjectured that it might proceed from *oats*. This induced Dr. Wollaston to examine the structure of the oat-seed, and the result fully verified Mr. Clift's conjecture. If the oat-seed be denuded of its husk, minute needles, or beards, forming a small brush, are seen planted at one of its ends. Dr. Wollaston, on examining these needles, and comparing them with similar ones detached from the calculi, satisfied himself of their perfect identity. Hence these concretions were owing to the use of oats as an article of food: as oats are employed by the common people of Scotland as a common article of food, we see a reason why these concretions have been observed chiefly in Scotland. Mr. Children gives an account of some formed in the human intestines, in Lancashire, where also oat-meal is in constant use by the common people.\* The other constituents of these calculi are albumen, common salt, phosphate of lime, and phosphate of soda.

These are not the only calculi which have been found in the human intestines. Mr. E. Brande described some composed entirely of *carbonate of magnesia*, resulting from an excessive and continued use of magnesia for a long time. In one case a collection of several pounds of this substance was found lodged at the head of the colon, which in consequence was much distended.†

Dr. Marcet describes intestinal calculi voided by the rectum possessing the properties of indurated curd or cheese.‡

He describes other small granular concretions, which were conjectured by Dr. Wollaston to be the small woody knots which are often found in certain pears; and upon close examination this conjecture was found correct.§

Some years ago the writer of this article received from an eminent physician in Birming-

ham a number of small flattened oval particles, which had been voided by a patient of his. They had all the appearance of seeds, but did not resemble any seed with which we were acquainted. At last, after carrying about the bodies for a considerable time and comparing them with the seeds of every species of fruit which we had an opportunity to inspect, we found that they were the seeds of figs. The patient had been eating green figs, the seeds of which had been voided entire.

Mr. Children gives an account of a very remarkable intestinal calculus which destroyed the life of John Chambers, a young carpenter at Clithero in Lancashire, who had been in the habit of eating large quantities of unripe plums, and of swallowing them together with the stones. Three concretions were formed in the arch of the colon, having a plum-stone for a nucleus, which in a short time destroyed his life. These concretions, together with some others collected by Mr. Barlow and Mr. Coultate, surgeons in Lancashire, which are deposited in the Museum of the Royal College of Surgeons, London, appear, from Mr. Children's description, to be intermediate between the *oaten* concretions in the collection of Dr. Monro and Dr. Hunter, and the triple phosphates, which occur so frequently in the intestines of the inferior animals. They were laminated, and composed of alternate layers of the felted fibres of the oat and the triple phosphates. The following table exhibits the constituents of one of these concretions as determined by Mr. Children:

|  |       |
|--|-------|
| Animal matter, chiefly gelatin . . . . | 25.20 |
| Resin . . . . .                        | 3.90  |
| Ammonia-phosphate of magnesia . .      | 5.16  |
| Phosphate of lime . . . . .            | 45.34 |
| Fibres of the oat . . . . .            | 20.30 |

99.90<sup>‡</sup>

The calculi found in the intestines of the inferior animals were examined with much care by Fourcroy and Vauquelin many years ago. They describe the following varieties:—

1. *Biphosphate of lime calculi*. They are composed of concentric layers, and very brittle. They redden vegetable blues, and are partially soluble in water.

2. *Phosphate of magnesia calculi*. These concretions are described as semi-transparent and of a yellowish colour. Their specific gravity is 2.160. They are laminated. They are doubtless very uncommon. We ourselves have never had an opportunity of seeing any of them.

3. *Ammonin-phosphate of magnesia calculi*—said to be very common. Their colour is grey or brown, and they are composed of crystals diverging like rays from a centre.

4. *Fungous calculi*.—These concretions are composed of pieces of the boletus igniarius, disposed in layers, and cemented by animal matters. These pieces had of course been swallowed by the animals in whose intestines they were found.

5. *Hairy calculi*.—These are found in the stomach and intestines of cows and sheep.

§ Ibid, p. 132.

\* Phil. Trans. 1822, p. 28.

They consist of balls of hair felted together, and generally coated externally with a very thin crust of animal matter. The hair had obviously been licked by the animals from their companions, and had been felted by the action of the stomach and intestines. There are several of these concretions in the collection of Dr. Hunter belonging to the University of Glasgow. The same collection contains enormous calculi composed almost entirely of phosphate of lime; but as there is no history attached to them, we have not ventured to describe them, because we do not know from what animal, or from what part of the animal, they were obtained.

6. In the same collection are five or six of the celebrated oriental *bezoars*, once so much sought after as medicines of approved efficacy. They are all smooth and polished, and have a greenish colour. They are small and round, and long, so as to have a considerable resemblance to a cylinder rounded off at the ends. Three of these bezoars, sent by the Schah of Persia to Bonaparte, were found by Berthollet to be composed of fragments of wood. Another kind of these bezoars, (probably artificial,) analysed by Fourcroy and Vauquelin, was found composed chiefly of resin.

IV. OSSIFICATIONS.—Concretions are apt to appear in various glands of the living body. These consist constantly of phosphate of lime and animal matter; or of a mixture of phosphate and carbonate of lime and animal matter. In some rare instances they consist almost exclusively of carbonate of lime and animal matter. The seats of these *ossifications*, as they may be called, are the pineal gland, the salivary glands, the pancreas, the lungs, the liver, and the spleen. The concretions coughed up from the lungs usually contain some carbonate of lime, and in some rare cases seem to be nearly destitute of phosphate of lime.

V. CALCULI OF THE PROSTATE GLAND.—Calculi occasionally form in the prostate gland, sometimes in great numbers at a time and of small size, but occasionally in smaller numbers and of a size nearly as large as that of a hazel-nut. Often they do not exceed the size of the head of an ordinary sized pin, and they are rarely larger, judging from those which we have seen, than a pea. These calculi were first examined by Dr. Wollaston, who found them composed of phosphate of lime, mixed with more or less animal matter. Dr. Prout informs us that he has met with calculi from the prostate gland containing a considerable proportion of carbonate of lime. The writer of this article has met with five or six which contained very little earthy matter, but which were composed chiefly of a substance having considerable analogy to cystic oxide.

These calculi, when small, are nearly spherical, and have a yellowish brown colour: those of a large size are smooth and polished, and have the appearance of porcelain; precisely similar, indeed, to the phosphate of lime calculi formerly described. Dr. Prout is of opinion that these porcelainous calculi always

originate in abscesses of the prostate gland. But there are not a few of them in Dr. Hunter's collection of such a size that they could not possibly have been deposited in any cyst of the prostate gland. These calculi sometimes give little uneasiness, and are not suspected till after death.

VI. URINARY CALCULI.—The constituents of urinary calculi, so far as we know at present, are the following substances:—

1. Uric acid.
2. Urate of ammonia.
3. Urate of soda.
4. Phosphate of lime.
5. Ammonia-phosphate of magnesia.
6. Carbonate of lime.
7. Silica?
8. Cystic oxide.
9. Xanthic oxide.
10. Colouring matter of urine.
11. Purpurate of ammonia.
12. Fibrin.
13. Mucus.
14. Urea.

These substances seldom appear insulated or constituting each a whole calculus. In general several of them appear together, either mixed or constituting alternate layers. To enable us to form correct notions respecting the way in which they make their appearance in the urinary organs, it will be requisite in the first place to make a few remarks upon urine.

Urine, as is well known, is a liquid secreted from the blood by two large glands called the kidneys, possessing a remarkable structure which has been minutely described by anatomists. The quantity of urine voided daily differs very much in different individuals, depending in some measure on the quantity of drink and upon the state of the skin. But perhaps two pounds avoirdupois or 14,000 grains approaches somewhat to the general average. It is transparent, has a light amber colour, and, when voided, has an aromatic odour which has been compared to that of violets. As it cools, this aromatic odour leaves it, and another succeeds, well known under the name of *urinous*. In two or three days this smell is succeeded by another, which has a considerable resemblance to that of *sour milk*. It has a disagreeable bitter taste, and a specific gravity which varies very much; but which may be stated as vibrating between 1.010 and 1.020; though in certain diseases it rises as high as 1.050 or sinks as low as 1.003.

It reddens vegetable blues, owing probably to the presence of a little urate of ammonia, and to some biphosphates which it always holds in solution. If we add to healthy urine a few drops of any acid, and set it aside for some time, small red coloured crystals are deposited. These consist of uric acid tinged by some colouring matter. If we evaporate a quantity of healthy urine to one half its natural bulk, and then mix it with nitric acid, and set it aside in an open vessel, a number of beautiful crystals in plates

make their appearance. They have a light yellowish brown colour and a silky lustre, and consist of *urea* combined with nitric acid.

The presence of sulphuric acid can be detected in urine by means of a solution of chloride of barium; muriatic acid may be detected by nitrate of silver; and phosphoric acid by nitrate of lead; the white precipitate thrown down by which, as far as it is a phosphate, being again dissolved by the addition of nitric acid. Lime may be detected by means of oxalate of ammonia. The quantity of magnesia in urine is so small that it is scarcely possible to detect its presence by re-agents. But if a quantity of healthy urine be left for two or three weeks in a cylindrical glass vessel, the mouth of which is covered with paper, and then be poured out, we shall find attached to the sides of the glass a number of small transparent crystals consisting of four-sided prisms with square bases. These crystals constitute a double salt composed of

One atom phosphate of ammonia 6.625

One atom phosphate of magnesia 7

The formation of these crystals proves evidently that magnesia exists in urine, though only in minute quantity. Urine also contains potash, soda, and ammonia; the last of which may be detected by the smell, if we add caustic potash to urine concentrated by evaporation over sulphuric acid in the vacuum of an air-pump. If we continue this evaporation nearly to dryness, crystals of sulphate of potash and sulphate of soda make their appearance in it, proving that both potash and soda enter into the constitution of urine. The following table exhibits the constituents of healthy urine according to Berzelius's analysis, which is the latest that we have.

|  |         |
|--|---------|
| Water .....  | 93.300  |
| Urea .....   | 3.010   |
| Uric acid .....  | 0.100   |
| Mucus .....  | 0.032   |
| Lactic acid, lactate of ammonia,<br>&c.* .....                 | 1.714   |
| Sulphate of potash .....                                       | 0.371   |
| Sulphate of soda .....   | 0.316   |
| Phosphate of soda .....  | 0.294   |
| Phosphate of ammonia .....                                     | 0.165   |

Besides these substances, which form constant ingredients of healthy urine, this liquid in different diseases has been found to contain albumen, fibrin, and red globules of the blood; nitric acid, purpuric acid, oxalic acid, carbonic acid, benzoic acid; cystic oxide, sugar, bile, pus, and doubtless also xanthic oxide, though

\* The writer of this article has in vain endeavoured to ascertain the presence of these bodies in urine.

that has not yet been ascertained by observation.

Of these different constituents of urine there are only two that it will be requisite to describe particularly in this place. These are urea and uric acid.

Urea, when pure, is a transparent colourless substance, having a pearly lustre and crystallizing in four-sided prisms. Its taste is feeble; but it leaves a sensible coldness on the tongue like nitre. Its smell is slight, but peculiar, and quite different from that of urine. When exposed to damp air it deliquesces, but does not seem to be decomposed. The specific gravity of its crystals, as determined by Dr. Prout, is 1.350. At 60° water dissolves more than its own weight of it, and the solution may be exposed to the air without undergoing any change, provided it be pure; but if it be contaminated with the smallest quantity of foreign matter, it is speedily converted into carbonate of ammonia. Boiling water dissolves any quantity of it whatever. Alcohol of 0.816 dissolves at 60° about the fifth part of its weight of it, and at a boiling heat more than its own weight; but when the liquid cools, the excess of urea separates in crystals. When mixed with the caustic alkalis or alkaline earths, and heated (provided water be present), it is decomposed and converted chiefly into carbonate of ammonia. A number of curious facts respecting the relation existing between urea and cyanogen have lately been discovered, which throw considerable light upon the occasional existence of prussic acid in urine,—a fact which seems to be pretty well established; but it would lead us too far from the subject of calculi to state them here.

Uric acid, when pure, is a white, tasteless substance, existing either in powder or in minute crystals, which seem to be four-sided prisms. It has no smell. According to Dr. Henry, it is soluble at 60° in 1720 parts of water; but Dr. Prout could not dissolve it in 10,000 times its weight of water.\* It dissolves readily in a solution of caustic potash or soda, from which it may again be precipitated in a white powder by the addition of almost any acid. It dissolves in nitric acid with effervescence, when assisted by heat. When the solution is gently concentrated, crystals of erythric acid form in it. When the liquid is evaporated to dryness, a beautiful pink sediment remains, which is a characteristic of this acid. On one occasion we have seen uric acid converted into urea by digestion in nitric acid. The

\* The probability is that both of these statements (incompatible as they may at first sight appear) are substantially correct. Dr. Henry probably digested uric acid in water of 60°, and evaporated a given weight of this water to dryness in a moderate heat, and weighed the uric acid remaining. Dr. Prout, on the other hand, digested one grain of uric acid in 10,000 grains of water without being able to dissolve it. The first experiment shows the quantity of uric acid which water can dissolve when the attraction of aggregation is destroyed; the second the power which water possesses to destroy this attraction of aggregation.

experiment was made by a surgeon who wished to determine the nature of a calculus which he had extracted. The result not being satisfactory, he brought both the calculus and the substance into which he had converted it, to the writer of this article. The calculus was the common uric acid calculus, mixed apparently with urate of ammonia. The substance into which it had been converted was urea. The surgeon could not give a satisfactory account of the process which he had followed, and we attempted in vain to repeat it successfully.

Uric acid combines with the different bases, and forms salts nearly insoluble. The urate of ammonia is the most soluble; it dissolves in about 480 times its weight of water, and the solution has the property of reddening vegetable blues. If we put a quantity of healthy urine under the exhausted receiver of an air-pump over sulphuric acid, and allow it to evaporate spontaneously, a sediment of urate of ammonia gradually attaches itself to the sides of the vessel in which the urine is. This seems to prove that in urine the uric acid is in the state of urate of ammonia.

Let us now take a view of the different urinary calculi, that we may see what light our knowledge of the urine will throw upon their formation.

1. *Uric acid calculi.*—The uric acid calculus is by far the most common of all, and to judge from the number of calculi which the writer of this article has had an opportunity of inspecting, at least two-thirds of the concretions formed in the kidney or urinary bladder owe their origin to the deposition of uric acid, either in a pure state, or combined with ammonia. As healthy urine contains urate of ammonia to the amount of about 1-813th part, and as this salt requires about 480 times its weight of water to dissolve it, we see at once that, if by any derangement in the digestive organs the quantity of urate of ammonia in urine should be tripled, a portion of it would of necessity be thrown down, as the urine would not be sufficient to hold the whole of it in solution: for the urate of ammonia would amount to 1-271st part of the urine; so that about three-eighths of it would precipitate. Calculi composed of urate of ammonia are always small, and seem nearly peculiar to children. They are undoubtedly to be ascribed to the existence of an excess of urate of ammonia in the urine, which is a very common consequence of indigestion, proceeding either from the use of an excessive quantity of food, or of food which does not agree with the constitution of the child.

Whenever a free acid makes its way into the urine, uric acid constantly precipitates, and may give origin to a calculus unless it be voided along with the urine. Now, as there is always a quantity of free muriatic acid in the stomach, and frequently also acetic acid, it is easy to see how these, when they become excessive, may make their way to the urine, and occasion a precipitation of uric acid.

It is probable that most of these calculi have

their origin in the kidney, from which they are not displaced till they have gained some size; for if either urate of ammonia or uric acid were to be precipitated in the bladder, as they would be in the state of a powder or of minute crystal, they would probably be voided along with the urine. But, after a nucleus has lodged in the bladder, it is easy to see how it increases in size; because the uric acid, &c. as precipitated, is deposited on its surface, and adheres to it.

Calculi composed of uric acid are generally of a brownish red or fawn colour, but occasionally approaching to the colour of mahogany. The surface is often smooth, but not unfrequently finely tuberculated. This kind of calculus is usually composed of concentric laminæ. Its fracture generally presents an imperfect crystalline texture, but sometimes an earthy one; in which case its colour is lighter, and it usually contains a mixture of urate of ammonia.

Before the blow-pipe this calculus blackens, emits a smoke having a peculiar colour, and is gradually consumed, leaving a minute quantity of white ash, which is generally alkaline. It is completely soluble in caustic potash, and precipitated again by any acid in the form of a white granular powder. When a fragment of it is mixed with nitric acid, and heated on a watch-glass, it dissolves with effervescence; and if the solution be evaporated to dryness, the residue assumes a beautiful pink colour.

This is by far the most common species of calculus. The number of calculi composed of uric acid alone, or only slightly mixed with other bodies, in the collection of Dr. Hunter deposited in the Hunterian Museum belonging to the University of Glasgow, amounts to ninety-eight. Of these sixty-seven are tuberculated on the surface. The largest of them measures three inches in length, and weighs 2340 grains. Another weighs 1817 grains. Most of them are composed of concentric laminæ, chiefly distinguishable by difference of colour, and in the density or looseness of texture. Some of them contain a small compact nucleus of uric acid; others not.

The uric acid calculi, quite smooth on the surface in the same collection, amount to twenty-three. No other difference between these and the tuberculated calculi can be pointed out, except the appearance of the surface. Several of them are crystallized, and they consist of laminæ like the others. In some of the internal laminæ, tubercles can be distinctly recognised.

There are eight uric acid calculi in the collection, of a much whiter colour and more chalky texture than the others. Probably they contain urate of soda. One of these contains a piece of bright iron as a nucleus.\*

Calculi of urate of ammonia are so rare that their existence has been denied altogether. There is not one of them in the collection of calculi in the Hunterian Museum belonging to

\* Most of these calculi have been varnished. This is the reason why the iron has remained bright.

the University of Glasgow; but the writer of this article has had an opportunity of inspecting and subjecting to a chemical analysis a considerable number of such calculi. The late Dr. Monteath, surgeon in Glasgow, had a high reputation as an operator for the stone. He had preserved all the calculi which he had extracted, and among them there were no fewer than seven consisting of urate of ammonia. Most of them had been extracted from infants between the ages of two years eleven months, and nine years, though one was from a man of forty. It was dark-coloured, and in layers, and about the size of a wren's egg.

They were all small, but sufficiently large to be subjected to analysis without any great diminution of their size. The diameter of the largest was one inch and five-eighths.

Urate of ammonia calculi have a clay colour; the surface is in most cases smooth, but sometimes tuberculated. The stone is composed of concentric layers, and the fracture is very fine earthy. Before the blow-pipe it usually decrepitates strongly. It is much more soluble in water than uric acid calculus,\* and when heated with caustic potash gives out a strong smell of ammonia. Liquid carbonate of potash or soda readily dissolves the urate of ammonia calculi, although they are incapable of dissolving uric acid calculi. The reason of this is, that a double decomposition takes place; the carbonic acid and ammonia unite together, and make their escape, while the caustic alkali combines with the uric acid. Two of these calculi consisted of urate of ammonia alone; two had a nucleus of uric acid, while the external part was urate of ammonia; and three were mixtures of uric acid and urate of ammonia.

Urate of ammonia calculi are certainly rare. They seem to be mostly confined to infants, or at least to persons under puberty. They occasion a degree of irritation in the patient scarcely credible. The opening or shutting of a door, or the least noise or motion, produces a paroxysm of the most distressing kind.

Uric acid exists very frequently as the nucleus of a calculus, the greatest part of which consists of other ingredients; showing clearly to what cause the origin of the disease must be ascribed.

2. *Mulberry or oxalate of lime calculi.*—Next to the uric acid, we conceive that the oxalate of lime constitutes most frequently the nucleus of urinary calculi. This calculus is usually of a dark brown colour, approaching to that of dried blood. Its surface is very rough and tuberculated. It is usually hard and compact, and, when cut through, exhibits an imperfectly laminated texture. Mulberry calculi commonly approach the spherical form, and are never very large. The diameter of the largest in the Hunterian collection belonging

to the University of Glasgow, is two inches. It weighs 1323 grains. Before the blow-pipe this calculus expands into a kind of white efflorescence, which, when moistened and brought in contact with turmeric paper, stains it red, owing to the lime being deprived of its acid, and rendered caustic by the heat. When pounded, it dissolves slowly in muriatic or nitric acid; and the oxalate of lime may be again thrown down by ammonia.

There is a variety of this calculus called *hemp-seed calculus*, from some resemblance which it bears in colour and lustre to hemp-seed. It is remarkably smooth and pale-coloured, and always of a small size. A number of these hemp-seed calculi usually exist in the bladder at once.

As oxalic acid is not a constituent of healthy urine, it is not easy to conceive to what alteration in the blood or in the functions of the kidney its formation is owing. Probably the appearance of this acid is the consequence of the mode of living. From a paper by Mr. R. Smith, of Bristol, entitled *A statistical Inquiry into the Frequency of Stone in the Bladder in Great Britain and Ireland*, it appears, that in the collection of calculi belonging to the Bristol Infirmary, amounting to two hundred and eighteen specimens, about five-twelfths, or almost one-half are either composed entirely of oxalate of lime, or contain at least a nucleus of that substance. Of the one hundred and eighty-seven calculi belonging to different practitioners in Manchester, described by Dr. Henry, about one-fourth are either composed of oxalate of lime, or contain it as a nucleus. In Dr. Hunter's collection belonging to the University of Glasgow, the number of calculi composed altogether of oxalate of lime amounts to only two. But those which contain a nucleus of oxalate of lime amount to fifteen. Of these, ten contain a nucleus of oxalate of lime, while the outer lamina is uric acid. Five have a nucleus of oxalate of lime, while the outer crust is triple phosphate. In three of the five there are three laminae; 1. a nucleus of oxalate of lime; 2. a thick lamina of phosphate of lime; 3. a thin crust of triple phosphate.

We can draw no conclusion from their numbers, because Dr. Hunter has left no documents by which the localities from which he procured his calculi can be authenticated. As he did not himself practise as a surgeon, it is obvious that his collection must have been made by presents from other persons; and being a great favourite with his pupils, who were settled in almost every district of Britain, it is probable that he drew his supplies indiscriminately from the whole island.

3. *Phosphate of lime calculus.*—This calculus is generally of a pale brown colour, and its surface is smooth like porcelain, so as to appear highly polished. It is very regularly laminated. The laminae are usually thick and very easily separated from each other. The shape is mostly oval, and the size is sometimes very considerable. We have seen one taken out of the bladder, after death, of such a size that it must have

\* It is not unlikely that the calculus originally examined by Scheele was composed of urate of ammonia. This would account for its solubility, which he found much greater than that of uric acid calculi ever is.

nearly filled it. It does not fuse before the blow-pipe. It dissolves readily in muriatic acid, without effervescence, and is precipitated undecomposed by caustic ammonia.

Judging from the statements of Mr. Brande, Dr. Mareet, Dr. Henry, and Mr. Smith, who have described the constitution of no fewer than 823 calculi, this calculus in a pure state is exceedingly rare, and generally of a small size. The number of calculi composed entirely of phosphate of lime, in Dr. Hunter's collection, is 43. The largest is 2·8 inches in length; but it is not certain that it was from a human bladder. It weighs 2142 grains. The finest of these calculi is composed of five laminæ, easily separable, and quite smooth and polished on the surface.

There are 11 calculi in the same collection composed chiefly of phosphate of lime, but the outermost coat of which is the triple phosphate. Thus the whole phosphate of lime calculi in this collection amount to 54, which approaches to one-fourth of the whole. But we are not certain that some of these may not have been from some of the inferior animals. The number containing a nucleus of phosphate of lime and an external coating of the triple phosphates is small, not amounting to a tenth part of the collection. There is not a single calculus in which a nucleus of phosphate of lime is followed by a lamina of uric acid or oxalate of lime.

As phosphate of lime (or at least *biphosphate of lime*) exists in urine, though in exceedingly minute quantity, there is no difficulty in conceiving how it might be deposited. Whatever has the property of rendering the urine alkaline, will of necessity precipitate phosphate of lime from it. For example, if the nature of the urea were so much changed that it should be converted into carbonate of ammonia, which happens out of the body whenever it is heated in contact with potash or soda and water, it is obvious that phosphate of lime would be thrown down.

4. *Ammonia-phosphate of magnesia calculi.* These are always nearly white. The surface is commonly uneven, and covered with minute shining crystals. The texture is not at all, or very imperfectly laminated. This calculus is soft, and easily broken and reduced to powder. But it is said sometimes to be hard and compact, and when broken, exhibits a crystallized texture, and is somewhat transparent. There is a remarkable calculus of this kind in the Hunterian Museum, belonging to the University of Glasgow. It was taken from the bladder after death, which it completely filled. It was sent to the museum by Dr. King, of Irvine. It is an oval stone, constituting a pretty exact cast of the bladder. Near the centre it is a little smaller, indicating a stricture of the bladder in that place. The length of this stone is five inches and a half. Its circumference where thickest is fourteen inches and one-sixteenth; but at the stricture only ten inches. Its weight is one pound fourteen ounces and eight grains avoirdupois. It is white and crystallized on the surface, bearing some resemblance to agalmatolite. It is composed of a nucleus of uric acid, having a brown colour, and composed of many concen-

tric laminæ. The external crust is ammonia-phosphate of magnesia, mixed with some animal matter. This calculus is the largest which the writer of this article has ever seen. Before the blow-pipe this calculus gives off the odour of ammonia, and at length melts with difficulty. It gives out ammonia when treated with caustic potash, and is very easily dissolved by very dilute acids.

It is a rare thing to meet with a calculus composed entirely of ammonia-phosphate of magnesia. In the Hunterian collection belonging to the College of Glasgow, which consists of 225 urinary calculi and about 75 intestinal calculi, biliary calculi, and calculi belonging to inferior animals, there is not a single specimen of this calculus in a state of purity. But mixed with phosphate of lime it is by no means uncommon, and then constitutes what Dr. Wollaston called *fusible calculus*. It is usually white and friable, somewhat like a mass of chalk. It is sometimes very large. It fuses very easily before the blow-pipe, and dissolves with great ease in dilute muriatic acid. There are fourteen such calculi in the Hunterian collection. The largest is three-fifths of an inch in length, and weighs 1758 grains. One of these calculi contains a piece of lead about the size of a crow-quill, and more than an inch long, which had served as a nucleus. A second has a nucleus of tin. Besides these fourteen composed entirely of the mixture of the two phosphates, there are seventeen calculi in the same collection having a nucleus of phosphate of lime, but whose external coat is the fusible calculus. It is curious that this external coat, which is usually much more abundant than the nucleus, is not concentric with it. The internal nucleus with which the calculus has obviously originated is frequently within a quarter of an inch of the outside of the calculus on one side, and more than an inch from it at the other side. It is obvious from this, that the accumulation of the fusible part of the calculus must have been very rapid.

As biphosphate of magnesia exists in urine, and as it becomes insoluble whenever the second atom of acid is saturated with ammonia, we can easily see that there ought to be a deposit of ammonia-phosphate of magnesia whenever the urine becomes charged with ammonia. Ammoniacal urine usually indicates a broken constitution; and it is remarkable that in such urine the quantity of earthy phosphates always increases enormously. Hence it happens that the fusible calculus frequently forms the outermost coat of large calculi, and that whatever may have been the original state of the urine when the calculous deposits began to be formed, it ultimately terminates, unless the irritating cause be removed, in the urine becoming alkaline, and the consequent deposition of the fusible calculous matter. Perhaps this may be owing in some cases to improper medical treatment; for Dr. Prout mentions calculi which he had examined, the outer crust of which consisted of urate of soda. In such cases the patient seems to have been subjected to a course of alkaline medicines till the urine was impregnated with

an excess of soda. This occasioned the deposition of urate of soda, and would ultimately have led to the deposition of the triple earthy phosphates, and probably to the increase of their quantity.

5. *Carbonate of lime calculi*.—These calculi are not very rare in the inferior animals, though they are very uncommon in man. Mr. Smith describes some which he had met with that bore a close resemblance to the mulberry calculi, and yet consisted of carbonate of lime.\* Dr. Prout mentions some small calculi which he had seen composed almost entirely of carbonate of lime. They were perfectly white and very friable.† In Dr. Montearth's collection, mentioned before, there was a small calculus, which had been extracted from a man in the 26th year of his age. It was white, but not friable, nor did it stain the fingers: it was composed of nearly one part of carbonate of lime and two parts of phosphate of lime. There was a very small internal nucleus composed of bright crystals, having the aspect of ammonia-phosphate of magnesia. This is the only calculus that we have seen having a nucleus of ammonia-phosphate, and the outer crust of which consisted of other constituents. Yet as the whole calculus was calcareous, it can hardly be considered as an exception from the general rule.

The carbonate of lime calculus is easily detected by the property which it has of dissolving in muriatic acid with effervescence, and the neutral solution is abundantly precipitated by oxalate of ammonia.

6. *Cystic oxide calculi*.—This calculus has a yellowish white colour, and its surface, which is commonly smooth, exhibits a kind of crystallized appearance. It is not composed of distinct lamina, but appears as one mass, confusedly crystallized throughout its substance. The fracture exhibits a peculiar glistening lustre, like that of a body having a high refractive density. When in small fragments it is semi-transparent. This calculus is very rare, only four or five specimens having yet been recognized. When treated by the blow-pipe, it gives out a peculiar and characteristic odour. It is very easily dissolved both in acids and alkalis, and crystallizes with both.

7. *Xanthic oxide calculi*.—Of this very rare calculus only a single example has been hitherto observed. It was given to Dr. Marcet by Dr. Babington, who had it from one of his patients; but nothing farther is known respecting its history. It had an oblong spherical shape, and weighed about eight grains. Its texture is compact, hard, and laminated; surface smooth, colour cinnamon brown, and much heightened by adding caustic alkali to the calculus in powder. Before the blow-pipe it splits in pieces, burns black, and is consumed, leaving a minute particle of white ash. When distilled it yields a fetid ammoniaical liquid, from which carbonate of ammonia crystallizes. It is mostly soluble in boiling water when in fine powder, and the solution reddens vegetable blues. On

cooling, the greatest part again subsides in white flocks. It dissolves both in acids and alkalis, though much more readily in the latter than the former. When its solution in nitric acid is evaporated to dryness, the residue has a bright lemon yellow colour. This residue is partly soluble in water, to which it communicates its colour. Thence the reason of the name xanthic oxide, by which Dr. Marcet distinguished it. It is insoluble in alcohol, ether, and oxalic acid, and very sparingly soluble in acetic acid.\*

8. *Alternating calculus*.—This, as the name imports, may consist of different layers of any of the preceding species. Hence its appearance may be very varied. The nucleus is usually uric acid or oxalate of lime; and the outermost crust is not unfrequently composed of triple phosphate. We have in the preceding account stated the different alternations, and the order in which they occur in the calculi belonging to the Hunterian collection in the College of Glasgow. There was an alternating calculus in the late Dr. Montearth's collection, which deserves to be noticed. It was oblong, being 1.75 inches long, and 1.375 inches broad where widest. It was composed of three distinct substances. The nucleus was oxalate of lime, not however pure, but mixed with a little phosphate of lime, and with distinct traces of uric acid. The second layer was composed of uric acid mixed with some phosphate of lime. The outermost coat consisted of phosphate of lime mixed with a little uric acid. This outermost coat was divided into three distinct layers, each of them composed of the same materials. This calculus was not only composed of alternating coats, but each coat was a mixture of two or more constituents. Indeed, this mixture of different ingredients in the same coat is a very frequent occurrence in calculi. The most common mixture is that of urate of ammonia with the phosphates. In such cases the urine was undoubtedly alkaline; and such a state, when it continues, is very apt to occasion a redundancy of earthy phosphates, which of course would be neutralized and precipitated by the alkali present. This alkali, it may be presumed, is most commonly ammonia.

9. *Fibrinous calculus*.—This calculus was sent to Dr. Marcet by Sir Astley Cooper. It was about the size of a pea, and had a yellowish brown colour, somewhat resembling that of bees'-wax. Its surface was uneven, but not rough to the touch: its texture rather fibrous than stratified, and the fibres seemed to radiate from the centre. When heated it took fire, swelled out, and burnt like an animal matter. It was insoluble in water and muriatic acid; but it formed a soapy solution when boiled with caustic alkali, from which it was precipitated by muriatic acid. Nitric acid dissolved it with difficulty. When boiled in very dilute acetic acid, it swelled to a great size, and was at last dissolved; and prussiate of potash, when added to the solution, threw down a yellow precipitate. These characters lead to the con-

\* Med. Chirurg. Trans. xi. 14.

† Prout's Inquiry, p. 93.

\* Marcet's Essay on the Chemical History and Medical Treatment of Calculous Disorders, p. 95.

clusion, that the calculus in question was composed of *fibrin*.\* This kind of calculus is very rare, having been observed only in the case of a gentleman between fifty and fifty-five years of age, who passed in succession three such calculi.

Such is the nature of the different calculi to which the urinary organs of man are liable. The mulberry calculi are the most difficult of explanation, as they consist of a salt which does not exist in healthy urine at all; yet they are not uncommon, the mulberry calculi in Dr. Hunter's collection amounting to one-thirteenth of the whole. But by far the most common calculus is the uric acid one. They amount, in the collection of Dr. Hunter, to five-elevenths of the whole; and they are still more numerous in the collections which have been described by others. In Dr. Monteat's collection, which consisted of about thirty calculi, all of which he had extracted himself, no fewer than ten-thirteenths, or rather more than three-fourths of the whole, consisted of uric acid or urate of ammonia.

There is reason to believe that, when uric acid is deposited, the urine is *acid*; a state which is very apt to follow indigestion, or excess in eating and drinking.

The phosphate of lime calculi are generally considered as rare, and it is supposed that they are always small in size. If any conclusion can be drawn from the number in Dr. Hunter's collection of calculi, they amount to very nearly one-fourth of the whole. Some of them are very large; but as there is no catalogue nor history accompanying this collection, we cannot be sure that some of them are not from the inferior animals. Yet, as the calculi of the inferior animals are in this collection arranged in a separate drawer, it seems to follow that all the calculi in this part of the collection were considered by Dr. Hunter as human calculi.

The fusible calculi usually indicate a broken constitution. Hence this matter commonly constitutes the last coat of those calculi that have been long in the bladder, and which have been taken out after death. The calculi belonging to this class in Dr. Hunter's collection amount to nearly one-seventh of the whole. But if we take the phosphate of lime and the fusible calculi together, they constitute two-fifths of the collection. Probably they may be nearly as numerous as the uric acid calculi; but as patients afflicted with them frequently die, many of them are not extracted at all, and thus the number appears much less than it ought to do; whereas the uric acid being a deposit which is apt to be formed in a state of comparative health, the operation is much more frequently had recourse to, and of course their numbers appear much more formidable than those of the phosphates.

(*Thomas Thomson.*)

**CALCULUS.** (PATHOLOGY AND TREATMENT.)—The calculi which are found within the urinary organs are, of all those enumerated

in the preceding article, the most important to the practitioner, and they have long attracted a large share of attention from medical men.

Urinary calculi are formed by the diseased action of the vessels which secrete the urine, or by a deposition from urine in a morbid state. They are also formed by the mucous membrane of the bladder, which sometimes secretes an altered fluid abounding in phosphate of lime; just as many of the concretions enumerated take place in other mucous cavities.

In considering the formation of urinary calculi, there are certain chemical facts which require to be stated before we can explain how precipitations from the urine occur. When any acid, even the carbonic, is added to healthy urine, a precipitation of lithic acid after a short time takes place; the acid thus added seizing upon the small proportion of ammonia in combination with the lithic acid, and by means of which it was held in solution.\* Thus we see how the presence of any uncombined acid in the urine will produce a lithic deposit, and give rise to calculous disease, or augment a calculus already in existence. The acid which seems most commonly to be the primary cause of lithic deposits, is the muriatic, and its source the stomach, where it abounds in most cases of indigestion.

On the other hand, by adding ammonia to healthy urine, a precipitate is produced, consisting partly of phosphate of lime, and partly of triple phosphate of ammonia and magnesia: part of the alkali uniting with the excess of phosphoric acid, which held the lime in solution, while another portion combines with the phosphate of magnesia, and forms a salt of very sparing solubility. Hence we perceive the connection which exists between ammoniacal urine and the deposition of the phosphates. The ammonia, thus performing so important a part in calculous disease, seems to be chiefly derived from the decomposition of urea, which is effected readily by the presence of the fixed alkalis and alkaline earths, and by various other substances. These remarks will serve to explain in what way precipitations from the urine do take place independent of a morbid excess of lithic acid, or of lime and magnesia; but it is by no means to be inferred that the excess of these constituents of urine is not respectively the immediate cause of a great majority of calculous cases.

When a calculous nucleus has been formed, if it do not escape by the natural outlet, it will receive from the urine by which it is washed, successive additions of solid matter. It does not appear, however, that in all such cases there is a continual increase of the stone; for we often find it to consist of many distinct concentric laminae, varying in thickness, and sometimes also in composition. It is, besides, obvious that the occurrence of a deposit will depend on the condition of the urine, which may

\* Marcet's Essay, &c. p. 101.

\* Dr. Prout on Diseases of the Urinary Organs. Second Edition, p. 12.

be, and frequently is, so healthy, that it lets fall no concreting matter. Calculi have been known to exist in the bladder for many years, yet without acquiring an extraordinary size, which they must have done had a continual increase been taking place. The mechanical process of the formation of calculi is sufficiently demonstrated by dividing them accurately through the centre; thus exhibiting their nucleus and the successive layers of which very many of them are composed. The nucleus is either itself a concrete formed by the kidney, in two cases out of three lithic acid, or some extraneous body which has found its way into the urinary cavities. The most common of such foreign bodies is a clot of blood; at other times the nucleus has been a fragment of a hougie, a small hair, a portion of lint introduced through the wound in lithotomy, a bit of straw, a musket-ball, a pin, a bodkin, and even a filbert. By such dissections of calculi we are enabled to trace out with accuracy the history of their formation, to mark the changes which the constitution of the urine underwent during the progress of the disease, and to satisfy ourselves that considerable intervals must have occasionally existed between the successive deposits.

Urinary calculi vary exceedingly in their size, form, and tenacity. Some calculi do not equal a millet-seed in size, while others have been found so large as to fill up the entire cavity of the bladder. Mr. Earle has described a very large stone which had been extracted, but with a fatal result, by the celebrated Cheselden. Its weight was  $18\frac{1}{2}$  ounces, its circumference in the large axis was  $11\frac{1}{4}$  inches, in its short axis 10 inches. Dr. Charles Preston relates in the Philosophical Transactions, that he saw, at La Charité, in Paris, a stone which weighed 51 ounces. The patient died under the hands of the operator. Mr. Harmer, of Norwich, extracted from the bladder a stone which weighed 15 ounces, and had a diameter of  $4\frac{3}{4}$  inches by  $3\frac{1}{2}$ . The patient recovered, but a fistulous opening remained.\* In the case of Sir David Ogilvie, Mr. Cline performed the operation, but could not extract the stone.† After death it was found to measure 16 inches in its longest diameter, and 14 in its shortest, and to weigh 44 ounces. The Breslau collection contains an account of a stone found in the bladder after death, which weighed 72 ounces.‡ Kesselning relates that he saw, in Moraud's Museum at Paris, a stone which weighed 6 pounds 3 ounces; and the model of another which was still larger.§

By far the largest calculus which we have ourselves seen is one presented to the Hunterian Museum at Glasgow, by Dr. King, of Irvine. It was taken after death from the body of a carter, who had for many years laboured under the disease. Its form is irregularly egg-shaped, with a slight constriction near the middle; its greatest circumference is  $14\frac{1}{4}$  inches, its shortest 10 inches. It has unfortunately

been broken, but is now so carefully cemented together by means of plaister of Paris, that its appearance is in no way injured. The weight of the calculus as it now lies, together with some fragments kept for examination, has been ascertained by Dr. Thomson to be 1 pound, 14 ounces, 8 grains avoirdupois. It consists of two substances: one resembling light brown indurated earth, and forming the great mass of the stone; the other, an incrustation of white closely crystallized matter, which envelopes all but one or two spots. The surface of this crystallized portion presents numerous short elevated lines and small indentations, corresponding apparently to the minute wrinkles of the mucous membrane with which it lay in contact.

Urinary calculi are usually spheroidal, and their surface is sometimes remarkably smooth, often covered with minute crystals, occasionally tuberculated, or beset with sharp projections. Calculi of the kidney, when of large size, sometimes present a complete cast of the dilated cavities of that gland, and have the appearance of corallines. When several stones are contained within a cyst or pouch, their surfaces become adapted to each other, and the whole often forms one globular cluster. Instances are recorded where calculi have occupied the neck of the bladder and prostatic portion of the urethra, moulding themselves to the form of the cavity, and allowing the urine to drain away by their sides,\* and several histories are to be met with of grooved† and even perforated calculi.‡ Many calculi are so hard that they cannot be penetrated without great difficulty, while others are so loosely agglutinated that the pressure of the forceps in extraction readily crushes them into a substance like mortar. In other cases the calculeous matter has never coalesced into a solid, but remains in a soft state, like newly mixed plaister of Paris.

In reference to the medical history of calculi, they may be conveniently divided according to the situation in which they are found; into renal, vesical, and urethral. A fourth description of calculus found in the genito-urinary organs is the prostatic; but there is reason for believing that it is not derived from the urine.

1. *Renal calculi*.—It is an observation as old as Fernelius, and it may be traced even higher, that all urinary calculi not formed on foreign bodies introduced into the bladder, originate in the kidney; and if we except phosphatic concretions, some of which appear to be formed in the bladder, the doctrine appears to be substantially correct. We will not attempt to describe in what exact mode a calculus is first formed in the kidney, nor is it likely that we shall even attain to more than a probable conjecture on this subject. As crystals of lithic acid have been found in the tubuli uriniferi, and even in the cortical part

of the kidney,\* there is good reason to believe that in many instances the material of calculus concretes almost at the moment of its secretion. If such solid granules be retained within the channels of the kidney, it is obvious that they must become the centres of attraction for other particles of concreting matter to arrange themselves around; and as they increase in size, they will serve, by their irritation, to derange the actions of the organs in which they are detained, and thus occasion the secretion of a morbid fluid, abounding in the materials of calculous concretions. Many dissections have shewn the great size to which renal calculi may attain, and the extraordinary tenuity to which the secreting organ which surrounds them may be reduced; and that too in some cases without destroying its secretory function. A remarkable instance of such a calculus occurred in the person of a natural daughter of Sir Richard Steele. No nephritic symptom took place until shortly before her death, when severe pain was felt in the region of the right kidney, fever followed, and speedily proved fatal. A calculus of oxalate of lime, weighing  $7\frac{1}{2}$  ounces, was found in the right kidney, which was so thinned by absorption as to be reduced to a mere membrane. In this instance the stone could be felt during life through the loins, inducing the belief that the kidney had become ossified.† Mr. Cline used to mention in his lectures that he had been able to detect the presence of calculus in the kidney in a very thin person. But such are extreme cases; and many instances are recorded, where, although renal calculus had been long in existence, no disease of the kidney was suspected during the lifetime of the patient. The symptoms are in general obscure, and rarely enable us to ascertain satisfactorily the presence of stone in the kidney. Among these may be enumerated, a feeling of weight and dull aching in the loins; sharp pricking sensations in the region of the kidney; obstinate pain, in some instances, at the scrobiculus cordis; frequent fits of vomiting; bloody urine, especially after exercise which shakes the body; numbness, cramp, pain, or œdema of the corresponding thigh; and, finally, occasional attacks of inflammation of the kidney. Attacks of this nature sometimes destroy the patient by their violence, but much more frequently end in the discharge of pus from the kidney, which escapes by the natural passages; while the patient gradually wastes away, and after much suffering from inflammation, or perhaps ulceration of the bladder, at length dies exhausted. It is from this propagation of disease to the bladder that frequent painful micturition comes to be a symptom of calculus of the kidney. In some rare instances the inflammation has produced thickening of the surrounding parts, and led to the formation of abscesses, which have presented in the loins and formed fistulæ, giving issue to the urine, and

occasionally to small calculi. Cases are recorded in several of the older authors, where stones of considerable size were extracted by the incision of such fistulæ. Hence surgeons have been emboldened to propose and sometimes to perform the operation named nephrotomy, for the removal of renal calculi; but no distinctly detailed and well authenticated case has come to our knowledge, where, without the previous existence of abscess of the loins, a calculus has been successfully removed by this operation.\* Nor is it likely that the pelvis of the kidney could be safely approached with the knife without the previous security of that matting of the parts which must occur before an abscess can make its way to the surface of the loins. When a stone has been formed in the kidney, its weight, and the current of the urine which is constantly passing off, naturally tend to carry it down through the ureter; but it may be detained by the deep situation in which it has concentered, or by some prominent points of crystal, which serve to fasten it to the soft surface on which it lies; or, after it is loose, its size may be such as to prevent it from entering the ureter. In some instances the calculus has lain in the orifice of that tube, and remained there as a plug, allowing the urine in part to escape, yet keeping, at the same time, the pelvis and infundibula generally distended, and in this manner dilating these cavities gradually to a great extent; causing absorption of the substance of the kidney, and reducing it at length to a mere capsule, having many cells communicating one with another. When the distended and attenuated kidney is seized with inflammation, pus is formed, the interior receives a lining of albumen, and the gland becomes like the cyst of a large chronic abscess. When the stone is very small, it occasionally passes along the ureter without producing any sensible effect; but in general the system feels the influence of the unwonted impressions which it induces. The patient is usually seized with nausea and vomiting; a feeling of alarm takes place, with cold chills and smart shivering; pain, often agonizing, shoots from the loins down to the fold of the thigh, and thence along the limb. The pain is usually felt on the inside of the thigh; but in the recent instance of a lady who passed an irregular pea-like calculus of oxalate of lime, the pain stretched from the loin, by the crest of the ilium, along the outside of the limb. In men, the passage of a calculus along the ureter is generally marked by the retraction of the corresponding testicle, and sometimes even by inflammation of that gland. It is remarkable that, amid all this commotion, the circulation is usually unaffected. The pulse is calm and regular, and the skin nearly of natural temperature; thus proving that the symptoms are occasioned by a powerful impression on the nerves, and are wholly independent of inflammatory disease. But here, as in other cases of strong nervous

\* *Wilson*, Lect. on the Urinary Organs, p. 213, 8vo. 1821.

† *Catal. Musæum R. Coll. of Surg. Lond.* Note by John Hunter.

\* See Mr. Hobson's relation of his own case. *Philos. Transact.* abridged, vol. iii.

impressions, inflammation will arise in consequence of this prolonged operation. Should the calculus be arrested in its progress down the ureter, all the symptoms become aggravated, inflammation in general speedily sets in, and, if not subdued, cuts off the patient. The greatest danger in such cases arises from the stone filling up the canal of the ureter, and obstructing entirely the passage of the urine; thus forcibly distending the cavities of the kidney, and inducing suppression of the secretion, which has been known to occur in both kidneys where only one of the ureters was obstructed.\* It might be supposed that the ureter would in some cases become so distended above the impacted stone as to burst; but if this ever occur, it is certainly an uncommon accident. Several circumstances render its occurrence unlikely; one of the first effects of the pressure of the confined urine is to act mechanically on the secreting organ, and diminish or altogether suspend its functions; absorption of the aqueous part of the fluid also takes place, which relieves the distension of the cavities; while fortunately the ureter is very dilatable, and its contents are not urged forward by the spasmodic action of powerful muscles, as when retention of urine arises from obstruction of the urethra. The ureter is well known to be capable of great dilatation, when the current of urine is obstructed; it has sometimes been found as large as the small intestine, and elongated so as to have a zigzag form. Cases have even been met with where the capacity of the ureter is said to have equalled that of the bladder. The consequences of suppression of urine and of its absorption are low delirium, coma, and death. (See *ISCHEMIA*.) A fatal result may also follow the retention of calculi in the ureter in a more gradual manner, by the occurrence of inflammation, ulceration of the ureter, and escape of the urine into the adjoining cellular tissue. In some rare cases of stone in the ureter, abscess has occurred, followed by fistula opening in the groin or lumbar region, and giving issue to the urine. Frank relates a case where a calculus was thus discharged from the left ureter. In many instances, although a calculus be detained in the ureter, its form is so irregular, or the relaxation of the tube is such, that the urine escapes by its sides, depositing new matter on its surface, and augmenting it far beyond the size capable of being transmitted along the ureter. The deposition of calculous matter under such circumstances is greatest above and below, thus giving the stone an oblong or cylindrical form. Sometimes one calculus only is found in the ureter; sometimes there are many smaller ones; and instances are recorded where its channel was found entirely filled up with gravel. A calculus has not unfrequently passed along the ureter until it reached the point where that tube pierces the coats of the bladder obliquely, and has there been arrested. Its extremity projecting into the bladder

has been felt by the sound, and lithotomy performed for its extraction, which, to the credit of surgery, has in more than one instance been successfully accomplished.\*

2. *Vesical calculus*.—If the calculus, happily, drop into the bladder, there is a cessation for a time of all urgent symptoms; and should its size permit, it is expelled through the urethra. In the female, where the urethra is short and easily dilated, the calculus is usually discharged; and hence the greater rarity of stone in the bladder among women. Even when the stone has rested in the female bladder, and grown to so great a size as to fill up and form a cast of the partially contracted organ, its pyramidal form has enabled it to pass by gradually dilating the urethra; and it has been expelled with throes resembling those of parturition. Calculi of extraordinary size are recorded, in the *Philosophical Transactions* and other publications, to have been discharged by females in this manner.

In males, the length and narrowness of the urethra, and the spasmodic action of the muscles which embrace it, render the expulsion of a calculus from the penis much more uncommon than its passage through the ureter. In very few cases is a calculus forced through the male urethra without considerable suffering, and sometimes an incision is required to relieve the patient. Retention of urine for a longer or shorter period usually occurs. In one instance, where the recent formation of a false passage prevented the introduction of a catheter, puncture of the bladder became necessary, and was successfully performed through the rectum; the small calculus being expelled when the congestion and irritation of the parts had subsided. Retention of urine in infants has not unfrequently arisen from calculus sticking in the urethra, or plugging up its internal orifice. The practitioner, therefore, ought to be aware of the possibility of such an occurrence, and have recourse to the necessary method of ascertaining and removing the obstruction. A curved probe will often suffice, or a slender gum catheter may be introduced, and the water drawn off. If relief be not speedily given, the bladder inflames, constitutional symptoms arise, and the little patient is soon carried off. Many instances are recorded in which symptoms of calculus existed from birth. A male child, mentioned by Mr. Wilson,† was unable, from his birth, to retain his urine; and, dying before he had completed seven months, a stone as large as a garden-pea was found in the bladder. Brendelius relates that two infants, one two days old, the other eight, passed calculi before death, and calculi were also found in their bladders.‡ Loescke found a calculus in the kidney of a new-born child.§ Fiseher relates that a boy, in his twelfth week, after suffering excruciating pains, passed a cal-

culus by the urethra as large as a date-stone.\* Hence we are warranted in believing that urinary calculi are sometimes formed during the fetal state.

Should the calculus be retained in the bladder, which in the male most commonly happens, it receives a gradual addition of substance, and becomes a source of greater and greater irritation. Although the existence of stone in the bladder cannot be fully ascertained without its being felt by an instrument introduced into that organ, yet there are many symptoms which, when they concur, afford strong presumptive evidence of the fact. When a calculus is loose in the bladder, it is liable to constant changes of position, which usually occasion sharp pain; and in evacuating the urine, the stone is apt to fall upon the internal orifice of the urethra, causing sudden stoppage and severe straining. After smart exercise or jolting of the body, the urine is generally mixed with blood, from the abrasion of the mucous membrane, which is loaded with red vessels, and resembles during life the richest vermilion-coloured velvet, as we have seen in a case of eversion through a vesico-vaginal fistula.

The appearance of blood in the urine would be much more frequent in cases of calculus, were it not for the protection afforded by an increased secretion of mucus, which acquires in this disease an unnatural degree of viscidness; thus enveloping the calculus, and shielding the tender surface of the bladder. A copious secretion of glairy mucus is a constant attendant on the advanced stages of calculus, and also on diseased prostate and other prolonged irritations of the bladder. It is to be observed that this mucus is seldom passed in a separate state, but generally diffused and suspended in the urine, from which it gradually subsides, and coalesces into a gelatinous viscid mass, which adheres to the bottom of the vessel, even when it is inverted. When this separation has taken place within the bladder, it is voided with difficulty, and often plugs up the urethra, and causes a temporary retention of urine. The colour of the mucus varies according to the degree of irritation and the length of time it has existed. From being clear it changes to grey, then to greenish yellow; and at length, when the mucous membrane has become extensively diseased, it is largely mixed with purulent matter. The character of the mucus is alkaline, even when the urine is decidedly acid; and it is justly considered as the source of many of those deposits and spongy concretions of phosphate of lime which are found in the bladder.

The agony of a fit of stone is generally known; consisting of excruciatingly painful efforts to expel the urine, during which the abdominal muscles, the diaphragm, the muscular coat of the bladder, and the levator ani are all in a state of strong spasmodic action, and alternate but brief relaxation. From time to time this straining forces out a few drops of

scalding urine, while part of the contents of the rectum are perhaps expelled at the same time, with eversion of the bowel; but from neither is the least alleviation of suffering obtained. A vivid and accurate picture of the miseries endured in a case of calculus is exhibited in a paper by Dr. Marcet, where the patient has described his own feelings;\* and if we are to give implicit credit to the histories of the blacksmith of Amsterdam† and the cooper of Königsberg,‡ who cut into their own bladders and extracted the stones, we shall have the strongest of all evidence that the sufferings from calculus are sometimes beyond human endurance.

The chief cause of all this agony seems to be the contact of the calculus with the sensitive internal surface of the neck of the bladder; at once irritating the parts to spasmodic contraction, and blocking up the passage of the urine; for the patient often finds that by reversing his posture, or perhaps resting on his head and shoulders, he obtains relief. The pain in the bladder shoots to the anus, the loins, down the limbs, and is felt in an especial manner at the extremity of the urethra, which causes boys affected with calculus to seize and pull at the penis. Hence elongation of the prepuce comes to be a symptom of stone, and the swelled and softened state of the little patient's fingers shows how often they are bedewed with urine. The ramifications of pain in a fit of stone are various and extensive, and in some cases reach even to the heel or sole of the foot; a fact which we have noted also in ulceration of the bladder. A reference to the multiplied connections of the lumbar plexus and the distribution of the great sciatic, the ultimate ramifications of which are sent to the sole of the foot, will serve to explain the great extent to which the pain of calculus shoots.

When a calculus is of great size, it is less liable to alter its position, and is therefore usually productive of less irritation; the excruciating pain is commonly exchanged for a distressing sense of weight at the neck of the bladder. Calculi occasion comparatively little uneasiness when they are supported by the moderate contraction of the bladder within its upper fundus behind the pubes, and when they get into fixed situations, as behind an enlarged prostate gland, or in cysts formed by the protrusion of the mucous membrane between the bundles of the overgrown muscular coat. This state of overgrowth of the muscular tunic of the bladder occurs in calculus, as in all diseases of that organ where frequent and long-continued but ineffectual efforts are made to expel the urine. Instances are occasionally met with when several, sometimes many stones are found separately lodged in such pouches in the same bladder; and preparations of this description are to be seen in most pathological collections. A stone, which had been distinctly felt by the sound, has sometimes been thrown into one of

\* *Med. Chirurg. Trans.* vol. x.

† *Tulpius. Obs. Med.* l. iv. c. 31.

‡ *Walther. Thes. Med. Chirurg. Obs. Cur.* p. 195, ob. 60.

\* *Haller. Disp. Chir.* t. iv. p. 79.

these cavities; thus an end has been put to the irritation, and it has eluded the examination of the sound, inducing the belief that there was no longer a calculus in the bladder. Both the formation of pouches in the bladder, and the enlargement of the prostate gland, are to be considered as consequences of the irritation of calculus; and they illustrate, in a striking manner, the operation of that conservative principle by which even the uncontrolled progress of disease produces changes which tend to the relief of the patient. A still more remarkable proof of the same fact is afforded by those cases where calculi have ulcerated through the coats of the bladder, and have been discharged from the body, sometimes through the walls of the hypogastrium, at others into the rectum, and in other instances into the vagina. Caumont and Deschamps relate cases of the first,\* and Johnstone of the second.† In Mr. Johnstone's case, the patient, after years of suffering from the usual symptoms of stone, at length discovered pieces of gravel in his stools, which Mr. Johnstone was confined were urinary concretions. From that time all the painful feelings ceased, and the patient recovered perfectly, without any fistula remaining. A female, who, at the age of twelve, got rid of a pretty large calculus by ulceration into the vagina, is now, after ten years, in good health, but still suffering under vesico-vaginal fistula.‡ It is probable that in such cases the stone had become imbedded in a pouch before ulceration commenced, otherwise it would have extended more widely over the internal surface, and proved fatal.

The occurrence of ulceration of the mucous membrane of the bladder is one of the last in the series of changes produced by calculus; and if the patient has withstood all the other exhausting circumstances of the disease, this seldom fails to put a period to his sufferings. In such prolonged cases the bladder after death exhibits various degrees of organic injury; the mucous membrane is extensively eroded, the ulceration sometimes reaching to the other coats of the bladder; or abscess has formed under its peritoneal covering. The internal surface is in many places lined with a layer of coagulated albumen, which is often encrusted with calculous matter. Such deposits appear never to fasten on the organized textures themselves, but on a layer of albumen which forms the medium of attachment between them. The urine is probably, in most cases, the source of this incrustation; but it may also be derived from the internal surface of the bladder, in the same way as earthy concretions are formed within the cavities of abscesses.

The effects of calculus in the bladder are not limited to that organ, but extend to the ureters and kidneys. The pressure of the urine, unable to escape by the urethra, dilates the ureters and cavities of the kidneys, and the latter often exhibit marks of inflammation, and

are sometimes found suppurated, or small deposits of pus are discovered under the peritoneal covering.

The long-continued irritation of a calculus in the bladder, or indeed within any of the urinary organs, produces a change in the constitution of the urine, which loses its acid character, begins to abound in the phosphates, and at length becomes ammoniacal. In undergoing this change, the urine first deposits the lithate of ammonia, then the ammoniaco-magnesian phosphate and the phosphate of lime. This morbid condition of the urine, termed the phosphatic diathesis, takes its rise under various other circumstances of impaired nervous energy of the kidneys and bladder, besides those connected with the wasting effects of protracted calculous disease. Thus injuries of the spinal cord; continued irritation of the urinary cavities from diseased prostate gland and strictures of the urethra; immoderate sexual indulgences; disordered health, and general irritability induced by excessive mental anxiety and fatigue; all have the effect of occasioning the phosphatic diathesis. Dr. Prout has satisfactorily shown that all varieties of calculus converge to this point, and ultimately end in the deposition of the phosphates. In proof of the correctness of this opinion it is sufficient to trace the progress of a long-continued calculous case, and to inspect the successive lamina of which urinary calculi of long standing are generally composed. The formation of the phosphatic diathesis affords a clear indication that the constitution is breaking down under the sufferings of the disease, and requires that the question of a surgical operation should be considered without delay.

3. *Urethral calculi.*—Calculi which have commenced their passage along the urethra may be detained in their way, and become imbedded in the side of the canal, where they will continue to receive new additions from the urine which washes over them. In this manner urethral calculi have occurred, and on many occasions they have attained a considerable magnitude. Their general situation is in the perineum, where they are found forming a hard prominent tumour. In some instances a single stone is contained in a cyst communicating with the urethra; in others there is a pouch filled with numerous small many-sided calculi, which have evidently lain closely packed together. On one occasion we witnessed the extraction of a stone from the perineum, which was as large as a pullet's egg, and consisted of two portions, one of them having its rounded extremity fitted into a cavity in the other. Mr. Sisley, in the *Philosophical Transactions*, gives an account of a calculus weighing five ounces two drams, which was expelled through a dilated urinary fistula at the upper part of the scrotum.\* In an instance which came under our own observation, eighteen stones, varying from the size of a mustard-seed to that of a horse-bean, many of them polyhedrons, were removed from a cyst forming a hard tumour

\* *Journal Générale de Méd.* t. 27, p. 353, &c.; an. 1806, No. 124.

† *Johnstone*, *Mem. Med. Soc. Lond.* iii. p. 536.

‡ *Etiol. Med. and Surg. Journ.* vol. xxi.

\* *Phil. Trans.* vol. xli. p. 351.

behind the scrotum, and communicating with the membranous portion of the urethra. The examination of one of these stones showed it to be composed chiefly of phosphate of lime deposited in concentric laminae, from which and the yellow polished surface which they almost all possessed, we were led to believe them of prostatic origin. The following is probably to be referred to the same source. A case of very large perineal calculus, supposed to be of twenty years' growth, is related in the *Philosophical Transactions*:\* a sharp angle of the stone was found to have penetrated the rectum. Its form was irregular, and it consisted of two parts, one jointed into the other.

The symptoms produced by calculi in the urethra, or in pouches communicating with it, are those of urinary irritation, and occasionally retention of urine; but they seldom attract much attention until the external tumour has become considerable.

4. *Prostatic calculi*.—Small calculi are frequently found within the ducts and in abscesses of the prostate gland: sometimes they are contained in one cavity, at others disseminated in separate cells through the thickened substance of the gland. Their surface is occasionally rough, more frequently smooth and of a porcelain-like polish—their colour yellow or light brown—their size varying from a mustard-seed to that of a hazel-nut. Their chemical composition, unlike that of urinary calculi, is always the same. It appears that they are produced by the mucous membrane of the prostatic ducts, or by the suppurating surfaces of abscesses of that gland; and are not secreted by the kidney, or deposited from the urine, and therefore cannot in strict propriety be termed urinary calculi. They may, however, readily become the nuclei of such stones, either from the urine having access to them while imbedded in the gland, or by their getting loose and escaping into the bladder. Prostatic calculi have often been found after death, where no symptom had indicated their presence; more frequently they cause some degree of irritation at the neck of the bladder, particularly when the urine is voided; and if any portion of such calculus project beyond the orifice of the duct or abscess, it will be felt by a sound entering the bladder. The instrument in these cases frequently forces the small stone deeper into the cavity, and thus prevents it from being touched by the sound in several subsequent examinations, however dexterously conducted. It appears probable, from some of the cases referred to under the head of urethral calculi, that those of the prostate, when accumulated in great numbers, or of large size, occasionally form tumours in the perineum, or penetrate into the rectum.

CAUSES OF URINARY CALCULUS.—The importance of acquiring a knowledge of the causes from which urinary calculi arise, must be apparent to every one who considers that it affords the only means by which we are enabled to pre-

vent the formation of this disease, the most painful in the catalogue of human maladies, and its recurrence after the sufferings and hazards of lithotomy. Calculus is more common in temperate than in warm or very cold climates: it is much more incident to early years than to any other period; and to old age more than to the prime of life. Among those beyond middle age, it occurs more frequently in persons of sedentary habits than in those who lead an active life; and in those who indulge in luxurious living much more than in the temperate and abstemious. Hence there has long been observed a marked connection between a calculous and a gouty tendency. But although the rich, the luxurious, and the indolent are at a certain age more prone to calculus than other classes, the poor and the destitute in early years enjoy no immunity from it; for the ill-fed and half-clothed children of the manufacturing and labouring population are frequently afflicted with stone. All authors who have written on this subject concur in stating, that females are greatly less subject to calculus than males, notwithstanding their more sedentary habits. The more temperate and regular modes of female life are less productive of the calculous tendency; and the absence of the prostate gland, and the short dilatable urethra of females, enable them much more readily to expel such calculi as have formed.

Much persevering research has been directed, by a succession of writers, to ascertain the comparative prevalence of calculus in different parts of the British islands, and among different classes of society. Ireland is still admitted to furnish very few instances of calculous disease; and there certainly are strong grounds for this opinion, although we have no doubt that the state of society in that island opposes many obstacles to the acquisition of a full knowledge of the facts on this subject. Scotland, which had been set down as affording a very small number of calculous cases, is now ascertained to have been quite underestimated.\* The large manufacturing town of Paisley appears, from the very accurate returns furnished by Dr. M'Kinlay,† to be almost as productive of calculous cases as Norwich itself, having yielded, in the ten years from 1820 to 1830, eighteen cases of lithotomy in a population of probably 42,000. Both Mr. Hutchinson and Dr. Yelloly‡ seem to us to have estimated the population of Paisley too low; but making allowance for this, and some abatement also for admitting into the enumeration private as well as hospital operations, it must be granted that calculus is of comparatively frequent occurrence in that town. In further support of this opinion, it appears, from information kindly furnished to us by Dr. M'Kinlay, that the number of cases of lithotomy between 1810 and 1820 was probably

\* *Mr. Hutchinson* in *Med. Chir. Trans.* vol. xvi.

† *Ibid.*

‡ *Dr. Yelloly* in *Phil. Trans.* 1830.

\* *Phil. Trans.* abridged, vol. iii.

greater than in the subsequent decade; and that, although no operation has occurred since his report, several cases of calculus in every respect favourable for lithotomy, are now (July 1831) known to exist in Paisley.

The comparative prevalence of urinary calculus in different parts of England has been elucidated by the inquiries of many able writers, from Dr. Dobson downwards. The number of hospital operations has been assumed by all of them as the basis of calculation; therefore the result must be considered as only a distant approximation to the truth; for the number of cases of lithotomy will not always preserve the same proportion to the real number of calculous cases, but will vary according to the dexterity, enterprise, and reputation of the surgeons of the place. Thus in Norwich, where distinguished operators have existed as far back as the beginning of the eighteenth century—witness the epitaph on the tomb of the ecclesiastic Havers—not a case of calculus can occur in the city or neighbourhood without being speedily detected, and probably operated on; while in many other districts, cases of stone are allowed to proceed for years unrelieved, and perhaps wholly unsuspected. The celebrity of an hospital surgeon, or his own exertions to obtain reputation, will often bring to him cases from very distant quarters, some of which may be assumed in calculation as belonging to the district where he resides. Frank\* tells us that, previous to the arrival of the celebrated Venetian lithotomist Pagola at Vienna, calculus was deemed rather uncommon in that metropolis, and only one or two operations were performed annually; but after the surgeons had acquired experience and dexterity from his example, the operation became frequent, and the cures numerous. He adds that calculus was believed to be very rare in Lithuania, until the establishment of the surgical clinic at Wilna; but that now the surgeons who are skilled in the art of sounding find the disease but too common.

Norwich appears to be more productive of calculous cases than any other part of Great Britain, yielding one hospital case of lithotomy for every 21,000 inhabitants. On the other hand, the city and county of Hereford appear to be wholly free from calculous disease: from 1775 till the date of Mr. Smith's statistical inquiry (1818), no patient suffering under calculus had applied at the Infirmary; and Mr. Smith could not learn that lithotomy had ever been performed within the bounds of the county,† which, it is worthy of remark, is noted for its cider, a beverage hitherto supposed to be favourable to the production of calculus. Thus we have the two extremes of the great prevalence, and the apparent non-existence of calculous disease, in different districts of England. It has been supposed that the diet of the inhabitants of Norfolk is a main cause of their liability to calculus—

a favourite article of food being hard boiled, ill fermented, greasy dumplings. These, no doubt, are likely to cause indigestion, and thus give rise to lithic acid deposits. To this it has been objected, that many cases of calculus occur in that district at so early an age that diet can have had no influence in their production: but the diet of the nurse is known uniformly to affect the infant at her breast.

Mr. A. C. Hutchinson has shewn in several able papers, that calculus is of particularly rare occurrence among seafaring people; and the hospital returns of the British army prove also that calculus is very seldom met with among our soldiers. The information which has been obtained by Dr. Yelloly respecting the armies of France and Russia, shews likewise that calculus is a rare disease among the military of those countries. In explanation of these facts, it ought to be remembered that none are admitted into either navy or army but the robust and active; and that their services are chiefly limited to that middle period of life when calculus is very rarely observed to originate among the labouring classes from whom soldiers and sailors are drawn. But, after taking this fairly into account, we are not disposed altogether to deny the greater immunity from calculus enjoyed by individuals of both land and sea forces; and we think that this serves to confirm, what other observations clearly shew, that a full supply of wholesome food, good clothing, active habits, and regular exercise, all tend to prevent the formation of calculus. The state of the digestion and of the cutaneous perspiration must be admitted to exert a powerful influence on the secretion of urine; for when the stomach habitually abounds with acid, the urine rarely fails to exhibit in excess a similar condition; and the perspiration influences, in a remarkable manner, the quantity of lithic acid contained in the urine, as the experiments of Dr. Wilson Philip have satisfactorily shewn.\* Probably free perspiration is a principal cause of the infrequency of calculus in warm climates. The connection between calculous disease and a dry and harsh state of the skin, or even scaly eruptions, has long been remarked. In the case of Horace Walpole, it was observed that a cutaneous eruption, to which he had been many years subject, yielded to the alkaline remedies which relieved his calculous symptoms.

The tendency to calculus appears in many instances to be hereditary, like the kindred disease of gout. Dr. Prout and Dr. Yelloly both relate remarkable facts in proof of this opinion; and we are inclined to ascribe to the hereditary nature of calculus a part, at least, of that extraordinary tendency to the disease which has long existed in certain districts. Hitherto we have been unable to discover those local peculiarities of soil and situation which favour the formation of calculus; but if we admit its hereditary nature, we have

\* *Frank, De Curand homin. morb. De Calculo.*

† *Medico.Chir. Trans. vol. ii. p. 20.*

\* *Wilson, on Urinary Gravel: 1792.*

obtained a key to some of those continued anomalies, which otherwise appear incapable of explanation. It is clear that, in a district where calculus is well understood, and lithotomy often successfully performed, a greater number of calculous individuals will be preserved to propagate their race, than in districts where the operation is most commonly fatal. And it is not beyond the range of probability that individuals who have come from distant quarters to some hospital of great repute, for the purpose of submitting to lithotomy, may settle in the city or its neighbourhood after the completion of their cure.

It has long been a popular opinion that hard waters are favourable to the production of calculus, and one of our latest and best writers on the subject expresses the same belief. The effects of such waters are diuretic and sometimes slightly purgative, and they are apt to disorder delicate stomachs; but it is very doubtful whether the earthy salts which they contain contribute in any more direct manner to the formation of calculus.

Injuries of the back have been remarked to produce a morbid condition of the urine, usually a change to an alkaline state; and cases of renal calculus have been distinctly traced to accidents of this nature; several very interesting examples of which have been related by Mr. Earle\* and Mr. Wilson.† Such injuries influence the function of the kidney in different ways. A general concussion of the spinal cord, or a blow on the spine in the region of the kidney, will enfeeble its powers by diminishing the nervous energy distributed to it, and thus induce a morbid condition of the urine: such injuries will also tend to weaken the expulsive powers of the bladder, and by preventing it from ever being completely emptied, lead to the decomposition of the urine, and hence to the deposition of the phosphates. A blow on the kidney itself is likely to prove a cause of calculous disease, by the immediate effects of the concussion deranging the action of the organ; and by small extravasations of blood, which cause irritation as foreign bodies, and furnish nuclei for future concretions. Although clots of blood have often been found in the centre of calculi, it is obvious that blood has very frequently been effused within the kidney, yet no calculus has followed; the blood being washed away before it had time to cause that irritation of the urinary organs which disorders the urine and occasions deposits. For it is in this manner that extraneous bodies introduced into the bladder become incrustated with calculous matter,—causing in the first instance by their irritation a derangement in the secretion of the kidney, and then furnishing a solid inorganic substance to which the deposit may attach itself. In such cases the deposit is almost uniformly composed of the phosphates, but instances are met with where it is formed of lithic acid; as an example of which, we

may mention a calculus in the museum of William Hunter, where this substance has formed a concretion, as large as a plum, around a fragment of iron.

Strictures of the urethra and enlargements of the prostate gland prove causes of calculus by the irritation which they produce on the urinary cavities, and by their subsequent effects on the general health, as well as by the obstruction which they present to the complete evacuation of the bladder.

*Treatment of calculus.*—In the treatment of calculous disease, several different and highly important objects demand the attention of the physician—to correct the calculous diathesis and prevent the formation of stone—to facilitate the expulsion of calculi when formed—to relieve the sufferings of the patient, and delay the progress of the disease—and to point out the period when a surgical operation offers the best means of relief.

When calculus has been observed in several members of the same family, or in successive generations, it is to be presumed that a strong tendency to the disease exists in their constitution; and precautions are therefore to be adopted against its development. For this purpose, active habits ought to be encouraged, and the digestion preserved in as vigorous a state as possible; the diet being nutritious, but not heavy or ascetic. A healthy state of the skin should be promoted by the use of the flesh-brush, by warm clothing, and occasional warm baths. Even a residence in a warmer climate during the early years of life may, under certain circumstances, be advisable. On the first appearance of anything unnatural in the urine, it ought to be carefully examined, for the purpose of adopting that plan of treatment which its chemical constitution requires.

The morbid states of the urine arrange themselves under the two great heads of the predominance of acid and the predominance of alkali or alkaline earths. The acid diathesis is chiefly prevalent in infancy, and at the commencement of the decline of life; and in the early stage of most calculous diseases. It may be truly said to be by far the slightest deviation of the two from the healthy condition of the urine; for the function of the kidney has been satisfactorily shewn to be an acidifying process; and the acid state of all healthy urine is proved by the change which it produces on litmus paper. The morbidly acid condition of the urine exists under various forms; from that in which lithic acid is deposited as a floeculent precipitate, or red gravel, to that where a calculus of lithic acid is receiving from day to day new additions of size. The urine in this diathesis, when first voided, is usually clear, not very plentiful, and is of a bright coppery colour. It occurs under circumstances apparently the most opposite—in the ill-lodged, half-starved, half-clothed child of the artisan or labourer, in connection with loose chalky stools, feeble digestion, and a pallid aspect,—as well as in the pampered plethoric adult, who enjoys the pleasures of a luxurious table and all the comforts of a modern house. The digestion of the latter indi-

\* London Med. Chir. Trans. vol. xi.

† Lectures on the Urinary Organs.

vidual is strong, but his stomach is overtaxed, and unable to accomplish the duty which is daily imposed on it: his countenance is florid, his frame robust, and his habit probably gouty. In both of these cases there is frequent acidity of the primæ viæ, but much greater in those of the luxurious liver than in the child: the difference, however, is more than compensated in the latter, by the harsh unhealthy state of the skin, which executes its function imperfectly, and leaves an additional task to be performed by the kidneys. Guided by these views, our first object in undertaking the cure of the child should be, to have him warmly clothed, comfortably lodged, and supplied with a nourishing diet, containing a moderate proportion of animal food. Excess in this article seems to dispose to the secretion of lithic acid. The medical treatment is to be commenced by a mild laxative of castor oil, or rhubarb and magnesia; and in many instances great benefit will be derived from small repeated doses of hydrarg. cum creta, or minute doses of calomel. After this, alkalies and tonics ought to be given for the purpose of correcting the acidity of the primæ viæ and of the urine, and of improving the powers of digestion. Rhubarb, gentian, calumba, and cinchona, may be enumerated as the best tonics; and of the fixed alkalies, potass is to be preferred to soda; for the lithate of potass is a very soluble salt, while the lithate of soda is so much the reverse, that it forms the *chalk-stones* of gout, and has been found by Dr. Prout to constitute occasionally a considerable portion of a urinary calculus. Although the fixed alkalies are usually employed, cases of the acid diathesis do occur, both in children and adults, where the stomach is enfeebled, and where ammonia will prove more beneficial. The volatile alkali has also the advantage of determining to the skin, which it is of great consequence to bring into a healthy state. This is the description of calculous cases which are so often met with in manufacturing districts, and which seem to have led Dr. Yelloly to suppose that there was a connection between the scrofulous and the calculous diathesis.

In the instances in which a calculous tendency is combined with fulness of habit, a mode of treatment in many respects the reverse of that now described becomes requisite. A spare regimen and more active habits ought to be recommended; blood should be taken by cupping from the loins, or from the arm by venesection. Calomel should be given freely over night, and followed next morning by rhubarb with magnesia, or Rochelle salts. The cure is to be completed and confirmed by the employment of alkalies and bitters, and by a rigid adherence to a system of moderate living and regular exercise.

Under the head of acid diathesis may be arranged, not only deposits of lithic acid, but those also of oxalate of lime and cystic oxide. It has been ascertained from the examination of calculi, that the lithic acid diathesis and that of the oxalate of lime alternate with each other, thus shewing their near alliance and mutual convertibility. The cystic oxide diathesis, on

the other hand, appears to be exclusive in its nature, all concretions of this kind being of remarkable purity: it is, however, sometimes followed by a deposition of lithic acid; and this, like the other species of urinary calculi, terminates in producing the alkaline or phosphatic diathesis.

The general principles of treatment in this class of calculous diseases is, certainly, to counteract the acid tendency by the use of alkaline remedies, but to this there are many exceptions. In the lithic diathesis it has sometimes been found very serviceable to produce a copious discharge of that acid, by the exhibition of turpentine combined with laudanum. Dr. Prout has employed, with advantage, the muriatic acid in cases of oxalate of lime diathesis; by which means he succeeded in converting it into that of the lithic acid, and thereby procured great relief to his patient. This eminent physician, who has so ably illustrated the various forms of urinary disease, and to whose writings the author of this article is so much indebted, proposes a similar practice in the cystic oxide diathesis, recommending the muriatic acid to be given wherever the state of irritation will permit, for the purpose of keeping the cystic oxide in solution, and establishing in its place the lithic acid diathesis.

Should a calculous tendency appear to be connected with injury of the kidney, or a diseased state of that organ, the employment of counter-irritation, and especially of setons in its neighbourhood, is distinctly indicated; and their beneficial effects have been placed beyond doubt by the observations of Mr. Earle.\*

When a gouty disposition coexists with a calculous tendency, the colchicum, in combination with the means already described, ought to be had recourse to; but if the bladder already contain a calculus, we cannot with safety push this medicine to its full effect on the bowels, which in cases of simple gout and rheumatism is often found beneficial.

In the alkaline or phosphatic diathesis, the naturally acid condition of the urine is exchanged for an alkaline state; and the deposits now consist of the phosphates. This is a much more formidable deviation from health than that which we last considered, for it arises as a consequence of other disease, and is usually connected with a shattered state of the constitution. Our first object ought to be, to ascertain the cause from which the phosphatic diathesis has arisen, and to remove or palliate it as far as we are able. The spinal cord should be relieved by counter-irritation, varying, according to circumstances, from a galbanum plaister to a seton or a caustic issue—the effects of diseased prostate alleviated by such means as we possess; and if the symptoms have arisen from calculus in the bladder, its early removal by operation presents the only mode of effecting a cure. A free air, gentle exercise, and a mild nutritious diet, ought to be prescribed; and the tone of the digestive

\* Lond. Med. Chir. Trans. vol. xi.

organs restored by means of the mineral acids, bitters, and astringents. The acids have been supposed to exert a direct influence on the urine, and there is no doubt that they do pass the kidneys unchanged; but their chief beneficial effects in the phosphatic diathesis are accomplished by influencing the organs of digestion. The sulphuric, nitric, and muriatic acids have all been employed; and the last has been found most generally useful. Among the bitters and astringents the *uva ursi* and *parcira brava* have deservedly obtained a preference. Medicines which cause a copious secretion of lithic acid, such as the turpentine, the seeds of the *daucus sylvestris*, and *alchemilla arvensis*, might be supposed to prove beneficial when an opposite diathesis was known to prevail; and cases do occur in which they are found serviceable: but in the greatest proportion of such diseases, the irritation of the urinary organs is so great as to render their employment improper. Indeed it is obviously of little consequence to induce for a time a free secretion of lithic acid, without also improving that shattered state of health with which the morbid condition of the urine is generally connected. It is worthy of remark that such remedies are powerfully diuretic; now in the phosphatic diathesis the urine is almost always superabundant, at times excessive, which forms another objection to their employment. This tendency to an unnatural increase of the urine, and the irritation, anxiety, and pain attending the alkaline diathesis, point out opium as a valuable remedy; and here, as in other states of prolonged suffering, it has proved truly a blessing. Among the various forms in which this drug may be administered, perhaps the best are the black drop, Battley's liquor, and Dover's powder. Other anodynes, as hyoseyamus, conium, and belladonna, may be employed under less urgent symptoms; and they often produce very excellent effects.

Although mercury is certainly entitled to a place among the causes of the phosphatic diathesis, and is therefore, on general principles, to be avoided, yet under certain circumstances mercurials are productive of great benefit. Dr. Prout has well remarked that in children whose urine deposits the phosphates, repeated doses of calomel and rhubarb are exceedingly useful; without doubt, by correcting the disordered functions of the digestive organs: and in cases of excessive irritation of the urinary cavities we have found the full operation of calomel and opium signally beneficial. The existence of the phosphatic diathesis is so generally combined with a morbid state of the alimentary canal—the stools being too pale, or too dark, or yeasty—that it is quite obvious laxatives and alteratives must be given; but drastic purgatives, and even free purging, are to be avoided on account of the tenesmus which they are apt to occasion. The great importance of attending to the feelings of the patient under this form of calculous diathesis, and of removing when it is possible every source of care and anxiety, is sufficiently obvious. Relief from the irritations of business and the fatigues of study is

equally required; and a change of scene and air, when the patient can be moved, is productive of great benefit.

Such are the modes of treatment which appear to be best adapted to correct the two principal forms of calculous diathesis, whether the morbid condition have recently arisen, or be combined with the existence of stone.

When symptoms indicate that a calculus is passing from the kidney to the bladder, the physician is usually called under circumstances of great anxiety and alarm. In such cases, although the pain be urgent, it is not always necessary to abstract blood: it is a remedy, however, which ought to be kept in view, and employed on the slightest appearance of a tendency to inflammation. In the robust and plethoric, venesection is a wise measure of precaution, and will have a useful effect as a relaxant: even in persons of a less vigorous frame, when inflammation threatens, the immediate relief obtained by bloodletting renders it preferable to cupping and the application of leeches. During the passing of a calculus, all the various methods of allaying pain are sometimes required;—warm fomentations, bags of hot salt, hot poultices, the warm bath, and anodynes in every various form and mode of exhibition. Some difference of opinion may exist as to the propriety of giving diluents freely in such cases, so as to produce an increased secretion of mild urine; but it does not appear likely that a copious flow of urine will in any case prove hurtful; for if the calculus be not too large to pass, the increased current of fluid will certainly render the process more easy; nay, there is reason to believe, that by exposing a calculus to the constant washing of any aqueous urine, some of those spiculæ which detain it in its passage may be dissolved or worn away. Should the calculus be so smooth and so impacted in the ureter that no urine can pass, the probably fatal result is not likely to be much hastened by the use of diluents.

When the calculus appears to be delayed in the ureter, a brisk purgative of rhubarb and sulphate of potass, followed by an enema, will be found to facilitate its progress. After the renal calculus has dropped into the bladder, free dilution with bland liquids or pure water ought to be persevered in to a still greater extent; and brisk purgatives of castor oil, or rhubarb and sulphate of potass repeated at intervals. Should the small stone still be retained, its removal should be attempted by dilatation of the urethra. By such means we shall often succeed in ridding the patient of what would entail torture on his future days, or bring his life into hazard by the operation of lithotomy.

When a calculus is lodged in the bladder, and there is no longer any prospect of its expulsion by the urethra, the exertions of the physician are chiefly limited to the two objects of lessening the sufferings of his patient and preventing an increase of the stone. The general treatment is to be conducted on the principles already laid down for the manage-

ment of the prevailing diathesis, whatever that may be; since by such means we shall be most likely to accomplish the two objects stated above. The irritation of calculus in the bladder is in most cases remarkably relieved by the administration of alkalies in the acid diathesis, and of acids in the phosphatic; but the soothing effects of the alkalies in the former of these cases, is by far the more striking and uniform. Nay, the power of the alkalies to allay the irritability of the urinary apparatus seems not always limited to those cases where the acid diathesis prevails; and it is worthy of remark that their efficacy is not diminished by combining them with the vegetable acids.

Gentle exercise on foot, frictions, shampooing, warm clothing, great attention to the diet and to the state of the bowels, are all necessary in the management of calculus of the bladder. Straining at stool, whether from a confined state of the bowels or the smart operation of medicine, is to be carefully avoided; therefore only the mildest laxatives should be used. Castor oil is perhaps of all others the best; but a combination of the colocynth pill with hyoseyamus and a small proportion of opium often answers remarkably well. Under the agony of a fit of stone, the warm hip-bath, heat applied in various other ways, hot opiate fomentations, and anodynes in suppository and injection, are our chief means of relief. Considerable benefit has also been obtained from a clyster composed of half an ounce of oil of turpentine mixed with yolk of egg, and diffused in a pint of thin warm starch.

Long before the chemical nature of calculi was accurately ascertained, physicians conjectured that they might be dissolved while in the body, by means of internal medicines; and the opinion was supported by the great and speedy alleviation of suffering which calculous patients often derived from alkaline remedies: hence the belief became general, and various nostrums were offered to the public as certain solvents of the stone. The most celebrated of these was the alkaline solvent of Mrs. Steevens, who obtained from the British Parliament five thousand pounds for the publication of its ingredients. As both alkalies and acids, when thrown into the stomach, are found to make their appearance in the urine, they are without doubt fitted to produce some alteration in calculi within the bladder; but their action in most instances seems to be exceedingly limited. When alkaline lixivia have been long persevered in, they seem to have had the effect of rendering calculi very brittle,\* and in some instances to have caused exfoliations of their superficial laminae. On examining the bladder of Horace Walpole, who had taken lime-water and soap for nine years, with great relief, some exfoliations from two of the calculi were observed.†

Dr. Marcet also gives a similar testimony,

regarding a case where alkalies had been used with benefit for ten years.\* In a case which fell under our own observation, where the fixed alkalies had long been employed, the patient passed many fragments of concentric layers of calculus, which were soluble in liquor potassæ; and he was for some years before his death, which occurred at an advanced age, nearly free from urinary irritation. When the alkalies have been exhibited for a considerable time in a case of lithic calculus, a superficial admixture of the phosphates with the acid is found to have taken place; and when this treatment is continued still longer, the whole surface has been found coated over with the same salts. In one instance related by Sir Everard Home,† where the alkalies had been followed after a time by an aggravation of symptoms, the stone, when extracted, was found beset with spicular crystals of the triple phosphate. The relief from the irritation of calculus procured by the employment of alkaline remedies has in some instances been so great as to lead to the belief that solution of the stone had actually taken place; but on dissection it has been found that the prostate gland was enlarged, and the calculus lying in the cavity behind it, and thus prevented from falling against the sensitive orifice of the bladder. In the administration of the alkalies it must ever be kept in view that the tendency of all calculous cases is towards the formation of the phosphatic diathesis, and that the employment of the alkalies will necessarily hasten the period of its occurrence; when the phosphates will be deposited in abundance, and the calculus will receive a more rapid increase than before. A vigilant attention, therefore, is required to prevent the establishment of this diathesis, which will readily be accomplished by abandoning the use of alkalies, and having recourse for a time to acids. A phosphatic diathesis thus artificially induced, is, without doubt, much more manageable, and the probable result far less dangerous than when it arises in the natural progress of disease, and in connection with an impaired constitution.

Proposals have been made to dissolve calculi by injecting appropriate fluids into the bladder; but the trials hitherto made with alkaline solutions have shown that the bladder will not bear them of sufficient strength to act effectively on calculi of lithic acid. On the other hand, loose concretions and amorphous deposits of the phosphates, and of carbonate of lime, appear, from some late experiments of Mr. Brodie, to be capable of being gradually removed from the bladder by a weak solution of nitric acid, sent in a stream through that organ, by means of a double catheter of pure gold.‡ This prospect is highly gratifying, and we trust the practice will prove as successful as the most sanguine can anticipate; but it must be remembered that cases of this description are in general complicated with such

derangement in the general health, and so much disease of the bladder, that nothing beyond a palliation of symptoms can be looked for.

In all cases of calculus in the bladder, the patient experiences most ease when there is a plentiful secretion of urine, which, by distending the bladder, prevents the stone from being grasped in the muscular contractions of this organ. It also probably preserves in solution what might otherwise form a new deposit on the stone; and therefore a free use of thin demulcent liquids, as barley-water, arrow-root, gruel, decoctions of prunes and raisins, and of the fibrous roots of the leek, are often productive of great relief to the calculous patient. But this system of dilution is obviously not adapted to all cases; for, as we remarked above, the phosphatic diathesis is not unfrequently attended with a superabundant secretion of urine; and in such cases any increase of the quantity would still prove more distressing.

Although we cannot remove a stone from the bladder by the internal administration of drugs, surgery has invented various methods by which this object may be accomplished.

The most ancient is that of cutting into the bladder, and extracting the stone through the incision; and to this the name of lithotomy has been given. The mortality from this operation has always been considerable, and uniformly very great in the hands of the inexperienced and unskilful. The proportion of deaths to recoveries has varied exceedingly in different hospitals; but it is gratifying to be enabled to state that, over the island generally, it has of late manifestly diminished; a result which we are inclined to ascribe to the more general diffusion of surgical skill. In the Norwich and Norfolk Hospital, the total rate of mortality in all ages and sexes, from the opening of the institution in 1772, has been only 1 in 7.29. Dr. Yelloly, who has made this statement,\* adds, that of late it has been reduced to 1 in 8.6. The following tables, constructed by Dr. Yelloly\* from the records of the hospital up to June 1828, exhibit the comparative results of lithotomy at different ages and in the two sexes. The data here are more extensive, and the success is greater, than in any other British hospital.

TABLE I.

| Age or Sex.        | Operations. | Cured. | Died. | Mortality. |
|--------------------|-------------|--------|-------|------------|
| Both sexes . . .   | 649         | 560    | 89    | 1 in 7.29  |
| Males . . . . .    | 618         | 531    | 87    | 1 in 7.1   |
| Females . . . . .  | 31          | 29     | 2     | 1 in 15.5  |
| Both sexes.        |             |        |       |            |
| Under 14 . . . . . | 292         | 272    | 20    | 1 in 14.6  |
| 14 and upwards.    | 357         | 288    | 69    | 1 in 5.17  |
| 14 to 40 . . . . . | 155         | 140    | 15    | 1 in 10.33 |
| 40 and upwards.    | 202         | 148    | 54    | 1 in 3.74  |
| 14 to 50 . . . . . | 196         | 171    | 25    | 1 in 7.84  |
| 50 and upwards.    | 161         | 117    | 44    | 1 in 3.56  |
| Under 16 . . . . . | 317         | 294    | 23    | 1 in 13.78 |
| 16 and upwards.    | 332         | 266    | 66    | 1 in 5.03  |

TABLE II.

| Age.               | Operations. | Cured. | Died. | Mortality. |
|--------------------|-------------|--------|-------|------------|
| Infancy to 10 .    | 255         | 237    | 18    | 1 in 14.16 |
| 10 to 14 . . . . . | 37          | 35     | 2     | 1 in 18.5  |
| 14 to 20 . . . . . | 62          | 55     | 7     | 1 in 8.85  |
| 20 to 30 . . . . . | 47          | 42     | 5     | 1 in 9.4   |
| 30 to 40 . . . . . | 46          | 43     | 3     | 1 in 15.33 |
| 40 to 50 . . . . . | 41          | 31     | 10    | 1 in 4.1   |
| 50 to 60 . . . . . | 92          | 69     | 23    | 1 in 4     |
| 60 to 70 . . . . . | 63          | 43     | 20    | 1 in 3.15  |
| 70 to 80 . . . . . | 6           | 5      | 1     | 1 in 6     |

These tables present several results deserving of particular notice. The rate of mortality between the ages of 30 and 40 is only 1 in 15.33, while the decade immediately above gives 1 in 9.4, and that below 1 in 4.1. Hence it may be inferred that this small proportion of deaths is an accidental anomaly, which will not be found to correspond with the results of a more extended experience. In respect to the rate of mortality in the two sexes, and before and after puberty, Dr. Yelloly's tables coincide completely with the general observation of medical men. The mortality in males is more than double what

it is in females; and the mortality before puberty is very much less than at any period after that age. The operation of lithotomy in females is now almost wholly superseded by the process of dilatation, which may be said to be wholly without danger; therefore, if in future calculations the results of the total cases of lithotomy do not appear proportionally more fatal than at present, it will obviously amount to a real diminution of deaths. The low rate of mortality before puberty is chiefly to be ascribed to the facility of reaching the bladder, owing to the small depth of the perineum, and to the imperfect development

\* Philos. Trans. 1829.

of the parts; which are greatly less vascular and less sensitive than after that age. Therefore it may be safely assumed as a rule, that whenever a calculus is ascertained to exist in the bladder, at almost any age before puberty, lithotomy ought to be performed as soon as convenient. A disordered state of the health, unless the bladder or kidneys be actually ulcerated, forms no sufficient objection; for we have known the lateral operation performed on an infant of two years and a quarter, though in a sickly and very feeble state, with the effect of speedily restoring him to sound health. The operation by being delayed becomes, after puberty, one of increased difficulty and danger; and a long train of suffering is inflicted on the patient, while organic changes are taking place in the urinary organs which will ultimately render any operation altogether nugatory. It would seem as if the operation of lithotomy often produced a change in the constitution, for it is rare that the disease is known to recur after the extraction of a calculus. This has been remarked by different writers, and particularly by the late Mr Martineau of Norwich, a very distinguished lithotomist. He observes that scarcely a case occurs in which the complaint returns; and when a second operation has been required, he believes that it may generally be traced to the stone having been broken, and a fragment left in the bladder.\* The propriety of performing lithotomy at a more advanced period of life admits of more question. Its difficulties and dangers are greatly increased. Many circumstances may then render it unwise to put life in hazard by an operation; and the patient has arrived at those years when he may be supposed likely to pursue with steadiness that plan of regimen and medicine which will render his sufferings more tolerable, and, in all probability, prevent the increase of the stone. So soon, however, as the phosphatic diathesis is fairly established, whatever be the period of life, medicine and regimen become of uncertain efficacy, even in the hands of the most skilful; and extraction of the calculus affords the only prospect of permanent relief to the patient.

A second method of removing calculi from the bladder is by detrition, or what has been named lithotritry; in which the stone is seized by an instrument introduced through the urethra, excavated and crushed, and the debris washed out of the bladder by injections and the natural flow of the urine. The first attempt of this nature was made by Colonel Martin, of the Indian army, who introduced an exceedingly delicate saw through a canula into the bladder, and wore down a calculus which it contained. Some years after this, Mr. Elderton invented an instrument for the same purpose; and more lately M. Civiale, M. Leroy, and the Baron Heurteloup have carried the plan into effective practice by a variety of ingenious instruments, and succeeded completely by this method in removing stones from the bladder. The number of cases to which lithotritry can be applied is very limited;

\* *Medico-Chirurg. Trans.* vol. xi. p. 413.

for the bladder and prostate gland must be healthy, and the patient of a very tolerant temperament, to admit of its being carried into operation. The principal evils which are apt to attend this mode of procedure are, inflammation of the bladder, and retention of small fragments of the stone, which may at no distant period renew the disease.

A third method of removing calculi from the bladder is the dilatation of the urethra; but it is limited, excepting for small stones, to female cases; to which it is now ascertained to be so perfectly suited, that it has in a manner wholly superseded in that sex the operation of lithotomy. It is worthy of remark that dilatation of the female urethra for this purpose is an operation as old as Franco and Fabricius Hildanus, and that it was practised with great success by Proby, of Dublin, in 1693.\*

*Prostatal calculi.*—Calculi in the prostate gland very often remain for a great length of time without causing any irritation, and in that case it is much better not to disturb the patients by attempts to extract them; but should they give trouble, the usual methods of allaying irritation of the bladder ought to be had recourse to, and surgical aid called in. The forceps of Sir Astley Cooper has often been used with success; at other times such calculi have been extracted by incisions made through the rectum or through the perineum.

CARDIALGIA. See GASTRODYNIA.

CARDITIS. See PERICARDITIS.

CATALEPSY, (derived from the Greek *καταλαμβάνω*, to seize,) is applied to a very rare form of disease, characterized by the sudden suspension of consciousness and of voluntary motion, the muscles continuing steadily in that state of contraction in which they happened to be at the instant of the attack,—and yet readily admitting of, and retaining any other position of the body and limbs, however inconvenient, in which they may be placed at the will of the bye-standers.

The extreme rarity of this affection has caused its existence to be doubted by several distinguished physicians, and amongst these, by Cullen, as he never happened to meet with any instances of it which were not feigned. There are now, however, a sufficient number of well authenticated cases on record to render its existence unquestionable.

The attack is sometimes announced by certain precursory symptoms, as lassitude, palpitation, head-ach, confusion of intellect, stiffness in the neck, or pain and slight cramps in the limbs; but more generally it is instantaneous, the sudden rigidity of the trunk and limbs, the suspension of the senses, and temporary interruption of the exercise of the intellectual faculties, having been preceded by no premonitory stage. The patient retains the posture of body and the expression of countenance which he

\* See Dr. Molyneux in *Philos. Trans.* abridged vol. iii.

chanced to have at the moment of seizure; and by this combination of fixed attitude and unvarying expression, presents the air of a statue rather than that of an animated being. The eyes continue either fixedly open or shut, as they happened to be at the commencement; whilst the pupil, though usually dilated, contracts on the approach of a strong light. The balance between the flexor and extensor muscles is so perfect, that any new position given to the head, trunk, or extremities, by an external force, is easily received and steadily maintained. This passive energy of the muscular system, permitting the body to be moulded into almost as great a variety of attitudes as if it were a figure of wax or lead, is the distinguishing characteristic of the disease.

Catalepsy is an intermittent disorder, unaccompanied by fever, and recurring in paroxysms of various duration; more generally of only a few minutes, but occasionally of several hours, or even days. The length of the intervals is equally liable to variation, and seems to depend in a great degree on the recurrence of the peculiar exciting causes.

The return to the natural state is usually rapid, almost instantaneous, accompanied by heavy sighing, and generally by a complete restitution of all the faculties both of body and mind. Occasionally, however, pain and confusion of head, with a sense of fatigue in the limbs, are felt for some time after. There is no recollection of anything which occurred during the fit, and the half-finished phrase which was cut short by the seizure, has been said to be taken up and completed on the instant of recovery.

During the paroxysm the countenance is for the most part little altered, though it has in some cases been slightly suffused, indicating, along with the more forcible pulsation in the carotid arteries, an increased determination of blood to the brain; whilst in other cases, on the contrary, the face has been observed even paler than natural. But these irregularities in the circulation, as well as frequent inequalities in the distribution of the animal heat, are in a manner common to all nervous affections. The respiration and action of the heart are often little affected, though in some cases the former has been observed to be much embarrassed, from the extension of the spasmodic state to the muscles concerned in inspiration; and the pulse has occasionally manifested a considerable deviation from its natural force and frequency, more usually tending to an increased quickness and diminished strength.

Such is *true catalepsy*. But the disease does not always appear in so perfect a form: more frequently, indeed, its attacks are of a partial nature, the senses not being altogether obliterated, and the individual continuing conscious of every thing passing around him, though utterly unable either to move or to speak. This is the *catochus* of most nosologists. Of this spurious or partial catalepsy a very remarkable instance is recorded in Duncan's Medical Commentaries, Vol. x. A woman was on the point of being buried alive in a trance, and endured all

the horrors of seeing her own body prepared for interment; for though in the perfect possession of all her senses, she was unable to move a muscle or give the slightest indication of life. Galen has recorded a similar instance of total loss of the power of voluntary motion, whilst the consciousness continued unimpaired; and the author of the *Philosophy of Sleep* endured in his own person an apparently similar affection, to which he has given the title of *day-mare*. In another class of cases, the patients, having still a certain degree of consciousness, are able to move one hand or limb, and to swallow food when put into their mouths.

*Ecstasy* is a disease nearly allied to, and by some authors treated of under the head of catalepsy; and so often do these disorders run into one another, that of those nosologists who have separated them, no two agree on their diagnostic signs. According to Dr. Mason Good, ecstasy is sufficiently distinguished by the inflexible rigidity of the muscles, whilst consciousness, as in catalepsy, is for the most part suspended. An instance of this kind occurs in the first volume of the Medical Observations, in the case of a woman of fifty, who was daily seized, for some years, with a rigid contraction of all the muscles of the body, and such a profound sleep that nothing could awaken her: she remained thus from sun-rise to sun-set, and then recovered, took her food, and continued awake all the night, but relapsed again into the same state every morning. The greater number of systematic writers, however, place the distinguishing characteristics of ecstasy in a high degree of mental excitement co-existing with a state of unconsciousness to all surrounding objects, the limbs being often quite relaxed. The fit is for the most part induced by deep and long-sustained contemplation of some subject capable of awakening an exalted enthusiasm; and during its continuance the patient often speaks with earnestness, prays with fervor, or sings with much pathos and expression. Vivid dreams or visions of an extraordinary nature occasionally occur, and are so firmly impressed on the memory that they can be minutely detailed afterwards. But there is much reason to suspect that a majority of these latter cases have been counterfeited. Dr. Chisholm has recorded a remarkable and apparently genuine instance in a young female, where ecstasy alternated with mania; the limbs becoming relaxed, and the patient beginning to sing in a most touching manner as often as the maniacal state recurred. To us, catalepsy and ecstasy seem to be mere modifications of the same morbid state: thus Sauvages gives a case in which the first part of the paroxysm consisted in violent declamation and gesticulation, and loud singing, the girl being quite insensible to external objects; whilst, in its termination, the fit had all the characters of true catalepsy.

As to the danger of catalepsy, though we have the high authority of Boerhaave for estimating it fatally, yet subsequent and more numerous observations prove that death during the fit is a rare occurrence; and where such a termination has ensued, it has usually been from

the affection being complicated with or passing into other diseases, as apoplexy, mania, &c. Ros-tan met with one fatal case where inflammation of the lung co-existed, and Pinel another which terminated in apoplexy. Forestus has been cited by Sprengel, in his History of Medicine, as an authority for instances of fatal catalepsy attacking simultaneously a great number of soldiers at the siege of Metz; but any one who reads his narrative must feel satisfied that both Forestus and Sprengel have fallen into error in applying the term to such cases, and that the sudden deaths attended with rigidity were simply the result of intense cold in their exposed night quarters. Forestus in a subsequent passage particularizes the case of a horseman, who, being frozen to death on the saddle, continued to maintain his seat, and rode, statue-like, into the camp, still firmly grasping the reins and his weapon. He supposes that in such cases the cold merely predisposed to catalepsy, and that the maintenance of the erect posture and the firm contraction of the muscles were sufficient evidences of remaining vitality; but this is evidently a gratuitous assumption. It was probably from such cases as these that Hoffmann came to the strange conclusion, that as catalepsy occurred most frequently in winter, it must depend on congelation of the nervous fluid.

Amongst the predisposing causes are, a highly nervous temperament, and whatever tends to increase the susceptibility of the nervous system. Of this nature are all such causes as are calculated directly to weaken the body, or to act powerfully on the mind; the depressing passions, as violent sorrow, continued anxiety, unrequited love; intense and long-sustained application of mind. Both sexes, and children as well as adults, have afforded instances of it; but females, and especially those who have a tendency to hysteria and hypochondriacism, melancholia or mania, are the most frequent subjects of these attacks. The late Dr. Gooch met with an exquisitely marked case of catalepsy supervening to puerperal melancholia, in a female debilitated by repeated miscarriages. The trunk, as she lay in bed, being raised to an obtuse angle, retained this painful posture; the limbs remained in any position in which they were placed; when set on her feet, the slightest push threw her off her balance, and no effort was made to regain it. The eyes were open, and the pupil, though dilated, contracted on the application of a strong light. Of these attacks she had three, each lasting several hours, and recurring at the intervals of one and two days. The case afterwards resumed the form of melancholia, and terminated favourably. This, which is one of the latest, best authenticated, and accurately detailed cases of the disease on record, is delineated with all the graphic power for which this distinguished physician was remarkable.

To the head of exciting causes may be referred strong mental emotions, as terror, suppressed rage, protracted meditation on deeply exciting subjects, &c. Fernelius mentions the case of a student who was seized whilst at his desk, and continued, during the fit, with his pen

in his hand, and in a fixed attitude of intense application. Bonetus gives the case of a soldier, who having deserted his colours, on being apprehended shortly afterwards, was so terrified that he lost the power of speech, became as immoveable as a statue, and apparently unconscious of every thing around him: after continuing in this senseless state twenty days, during which he took no food, nor had any natural evacuation, he expired.

General plethora, suppressed evacuations, repelled eruptions, worms, and other sources of irritation in the digestive organs, are reckoned amongst the occasional causes of this disease.

The paroxysm is sometimes induced by very trifling circumstances, as a sudden noise, a slight contradiction, an unexpected visit, or a passing fit of anger or impatience.

Catalepsy is closely allied to the comatose diseases, apoplexy, carus, lethargy; and accordingly we find it classed by Cullen under the order Comata, genus apoplexia cataleptica. To epilepsy, also, it is nearly related, as we find this disorder occasionally assuming the cataleptic form, or the diseases alternating.

But in far the greater number of authentic and fully detailed cases, catalepsy has appeared to bear the strongest affinity to hysteria; and, indeed, in some of these seems to have been merely one of the innumerable forms of this Protean disorder. In support of this view we find that females and hypochondriacs are by far the most frequent subjects of both these affections; that they occur in similar constitutions, viz. those characterized by a high degree of nervous mobility; that they are convertible into each other; and, finally, that they are susceptible of relief from similar modes of treatment.

In illustration of this opinion we shall briefly mention a case of catalepsy, which we witnessed some years since. The patient, a young woman of eighteen years of age, having been cruelly treated by a man who was under promise of marriage to her, and received a slight wound in the head and some bruises in the breast, was seized with severe and repeated fits of catalepsy. These were usually preceded by headach, vertigo, and tinnitus aurium. During the continuance of the paroxysm she remained perfectly insensible to surrounding objects; the breathing was considerably affected, and the pulse rather quick and small; the pupils were dilated, the face assumed the expression of a smile; and the limbs steadily maintained any position in which they were placed. The duration of the fits was from five to ten minutes, and they recurred very frequently in the course of the day. After each attack, pain in the præcordia, headach, and a general sense of uneasiness were complained of. In the intervals the intellectual functions were usually unimpaired, though on some occasions a slight degree of stupor was observable. After the disease had existed some weeks, the fits were occasionally accompanied with screaming and struggling. She now suffered from severe lancinating pain at the epigastrium, increased by pressure, and accompanied with difficulty of

respiration, pain in the small of the back and in the right lumbar region, and subsequently some difficulty in voiding the urine, and frequent constipation. The most usual appearance of the paroxysms now became that of sound sleep, and their recurrence was much more frequent. The menstrual flux was not interrupted. The fits daily assumed more and more of the hysterical form; and by the use of aperients, local and general bleeding, and counter-irritants to the spine, ceased altogether in about two months from the commencement of her illness. The transition from well-marked catalepsy into hysteria was so remarkable in this case as to leave little doubt of the close affinity, if not the identity, of the two diseases. The case of Helena Renault, recorded by Sauvages, seems to have partaken of the nature of catalepsy, hysteria, and epilepsy conjointly—all ceased on the spontaneous return of the menses.

One of the most remarkable cases given by M. Petetin in his treatise on catalepsy, if it be at all worthy of credit, would seem to fall rather under the head of animal magnetism, or lucid somnambulism, than true catalepsy. He asserts, not merely that consciousness and the power of voluntary motion were abolished, but that the functions of the senses were transplanted into the epigastrium and into the extremities of the fingers and toes; so that when objects of taste, smell, &c. were applied to these parts, they were as accurately appreciated as they would have been by the tongue, the nose, &c. in the natural state. Strange to say, these and some still more startling facts do not rest solely on the authority of M. Petetin; he is supported in his assertions by other and equally respectable testimony.

*Diagnosis.*—The diagnosis of catalepsy from asphyxia, syncope, apoplexy, and apparent death, usually presents little difficulty. The suspension of the circulation and respiration, the flexibility of the limbs, and the colour of the face or lips, sufficiently distinguish asphyxia; whilst syncope is readily recognised by the three former circumstances coexisting with paleness of the countenance. In apoplexy there is usually paralysis of one side of the body and flexibility of the limbs, whilst stertorous breathing and congestion of the face are common attendants. To discriminate between catalepsy and apparent death is often a matter of less facility, and more than one case is on record in which individuals in the state of trance have narrowly escaped being buried alive. In such instances the disease must have existed in a very intense form, and been accompanied with paleness, suppression of the pulse, weak respiration, and a cold skin; and here the stiffness of the limbs might be very readily mistaken for that rigidity of the muscles which characterizes the dead body. But as the pulse and respiration are never quite extinct in catalepsy, the use of the stethoscope to the region of the heart, or even the application of the finger over the seat of any of the larger arteries, will enable us to detect the one; whilst the exploration of the lungs by the same instrument, and the holding of a polished mirror over the

mouth of the patient, so as to intercept and condense the pulmonary exhalation, will leave us in little doubt as to the existence of the other. The expression of the eyes and of the whole physiognomy might perhaps occasionally afford us additional assistance, as would also a knowledge of the previous state of the health, the mode of attack, and other circumstances of the case. If, after all, there shall still remain even the shadow of a doubt, we must wait for the indubitable evidence of incipient putrefaction.

Numerous instances of a state in some degree resembling catalepsy having been feigned, are on record, some of which have resisted the infliction of the severest modes of investigation. One of these stood out against the shower bath, electricity, and a variety of other energetic kinds of treatment, but was detected by the pulse of the individual being found to rise, when a proposal for applying the active cautery was made within his hearing. Another young soldier resisted measures of still greater severity, such as the thrusting of pins under his finger nails, scalping and trephining the head, &c. and persisted in the deception till he obtained his discharge; immediately after which he was seen in perfect health, and engaged in active occupations about his father's house. John Hunter, as Mr. Abernethy used to relate in his lectures, proposed to detect cases of feigned catalepsy by appending a weight to the arm, and after some time suddenly cutting the string by which it was attached: if any resiliency of the limb took place, he considered it a proof that additional force had been voluntarily exerted for the sustaining of the additional weight, and that, consequently, the powers of the mind were not really suspended. But even this would scarcely be conclusive, as it seems to leave the natural elasticity of the muscles altogether out of the account. Indeed, after making all due allowance for what practice and a firm determination can effect, we much doubt whether the peculiar state of the muscular system which exists in perfect catalepsy could by any effort of the will be successfully counterfeited, or whether very painful postures of the trunk and limbs could be long supported without the occurrence of such a tremor in the muscles as would reveal the deceit. And accordingly we find that impostors rarely attempt an imitation of perfect catalepsy, but content themselves with the easier task of assuming a state of profound insensibility coupled with relaxation of the muscles.

Morbid anatomy has hitherto thrown little or no light on the nature of this curious affection. As it is rarely fatal, few opportunities of dissecting such cases have occurred; and in those few, though the brain and nervous system have been carefully examined, no morbid changes have for the most part been discovered. Still, if we are to adopt the axiom of some modern French pathologists, namely, that every change of action implies a change of structure, we should conclude that such morbid alterations, though inappreciable by our senses, must needs exist. In science, however, such dogmatical

assertions, with nothing but vague analogy for their support, are misplaced. The converse of the proposition, or that change of structure necessarily implies a previous change of action, might be maintained with at least an equal show of reason. The great truth that the nervous system generally gives the initiative both to disorder and disease, has of late years been too much lost sight of. The younger Pinel has attributed the symptoms to an inflammation of the spinal marrow; but this does not rest on a sufficient basis of observation to entitle it to much credit; nor, indeed, is it probable, *a priori*, that an affection, the attacks of which commence and terminate so instantaneously, and which have been known to recur at various intervals during a period of many years, should have inflammation for their cause. A temporary state of irritation and congestion of the cerebro-spinal system, would seem to be more consistent with some of the phenomena, and to give an equally satisfactory explanation of the remainder. As the disease seems to be often induced by sympathy with the stomach, intestines, or uterus, the ganglionic system is probably also not unfrequently implicated.

As to those theories which propose to explain the singular symptoms of catalepsy by a supposed excess, deficiency, or immobility of the nervous fluid, though supported by the authority of high names, they are surely unworthy of notice in the present state of physiological science. We know little of the mode of action of the nervous system, and still less of its irregularities: a candid confession of ignorance in such a case is infinitely more favourable to the advancement of knowledge than the reproduction of such gratuitous hypotheses.

In the treatment of this disease the chief indications are, to subdue general plethora when it exists, by venesection and other depletions, and to obviate irregular determination of blood to the brain and spinal chord, by the use of leeches or cupping in the neighbourhood of these important organs; or (as some continental practitioners, guided by the old theory of derivation, prefer,) to a more distant part, as the feet or thighs. The existence of headach, confusion of ideas, and flushing of the face; or of pain, and tenderness on pressure in the course of the spine, will leave us little doubt as to the propriety of these measures. Counter-irritation in the form of blisters, issues, or moxa, will subsequently be called for.

The state of the stomach, bowels, and liver must be carefully investigated, and every effort made to counteract any irregularity in their functions. From the well known influence which these organs exert over the nervous system through the medium of sympathy, the importance of this part of the treatment cannot be too much insisted on; but generally speaking, our object should rather be to keep up the natural action of the alimentary canal, than to stimulate it to excessive secretion by drastic medicines, as the local irritation and the constitutional exhaustion induced by such means would, in many cases, tend to exasperate the nervous symptoms. The existence of general

plethora will, however, justify the use of free and long-continued catharsis; and Dr. Cheyne, in his valuable work on *Connatose Diseases*, has signalized the utility of aloetic purgatives in such cases.

A careful examination must also be made into the state of the uterine functions, and if not duly performed, every measure taken to restore them to their natural state. In those cases partaking largely of the nature of hysteria, the operation of cupping over the loins or the occiput, along with large turpentine enemata, should not be neglected.

In the intervals of the fits, exercise, diversified amusement, country air, and a mild diet should be insisted on. Sauvages records instances of the disease being removed by a milk diet and country air alone.

In those cases which appear to be purely nervous, the cold shower bath, if not peculiarly disagreeable to the feelings of the patient, and tonics should be tried. But above all things the undue excitement of the feelings and of the intellect must be cautiously avoided.

During the paroxysm, the application of cold, in the form of ice or evaporating lotions, to the head, provided there be any proof of determination to the brain, and the immersion of the feet into a warm stimulating foot-bath, are perhaps the only measures we should put in practice. Valerian, ammonia, musk, assafetida, and other antispasmodics, both in draughts and enemata, are usually employed, with the view either of warding off or shortening the duration of the fit, but generally with no very marked advantage. The older writers recommend ligatures to the limbs, and assiduous friction with stimulant liniments; but if the seat of the disease be, as we have every reason to believe, in the brain or spinal chord, little can be expected from such means. Electricity and galvanism have also been suggested, and are said in some instances to have cut short the attack. In the *Dictionnaire des Sciences Médicales*, it is recommended to direct all our efforts to rousing the dormant sensibility of some one organ; and a case is given from the *Ephemerid. Naturæ Curios.* where this was done with success: but the mode of effecting it there alluded to is one which, we believe, few practitioners in this country would venture to recommend. M. Petroz has occasionally known music to exercise a singular influence over the paroxysm, diminishing it materially both as to duration and intensity.

Should the attack end in apparent death, the importance of the immediate employment of artificial respiration is obvious; and indeed, in any of these cases where the action of the heart and lungs is greatly depressed, we should not be justified in neglecting it. In similar circumstances the application of moderate warmth and the free access of pure air are of the highest moment.

(W. B. Joy.)

CATAMENIA. See MENSTRUATION. See also AMENORRHEA, DYSMENORRHEA, MENORRHAGIA.

CATARRH, PULMONARY.—Every disorder of the mucous membrane of the bronchi has been included under this name. Thus Laennec makes the term generic, applied to the several species, *the mucous* (acute and chronic), *the suffocative*, *the pituitous*, *the dry*, and *the convulsive catarrhs*. But as the etymology of the word (*χατᾶ*, *deorsum*, *ῥέω*, *fluo*,) has relation rather to the secretion than to the pathological state of the diseased membrane itself, it is better to reserve the term for those forms of the disease in which unnatural secretion is the only constant or appreciable phenomenon. We have accordingly included under the head bronchitis all those affections of the bronchial membranes which are in any appreciable degree inflammatory, except whooping-cough, which will be found in its place. The cases, therefore, excluded from that head that require consideration under the name of catarrh, are those which Laennec denominates the *pituitous* and the *dry catarrh*, and this rather from want of another term, than from the aptness of the term employed.

Both the pituitous and the dry catarrhs attack the nasal as well as the pulmonary mucous membrane, and, like the inflammatory influenza, frequently pass from one to the other. According to the extent of the membrane affected, they may amount to a very trivial or a very serious malady; and when they affect extensively the bronchial membrane, they constitute the disease in a great number of the cases which are commonly called asthmatic.

1. *Pituitous catarrh*.—This form of catarrh is distinguished by the secretion of a thin, colourless, glairy liquid from the bronchial membrane. This flux comes on in paroxysms, attended with dyspnoea and cough, which are relieved by the expectoration of a liquid, “frothy on the surface, and underneath like the white of egg diluted with water.” Such a secretion frequently attends bronchitis when it attacks persons of lax habit of body; and, in fact, those cases which have been called *pneumonia notha* seem to owe their peculiar character to the pituitous secretion that occurs in them. It is likewise sometimes present in cases of œdema of the lungs and the first stage of phthisis. It does occur also idiosyncratically, and as such we have to consider it here. It is either acute or chronic. In its acute form it sometimes commences as a common cold, but with a sense of oppression and dyspnoea greatly disproportioned to the slight febrile symptoms. The attacks are sometimes of short duration, passing off entirely in the course of a few hours, after the expectoration of a quantity of the fluid before described, which sometimes amounts to several pints. Not unfrequently they assume a periodic character, coming on twice or three times a day, the symptoms in the intervals generally disappearing entirely. Sometimes this affection is combined or alternated with what Laennec terms dry catarrh, and the tough pearly mucus characterizing the latter is often seen in the expectorated matter. The stethoscope dis-

covers a variety of sibilant and bubbling rhonchi in the chest, often resembling the chirping of birds, whilst during the paroxysm the sound of respiration is impaired. The chest sounds well on percussion. During the intervals the same rhonchi are present, but in a much slighter degree, and the respiratory sound resumes its distinct character. The examination of those who have died during a paroxysm of pituitous catarrh discovers little or no trace of inflammation in the bronchial membrane. It is sometimes a little thickened and softer than natural, from the infiltration of serum; often perfectly pale; and any blushes or striæ of red that may occasionally appear are very slight, and of trifling extent. These circumstances, and the fact that it attacks most commonly those of weakly habit, languid circulation, and little disposed to inflammatory symptoms, seem to indicate that it is rather of the nature of a *profluvium*, arising from want of tone in the vessels, than an inflammation. The effects of remedies and the nature of the predisposing causes confirm this supposition. It most commonly arises in persons who have for a long time suffered from disordered digestion, whether arising from habits of excess or from natural weakness of the digestive powers. In certain individuals a form of pituitous catarrh sometimes happens during the summer months, and it is commonly attributed to an inhalation of the effluvia of hay-fields, whence it has gained the name of hay-fever or hay-asthma; but this is apparently more of the nature of influenza. After one attack, pituitous catarrh is extremely apt to recur; alternations of temperature or irregularities of diet being sufficient to re-excite it. When it has once established itself, like most other serous fluxes, it is very difficult to remove; for the habit of occasional profuse secretion being acquired, it frequently does not yield on the removal of the original exciting causes. Laennec remarks that it is common in gouty subjects advanced in age, and in whom the gout has become milder and less regular. The importance of pituitous catarrh varies much according to the state of the individual whom it attacks. When it seizes a subject enfeebled by present or previous disease, it may prove fatal in a few hours. Again, its long continuance, when it has by habit become established in the system, sometimes wastes the body, and brings on disease of the heart, pulmonary œdema, or some other loss of balance among the vital functions, that leads to the extinction of life.

In other instances, where the body is strong, or the disease slight, it may go on for years, injuring the comfort rather than the general health of persons even far advanced in life. Andral records an instance in which a sudden and temporary attack of pituitous catarrh, with very profuse discharge, was attended with the removal of a hydrothorax. We have before remarked that it sometimes is excited by miliary tubercles in the tissue of the lungs; and in all cases where the constitution of the subject, irregular resonance of the chest on

percussion, with bronchophony, and constancy of cough and pituitous expectoration (not in paroxysms), indicate this lesion, the prognosis must be more unfavourable.

The treatment of pituitous catarrh must be considered in relation to the paroxysms, and likewise to the disposition to them. The indications during the paroxysm are to facilitate the removal of the redundant secretion, and to prevent its further effusion. The means which we employ under the name of expectorants have probably, in some instances, both these effects, but in a very uncertain degree, and rarely in a manner available in these cases. Ipecacuanha, whether as an emetic, or in a nauseating dose, is perhaps the one from which most advantage has been derived. It is best to obtain at first its emetic effect, and afterwards to repeat it in such quantities as will keep up a slight sensation of nausea. The power which this remedy has in restraining hemorrhages is probably of the same character which renders it useful here; but it is extremely difficult to say whether this is from any direct action on the affected vessels, or from its general effects on the circulation. Tartar emetic, in large doses, which Laennec found effectual in two cases of an alarming aspect, probably has a similar mode of action; and from what we know of its effects in peripneumony, it seems difficult to avoid attributing to it a sorbefacient power. The lobelia inflata would perhaps more properly than these come under the class of expectorants. Of its utility in pituitous catarrh we have the testimony of practitioners of great sagacity and experience. The tincture has been given in doses of fifteen or twenty-five minims every two or three hours, with marked effect in relieving the dyspnœa. As has already been remarked, (see CHRONIC BRONCHITIS,) it is a medicine that must be watched, and stopped or diminished if vertigo or nausea shew that its effect on the system has been produced.

Of evacuants, which it may be necessary to resort to, to divert the determination from the pulmonary vessels, those which produce watery discharge are to be preferred to bleeding, which is seldom admissible, and only where there is marked plethora of the system. Diaphoretics and diuretics, if they can be brought to act, will have a tendency to shorten the paroxysm. Antimony and ipecacuanha, as already recommended, will best fulfil the first effect, and squill may be used with advantage as a diuretic. Drastic purgatives are not generally useful, often injurious; but those of a milder kind may be given with advantage; and when irregularities of diet have been the exciting cause of the paroxysm, a free evacuation of the bowels may contribute most materially to its removal.

In many cases these means are of but little avail; and when they do abridge or remove a paroxysm, they are scarcely effectual enough to prevent its recurrence. Strengthening the system by a mild but tonic regimen, removing disorder of the digestive organs, and the adoption of every means calculated

to improve the general health and strength, often succeed better in curing pituitous catarrh than any remedy directed against the disease itself. The diet should be mild and nutritive, consisting chiefly of farinaceous food and plain meat. The hours of eating should be regular, and the quantity moderate. All spirituous and fermented liquors are best avoided, and liquids of all kinds should be taken sparingly. Coffee made by infusion is the best beverage, and seems positively useful in some cases in preventing the recurrence of the paroxysm. To strengthen the digestive powers, calumba, rhubarb, or some other bitter may be given; and in some cases the sulphate of quinine, with a mineral acid, will be found of good effect. But the safest and most efficacious tonics are country air of a bracing quality, such as that of Brighton, and the cold shower or plunge bath. Regular exercise is highly necessary; and that on horseback is generally the most suitable. It is of importance to attend to the clothing, that it be sufficient to prevent the cuticular exhalation from being checked by occasional winds.

2. *Dry catarrh.*—This disease is more recognised as an asthmatic than a catarrhal affection. In fact, the term catarrh is not by any means appropriate in a disorder that is unattended with flux; and but for the absolute want of another term, it should not be employed. The pathological state of the membrane, however, does not so much differ, as the nature of the secretion, from that in the disease just described. There appears to be a passive or venous congestion in the mucous membrane of the bronchi, which neither in its nature or effects resembles inflammation. An improved nomenclature, founded on pathology, is much to be desired; but it may be doubted whether it be expedient to frame one until our knowledge of pathology itself be much more extended and definite than at present.

The symptoms of dry catarrh vary much according to its extent. In its slightest degrees it occurs in those individuals who, without any other derangement of health than a slight shortness of breath felt on exertion, expectorate every morning a small portion of tough mucus of a pearl grey colour. Sometimes, however, there are cough and dyspnœa, which, coming on in paroxysms, assume the form of asthma, each fit terminating with an expectoration of pellets of the same dense mucus. Occasionally there is a tolerably copious pituitous secretion at the same time; but this is uncertain, and bears no relation to the severity of the preceding fit, which seems to be connected with the formation of the thick mucus. Sometimes there is little or no cough; and the dyspnœa, or rather shortness of breath, may continue for months, and even years, without other symptoms. If an attack of bronchitis supervene, there is generally an aggravation of the dyspnœa, sometimes amounting to a fit of asthma. Lacmee, who is the only writer who has given a distinct account of this disease, remarks that it most commonly attacks gouty persons,

those affected with cutaneous eruptions, and those disordered by long excesses; and he considers the slight and dry coughs frequently attendant on various functional disorders of the abdominal viscera, and which are generally called nervous, to arise from a degree of dry catarrh.

The physical sign of this disease is a suspension of the sound of respiration in the part affected, while the corresponding part of the chest sounds well on percussion. This arises from a tumefaction of the bronchial membrane, which either of itself, or assisted by the pellets of thick mucus before described, more or less completely obstructs the caliber of one or more of the tubes. When the obstruction is not complete, a dull whistling or clicking sound accompanies the breathing; and a cough or forcible inspiration may sometimes discover the same sounds where in ordinary breathing the air does not enter. According to the extent of the bronchi thus affected, the severity of the disease will vary; but in all cases the expectoration of the thick mucus brings with it some relief of the dyspnoea. Andral records two cases in which a fatal asphyxia was caused by such obstructions occurring in one of the great bronchi, and which no efforts of coughing were able to remove; but these are to be considered as accidental rather than as common cases.

On anatomical examination, the membrane of the bronchi affected is found tumefied, and of dull red or violet colour, but without softening or ulceration. These circumstances, together with its duration, seem to indicate this affection, although occasionally originating in inflammation, to be of the nature of passive congestion, with interrupted secretion. Although not frequently in itself a dangerous disease, dry catarrh often much aggravates the symptoms of any other affection attacking the chest; and is in itself apt to induce the organic change called emphysema of the lungs.

The congestion of the mucous membrane constituting dry catarrh chiefly occurs, like other congestions, in those persons in whom some functional derangement has injured the balance of the circulation, and impaired the tone of the extreme vessels. Disordered digestion, imperfect secretion of the bile, and irregular alvine excretion, are the most common of these derangements; and, although they do not always give notable and direct evidence of their existence, the success attending treatment calculated to remove them is so efficacious in relieving the affection in question that it should be adopted in all severe cases of dry catarrh. It is unnecessary here to particularize the treatment alluded to; but it may be observed that a proper regulation of the diet, to the exclusion of rich, irritating, or acescent articles of food and all fermented liquors; the promoting regular alvine evacuations of proper colour by the aid of small doses of blue pill and ipecacuanha, followed by castor oil, saline, or other mild aperients; and afterwards giving tone to the stomach and system

by a judicious administration of tonics;—all these measures, as the circumstances may require, may be resorted to with the greatest advantage, and are often more successful in the permanent relief of the dyspnoea or asthma of dry catarrh than any measures directed against the disorder itself.

Laennec remarks that the means found useful in chronic bronchitis and other forms of catarrh, make no impression on this, and are only indicated when any of these are combined with it. The indications are, to remove the congested state of the bronchial membrane, and to facilitate the expectoration of the dense portions of mucus that obstruct the tubes. Blood-letting, blisters, and evacuations in general, have not the effect on congestion that they have on inflammation; and the state of the system is generally not such as to make the trivial benefit that may result from them equivalent to their weakening effect: but the same objection cannot be urged against dry cupping, which Laennec recommends; and friction of the chest with rubefacient substances, the occasional short application of a blister, wearing a pitch-plaister, or any of those means that may excite the superficial circulation without weakening the system, may be resorted to in most instances with more or less temporary relief.

With these measures we may properly combine such expectorant medicines as may fulfil the second indication, namely, to facilitate the expectoration of the thick mucus, which by obstructing the bronchial tubes becomes a principal cause of the dyspnoea. As Laennec remarks, we may effect this by any means which will diminish the glutinous tenacity of this matter; and he conceives that we possess medicines capable of attenuating the secretions and rendering them more liquid, in the mild or very dilute alkalies. He recommends either almond soap, in form of pills, with the patient's meals, to the amount of  $3\frac{1}{2}$  to  $5i$  a day, or the carbonated alkalies in doses of from twelve to thirty-six grains. He likewise made use of baths, both salt water and alkaline, made with four ounces of a carbonated alkali. He considered sulphur baths serviceable in cases complicated with herpetic diseases. To the efficacy of alkaline medicines in dry catarrh we can add our testimony. We have already spoken of their utility in other bronchial affections besides those accompanied by a viscid secretion. But in these their effect is more marked and unequivocal, and far from being so inexplicable as Laennec seems to consider it. The power of alkalies and acids to change the quality of the urine is well ascertained; and whether it be by an effect on the whole mass of blood, or by the agent passing immediately to the kidneys, it is quite certain that an acid or an alkaline quality may at pleasure be communicated to the urine by repeated doses of the corresponding medicine given by the mouth. Now it is not indulging a supposition too chemical, to consider that the formation of thick tough mucus is incompatible with an alkaline state of the fluids,

exposed to the light loses both its colour and its activity, while that on the opposite side retains both unaltered. The last circumstance which we shall notice as influencing the operation of cathartics is *combination*. Thus, in cases of spasm, the operation of a cathartic is promoted by its combination with opium; and under all circumstances, mixture,—as for example, the mixture of sulphate of magnesia and bitartrate of potassa, of infusion of senna and camphor mixture, and compounds of the resinous cathartics and camphor, and the union of calomel with jalap, scammony, gamboge, colocynth, or rhubarb,—promote the action of purgatives, and cause cathartic substances to operate with more certainty than when taken alone.

Cathartics differ in the time necessary for the production of their effects; some operating in a few hours, others requiring from eight to twelve. These differences depend, in some degree, on the solubility of the substances in the fluids of the alimentary canal. Thus the saline purgatives operate most quickly; the resinous require the longest time. It is probable also that their action in different parts of the intestinal canal is, in part, to be ascribed to their different degrees of solubility. Some, as jalap, are very soluble in the fluids of the duodenum, and act immediately on that portion of the canal; others dissolve more slowly, and act on the lower intestines; whilst others, as, for instance, calomel, acquire activity from meeting with acid in the stomach and undergoing a chemical change. This rule, however, is not without exceptions: thus aloës is more soluble than jalap, yet it operates chiefly on the colon and rectum; and even when applied to an ulcer on the surface, its influence is still exerted on the large intestines. A knowledge of the time required for the operation of different cathartics is useful in a practical point of view, as it enables us to adapt our remedy to the urgency of the case: the saline purgatives, owing to the rapidity of their operation, are well adapted to acute diseases, especially those of a febrile and inflammatory character; the resinous, from the tardiness of their action, are better calculated for chronic affections.

Cathartics differ in their ultimate effects upon the system. In general they induce a subsequent costiveness; and this is supposed to depend on the evacuation of the fluids of the intestines being so considerable, that some time is requisite to replace them; but it is more probable that it is the result of that law of the constitution which determines that every increased action must be followed by a state of inactivity or collapse. The more general, also, the action of a purgative, the more likely is costiveness to follow: an exception, however, must be made, as relates to castor oil, which, when given daily, operates in such a manner, that the dose may be gradually reduced to a few drops, and yet the effect of a full dose be maintained. Saline purgatives, owing to their operation on the whole intestinal canal, often leave a greater sluggishness of the bowels than existed before their exhibition. Rhubarb, also, has this effect: but, on the contrary, those resinous ca-

thartics which operate on the lower portion of the canal, induce a more open state of bowels.

In the administration of cathartics, some attention must be paid to the following circumstances.

1. Cathartics are more necessary and serviceable in warm than in cold climates; owing, not only to the greater vitiation of the contents of the bowels and the augmented secretion of bile in high than in low temperatures; but to the great determination of fluids to the skin in warm climates favouring the formation of scybala. As to the influence of season, it is an old maxim that purgatives should be given in the spring and autumn: and it is true that more inflammatory diseases prevail at those seasons than at other periods of the year; but the custom ought not to be followed by persons in health, as it is apt to induce a habit which may prove hurtful.

2. The constitution of the patient must be attended to. Cathartics are more required by persons of a melancholic than those of a sanguine temperament, the bowels being generally more torpid in the former than in the latter. There is an exception, however, to this rule in women, who, although they are more commonly of a sanguine temperament, yet are generally more disposed to costiveness than men; they do not however bear the operation of purgatives so well. In pregnancy, and during menstruation, drastic purgatives should not be administered, nor should cathartics of any kind be freely employed in states of debility. In attending to this rule, however, it must be recollected that debility may arise from very opposite conditions of the system. Where any idiosyncrasy exists, connected with the operation of cathartics, it should not be disregarded, as much injury may follow the employment of certain kinds of purgatives in such instances: thus, in some individuals a dose of rhubarb will cause convulsions closely resembling those of epilepsy; in others the smallest quantity of calomel will produce alarming syncope. The readiness with which pyalism is induced in some individuals by the last mentioned medicine is also a circumstance which sometimes requires consideration.

3. Although a costive state of body is to be strictly guarded against in childhood, yet it is certain that children bear the action of cathartics worse than adults. On account of the depressing effects of saline purgatives, those of a warm character are the best adapted for aged persons.

4. Cathartics ought not to be too frequently taken, as, by the excitement they produce in the mouths of the hepatic and pancreatic ducts, they cause a hasty, irregular, and imperfect secretion of bile and pancreatic juice, which is highly injurious to the digestive function.

5. As a general rule, cathartics are inadmissible in inflammatory states of the alimentary canal which have gone on to ulceration.

6. The nature of a cathartic determines the period of the day in which it should be administered: if it require a long time to operate,

it should be given at bed-time; if it act quickly, in the morning: thus saline purgatives, senna, castor-oil, croton-oil, and elaterium are best administered in the morning; the gum resins, sulphur, and calomel in the evening. But the action of a cathartic may at any time be quickened by copious dilution with warm aqueous fluids.

7. During the operation of a purgative, it is necessary to distinguish carefully those appearances of the alvine discharges which are the results of disease from those produced by the cathartic. Calomel always causes the evacuations to appear unnatural; and, if it be requisite to ascertain their real aspect, the use of the medicine must be suspended for a few days. During the operation of calomel the stools are of a bilious appearance; during that of full doses of saline purgatives, daily repeated, they assume a peculiar colour; and the effect of elaterium is to produce stools resembling water in which meat has been partially boiled.

With respect to the peculiar action of cathartics it is necessary to make a few remarks.

Among the laxatives, honey is apt to gripe and to prove flatulent, and the older it is the more likely are these effects to follow its administration. Cassia-pulp, which is now seldom employed alone in this country, produces nausea, flatulence, and griping. Tamarind-pulp, although an agreeable laxative, yet operates too gently to render it useful when given alone; it is, therefore, usually combined with neutral salts. The same observation applies to manna. Olive-oil operates as a mild laxative in doses of  $\mathcal{f}\mathfrak{z}\mathfrak{i}$ . Sulphur, whether in the simple sublimed state, (the sulphur lotum of the pharmacopœia,) or in that of a hydrate, (sulphur precipitatum,) is a mild but certain laxative, well adapted to cases of habitual dyspnœa, in which it is of much importance to keep the bowels open; and in hemorrhoids it is preferable to purgatives, not only on account of the mildness of its operation, but because it produces soft, easily moulded stools, which pass from the rectum without irritating the highly-sensitive piles. It may be given daily, in doses of from  $\mathfrak{z}\mathfrak{i}\mathfrak{s}$  to  $\mathfrak{z}\mathfrak{i}\mathfrak{s}\mathfrak{s}$ , combined with gr. x. or gr. xv. of magnesia, until its odour is manifested on the skin, when its employment should be intermitted for a few days. Magnesia and its carbonate operate with some degree of energy when they meet with much acid in the stomach. The pure magnesia is usually preferred to the carbonate, on account of the inconvenience produced by the extrication of the carbonic acid of the latter in the stomach. Both of them, when they do not act freely as laxatives, are apt to accumulate, and form concretions in the stomach, if taken daily for some length of time; hence, in such cases, it is proper occasionally to clear out the bowels by means of a brisk cathartic. Magnesia, besides exercising its laxative influence, allays the irritability of the stomach; it is consequently useful in the dentition of infants and children, at which periods of life there is both much irritability

and a prevailing acescency of the stomach. The dose of the magnesia is from gr. xv to  $\mathfrak{z}\mathfrak{i}\mathfrak{i}$  for an adult; that of the carbonate from  $\mathfrak{z}\mathfrak{i}$  to  $\mathfrak{z}\mathfrak{i}\mathfrak{i}$ : when it is taken alone, the best vehicle is milk.

Among the purgatives no animal substances are found; and the vegetable products, although they may be in some degree digestible substances, are not dietetical. They may be noticed according to their effects. Castor-oil, which seems to be intermediate between fixed and volatile oil, owes its properties to an acrid principle which is obtained, mingled with bland oil, by the expression of the seeds of the ricinus communis, and is more or less active according to the degree of temperature employed in the process; that now generally employed is expressed in India without heat. From its quick and mild operation it is peculiarly adapted for children, puerperal women, and all cases in which it is necessary to procure the evacuations with little constitutional disturbance. As its effects are not influenced by combining it with opium, it is generally preferred to other purgatives in colica piétonum and calculous affections. None of the purgatives can be so much relied upon for overcoming habitual costiveness as castor-oil, given daily for some weeks, gradually reducing the dose until less than half a teaspoonful be taken; after which the bowels generally continue to act without farther artificial assistance; even its occasional administration leaves the bowels in a relaxed state. The tendency of castor-oil to nauseate is a disadvantage, but it is counteracted by the addition of an aromatic. The dose for an adult, to produce a full operation, is from  $\mathcal{f}\mathfrak{z}\mathfrak{i}\mathfrak{v}$  to  $\mathcal{f}\mathfrak{z}\mathfrak{i}\mathfrak{s}$ .

The terebinthinate purgatives, for example the balsams, as they are incorrectly termed, of copaiba and of Gilead, common turpentine, Chian turpentine, and Canada balsam are stimulant in proportion to the extent of the dose. In doses of  $\mathcal{f}\mathfrak{z}\mathfrak{i}$ , rubbed into an emulsion with mucilage of gum, balsam of copaiba affords much relief in hemorrhoids; and owing to the determination which it induces to the kidneys, acts in some respects as a counter-irritant. It may be administered in the form of pills, by mixing it with one-sixteenth of its weight of calcined magnesia, and exposing this mixture to the air until it acquires a consistence fit for forming it into pills. The other turpentines are most commonly exhibited in the form of enema, in torpid conditions of the bowels, and in the sinking stage of some febrile diseases, particularly in erysipelas of a malignant kind. Under such circumstances the dose is from  $\mathcal{f}\mathfrak{z}\mathfrak{i}$  to  $\mathcal{f}\mathfrak{z}\mathfrak{i}\mathfrak{v}$ , rubbed up with mucilage and manna. In some habits the turpentines are apt to cause an eruption on the skin, closely resembling eczema; in which case their use should be discontinued.

The resinous purgatives, jalap, aloes, and rhubarb, operate variously according to circumstances of extent of dose, combination, and the state of the patient. In a moderate dose, for

instance from gr. xii. to ʒi of the powder, jalap operates effectually without griping; in larger doses it gripes, and produces copious watery stools; and when given in an overdose it excites hazardous inflammation of the mucous membranes. It operates chiefly through the medium of the nervous system; for when it is injected into the veins it does not act on the bowels, although when it is combined with lard and rubbed on the skin it causes brisk purging. The fineness or coarseness of the powder, also, modifies the operation of jalap; and it is probable that its augmented activity, when united with bitartrate of potassa and other neutral salts, is in part owing to the aid which they afford to its continuation. In conjunction with calomel, the activity of jalap is increased, owing to the calomel aiding its stimulant influence on the hepatic duct in the duodenum. The watery extract operates mildly, and is on that account well adapted to children; the resinous extract gripes violently, and displays all the characters of a drastic cathartic without purging much. With respect to the state of the patient—in nervous and irritable habits jalap operates too violently; whereas in languid and torpid individuals its purgative influence requires to be aided by other cathartics. Jalap is chiefly useful as a general purgative in febrile affections connected with an increased action of the liver, and a more than natural discharge of vitiated bile into the duodenum.

Aloes is a warm stimulating purgative, exerting little action on the duodenum and small intestines, but affecting powerfully the colon and rectum, a peculiarity which has been erroneously attributed to the little solubility of the aloes in the fluids of the intestinal canal permitting it to pass nearly through its whole length before it is sufficiently dissolved to exert its purgative influence. In small doses, for instance from gr. v. to gr. x, aloes does not induce an attack of hemorrhoids, which, however, is not an unfrequent result of large doses. It has been found useful in the dyspeptic affections of cold and languid habits, particularly of the sedentary and hypochondriacal. In combination with calomel or blue pill, or with alkalies, it has been found more beneficial in jaundice than when given alone, notwithstanding the opinion of Cullen\* that nothing is obtained by combining aloes with other substances. From the influence of aloes on the rectum it is generally thought to be an improper medicine in pregnancy; but Dr. Denman has remarked that the lower classes of people use aloes on account of the cheapness of the medicine, and because it can be conveniently administered in the form of pills without any bad effects in such cases.† The addition of camphor to aloes renders its operation both milder and more certain.

Rhubarb is one of the most useful of the resinous purgatives, acting chiefly through the medium of the nervous system, a fact demon-

strated by the effects of its application in the form of cataplasm to the surface; for were it absorbed, the colouring matter would be detected in the urine, which is not the case; yet the application of such a cataplasm purges briskly.

Senna owes its purgative property to a peculiar principle, discovered by MM. Lassaigue and Feneulle, called *cathartina*. This principle is dissolved by water at a temperature of 96°, which takes up little of the extractive and other matters on which the griping quality of senna is supposed to depend; an infusion, therefore, made with distilled water at this temperature, purges without griping. When the infusion is kept ready-made and exposed to the air, the cathartina is decomposed and the extractive oxidized. Senna is a useful and very general purgative, there being scarcely any disease in which purgation is indicated where it may not be administered. The purgative power of the infusion is greatly augmented by the addition of camphor mixture, or of the decoction of guaiacum: it is seldom given alone; but some of the adjuncts frequently prescribed with it, such, for example, as magnesia, rhubarb, and the carbonates of alkalis, destroy its active properties.

Notwithstanding the virulent effects of colchicum when given in an over-dose, it is an efficacious and valuable purgative; operating chiefly on the duodenum, and, by stimulating the excretory ducts of the liver and the pancreas, producing copious bilious stools; diminishing febrile action, and allaying pain. To these effects we may ascribe the beneficial influence of colchicum in gout and rheumatism. It may be demanded, why do not other purgatives equally relieve these diseases? We reply,—present us with one that will act as decidedly on the hepatic and pancreatic ducts, and we will equally rely on its powers. The wine is the best form of the medicine, because the acetic acid in it is sufficient, in conjunction with the alcohol, to take up the whole of the veratria, and is not enough to determine its action chiefly to the kidneys, which is the effect of the vinegar of colchicum.

The inorganic purgatives are principally neutral salts. The most commonly employed of these, sulphate of magnesia, purges freely without griping; but as it frequently causes flatulence, it requires in most instances to be conjoined with aromatics, or some warm bitter infusion, such as that of cascarrilla. It operates chiefly on the duodenum; and it is to its presence that many of the mineral purging springs, as those of Kilburn, Cheltenham, Moffat, Seidlitz, and others, owe their active properties.

Soda is the basis of at least three purgative salts, the phosphate, sulphate, and muriate. The phosphate, on account of its similarity to common salt, and the mildness of its operation, is well adapted to children and delicate persons: it acts moderately in doses of from ʒiv. to ʒii. Before the introduction of the sulphate of magnesia, sulphate of soda was

\* *Materia Medica*.

† *Introduction to the Practice of Midwifery*.

the most commonly employed purgative: it is now less used. Its nauseous taste is readily and effectually covered by citric or tartaric acids; and when a purgative is required to lessen rapidly the mass of the circulating fluids, none answers more effectually than a combination of three parts of sulphate of soda, and one part of bitartrate of potassa. Sea-water owes its purgative influence to a combination of muriates, of which that of soda is predominant. All the salts of soda operate upon the whole length of the intestinal canal, stimulating the orifices of the exhalent vessels, and, consequently, causing serous discharges in the form of thin watery stools: they are, therefore, well calculated for cases of febrile excitement, and those in which there is a tendency to plethora. Their influence on the exhalent vessels also promotes absorption, for the action of the exhalents cannot be augmented without a corresponding increased action of the absorbents. In prescribing the salts of magnesia and of soda, it is important to understand the variation of their action produced by various combinations. Thus, the addition of sulphate of magnesia quickens greatly the action of infusion of senna; while, for those who can scarcely bear the operation of purgatives, the sulphate should be combined with bitter or aromatic infusion, or even with sulphate of iron, as circumstances may direct; and this rule holds good, also, respecting the others.

The salts of potassa are more diversified in their action than those of magnesia and soda. The sulphate and bisulphates of potassa are useful adjuncts to rhubarb and aromatic bitters in dyspepsia, accompanied, as it usually is, with torpid bowels. The dose of the sulphate is from gr. x. to ℥ii, that of the bisulphate ℥ss to ℥i. It must be recollected that the sulphate is decomposed by tartaric acid and converted into the bitartrate; hence it cannot properly be prescribed with infusions of tamarinds, nor with the infusion of senna with tamarinds of the Edinburgh Pharmacopœia. As a purgative, the neutral sulphate is supposed to extend its action beyond the intestinal canal; and, therefore, it is generally selected in cases of obstructions of the mesenteric glands. In combination with aloes, it has been found to answer well in cases of jaundice, in dyspeptic affections, and in habitual costiveness. The tartrate and bitartrate of potassa differ considerably in their mode of operation. The former is a mild and efficient purgative, operating without griping; and it has, also, the property of lessening the griping quality of senna and scammony. It acts on the whole of the intestinal tube; and, as it operates rapidly, it is well suited to cases requiring the aid of a quick and effectual purgative. The average dose is from ℥i. to ℥iv. It is perhaps the best purgative that can be prescribed, to assist the effect of a large dose of calomel given at bed-time; thus, from ℥i. to ℥ii. of tartrate of potassa, in ℥ss of infusion of senna, administered in the morning, after a dose of calomel taken on the preceding

night, operates rapidly, and sweeps away the bile which the calomel has brought from the liver. The bitartrate operates more on the exhalents of the smaller intestines than the tartrate, producing watery stools, flatulence, and, in some persons, griping. From its property of acting on the exhalents, it is advantageously prescribed in cases of ascites and other dropsical accumulations; thence its continued use is productive of emaciation, and to this property, also, may be ascribed its utility in cases of plethora and obesity. As it is not very soluble, it may be given either in the form of powder or of electuary, combined with jalap, scammony, or sulphur. The acetate of potassa in small doses operates as a diuretic; but in doses of from ℥ii. to ℥iv. it purges freely, if the surface of the body be kept warm. It is, nevertheless, much inferior to any of the other saline purgatives.

With respect to the mercurial oxides and salts, the mercurial or blue pill and calomel may be regarded rather as preparatives for active purgatives than as purgatives themselves: they operate chiefly by stimulating the gall ducts, when given in full doses; and as alteratives, improving the biliary secretion and increasing it, when the liver is in a torpid state. The hydrargyrum eum creta operates also mildly; but it is seldom employed except in cases requiring the aid of a mild alterative, or as a purgative for children in whom there is much acescency of stomach, and in whom there are, at the same time, glandular obstructions. When calomel is intended to operate as a purgative, it should be given in much larger doses than are usually prescribed: in such doses, for example as from gr. x. to gr. xv. it lessens the irritability of the stomach when this is excessive, combines with, renders more fluid, and detaches the viscid mucous secretions adhering to the small intestines, and augments the vascular and capillary circulation in the mucous coat of the colon and rectum.

During its administration it has been said that the aspect of the alvine discharges is rarely natural; the medicine should, therefore, be frequently intermitted for a few days, in order to ascertain the real state of the abdominal secretions.

The last division of cathartics, the *drastic purgatives*, consist, almost entirely, of organic products, involving some very active principle. Their operation is commonly attended with griping; and in some instances the effects are so violent, that, unless they be closely watched, much mischief may result from their employment. They exert a powerful influence on the exhalents and absorbents, and merit more justly the name of hydragogues than any other set of purgatives. Amongst them, colocynth is supposed to owe its cathartic power to a peculiar principle which has been named *colocynthine*; but this is uncertain. Colocynth operates chiefly on the larger intestines; and, as with aloes, this happens even when it is applied to an ulcer on the surface

instance from gr. xii. to ʒi of the powder, jalap operates effectually without griping; in larger doses it gripes, and produces copious watery stools; and when given in an over-dose it excites hazardous inflammation of the mucous membranes. It operates chiefly through the medium of the nervous system; for when it is injected into the veins it does not act on the bowels, although when it is combined with lard and rubbed on the skin it causes brisk purging. The fineness or coarseness of the powder, also, modifies the operation of jalap; and it is probable that its augmented activity, when united with bitartrate of potassa and other neutral salts, is in part owing to the aid which they afford to its comminution. In conjunction with calomel, the activity of jalap is increased, owing to the calomel aiding its stimulant influence on the hepatic duct in the duodenum. The watery extract operates mildly, and is on that account well adapted to children; the resinous extract gripes violently, and displays all the characters of a drastic cathartic without purging much. With respect to the state of the patient—in nervous and irritable habits jalap operates too violently; whereas in languid and torpid individuals its purgative influence requires to be aided by other cathartics. Jalap is chiefly useful as a general purgative in febrile affections connected with an increased action of the liver, and a more than natural discharge of vitiated bile into the duodenum.

Aloes is a warm stimulating purgative, exerting little action on the duodenum and small intestines, but affecting powerfully the colon and rectum, a peculiarity which has been erroneously attributed to the little solubility of the aloes in the fluids of the intestinal canal permitting it to pass nearly through its whole length before it is sufficiently dissolved to exert its purgative influence. In small doses, for instance from gr. v. to gr. x, aloes does not induce an attack of hemorrhoids, which, however, is not an unfrequent result of large doses. It has been found useful in the dyspeptic affections of cold and languid habits, particularly of the sedentary and hypochondriacal. In combination with calomel or blue pill, or with alkalies, it has been found more beneficial in jaundice than when given alone, notwithstanding the opinion of Cullen\* that nothing is obtained by combining aloes with other substances. From the influence of aloes on the rectum it is generally thought to be an improper medicine in pregnancy; but Dr. Denman has remarked that the lower classes of people use aloes on account of the cheapness of the medicine, and because it can be conveniently administered in the form of pills without any bad effects in such cases.† The addition of camphor to aloes renders its operation both milder and more certain.

Rhubarb is one of the most useful of the resinous purgatives, acting chiefly through the medium of the nervous system, a fact demon-

strated by the effects of its application in the form of cataplasm to the surface; for were it absorbed, the colouring matter would be detected in the urine, which is not the case; yet the application of such a cataplasm purges briskly.

Senna owes its purgative property to a peculiar principle, discovered by MM. Lassaigne and Feneulle, called *cathartina*. This principle is dissolved by water at a temperature of 96°, which takes up little of the extractive and other matters on which the griping quality of senna is supposed to depend; an infusion, therefore, made with distilled water at this temperature, purges without griping. When the infusion is kept ready-made and exposed to the air, the *cathartina* is decomposed and the extractive oxidized. Senna is a useful and very general purgative, there being scarcely any disease in which purgation is indicated where it may not be administered. The purgative power of the infusion is greatly augmented by the addition of camphor mixture, or of the decoction of guaiacum: it is seldom given alone; but some of the adjuncts frequently prescribed with it, such, for example, as magnesia, rhubarb, and the carbonates of alkalies, destroy its active properties.

Notwithstanding the virulent effects of colchicum when given in an over-dose, it is an efficacious and valuable purgative; operating chiefly on the duodenum, and, by stimulating the excretory ducts of the liver and the pancreas, producing copious bilious stools; diminishing febrile action, and allaying pain. To these effects we may ascribe the beneficial influence of colchicum in gout and rheumatism. It may be demanded, why do not other purgatives equally relieve these diseases? We reply,—present us with one that will act as decidedly on the hepatic and pancreatic ducts, and we will equally rely on its powers. The wine is the best form of the medicine, because the acetic acid in it is sufficient, in conjunction with the alcohol, to take up the whole of the veratria, and is not enough to determine its action chiefly to the kidneys, which is the effect of the vinegar of colchicum.

The inorganic purgatives are principally neutral salts. The most commonly employed of these, sulphate of magnesia, purges freely without griping; but as it frequently causes flatulence, it requires in most instances to be conjoined with aromatics, or some warm bitter infusion, such as that of cascarrilla. It operates chiefly on the duodenum; and it is to its presence that many of the mineral purging springs, as those of Kilburn, Cheltenham, Moffat, Seidlitz, and others, owe their active properties.

Soda is the basis of at least three purgative salts, the phosphate, sulphate, and muriate. As a purgative, the neutral sulphate is supposed to extend its action beyond the intestinal canal; and, therefore, it is generally selected in cases of obstructions of the mesenteric glands. In combination with aloes, it has been found to answer well in cases of jaundice, in dyspeptic affections, and in habitual costiveness. The tartrate and bitartrate of potassa differ considerably in their mode of operation. The former is a mild and efficient purgative, operating without griping; and it has, also, the property of lessening the griping quality of senna and scammony. It acts on the whole of the intestinal tube; and, as it operates rapidly, it is well suited to cases requiring the aid of a quick and effectual purgative. The average dose is from ℥i. to ℥iv. It is perhaps the best purgative that can be prescribed, to assist the effect of a large dose of calomel given at bed-time; thus, from ℥i. to ℥ii. of tartrate of potassa, in ℥℥ss of infusion of senna, administered in the morning, after a dose of calomel taken on the preceding

night, operates rapidly, and sweeps away the bile which the calomel has brought from the liver. The bitartrate operates more on the exhalents of the smaller intestines than the tartrate, producing watery stools, flatulence, and, in some persons, griping. From its property of acting on the exhalents, it is advantageously prescribed in cases of ascites and other dropsical accumulations; thence its continued use is productive of emaciation, and to this property, also, may be ascribed its utility in cases of plethora and obesity. As it is not very soluble, it may be given either in the form of powder or of electuary, combined with jalap, scammony, or sulphur. The acetate of potassa in small doses operates as a diuretic; but in doses of from ℥ii. to ℥iv. it purges freely, if the surface of the body be kept warm. It is, nevertheless, much inferior to any of the other saline purgatives.

With respect to the mercurial oxides and salts, the mercurial or blue pill and calomel may be regarded rather as preparatives for active purgatives than as purgatives themselves: they operate chiefly by stimulating the gall ducts, when given in full doses; and as alteratives, improving the biliary secretion and increasing it, when the liver is in a torpid state. The hydrargyrum eum creta operates also mildly; but it is seldom employed except in cases requiring the aid of a mild alterative, or as a purgative for children in whom there is much aciesency of stomach, and in whom there are, at the same time, glandular obstructions. When calomel is intended to operate as a purgative, it should be given in much larger doses than are usually prescribed: in such doses, for example as from gr. x. to gr. xv. it lessens the irritability of the stomach when this is excessive, combines with, and renders more fluid, and detaches the viscid mucous secretions adhering to the small intestines, and augments the vascular and capillary circulation in the mucous coat of the colon and rectum.

During its administration it has been said that the aspect of the alvine discharges is rarely natural; the medicine should, therefore, be frequently intermitted for a few days, in order to ascertain the real state of the abdominal secretions.

The last division of cathartics, the *drastic purgatives*, consist, almost entirely, of organic products, involving some very active principle. Their operation is commonly attended with griping; and in some instances the effects are so violent, that, unless they be closely watched, much mischief may result from their employment. They exert a powerful influence on the exhalents and absorbents, and merit more justly the name of hydragogues than any other set of purgatives. Amongst them, colocynth is supposed to owe its cathartic power to a peculiar principle which has been named *colocynthine*; but this is uncertain. Colocynth operates chiefly on the larger intestines; and, as with aloes, this happens even when it is applied to an ulcer on the surface

of the body. When given in substance, the violence of its operation should be moderated by triturating it with gum or farinaceous matters. It is most usually administered in the form of extract, in doses of from gr. vi. to gr. xv.; but the aqueous decoction is milder in its effects than the extract. The resinous drastic purgatives most commonly employed are scammony and canboge. Scammony is a powerful griping cathartic. It is generally combined with calomel, and is one of those substances the acrimony of which is greatly modified by combining with it sulphate of potassa. From its activity, it is well adapted for removing the scybala that frequently remain, for a long time, in the cells of the colon in maniacal cases; and in combination with calomel and sulphate of potassa, it aids greatly in removing ascariides from the rectum. The dose is from gr. v. to gr. xv.; it is advisable generally to conjoin with it a drop or two of some volatile oil; and when the bowels are irritable, if it be ever proper in such a case to prescribe a drastic purgative, the watery emulsion of scammony, allowed to settle and deposit the resin, will answer the purpose, as it operates with sufficient activity without griping. Canboge is more drastic than scammony, and frequently excites vomiting when given alone, even in moderate doses. It is usual to combine it with calomel, soap, rhubarb, or sulphate of potassa. The average dose is from gr. iv. to gr. viii. The drastic character of the root of black hellebore as a cathartic was well known to the ancients, and one of their chief resources in the management of mania; but it may be doubted whether it possesses any superior advantages over other active cathartics in that disease, or even as a hydragogue. One of the most active of the drastic cathartics is, undoubtedly, the expressed oil of the seeds of the *eroton tiglium*. Like castor oil, it is the solution of an acrid principle in a bland oil, in the proportion of forty-five parts of the former to fifty-five of the latter. The acrimony of this principle is so great, that the oil operates briskly by merely applying a single drop of it to the tongue; nevertheless it seldom excites nausea or vomiting, and rarely griping. In maniacal cases, in visceral obstructions, in dropsical accumulations, in delirium tremens, in apoplexy, and in all cases requiring ample and prompt evacuations, the oil of *tiglium* may be prescribed with advantage. The best mode of using it is to rub it up with sugar, as an oleo-saccharum, in the almond emulsion; or to dissolve it in alcohol, as recommended by Dr. Nimmo.

The last of this class of cathartics which it is requisite to notice is elaterium, a vegetable product, which owes its activity to *clatin*, a peculiar principle discovered by Dr. Paris,\* and the most powerful purgative agent yet known, as it constitutes one-twelfth only of the weight of elaterium, of which one-eighth of a grain only is required to produce brisk purging.

\* Dr. Clutterbuck first discovered the fecula now called *clatin*.—See his paper in the Medical Repository, quoted by Dr. Paris. EDITORS.

Elaterium, when properly managed, is an excellent drastic hydragogue. Sydenham employed it successfully in dropsy; but it fell into disrepute from the indiscreet use made of it, until Dr. Ferriar, of Manchester, restored it to practice for the cure of hydrothorax. In administering it, the strength should be supported with moderate stimuli, particularly ammonia, capsicum, or camphor: under every circumstance the utmost caution is required in its administration, and no practitioner ought to prescribe it unless he is able personally to watch its effects. The average dose to an adult is one-sixth of a grain; and this should be repeated every sixth hour, until copious stools are procured.

Among the inorganic drastic purgatives, the only substance requiring to be noticed is the precipitated sulphuret of antimony, which, however, is employed merely as a component of the compound calomel pill. It is a violent but very uncertain cathartic.

(A. T. Thomson.)

CEPHALÆA, CEPHALALGIA. See HEADACH.

CHEST, CONTRACTION OF. See PLEURITIS.

CHEST, EXPLORATION OF.—The methods employed by physicians for exploring or physically examining the external parts of the chest, with the view of discovering or discriminating the diseases of this cavity, are the following:—*inspection, manual examination, mensuration, auscultation, percussion, succussion*. The three latter methods have been fully discussed in the article AUSCULTATION; it therefore only remains to notice the three former in this place.

The relationship of the external to the internal parts is much more easily ascertained in the case of the thorax than the abdomen, owing to the less complexity and greater fixedness of the contents of the former cavity. The thoracic viscera are few in number, and their boundaries are, in general, accurately defined. In the state of health they cannot vary their position; and their displacement is produced by only a small number of well-defined causes, the chief of which are preternatural growths, or the accumulation of fluids within the cavity of the chest, encroachment of the abdominal viscera from below, or alteration of the solid walls of the chest, chiefly from distortion of the spine.

In the article EXPLORATION OF THE ABDOMEN, the importance of knowing the topographical relations of the external and internal parts of the great cavities was pointed out, and also the means of rendering this knowledge more precise by the aid of artificial subdivisions of the anterior of the body. The principles adopted in dividing the whole trunk of the body are there explained; and the figures in pages 2 and 3 exhibit a representation of the thoracic regions along with those of the abdomen. We must, therefore, refer the reader to those figures, while we now proceed verbally to define the regions which belong exclusively to the chest.

All the regions, as is explained in the article referred to, are bounded by direct lines drawn from fixed and conspicuous points on the surface of the body, and which lines are either vertical or horizontal. The vertical lines having relation to the chest are eight in number, and run as follows:—1. along the middle of the sternum from its upper to its lower extremity; 2. from the acromial extremity of the clavicle to the external tubercle of the pube (right and left); 3. from the posterior boundary of the axilla, or inferior edge of the latissimus dorsi, to that point of the crest of the ilium on which it falls vertically (right and left); 4. along the spinous processes of the cervical and dorsal vertebræ; 5. along the posterior or spinal border of the scapulæ, from the clavicular transverse line to the mammary transverse line. The horizontal or transverse lines are four in number, and are as follows:—1. around the lower part of the neck, sloping downwards to the upper end of the sternum anteriorly, and to the last cervical vertebra posteriorly; 2. around the upper part of the chest in the line of the clavicles; 3. around the middle of the chest, crossing the nipples anteriorly, and touching the inferior borders of the scapulæ behind; 4. around the lower part of the chest on the scyphoid cartilage.

By these imaginary lines the trunk is divided

Fig. 4.

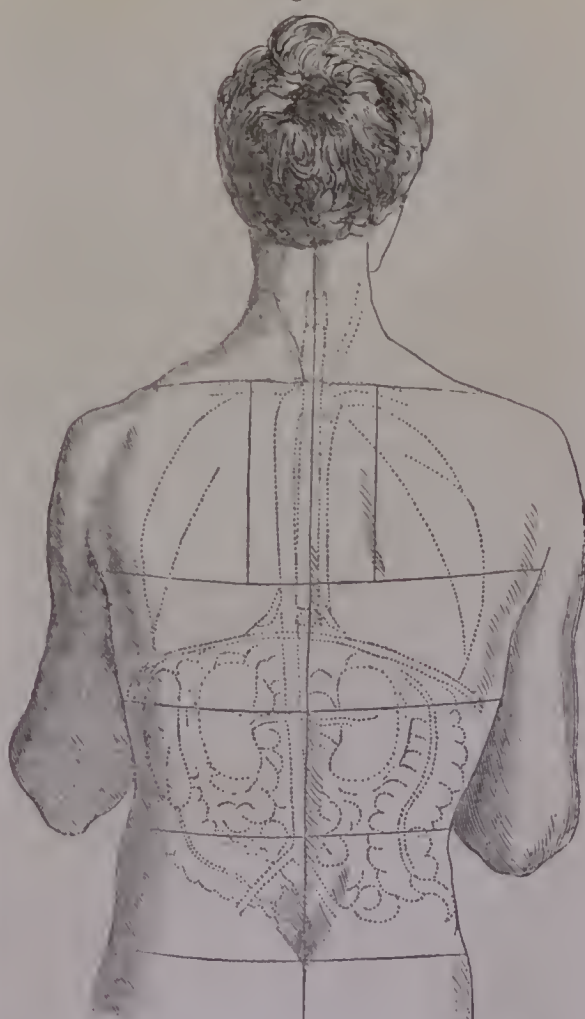

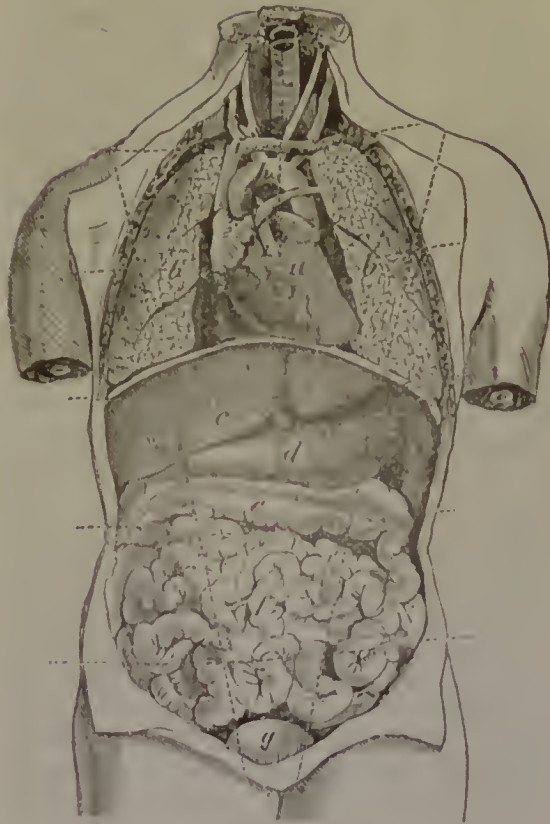

Fig. 5.

\* As belonging all to the same series, we have continued the numeration of the figures begun in the former article.

Fig. 6.

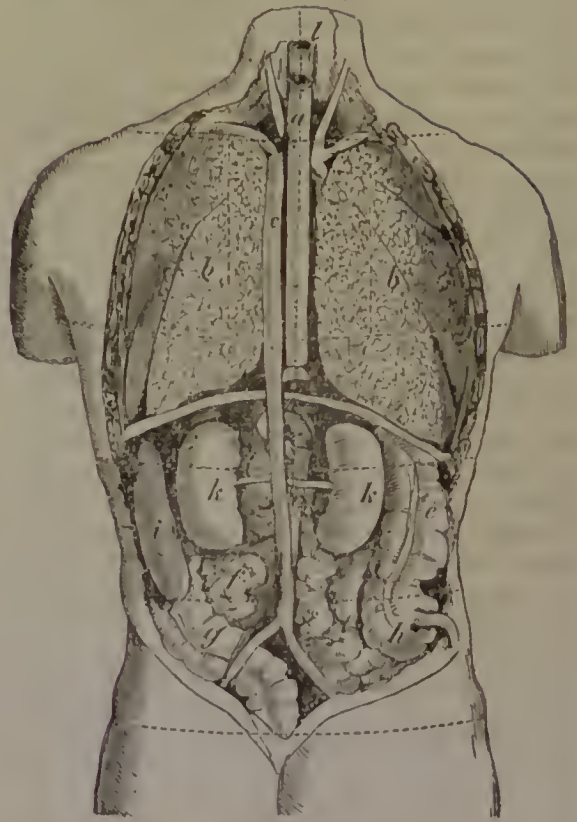

Front View.

- a. The heart.
- b. The lungs.
- c. The liver.
- d. The stomach.
- e. The transverse arch of the colon.
- f. The small intestines.
- g. The bladder.
- h. The arch of the aorta.
- i. The left subclavian vein.

The natural boundaries of the two great organs contained in the chest scarcely require to be pointed out. Separated from each other by the mediastinum, which at its lower part includes the heart, the two lungs are in contact with the solid walls of the chest in every other point, and rest on the diaphragm below. The heart rests on the diaphragm on the left side of the sternum, and extends upwards beneath this bone midway to the upper part of the chest. Both lungs descend much lower on the sides and back than on the fore part of the chest, on account of the position of the diaphragm, which stretches upwards from behind forwards, so as to form an acute angle with the spine. The lungs are consequently prolonged downwards, in very thin lappets, behind, and reach much lower than persons not very well versed in anatomy are apt to believe. It is not unusual to find painful affections of the dorsal pleura referred to the kidneys. An opposite mistake is occasionally committed on the fore part of the body, affections of the liver and stomach being referred to the lungs or heart, because the site of the pain is considerably above the margin of the ribs. We do not allude to those sympathetic pains which in dyspeptic cases radiate far within the true boundaries of the chest, but to pains fixed in the organs themselves.

Fig. 7.

Back View.

- a. The œsophagus.

- f. The small intestines.
- g. The descending colon.
- h. The caput coli.
- i. The spleen.
- k. The kidney.—l. The trachea.

The general shape of the lungs corresponds with that of the cavity in which they are placed. The right lung is larger than the left, but does not descend so low anteriorly, owing to the position of the liver on that side. The upper lobes of the lungs rise as high as the first rib and clavicle, and in the space between the last-mentioned bone and the anterior edge of the trapezius muscle the pulmonary structure is undefended by any bony or thick muscular covering, and consequently lies very near the surface.

I. *Inspection.*—By inspection of the chest we mean in this place the ocular examination of the chest freed from covering; and it is by this alone that the actual configuration of this cavity, whether natural or morbid, can be ascertained with certainty.

The relative size of the cavity of the chest varies considerably in different individuals even of the same age, sex, and stature. This is a circumstance of much practical importance, more especially in relation to prognosis. A very small chest not merely predisposes to diseases of the lungs, but renders them, when they occur, more dangerous. It even tends to enfeeble the constitution generally by diminishing the energy of the respiratory and circulatory functions, and may thereby become a source of aggravation of many dis-

eases which have not their seat within the chest.

A well-proportioned chest should be large in all directions, more particularly in its antero-posterior and lateral directions. Sometimes we see great disproportion in this respect overlooked from imperfect examination. Generally speaking, the cavity of the chest is proportionally smaller in women than in men; and this natural conformation is commonly increased by the use of stays; often it is aggravated in an extreme and most injurious degree. The effect of stays tends to diminish the capacity of the chest chiefly in two ways: first, in its transverse diameter, by compressing it in every point towards the axis of the trunk on its lower half; and, secondly, in its vertical diameter, by forcing the diaphragm upwards before the compressed abdominal viscera. In these cases, although the longitudinal extent of the proper cavity of the chest is greatly diminished, the external bony compages of the thorax is often lengthened, the lower ribs being forced downwards towards the pelvis. When this happens, the usual topographical relations of the external and internal parts are often greatly altered; and mistakes in diagnosis are only to be prevented in such cases by careful examination of the body freed from its coverings, and by the habit of inspecting bodies, so distorted, after death. Another very frequent cause of alteration of the natural configuration of the chest in women is distortion of the spine. Every experienced practitioner is aware of the great frequency of this affection among young women educated at boarding-schools, or subjected to sedentary employments. The effects of this change in the natural direction of the spine in altering the shape of the chest are well described by many of our recent surgical writers; but they are still too imperfectly known by practitioners in general. The real nature of such cases can only be ascertained by inspection, more particularly of the back.

It is, no doubt, by inspection that we can judge most accurately of the condition of the respiratory function generally; but it is not necessary to have recourse to this expedient in order to ascertain the mere frequency or quickness of the inspirations and expirations. This we can do by merely watching the respiratory sounds; and the signs and indications thence derived for the purposes of diagnosis, prognosis, and practice, belong more to the general subject of diagnosis than to the physical exploration of the chest. But it is impossible to ascertain the degree of mobility of the whole thorax relatively with that of the abdominal parietes, or of one side of the thorax relatively with the other, without inspection; and such knowledge is often of much importance. In certain inflammatory diseases of the chest, as pleurisy, more particularly when both sides are affected, the walls of the thorax often remain nearly unmoved, respiration being carried on almost entirely by the diaphragm and abdominal muscles. In this case the abdominal movements are quick and extensive, while those of the chest are the reverse; such a condition

of the respiration has been termed *abdominal*. When inflammation exists in the abdominal cavity, the thoracic parietes are preternaturally mobile while those of the abdomen are inactive: in this state the respiration is said to be *thoracic*. It is only by inspection also that we can ascertain certain conditions of the mere surface, which are, however, often of importance to diagnosis. Of this kind are œdema of a portion of the chest, the relative width of the intercostal spaces, their degree of prominence, &c.

But it is by enabling us to ascertain partial contractions or dilatations of the chest, not dependent on spinal distortion, that inspection is most useful. In some cases, these partial alterations of shape extend to both sides, but they are much more commonly confined to one. In phthisis which has been very slow in its progress, and when tubercles exist in both lungs, as usually happens, we find both sides of the chest contracted, particularly in the subclavian regions. In asthma, on the contrary, both sides are usually considerably dilated, more particularly about the middle of the chest, and rendered much more convex both before and behind. In old asthmatics this configuration of the chest is sufficiently conspicuous, even when the body is covered. Its presence is always a proof of a permanent dilatation of the pulmonary cells, and, generally, of an incurable disease.

But the alteration of configuration produced by disease in the chest is much more generally confined to one side; and the diseases in which this change occurs are chiefly pleurisy and pneumothorax. In acute pleurisy, when the effusion is at all considerable, the affected side is perceptibly dilated; and Laennec assures us that he has often observed this effect on the second day of the disease. The eye readily detects the dilatation when it does not exceed half an inch in the whole semi-circumference of the chest. In chronic pleurisy, when the accumulation of fluid is very great, the affected side is often very considerably dilated: the disease, however, frequently exists without any dilatation. In pneumothorax the affected side is often much dilated; and here, as in simple empyema, we sometimes see the intercostal spaces elevated to the level of the ribs, or even above this. Some of the same diseases which produce dilatation of the chest, occasion at other times a contraction of it, either generally or partially. Contraction of one whole side of the chest is a frequent result of pleurisy, the side being diminished in all its dimensions, the ribs being pressed together, and the intercostal spaces consequently nearly abolished. Partial contraction or dilatation of the chest, permanent or temporary, is still more common than a similar condition of the whole side. When not dependent on distortion of the spine, it may always be regarded as a sign of disease within the chest, either now or formerly existing. By far the most common cause of partial contraction of the chest is circumscribed pleurisy. In the history of the individual diseases—phthisis, hydrothorax, pneumonia, pleurisy, empyema, pneumotho-

rax, &c.—the significance and value of the foregoing signs will be more particularly pointed out.

II. *Manual examination.*—There are only a few circumstances relating to the physical condition of the chest which cannot be ascertained without the direct application of the hand. Of this kind is soreness or tenderness of the surface. Much tenderness of the surface of the chest on simple touch usually indicates an affection of the external parts, either of the skin or muscles, as in the rheumatic affection termed *pleurodync*. It is, however, sometimes produced by internal diseases, as when a collection of pus in the pleura is making its way outwards by perforation of an intercostal space. When, however, considerable pressure is made in the intercostal spaces, pain is very frequently experienced in pleuritic affections, more particularly of a chronic kind. In chronic pneumonia also, and in phthisis, when the lungs, as frequently happens, are adherent to the costal pleura, the same effect is frequently observed; and in cases of this kind we have often found much uneasiness produced by even the gentlest percussion, more particularly if made without the pleximeter.

A preternatural degree of temperature of any part of the surface of the body has been always considered indicative of disease of the particular part, or of those which lie beneath it.\* The same rule is, no doubt, equally applicable to the diseases of the chest; but although the fact may be so, it is interesting more as a pathological phenomenon than as a means of diagnosis, as it scarcely ever exists where we are not provided with more certain indications. In acute pleurisy and pneumonia, and yet more in the complication of these, pleuro-pneumonia, the external surface is often much increased in temperature; and this fact was taken advantage of by Avicenna as a means of detecting the part affected. For this purpose he proposed to apply wetted cloths upon both sides of the chest, and concluded that the side on which the cloth dried soonest, on account of the greatest heat, was that in which the inflammation existed.

Manual examination discovers the presence and degree of muscular robustness, obesity, or emaciation, also œdema, emphysema, &c. with much greater certainty and accuracy than mere inspection: it also enables us to judge of the natural degree of thickness of the thoracic parietes, a circumstance sometimes of considerable importance in appreciating the value of other signs derived from different methods of physical exploration.

III. *Mensuration.*—This process is confined chiefly to ascertaining the comparative size of the two sides of the chest, which relation it ascertains with much greater preciseness than either of the two former methods. It consists simply in measuring the superficial extent of the chest by means of a piece of tape stretched over it from certain fixed points. As the con-

traction or dilatation may be in both the transverse and vertical directions, it is necessary, if we wish to be extremely precise, to make two admeasurements, one from the spine to the sternum, the other from the top of the shoulder to the lowest rib. In general, however, the transverse admeasurement is all that is requisite. In measuring the two sides, we must be careful to apply our tapes in a precisely similar manner to each side. In ascertaining the transverse extent, we first make our measurements after a complete expiration, and then after a full inspiration. It will thus frequently be seen that, although little or no difference is found between the two sides in the former case, it is very considerable in the latter,—the chest on the diseased side not at all expanding during inspiration, and probably expanding even more than in the state of health on the sound side. This effect is rendered particularly striking by fixing the *middle* of the piece of tape on the spine, and allowing the two ends to rest somewhat loosely on the sternum, so as to be moved by the motions of the chest: on the patient taking a deep breath, the end on the sound side is seen gradually to recede from the sternum, while that on the diseased side either remains stationary, or recedes to a very small extent. In cases of contracted chest succeeding acute pleurisy, in which a cure has been effected, it is interesting to watch, month by month, the gradual expansion of the contracted side. In such instances we have been accustomed to supply the patient with a marked piece of tape, and have been gratified to prove by this means, at certain intervals, the progressive return of the chest to its natural size.

It has been endeavoured to ascertain the capacity of the chest, or rather of the lungs, on another principle, namely, by ascertaining the quantity of air the lungs were capable of containing. This method was proposed by the late Mr. Abernethy. It is obvious that it does not lead to the same results as mensuration of the external surface of the chest; this latter giving the capacity of the containing, the former the capacity of the contained parts. Mr. Abernethy's method consists in making the patient take as deep an inspiration as possible, and then expire through a bent tube communicating with an inverted jar containing water. The quantity of water displaced by the air is a measure of the capacity of the lungs to contain air. A person in good health with sound lungs is able to displace six or eight pints; and if the amount be greatly less than this, as for example, only one-third or one-quarter, it may be inferred that the lungs are either obstructed by disease of their own substance, or compressed from without. "Muscular debility or spasm," says Mr. Abernethy, "may occasionally make the result of this experiment doubtful, yet in general I believe it will afford useful information." (Essays, Part II. p. 157.) In this judgment we agree with Mr. Abernethy.

A more simple test of the capacity of the lungs, founded on the same principle, has

\* Et ubi in corpore caliditas aut frigiditas, istic morbus est. *Hippoc. Aph.* 39, sect. 4.

been proposed: (Edin. Med. Journ. vol. xxxviii. p. 453.) It consists in measuring the comparative length of time occupied in making a complete expiration after a complete inspiration. With the view of proving that the expiration is continuous, the patient is desired to *count* from one upwards, as far as he can, slowly and audibly; and the number of seconds during which he is able to count, without drawing breath, is noted by a watch: the number of seconds is considered a proportional sign of the quantity of air expired, and consequently of the capacity of the lungs. Dr. Lyons, who proposes this method, says that the most healthy individual will not continue counting beyond thirty-five seconds; but in this he is certainly mistaken, as any of our long-winded readers may prove by personal experiment. In confirmed phthisis, Dr. L. says, the period of expiration never exceeds eight, and is frequently less than six seconds; while in pleurisy and pneumonia it may range from four to nine. This test is of much easier application than Mr. Abernethy's, but it is much less accurate: it is liable to vitiation from many causes, but still, like Mr. Abernethy's, it may be occasionally useful.

(John Forbes.)

CHICKEN-POX.—The terms chicken-pox and swine-pox seem to have been in use in England from a very early period, to express those lighter cases of eruptive disorder, which, bearing a general resemblance to small-pox, yet differ from that disease in the mildness of the accompanying fever and the shorter duration of the eruption. Morton, the contemporary of Sydenham, introduced the term chicken-pox into scientific nomenclature, and it is now so universally adopted that it is proper to inquire what are the pathological characters of the disease thereby designated. Is the chicken-pox allied to small-pox? Does it arise from the same contagion? Does it give security against small-pox? Can it be communicated by inoculation? These questions have been argued for the last hundred years, and the opinions of pathologists are still far from being made up concerning them. It is obvious that before we can undertake to establish the diagnostic characters of chicken-pox, we must have previously fixed the distinguishing features of small-pox. On this account it is proposed to defer the regular consideration of the former until the latter disease has been described. A brief sketch, however, of the eruptions commonly known in England as the *chicken-pox* may find a place here.

This term is familiarly applied to all those eruptive complaints in which, after a brief attack of fever, the skin is covered, generally or partially, with vesicles or imperfect pustules, which run through their stages of maturation and decline in three, four, or at furthest five days, the attending constitutional symptoms being very slight, without any threatening of danger. Such disorders are very common. They are met with in infancy and mature age. They

often appear to prevail epidemically. Dr. John Thomson, of Edinburgh, believes that the whole of them are modifications of small-pox, and the result of the variolous virus. Other pathologists, again, consider that under the term *chicken-pox* are included different *kinds* of disease, analogous to each other in their progress and termination, but differing in their causes and in their earlier phenomena. This latter is the opinion which, after very careful consideration of the subject, will be adopted here. Accordingly, the reader will find under the head of SMALL-POX (*Modified*) a description of that class of cases which are characterised by imperfect pustulation, occurring chiefly in adults, and preceded by two or three days of fever; while under the head of VARICELLA LYMPHATICA he will look for those which have for their chief features a sudden eruption of vesicles, preceded by little or no fever, and occurring almost exclusively in the periods of infancy and childhood.

(George Gregory.)

CHLOROSIS, from  $\chiλωρός$ , green; the disease known by the designation *green-sickness*. This singular affection is chiefly incidental to female youth; it occurs sometimes, however, in the age of childhood, not unfrequently in married women, and occasionally in the young and delicate of the male sex; and in these several cases it assumes modified forms, which will be carefully described in the sequel.

*History and symptoms.*—Chlorosis steals upon the patient very insidiously. It has pretty distinctly three stages; the incipient, the confirmed, and the inveterate. It may be characterized, in general, as uniting a morbid paleness of the complexion, tongue, and general surface, with recurrent pain of the head or of the side, generally the left; palpitation, fluttering, breathlessness, nervousness, and frequently attacks of hysteria, with some tendency to loss of flesh and œdema.

The first stage or period of chlorosis is usually little observed by the patient or friends. There is slight paleness, or a little fading of a wonted florid complexion, and the patient is only a little more languid and listless than usual, the ordinary amusements or occupations, whether mental or bodily, being accompanied by fatigue, the nights restless, the mornings heavy. With these changes, however, there is invariably a confined state of the bowels, a deranged condition of the stomach, a tainted breath, a white and pasty tongue, and a morbid appetite; and there is recurrent headache, pain of the left side, palpitation, &c. The catamenia are supposed to flow as usual, but an attentive inquiry discovers, that with the complexion, the uterine discharges also lose their colour.

In the second or confirmed stage, every morbid appearance, every symptom is aggravated; the countenance, the prolabia, the tongue, the gums, the internal parts of the cheeks, the conjunctiva, the general surface,

and especially the fingers and the finger-nails, become absolutely exanguinous, sometimes with a pearly, sometimes with an icterode hue; the eye-lids are sometimes slightly œdematous, especially in the morning; the tongue, besides being pale and exanguinous, is œdematous and impressed with the teeth; sometimes slightly loaded, sometimes morbidly clear, and glossy in various parts; the teeth are apt to decay; the skin becomes gradually rather dry; a singular change takes place eventually in the finger-nails, which become brittle, and easily split or break off, so that frequently a pin can scarcely be taken out of the dress. An equally remarkable change is also occasionally observed in the hair, which becomes dry and harsh, frequently splitting, and not remaining "in curl;" the ankles become tumid, and more and more œdematous. With the accession and progress of these symptoms, the catamenia are found to become more and more scanty and pale, and then to disappear; the bowels continue constipated, with or without alternations of diarrhœa; the stomach is oppressed after eating; there are various forms of pica or morbid appetite, as for pickles, magnesia, cinders, &c.

With this state of things there is frequently one predominant symptom, which absorbs the attention of the patient and friends, and sometimes even deludes the medical practitioner. This symptom is sometimes a violent recurrent headach; sometimes pain of the side, especially the left side, just under the mamma; sometimes palpitation of the heart; sometimes cough; in other cases these symptoms vary and interchange, and there is frequently every variety of affection comprised in hysteria. This predominant symptom frequently leads to the idea of *arachnitis*, of *pleuritis*, of *disease of the heart*, or of *incipient phthisis*.

Chlorosis is frequently complicated with hæmatemesis and melæna, and with epistaxis. In the latter affection the blood occasionally scarcely tinges the linen on which it drops.

There is also frequently in this disease the peculiar affection designated by Dr. Willan the erythema nodosum, and of which an account will be given in its proper place.

The second stage gradually passes into the third, in which some degree of emaciation is added, the œdema assumes a more or less aggravated form of anasarca, and a proportionate degree of danger now attends the complaint.

It frequently happens, from the insidious character of this affection, and from the severity of the predominant symptoms, that the case is mistaken for one of an inflammatory character. The affection of the head, the pain of the side, the palpitation of the heart, have severally led, in many instances, to an abstraction of blood, equally inappropriate and useless, if not absolutely injurious and dangerous.

The distinction is not always easy. One of the best sources of the diagnosis, in doubtful cases, is the degree of susceptibility to faint from the detraction of blood. This circum-

stance, added to the general symptoms and to the inefficiency of those remedies which are adapted to the case of inflammation, is an important criterion of pains which are not inflammatory. (See BLOODLETTING.) The quantity of blood which has been unwittingly detracted, and the number of leeches and of blisters which have been uselessly as well as needlessly applied in some of these cases, are quite extraordinary.

*Causes.*—The most usual exciting causes of chlorosis are delicate and sedentary habits; the predisposing causes are those peculiarities of the constitution involved in the lymphatic temperament. From the influence of one or both of these causes, chlorosis frequently prevails amongst young persons of the same family; and when the female part of a family suffers in this manner, a slight degree of the same or of a similar affection is frequently traceable in the males, denoted by unwonted pallor of the lips, and an œdematous condition of the tongue.

The influence of such habits in such a temperament as has been described, is first seen in a confined state of the bowels; the colon becomes loaded, and the functions of the other digestive organs, with the processes of assimilation and sanguification, become deranged.

In an early stage of chlorosis the catamenia are observed to become pale and scanty, and eventually they cease. This circumstance has led to the opinion that the peculiar condition of the generative organs, about the age of puberty, had much influence in inducing the state of chlorosis. Dr. Cullen contends that the retention of the catamenia in these cases "is to be referred to a certain state or affection of the ovaria;" but this he does not "pretend to explain." Dr. Hamilton, in his admirable work on Purgative Medicines, has argued against this notion so satisfactorily as to leave little for subsequent writers to do. It is quite obvious, on carefully tracing the succession of symptoms, that the first link in the chain is constipation, and that the subsequent links are the effects of the continued operation of this cause.

In some manufacturing districts, chlorosis and some affections strictly allied to it, may, from the habits of the people, be justly said to be endemic. In manufacturing towns, in Nottingham for instance, the youthful and almost the infantine parts of the population are engaged during many hours of the day bending over the tambour or lace-frame. The baneful influence of the want of air and exercise, and of a sedentary occupation, are speedily visible in the pallid and icterode states of the complexion, and in the listless manner of these youthful sufferers. The bowels first become confined and loaded; the appetite repels simple food; the breath becomes tainted; the gums become swollen and pale, and the teeth decayed. This state is gradually followed by the other appearances and affections observed in chlorosis.

Servants, and especially cooks, are particu-

arly liable to chlorosis. But the delicate and inert habits of the rich not less frequently lead to this affection.

In all there is the same torpor of the bowels, the same defective digestion, assimilation and formation of blood.

*Pathology.*—Amongst the series of morbid changes induced in chlorosis, is an impaired condition of the blood itself. This fact is particularly noticed by M. Andral in his *Anatomie Pathologique*, t. i. p. 87. The quantity of serum is proportionately augmented, that of the crassamentum diminished. This appears to be the true source of the pallor characteristic of this disease, and of the greater or less deficiency in colour and in quantity of the catamenia. This is also most probably the cause of many of the symptoms of chlorosis which resemble, in so many respects, the case of anæmia from actual loss of blood. The same circumstance is also the cause of two events occasionally observed to take place in cases of chlorosis; namely, *delirium* or *mania*, and *sudden death*.

In two cases the writer has witnessed complete mania in chlorosis. One of the patients speedily recovered; the other was conveyed to a distant hospital, and died from the effort.

Four cases of chlorosis in which death took place suddenly have fallen within the writer's knowledge. In one of these a careful post-mortem examination was made. The patient having been confined to bed for a few days with cold, became much better, and was in good spirits; after having sat up for a quarter of an hour, and talked cheerfully, she suddenly became faint, gasped, and expired. On examination, some effusion was found in the ventricles of the brain, in the pericardium, and the left cavity of the pleura, the right cavity being obliterated by adhesion; the lungs were gorged with serum; the heart was large; the liver much enlarged; the hands were of an ivory whiteness; the ankles were slightly œdematous; and there was abundance of adipose substance. The blood was pale and aqueous, and the clots formed in the large vessels were small and light coloured.

The occurrence of sudden death in some affections termed nervous, and deemed innocuous, is a fact which has not been sufficiently noticed. The writer has been informed of several such cases within the last two years. He suspects that the patients have been chlorotic and bloodless, and that the case is like that of sudden death occurring after great loss of blood.

*Treatment.*—The remedies for chlorosis are principally, mild but efficient aperient medicines and chalybeates. It is important, in the first place, to remove any load from the bowels by an ample dose of medicine, such as an ounce of the oleum ricini. Afterwards, pills consisting of two grains of the Barbadoes aloes and the same quantity of the sulphate of iron, taken daily during dinner, are most efficacious, and indeed, in the writer's experience, almost specific.

It is sometimes useful to interpose a draught of the tinctura and infusum rhei with manna;

at other times, senna and the Epsom salt are required to move the bowels sufficiently. In other cases the warm water enema is necessary to ensure the due effect of the aperient medicines.

Other forms of the chalybeates are also occasionally advantageous, and especially the ammoniuret in the form of tincture, and the carbonate.

A mild, light, nutritious diet must be enjoined with these medicines; and a system of moderate exercises, in the free open air, especially riding on horseback, must be enjoined, carefully avoiding fatigue. The general surface, but especially the feet, must be kept warm.

It is often necessary to employ some distinct remedy for the pain of the head or of the side; and a blister is the best. The palpitation also occasionally demands a remedy, and the tinctura hyoscyami relieves this symptom. Leeches, and, *à fortiori*, general bloodletting are highly injurious, perpetuating the constitutional disease.

Chlorosis is frequently produced, and frequently aggravated or protracted by some mental cause. It is important that the physician should at least be aware of this fact; he may then sometimes be enabled to remove an obstacle to the recovery of the patient, which, whilst it existed, might frustrate all his efforts.

The remedies for chlorosis may be enumerated thus: the aloëtic chalybeate; mild nutritious diet; exercise and air: horse-exercise, and the sea-breezes are also highly useful.

Many other remedies have been proposed for chlorosis; but, in the writer's opinion, they are both inefficient and unnecessary. Those which have been enumerated have seldom failed to remove the disease; whilst the other forms of aperients and chalybeates have appeared far less efficacious. The well known Griffith's mixture, the mistura ferri composita, and the precipitated carbonate of iron, are of this character.

A disease similar to chlorosis, which yields to similar remedies, occurs in infants and children, and might, for the sake of distinction, be termed *leucosis*, from λευκός, *white*. The lips and cheeks are of a waxen pallor; the tongue, the hands, and the general surface are perfectly exanguious; and there is extreme feebleness. A few grains of rhubarb with one fourth of a grain of the sulphate of iron, given twice a day, with a light nutrient diet, and the fresh air, and attention to warmth, speedily restore the little patient to its wonted strength and colour. This affection has been little noticed. If neglected, it sometimes takes the patient off with symptoms resembling those of hydrocephalus.

A disease similar to chlorosis also occurs in married females. This affection sometimes, but not always, arises from actual loss of blood; the late Dr. Gooch has designated such a case *acute chlorosis*. More frequently an exanguious condition of the system arises from a defective assimilation and formation

of blood. The aloëtic chalybeate is the remedy of greatest efficacy in restoring the hæmatisis.

The occurrence of chlorosis in the delicate of the male sex has been noticed by Dr. Hamilton, Sir Gilbert Blane, and others, and will become familiar to all who study this affection with attention. It has been already stated that in families in which chlorosis prevails amongst the females, a similar affection seems to attack the males. In some such instances the writer has seen chlorosis in its most marked character in the male sex. It is removed by the aloëtic chalybeate.

(*Marshall Hall.*)

**CHOLERA.**—This word is generally supposed to be derived from  $\chiολη$ , *bilis*, and the authority of Celsus is ordinarily quoted in support of this etymology. There is, however, an obscurity in the passage usually referred to in the works of this writer, which renders it doubtful whether he means that bile or the forcible manner in which it is ejected has given origin to the name of the disease; for the Greek word  $\chiολερα$  signifies a water-spout as well as the disorder of which we are treating, and it has been suggested that the adjunct *morbis*, so frequently annexed to it, when employed in the latter sense, was thereby rendered necessary for the purpose of due discrimination. However this may be, it is manifest from passages of different writers, especially from one of Celsus himself, that the words  $\chiολη$  and *bilis* had a much more extended sense than our word bile, being by no means restricted to the secretion of the liver, but applied to any liquid discharge from the intestines. By Trallian the word is derived from  $\chiολαδες$ , *intestina*.

The disease being one of frequent occurrence at certain seasons in various climates, and its symptoms being of a very manifest nature, it early attracted the attention of medical writers. It is mentioned at some length by Hippocrates (*Epidem. lib. v.*), who divides it into the moist and dry species, an arrangement which has been adopted by some much more recent authors. Celsus has a chapter upon it (*cap. xi. lib. iv.*) in which its symptoms are detailed with his accustomed accuracy, brevity, and elegance; and notice is taken of the occasional occurrence of a watery and a white discharge, circumstances which recent events have invested with considerable importance. He regards it as a highly dangerous disease, and speaks of the deaths produced by it as of sudden occurrence. Aretæus treats of the disease, and is rather minute in his description of the discharges. The matter vomited is at first, he informs us, like water, and the alvine dejections are liquid and stercoraceous; whilst, if long indigestion has been the exciting cause of the disease, the discharges are at first *pituitous*, then *bilious*. Of more modern writers, our own Sydenham treats of the disease with that accuracy of observation and practical good sense which are his chief characteristics as a writer. He regards cholera as having in this country an epidemic prevalence only during

the month of August and the early part of September, and declares that any occasional case which may occur at another season, however similar to the epidemic in character, is in its nature essentially distinct from it. Morton (*Pyretologia*, p. 16, &c.) and Torti (*lib. iii. cap. i. p. 124.*) have described cholera as appearing in an intermitting form and curable by bark.

The disease is placed in the class *fluxus* and order *alvi fluxus* of Sauvages; in the class *neuroses* and order *spasmi* of Cullen, and very appropriately in the class *caliaca* and order *enterica* of Dr. Good.

The following definition will probably comprise every case really belonging to the genus cholera:—vomiting, purging, spasms, prostration, and collapse, or any four of these symptoms occurring simultaneously or in a succession more or less rapid.\*

For practical purposes it seems sufficient to consider cholera as divided into two species, ordinary cholera and the epidemic or malignant disease; such deviations from the common type of these disorders as are occasionally met with being indicated in the course of the article.

**I.—COMMON, OR SPORADIC CHOLERA.**—Ordinary cholera may be thus defined: vomiting and purging, the discharges during great part of the course of the disease containing generally a large proportion of bile; pain in the stomach and intestines; spasms, especially of the muscles of the abdomen and lower extremities, and prostration. If collapse occur, it takes place after the disease has endured some time, apparently as an effect of the great discharge, spasm, and irritation.

Besides these distinctive marks of the disorder, there is generally found great inflation of the stomach and bowels; the fluid vomited is frequently enormous in quantity, consisting at first of the food in the stomach, and subsequently of matters variously coloured from light brown to dark green, and expelled with great force; and the stools, the appearance of which indicates, during the greater part of the course of the disease, the same redundancy of biliary secretion as is denoted by the matters vomited, are generally copiously and forcibly expelled, though sometimes sparingly and with difficulty. The dark appearance here attributed to the discharges in ordinary cholera must be considered as generally applicable only to this disease as it occurs in our own and other temperate climates; for a white appearance of such matters had been remarked as an occasional circumstance, by Celsus and various other physicians, in the warmer regions long before the occurrence of the epidemic which has recently attracted so much attention. At the commencement of the attack the skin is generally warm and dry; but after a few hours its temperature falls considerably below the standard of health, and it is bedewed with a cold and clammy moisture. The tongue is dry and the

\* This definition is modified from that of Dr. Macann.

thirst excessive; the urine scanty and high-coloured; the pulse rapid, and generally small and irregular; and the spasms which affect the muscles of the abdomen and of the inferior extremities, and occasionally those of the hands and arms, recur at short intervals, and are attended with great pain. After the disease has continued some time, the countenance appears anxious, ghastly, and shrunk; the voice is feeble and interrupted; the sense of exhaustion is extreme, and in severe and protracted cases the tendency to fainting is great and alarming.

Ordinary cholera in temperate climates is not very often fatal; yet is it a dangerous disease, and one which requires much attention on the part of the practitioner. The approach of death is denoted by the continuance of the vomiting and purging, especially of the latter; by hurried breathing; a countenance either of a purple hue, or pale, anxious, and contracted; a feeble and fluttering pulse, and coldness of the extremities and surface generally. Cessation of the vomiting and purging; warmth of the skin; the pulse approaching the surface with a diminution of its frequency; the restoration of a tranquil expression to the countenance, and the recruiting of the powers of the patient from a state of oppression and exhaustion, indicate recovery.

It not unfrequently happens that for some days after the subsidence of vomiting, purging, spasms, and other violent symptoms mentioned, the patient feels some uneasiness in the epigastrium and other parts of the abdomen, which is increased on pressure. The pulse is at the same time sharp and frequent; the tongue always dry, and either red and glazed, or covered with a brown fur; there is great thirst with complete inappetency, and occasionally nausea, and the bowels are generally costive, though they may be readily excited to action by laxative medicine if the stomach can be made to retain it, the discharges procured being usually of a dark green appearance. These symptoms, which denote gastro-enteritis supervening on the high degree of irritation of the lining of the digestive canal, require diligent attention; for some cases in which they had been overlooked have proved fatal, though the patients had previously emerged from a state apparently more urgent and dangerous.

*Diagnosis.*—The factitious disorder produced by an irritating poison, and the epidemic species of the disease, are the only affections of the system with which there is any risk of our confounding the form of cholera at present under discussion. The distinction from the latter affection we shall endeavour to point out in a subsequent part of the article. Professor Christison\* places some reliance on the respective duration of cases of fatal cholera and of poisoning from the irritants, as a ground of distinction between them. He informs us that death from irritant poisons is seldom delayed beyond two days and a half, and frequently happens within thirty-six hours,

sometimes within twelve hours, or even less; whilst death from cholera at any time is rare, but within three days very rare indeed, though it may occur in twelve hours. This statement itself shews that the comparative duration of these affections furnishes no secure means of distinguishing them; and our experience tells us, besides, that death from cholera within three days, or even in twelve hours, is much less rare than this able writer supposes. Another discriminating test pointed out in the Treatise on Poisons, the sanguinolent vomiting which attends cases of poisoning, we fear is not more tenable than the preceding; for though a rare, we know from observation that it is not an unexampled accompaniment of cholera.

Though these circumstances, the duration of the disease when fatal, and the presence or absence of sanguinolent vomiting, seem insufficient to distinguish the two affections, yet the conclusion to be arrived at is, that the diagnosis between cholera and poisoning may in many cases be formed from symptoms alone; and certainly, that no observing practitioner would be long at the bed-side of a patient who had swallowed an irritating poison in a dose likely to prove fatal, without discovering that he had something different from natural disease to contend with. It is true that he might not have evidence of the fact sufficient to establish it in a court of justice, but his conviction would be such as to excite him to an examination calculated to elicit satisfactory legal testimony. The sense of burning in the throat, extending thence down the œsophagus to the stomach, is dwelt upon by the sufferer in a way that is never observed in cases of cholera, in which the patient complains of intense pain, but never dwells upon this burning feeling as constituting the chief source of his sufferings, though he may acknowledge its existence if questioned. Besides, as Professor Christison justly observes, it is certain that the sense of acidity or burning sometimes remarked in cholera never begins before the vomiting, whereas in many cases of poisoning, though certainly not in all, it is the first symptom. It may be remarked, too, that it is often stated by the sufferer to have occurred either immediately or shortly after the swallowing of something.

*Nature of the disease.*—The first effect of the application of the cause of cholera seems to be a violent irritation of the mucous lining of the stomach and small intestines, which is propagated to the liver either by continuity along its ducts, or by sympathy between organs whose actions are so intimately associated. Some writers, reversing the order here stated, consider the liver as the part first affected, and the manifest disorder of the digestive canal to be the effect of the derangement of that organ. The order first mentioned seems more in accordance with the agency of the usually assigned causes of the disease, with its phenomena, the effects of remedies upon it, and the appearances on dissection. The irritation is extended, it would appear, not merely to the

\* Treatise on Poisons, p. 93 et seq.

liver, but likewise to the spinal marrow; at least the parts supplied with spinal nerves are the seat of violent spasms. The state of the heart's action at the onset of the disease, before exhaustion can be supposed to have resulted from the mere effect of the discharges, renders it probable that it is affected through the medium of the ganglionic nerves or spinal marrow. Whatever view may be taken of the structures primarily affected in cholera, it seems beyond all question that those we have enumerated are the parts principally concerned in producing its symptoms.

*Appearances on dissection.*—When the disease is rapidly fatal, there is no discernible lesion of structure; but if death occur after the lapse of some days, and especially if it take place from the gastro-enteritis which has been described as supervening on cholera, the mucous lining of the stomach and small intestines is found more or less strongly injected.

*Causes.*—This disease was supposed by Sydenham to be peculiar to the month of August, and it certainly in this country occurs more frequently during this month than any other; but it may be observed at any season of the year when a warm atmosphere during the day alternates with a considerable degree of cold at night. As might be supposed from this statement, its most frequent exciting cause is exposure to the chill of damp or cold air after unusual heat. On the same principle, drinking cold water when the body is heated has occasionally produced an attack. Cases occur, too, in consequence of taking food or liquid calculated to irritate the stomach and bowels. Malaria has been supposed to be a cause of the disease; and this opinion derives a great degree of probability from its appearing at the season when autumnal intermittents and remittents prevail, and the fact that many cases of sub-continued or slightly remitting fever, and even of ague, have been observed, which commenced with symptoms identically similar to those of cholera.\* A remarkable example of the malarious origin of the disease occurred at a school at Clapham, in August, 1829. A very foul drain, or cesspool, was opened, and its contents were thrown into a garden adjoining the school. A day or two afterwards one of the boys was attacked, and in two days more twenty others out of the total of thirty. The disease appears to have considerably resembled the Indian epidemic, the evacuations being much less tinged with bile than is usual in the ordinary cholera of temperate climates. Two cases terminated fatally. It was held by the highly respectable medical authorities assembled on the occasion, that the effluvia from the putrid matter had produced the disease.†

*Treatment.*—The counsel ordinarily given is to defer the employment of medicine for some hours after the commencement of the disease, limiting our endeavours during this period to the administering of diluents, such as gruel,

thin chicken-broth, beef-tea, barley-water, &c.; but even if the patient's earnest appeals for relief would allow of this delay, it seems more than questionable whether it would be justifiable; for some time has generally elapsed before medical aid is obtained, and the cases must be rare indeed in which more powerful agents than those mentioned may not be employed at the time of our arrival, and are not, in fact, demanded.

Opium is the remedy which, from its well known effects in other diseases, would naturally present itself to the mind of the physician as likely to allay the irritation; and it is in reality the best which he can employ. In mild cases, it is often found to be the only medicine required; but in more severe attacks it may be advantageously conjoined with calomel, the combination of these medicines having an excellent effect in allaying gastric and intestinal irritation. In slight cases, a grain of opium, or a proportionate quantity of laudanum, may be given every second hour till relief be obtained. In those which are more severe, two or three grains of calomel, combined with a grain of opium, may be given at the same interval till three or four doses shall have been taken; or, the calomel being administered in pill, a draught containing a proportion of laudanum or black-drop, equivalent to a grain of opium, may be exhibited along with it.

Subsidiary measures should accompany the employment of these medicines. The diluent drinks already mentioned should be given at intervals to allay the urgent thirst of the patient, but in small quantities, lest they excite vomiting. Hot fomentations to the abdomen are well calculated to afford relief; and the patient, if not much exhausted, may remain for a quarter of an hour in a bath of 100°, if it can be obtained. It must be observed, however, with regard to the warm-bath, that in the epidemic disease the most experienced practitioners decline its employment where there is much collapse, on account of the distress it occasions, and, indeed, from the positive mischief arising from the necessity of removing the sick from the horizontal position: *dry heat* is now generally preferred in those cases, and it will be proper to keep this fact in view in our treatment of the ordinary species, when the exhaustion is considerable. A large blister to the epigastrium, previously fomented with hot vinegar, is frequently useful in relieving the vomiting and internal irritation; or sinapisms are sometimes advantageously employed to produce the same effect more rapidly. Scalding the epigastrium, or, as it is called, the warm water blister, is the prompt mode occasionally employed in the cholera of the east; but there is reason to apprehend that it would prove abhorrent to the feelings of patients in this country, and would be deemed a needlessly severe treatment of ordinary cholera.

Should there be considerable exhaustion, indicated by coldness of the skin and feebleness of the pulse, diffusible stimulants, such as

\* Medical Essays, by J. Brown, M.D. p. 38.

† Searle on Cholera, and Orton, p. 415.

brandy, ether, and ammonia, should be given in small quantities. Draughts composed of carbonate of magnesia, aromatic spirit of ammonia, compound tincture of cardamoms, and laudanum, are frequently well retained by the stomach, and have a good effect in such a state. Strong beef-tea may be given, if the stomach become tranquil, in small quantities at short intervals, alternately with brandy and water.

General bleeding is neither required nor perhaps admissible, in the course of the symptoms of what may be strictly termed cholera in a temperate climate; but even during such symptoms either there is occasionally such permanent tenderness of the epigastrium, perceived in the intervals of severe pain, vomiting, and spasm, as induces us to conclude that the irritation of the digestive canal has passed into inflammation; or the glazed or furred state of the tongue, the intensity of the thirst, the sharpness of the pulse, and general uneasiness of the patient, without the existence of permanent pain, may lead us to the same conclusion. In either case the application of a dozen or eighteen leeches to the epigastrium will be attended with much benefit. After the leeching, a large emollient poultice may be applied, followed, on the total subsiding of the oozing from the leech-bites, by the application of a blister to the epigastrium.

In the gastro-enteritis, described as sometimes occurring after the cessation of the actual symptoms of cholera, general bleeding may be performed to the extent the patient's strength will admit, not only with safety, but with great benefit. Leeches and blisters to the abdomen, and mild mercurials, particularly hydrargyrus cum creta in doses of three or four grains every fourth hour, till some affection of the mouth is perceived, will be found the best subsidiary remedies.

Cholera frequently leaves the patient in a state of extreme debility, which should be sedulously watched, for persons have occasionally died suddenly, when supposed to be recovering from the disease, apparently from exhaustion. The horizontal posture, and mild and nutritious diet, consisting of sago with milk, beef-tea, or chicken-broth, with bread or biscuit, animal-jelly, &c. are the appropriate remedies. If the bowels are costive, they should be moved by enemata, for all the symptoms of cholera have been reproduced, three days after their subsidence, by so gentle an irritant to the digestive canal as a dose of rhubarb.

We had proposed to ourselves to terminate here all that it appeared to us necessary to say under the present head; but we are bound towards the profession to admit that the details which had been laid before us, previously to the manifest appearance of the epidemic disease in this country, through the channels of medical journals, of sporadic cases which occurred in various parts of England during the autumn of last year (1831), preclude the possibility of our hesitating to acknowledge a perfect identity between the group of symptoms

in some of those cases, and the symptoms of the choleric stage of the malignant epidemic form in which cholera has of late years committed such ravages. The fullest details are given in several instances, and by persons of whose accuracy we cannot have the remotest doubt. Respecting a case in the seventh regiment at Hull, which proved fatal on the 11th of August, after an illness of sixteen hours and a half, and in which the assemblage of symptoms held to be characteristic of Indian cholera were so very strongly marked, we may state that the gentleman who forwarded the details to the journal in which they appeared has sent us his name, and pledges himself for their fidelity. In this case there were the *blue skin*, the *total absence* of pulsation in the extremities for some time before death, the *sudden appearance of the fingers*, the *coldness of the tongue*, the *change in the voice*, and the *suppression of urine*, all which are so particularly dwelt upon by innumerable authorities as peculiarly marking the cholera spasmodica.

II.—EPIDEMIC; OR MALIGNANT CHOLERA.—Long prior to the appearance of the present epidemic in the Delta of the Ganges in 1817, and its subsequent diffusion over so large a portion of the globe, extensive and destructive visitations of cholera had been noticed by various writers. One of these, we learn, occurred in Europe at the close of the seventeenth century; but most of them originated in the east, and limited their devastations to that quarter of the world. The indefatigable Mr. Scot has quoted, from the Madras Courier of 1819, a letter, which suggests the opinion that a description, though certainly a very obscure one, of a disease resembling that which now prevails, is to be found in a Hindoo work of great antiquity; and cites instances of the epidemic prevalence and great fatality of cholera from the time of Bontius, in 1629, to the present century; but the description of these epidemic visitations has not always reached us in so detailed a form as to enable us to judge correctly of their identity with what has been recently observed: enough, however, may be gleaned to prevent our denying this identity in some instances; indeed, it is impossible not to be struck with the resemblance which certain of the more accurately reported of these examples—especially one which occurred at Ganjam, in 1781—bear to that now existing. But this much seems certain, that, however cases in previous visitations may have resembled in character those of the prevailing disease, no recorded epidemic of cholera has equalled this in the wideness of its diffusion and the amount of its ravages, or has preserved its character and intensity so little influenced by climate and temperature.

The question of the identity of the disease which now prevails in Great Britain and on the continent of Europe, and that which ravaged Hindostan, having been settled in the affirmative, at least as regards certain of their most important practical points, by the various respectable physicians who have witnessed both diseases, we may assume that much of the valuable in-

formation transmitted to us from India respecting the nature and treatment of the malady which raged there, is applicable to that which is now committing its ravages in Europe.

1. *Symptoms of cholera in India.*—The disease generally makes its attack in the night, or towards morning, with vomiting so excessive, that the whole contents of the stomach appear to be discharged; and nearly at the same time the bowels are copiously emptied, as though all the solid matters in the intestinal canal were evacuated. In some cases a watery purging precedes the vomiting by some hours; but they more frequently occur simultaneously. After the first copious discharge, the patient experiences a distressing feeling of exhaustion and faintness, with ringing in the ears and giddiness. The subsequent discharges from the stomach and those from the bowels do not differ from each other in appearance, excepting as the matters ejected from the stomach may be tinged by medicines or other ingesta: they are generally watery, colourless, and inodorous, and are compared in their appearance to barley-broth, or more frequently to rice-water. Sometimes they are like milk, occasionally yellowish, greenish, like muddy water or yeast; but the “conjee-stools,” as they are emphatically termed, which consist of albuminous flakes floating in serum, or discharges of pure serum, are of the most frequent occurrence. The dejections sometimes take place without effort or uneasiness, but occasionally very forcibly, with simultaneous vomiting, spasm, and sinking of the pulse. This violent action of the alimentary canal is not of long continuance, the powers of the system being unable to support it: hence the vomiting and purging generally cease some hours before death; but in some cases a discharge of serum takes place from the rectum on any movement of the body till the fatal close.

In most cases some time after the commencement of this affection of the intestinal tube, but in others previously to it, spasmodic contractions of the muscles of the fingers and toes are felt, and these affections gradually extend along the limbs to the trunk. The spasms are imperfectly clonic or convulsive, with infrequent relaxations, are attended with great pain, and leave for some days afterwards a degree of stiffness in the affected muscles. The pulse is from the first small, weak, and accelerated; and after a certain interval, but especially on the accession of spasms or severe vomiting, it sinks suddenly, so as to be speedily lost in the external parts. The length of time during which a patient will live in this pulseless state is remarkable. In a case related by Dr. Kellett, the pulse was gone within three hours from the attack, yet the man lived twenty-two hours in that state. On the cessation of spasm and vomiting, and sometimes apparently from the exhibition of remedies, the pulse will return in the extremities for a short time, and again cease. The skin is cold from the commencement of the disease, and as it advances, becomes gradually colder, and is covered either with a

profuse sweat or a clammy moisture. The state of its circulation and its insensibility are sometimes strongly denoted by the following circumstances: leeches will not draw blood from it; blisters and other vesicatories will not act; and even the mineral acids and boiling water produce no effect, and some patients are not even sensible of their application. In Europeans the colour of the surface is often livid; the lips and nails present a blue tint; and the skin of the feet and hands becomes corrugated, and exhibits a sodden appearance, as if from long immersion in hot water.

With these symptoms co-exist violent pain of the intestines, with a sensation of writhing and twisting there; heartburn, which the sufferer compares to a fire consuming his entrails; excessive thirst; anxiety, with inexpressible uneasiness about the præcordia; hiccup; jactitation; and, notwithstanding the actual coldness of the surface, and even of internal parts which are accessible to the touch, the tongue for instance, a *sense* of heat which impels the patient incessantly to throw off the bed-clothes. The breathing is much affected, being performed either more slowly than usual, sometimes for instance, in the advanced stage, only at the rate of seven respirations in a minute, or the inspirations are short and sudden, with violent pain from spasm of the diaphragm; the voice being feeble, hollow, hoarse, and interrupted. The eyes are sunk in their orbits; the cornea flaccid, the conjunctivæ frequently suffused with blood; the features of the face collapsed; and the whole countenance wears a cadaverous aspect. The secretions, those of the skin and intestines excepted, are generally suspended. The functions of the mind are undisturbed almost to the very last moment of existence.

The approach of recovery is denoted by the rising of the pulse, the return of heat to the surface, inclination to natural sleep, diminution or cessation of vomiting, purging, and spasms, and, after an interval, the re-appearance of bilious stools, urine, and saliva.\*

Regarding the above as a picture of the general type of a disease rather variable in character, we shall proceed to relate the more striking deviations from the ordinary form which were observed in India.

Instead of the exceedingly sunk state, there was a marked excitement, with a hot and dry skin, and a pulse of considerable force, in several instances throughout great part of the course of the disease.† This in some cases arose from the early exhibition of stimulants, but in others it appeared to be an essential part of the disorder. These cases yielded most certainly and readily to treatment; and hence, many of them having been subdued without the occurrence of sinking or debility, it was a matter of doubt whether this description of

\* *Scot's Reports on the Epidemic Cholera; Anderson on Cholera, E. M. and S. Journal, vol. xv. p. 324; Christie on Cholera and the Pathology of Mucous Membranes; Annesley's Sketch of the Diseases of India, &c.*

† *Madras Reports, p. xxv.*

disorder really belonged to the epidemic; but that it did so was placed beyond all question by some of the more protracted cases degenerating into the ordinary low form.

The most fatal variety of the disease was denoted by the slightness of the commotion in the system: there was no vomiting; hardly any purging, perhaps there were only one or two stools; with no perceptible spasm; no pain of any kind; a mortal coldness with arrest of the circulation coming on from the beginning, and the patient dying without a struggle within three or four hours. Several instances were heard of, at Hoobly and other places, of natives being struck with the disease whilst walking in the open air, and who, having fallen down, retched a little, complained of vertigo, deafness, and blindness, and expired in a few minutes. Mr. Scot informs us that this most deadly form of the disease frequently manifested itself in local epidemic visitations, which were often observed in India, all the cases occurring at the same time in a given district partaking of the same peculiarity of character.

The collapsed form of disease first described is that which has been most frequently observed. In fatal cases its duration varies from four to eight hours; whilst in those which terminate favourably, a result often apparently due to early medical assistance, the patient may be restored to perfect convalescence in a period ranging from twenty-four to forty-eight hours. But in many cases considerable disturbance of the system intervenes between the period of collapse and restoration to health, or this disturbance may itself cause death. The Indian reporters mention two forms of this disorder. In the one, with some excitement in the system, the bowels continue to discharge, for many days, first brown and watery, then dark, black, and pitchy stools, sometimes with blood, and with peculiar pains in the bowels, particularly in the rectum. The other, a distinct febrile form, we shall describe in the language of the Bengal Report:—

“The fever which almost invariably attended this second stage of the disease (in Europeans), partook much of the nature of the common bilious attacks of these latitudes. There was a hot dry skin, a foul deeply-furred tongue, parched mouth, thirst, sick stomach, restlessness, watchfulness, and quick variable pulse, sometimes with delirium and stupor, and other marked affections of the brain. Generally, when the disorder proved fatal in this stage, the tongue, from being cream-coloured, became brown, and sometimes black, hard, and more deeply furred; the teeth and lips were covered with sordes; the state of the skin varied, chills alternating with heats; the pulse became extremely quick, weak, and tremulous; hiccough, catching of the breath, great restlessness, and deep moaning succeeded; and the patient soon sunk, incoherent and insensible, under the debilitating effects of low nervous fever, and frequent, dark, tarry, alvine discharges.”

A consecutive fever, similar to this, we learn

from Drs. Russell and Barry, is of more frequent occurrence in Russia than in India. The following description of it we owe to these gentlemen:—

“After the blue cold period has lasted from twelve to twenty-four, seldom to forty-eight hours or upwards, the pulse and external heat begin gradually to return, headach is complained of, with noise in the ears, the tongue becomes more loaded, redder at the tip and edges, and also drier. High-coloured urine is passed with pain and in small quantities, the pupil is often dilated, soreness is felt on pressure over the liver, stomach, and belly; bleeding by the lancet or leeches is required. Ice to the head gives great relief. In short, the patient is now labouring under a continued fever, not to be distinguished from ordinary fever. A profuse critical perspiration may come on from the second or third day, and leave the sufferer convalescent; but much more frequently the quickness of pulse and heat of skin continue, the tongue becomes brown and parched, the eyes are suffused and drowsy; there is a dull flush with stupor and heaviness about the countenance much resembling typhus, dark sordes collect about the lips and teeth, sometimes the patient is pale, squalid, and low, with the pulse and heat below natural, but, with the typhous stupor, delirium supervenes, and death takes place from the fourth to the eighth day, or even later, in the very individual, too, whom the most assiduous attention had barely saved in the first or cold stage. To give a notion of the importance and danger of cholera fever, a most intelligent physician, Dr. Reimer, of the Merchant-Hospital, informs us, that of twenty cases treated under his own eye, who fell victims to the disease, seven died in the cold stage, and thirteen in the consecutive fever.”\*

The same gentlemen state, as the result of their observation, that the following are the points of difference between the European epidemic and that of India:—

“First, the evacuations, both upwards and downwards, seem to have been much more profuse and ungovernable in the Indian than in the present cholera, though the characters of the evacuations are precisely the same.

“Secondly, restoration to health from the cold stage, without passing through consecutive fever of any kind, was by far more frequent in India than here (St. Petersburg), nor did the consecutive fever there assume a typhoid type.†

\* Report of Drs. Russell and Barry to C. C. Groville, Esq., published, among other papers, by authority of His Majesty's Most Honourable Privy Council.

† If we compare the symptoms attributed to this consecutive fever by Drs. Russell and Barry, with those quoted from the Bengal Reports, the difference between this stage of the respective epidemics does not appear very striking: the epithet *typhoid* seems almost equally applicable to both. Varieties were observed in the disease as it prevailed in the different Indian presidencies, and likewise between that which existed in Hindostan and Ceylon, perhaps as considerable as those now observed by these intelligent physicians. In regard to what is stated in the extract referred to, relative to the greater frequency

“Thirdly, the proportion of deaths in the cold stage, compared with those in the hot, was far greater in India, according to Dr. Russell’s experience, than here.

“Fourthly, the number of medical men and hospital attendants attacked with cholera during the present epidemic, in proportion to the whole employed, and to other classes of society, has been beyond all comparison greater here than in India under similar circumstances.”

Dr. Keir of Moscow gives the following description of the consecutive or secondary morbid state. “A second ordeal now begins, sometimes as severe, and frequently not less fatal, though more slowly so, than the first; this is probably the effect of the morbid changes which have been induced during the first period of the disease. The appearance of the complaint is now entirely changed, insomuch that one who had not seen the patient during the first period, or been told of the symptoms, could not possibly know that he was suffering from the epidemic. I have observed the disease in this, its second period, to assume four forms: the first, an inflammatory, or rather sub-inflammatory state of the stomach and bowels, most frequently the latter, sometimes conjoined: the second, inflammatory irritation of the lungs, with pain of the chest, cough, viscid expectoration, and fever, appearing as a critical metastasis of the disease: the third, bilious or bilio-nervous fever, with suppuration of the parotid glands; in one case, with axillary suppurating bubo, towards the end of the fever, an inflammatory irritation of the lungs took place, ending in vomica: and the fourth, a congestive sub-inflammatory state of the brain and spinal chord. This last, as was natural to expect from the nature and seat of the affection, proved by far the most dangerous and most frequently fatal form of the second period: it appeared generally to supervene after the purging, vomiting, and cramps had been relieved, and the external heat in some degree restored; the patient complained of pain in the back, between the shoulder-blades, or in some other part of the spine, sometimes along its whole tract; he appeared sleepy to such a degree that at first I was disposed to attribute this state, in part at least, to the effects of the opium given in the first period. But I was soon convinced that the cause of this symptom, and of another strongly characteristic of this form of the disease, namely, the filling of the vessels of the scleroticæ with red blood, was a congestive sub-inflammatory state of the brain and spinal chord. This striking symptom at first began to show

at Petersburg of the secondary “typhoid,” or, as more commonly designated in India, low biliary symptoms, we confess that we observe a discrepancy when we read a subsequent part of the same Report, in which Drs. Russell and Barry state, “Convalescence from cholera has been rapid and perfect here, as is proved by the following fact. The Minister of the Interior had given orders that all convalescents, civil as well as military, at the General Hospital, should be detained fourteen days. We inspected about two hundred of these *déténus* some days back, with Sir J. Wylie, and found them in excellent health, without a single morbid sequela.”

itself in the inferior part of the globe of the eyes; it gradually increased, and little by little reached the upper part, while the eyes turned upwards, exposing the lower part gorged with blood. This state of the patient generally ended in a complete coma, and proved fatal a few hours afterwards.”

Besides the various and appalling symptoms which indicate general derangement of the action of the solids, there are appearances in the blood drawn during the collapsed stage, shewing that the fluids feel the influence of this formidable disease. These appearances are very uniformly expressed by the terms dark, black, or tarry, in regard to colour, and by thick, ropy, syrupy or semi-coagulated, in respect to consistence. This change in the condition of the circulating fluid is fully proved to be in the ratio of the duration of the disease; the blood at the commencement seeming to be nearly or altogether natural, and more or less rapidly assuming a morbid state as the malady advances. This condition was less conspicuous in cases of cholera ushered in by symptoms of excitement, than where the collapsed state of the system had occurred early; and in certain rare cases it was not observable at all, and the blood flowed readily from the vein; but the reverse was the fact, both with respect to its condition and the manner of its flowing from the arm, in an immense majority of instances. In general, after a certain quantity of dark, thick blood had been drawn, its colour became lighter, its consistence less thick, and the circulation revived, such appearances always affording grounds for a proportionably favourable prognosis. There is some discrepancy in the accounts transmitted to us of the mode in which this diseased blood coagulates. In some instances, we learn, the coagulation is rapid, whilst in others it is slow and imperfect. Reporters are unanimous in declaring it deficient in serum, and destitute of the buffy coat. The latter is occasionally observed in cases attended with reaction, in which the blood is not black and thick.\*

The discharges from patients suffering under this disease were subjected to experiment by Dr. Christie. The secretion consists of two substances, the one a transparent serous fluid, the other an opaque white coagulum; the former perfectly soluble in cold water, the latter quite insoluble. These matters being submitted to the action of re-agents, the fluid part was found to be pure serum, and the coagulated portion fibrin. The secretion, therefore, as the author remarks, has a composition similar to that of the blood deprived of its colouring matter; but the serum is in much larger proportion to the fibrin than in that fluid.

Chemistry has been occupied in researches into the composition of the blood and of the secretions in this disease since it has extended into Europe. Mr. Herrman of St. Petersburg, who regards free acetic acid as an essential constituent of the blood when in a healthy state, finds a deficiency of it in that of choleric pa-

\* Madras Report, p. xxx. &c.

tients. This gentleman, like our Indian practitioners, has observed that the crassamentum bears a larger proportion to the serum in this disease than in health; and this increased relative quantity of crassamentum was found to be in direct proportion to the intensity of the disease. The fluids voided by stool and vomiting contained, he informs us, besides water, some acetic acid, a small quantity of osmazome, salivary matter, butyric acid and mucus. They very much resemble gastric juice, but do not contain any free muriatic acid. In the alvine discharges, the quantity of butyric acid is greater than in the fluid voided by vomiting; and they contain, besides, some albumen, a fetid, oily matter, and a small admixture of bile.\*

2. *Character of the epidemic as it appeared in Sunderland in 1831.* Thus far our account of this formidable malady has been derived from the very valuable mass of information with which we have been favoured by our medical brethren in India, and the many intelligent men who have witnessed its ravages on the continent of Europe. Circumstances having brought it under our own observation, we shall endeavour to convey succinctly to the reader the results of our experience, prefaced by a few reflections on the character and designation of the disease which this experience has suggested to us.

A question has been repeatedly discussed, but without having been so far settled as either to lead the profession to feel satisfied with the name first given to the disease, or to adopt a designation more consonant with its nature; viz.—can it be properly considered as belonging to the genus cholera? or is its character so much more closely related to that of fever as to render it advisable, consistently with accuracy of arrangement and precision of nomenclature, to place it among febrile disorders, and give it a designation more corresponding than its present one with its new nosological position? The vomiting, purging, spasms, and prostration which are generally considered as the pathognomic symptoms of cholera, belong equally to a certain stage of this disease as to the ordinary form; and in addition to this argument, it may be urged that only a strong affinity could have led men so intelligent as our Indian practitioners unanimously to designate it by the term cholera. It is true, that if we limit our view to one stage only of the disease, the former reason is forcible; but if we embrace, as we ought to do, all its parts as we witness them in Europe,—if we consider that the choleric symptoms, if not fatal, prove but the commencement of a series of changes to which any one who witnessed them alone would give the appellation of fever, and which men of great experience in the disease have declared they could

not distinguish from typhus,—if we observe, too, that long before this epidemic excited attention, symptoms strikingly resembling those of cholera had been observed to form the initiatory stage of certain malignant fevers,\*—we are disposed to admit that it is in reality a fever, and that to designate it merely cholera is to take a part for the whole, and to give to the inexperienced, as far as a name can give it, an erroneous idea of the disease. At the same time it would be advisable to mark its relation, a relation which it unquestionably possesses, to the disease from which it is dissociated, and to apply to it the trivial epithet *choleric*. Consonantly with these views, we should advise that the name suggested by Dr. Johnson, *epidemic choleric fever*, be in future adopted as its designation.

The argument against this change derived from the universal employment of the other name by our Indian practitioners, is not of much force; for it is manifest, from many circumstances, that in Hindostan the disease, in the majority of instances, consisted of the cold stage only, many reporters not at all advert- ing to the consecutive fever; and Mr. Jameson alone, in the Bengal Reports, treats of it at any considerable length. So rare indeed was it, that we have met with Indian physicians of no inconsiderable experience in the disease, whose observation it had escaped altogether. It should be remarked, too, that Mr. Jameson declares the febrile stage to have been rare and slight among natives in general; but that it frequently occurred in Europeans and natives of robust and athletic make. It would appear that, in proportion as the disease has receded from its original source, it has been undergoing more and more a transmutation into a febrile character. Drs. Russell and Barry, it will have been remarked, state that restoration to health from the cold stage, without passing through consecutive fever of any kind, was by far more frequent in India than at St. Petersburg, a statement which, while it asserts the increased frequency of fever, certainly implies that restoration to health sometimes takes place without its occurrence. Now we can positively assert that we have not met with a single case in England, in which fever did not intervene between the choleric or cold stage and restoration to health; and the result of inquiries we have addressed to individuals the most observing and most familiar with the disease in this country, has proved that their experience has coincided with our own. It is true that in some cases this fever has been slight, but the choleric stage has been so likewise; *for we have always observed a correspondence in intensity between these stages.*

Were we to attempt a definition of epidemic choleric fever, the following, according to our experience, would comprise its distinctive symptoms.

\* For further information on this point consult Dr. Negri's Letter to Dr. Barry; Morton, *Pyretologin*, pp. 16, 33, 81; Torti de *Febribus*, lib. iii. cap. i. p. 124; and *Med. Essays*, by J. Brown, M.D. pp. 37-39.

\* Letter to Dr. Todd, (*Medico-Chirurgical Review*, July 1831, p. 285.)

A specimen of the intestinal discharge from a child three years old, labouring under the disease, with which we furnished M. Majendie when he visited Sunderland, was analysed by that gentleman; and he informed us that it contained albumen and mucus, and was *alkaline*.

Afterwatery diarrhœa, or other generally slight indisposition, vomiting and purging of a white or colourless fluid, violent cramps, great prostration and collapse,\* the last occurring simultaneously with the vomiting and cramps, or shortly after them. Should the patient survive the last train of symptoms, a state of excitement and fever supervenes.

We can convey a correct idea of the disease only by dividing it into three stages, *the incipient, the cold or choleric, and the febrile*: the division is a natural one, according with the character of the disease.

1. *Symptoms of the incipient stage.* In an immense majority of instances, diarrhœa has been the prominent symptom of this stage. Langnor and lassitude, and occasionally nausea and vertigo coexisted with the disorder of the bowels, and sometimes certain of these symptoms may have appeared without it; but its occurrence has been so common, that we have treated few cases in which it had not preceded the more formidable symptoms. On examining the discharges, if we have an opportunity of doing so shortly after the occurrence of the diarrhœa, they will be observed to be fecal and bilious, but we shall find that they subsequently bear the serous character of those which occur after the choleric stage is fully formed; they are passed copiously and without much griping; the feeling of debility which attends them is great, and this diarrhœa is so exhausting, that we have met with patients, especially those advanced in life, in whom a considerable degree of collapse had occurred, with a feeble pulse, scarcely exceeding fifty, before the accession of vomiting and cramps. The natural tendency of this purging is, we believe, to pass into the choleric stage; but the transition has frequently occurred shortly after some dietetic error, either as to quantity or quality of food, or after exposure to cold. The commencement of the purging has sometimes preceded by several days the accession of the choleric stage, and occasionally only by eight or ten hours; but forty-eight hours has been its mean duration, calculated from a great number of instances. We have dwelt the more on this incipient stage from a conviction, the result of considerable observation of the disease, that subsequent symptoms might often be prevented, and life preserved, by the early and appropriate treatment of the diarrhœa.

2. *Symptoms of the cold or choleric stage.* Our description will be more intelligible if we divide into two periods this very important

stage, which has in truth given its name to the disease, and, by its fearful symptoms, has engrossed such general attention, that the facts of its being but part of a series of changes has been too often lost sight of.

*First period.*—The time of invasion has been, as in India, in a great majority of instances, from two to four o'clock in the morning. The patient is attacked with uneasiness of the stomach, occasionally amounting to pain, to which speedily succeeds vomiting of the characteristic fluid so frequently described; and, if diarrhœa have preceded, which in almost all the cases that have fallen under our observation has been the case, a purging of the same fluid, the fecal contents of the canal having been previously expelled. The vomiting is rarely full and effectual, consisting rather of apparently unsatisfactory retchings than of a full discharge of the contents of the stomach; but sometimes these contents are expelled forcibly, as if squirted from a large syringe. The discharges from the bowels are occasionally scanty, but much more frequently they take place copiously and forcibly. Simultaneously with the vomiting, or not unfrequently before this symptom has occurred, cramps take place, and the agony which attends them constitutes great part of the sufferings of the patient, who incessantly entreats that friction may be applied to the parts they affect. However soon our visit may be made, the pulse will generally be found to be feeble and frequent; the skin in point of heat below the healthy standard; the countenance shrunk, and, if not livid, pallid; and the respiration hurried, if not checked, as it frequently is, by spasm of the diaphragm and intercostal muscles. The circulation sinks remarkably, and sometimes appears momentarily to cease, on every accession of severe vomiting or spasm.

*Second period.*—The mean duration of the preceding period varies from about eight to twelve hours; the vomiting and spasms then either totally subside or recur at much longer intervals, and the patient sinks into a state of extreme collapse. The pulse at the wrist is scarcely or not at all perceptible; the surface is universally moist and cold, excepting as heat is imparted from without, for the instant that the hands or other parts are exposed, they become of an icy coldness; blueness, if it exist at all,—but it is by no means an uniform symptom,—is now conspicuous on the face and hands, which last have the shrunk and soddened appearance so generally described; the tongue is moist, and, if not actually cold, at least cooler than natural; and the voice is of that mingled huskiness and feebleness which strikes the ear so peculiarly. In this condition there is little suffering, excepting from the sense of weight and oppression at the præcordia, of which the patient complains much; for even should spasms occur, they are now too feeble to excite much pain; the respiration is slow; the conjunctivæ, especially in their inferior hemisphere, are frequently injected with dark-coloured blood;

\* By *collapse*, in this definition, is meant the feebleness or almost the arrest of the circulation; the death-like appearance, the coldness, shrinking, and occasional blueness of the surface, which may in other diseases be observed after they have existed some time, and as the powers of life are passing away; but which occur in what we shall call the cold or choleric stage of the epidemic, in a short time after its commencement, as though they formed an essential part of it. The degree and early accession of this collapse, and the white discharge, are the only distinctive marks that we are aware of between this stage of the epidemic and ordinary cholera.

and the insensibility of the stomach is so great, that the most powerful stimulants may be given and retained without the organ being apparently more sensible of their presence than if it were a lifeless pouch. The urine is suspended throughout the whole course of a choleric stage so intense as we have described.

However hopeless such a state might appear, we have seen more than one patient emerge from it by the powers of the constitution, to have a faint chance for life in a very bad form of fever, after all the efforts of art had proved ineffectual for bringing on reaction. We have seen this apparently spontaneous transition into the febrile stage take place after the patient had remained for many hours without any perceptible pulse at the extremities.

Premising that the danger in the cold stage, and the degree and malignancy of the subsequent fever, are in proportion to the collapse which is observed in this stage, we shall depict one of the lighter cases which occurred during the epidemic, remarking that the shades of intensity in the disease are so infinite that its intermediate degrees must be supplied by clinical observation.

In one of the milder cases extreme collapse does not take place. Whether by the powers of the constitution, or the remedies employed, there is a subsidence, after a period varying from eight to twelve hours, of the cramp and diarrhœa; the patient becomes calm and composed, but appears rather low and sunk; the stomach remains irritable, occasionally retaining, occasionally rejecting, food or medicine administered; the skin becomes of a moderate warmth, but yet is cooler than natural, and a good deal of adventitious heat is required; the pulse emerges to a condition of moderate force, without much frequency, being probably about eighty, and soft; the urinary secretion, if it has been suspended during the spasmodic period, which it is not always in the milder cases, is restored; after the lapse of a few hours, should vomiting occur, bile is perceptible in the matters vomited, and, generally by the assistance of calomel or other laxatives, bilious stools are discharged.

The transition from such a case is into a mild inflammatory fever, generally with some affection of the head; from which the patient recovers in a few days, by measures to be subsequently adverted to.

3. *Symptoms of the febrile stage.*—The preceding stage, in most instances, makes a very gradual transition into the present one. After the patient has remained in the collapsed state probably for a considerably longer time than the medical attendant expected, some degree of warmth will be found returning to the surface, which for a variable period, perhaps for a couple of days, has been almost of icy coldness; and the pulse is proportionably developed, being very perceptible at the wrist, generally about eighty and soft; the vessels of the conjunctiva gradually become distended with blood; or if those of the inferior hemisphere have been so during the

stage of collapse, the distension now diffuses itself over the whole membrane; the patient, who on his attention being roused is perfectly sensible, complains of severe pain in the head, of a sense of giddiness, and that the light distresses his eyes. The tongue in this early stage is clean and moist; the bowels are readily acted upon by medicine, and the discharges are feculent, and though somewhat clayey, contain a proportion of bile; but the urinary secretion is sometimes either not restored, or is considerably deficient for a day or two after the establishment of fever. In the progress of the fever, the tongue becomes black, and sordes accumulate about the teeth; the eyes become more and more injected; the intellect more and more torpid, though still the patient can be roused to answer questions, and even may make one or two sensible remarks on his condition; but the instant the conversation ceases, the eyes are turned up in the orbit, exposing through the half-closed eye-lids the red sclerotica, and the patient is in a state of profound stupor: the urinary secretion is now established, and the urine, which at first was dark-coloured and cloudy, is now limpid and pale; the alvine discharges are darker coloured than at first; and throughout the disease there is a deficiency of vascular action and of temperature, which we have not observed to the same extent in typhus or any other fever. However flushed the countenance may appear, and it is often very considerably so, the temperature of the surface is below the healthy standard, and we have not often found the pulse above ninety. *Typhoid* is not an inappropriate designation of the condition we have endeavoured to describe; but we think that an individual who had once watched the progress of such a case, would run no risk of confounding it on future occasions with typhus;—the deficiency of vascular and calorific power; the peculiar vascularity of the eye; the absence of subsultus and muttering delirium, (for though delirium occasionally occurs during night, the condition of the intellect is throughout much more one of torpor than of irregularity,) would be the marks by which he would discriminate the two affections.

The duration of such a febrile stage as we have described is from a week to ten days. Its termination has been in a considerable majority of instances, which have fallen under our observation, fatal. The brain has appeared to us to be the organ mainly affected, and by this view our treatment has been chiefly guided, though at the same time the condition of the intestinal canal has not been neglected.

In another form, and one which supervenes on a minor degree of collapse than the preceding, the symptoms do not differ from those described above, excepting that there are indications of greater excitement,—more warmth of surface, and more force and frequency of pulse. Depletion could be more freely practised, and it was altogether a more tractable form of disease.

The mildest and most tractable type of the

febrile stage was denoted by symptoms of general but moderate excitement, with epigastric pain on pressure, head-ach, and giddiness; the tongue being at the same time either clean, with a disposition to become dry and glazed, or slightly white and furred; the skin warm; the pulse free and forcible; the urine high-coloured, and the thirst considerable. In such a case there is little or no confusion of thought or delirium, and the eyes are not injected. We need scarcely remark that examples of this mild and tractable type of the febrile stage occurred after a choleric stage, in which the symptoms of collapse had been inconsiderable, in which the urinary secretion had not been suspended, or which had not always been attended with vomiting, a symptom occasionally wanting in slight cases.

The writer met with but one example of considerable affection of the thoracic organs, and this occurred in a case in point of general character not unlike the form last described, though somewhat more collapsed. The affection was bronchial, and was relieved by a copious expectoration of very dark-coloured sputa,—the patient recovering.

In the preceding sketch of the febrile stage, it will be understood that, as in the case of the choleric stage, we have not attempted to depict all the various shades of intensity in which the disease manifested itself. The extremes are given: to have essayed to describe all the intermediate degrees would have swelled the article beyond reasonable limits, and would have proved a burthen to the memory of the reader, rather embarrassing than beneficial at the bed-side.

The varieties in the different stages which we have left to be discerned clinically by the reader were, it ought to be remarked, essentially the same in character with the forms we have depicted, differing only from them and each other in shades of intensity more or less minute; but there were cases observed in Sunderland, as in India, of which the character constituted so considerable a deviation from the ordinary type, that our description would be incomplete did we pass them unnoticed.

In one such deviation from the usual type, the discharges were bilious during the choleric stage, which, in fact, could not be discriminated from an attack of ordinary cholera; a mild and tractable form of fever ensued, and the patients recovered. One case of this kind occurred under the following circumstances. The wife died of what was then designated malignant cholera. The order for prompt funerals did not at that time exist; and on the day of her interment, three days after her death, the husband sickened of the form of disease we are now describing, and recovered after a few days of fever.

We witnessed a solitary example of a form of disease which has been particularly described by Mr. Orton, as being occasionally intermingled with the customary type of the malady in India. In our case there were trismus, and spasms of the muscles of the throat so violent, that, till they were allayed by blood-letting,

swallowing was impracticable; and when it could be performed, it was done with an effort resembling that with which a patient in hydrophobia swallows water, after having, by a strong mental effort, brought himself to make the attempt in spite of his abhorrence of it. It ought to be remarked, however, that there was no dread of water, nor any characteristic symptom of hydrophobia,—the resemblance was merely in the manner of swallowing. The patient was in an excited state throughout the disease, which was of twenty-four hours' duration, till within two hours of death, when collapse occurred. The complaint commenced with vomiting and purging; the matter vomitted we were informed was colourless; that discharged by purging we learned was at first rather yellow; but the intestinal discharge which we saw, after the complaint had lasted some hours, was colourless and mucous. This being a solitary case of the kind, and fatal in the stage which we considered as corresponding with the choleric stage of the ordinary type, we had no opportunity of ascertaining whether any or what form of fever would ensue.

3. *Prognosis.*—The danger of the disease is in all cases, we believe, to be estimated from the degree of collapse attending the cold or choleric stage. In India, it was remarked that the cases in which the spasms and vomiting were the most violent were by no means fraught with the most peril, and what we have seen of the disease enables us to bear testimony to the accuracy of the remark; for when we have heard the attendants exulting in the cessation of the spasms and the facility with which the stomach retained medicine or food, and have felt at the same time the pulseless wrist and the cold and clammy hand, we have seen in these apparently favourable omens only the natural progress of the disease from a bad condition to one still worse. Whether we are to dread a fatal result in the cold or the excited stage, the intensity and duration of the collapse in the former of these stages are the measure of the danger; for if the patient die in this stage, he dies of collapse, and if he survive it and pass into the state of fever, the character of this fever is malignant and dangerous in proportion to the same collapse.

4. *Diagnosis.*—From ordinary cholera the cold stage is to be distinguished, as it appears to us, by the peculiar character of the discharges, which has been sufficiently dwelt upon, and by the degree of collapse and its early occurrence. Cases have been adverted to, which, at least in the choleric stage, could not be discriminated from ordinary cholera, excepting perhaps from their taking place at a season of the year when ordinary cholera is never observed; but it may be remarked that no one would infer the existence of the epidemic from such cases, though he might be disposed to acknowledge that they belonged to it, if cases less equivocal were simultaneously prevalent, and especially if they originated under the circumstances mentioned in the preceding page.

Notice has been taken of sporadic cases

which have occurred in several parts of the kingdom during the last year, and which have been reported in various publications. We have already stated our opinion as to the perfect identity of the group of symptoms in certain of these cases and those which characterise the choleric stage of the epidemic. These cases have generally been fatal as cases of cholera, and probably on this account have attracted attention and been reported; and hence what we should consider the *experimentum crucis* by which their essential alliance to the epidemic, as it has manifested itself in this country, or difference from it, can alone be proved,—the intervention, or otherwise, of fever between the cold stage and recovery,—is necessarily wanting.\* We have been favoured by a gentleman of high character and attainments\* with a report of two cases regarded, at the time they occurred, as aggravated cases of the ordinary disease; both took place in the interior, under circumstances in which there was not the slightest ground to suspect contagion, and previously to there being any suspicion of the existence of the epidemic in this country. In one the symptoms bore, unquestionably, a considerable resemblance to the choleric stage of the epidemic, but no fever supervened. The symptoms of the other shall be given in the words of the writer:—"The total, or nearly total suspension of the secretion by the kidneys; the watery vomiting and stools; the severity of the spasms; the shrunk and corrugated state of the skin on the hands and feet, and the blueness of his nails, persuade me that his disease was of the spasmodic type. In him, moreover, a slow fever succeeded the original symptoms, and long retarded his recovery." We need not remark that we would not attempt to discriminate between such a case as this and examples of the epidemic, believing their character to be identical. This case occurred in the beginning of July, 1831.

There is a certain form of the febrile stage, that which supervenes on a choleric stage, attended with extreme collapse, which the deficiency of the temperature and the circulation, the congested state of the conjunctiva from the very commencement of the fever, and the peculiar torpor of the intellect, would enable, as it appears to us, the observer to discriminate from any fever which we are in the habit of witnessing in this country, provided he saw the patient early and watched him throughout; but in the majority of instances the diagnosis can only be correctly drawn by coupling the preceding history of the case with the existence of fever and with its character.

5. *Appearances on dissection.*—The external appearance of the body closely resembles that which has been noticed during life: the solids are shrunk, the surface is livid, the skin of the hands and feet is corrugated, the nails are blue, and the fingers often rigidly contracted. There is no evidence of any unwonted tendency to putrefaction, nor any characteristic fœtor from the abdominal cavity.

\* Dr. Fenwick, of Durham.

In the *head* are found marks of congestion, and even occasionally of extravasation. Such appearances were not of uniform occurrence in the dissections performed in Hindostan, but they were found very constantly in those made by Dr. Davy, in Ceylon; and Dr. Keir, of Moscow, discovered in the Russian disease the blood-vessels of the brain and its membranes more or less turgid with blood, particularly towards the base, with a fluid effused into its convolutions, and more or less of serum in the lateral ventricles.

In the *thorax*, the pleura and pericardium are found, as the serous membranes generally are in this disease, perfectly healthy, with the exception occasionally of an unusual dryness. The lungs are sometimes in a natural state, but more frequently gorged with dark-coloured blood, so as to resemble liver or spleen; or they have been found collapsed on each side of the spine, leaving the thorax nearly empty. This latter appearance Dr. Pollock, of the fifty-third regiment, explained by supposing gas to be extricated within the cavity of the pleura; but the thorax having been opened in such cases under water, and no air having been found, Mr. Scot is disposed to ascribe it to a contractile power exerted by the viscus, sufficient to overcome the atmospheric pressure. Both sides of the heart are in general distended with dark blood, and the bronchi are frequently filled with mucus.

In the *abdomen*, the vessels of the liver are often much congested, and pour forth blood copiously when incisions are made into the organ; but this congestion is not uniformly found; the gall-bladder is turgid with black bile, and its ducts are sometimes constricted and impermeable, though occasionally in an opposite state. The peritoneum is often quite healthy, but the portion investing the alimentary canal has frequently an inflamed appearance from the exceedingly loaded state of its blood-vessels. This congestion is sometimes so great as to give the appearance of gangrene; but by drawing the finger over the surface, innumerable small veins may be found running in every direction, as in a preparation nicely injected, and the texture is found to be resisting and firm. This portion of the peritoneum, however, occasionally bears marks of actual inflammation, especially if the patient has lingered long before death. It then presents a thickened appearance externally, and its colour varies from a pale vermilion, through all the deeper shades, to a dark purplish hue; the former being chiefly remarkable on the surface of the duodenum and jejunum, the latter on the ileum where it terminates in the cæcum. At other times, the whole alimentary tube, instead of this congested state, presents a blanched appearance both internally and externally. The omentum is sometimes healthy; at others, it presents the same appearance of extreme vascularity as the peritoneal surface of the alimentary canal.

The following appearances are discovered on laying open the stomach and intestinal tube. A white, opaque, and viscid substance

is found adhering to the surface of some portions of the mucous membrane; and in many cases it is so abundant in the intestines as completely to fill parts of them of a greater or less extent. The stomach and portions of the intestine are filled with a transparent or turbid serous fluid, and frequently the viscid matter mentioned above is found intimately mixed with the serous fluid, or floating in it in the form of flakes. The mucous membrane, except when inflamed, which it not unfrequently is, has an unnatural whiteness, is often soft and pulpy, and in general—especially in the stomach and small intestines—can be easily detached by scraping, in the form of a thick pulp, from the subjacent coat. These appearances are sometimes more or less partial; but some of them are generally found throughout the whole extent of the tube. They extend in some cases to the mucous membrane of the bladder and ureters, and have been found in two or three instances in that lining the bronchi.

In one case only in India was the state of the spinal marrow examined; and in that, strong indications of inflammation were detected in its sheath; the case, however, was in some degree a mixed one. But Dr. Keir found, at Moscow, the blood-vessels of the vertebral column and spinal chord more or less loaded with blood, which was sometimes effused between its arachnoid and dura mater; partial softening of the substance of the spinal chord was sometimes met with, and marks of inflammatory congestion in the larger nerves were detected.\*

The dissections performed in Sunderland have generally furnished results corresponding with those obtained elsewhere.

In the *head*, venous congestion of the brain and its membranes has been the most uniform and prominent appearance. Serum has been found in the ventricles of the brain and at its base; but in many cases this has been in small quantity, not exceeding that frequently observed after diseases in which no affection of the encephalon was supposed to exist. In some cases, especially those in which death took place in a protracted stage, but occasionally in a rapid disease, fibrinous depositions existed between the membranes.

In the *thorax*, the lungs have uniformly been found more or less gorged with blood, though in many cases the engorgement was in the posterior part, and probably resulted from position. These organs were generally crepitating, and free from structural change. Softness or flabbiness of the heart has been noticed in several instances, and both its cavities, and the venæ cavæ and coronary vein, have been distended with dark-coloured blood.

In the *abdomen*, the liver has been found gorged, but occasionally its condition was

natural. The gall-bladder was generally distended, and the ducts were constricted, so that the viscus could not be emptied by pressure; but in some cases they were pervious. The abdominal veins have been found generally distended; but in several instances, the vena portæ and meseraic veins have constituted an exception to this rule, having been found empty. Vascularity and pulpiness of the mucous lining of the stomach have been frequently noticed; but the former has often been slight in degree, and observers have felt disposed occasionally to attribute it to the exhibition of mustard or other stimulants; whilst the latter has by no means been invariably found. The lining of the intestines has been found in many parts vascular and pulpy; but these appearances are not invariable, both lesions having been found wanting, and the pulpiness more frequently than the vascularity. The peculiar secretion has generally been found in the intestines.

The kidneys have been observed to partake of the general congestion of the venous system. The bladder has generally been found contracted, and either empty, or containing a small quantity of urine. In the case mentioned, which was attended with trismus and other peculiarities remarked in India, but not in other examples of the disease in Sunderland, it was considerably distended.

No softening or other disease of the spinal marrow, a little venous congestion excepted, was discovered in the few examinations of this organ made here.

In concluding this rather unsatisfactory portion of our subject, we cannot refrain from expressing a conviction that symptoms during life throw much more light on the nature of the disease and its appropriate treatment, than appearances after death.

6. *Nature of the disease.*—Many writers of great talent have preceded us in this very intricate branch of the subject, and much ingenuity has been displayed in the endeavour to trace all the phenomena of the choleric stage, which has been the principal subject of investigation, to a change in one part of the system. But it must be remarked that there is little accordance among medical reasoners as to the part of the body in which the phenomena of the disease are presumed to originate; for the nervous system generally, the ganglionic portion of it exclusively, the blood itself, and the lining of the digestive canal, have each found advocates equal in ability to plead their cause.\*

The diversity of these views is a proof of the intricacy of the subject; and probably, also, since they have all emanated from observing and ingenious men, an evidence of the variable nature of the disease; each reasoner being perhaps influenced by that portion of the general phenomena of the epidemic which predominated in the cases it

\* Madras Reports, pp. 32, 34. *Anderson on Cholera Morbus*, Edinburgh Medical and Surgical Journal, vol. xv. *Christie on Cholera*, p. 47. *Annesley, Diseases of India*, 2d edit. p. 106, et seq. Account of the Appearances after Death observed at Moscow, drawn up by *Dr. Keir*.

\* These are Dr. Kennedy and Mr. Orton for the first, Mr. Bell for the second, Mr. Annesley and others for the third, and Mr. Christie, with Roche and other French writers, for the last.

was his lot most frequently to witness. Their partial nature, too, may be in a considerable degree ascribed to the unfortunate influence of the expression, *proximate cause*, as a substitute for the more comprehensive term, essence or nature of the disease, on medical reasoning. Even those who affect to use it as an equivalent term for *nature of the disease*, are yet insensibly influenced by the words they employ. Amidst the crowd of phenomena presented to their notice in certain maladies, they often assume, on very insufficient grounds, that some one fact is the original of all others, and this they invest with the title of proximate cause.

If the facts related respecting epidemic choleric fever are compared with the explanations offered of them, it will be found that each medical reasoner has attributed the commencement of the phenomena of the disease to an affection of some part of the frame, which affection unquestionably exists in a very great number of instances, but neither with that uniformity nor with that priority of time which can warrant us in concluding that it was the cause of all the other symptoms. It seems a rational supposition that the remote cause of a disease may act, in some instances, first on one, in others on another part of the system, from some local weakness or peculiarity of individual constitution, or from some speciality in the mode of application of the cause; and yet that the disease shall retain in each case such a resemblance to a common type as shall prove its identity. It is likewise supposable that the remote cause may make a simultaneous attack on more than one organ or part of the system. Complex diseases, such as fever, appear to furnish examples of both these cases. The real philosophy of medicine seems to consist in ascertaining the actual state of the system of which symptoms are the signs; and if we can proceed, through the medium of these signs and post-mortem appearances, to one sole change in one organ, the treatment is simplified, and science and art are gainers. But there are diseases, and this seems to be one of them, in which we meet with a variety and complexity of pathological conditions, all of importance, and all to be kept in view in their treatment. It is true that of these conditions some may arise from others according to known physiological laws, as dark-coloured blood from impeded respiration, and it is right thus to explain them when possible; but the uniform endeavour to trace all to one primary change, or rather, as is more frequently done, to assume one change to be primary, and all other morbid states to be but emanations from it, is not only unphilosophical, but is too apt to tinge our practice with undue partiality.

Whilst we deem that no one writer has attained, either by inferences drawn from symptoms, appearances after death, or both, a knowledge of the affection of any one organ in cholera which can be properly termed a proximate cause whence all the other phenomena

arise; or acquired precise ideas respecting the nature of the affection of many organs which manifestly participate in the disorder; it is gratifying to acknowledge that their labours have thrown much light on the condition of many parts, and that very great practical good has resulted from the information thus obtained.

That the nervous system generally, and especially the ganglionic and spinal nerves, and the spinal medulla itself are affected, is manifest from many symptoms; but whether this affection arises from a direct impression of the remote cause of the disease on these organs, or from irritation propagated from the alimentary canal along the ganglionic nerves to the spine, we are ignorant. Dr. Keir's able researches have shewn that in some fatal cases inflammation of a portion of this system has existed; but its precise pathological condition in cases which terminate favourably remains yet to be ascertained; and it must be remarked, too, that in fatal cases this inflammation has not been always detected. The state of the sanguiferous system is very remarkable; but here too we must feel some doubt whether the feebleness or almost complete arrest of the heart's action is a primary effect of the cause of the disease, or, as suggested by Mr. Bell, arises from the affection of the ganglionic system; or, again, whether it results, through the medium of this system, from the condition of the alimentary canal. Is the dark appearance of the blood to be explained by the feebleness of the action of the right ventricle, as a consequence of which but little blood is transmitted through the lungs and exposed to the influence of the air? According to this view, which is suggested with diffidence, the imperfection of the respiratory process will arise from the same cause as in congenital malformation of the heart, such as the persistence after birth of the foramen ovale, or the aorta arising from both ventricles, in which a very small proportion of the whole mass of blood is oxydized. This hypothesis explains readily the dark appearance of the blood, its accumulation in the great veins of the viscera, the coldness and lividity of the skin, and the imperfection of the respiratory process, which has been so ably illustrated by Dr. Davy. This gentleman was the first to shew that the air expired by patients in the choleric stage is colder and contains less than the usual proportion of carbonic acid; and that this is the case even when the breathing is full, free, and rapid. The explanation offered is confirmed by an observation of Mr. Ellis in his experiments on respiration, that "as the circulation declined, so likewise did the emission of carbon, and, consequently, the production of carbonic acid." The thickened consistence of the blood receives a ready explanation from the loss of its serous part by the abundant discharge from the inner intestinal surface.

There are two morbid conditions of the lining of the digestive canal. In one it is in a state of manifest inflammation; in the other it is white and pulpy, and easily detached from the subjacent coat. Is this latter condition the

result of a disorganising inflammation which has itself passed away, or must we be content to describe the action which has produced it by the very unsatisfactory and vague expression, disturbance of the function of nutrition? This is a question rather of general pathology than one connected solely with this disease, but it is one as yet undecided. The affection of the alimentary canal is essential and primary, if any part of the disease is so; and it were vain to attempt to trace it to a morbid condition of any other organ or system of organs.

The general suspension of secretion, which is complete only when the collapse is extreme, appears to result from the disorder of those systems, the nervous and vascular, on which this important function depends. The apparent anomaly presented by the continuance of the cutaneous and intestinal discharges amidst the general suspension of secretion is well explained by Mr. Bell's distinction between this function and exudation or exhalation.\*

Were we to endeavour to illustrate in a few words the nature of cholera by examples drawn from analogous diseases, we should say that its choleric stage presented in a more intense degree the initiatory collapsed symptoms of certain bad fevers before reaction had taken place, combined with excessive gastro-intestinal irritation; whilst the febrile stage bore a very close resemblance to such fevers after the establishment of re-action, or in many cases was, at least in external character, perfectly identical with them.

That the whole series of phenomena results from the action of a morbid poison on the body there can be no doubt; but as yet, as in the case of other fevers, we are ignorant of the precise nature of the primary change effected by it in various organs or systems; and it is to be feared that till more accurate ideas are attained respecting the pathology of fever in general, this ignorance will remain. In the febrile stage, we would remark, there are indications by no means equivocal of inflammatory affection of the brain, and occasionally of other organs, the analogy to fevers in general being in this respect preserved. Were we to judge solely from what we have ourselves observed of the commencement of the disease, we should consider the alimentary canal to be the part of the frame which first felt the influence of the poison; but we should consider the condition of the nervous and vascular systems much too intense in degree to be merely sympathetic of the state of the stomach and bowels. Many cases, moreover, which have been reported from abroad, particularly from India, lead to the opinion that in various instances the nervous system is primarily affected.

5. *Proportionate mortality.*—The mortality during the early prevalence of the epidemic in India in 1817 and 1818 was very great, but either from the abatement of the intensity of the disease, or from the improvement of the method of treatment adopted by our medical

men, or, as is more probable, from the co-operation of both these circumstances, it was subsequently very much reduced. There is no disease in which unassisted nature seems more powerless than this. We learn from the report to the Medical Board at Bombay, that there is reason to believe that of 1,294 cases which received no medical assistance, every individual perished; and it is added, that it is not ascertained that any case has recovered in which medicine had not been administered. From this appalling statement, it is gratifying to humanity to turn to the following records. According to the documents collected by the Madras Medical Board, the number of deaths caused by it in the army of that presidency during 1818 and the four subsequent years, was 4,430, of which 695 occurred among the European troops, and 3,735 among the sepoy. The number attacked was 19,494, namely, 3,664 Europeans and 15,830 natives. The average strength of the army during the period included in the reports being 10,112 Europeans and 73,254 natives, it follows that in five years  $23\frac{1}{2}$  per cent. of the troops were attacked, and that of these  $22\frac{3}{4}$  per cent. were carried off, or  $5\frac{1}{2}$  per cent. of the whole force of the army. This statement, though sufficiently distressing, is still a proud monument to the skill of the medical men employed, and to medical science in general.

We hear, in different situations, of rates of mortality infinitely lower than this. Dr. Burrell, surgeon of the 65th regiment, reports, for instance, from Seroor, that out of sixty cases he lost four, being at the rate of 6.6 per cent.; whilst Mr. Crow, at the same station, makes the mortality much less, declaring that the disease is not fatal in more than one in a hundred of those who are early succoured. Dr. Burrell found, too, that of a certain description of cases, those attended with violent spasms, he saved eighty-eight out of ninety.\* In taking these estimates into consideration, we must always recollect, however, that in epidemics there is often a very wide difference in the gravity of the disease at different points or in different years,—indeed, sometimes at nearly the same point and in the same year; so that when we hear of an extremely small loss in proportion to the number attacked, long experience does not permit us to doubt that in such a case the type of the disease has been very mild.

The ravages of the disease in civil life, amid a comparatively unorganized population, where prompt assistance could not always be rendered to the sufferers, furnish a considerable contrast to this statement from the British army, and strongly confirm the opinion expressed, of the importance of early treatment in a malady so rapid in its course, and in which the efforts of nature are so impotent.

At Busheer, in the Persian Gulph, we learn from Moreau de Jonnés, that in 1821 a sixth part of the inhabitants perished; and at Basora, in the same year, Mr. Rich informs us

\* Treatise on Cholera Asphyxia, p. 56, 57.

\* Bombay Reports, p. 68, &c.

that eighteen thousand died, of whom fourteen thousand perished within a fortnight. The number attacked in Moscow from September 1830 to January of the following year, was 8,130, of which perished 4,385, or 54 per cent.\* In the small town of Redilscheft, of eight hundred sick, we learn from Dr. Reimann, that seven hundred died in one week. The greatest success which has attended the treatment of the disease in the Russian empire, so far as the records have reached us, occurred in the district of Orenburg, the number attacked being 3,590, of whom 865 perished, or about 24½ per cent., a result creditable to the vigilance of the Russian government, and to the skill and care of the medical men employed. The treatment adopted was that of our Indian practitioners; bleeding, calomel, opium, warmth, and friction.†

The disease having, there is every reason to think, run its course through the town in which these observations were written, it may not be uninteresting to mark the amount of ravage which it has inflicted.

The town comprised under the general name of Sunderland consists of three parishes, viz.

|  | Inhabitants. |
|--|--------------|
| That of Sunderland, containing . . .   | 17,060       |
| Bishopwearmouth . . . . .  | 14,825       |
| Monkwearmouth and its immediate dependencies, in all which the disease existed . . . . . | 8,850        |
| Total . . . . .  | 40,735       |

This computation is exclusive of certain out-townships, to which the disease did not extend.

The total number attacked with epidemic choleric fever out of this population from its manifest appearance on the 26th of October to its cessation in the middle of January, was 534, of whom 202 perished. These deaths are computed, with all the accuracy which the parish registers and other sources of information permit, to have occurred in the following proportions:—

|                              |     |
|------------------------------|-----|
| In Sunderland . . . . .      | 156 |
| In Bishopwearmouth . . . . . | 21  |
| In Monkwearmouth . . . . .   | 25  |
| Total . . . . .              | 202 |

From this statement it is manifest that, if the disease pursue the same course elsewhere that it has done in Sunderland, the danger to a population is to be estimated less from their numbers than from various circumstances in their condition, and particularly from the proportion which the labouring class bears to the rest of the community; for the parish of Sun-

derland, in which the mortality was in so much higher a ratio to the population than in the other parts of the town, is that in which the proportion of the labouring poor is greatest; though their situation is by no means so comparatively wretched as persons unacquainted with the habits of the labouring class in general, (and especially of that portion of it dwelling in sea-port towns,) and consequently destitute of the means of accurate comparison, have taken pains to describe. Besides the smaller number of the labouring class residing in Bishopwearmouth, there are various circumstances, such as its situation being higher, its streets wider and better ventilated, &c. which probably contributed to its proportionate exemption from the disease. Of the small number of its population who suffered, it must be remarked, moreover, that a large proportion lived in an inconsiderable part of the parish, at its outskirts, near the river, called Ayre's Quay, inhabited almost exclusively by the labouring class. In this small locality nine out of the twenty-one deaths occurred. It should be observed, too, that in Monkwearmouth, situated on the north bank of the Wear, the disease was confined almost exclusively to the lowest, dirtiest, and most populous district, situated near the river, and called *the shore*.

It is a fact of some importance that of the victims of the disease, seven only, so far as we have been able to discover, were, in point of situation in life, at all above the labouring class.

A simple calculation shows that the mortality amounted to one in two hundred and one and a fraction of the whole population in which the disease prevailed; that of Sunderland was as one to about a hundred and fifteen of its population; that of Bishopwearmouth as one to seven hundred and six, and exclusive of Ayre's Quay, as one to somewhat more than one thousand; and that of Monkwearmouth as one to three hundred and fifty-four.

There is nothing very alarming in such a rate of mortality as we have described; it is high on the number attacked, but low on the amount of population: and the former circumstance and the rapidity of the disease will probably be found to constitute its most appalling features, if its course elsewhere in this country resemble that observed here. Other epidemics which visit us exceed it, whether we regard the number or the quality of victims, in the amount of evil inflicted; but none is to be compared with it in fatality in proportion to the number attacked, or in the rapidity with which it accomplishes the work of destruction.

Our friend Dr. Ogden has furnished us with the following calculation, which is interesting provided the results of similar calculations made elsewhere in this island correspond with it; for it will thus be shown that in one point of some importance, the proportion of the sexes attacked, the disease here observes a course directly the reverse of that witnessed elsewhere in its progress.

Cases of cholera, known to be such, buried

\* Memoir of Dr. Loder, physician to the Emperor at St. Petersburg, dated January 1831, and read at the Academy of Medicine at Paris.

† Substance of a report published by the Supreme Medical Board of Russia.

at Sunderland between the 28th of October and 22d of December:—

| Age.                 | Males. | Females. | Total. |
|----------------------|--------|----------|--------|
| 15 and under . . . . | 12 ..  | 13 ..    | 25     |
| From 15 to 50 . . .  | 14 ..  | 33 ..    | 47     |
| Above 50 . . . . .   | 37 ..  | 36 ..    | 73     |
|                      | 63     | 82       | 145    |
|                      | —      | —        | —      |

Besides shewing that at the period of middle life the number of female victims of the disease is double that of males, and that at the two extremes the numbers are as nearly equal as possible, this table shows how large a proportion of aged persons the whole amount of mortality comprises, these constituting more than one half of the total of deaths.

The preponderance of attacks in females over those in males at the period of middle life is probably to be explained partly in the manner suggested by Dr. Ogden, that the dress of the latter sex furnishes a better security against cold than that of the former; and in part by the circumstance that males at the working period of life are better nourished than females, being frequently the only members of families of their class of society who partake of animal food.

For obvious reasons, we abstain from any statistical details connected with neighbouring towns in which the disease is, at the time this is writing, only in progress.

6. *Extent of diffusion, and causes.*—On the first branch of this subject we cannot be wrong, so frequently have its details been presented to the public, in assuming considerable knowledge on the part of our readers; or in referring those who may wish for more minute information than is ordinarily possessed or than we have space to give, to the admirable chronological table of M. Moreau de Jonnés. The present epidemic originated in the district of Nuddea, and perhaps in some other parts of the Delta of the Ganges, about the end of May or the beginning of June, 1817. It did not during that year extend beyond the territory of Lower Bengal; but in 1818 and the early part of 1819 it diffused itself throughout the extreme length and breadth of the Indian peninsula, moving in lines more or less diverging, and attacking in succession places generally more remote from the seat of its origin, (though striking deviations from this rule were occasionally observed,) and situated in various directions from it; but leaving untouched many districts placed between its lines of movement. Its progress along the lines it selected was wonderfully uniform, being for some successive months at the rate of about one degree in a month. As early as 1818 it extended itself beyond the boundaries of Hindostan into the Burmese empire and other territories of Eastern Asia, and, making gradual progress through these extensive realms, reached China in 1820, and in the following year visited the numerous and populous islands situated in the Indian Archipelago. The Isle of France suffered its invasion in 1819, and some cases occurred in

the same year at one point in Bourbon, in which island it has not since appeared. In 1821 it extended along the shores of the Persian Gulf, and during this and the following year spread through parts of Arabia, Persia, Mesopotamia, Syria, and Judea, and closely threatened Europe. It appeared in the Russian territories in 1823, at Saillan, Ghillan, Orenburg, and Astracan; but its further northern and western progress was for a time arrested. It, however, re-appeared in Orenburg in 1828, and again in 1829, and in 1830 advanced through the southern provinces of the Russian empire till it reached Moscow on the 28th of September of that year. Its subsequent progress through Russia, Poland, the Austrian dominions, the north of Germany, and in England, is too familiarly known to render it needful that we should present its details to the reader.

The space traversed as yet by this extraordinary epidemic may be conceived from the following simple calculation. The Philippine Islands form (so far as is known) the eastern, and Mauritius the southern, boundary of the disease. The former lie in east longitude 125°, and the latter is in south latitude 20°. Archangel is the most northern, and the vicinity of Edinburgh the most western point to which it has extended. The former is in north latitude 64°, the latter in west longitude 3°. Hence it is manifest that the disease has passed over 128° of longitude and 84° of latitude.

The questions naturally occur, what agent first generated the disease? and what has subsequently diffused it over so large a portion of the globe?

The first question must be answered by a simple statement of the facts, that it originated in the district mentioned after an unusual disturbance of the seasons with respect to alternations of heat and moisture; that it made its appearance at the commencement of a rainy season, so excessive that the Gangetic Delta was converted into a sheet of water; and that the very first point in which it was observed was the district of Nuddea, noted for the endemic prevalence of cholera, where the whole year had been rainy, and during every week of April and May (it began to manifest itself in the latter month) there had been a succession of thunder-storms. From this district it appeared to diffuse itself over the rest of Hindostan, its progress throughout the country being accompanied, as Mr. Orton informs us, by circumstances somewhat similar to those which attended its origin.

The second part of the question cannot be dismissed so lightly. As is well known, the doubt and difficulty regarding the subject exist chiefly with respect to the share which *contagion* has had in its diffusion; and this question we shall endeavour to discuss as succinctly, and certainly as dispassionately and fairly as possible. That our opinion, in the course of the investigation, has fluctuated, we feel it no discredit to avow. This fluctuation was either prior to the appearance of the disease

in this country, or to our having it a sufficient length of time under observation to enable us to attain a settled conclusion; and when we show the conflicting nature of the evidence from which, under the circumstances mentioned, a conclusion was to be drawn, it will be manifest that fluctuation or total scepticism must have been its result. As this evidence consists of facts already before the public, we shall, for the sake of brevity, rather refer to than detail them, classing them, as nearly as their nature admits, according to the very precise rules laid down by Dr. Alison for discriminating the operation of contagion.

1. Strong evidence of a disease being contagious is furnished by its appearance in communities previously healthy shortly after the arrival of persons from infected districts, who are themselves suffering under the disease, or who sicken of it soon after their arrival. A striking example of this sort is related in the Madras Report of the appearance of the disease at Jaulnah, after the arrival of a detachment there from Nagpore, then infected, and its subsequent diffusion from the former place to the towns of Malligaum and Hydrabad, and various villages.

Other cases, though few so striking as this, might be selected from the Indian records, but we prefer referring to examples which occurred in the Russian epidemic. In the fortress of Razipna, in that of Iletsk, and, towards the close of the epidemic, at Caramala-Gubeerra, all in the government of Orenburg, the invasion of the epidemic coincided, in point of time, with the arrival in them and sickening of persons coming from infected places. It should be remarked, however, that in these cases communication was not always traced between the individuals subsequently and those first attacked; and in the case at Razipna, it is distinctly mentioned, that of the individuals who visited the man first seized on his arrival from Orenburg, then infected, not one took the disorder.\*

Into the opposite scale, that of the non-contagionists, may be thrown facts which tend to prove that it has originated in districts previously healthy without any ascertained communication with infected persons, and that, on the other hand, the most ample intercourse has existed on various occasions between healthy and infected communities without the former having participated in the disease. Its introduction into the city of Orenburg in 1829 was not only not traced to communication from an infected district, but a conjecture that it might have been introduced either by the caravan which arrives from central Asia at midsummer, or by the Kirghis, a semi-barbarous Tartar horde, from whom the government of Orenburg is separated by the river Oural, was, if not disproved, rendered in the highest degree improbable.†

\* On the Asiatic cholera as it appeared in Russia in the years 1829 and 1830, by *Dr. J. R. Lichtenstadt*. (Translated in the *Edinburgh Medical and Surgical Journal*, No. cviii.)

† *Ibid.*

“When the disease attacked the sixth regiment at Colabah in July, 1828,” says Mr. Assistant-Surgeon Spence, of the 52d regiment, “its commencement was a remarkable proof against its contagious nature. It was in the midst of the rainy season, and not a case had been seen for months either in or near Bombay, when Assistant-Surgeon Campbell, in paying his evening visit to the hospital, found an old soldier, who had been under treatment some time for hepatic affection, suddenly seized with cholera. He went to the opposite extremity of the building for the purpose of consulting with the surgeon, and found him busily employed with another man, who had been almost simultaneously affected. Now it is physically impossible that these two individuals could have received the disease by contagion, because that which does not exist cannot have issue.” The disease proceeded with unabated violence till it destroyed sixty men and several women.\*

The following example of personal intercourse between the healthy and infected without communication of the disease, is taken from Mr. Annesley's Sketch of the Diseases of India. Cholera attacked the field force stationed at Shalligaum in Kandiesh, and raged with great violence among the corps posted on the left of the line, while the 17th battalion of native infantry, who were posted on the right of the line, were exempt from it, though they had constant communication with the other men.

2. The gradual diffusion of a disease through a limited community, those near the sick being first attacked, and others in succession in proportion to their proximity, is strong evidence of a disease being contagious. But this evidence has rarely been furnished by cholera; the general statement from India, indeed, is of a totally opposite nature; for we learn that, on its appearance in any place, numbers are simultaneously attacked, and that, after committing unheard-of ravages for a short period, its cessation is as sudden as its invasion. One example, however, resembling in some degree this gradual diffusion, is given in the Russian reports, and this is furnished by the staff-physician, Dr. Schimanski, with regard to the extension of the disease at Iletsk. He says he was able to trace the progress of the disease in the first eight cases, thus:—The husband of the woman, (a soldier's wife,) from Orenburg, was taken ill three days after her; and about the same time also, two girls who lived in the immediate neighbourhood of the soldier, and who visited him soon after his arrival from Orenburg: the aunt of these girls, who nursed him, was next attacked; and from her it passed to her own two sons.†

3. There is no circumstance connected with the disease on which the information received from different quarters is more contradictory

\* Taken from Mr. Spence's MS. since published in the *Medical Gazette*.

† *Edinburgh Medical and Surgical Journal*, No. cviii. p. 130.

than the comparative liability to it of attendants on the sick and other members of the community. From India the testimony on this head is so conflicting that no conclusion can possibly be drawn from it: a state of complete scepticism is that in which it leaves the mind of an honest enquirer after truth. That from Russia is not of a much more decisive character; such as it is, we shall present it to the reader.

During two months, observes Professor Lichtenstadt, while the disease prevailed at Orenburg, and two hundred and ninety-nine patients were admitted with cholera into the military hospital, the personal attendants on the sick remained entirely exempt from the disease. They consisted of one hospital assistant, six pupils, as many Baschkir lads, and fourteen hospital servants, in all twenty-seven; and their duties were to perform bloodlettings, apply leeches, poultices, and frictions, and administer baths and the like, so that they were compelled to be constantly breathing the exhalations from the bodies and clothes of the sick, as well as to touch and handle them. The washerwomen of the hospital likewise escaped; a class of individuals, who, it is well known, are extremely apt to suffer from contagious diseases.

On the other hand, Drs. Russell and Barry inform us, "that the number of medical men and hospital attendants attacked with cholera during the present epidemic, in proportion to the whole employed, and to the other classes of society, has been beyond all comparison greater here (St. Petersburg) than in India under similar circumstances; twenty-five medical men have been already seized, and nine have died out of two hundred and sixty-four. Four others have died at Cronstadt, out of a very small number residing in that fortress at the time the disease broke out there. Six attendants have been taken ill at a small temporary hospital behind the Aboucoff." With regard to this last circumstance, it is not stated, as in another report by the same gentlemen (not published) bearing date 4-16 July, that "In the great Aboucoff hospital, where there were no cholera patients, but to which a temporary cholera hospital was attached behind the building, ten persons residing within the area of the establishment had been severely attacked up to the 12th instant (N. S.) with cholera." This leaves a very different impression, and not being aware of what is meant by "the area of the establishment," we cannot form an opinion how it may or may not bear towards the side of contagion. In the last mentioned report, those gentlemen also state, that in the Military General Hospital, in which four hundred cholera patients had been admitted from distant quarters, up to the morning of the 13th, "one attendant had been attacked." But one attendant where so many cases had been treated!

These specimens, taken from an immense mass of foreign evidence, will suffice to show its conflicting nature on points essential to the

decision of a much litigated and very important question. There are certain branches of the subject, such as the immunity apparently afforded by seclusion, which we have designedly omitted; partly because they were unavoidably exposed to sources of fallacy, and the testimony regarding them was of the same conflicting nature as the specimens which we have already presented to the reader; and partly that we might preserve space for an examination of the question, how far the general progress of the disease favours the opinion that human intercourse has been the instrument of its diffusion; and for the narration of certain facts illustrative of the general question which have fallen under our observation.

The progress of the disease on the great scale having been tolerably regular both geographically and chronologically,—that is, its having passed from country to country without leaving interjacent countries untouched, and those infected having been so in some proportion, in point of time, to their distance from its original source,—has been appealed to by two parties as evidence of the accuracy of their opinions; the one seeing in it a proof of a continuous stream of epidemic influence flowing from the point where the disease originated; the other a transport of the malady by human intercourse from the same source. To the opinion of a flow of epidemic influence, have been objected, and apparently with justice, the slowness of the progress of the disease; that it has extended its territory in spite of the opposition of continued and violent monsoons; and that, notwithstanding a degree of general regularity of progress, there have been anomalies observed in its course, such as its having left districts untouched whilst all around them were suffering, utterly irreconcilable with the opinion advanced. On the other hand, circumstances have been observed, which render it almost equally questionable whether contagion has been the sole instrument of its diffusion.

It has been asserted by the advocates of the exclusive operation of this principle, that the disease has always been found to move in the line of human intercourse, and it must be acknowledged that, whilst so migratory an animal as man inhabits the earth, it cannot well do otherwise; but if it is meant to be asserted that its diffusion has been in proportion to the intercourse between infected and healthy districts, the assertion is by no means supported by facts. Its appearance at Madras, for instance, whither according to this doctrine it ought to have been conveyed almost three months earlier by trading vessels from the infected districts, was simultaneous, as Mr. Bell informs us, with its origin in parallel latitudes in the interior. It did not reach Ceylon, to which, on the contagious principle, it ought to have been conveyed at a much earlier period, by shipping from infected points of the coast, until it had previously gained the nearest point to it on the continent, about Adam's Bridge, and had

been long prevailing on both coasts of the peninsula.\* Unfrequented villages have been observed to suffer the invasion of the disease as early as the marts of intercourse and commerce; thus, from a statement of Mr. Orton, it seems to have reached some villages on the north bank of the Cavery,—detached from any frequented road, and considerably to the eastward of Trichinopoly,—quite as soon as this large and frequented town, whether it *appeared* to have been imported by a company of sepoys.†

Its movement along *navigable* rivers has been dwelt upon as evidence that human intercourse has been the means of its diffusion; and it is an argument of some force in showing that such intercourse may have occasionally been instrumental in effecting it: but when we are informed by Mr. Orton that the disease manifested this predilection for the course of rivers in the peninsula of Hindostan, “where navigation is scarcely carried on, even to the most trifling extent, on any river, and scarcely an instance can be mentioned of a great road running on the bank of a river, for they almost all cross them,” we must acknowledge that more weight has been attached to the argument than it is calculated to bear.

The disease, in its general course, has manifested a preference for one line of movement, and has rejected another, though there has been no striking difference in the amount of human intercourse between the two directions to explain the preference and rejection. Its progress in a north-western direction across the European continent has been briefly described, and is fully known to the reader. For three years it prevailed in the Ottoman territories bordering on the Levant; and it would appear, without any deficiency in the productive (or at least destructive) force of those germs of which we have recently heard so much; for in November, 1822, it numbered 4,000 victims in eighteen days in Aleppo; yet it has not penetrated into Turkey in Europe, and other extensive realms on the shores of the Mediterranean. Assuredly this could not arise from want of means of transport, and few will be disposed to ascribe it to the perfection of the quarantine department of the Sublime Porte. Since its appearance in this country a similar predilection has been displayed; for we find it at this instant a hundred and forty miles to the north-west of Sunderland, whilst six miles south is the extreme distance to which it has reached in that direction; and from the point which it attained, Seaham Harbour, after attacking eight persons and destroying three, it has since vanished.

A circumstance which may be urged against the exclusive operation of contagion, (and it is against attributing too much to one principle alone that we are arguing,) is the unusual prevalence of disease, bearing a considerable relation to epidemic choleric fever, which generally occurs prior to the appearance of this

in any given locality. The facts which might be mustered in proof of the antecedence of such disease are far too numerous and consistent to be accidental. Ordinary cholera, sporadic cases not distinguishable from the epidemic, excepting by the isolated manner in which they occur; epidemic diarrhoea; gastric and intestinal fever, have been observed in so many situations and by so many individuals, from 1817 to the present instant, to have been the precursors of the disease, that there cannot be a reasonable doubt of the accuracy of the observation. During the last year the prevalence of these affections in various parts of this country has been matter of familiar remark among medical men, and many of them have very properly taken care to record their observations.\* In this neighbourhood, what Mr. Orton felicitously terms the skirts of the approaching shower were manifest long before the epidemic made its formal inroad. Ordinary cholera was most unusually prevalent; whilst cases of disease, certainly not distinguishable by symptoms from the epidemic, occurred on the 5th, 8th, 14th, and 27th of August; and cholera continued to be very prevalent and severe throughout September. The cases which occurred in August were not matters of secrecy, but were the subject of conversation among the medical men of the place; and the writer frequently made the remark, that we were partakers of an inferior degree of the epidemic influence which existed on the continent. But certainly at the time he did not (nor does he yet) ascribe them to imported contagion; nor did he then conceive that we had, properly speaking, the epidemic among us. Whatever view others may now feel disposed to take of these cases, it would be difficult for them to suppose that the case we have mentioned, as having occurred in the interior in the beginning of July, was attributable to foreign importation.

Under either view, as it appears, whether we conceive that a current of contagion flows towards a district, or suppose the disease to be engendered there by indigenous causes, (not customary ones certainly, any more than those which existed in the Delta of the Ganges in 1817,) and then to be invested with some contagious property, which observation of the disease will induce most candid persons to admit it possesses, it requires the operation of two principles to explain all the facts of the case; for even on the first supposition we are compelled to imagine this double operation to be in progress,—a current of contagion to be flowing from one point, and a *nidus* for its reception to be preparing in another.

We have been led to the conclusion that the disease possesses a contagious property from having observed that a considerable proportion of attacks have taken place in individuals shortly after communication with the sick, or exposure to emanations from the dead bodies, and, in part, from a few examples having occurred of the disease appearing in parts of the

\* Orton on Cholera, 2d edit. p. 332.

† Ibid. p. 331.

\* See Dr. Burne's Dispensary Reports, in the Medical Gazette for July 2d, and July 16, 1831.

town or neighbourhood where it did not previously exist, on the sickening there of persons who had communicated with the infected districts; but at the same time we beg to remark that there are circumstances which tend to show that this property is abstractedly feeble in degree, and to render it more than questionable whether it can be the sole agent in diffusing the disease.

This opinion is founded on the singular anomalies observed in the course of the disease and which still mark its progress, and on the following considerations:—

1. Members of that class of society which has manifested the strongest predisposition to the disease have been very long exposed to the emanations from the sick, under circumstances the most favourable to the propagation of the disease, without being infected.

2. No death, and scarcely an attack of serious indisposition, has occurred among the medical men, though they have spent hours in the patients' chambers, assisting in frictions and other offices usually performed by nurses, and from the fatigue they were undergoing might be supposed to be peculiarly obnoxious to contagion.

3. Medical practitioners have not in any ascertained case conveyed the infection in their clothes to patients whom they were attending for other diseases, or to their families. Certain of them have mingled unreservedly with their own families after long attendance on cholera patients, without any indisposition, however slight, occurring in consequence. It is proper, however, to remark that two cases have occurred, one of them a fatal one, which might be attributed to the intercourse of medical men with their families.

4. When the disease has appeared in a private family in a situation in life above the labouring class, it has been confined, so far as the writer's knowledge extends, and he is of opinion that he is acquainted with the circumstances of all the cases of the kind which have occurred, to the individual first attacked, and has not in any instance spread to the other members of the family; nor have in these instances nurses or other casual attendants on the sick suffered, though belonging to a class more obnoxious to the disease.

5. The *agricultural* villages in the immediate neighbourhood of Sunderland, which had throughout the whole progress of the epidemic the most unreserved intercourse with us, remained and still remain exempt from the disease. The populous village of Deptford, situated near the river, at the distance of half a mile from Ayre's Quay, where the disease was very prevalent and fatal, and having the most constant communication with it, partakes of this exemption.\* The town of South Shields, containing nearly 14,000 inhabitants, and distant from Sunderland but seven miles, remained exempt from the disease (with the exception of two cases, stated to be very slight,

and not traceable to any communication with this place,) during the whole of its epidemic prevalence here, though calculations have shewn that eleven hundred persons pass weekly between the two places. Explanations have been offered of this exemption; but they appear inadequate if we suppose this disease transmissible to every locality by human intercourse, since typhus, scarlatina, and other infectious diseases frequently prevail there to a great extent. Even to the present moment, (February 2, 1832,) though its intercourse with Newcastle and other infected places has been incessant, but seven cases have occurred, and, as our intelligent correspondent there remarks, "We have not as yet got the disease as an epidemic, the cases have been so few and far between."

6. Though the disease has appeared, in certain cases, to be transferred to previously uninfected districts by spreading from persons who had sickened there after arriving from places where the disease prevailed, yet facts have occurred which tend to shew that the sickening of such persons and the diffusion of the disease have, at least in some instances, been mere coincidences. A woman of the name of Liddle, who lived in Sunderland, sickened at the town of Houghton-le-Spring, six miles from this place, and died on the 5th of December. The next case occurred on the 8th of the same month, in the person of a female named Cockburn, who lived at a considerable distance from the house where Liddle died, and in a different street, and had had no communication with her, direct or indirect; the family of the house in which the death occurred, and the persons who surrounded Liddle in her illness, escaping all infection. In many other instances in which the disease has appeared in a mining district or village, (and it has spread extensively in such situations,) the first cases could not be traced to communication with infected places. In certain cases, however, and we shall mention that of Hetton, the persons first seized had been in communication with infected districts.

7. On the first appearance of the epidemic in certain places, several have been simultaneously attacked; at Farsden Colliery, for example, thirty-two. On its first breaking out here, it manifested itself in three distinct points, between which no communication could be discovered; and the attacks in two of these points were simultaneous. It could not be traced from any source of infection to the individuals first attacked. In many instances, likewise, instead of residents in the same house being successively attacked, its invasion of several has been simultaneous.

8. There were feelings experienced by various persons, either otherwise in perfect health, or labouring under complaints distinct from the epidemic during its prevalence here, such as spasms, thrilling sensations of the extremities, and various affections of the nervous system, which appeared to betoken the influence of some cause more generally diffused than contagion; since many persons thus affected had not been exposed to any source of infection.

\* There were two slight cases in this crowded village inhabited by the class most susceptible of the disease, but it did not spread from them to the rest of the population.

The writer was at first disposed to attribute these occurrences to the influence of imagination; but they occurred in too many instances, and in persons too little sensitive and imaginative, to allow him to adhere to this explanation.

After assigning these reasons for questioning the exclusive operation of contagion, we think it right to remark that epidemic choleric fever has committed fearful ravages in some families, especially in those of which the circumstances were calculated at once to give intensity to the causes of the disease, and to render the individuals composing them more obnoxious to the action of such causes. Of one family seven were attacked with the disease, of whom five perished. The case of the first individual of the series constituted one of the sporadic cases, and it is incredible that the next in succession should have received infection from him, four months having elapsed between the dates of the respective attacks; but it is probable that contagion was transmitted from the second and subsequent cases, the diseases having commenced on the following successive dates, the 11th, 12th, 13th, 16th, 17th, and 20th of December. The case which occurred on the 20th was that of an infant, aged thirteen months, taken from the breast of the fifth patient in the order of succession.

Many other examples of transmission through families have occurred, but few so striking as this. We are disposed to attribute to contagion its full share in the production of such cases, aided by the circumstances of night-watching, neglect of order and cleanliness, &c. which are accompaniments of sickness in the dwellings of the poor; but we must remark that cases have fallen under our observation and come to our knowledge, which show a proneness to the disease in certain families, independent of reception from a contagious source. The following is an example of this kind. A respectable female, living in the village of Jesmond Vale, where the disease did not exist, and who had had no intercourse with the sick, received a letter announcing that a sister, whom she had not visited during her illness, and who resided at Hartley, a distance of nine miles, had died of the complaint. She sickened in an hour from the receipt of the intelligence, and died in thirteen hours from the commencement of the attack.\*

The following propositions appear to be reasonable corollaries from the facts presented by this extensive and intricate subject.

1. Epidemic choleric fever originated in a certain district under peculiar atmospheric circumstances; but these circumstances having previously occurred in the same district without the production of a disease identically the same, we must regard its terrestrial or atmospheric cause unascertained.

2. On many subsequent occasions there have been marks of its commencement and gradual rise in other districts, which show

that, in their soil or atmosphere, there has been a tendency to the production of the disease from causes equally unascertained as those which first originated it, and in such districts it has ultimately displayed itself.

3. It has thus appeared to arise in various districts not by any means always continuous with those previously contaminated, but often situated in some general direction with regard to them, declining in one district as it arises in another, and thus appearing to move in a succession of local epidemic visitations.

4. Within the district which it occupies it possesses a contagious property, or, in other words, those individuals who have intercourse with the sick, especially in a locally impure atmosphere, are attacked in a greater proportion than other members of the community; and it is probable that this same contagious property may be the means of diffusing it through a district disposed to the production of the disease, earlier than it might have risen spontaneously there, or of exciting it in a district in which, notwithstanding a degree of predisposition, epidemic choleric fever might not have arisen spontaneously; but facts which we have mentioned tend to render it questionable whether it can be thus transferred to districts unprepared to receive or engender it.

5. Within the district where it prevails, ordinary endemial causes mingle their agency with that of the general cause of the disease, and the malady is found to vary in prevalence and intensity in different portions of the same district: thus the disorder is found to assail more individuals, and to be more destructive in parts which are dirty, and in those placed low or near the banks of a river, than in portions of the district differently situated. The effect of these endemial influences is illustrated by the progress of the disease in the town of Sunderland, and by the ravages it has committed in the village of Newburn. The latter place is built along the margin of the river Tyne, and between it and the river there intervenes only a bank, formed of a mixture of mud and sand, partially covered at high water; whilst a shallow stream of water flows through the village. Here, although the disease has not yet ceased, three hundred and twenty persons have been attacked, and fifty-five have perished, out of a population of five hundred and fifty.

6. The character of the disease varies considerably in the different districts which it invades. Thus we had occasion to observe that in a mining population dispersed over an extensive tract of country, the township of Hetton, the disease was attended with less collapse than in the lanes and alleys of a populous commercial town, and the mortality was consequently much less; for we cannot too strongly repeat what we have already remarked, that the collapse is the measure of the danger. These observations are made with no view of depreciating the medical practice adopted in that district, which was extremely skilful and prompt, and even, with due allowance for the difference of the character of

\* Related to the writer by Mr. Greenhow, surgeon, of Newcastle, who attended the case.

the disease, very successful. It should be remarked, moreover, that extremely collapsed were intermingled with the milder cases, but in proportions the very reverse of those we had observed elsewhere. In certain districts in Northumberland, we have reason to know the disease resembled, in its general character, that which prevailed at Hetton; but among some other mining communities the extremely collapsed has been the common form of the disease. We have remarked, too, that whilst in some situations the cases have, almost without exception, commenced with diarrhœa, in others the proportion of instances in which this has constituted the initiatory symptom has been smaller.

This difference in the form of choleric fever in different local epidemic visitations, the cases occurring in any given district possessing a general correspondence in character, and being distinguished from those which occurred elsewhere, was observed in India by Mr. Scot; and it appears to us that this circumstance, coupled with the transmutation of the disease more and more into a febrile form as it has approached more northern climes, displays a deviation from that sameness of character observed in diseases engendered exclusively by human contagion.

It will hardly be expected that we should leave entirely untouched the question, whether the disease originated spontaneously in Sunderland, or was introduced from abroad; but the extent to which we have already pursued this intricate portion of our subject forbids our discussing it at any considerable length. Those who reason from the postulate that the disease is diffused only by human contagion will of course decide for importation; but others will very reasonably expect that before this be admitted, it should be proved by the same positive evidence that would be required to substantiate any other fact of importance. Any thing approaching to this, or even any considerable probability of such an occurrence, we have been unable to discover; and we cannot but agree with Dr. Ogden, that, whatever were the facilities for the importation of cholera here, they were much greater in other places; and that if it has been imported, so far from following the great routes of human intercourse, it has chosen one of the least frequented paths.\*

The predisposing causes of the disease, and the means to be adopted for preventing its diffusion, have been published to the world in such multitudinous documents, that we consider it unnecessary to occupy our pages with remarks on subjects now so familiar.

*Treatment.*—Previously to entering on this very important subject, we think it advisable to endeavour to correct the misconception which appears to prevail very generally among members of the profession, who have not as yet witnessed the disease, that some one specific remedy, or, at least, plan of treatment, must be sought for, and when

discovered invariably adopted. The importance very properly attached by all writers to collapse as a feature of the malady, and their candid avowal of the difficulty they have encountered in combating it, is the explanation of the fact that medical men who are practically unacquainted with epidemic choleric fever, have taken a view of its treatment which in the case of almost any other disease they would have repudiated as unscientific. We know no condition more hopeless than that of extreme collapse in the disease:—so hopeless, indeed, is it, that often have we questioned, in watching a patient in this state, whether our art at present possesses or is likely to possess any resources against it, or, in seeing him emerge from it, and he has sometimes done so most unexpectedly, whether the remedies employed, or some hidden power of the constitution, had been instrumental in effecting reaction. But it should be remarked that only in a proportion of cases—a proportion varying, as we have already observed, in different localities, and in the same locality at different periods of the epidemic—does this extreme collapse occur; and that even in cases of which the natural tendency is to pass into this deplorable condition, much may be done by early treatment for its prevention. These considerations should teach physicians and patients that safety is to be found only in the early administration of remedies; and the former, when brought into contact with the disease, will soon discover that success in its treatment must result, as in the treatment of other fevers, from adapting his remedies to the varying circumstances of individual cases and of the different stages of the same case, rather than from the trial of specifics for one portion only of an extensive series of changes;—that his practice, in short, to be successful, must be rational, not empirical.

In the observations we have to make on the treatment, we shall follow the natural subdivisions adopted in describing the disease.

1. *Treatment of the incipient stage.*—We have adverted to two forms which this stage assumes. In the one, there is some general uneasiness, nausea, and vertigo: in the other these affections may coexist with diarrhœa, but the latter is frequently present without the former being discernible. The first of these forms, in which it may be remarked that medical aid is rarely requested, requires that the stomach should be unloaded by an emetic, and a table-spoonful of good mustard constitutes a very efficient one; a few ounces of blood should be drawn from a vein; a laxative of calomel and rhubarb administered; and the patient restricted to a diluent diet, and kept within doors and warm. The treatment of the diarrhœal form, to which circumstances witnessed by us lead us to attach considerable importance, must be noticed more at length.

It was mentioned that, in this diarrhœal form of the incipient stage, the evacuations are at first found to be fecal and bilious; but at the time medical aid is summoned, they have

\* See Medical Gazette for January 21, 1832.

generally assumed the serous character which they bear in the choleric stage. A state of the system resembling, in some degree, collapse, it was observed, coincided with this condition of the alvine discharges. In this state it was found very advantageous to give a dose of calomel, conjoined with a proportion of opium and some aromatic,\* and in twelve or fourteen hours afterwards a dose of castor oil. On first visiting such a patient, a large blister was generally applied to the abdomen, in the cases under our care; warmth was enjoined,—indeed where compliance with our wishes could be enforced the patient was confined to bed,—and it was directed that the diet should be diluent. The subsequent treatment consisted in the employment of smaller doses of calomel and opium for one or two successive nights, and a second dose of oleum ricini was sometimes administered.

In certain localities the writer has found the constitutional state accompanying this stage of the disease to be one of marked excitement rather than of feebleness and collapse, and some points of the abdomen have been painful on pressure. In such cases one general bleeding, or the very liberal application of leeches to the abdomen, has preceded the employment of other remedies. In other respects the same treatment has been found successful as that adopted in the preceding form, excepting that no stimulating ingredient was mixed with the calomel and opium.†

Under these plans of treatment we have the satisfaction to state that, in every case which has fallen under our immediate observation, the discharges have resumed their natural bilious appearance, and the diarrhœa has been finally arrested without the supervention of a cold stage, and, consequently, of fever, though the disease had occurred in various instances in persons who had been in incessant attendance on those ill of the feverish stage, and though in all the cases it bore the characteristic marks of what we may term choleric diarrhœa. It should be remarked, however, that the choleric stage has supervened, as we have been informed, on diarrhœa which had been skilfully treated; but our inquiries have uniformly convinced us that in such cases medical aid

had not been summoned till the diarrhœa had existed some time, and the subsequent stage was closely impending.

2. *Treatment of the cold or choleric stage.*—In order that we may be distinctly understood in our observations on the mode of conducting this very important stage, it is necessary that we should adhere to its subdivision into two periods.\*

The first period is certainly that in which alone our most powerful means of arresting morbid actions can be employed with a considerable prospect of success. It may be considered an axiom in medicine that fevers, to be successfully, must be early treated, and the rule has a powerful application to a fever so rapid in its course as that under consideration. But there are many obstacles to its being generally acted upon amid a town population; and one considerable obstacle, we apprehend, will every where be found in that self-deception which seems to be quite a feature of the disease. We have met with persons to whom, from their peculiar situation, all the symptoms of this fever were as familiarly known as to medical men, yet when they were attacked with it, they did not or would not recognize it; and one such individual actually walked out with the disease upon him, and failed to send for assistance till eight hours after its invasion, though it was so severe as to destroy him in twelve. So strong is this tendency to self-deception regarding the nature of the disease when the choleric stage actually occurs, that wherever choleric fever prevails, strong appeals should be made to the public on the necessity of early treatment of this stage as well as of due care of that which generally precedes it.

The first remedy to be considered is *blood-letting*, and we shall endeavour to point out the circumstances which, so far as our observation extends, indicate, and those which forbid its employment. Its safe administration should be early, not according to mere time only, but with respect likewise to the rapidity of the disease, for one case will have made as considerable a progress towards actual collapse in two hours as another will have done in ten; and we should regard a considerable degree of collapse, indicated by feebleness or arrest of the circulation, and perceptible in the intervals of pain and spasm, (for when these occur, the pulse often sinks instantly, though only a second before it had been beating with considerable vigour†,) as an imperative reason for abstaining from drawing blood. But if we find the temperature not below or but little below the healthy standard, a pulse of tolerable force, and strong spasms recurring at short intervals, *provided collapse have not preceded this favourable condition*, we should

\* The following is the formula we have usually employed.

R Hydrargyri submuriatis, gr. viii. vel x.  
Opii, gr. ii.  
Pulveris baccarum capsici, gr. i fs.  
Confectionis rosæ, q. ss. ut fiat bolus, statim sumendus.

† We think it proper to remark, as probably the reader will perceive the discrepancy, that this excited state of the system was not enumerated among the symptoms of the incipient stage of the disease in our description of epidemic choleric fever. In extenuation of this omission, and, perhaps, of certain deviations from strict order that may be discernible, it should be mentioned that the composition of this article and our acquaintance with the disease, in various localities, have been simultaneously in progress, and we have deemed it better to sacrifice some degree of regularity than to withhold from the reader information which may speedily prove valuable.

\* The credit of this subdivision belongs originally to Mr. Kennedy. Experience in the disease having convinced us of its practical importance, we have adopted it in this article.

† Query—Does this sudden and momentary arrest of the circulation arise from spasm of the heart?

at once open a vein, and not lose an opportunity, which will never be restored, of probably preventing extreme collapse, and either its immediate fatality, or its more remote but scarcely less fearful evils. But should this condition, with respect to circulation and temperature, have succeeded to collapse, either spontaneously or by the administration of remedies, our experience would dictate that bloodletting should be carefully abstained from, as we have seen great injury produced under such circumstances by its employment; cases having fallen under our notice in which the loss of three or four ounces of blood has destroyed the fruits of two or three hours' assiduous labour. The difference in the effect of bloodletting on conditions apparently very analogous, but differing in the periods from the commencement of the attack at which they manifest themselves, cannot be too strongly impressed on the reader's attention. Perhaps the only difference in external character which can be discovered between the two states will be the existence of spasms of considerable strength in the early period, whilst in that more advanced they have nearly, if not altogether, ceased; but in the one case bloodletting breaks the morbid concatenations, and prevents collapse and congestion; in the other it lowers the vital energies which are freeing themselves from a state of oppression. But again, in a more advanced stage, when the constitution is no longer balancing between collapse and fever, and the latter may be considered as established, bleeding is a suitable remedy if the state of the circulation and the general condition of the patient render it admissible. Thus, then, there are three periods of the disease at which, according to our experience, bloodletting may be employed: occasionally in the incipient stage, as has already been stated; in the early part of the first period of the cold stage; and at the commencement of the feverish stage, under circumstances to be subsequently mentioned.

We have been explicit on this head perhaps to prolixity, because we found great discrepancy in the testimony of various Indian and continental authorities regarding it; and in the early part of our experience of the disease, the selection of the appropriate time for bleeding, and the circumstances which indicated or forbade it, constituted the greatest difficulty we had to encounter.

The measure to be adopted next in succession to bloodletting will depend on the condition of the patient. If in a short time after bleeding we find a circulation of tolerable force, without much tendency to general or partial deficiency of heat, and if at the same time there be pain in the epigastrium increased on pressure, a very common accompaniment of cases in which the tendency to collapse is least conspicuous, a large blister or sinapism to the abdomen, and a dose of calomel and opium, in the proportion of from eight to twelve grains of the former to one and a half or two of the latter, will be suitable remedies. Should the circulation, on the other hand, be feeble, with general or

partial deficiency of warmth, we should endeavour to rouse the system by full vomiting, and powdered mustard is a very proper means of accomplishing the object. Half an ounce of this substance, suspended in half an ordinary tumbler of warm water, may be considered a medium dose, and one which, in a great majority of instances, will act promptly and powerfully; but in a more advanced stage of the disease, when the collapse has been extreme, a whole ounce has been required to produce the full effect.\* After full vomiting, sinapisms may be applied to the abdomen and along the spine; whilst the warmth of the patient is supported by bottles of hot water wrapped in flannel, bags of hot oats, and other familiar methods of applying dry heat, directed to the extremities or other points of which the temperature seems deficient. Frictions of the parts affected with spasm will at the same time be probably required, and should be performed under the bed-clothes. We have not found any beneficial effect, in relieving the spasms, from oil of turpentine or other stimulating embrocations; the coldness produced by their evaporation probably more than compensating for any benefit they are in other respects calculated to effect. A bolus of calomel, capsicum, and opium, the latter not in a proportion exceeding a grain and a half or two grains, may be administered as soon as the vomiting from the mustard has totally ceased. The quality of the liquid given at this period ought to depend on the condition of the patient: if, for instance, the tendency to collapse be considerable, a little weak brandy and water should be given at short intervals; but, should the circulation be tolerably vigorous, and the temperature good, simple diluents, such as toast and water, constitute the most suitable beverage.

Should the patient be in a state of considerable collapse, whether consequent on neglect of the earlier stage, or occurring, which will occasionally prove to be the case, in spite of the most diligent attention to it, bloodletting should not form part of the remedial agents selected. If the temperature be in any considerable degree below the healthy standard, with the hands cooling rapidly on exposure to the air; the pulse at the wrist either very feeble or totally suspended; the breath and tongue cool; the surface shrunk and pallid, or in certain parts livid; the vomiting and spasms diminishing in their intensity, or totally ceased;—at whatever period from the commencement of the disease this state of things may exist, bleeding should be abstained from. It will be advisable to endeavour to rouse the system by full vomiting; and half an ounce of mustard, or, if the attendant prefer another mode of accomplishing the object, two table-spoonfuls of common salt, a scruple of sulphate of zinc, or half a drachm of ipecacuanha with

\* It may save the reader some trouble to inform him that an ordinary table-spoon, unheaped, contains half an ounce of mustard; and that the mustard sold in the shops under the name of Durham mustard, which is of a uniform bright yellow colour, is the most pungent and efficacious.

a small proportion of brandy, may be administered. Should the emetic selected fail to produce its effect in a quarter of an hour, it ought to be repeated; or should the circumstances of the case lead the attendant to suppose that the sensibility of the stomach is very low, a larger dose of the emetic drug may be administered: we recollect having produced full vomiting by an ounce of mustard in a case of extreme collapse, in which two smaller doses had been administered successively without effect. Simultaneously with the exhibition of the emetic, dry heat should be applied by some of the methods already mentioned, or by that very convenient and simple apparatus, the hot air-bath.

Various internal medicines of the stimulating class have been recommended for this state. Those of which we have been led to form the most favourable opinion are mustard, carbonate of ammonia, and oil of turpentine. The first named substance we have not unfrequently administered in doses of a drachm (a tea-spoonful unheaped,) at intervals of an hour or an hour and a half, apparently with the effect of giving additional vigour to the pulse, which had perhaps been restored by the vomiting; of producing bilious discharges from the bowels; of restoring the urinary secretion, and aiding the system in the transition into the febrile stage. If the carbonate of ammonia be the stimulant employed, a convenient mode of giving it is in doses of five grains every hour, with carbonate of magnesia, which makes it more easily retained should the stomach still retain its irritability. Should oleum terebinthinae be selected, doses of two drachms may be given every second hour. Whatever stimulant medicine be employed, we should advise that calomel in doses of five or six grains, repeated at intervals of three or four hours, should be given at the same time, with the view of aiding the restoration of secretion; and, with the intention of at once rousing the system and lessening the irritability of the stomach, that a large sinapism should be applied to the abdomen, and another along the course of the spine.

Various stimulating nostrums, if applicable to any, certainly only to this period of the fever, have been bruited forth to the world as specifics for the disease. In many of these we are of course inexperienced, and of all we are convinced the powers have been overrated, in some instances from partial and mistaken views of the malady, and in others from less pardonable reasons. It will not be deemed necessary that we should pass them all in review; but of certain remedies which have been proposed for collapse, the professional reader will require some notice.

The inhalation of oxygen gas has been suggested from many quarters; and in some cases in which it has been tried here an instantaneous amelioration has been manifest, the pulse having become more vigorous, the lips florid, and the patient having experienced relief from præcordial oppression and other distressful feelings, to an extent and with a promptitude

not afforded by any other measure. But the experience of medical observers in general has led them to conclude that this effect is very transitory; and some are of opinion that they have witnessed an increase of the collapse after the temporary excitement, as if the vital power, instead of being permanently increased by the measure, had been expended in a momentary flash. Of some gentlemen, however, the opinion regarding it is more favourable. Our own opinion is, that inspired for a few seconds in single bladders, no great benefit is likely to accrue from it; but we should speak less positively of the effect of an atmosphere of diluted oxygen breathed for a considerable period.

The tobacco enema has been suggested by Mr. Baird of Newcastle, and, as he assures us, employed with considerable success. We acknowledge that *à priori* reasoning would rather have led us from this remedy than suggested it to us; but knowing the fallacy of such reasoning in medicine, we are not disposed to treat with neglect, still less with contempt, a measure of the beneficial effect of which a gentleman of talent and character adduces several examples. It was proposed after the disappearance of the epidemic from Sunderland, and we have no experience of it; but we would recommend that it should be tried in a case to the successful treatment of which other measures seemed inadequate, the practitioner being governed, as to its subsequent employment or rejection, by its effect.

Two remedies have also been mentioned to us by an individual of talent, and of great experience in the epidemic, Mr. John Fyfe of Newcastle: we shall, with his permission, make the reader acquainted with them. One is the employment, in the period of extreme collapse, of an enema, consisting of two pints of warm water, from four to eight ounces of brandy, and from one drachm to two drachms of laudanum or Battley's sedative liquor. This, he assures us, has the happiest effect, in abridging that stage of the disease on the intensity and duration of which so much of the danger depends. The other is an enema containing a drachm of powdered mustard, which he has found to be very speedily instrumental in restoring the urinary secretion. This accords with our experience, as already stated, of the efficacy of this substance given by the mouth, in accomplishing the same object and the restoration of the secretions generally.

Weak brandy and water may be given occasionally during the collapse; and we have observed no injurious effect in this or any stage of the disease from the ordinary diluents taken in moderate quantities.

3. *Treatment of the excited or febrile stage.*—The treatment to be now pursued will not require such lengthened discussion as that of the preceding stages, which may be considered as more exclusively belonging to this disease; for recognised principles, applicable to the treatment of pyrexia in general, must be our guides in conducting this fever.

The fever constituting this stage, be it in essence what it may, has inflammation accompanying it, of which the principal sites are the brain and the lining of the digestive canal, and to the subduing of these, by such measures as the state of the system admits, our attention should be carefully directed.

A form of fever has been described as supervening on an extreme and long continued collapse in the cold stage, and in which fever it was mentioned that the vascular action was low and feeble, the temperature of the surface under the healthy standard, and the distribution of warmth very partial. In this low form of disease we have not ventured on general blood-letting; local bleeding from the temples has been freely performed, and occasionally too from the integuments of the abdomen when there were any indications of inflammatory affection of the digestive canal; but the great degree of intellectual torpor and insensibility which attends these extreme cases renders the discovery of such an affection extremely difficult. Blistering the nape of the neck, and shaving the head, so as to permit the application of cold, will be found very suitable measures. A degree of irritability of stomach, with occasional vomiting, is a very frequent accompaniment of such a case for the first two or three days; and under such circumstances leeches and subsequently a blister to the epigastrium have been resorted to with benefit.

Of internal remedies, that on which most reliance is to be placed is calomel, from its effects on the secretions, particularly of the intestinal canal, and from its facilitating the action of the laxatives which the state of the brain renders it advisable to administer. If two grains of calomel are given at intervals of three or four hours, an occasional gentle laxative, such as castor oil or calcined magnesia, will generally produce two or three bilious discharges from the bowels. Simultaneously with the administration of these remedies, the imperfect development of heat and its partial distribution require attention. The patient should be placed near a stove or in some warm situation, and bottles of hot water, or hot flannels, should be applied to the feet or other parts which are chilled. Even whilst endeavouring, by local depletion, to relieve partial determinations of blood, the general state of the system has been such as to require a little stimulus, and wine and water has been given, especially at an advanced stage of the disease, and occasionally medicinal stimulants, such as carbonate of ammonia, camphor, and sometimes, as a tonic, sulphate of quinine; but we cannot say that much benefit has resulted from the latter class of agents.

Such is the treatment we have generally adopted in that form of the febrile stage which is distinguishable from any fever we have been in the habit of observing here or elsewhere. The more excited form admits of one general bleeding with advantage, the amount of blood drawn being regulated by the degree of vascular action, of headach, of injection of the eyes, and various circumstances which would

influence our proceeding in any ordinary fever. Should the head, as it generally does, continue affected after the bloodletting, the application of leeches and cold should be resorted to, the former being repeated, if necessary, to such extent and at such intervals, as the degree of headach, intellectual torpor, and vascular excitement may seem to require. Laxative medicine should be administered; and the purpose is exceedingly well answered by calomel in doses of four or five grains nightly, and six drachms or an ounce of castor oil every morning. The diet under such circumstances should consist of the mildest and simplest diluents, such as would be demanded in any case of inflammatory fever: after the case has subsisted some days, a little wine and water may be given if exhaustion be manifest, but it should not be continued beyond the necessities of the case. Though we have seen few or no cases without a degree of cerebral affection, examples are met with in which the disorder of the intestinal canal is more considerable than that of the brain. Diarrhœa, the discharges being deeply bilious; a red, glazed, and very dry tongue; some degree of fulness and tension of the abdomen, and of pain on pressure there; and scanty high-coloured urine, generally attend such cases. The general treatment of cases in which such an affection exists, must depend on the state of the system; but the intestinal disorder demands the free application of leeches to the parietes of the abdomen, repeated according to circumstances, and the internal exhibition of mild mercurials, such as hydrargyrum cum cretâ, or blue pill, with a small quantity of opium. That kind of permanent fomentation which is afforded by hot poultices to the abdomen, after the application of leeches, has been found beneficial. The diet throughout a case in which this inflammation of the mucous lining of the intestines exists, should be mild and demulcent. In cases of this description—indeed in the most excited as well as in the lowest forms of the disease in which the collapse of the cold seems prolonged through the febrile stage—it is advisable to counteract, by warmth to the extremities and other points, that tendency to irregular distribution of blood which forms so striking a feature of the disease. Cases are occasionally met with, so mild in all their stages, that the fever requires no medical treatment but a few leeches to the head, a little laxative medicine, and abstemious diet for a few days.

Convalescence is in many cases tedious, the strength being slowly restored, and slight irregularities of diet sufficing to disorder the system, and even to produce relapse. For weeks after the fever we have found the patient still languid, and exceedingly prone to irregular distribution of blood, especially to undue determination to the head, inducing headach (requiring the application of leeches) on any considerable exertion. To prevent such occurrences we have found it advisable that the diet should consist, in the early period of convalescence, of a moderate quantity of vegetable matter only, and that the transition to more abundant and substantial

food should be very gradual; in short, that convalescence from this disease should be conducted in the same manner as that from other fevers.

We have stated that relapse may be produced by dietetic irregularities; and it is important to observe that even the best directed treatment of the incipient or diarrhœal stage may fail in its object, that of cutting short the disease, if such irregularities are indulged in. The relapses, properly so called, have occurred at an early period of convalescence; but we have witnessed one example, and that a very severe one, of the recurrence of epidemic choleric fever after an interval of two months from the preceding attack. This we were disposed to consider rather as an example of a second invasion than one of relapse, though it is proper to remark that the patient had remained feeble from the period of the previous disease. No assignable cause existed for the second attack.

(Joseph Brown.)

CHOREA.—The word *chorea*, as used by the ancients, signified a dance of many people to music, being derived from  $\chi\omicron\rho\omicron\delta\iota\varsigma$ , a band of singers and dancers. The origin of its application to nosology is involved in some obscurity. Sydenham and other writers have treated of the disease under the name of *chorea Sancti Viti*, a designation which has been very properly curtailed by Cullen and most subsequent authors. This latter appellation, we are told by Horstius, was acquired in consequence of some women of disordered minds and affected with a peculiar restlessness of their bodies, repairing, once a year, to the chapel of St. Vitus, near Ulm, and continuing there, night and day, leaping and dancing, until they were completely exhausted. By this means they were said to be cured for a time; but at the expiration of a year the disease returned, and was again removed in the same manner. The malady, however, which is commonly known by the name of chorea, is very different in its symptoms from the original disease so called, although they have been classed together, and sometimes supposed to arise from the same causes.

In this, as in many other instances, it is difficult to determine by what name the disease was known to ancient authors. Probably it was for the most part confounded with other convulsive diseases. Even Cullen, in the first edition of his Nosology, included it in the general term convulsio, from which, however, he afterwards saw reason to separate it. Galen appears to describe it with tolerable accuracy under the name of *scelotyrbe*, which means "an agitation of the leg." "It is a species of atony or paralysis," says he, "in which a man is incapable of walking straight on, and is turned round to the left when the right leg is put forward, and to the right when the left is put forward, alternately. Sometimes he is incapable of raising the foot, and hence drags it awkwardly, as those who are climbing up steep cliffs." It is also placed as a species of *scelotyrbe* in the nosological systems of Sauvages

and Sagar. Dr. Mason Good, in his arrangement, ranks it as a species of synclonus, the term by which he expresses "a multiplied, conjunctive, or compound agitation of the muscles."

Cullen defines chorea in the following manner: "Convulsive motions, partly voluntary, and for the most part of one side, attacking either sex before puberty, generally between the tenth and fourteenth year; the motions of the hands and arms resembling the gesticulations of players; one foot being rather dragged than lifted in walking." Sydenham has described it in a very graphic and accurate manner, as being "a species of convulsion which for the most part attacks boys or girls, from the tenth year to puberty. It first announces itself by a kind of halting, or rather instability, of one leg, which the patient drags after him, as idiots do. Afterwards it shews itself in the hand of the same side, which, when applied to the chest, or any other part of his body, cannot be retained in the same situation by the patient even for a moment, but is twisted about from one place to another, however much he strive to prevent it. If a full vessel be given him to drink from, before he can bring it to his mouth he exhibits a thousand gesticulations, like a mountebank; for as he cannot carry the cup in a straight line to his lips, the hand being diverted by the spasm, he tips it from side to side for some time, until at length, by good fortune, approaching it nearer to his lips, he jerks the liquor suddenly into his mouth and drinks it with eagerness, as if the poor creature were merely performing a feat to excite the laughter of by-standers."\* Dr. Hamilton, in his Treatise on Purgative Medicines,—after stating that the disease chiefly occurs from the eighth to the fourteenth year, in those who are of a weak constitution, natural or acquired; that it is generally preceded by a variable appetite, loss of vivacity, a tumid belly, and constipated bowels; and that the convulsive motions are ushered in by slight, irregular, involuntary twitchings, particularly of the muscles of the face,—presents us with the following description of the disease in its more aggravated shape. "These convulsive motions vary. The muscles of the extremities and of the face, those moving the lower jaw, the head, and the trunk of the body, are at different times and in different instances affected by it. In this state the patient does not walk steadily; his gait resembles a jumping or starting; he sometimes cannot walk at all, and seems palsied; he cannot perform the common and necessary motions with the affected arms. This convulsive motion is more or less violent, and is constant, except during sleep, when, in most instances, it ceases altogether. Although different muscles are sometimes successively convulsed, yet in general the muscles affected in the early part of the disease remain so during the course of it. Articulation is now impeded, and is frequently completely suspended. Deglutition is also

\* Sydenhami Opera, p. 468. Lipsiæ, 1827.

occasionally performed with difficulty. The eye loses its lustre and intelligence; the countenance is pale and expressive of vacancy and languor. These circumstances give the patient a fatuous appearance. Indeed, there is every reason to believe that, when the complaint has subsisted for some time, fatuity to a certain extent interrupts the exercise of the mental faculties. Fever, such as arises in marasmus, is not a necessary attendant on chorea; nevertheless, in the advanced period of the disease, flaccidity and wasting of the muscular flesh take place, the consequence of constant irritation, of abating appetite, and impaired digestion, the common attendants of protracted chorea.\* The sensations are little, if at all, disturbed; but in extreme cases there are hardly any of the voluntary muscles exempted from the spasmodic affection. The tongue is occasionally protruded, the mouth drivels, and the eye itself is twisted in various directions. Not unfrequently there is some pain of the head, for the most part in the occipital region; vertigo; and imperfect vision. The patient is often fretful, and liable to the same varied, desultory, and causeless emotions which occur in hysteria. The disease is apt to recur more than once in the same individual. Occasionally it has passed into hemiplegia or epilepsy, and instances are recorded of its proving fatal in that manner, or by exhaustion. Dr. Elliotson mentions that, when a student, he saw a young woman, labouring under the disease, die apoplectic.† In most cases, however, it terminates favourably, after a duration of variable length. In eighty-four cases occurring at the Norwich Hospital, Dr. Reeves states that the shortest period of medical treatment was two weeks; the longest eight months; and the common average, seven weeks.‡ Although the disease commonly occurs between the ages of eight and fifteen, it is met with as early as the fifth or sixth, and, on the other hand, even in mature years. Dr. Powell mentions an instance of it in a lady of seventy:§ and Dr. Bouteille relates one which occurred in a lady eighty years old, after hemiplegia.|| It oftener attacks girls than boys. Heberden found it to do so in the proportion of three to one, and Dr. Elliotson states that his experience presents nearly the same result.¶ Of the eighty-four cases reported by Dr. Reeves, fifty-seven were females and twenty-seven males. Of seventy-two occurring in Dr. Mason's practice, at Nottingham, fifty-three were females, nineteen males.\* Of eighteen cases in the Hampshire County Hospital, during the last ten years, six were boys and the rest girls.

Occasionally, chorea is complicated with

hysteria or other disorders, and thus a confusion of symptoms occurs. In some cases the disease is of so partial a description as to continue through life without any injurious effects to the general health, or even any serious inconvenience. Dr. Mason Good mentions the case of a barrister of great reputation, in whom the only symptom was an occasional awkward snatching of the arms and neck; and another of a person who, though a distinguished vocal and instrumental musician, had extraordinary gesticulations of the face and curvettings of the neck and head. Most practitioners have doubtless witnessed similar instances.

The characteristic signs of the ordinary disease are the permanency, the irregularity, and the partly voluntary nature of the motions. There are other diseases of clonic spasm, in which the motions are perhaps as unintermitting as in this, but they present a regular and unvarying appearance. On the other hand, spasms of an irregular description, but not continuing, are daily met with. In both these cases, however, the affection should be classed under the general term convulsion. The partial influence of the will over the muscular contractions is, for the most part, a circumstance which of itself distinguishes the ordinary chorea from every other spasmodic affection. It has, however, been customary to include under the same name some more rare diseases not always possessed of these characters; and the term seems to be somewhat loosely assigned to many abnormal affections of a spasmodic nature. We admit, indeed, that the very malady to which the name was originally given does not present the characteristic signs we have mentioned; and it might seem arbitrary to separate it entirely from that which has received the appellation, solely from somewhat resembling it in appearance. When it is considered, however, that there are no sufficient reasons for concluding that they are of similar origin, and that the disease to which the above characteristics do apply is of infinitely more frequent occurrence, and is at the same time universally known by the name of chorea, we think it right, for the sake of avoiding confusion and error, to confine our attention at present to the latter. Afterwards we will subjoin some account of the original disease, and other affections which resemble it or have received the same appellation. Some of the German writers have distinguished the two diseases by calling one the German, or great St. Vitus's dance, the other the minor St. Vitus's dance, or chorea of England. If they are still to be included under the same genus, the difference of their character might be better expressed by styling the one *intermittens*, or *periodica*; the other *continua*: the former *methodica*, the latter *abnormis*; according as the circumstances above mentioned shall, one or other of them, be considered the most characteristic of the chorea commonly met with in this country.

*Causes.*—The ordinary chorea has been attributed to various causes. Sydenham ascribed it to a humour thrown upon the nerves. By

very many authors it has been considered as a disease of general weakness of the constitution. And others there are who conceive it to arise from a partial and slow inflammation of the brain. With regard to Sydenham's hypothesis, it has followed the rest of the humoral theories, and does not now require notice. That the disease is always simply one of general debility, is a notion opposed by the benefit sometimes obtained from bleeding, the very uniform advantage arising from purgatives, and the occasional failure of tonic medicines, when uncombined with other remedies, in the treatment of the disease. Many circumstances, however, concur in shewing that, though debility may not be the original cause of the disease, yet it is often the principal reason of its continuance when once established. On the other hand, the idea that it is in general an inflammatory affection of the brain, as Dr. Clutterbuck and others have supposed, is contravened by the experience of Sauvages, Cullen, and many other practitioners, who have found bleeding very prejudicial in a great many cases. And although this was one of Sydenham's remedies at the beginning of the disease, he does not advise it to be repeated frequently; recommending, however, the purgatives and tonics with which he accompanied it to be continued through the whole course of the complaint.\* Whether, as Professor Gregory supposed,† the success of Sydenham's practice was entirely owing to the tonics, or whether it was attributable to the purgatives, or to both together, may possibly be a matter of dispute; but we think there is not much reason to attribute it, in general or chiefly, to the venesection. Dr. Armstrong, who mentions a case in which the free use of the lancet was nearly fatal, states that he considers chorea to arise from irritation of the mucous membrane of the stomach and smaller intestines, accompanied with a torpor of the skin, liver, and colon.‡ Dr. Hamilton, sen. from extensive experience of the benefit derived from purgative medicines, and the general appearance of the alvine evacuations, considers the disease to arise from disordered bowels. It has, however, been suggested by Dr. Coxe,§ Dr. Uwins,|| Dr. Manson,¶ and others, that such torpor and derangement may be merely an effect of the disorder, or at most a simultaneous expression of disease. Cullen thought that the malady depended upon "a state of mobility" in the system;\*\*\* and we are so far of opinion with him as to believe that chorea may be induced by any irritating cause operating upon a sufficiently excitable habit of body. The greater number of diseases arising before puberty are perhaps connected or complicated with intestinal irritation; and chorea, among others, doubtless frequently proceeds

from disordered alvine secretions, from worms, from accumulated fæces, improper diet, &c. But it has also been occasioned by affections of the mind, such as fright.\* Dr. Reeves states that in the majority of cases the disease is attributed by the parents to this cause;† and Mr. Bedingfield tells us, that of upwards of forty cases which occurred at the Bristol Infirmary, by far the greater number were induced by fright.‡ It has also sometimes arisen from irritation.§ It has been occasioned by a wound of the brain through the orbit,|| and other injuries about the head.¶ A case, in which it was induced in a man twenty-three years of age by injury to the scapula, is related in the *Medico-Chirurgical Review*.\*\*\* It has also been occasioned by teething;†† by the deleterious influence of certain metals and their compounds; preparations of lead, for example, or of mercury;‡‡ by suppressed eruptions of the skin;§§ and frequently by retarded or difficult menstruation.||||

It is extremely probable that the convulsive motions may be continued, merely from habit, a considerable time after the original cause is removed.¶¶ Mr. Hunter, of Glasgow, conceives that, although the motions are not at first dependent on any derangement of the brain or spinal cord, yet the irritation, which acts at first locally on the nerves of the affected muscles, may spread till it affect the root of the nervous system itself; and in this way he would explain the continuance of the convulsive motions after the removal of the original cause.\*\*\* May the morbid appearances, such as the following, which have been observed in some cases of chorea after death, be accounted for in this manner?

In two instances Dr. Willan found some ounces of serum in the ventricles of the brain.††† Dr. Coxe, of Philadelphia, who conceives that chorea uniformly arises either

from hydrocephalus or its forerunner, inflammation and turgescence of the blood vessels, found, in a fatal case, the vessels turgid, and twelve ounces of serum in the ventricles.\* Dr. Patterson, of Londonderry, (who, in opposition to Dr. Coxe's views, and in accordance with Dr. Percival, of Manchester,—see Medical Tracts, vol. i. p. 125, 1791,—considers that in chorea, as in other convulsive diseases, hydrocephalus is for the most part rather a result than the cause,†) has related a case in which he found the bloodvessels turgid, and traces of inflammation in the brain, a kind of serous diffusion over the convolutions, and three ounces of serum in the ventricles.‡ He also mentions a case in which the patient, after being cured of chorea, very soon fell a victim to hydrocephalus.§ M. Serres states that in one case he found a fatty tumour resting on the tubercula quadrigemina; in another, marks of considerable excitement, with bloody effusion at the base of these bodies; and in two others the whole of their substance was inflamed, and the inflammation extended to the roof of the fourth ventricle.|| It appears also that he has, by experiments on living animals, found that injury of these parts is followed by motions similar to those of chorea. We are not aware that these experiments have been published in detail, and are therefore unable to estimate their accuracy or conclusiveness. We would, however, express a doubt whether M. Serres's cases of chorea were of the ordinary species; and we think that the simple fact of their proving fatal in some measure justifies us in this hesitation, especially when the vagueness with which the term has been often used is taken into consideration. We shall presently remark on the probable origin of those more rare diseases which have been denominated chorea. In the meantime, we shall only mention that M. Serres admits that he has seen cases of chorea in which no injury in the brain could be discovered after death. In a fatal case of a somewhat anomalous character, published by Dr. Hawkins, there was no morbid appearance discovered within the cranium, but earthy concretions were found in the pancreas, omentum, and mesentery; tubercles in the lungs; and the uterus was large and vascular, with its lining membrane highly injected.¶

*Treatment.*—If proof were wanting of the varied origin of chorea, it might perhaps be found in the numerous and sometimes conflicting remedies, which have from time to time been extolled as successful in its treatment. From this circumstance, indeed, it has been

concluded by some that the disease in general subsides spontaneously, and is but little under the control of medicine; a belief which receives some degree of countenance from the general tediousness of the complaint, under any mode of treatment. It is, doubtless, quite as difficult in this disease as in many others to distinguish between mere *sequence* and *consequence*. As we have, however, a perfect conviction of the efficacy of certain remedies, almost opposite in their nature to others which have been sanctioned by high authority, we must either admit a difference in the exciting causes, or explain the seeming inconsistency by supposing that one remedy cures the disease by removing the apparent cause, and another by correcting some state of the system which may either render it susceptible of its influence or be itself an intermediate and essential link between that cause and the symptoms of the disorder: for example, that, of the two most approved methods of treatment in the present day, purgative medicines may be beneficial by removing causes of irritation from the intestinal canal; while metallic tonics may cure the malady by correcting a weak, mobile, or irritable state of the body, without which such irritating causes would not have produced the disease, and in consequence of which, indeed, it may often be prolonged after such causes are removed.

Since the publication of Dr. Hamilton's work, "On the Utility of Purgative Medicines," the administration of cathartics has almost uniformly entered into, if it has not constituted, the sole treatment in chorea. Though it formed, perhaps, the principal part of Sydenham's practice in this disease, it had become in a great measure discontinued; and Dr. Hamilton undoubtedly produced by his treatise a most important and useful change in this respect; and proved, in a vast many cases, not only the safety, but the extraordinary efficacy of very powerful cathartics. When the disease is yet in an early stage and scarcely established, gentle aperients may be sufficient, or indeed all that it is proper to administer. But he tells us that in the confirmed stage, when the intestines have in a great degree lost their sensibility, and the accumulation of faeces is great, whoever undertakes the cure of chorea by purgatives must be decided and firm to his purpose. Powerful medicines must be given, in successive doses, in such manner that the latter doses may support the effect of the former, till the expulsion of the accumulated matter is completely effected. When worms are known to have been passed by the bowels, or are suspected to be the cause of the complaint, the most successful, if not a specific remedy, is the oil of turpentine, in a full dose of from three to six drachms, or more, according to the age of the patient and other circumstances.

Although purgatives, however, are in many cases the most efficacious remedies, and perhaps necessary in the greater number, both in commencing the treatment, and at intervals afterwards, we believe most practitioners will admit that they have often failed in removing

the disease, and that medicines of another kind have succeeded without their assistance; while Cullen and other high authorities state that they have found repeated evacuations, of any kind, in many cases injurious.

In most instances, more especially after the exhibition of purgatives, we conceive that of all remedies tonics are the most successful. Sydenham used only the vegetable tonics; and Cullen preferred *eineliona* to the metallic preparations, as being of safer administration. We think there is no doubt, however, that the latter possess considerably more efficacy, and many of them are now found to be perfectly safe, in infinitely larger doses than were formerly considered prudent. The preparations of iron, zinc, copper, silver, and arsenic, are those which have principally been exhibited.

Dr. Elliotson has contributed much to establish the efficacy of the subcarbonate of iron in chorea. In the thirteenth volume of the *Medico-Chirurgical Transactions*, he published an account of eight cases cured by it, and proved that it might, and required to be given in much larger doses than had before been usual. Even the presence of headach, giddiness, and symptoms of paralysis, do not always, he says, forbid its use, but frequently disappear under its exhibition. In four of these cases no purgatives were administered, and in some of the others they could have aided but little in the cure. In his lectures, published in the *Medical Gazette*, he tells us that he has since cured many dozen cases by the same medicine, and has scarcely failed in a single instance; and adds that he thinks it will prove effectual in more cases than any other remedy. Occasionally it has been necessary to continue it for three months.\* The dose of the medicine may at first be from half a drachm to a drachm, increased by degrees to three or four drachms, and taken every six hours, in gruel, mucilage, or treacle; which latter may obviate any constipating effect from it. The sulphate of iron has also been found of some efficacy in chorea, and may be administered in doses of from one to four grains.

The sulphate of zinc has great power over the disease, and may be given in considerable doses, when they are increased in a gradual manner. The oxyd of that metal, however, is a more manageable preparation, and we have found it of the most uniform efficacy. It may at first be given in doses of five grains, and gradually increased. We have given it, in one case, in doses of twenty-five grains. Mr. Beddingfield states that this remedy was so speedily and decidedly successful in the Bristol Infirmary, that he cannot help regarding it as a specific. Upwards of forty cases, occurring there, were, with one exception, cured by it; and he attributes its failure in other hands to its not having been administered with sufficient regularity, or in sufficient doses to excite nausea. Some of the cases, however, were cured without the nauseating effect.†

The preparations of copper having been sometimes efficacious in other convulsive diseases, such as epilepsy and hysteria, have been given in chorea. The sulphate may be administered in doses of a quarter of a grain, or half a grain, twice a day, and the quantity increased if the stomach will bear it. The ammoniaret, or the *cuprum ammoniatum*, introduced into practice by Cullen, is of safer exhibition, though it should also be begun in very small doses. Cullen states that he had in some cases increased the dose by degrees to five grains and upwards, and that he had often found it to cure epilepsy. In chorea its virtues do not appear to have been by any means so striking as those of iron and zinc. Dr. Uwins relates a case which got well under its use, combined with *digitalis* and *myrrh*.\*

The nitrate of silver, likewise a successful remedy in epilepsy, has been occasionally administered in chorea. In our own practice it has almost uniformly disappointed our expectations. By others, however, it has sometimes been found successful, as in a case related by Dr. Uwins, in the *Edinburgh Medical and Surgical Journal*; † in two, by M. Priou, in the *Medical and Physical Journal*; ‡ in another, by Mr. Franklin, in the same work; § and in another, by Dr. Crampton, in the *Transactions of the King and Queen's College of Physicians*.||

The liquor arsenicalis has been used as a tonic, in this as in some other diseases, with considerable success. Several cases of its efficacy are published in the fourth, tenth, and eleventh volumes of the *Medico-Chirurgical Transactions*. In two of these arsenic was the only remedy used; ¶ in the others it had been preceded by purgatives. The dose of the solution should at first be three drops thrice a day, and it may be increased to ten drops or more, according to its effects.

Of the vegetable tonics, Peruvian bark will be found the most powerful. Cullen says that he found it remarkably useful in this disease. Gentian, likewise, and other bitters, have occasionally been of service. De Haen used the leaves of the Seville orange-tree as a stimulant and tonic in spasmodic diseases, with considerable success.

Iodine is a medicine which has lately been used with some success in chorea, probably from possessing a tonic and stimulating power. Dr. Manson has published a number of cases which were successfully treated by it, in combination with mild cathartics.\*\* Dr. Gibney, of Cheltenham, has also published two cases in which it was used with success along with other medicines; †† and Dr. Peltz relates a similar case in the *Philadelphia Journal*. †† It may

be given in the form of tincture, or the solution of the hydriodate of potass. The former, Dr. Manson directs to be made by dissolving twenty-four grains of iodine in an ounce of rectified spirit; and the dose may be from five to ten or fifteen drops three times a day, in some distilled water. He makes the solution by dissolving twenty-four grains of the hydriodate of potass in an ounce of distilled water; the dose is ten drops to twenty. As the preparations of iodine, however, have been made of various strength by its various advocates, and will probably continue so until admitted into our pharmacopœia, they ought to be administered with due consideration; very mischievous effects, and in some cases an affection not unlike chorea itself, having been occasioned by its incautious exhibitions. (See BRONCHOCELE.)

Of the remedies used for the purpose of giving tone or strength to the system, cold bathing and cold affusion are not to be overlooked. Electricity and galvanism, also, have been recommended, and the former employed in some instances with advantage.

Narcotic medicines have been frequently used with benefit, though they have occasionally been useless if not injurious. Stoll used the extract of belladonna, in doses of one sixth or one fourth of a grain, every six hours, with great advantage; and Cullen says that he found opium very generally useful in chorea.\* Dr. Patterson mentions that an unusually severe case in the Bristol Infirmary was cured by opium and camphor; and Mr. Bedingfield tells us that the only case under his observation there which resisted the oxyd of zinc, was cured by laudanum and tartarized antimony. Digitalis has by some been occasionally found of service; and in the twenty-eighth volume of the Edinburgh Medical and Surgical Journal two cases are related, in which the convulsive motions ceased under the use of hydro-cyanic acid, preceded by purgatives. Some cases are related in the Medical and Physical Journal, in which a speedy cure was effected by colchicum, without its producing a cathartic, or any other sensible operation.†

Musk, valerian, camphor, and other antispasmodics have occasionally been given, but in general without any benefit. Two cases, however, are related in the fifth volume of the Medical Transactions, in which Drs. Powell and Maton found the first of these successful. The cardamine pratensis, also, had at one time a reputation in this disease. Sir George Baker published some cases of spasmodic affection, two of them chorea, in which it appeared to him to be of decided benefit; but there is little confidence now placed in it.

Although we conceive that in the great majority of cases chorea will be most successfully treated by means of purgatives and tonics, more especially the latter, it cannot be denied that instances have occurred, in which there has been such affection of the head as to indicate

the propriety of local, or even general bleeding, and other antiphlogistic means of cure. Bleeding, as we have seen, was one of Sydenham's remedies; and Cullen admits that he had in some instances found it useful, though frequently very hurtful. In one case, Dr. Robert Watt found that it had an almost immediate effect in allaying the convulsive movements.\* Dr. Clutterbuck has in a number of instances prescribed it, at intervals of a few days, ten or a dozen times, and even oftener, without any other active remedies, and without failing of success.† Dr. Armstrong, who trusted principally to cathartics, aided by diet, exercise, air, and the tepid bath to restore the functions of the skin, cautions us against the free use of the lancet, and mentions a case, as we stated above, in which it nearly proved fatal.‡

The use of external counter-irritants has often been of much service, especially when there has been any considerable affection of the head. Blistering the scalp, or rubbing it with tartar-emetic ointment, has been adopted with this indication. The same remedies have been applied in the course of the vertebral column, a mode of treatment which accords with the conclusion drawn by Majendie, from the experiments presently to be recounted, that the direct cause of motion is in the spinal cord; and which would therefore promise, as it has afforded, in cases of a more permanent description, especial advantage. For such purpose, also, a seton in the neck, the moxa, &c. have been recommended. As the disease often arises about the period of puberty, from impeded menstruation, the application of a blister to the sacrum promises to be useful. Dr. Chisholm states that he found it successful after purgatives and antispasmodics had failed.§ Mr. Swan, of Lincoln, found it to have an immediate effect in allaying the convulsive motions.¶

When chorea arises from the coming of the second set of teeth, lancing the gums, or the removal of some of the first set will be proper. Instances in which the disease was speedily removed in this manner by Drs. Monro and Gregory, are referred to in the first volume of the Edinburgh Medical and Surgical Journal, p. 32.

Darwin, as he conceived the disorder to arise sometimes from the itch being hastily repelled, begins his directions for the cure by telling us to "give the patient the itch again."¶ He also furnishes us with an ingenious suggestion, that perpetual and repeated efforts should be made to move each limb in the designed direction, in expectation of the same good effects that follow from such efforts in stammering. Independently of any other benefit from such an exercise, one evident advantage would be, the abstraction of the patient's attention from his complaint—a matter of no slight importance in this and many

† Vol. xxxvi. pp. 181, 292.

other convulsive diseases. M. Louvet Lamarre found the exercise of the skipping-rope of much use in one instance.\* On this subject Dr. Mason Good remarks that a long and punctual discipline of the affected limbs to regular and measured movements, might, where the disease is not very severe, recal them to their wonted order and firmness; and adds that with this view the exercise of dancing, by which the original chorea Sancti Viti is said to have been cured so singularly, may be well worthy of attention.† The influence also of music alone, independent of the measured efforts in dancing, ought not to be overlooked. In some of the diseases resembling the original St. Vitus's dance, as we shall presently see, an extraordinary passion for music has been among the most prominent symptoms; and Dr. Armstrong relates a case in which music had the effect of procuring sleep, and of ultimately curing the disease altogether, after it had resisted purgatives, sulphate of zinc, the arsenical solution, and various other means.‡ When the will retains any power over muscular action, as it does in the ordinary form of the malady, it might be expected that such power, in a person susceptible to music, would be irresistibly or unconsciously exerted, to reduce the erratic movements as much as possible into harmony with its measured cadences. Nor will this appear fanciful to any one, who, being endowed with a musical ear, may have experienced how difficult it is, while music is sounding, even to obey the will in movements which do not accord with its measures.

We shall now advert to those singular affections which seem to have been erroneously classed with the foregoing disease, as well as to some others which appear to have been equally entitled to the appellation of chorea.

There is the following curious account of the original chorea Sancti Viti, in Burton's Anatomy of Melancholy. "Chorus Sancti Viti, or St. Vitus's dance; the lascivious dance Paracelsus calls it, because they that are taken with it can do nothing but dance till they be dead or cured. It is so called, for that the parties so troubled were wont to go to St. Vitus for help; and after they had danced there a while, they were certainly freed. 'Tis strange to hear how long they will dance, and in what manner, over stools, forms, tables; even great bellied women sometimes, (and yet never hurt their children,) will dance so long that they can stir neither hand nor foot, but seem to be quite dead. One in red cloaths they cannot abide. Music above all things they love; and therefore magistrates in Germany will hire musicians to play to them, and some lusty sturdy companions to dance with them. This disease hath been very common in Germany, as appears by those relations of Schenkius, and Paracelsus in his Book of Madness, who brags how many several persons he hath cured of it. Felix Platerus (de Mentis

Alienat. eap. iii.) reports of a woman in Basil, whom he saw, that danced a whole month together."\* This malady appears to have been generally considered as a disease of the mind, and we learn from Horstius and others, that it was liable to recur every year at the same period. The movements do not seem to have been actually spasmodic, but rather to have arisen from an irresistible propensity to muscular action, increased to a sort of phrensy by the sound of music and the force of imitation. The frequency of the disease, as reported, however, gives rise to suspicions of imposture.

Baglivi, who has given us an account of somewhat similar symptoms arising from the bite of the tarantula, or venomous spider, in Apulia, and cured exactly in the same manner, states that the disease was very often counterfeited by the women, who in that country lived solitary lives, for the purpose of enjoying the agreeable diversion of music and dancing, which was only allowed to those afflicted with the malady. "In fine," says he, "the musical entertainment of this country" (in allusion to the mode of curing the disease) "is so very agreeable to the women, that 'tis a proverb with us, '*Il carnevalletto delle donne.*'" He informs us, however, that there really was an unfeigned disease arising from the bite of the tarantula; Sauvages has named it tarantismus; and says that "those who are stung die in a little time without the present assistance of music, all other remedies giving no relief." His description of the symptoms and the mode of cure are very singular. "A few hours after the bite," says he, "the patient is seized with a great difficulty of breathing, a heavy anguish of heart, and a prodigious sadness," &c. The malady, "after the sharp fit of the violent symptoms, which appear for the first days, is over, ends at last in a peculiar kind of melancholy, which continually hangs upon the sick person, till by dancing, or singing, or change of age, those violent impressions are quite extirpated."—"Many of these persons are never well but among graves and in solitary places; and they'll lay themselves along on a bier, as if they were really dead; they'll throw themselves into a pit as if they were in despair. Maids and women, otherwise chaste enough, without any regard to modesty, fall a sighing, howling, and into very indecent motions, discovering their nakedness; they love to be tossed to and again in the air; and the like. There are some that will roll themselves in the dirt like swine, and are mightily pleased with the exercise. Others, again, you cannot please, unless they be soundly drubbed on the breech, heels, feet, back, &c. And there are some that take a great pleasure in running. There are also curious observations made about colours; some of which are very agreeable to those persons, as others are offensive to them." In describing the manner in which they are worked upon by music, he says, "When any are stung, shortly after it they fall down upon the ground, half dead, their strength and senses

\* Med. and Phys. Journ. Vol. ix. p. 89.

\* Vol. i. p. 15. 8vo. Edition. London, 1826.

going quite from them. Sometimes they breathe with a great deal of difficulty, and sometimes they sigh piteously; but frequently they lie without any manner of motion, as if they were quite dead. Upon the first sounding of the music the forementioned symptoms begin slowly to abate; the patient begins to move his fingers, hands, feet, and successively all the parts of the body; and as the music increases, their motion is accelerated; and, if he was lying on the ground, up he gets, (as in a fury,) falls a dancing, sighing, and into a thousand mimic gestures. These first and violent motions continue for several hours, commonly for two or three. After a little breathing in bed, where he is laid to carry off the sweat, and that he may pick up a little strength, to work he goes again, with as much eagerness as he did before, and every day spends almost twelve hours by the clock in repeated dancing; and, which is truly wonderful, so far is he from being wearied or spent by this vehement exercise, that (as they say) it makes him more sprightly and strong. There are, however, some stops made; not from any weariness, but because they observe the musical instruments to be out of tune; upon the discovery of which, one would not believe what vehement sighings and anguish at heart they are seized with; and in this case they continue till the instrument is got into tune again, and the dance renewed. This way of dancing commonly holds four days, it seldom reaches to the sixth. Every patient has not only his particular tune, but also his particular instrument; some a pastoral pipe, others a little drum, eittern, harp, tumbrel, violins, and pipes of several sorts. Here 'tis remarkable that sometimes the musicians will tune three or four different sorts of sounds without having the least effect upon the patient. But when they fall into a tune that's accommodated to the poison, they presently receive the benefit of it. However, this must be taken for a truth, that how much soever they vary in their particular tunes, yet they all agree in this—to have the notes run over with the greatest quickness imaginable, (which quickness of sound is commonly called *tarantella*). And therefore the players that have not their lesson to learn in these matters, easily discover the cheat of the women; for if they find that they presently take any motions, and jog on indifferently, without any regard to the swiftness, slowness, or other difference of sounds, they give to understand that the honest woman is but in jest, and afterwards experience puts the matter out of doubt.\* He states that the disease, like the German chorea Sancti Viti, generally returned about the same time of the year that the patient was stung; and seems much at a loss to understand either how it was produced, or in what manner it was cured. He appears inclined, indeed, to account for the latter, by the profuse sweatings induced by the violent exercise; but he admits that the physicians could not cure it by artificial sweatings.

A cony, which was stung by a tarantula and died on the fifth day after, was not at all influenced by music. On opening it after death, he tells us that "the veins and arteries of the brain were swelled up, and the brain itself a little inflamed, and set about with blackish spots here and there. The lungs and other entrails were distended with clotted and black blood. In the ventricles of the heart were observed greater clots of blood, and small branches of a polypous concretion. There was abundance of serum lying about the outward parts of the brain. The other parts were all sound and untainted."\* There is a case related in the New York Repository,† of a convulsive disease, ascribed to the bite of a spider, which, like that from the tarantula, was most effectually counteracted by music. In the latter malady, as in the original St. Vitus's dance, the principal peculiarities were the excessive love for music, and desire of muscular motion, especially in regulated measures. In both there was a liking or dislike of certain colours; and in both, the imagination at least, if not the intellect, was from the commencement disordered. Such, however, it is almost needless to observe, are far from being the characteristics of the ordinary chorea.

Mr. Kinder Wood has related a singular case in the Medico-Chirurgical Transactions, which he names chorea Sancti Viti; and it certainly had much in common with the original disease of that name. The patient, a married woman, aged twenty-two, after complaining of severe pains in the right side of the face, succeeded by heaviness and wildness of the eyes, became affected with extraordinary involuntary motions, commencing in the eyelids, which were opened and shut with excessive rapidity. They then affected the muscles of the extremities. The palms of the hands were beat rapidly on the thighs, and the feet on the floor, the arms being at times extended, the palms turned outwards and inwards, and the backs of the wrists struck violently on each other, or the middle fingers on the palms of the hands with great quickness. The motions soon extended to the trunk of the body and the pelvis; and the patient was half raised from the chair, and instantly re-seated in rapid succession. Sometimes she was forcibly thrown on her feet, when she jumped and stamped violently, and she had often a propensity to spring or leap upwards, and strike the top of the room with the palm of the hand. Frequently she would dance on one leg, holding the other with the hand. These attacks were accompanied with headach, sickness, and vomiting, which generally succeeded the affection of the eyelids. On the third day she began to strike the furniture and doors violently with her hand, and was greatly pleased with the sound. At length the bystanders observed that the strokes assumed a regular tune and measure, and the motions were changed into a step about the room, regulated by an air, or

\* P. 386.

† Hex. ii. vol. i. p. 1—11. Med. and Phys. Journ. vol. xv.

\* Baglivi's Practice of Physic, p. 363 to 382, *passim*. London, 1704.

series of strokes upon the furniture as she passed. Though, previous to her illness, she could not even dance a country dance, she would now move about in all the elegance of a minuet. When she looked around, she had an irresistible propensity to spring up and touch little spots or holes in the ceiling; and she would dart the forefinger with amazing rapidity and precision through a hole in a wooden skreen. A person, thinking he recognized the tune which she beat on the furniture, began to sing it, and she danced directly up to him and continued dancing till he was out of breath. A drum and fife were now procured, and she immediately danced up to the drum, and as close to it as possible, till she missed the step, when the motions instantly ceased; and this was always found to be the case. The motions were always found to cease, also, when the measure was changed, or increased in rapidity beyond her power to keep pace with it. When a continued roll was kept up on the drum, it had likewise the effect of stopping the motions. Their approach was therefore watched, and by uniformly rolling the drum when it was observed, the chain of associations which constituted the disease was at length broken. Mr. Wood states that the alvine excretions were unnatural during the complaint, and that the menstrual discharge appeared on the evening of the day on which it ceased; together with an eruption on the skin, in diffused patches, of a bright red colour. Whether these were essential circumstances in the history of the case is a question worthy of consideration. Mr. Wood thinks that the case establishes the connection of such instances of inordinate muscular action with some peculiar state of the mind. He tells us, however, that the patient's spirits were good, her perception and judgment accurate and just; that during the absence of the paroxysms she went about many household affairs; and that she had a correct knowledge of her situation, and of the advantages she derived from the agency of the drum, with an anxious desire to continue its use. A subsequent less severe attack of the complaint disappeared under the use of aperients and tonics; and the third and last, which terminated in spasmodic affections of the abdomen, chest, neck, and face, seems to have been chiefly benefited by bleeding. It is curious that, after the nature of the motions were changed in this last attack, the drum had no effect upon them.\*

Of the disease which has been at times prevalent in some parts of Scotland, and known by the name of "the leaping ague," the following is a concise description:—"Those affected first complain of a pain in the head or lower part of the back, to which succeed convulsive fits, or fits of dancing at certain periods. During the paroxysm they have all the appearance of madness, distorting their bodies in various ways, and leaping and springing in a surprising manner, whence the disease has derived its vulgar name. Sometimes they

run with astonishing velocity, and often over dangerous passes, to some place out of doors, which they have fixed on in their own minds, or perhaps even mentioned to those in company with them, and then drop down quite exhausted. At other times, especially when confined to the house, they climb in the most singular manner. In cottages, for example, they leap from the floor to what are called the baulks, or those beams by which the rafters are joined together, springing from one to another with the agility of a cat, or whirling round one of them with a motion resembling the fly of a jack."\*

The most recent published case of this disease, so far as we are aware, will be found in the 31st volume of the Edinburgh Medical and Surgical Journal. Mr. Crichton states that the patient was a girl fifteen years old, and that the affection was announced by frequent shakings, with foaming at the mouth, followed by coma. In addition to many of the symptoms mentioned in the foregoing passage, such as dancing, jumping upon the furniture of the room, running round a table, springing on the top of a door to swing backwards and forwards, leaping over a staircase at one bound, and desiring to spring out of a window; she had likewise the following singular affection: "she would occasionally converse with those in the room, but in a language that no stranger, and hardly even those of the family who were constantly beside her, could understand. This arose from her commencing the sentences with the last word, and very frequently pronouncing the words themselves with the last letter foremost. At times, when by no possibility she could make herself be understood by her parents or sisters, she became irritated, and would write down what she wished to convey; but her manner of writing was equally singular, beginning at the right edge of the paper, and writing backwards towards the left, the last word of the sentences first, and often the last letter of the word first; and this she performed with great rapidity, and seemingly without consideration."† She had a propensity to secrete things; and so irresistible were the impulses to motion, that the strength of several people was insufficient to constrain her. Purgatives afforded her little benefit. Opium before the paroxysm sometimes prevented it; and the shower-bath cured the disease, though it produced locked jaw for eight days. The "leaping ague" may be said to consist, generally, of a morbid propensity to running, leaping, dancing, or tumbling, which the patient is unable to resist. The muscular motions, though in a great degree involuntary, are performed with more agility and exactness than usual; for the person affected can run with greater velocity, leap with greater vigour, and do feats which even professed tumblers

could not equal, balancing the body with correctness, and dexterously avoiding dangers. It is scarcely necessary to point out how widely the disease differs in all these respects from the ordinary chorea.

M. Piedagnel has related the case of a man, who, after some symptoms of cerebral affection, was seized with an irresistible propensity to move forwards, only stopping when exhausted. Finding his apartment too confined for the gratification of his propensity, he would sally into the streets, and continue walking straight forward until he dropped down, and was obliged to be brought home in a litter. On opening the head, several tubercles were found, involving in a particular manner the anterior part of the hemisphere.\* In direct opposition to this case, Dr. Laurent, of Versailles, exhibited a young girl to the Academy of Medicine, who, in the attacks of a nervous disease, was irresistibly propelled backwards, and with some rapidity, being unable to avoid obstacles or hollows, and, consequently, receiving many bruises and falls in her course.†

An account of a very remarkable case, in which a young girl, in Renfrewshire, was affected with violent fits of leaping, dancing, running, crying, fainting, &c. was published at Edinburgh, in 1698. It was entitled "A True Narrative of the Sufferings of a Young Girl, who was strangely molested by Evil Spirits, and their Instruments, &c." The disease being ascribed to witchcraft, a commission was appointed by the king to inquire into the matter, and seven unfortunate beings, in consequence, were condemned to the flames!

One of the most extraordinary cases of convulsive disease on record has been related by Dr. Robert Watt, of Glasgow, in the 5th volume of the *Medico-Chirurgical Transactions*, under the title of *Chorea*, or "Periodical Jactitation." The patient was a lively, but rather delicate girl, ten years old, from Ayrshire. She was first seized with excruciating headach, and almost incessant vomiting, increased by the slightest inclination of the body, either backwards or forwards. These symptoms continued for a month, during which time she lost the power of speech and of walking. At the end of that time she was seized with a propensity to turn round on her feet, like a top, with great velocity, always in one direction, and was gratified when the attendants assisted her in increasing the rapidity of her movements. After continuing nearly a month, these motions ceased, the headach returned with increased severity, and was succeeded by a total loss of power over the muscles of the neck. In a short time after she was seized with a new kind of motion. She would lay herself across the bed, and, turning round like a roller, move rapidly from one end of it to the other. The fits continued at first for about two hours; but they

gradually increased to six or seven hours daily. On being carried into the garden, she rolled rapidly from one end of a walk to the other; and, even when laid in the shallow part of a river, though at the point of being drowned, she began to turn round as usual. Nor did the sudden dashing of cold water over her interrupt her movements. Her rotations were about sixty in a minute. In a month or six weeks, the movements became of an entirely new kind. The patient now lay upon her back, and, by drawing her head and heels together, bent herself like a bow, and then allowing her head and heels to separate, her buttocks fell with considerable force upon the bed. She repeated these movements ten or twelve times in a minute; at first for six hours daily, and at length for fourteen. After this had continued for about five weeks, she was seized with a propensity to stand upon her head with her feet perpendicularly upwards. As soon as the feet were elevated in this manner, all muscular exertion seemed to be withdrawn, and the body fell down as if dead; her knees first striking the bed, and her buttocks striking her heels. This was no sooner done than she instantly mounted as before, and continued to do so, from twelve to fifteen times in a minute, for fifteen hours a day. The disease left her after a spontaneous diarrhoea, having previously resisted cathartics, an emetic, local bleeding, blistering, a seton in the neck, &c. Dr. Watt states that another instance, similar to this, had occurred some years before in Ayrshire, and that he had been informed of a third in the same county: in both of these, also, the patients were young women. There is a case mentioned in the 3d volume of the *Edinburgh Medical and Surgical Journal*, page 437, in which a young girl was affected with a species of motion similar to the first which Dr. Watt's patient presented. "Her complaint began with convulsions of the diaphragm and abdominal muscles, producing an action like retching, or something between hicough and retching. Convulsions of the extremities supervened, and in the paroxysms, which lasted several hours, she performed the most singular motions; at one time bounding upon her bed, then turning round and round, as upon an axis; then running round the outside of the ropes by which her hammock was suspended." She had several paroxysms a day, coming on at stated intervals, and she had constant pain, which she referred to the region of the uterus. Nothing was discovered on dissection after death, which could at all explain the nature of the disease: some time before she was affected, she had rather a severe fall upon her head.

Mr. Hunter, of Glasgow, relates a case in which the principal symptom was a convulsive rotation of the head and trunk; he entitles it, therefore, "*rotatio*," or chorea. The patient was a female, twenty-three years old, and unmarried. While lying on her back, the head was rolling from side to side, with a quick, regular, and continued movement.

\* *Journal de Physiologie*, tom. iii. or *Majendie's Physiology*, translated by Dr. Milligen, 3d edit. p. 189.

† *Majendie's Physiology*, p. 191.

When a fit came on, "she sprang with a strong convulsive movement from her back, and sat up in the bed. The rotatory motions of the head now became furious and alarming. They were executed with such immense rapidity, that it was difficult even for eye to follow them. She appeared absolutely to be looking backwards and forwards, and in every direction, at the same instant. The movements, while in the sitting posture, were not confined to the head; for the whole trunk likewise partook of the rotatory motions, the breech being the pivot upon which the whole turned. These convulsive motions continued about a minute, when they took a new but equally strange direction. The flexor and extensor muscles of the head and trunk were alternately called into action, and without the breech of the patient moving from its first position, her head was rapidly carried forwards to her knees, and backwards to her pillow, for about half a minute, when the paroxysm ceased, and left the patient greatly exhausted."\* She was perfectly rational, but the external senses were blunted and torpid. She sometimes had fifty paroxysms in a day. The disease appeared to commence in the uterine region, where there was pain on pressure; and it was cured by rubbing tartar emetic ointment on the scalp, and along the course of the vertebræ. A case in some respects similar to this has occurred in our own practice, in the person of a young woman, who was affected for a long time with rotation of the head, without pain, but accompanied by intolerance of light. The motions, however, were far more gentle and slow than in Mr. Hunter's case, and they were unintermitting.

A patient attended by Dr. Conolly became subject, about the period of the cessation of the catamenia, and when menstruation had become irregularly performed, to violent paroxysms of rotation: they occurred many times in a day, and were always preceded by an inordinate disposition to talk. When the fits came on, the head was forcibly rotated from side to side about eight times in a second, and the paroxysm commonly lasted three or four minutes. In this case, the affection yielded to cupping behind the neck, the application of leeches to the head, and the persevering use of aloetic purgatives.

Another singular form of disease which has at times been ranked with chorea, is that affection, by some authors called *mallectio*, and consisting, principally, of a striking of the knees with one or both hands, as with a hammer. The hands are generally open, but sometimes they are clenched. Morgagni mentions a case of this description, in which one hand was convulsed; on extending any of its fingers the other hand became affected also; and if attempts were made to arrest the motions by force, they became both more violent and more general. We ourselves recollect the case of a man, in the Hampshire County Hospital, in

whom there was a constant and uniform striking of the palm of one hand upon the side of the thigh, to such a degree, as speedily to wear out the part of his dress on which it fell.

In the preceding cases of anomalous convulsions, it will be observed that there was for the most part a periodical return and intermission of the spasms, as well as some method or regularity in the movements themselves. In both these respects they differ from the common chorea of this country. Other cases have been met with, occurring in paroxysms, but in which the motions were obedient to no rule or method. Dr. White, of York, describes a case of this kind in the fourth volume of the Edinburgh Medical Commentaries, p. 326, in which the muscles of various parts were, not simultaneously, but in succession, painfully convulsed, producing appearances so grotesque as to defy description. Three cases, occurring in one family in the county of Rutland, are related by Dr. Armstrong, in the ninth volume of the same work, p. 317, in which the patients were affected periodically, and suddenly, with fits of shrieking, jumping, writhing, &c. The disease first occurred after hooping-cough, and Dr. Armstrong considered it as epileptic.

There are some singular instances recorded of affections like the last being propagated by sympathy or imitation. These have generally been attended, and, in the first instance, excited by religious or some other species of enthusiasm. This was strikingly the case in that extraordinary epidemic, as it has been called, which prevailed in 1742 in the parish of Cambuslang, in Lanarkshire, during the ministry of Mr. Macculloch, and produced by his preaching and exhortations on the subject of regeneration.\* A similar epidemic occurred in the western districts of America, in consequence of the electrical spread of religious enthusiasm throughout the states of Tennessee and Kentucky, about the year 1800. Dr. Robertson, who published an account of it, states that the converts indulged in alternate fits of coughing, laughing, singing, shouting, and extravagant gesticulations, until, at length, "to their own astonishment, and the diversion of many of the spectators, they continued to act from *necessity* the curious character which they had commenced from *choice*."† He informs us that the convulsions were generally in the muscles of the neck, trunk, and superior extremities; and that they were sometimes so violent as to throw the patient on the ground, "where, for some time, his motions resembled those of a live fish when thrown on land, more than any thing else."

M. Majendie relates a case of the most extraordinary nature, in which the power of the will over the muscular motions was, at intervals, entirely lost; but instead of the muscles being paralysed or remaining at rest, they were abandoned to the most irregular and indescribable movements for hours together. After stat-

\* Edin. Med. and Surg. Journ. (the Inquirer, No. 11.) Vol. iii. p. 441.

† Ed. Med. & Surg. Journ. vol. iii. p. 446; or an Inaugural Essay on Chorea Sancti Viti, by Felix Robertson, of Tennessee. 8vo. Philadelphia, 1805.

\* Edinb. Med. and Surg. Journal, vol. xxiii. p. 261.

ing that the disease was preceded by great mental anxiety, followed by melancholy, the understanding remaining however entire in all other respects, M. Majendie describes the peculiar symptoms of the case in the following words: "It is impossible to paint, by language, the variety and oddity of his motions and positions. Had he lived in the times of ignorance, he would, beyond all doubt, have passed for one possessed; for his contortions were so far removed from the motions proper to mankind, that they might easily have passed for diabolical. It was worthy of remark that, in the midst of these contortions, in which his slender and pliant body was sometimes carried forward, sometimes thrown back, or to one side, like certain tumblers, he never lost his equilibrium; and that in the multiplicity of attitudes and singular motions which he exhibited for several months, he never once happened to fall. At certain times his motions would pass into the train of ordinary actions. Thus, without the least participation of his will, he was seen to rise and walk with rapidity, until he met with a solid body that opposed his passage. Sometimes he walked backwards with the same readiness, and was only stopped by a similar cause. He has often been observed to re-assume the power over certain motions without being in any way capable of directing others. Thus his arms and hands frequently obeyed his will, and more frequently still, the muscles of his countenance and speech. It was sometimes possible for him to retrograde in an instant where progression forwards was any how prevented; and he then employed that retrograde motion to direct himself towards objects to which he wished to attain. Finally, these movements, which might be called automatic, never lasted an entire day. He enjoyed pretty long quiet intervals between the accessions; his nights were always tranquil. Although his muscular contractions were extremely violent, even to the extent of producing abundant sweats, when they had ceased, he perceived no sensation of fatigue in proportion to the efforts which he had made; as if the intellectual action which we exert to excite our motions were that which in the healthy suffers most exhaustion."\*

The causes of such anomalous cases of convulsion, and the manner in which they operate, are exceedingly obscure. Modern physiologists, however, have afforded us some light on the subject. Thus, Majendie has, by experiments on some of the lower animals, shewn great reason to believe that the *will* has more particularly its seat in the cerebral hemispheres, while the direct cause of motion is in the spinal marrow. We can easily conceive, therefore, says he, "why, in certain cases, these motions are not produced, though commanded by the will; and why, in certain circumstances of a contrary nature, very extensive and energetic motions are developed without any participation of the will."† In some of the following experiments confirmatory of this view, it will be observed

that many of the anomalous symptoms in the cases we have just related, were produced by artificial means.

M. Majendie found that the cerebral hemispheres might be deeply cut into, or even entirely removed, provided the corpora striata were not injured, without any marked alteration of motion taking place. In a number of cases he has seen birds, reptiles, and fishes, run, leap, and swim, after the hemispheres were removed. Neither does the longitudinal section of the corpus callosum, or its entire removal, produce any additional effect upon the motions. But if the corpora striata be removed, the animal immediately darts forward, and runs rapidly, as if impelled by a power within which it cannot resist. This effect arises from the destruction of the white and striated portion of these bodies, for the removal of the brown matter does not produce any change in the movements of the animal. In unison with these facts, M. Majendie has opened several *immoveable* horses, or horses that cannot go backwards, though they can move forward with rapidity; and he has in all of them found a collection of water in the lateral ventricles, which must have compressed the corpora striata, and had even disorganized their surface. He considers it extremely probable, therefore, that there exists in man and the mammalia a force or impulse which tends to carry them forward, and which in a state of health is directed by the will. Again, both he and others have found that lesions of the cerebellum cause animals to move backwards contrary to their will. He found also that injuries of the medulla oblongata produce the same effect. Pigeons, into which he forced a pin through that part, constantly receded, for more than a month, and even *flew* backwards. The energies of the cerebellum and medulla oblongata appear, therefore, to be directly opposed to those of the corpora striata; those of the one counterbalancing the other in the sound state, and being rendered preponderant, or otherwise, by disease or injuries of the respective parts. A still different effect was produced upon the movements of the animals when the peduncles of the cerebellum were divided. In that case the creature rolled laterally upon itself, as if impelled by a great force; the rotation being made upon the side on which the peduncle was cut; the animal making sometimes more than sixty revolutions in a minute, and the motions continuing frequently for eight days without a moment's interval. The same effect was produced by vertical and entire sections of the cerebellum; the motions being more rapid according as the section was nearer to the origin of the peduncles. When the cerebellum was cut vertically into two perfectly equal parts, the animal first rolled once or twice to one side, and then as often to the other, as if for relief. Similar effects to these were obtained by sections of the pons varolii, which, together with the peduncles of the cerebellum, forms a circle round the medulla oblongata. Sections to the left of the median line produced rotation to the left, and sections on the right side of the line, rotations to the right. A movement in a circle, resem-

† Op. Cit. p. 202.

bling that of the *manège*, was occasioned by a section of the medulla oblongata, where it approaches the exterior of the anterior pyramid. If cut on the right side, the animal turned to the right; and when cut on the left it turned to the left. Lastly, when the spinal marrow was separated from the brain by a section made behind the occipital bone, the influence of the will appeared to be entirely cut off from the movements; which, however, did not cease, but became very irregular in extent, rapidity, duration, direction, &c.\*

These experiments, as well as those of Roldo and of Flourens, are strongly in favour of the opinion, that individual parts of the brain answer individual purposes, so far, at least, as regards the power of regulating our movements. Such singular and anomalous instances of muscular action, therefore, as those we have related, may arise from causes which produce an excitement or oppression of certain parts of the encephalon, without affecting the other parts. Certainly in many, or most of the cases, marks of cerebral affection were observed. In M. Piedagnel's case, as we have already mentioned, several tubercles were found pressing upon the brain; in the immoveable horses, water was uniformly discovered in the ventricles; in the rabbit that died from the bite of the tarantula there were marks of inflammation, congestion, and effusion of serum on the brain. In the leaping ague, one of the first symptoms is pain in the head. Dr. Watt's case was preceded by excruciating headache and incessant vomiting; Mr. Kinder Wood's was attended with the same symptoms; and the patient whose case is referred to in the third volume of the Edinburgh Medical and Surgical Journal, had had a severe fall on the head some time previous to the convulsive affection. Although the existence, therefore, of partial pressure or other affections of the brain may not in all cases have been discovered, or even discoverable,—since, unless it arise from a permanent cause, it may be impossible to detect it after death,—yet it must be admitted that there are strong grounds for attributing these cases to such an origin, and for directing our remedial intentions accordingly. Whether the strange mental or monomaniacal symptoms which have sometimes accompanied the convulsive motions, may, as well as the latter, be attributed to an affection of certain individual parts of the brain, is more problematical. The disciples of Gall and Spurzheim, however, would doubtless advert with complacency in Mr. Wood's case to the prominent symptoms of excitement in the vicinity of their organs of *time* and *tune*, as confirmatory of their doctrines.

(*Andrew Crawford.*)

CLIMACTERIC DISEASE. See AGE.

CLIMATE. The general import of the word climate (from *κλίμα*, regio,) is sufficiently understood, although it is not easy to give an

accurate definition of it. In medicine the term is used to designate those habitual conditions of the atmosphere, in connection with the state of the surface, soil, exposure, &c. of particular countries, or districts, which are capable of influencing the health of persons inhabiting them.

The subject of climate may be treated under two distinct divisions, physical and medical. The consideration of the former, or physical climate, we must leave to the natural historian, as not coming properly within the scope of this work, although affording matter of the greatest interest to the medical philosopher. The latter, or medical climate, may also be considered under two separate heads,—as it affects the body either in causing or curing disease. The latter part of the subject, or the consideration of climate as an agent in the prevention and cure of disease, is that which we propose to treat in the present article; availing ourselves, however, of the physical characters of climate and the geography of disease, as far as a knowledge of these departments of the subject tends to illustrate the medical application of climate.

We shall first give a brief account of the climate of the principal places in our own Island, in the South of Europe, and in the Northern Atlantic, which have been most frequented by invalids; and endeavour, at the same time, to determine their respective characters and their relative merits. We shall then point out the diseases which are most decidedly benefited by change of climate, and the particular situations most suitable to each.

The influence of climate on the animal economy is now so well known and appreciated by the more observant part of the profession, that it would be waste of time, in a work of this nature, to enlarge upon the advantages which may be derived from a well-timed and judicious change of it in the treatment of disease. The removal, for example, from a cold, humid, and variable climate, to one which is warm, dry, and more equable, is well known to be productive of the most beneficial effects on a large class of invalids, when other therapeutical agents are of little avail; while, on the other hand, a contrary change is as certainly attended by a deterioration of the health, and often by the superintention of fatal diseases, even in persons previously in the enjoyment of good health.

If our limits permitted, it would not be difficult to account for many of the effects of climate, whether favourable to health, or the reverse. For instance, when we reflect on the powerful influence of a warm dry air on almost all the functions of the animal economy, but more especially its obvious agency in promoting an equable distribution of the circulating fluids over the whole system, and particularly its effect in augmenting the activity of the circulation in the capillaries of the surface, and in diminishing in the same proportion the congestion of the internal vessels, (a state which very generally obtains in chronic ailments,)—we have a satisfactory explanation of much of the benefit which invalids experience by a removal from a cold to a warm climate. If we take into ac-

\* Compendium of Physiology, p. 187 to 193—200 and 201.

count also the effect of the continual action of a bland atmosphere on the extensive surface of the respiratory organs, both as abating irritation of the lungs, and enabling them more effectually to produce those changes in the blood that are essential to health, we have another very obvious explanation of the results observed. And if to these we add the influence produced on the nervous system generally, on the external senses, and through them on the mind, and, reversely, the reaction of the mind on the bodily functions,—we need have little difficulty in accounting for the beneficial influence of the change of climate which we are now considering.

The contrary state of the functions and of the circulation, and the diminished energy of the nervous system induced by a change from a genial to a cold and humid climate, will with equal readiness account for most of the evil consequences so frequently observed under such circumstances.

Independently, however, of these effects, more directly attributable to climate, properly so called, there are many incidental circumstances attending a change of this kind, which have often no small share in improving the condition of the invalid. The hopes inspired by the measure itself, the influence of the journey or voyage, the change of scene, of occupation, and often also the escape from business and other sources of discomfort and care,—all claim a part in the benefit produced.

While all these circumstances will, therefore, have their due weight with the physician, when deciding upon such a change of climate as we are now contemplating, he must not omit, at the same time, to take into account the inconveniences, and even disadvantages, which in many cases are inseparable from the removal of the delicate invalid from his own home and country. These latter considerations will rise in importance in his mind according to the advanced state of his patient's disease, and consequently the diminished prospect of permanent advantage from the measure. So many circumstances of a conflicting nature often present themselves for our consideration in such cases, that it is only by a comprehensive and dispassionate view of all the bearings of the case, that we can come to a right decision, and then often not without difficulty. It is perhaps the rarer case, that we have merely to consider the nature of the patient's disease, and the probability of its being benefited or cured by any particular climate.

Among the numerous circumstances which require attention in recommending a change of climate, one of much importance is often entirely lost sight of, both by the physician and his patient:—we mean the necessity of perseverance in the regimen and mode of life which the peculiar nature of the disease demands. This must be urged upon the invalid as the condition on which alone he can expect to derive benefit from the prescribed measure.

We would press upon the minds of our professional brethren the importance of giving a full consideration to all the circumstances which

have been just noticed; as we are satisfied, from ample observation, that change of climate has not hitherto been productive of all the benefit which it is calculated to effect,—nay, that it has often done positive mischief, chiefly on account of the inconsiderate and injudicious manner in which it has too generally been prescribed and carried into effect.

We shall now proceed to give some account of the individual places in this and other countries which have been chiefly resorted to by invalids, on account of the mildness or other peculiarities of their climates.

ENGLISH CLIMATES.—The great desideratum in this country is to find a mild climate and sheltered residence for our pulmonary and other delicate invalids during the winter and spring; we shall therefore direct our attention principally to this point.

Our warmest winter residences in England are mostly found on the southern and south-western shores; indeed it is their vicinity to the sea which in a great degree renders them warmer than the inland parts in their respective vicinities.

The mild region of England admits of a natural division into four districts or groups, each having some peculiar features in its climate which characterise it and distinguish it from the others, both as regards its physical and medical qualities. These are—

1. The *south coast*, comprehending the tract of coast between Hastings and Portland Island, including the Isle of Wight;
2. the *south-west coast*, from the latter point to Cornwall;
3. the district of the *Land's End*; and
4. the *western group*, comprehending the places along the borders of the Bristol Channel and estuary of the Severn.

SOUTH COAST.—The superiority of the climate of this district exists chiefly during the months of December, January, and February. In March the temperature of this coast, and that of the interior, (e.g. the vicinity of London, which we select as a convenient point of comparison,) is nearly the same. In April and May, the temperature of the interior rises above that of the coast and continues higher, though in a less ratio, through the summer months. In October the mean temperatures are again equal, and in November that of the coast begins to exceed the interior. The only places on the south coast which we consider deserving of particular notice, are, Undercliff in the Isle of Wight, and Hastings and Brighton on the coast of Sussex.

*Undercliff* is decidedly the most sheltered and warmest of these places, and it has moreover this convenience over most of our other winter residences, that it also affords a good summer climate, a circumstance of considerable importance to many invalids. Unfortunately, at present, few can avail themselves of the advantages of this sheltered district, from the want of the necessary accommodations.

*Hastings* follows *Undercliff* in point of shelter and warmth during the winter and spring months. Its situation at the base of a range of steep hills, which protect it in a considerable

degree from the north and north-east winds, render it a milder and more sheltered residence during this season than the other parts of the coast of Sussex.

*Brighton* differs materially in the character of its climate from both these places. It is more exposed to northerly winds, but the atmosphere is drier and more bracing. While inferior to *Underliff* and *Hastings* as a residence in diseases of the respiratory organs accompanied with much irritation, it offers advantages over both to invalids of a relaxed and nervous habit who are not very excitable. Autumn is the season during which the climate of this place possesses the greatest advantages; and even to the end of December it is one of the mildest climates in our island, and most favourable for a large class of invalids; more especially for cases in which a relaxed state of the system is a leading feature.

Invalids who select the coast of Sussex as their winter residence, might find it advantageous to pass the autumn at *Brighton* and the winter at *Hastings*.

**SOUTH-WEST COAST.**—The winter climate of the south coast of Devon has long been noted for its mildness. The temperature of its more sheltered spots during the months of November, December, and January, (when the difference is greatest,) is, in the average, about five degrees higher than that of London during the same period; whereas, on the south coast, the difference scarcely exceeds two degrees. This superiority of temperature over London at both places, occurs chiefly during the night; though the days are proportionally warmer, and the temperature more steady on the south-west than on the south coast. In making this comparison, however, between these two districts, it is right to observe that *Underliff* is not taken into the account, for want of sufficient data.

Various places on the coast of Devonshire are held in repute on account of the beneficial effects of their climate, more especially in pulmonary diseases. The principal of these are *Torquay*, *Dawlish*, *Sidmouth*, and *Exmouth*. *Saleombe*, the *Montpellier* of *Huxham*, is unquestionably one of the warmest spots in our island during the winter; but it possesses few accommodations, and its sheltered climate is confined to too small a space to admit of its ever acquiring importance as a residence for invalids. Indeed, this limited character of the climate is the great defect of all the places on this coast, with the exception of *Torquay*. Here the invalid has the advantage of a considerable tract of sheltered country, some part or other of which will afford a protected ride or walk, in whatever direction the wind blows. *Torquay* is superior in this respect to every place in our island. Its position also on the southern declivity of a range of pretty steep hills, composed chiefly of calcareous rocks, renders it comparatively dry. Hence, while *Torquay* possesses all the advantages of the climate of this coast, its chief disadvantage (humidity) is felt in a less degree than elsewhere.

**LAND'S-END.**—The only place in this district deserving particular notice is *Penzance*,

which has long been frequented by invalids on account of the mildness of its winters. *Penzance* has a very peculiar climate, which depends on its almost peninsular situation at the south-western extremity of the island. A remarkable equality in the distribution of the temperature throughout the year, and throughout the day and night, is a striking character of this place. In this respect, indeed, the climate of *Penzance* is superior to that of the south of Europe, and the only climate which we have examined that excels it is that of *Madeira*. This peculiarity of the climate of *Penzance* will be shewn at once by comparing it with that of London, where the difference between the warmest and coldest months is 26°, while at *Penzance* it is only 18°. In winter, *Penzance* is, on an average, nearly six degrees and a half warmer than London during the night, and but little more than three degrees during the day.

In other respects the climate of the *Land's-End* does not stand so high in a medical point of view. It is very humid; the quantity of rain which falls annually at *Penzance* being nearly double that which falls in London, and the number of rainy days much greater. This district is also proverbial for the frequency and violence of its gales; and *Penzance*, owing to its total want of shelter from the northerly and easterly winds, is colder during the spring than either *Torquay* or *Underliff*. Hence it is, that although *Penzance* possesses a decided superiority over all the other situations in our island in the mildness and equality of its winter climate, its humidity, exposed situation, and liability to winds, render it inferior to several other places as a residence for invalids.

In giving the above as the character of the climate of the *Land's-End*, we are fully borne out by the experience of *Dr. Forbes* of *Chichester*, who resided there for some years, and to whose excellent *Medical Topography* of this district we are chiefly indebted for our information respecting its climate, and the influence of this on disease.

*Flushing*, a small village in the vicinity of *Falmouth*, is the only other place in this district deserving notice. The position of *Flushing* differs from that of *Penzance* only in being somewhat protected from the north and east winds by a low range of hills which rises immediately behind it. But the place is extremely confined, and deficient in accommodations for invalids.

Before quitting the south-west coast and *Land's-End*, it is proper to remark, that, though varying somewhat in degree at different places, the predominant character of the climate is that of softness and humidity: on the system generally, it has a soothing but relaxing influence.

From this character of the climate of the whole south-western coast of our island, it will be at once understood that it is most suitable for the irritable and inflammatory habit, and least so for the relaxed nervous constitution; that in the dry, irritated conditions of the mucous membranes, with a parched state of the skin, it will prove beneficial; while in the mor-

bid states of the same membranes, accompanied with copious secretion, or when there exists a disposition to profuse discharges of any kind, it will prove injurious. Even many of those cases which are benefited by a temporary sojourn, would be injured by a permanent residence in this district. The climate, indeed, possesses qualities of so marked a kind, that when it ceases to do good, it generally begins to do harm; hence it will seldom be prudent, much less advantageous, for the invalid who has passed the winter and spring on this coast, to prolong his residence through the summer; he will in general do well to betake himself to a drier and more bracing air, especially if he intends to return the succeeding winter.

Unless the circumstances which we have just pointed out respecting the character and effects of this climate, and the nature of the constitution and diseases of the invalid are kept in view, little benefit will be derived from a residence in Devonshire.

WEST OF ENGLAND. — *Clifton*, the only place in the western district which we deem it necessary to notice, has several local advantages, and possesses the best climate in the part of the country where it is situated. Compared with that of the south-west coast, it is more exciting, more bracing, and drier, but not so mild. It is therefore less suited for pulmonary and other diseases, accompanied with much irritation, and with a tendency to inflammation. On the other hand, it is better adapted to invalids of a relaxed, languid habit; and is also very beneficial in many cases of dyspepsia, in affections of the mucous membranes with much secretion, and in the serofulous affections of young persons.

In making a selection among these, which we consider the best winter climates in our island, in any particular case, we must consider well the character of the patient's disease and the nature of his constitution, before we venture to decide upon the situation best suited to him. But by attention to these points, and to the qualities of the different climates, which we have endeavoured to state as clearly as the nature of the subject and the extent of our knowledge would admit, the medical practitioner will not err greatly. In order, however, to illustrate the subject further, we shall add a few more particular observations on the practical application of English climates to disease.

The climate of the south coasts of Devon and Cornwall will be found very efficacious in soothing an irritated and irritable state of the respiratory organs, and of the mucous surfaces generally; as in chronic inflammation of the fauces, and of the laryngeal, tracheal, and bronchial membrane, of a dry irritable character, or at least accompanied with little secretion, and highly susceptible of increased irritation from sharp, dry winds. In dyspepsia depending chiefly on an inflammatory condition of the mucous membrane of the digestive organs; in disorders of the uterine system, arising from a similar condition of the parts, giving rise to dysmenorrhœa; also in the numerous nervous affections originating in the disorders of these

two influential classes of organs, this climate may be confidently recommended, and will generally be found beneficial. To these may be added cutaneous diseases of a dry, irritable character. On the other hand, in disorders of the same organs and parts attended with passive congestion, or very copious secretion; in dyspepsia from an atonic state of the stomach, and in disorder of the uterine system, accompanied with an excessive flow of the catamenia, or leucorrhœa; and, in short, in all diseases attended with a relaxed state of the system generally, benefit is not to be expected from the climate of the south-west coast; more especially if the invalid prolongs his residence beyond a few months. The climate of Clifton, as has been already remarked, will prove more favourable in the cases last referred to. Brighton also presents an excellent autumnal climate for such invalids, and to persons of little constitutional sensibility offers a good residence throughout the winter, provided the more sheltered situations be selected. Hastings is a residence better adapted to invalids suffering from pulmonary irritation. During the spring months, that is, after March, any dry sheltered situation in the milder districts of the interior we believe to be superior to the south-coast, with the exception of Undercliff.

After this survey of the best winter climates in England, it may be expected that we should take some notice of our more salubrious summer residences. On this subject, however, it is not necessary to go into detail, as there is no lack of healthy situations to which our invalids may repair with advantage during this season. In the selection of a summer, as of a winter residence, the same circumstances require attention, both as regards the character of the climate and the nature of the invalid's disease. The milder and more sheltered situations must be chosen, even during this season, for delicate and very sensitive invalids; while for the relaxed and enervated, and those possessing less sensibility, the bracing air of the higher and drier localities will prove more suitable. To a large class of invalids our sea-side watering places offer a variety of excellent situations; and for those cases in which sea-bathing promises benefit, they deserve a preference over the interior, especially during the latter part of the summer and autumn. Several of our inland watering places, independently of the advantages to be obtained in many cases from the use of their mineral waters, afford good summer climates; and, indeed, some of them, more on this account than any other, have become places of fashionable resort. Among these we may mention Malvern, Cheltenham, Leamington, Tunbridge Wells, Matlock, Buxton, &c. When the intention is to use the mineral water, the climate must of course be made subservient to this object; but when a choice of waters is admissible, it is of importance to many invalids that the climate selected also be suitable to them. In general it will be advantageous to invalids who have taken a course of mineral waters at any of those places, to pass the autumn by the sea side, as

at some of the driest places on the south, or south-east coast. In the greater number of cases in which travelling is borne without inconvenience, several changes, or a succession of short journeys, will be more beneficial than a residence at any one place during the whole season. It is remarkable how such repeated changes, with frequent gentle exercise, especially on horseback, renovate the constitution enfeebled by disease, enable it to overcome many chronic affections, and contribute to the restoration of permanent health. But we shall have occasion to recur to this subject.

Before commencing our review of foreign climates, the islands of *Guernsey* and *Jersey* require some notice, as they are occasionally resorted to by invalids from this country. The climate of these islands resembles in its general characters that of the coast of Devonshire; it is somewhat warmer but not more steady, and is more exposed to high winds. Those from the south-west prevail during the autumn and winter, while those from the north-east often continue for weeks together during the spring, producing the same unpleasant effects on invalids which arise from them in this country. The climate is found by experience to be beneficial in the same diseases, and in constitutions of a similar character, as that of our south-west coast; the observations therefore formerly made relative to the class of invalids that may expect to derive advantage from the latter, apply equally to persons who may be sent to Jersey, which, of the two islands, is in all respects the best suited for invalids. The summer climate of these islands is delightful.

FOREIGN CLIMATES.—The climate of the *South of France* has long been held in repute, but all the southern provinces of that country are far from possessing the same climate; those situated on the eastern frontier being very different in this respect from those on the western. It is highly important, as we shall presently shew, to attend to this distinction in recommending the south of France as a place of residence for invalids.

SOUTH-WEST OF FRANCE.—We comprehend under this division the tract of country which extends from Bourdeaux and Bayonne to Toulouse.

The transition from the climate of the southwestern shores of our own island to that of the south-west of France is easy and natural, inasmuch as they exhibit a striking similarity in their general characters. Taking the south-west of France generally, the mean annual temperature is only about 4° higher than that of the south-west of England. Both climates are soft and rather humid, and agree and disagree, generally speaking, with diseases of the same character.

*Pau* is the only place in this district of France which we deem it necessary to notice particularly. This little town, which has been a good deal frequented of late years by invalids from this country, is pleasantly situated at the base of the Pyrenees; and when its close vicinity to that range of lofty mountains is consi-

dered, it certainly possesses a far milder winter and spring climate, and is much less subject to high winds and extensive transitions of temperature, than might be expected. One remarkable circumstance in the character of its climate is the mildness of the spring, and its comparative exemption from sharp cold winds during that season. In this respect it bears a very favourable comparison with the climates of the south of Italy. While *Pau* is 6° colder than *Rome* during the winter, it is only 2½° colder in the spring. Compared with the warmest parts of England, the same superiority of its spring climate holds good. *Penzance* during the winter months is 3° higher than *Pau*, but 5° lower in the spring. This mild character of the spring constitutes the great advantage of the climate. *Pau* is also very free from fogs, and possesses a dry soil. Its chief fault is the unsteadiness of its temperature. It may however be considered, upon the whole, the most favourable residence for invalids in the south-west of France, as far as we have had the means of judging. The difference between the climate of *Pau* and that of the best situations in England is not great. It is drier and warmer in the spring, and the northerly winds are much less trying to invalids than in this country. One advantage possessed by it is its vicinity to the delightful watering places among the higher Pyrenees, which offer to the invalid who has passed the winter at *Pau* a healthy summer climate without the inconvenience of a long journey.

SOUTH-EAST OF FRANCE.—Under this division we include that extensive tract of country which stretches along the shores of the Mediterranean, from Montpellier to the banks of the Var, the boundary stream between France and Piedmont. The climate of this district is warmer and drier, but more irritating and exciting than that of the south-west. It is also subject to sudden vicissitudes of temperature, and to frequent harsh, cold winds. This great liability to cold piercing winds, more especially the north-west, (*mistral*), which often continues to blow with considerable force for many days together, renders the whole of this country an improper residence for patients suffering under, or peculiarly disposed to inflammation or irritation of the respiratory organs. We consider the custom, therefore, which has long prevailed, of sending consumptive patients to the south of France, a grievous error; an error which the obvious character of the climate, and the result of ample experience of its effects, should have long since corrected. There may be constitutions having a tendency to tuberculous disease, which might even derive some benefit from a temporary residence in this climate; but when tubercles already exist in the lungs, it will certainly prove injurious.

After this account of the climate and its effects on phthisical patients, (the cases which have been chiefly sent thither,) it will be unnecessary to say much of the different places in this district which have been most frequented by invalids. We shall, however, notice the principal of these briefly.

*Montpellier*.—This place has now so completely lost the character which it once possessed as a mild climate, that it may suffice to remark here, that a more improper residence could scarcely be selected for a person disposed to pulmonary disease. Its high, exposed situation renders it liable to all the evils of this climate in a remarkable degree; and it is, moreover, well ascertained that pulmonary inflammation and phthisis are among the most prevailing diseases of the place.

*Marseilles*.—Although less exposed than Montpellier, this is an equally improper residence for consumptive invalids. From the manner in which the environs of Marseilles are divided into small properties, surrounded with high walls, the invalid has no means of taking proper exercise, or of breathing country air; and without these, consumptive invalids can derive little advantage from any climate. For cases likely to benefit by a dry sharp air, Marseilles forms a good winter residence. It is said to prove particularly favourable to persons who have suffered from intermittent fever.

*Hyères* possesses the mildest climate in the whole of this district, and this advantage it owes chiefly to its sheltered situation at the base of a range of hills which protect it, in a considerable degree, from northerly winds. The country also around this little town differs in its character from that of Provence generally, (which comprehends the larger portion of the district now under consideration.) The hills here present the appearance of verdure, being covered with shrubs, many of them evergreens, affording a pleasing contrast to the bare and rugged mountain masses which form so striking a feature, and compose so large a portion of Provence; a country which very generally disappoints the expectations of the traveller, and especially of the invalid, whose hopes have been raised high respecting the beauty of the South of France. The extensive orange gardens which flourish under the immediate shelter of Hyères, and the verdure of its hills, afford evident proofs of the amenity of its climate, while by experience it is known to be one of the most favourable residences for invalids in this part of France,—certainly the best with which we are acquainted.

*NICE*.—This place has long been celebrated for the mildness of its climate, and continues to form the favourite resort of a numerous class of invalids, both from this and other northern countries. Although situated in the same line of coast as Provence, Nice is superior to it in several respects. In the general qualities of its climate it certainly resembles that of the south-east of France; but it has some important local advantages over the best parts of that country. By its steep and lofty range of mountains it is protected from the northerly winds, and especially from the mistral, which we have stated to be so prevalent, and which experience proves to be so injurious to delicate invalids, in Provence. This circumstance gives a comparative degree of softness to the climate; but it is still rather exciting. Nice

is not exempt from cold winds, especially during the spring; indeed, the prevalence of these constitutes one of the principal objections to the climate of this place in pulmonary diseases generally. For consumption, even in its earlier stages, we consider Nice an unfavourable situation, in a very large proportion of cases. In bronchial diseases of the dry irritable character, it is also prejudicial; and in dyspepsia, depending on an irritated or inflammatory condition of the mucous membrane of the stomach, it is equally so. So decidedly, indeed, is this the case, that when such a state of the digestive organs exists, the invalid will derive little benefit from a residence at Nice, whatever may be his disease. Though warm and dry, the climate is ill suited to irritable habits. With languid, torpid constitutions, on the other hand, it agrees well. In the scrofulous affections of young persons possessing this character of constitution, it produces the best effects; as it does in chronic bronchial disease accompanied with copious expectoration, and in what has been termed humoral asthma. In chronic rheumatism it is found very beneficial; and in deranged health from various causes, in which a dry, warm, and rather exciting climate is indicated, advantage will be derived from a winter spent at Nice; provided always that the state of the digestive organs which we have adverted to does not exist. In consequence of the tendency of the climate to aggravate and even excite gastric irritation, a more abstemious diet is requisite for invalids than in England. The summer at Nice is too hot for any class of invalids.

*ITALY*.—The climate of the south of Italy differs little in actual temperature from that of Provence and Nice, but it is softer, more humid, and less exciting. On the other hand the sirocco, which is scarcely felt at the latter places, forms an objection to the Italian climate, though this objection is not of much weight during the winter.

The only places which we consider deserving of notice as winter climates in Italy, are *Pisa*, *Rome*, and *Naples*.

The climates of Pisa and Rome resemble each other in their general qualities. Rome is somewhat warmer in the winter. It is also drier than Pisa, though more humid than Nice and the parching climate of Provence. About one-third more rain falls at Rome than in the latter country, and the number of rainy days is considerably greater. Taking into account all the qualities of the climate of Rome, we consider it one of the best of Italy: to the invalid capable of taking exercise in the open air, it affords advantages over both Naples and Pisa. Patients, on the other hand, who can bear little exposure to the air, and who must therefore confine themselves to the most sheltered situations, will find in the Lang'Arno in Pisa a residence possessing advantages, perhaps, over every other place in Italy.

Naples differs somewhat in the character of its climate from both the last named places.

Independently of the effect which its immediate vicinity to the sea may have in modifying the climate, it is more subject to winds, and the air is more exciting than that of Pisa or Rome. As a residence for invalids labouring under pulmonary irritation, or chronic rheumatism, it is inferior to both; nor are we aware of any cases in which it ought to be considered a more favourable climate. The beauty of the scenery around Naples, however, and the gaiety and excitement of the place and climate altogether, prove very attractive to strangers generally, and render it a very agreeable winter residence for persons who visit Italy rather as a recreation than for the removal of actual disease.

The diseases in which the climate of Italy proves most beneficial, are chronic bronchitis and rheumatism. We have, in particular, observed many decided examples of the beneficial effects of a residence at Rome in both these diseases. But it is still more in the numerous cases of deranged health which scarcely admit of being defined, though well known to the medical practitioner, that a tour and winter spent in Italy will prove beneficial. Such persons need not be limited to any particular situation, but may, with proper caution, visit the different places frequented by strangers in the south of Italy, and that even with greater advantage to their health than if they had remained stationary at any one of them.

These observations have reference to the climate of Italy during the winter and spring, that is, from October till May or June. To such as are under the necessity of remaining in that country through the summer, the baths of Lucca, Sienna, and the vicinity of Naples afford the coolest residences.

There may be several situations on the shores of the Mediterranean which have climates equal, and perhaps superior, to those which have been mentioned. Malaga has been particularly mentioned to us as possessing a very mild winter climate; but our information respecting the south of Spain is too imperfect to enable us to speak positively on this subject. And even were the climate of that country superior to that of the south of Italy, the want of proper accommodations and the various comforts which are as necessary to the invalid as climate, forms an insuperable objection to them as places of residence for delicate English invalids.

The MEDITERRANEAN ISLANDS do not merit much notice. Some parts of the coast of Sicily afford a pretty good winter climate; but here again the difficulty of obtaining the necessary comforts, and even conveniences of life, renders them almost useless to English invalids.

This objection, however, cannot be made to *Malta*, the only island in the Mediterranean belonging to this country. All the wants of the invalid may be supplied here, and the packets which are established between this place and England afford the means of

reaching it conveniently. But, unfortunately, the climate of Malta has little to recommend it to any class of invalids, and least of all to such as suffer from pulmonary affections. The arid nature of the soil, the quantity of impalpable dust which is suspended in the atmosphere whenever the weather is dry, the currents of cold air to which the capital (the residence of invalids) is subject during the winter, and the frequent and heavy rains which prevail during the same season, render it an unsuitable residence for patients of this class. It may not be irrelevant to mention also that phthisis carries off a large proportion of the inhabitants of Malta, constituting nearly one-tenth of the whole mortality, according to Dr. Hennen. Indeed, the full and satisfactory information respecting the medical topography of Malta, supplied by this gentleman, affords more than sufficient grounds for excluding it from the list of climates which promise any advantage to phthisical patients. We are not, indeed, aware of any class of invalids likely to derive much advantage from the winter climate of Malta, and we are not acquainted with any to whom its summer climate would not prove injurious.\*

ATLANTIC CLIMATE.—The climate of the Northern Atlantic in the temperate latitudes is more steady than that of the Mediterranean, and imparts a similar character to the climate of its islands. Various groups of islands scattered over this ocean, between the 28th and 38th degrees of latitude, having been praised for the excellence of their climate, and occasionally frequented by invalids in consequence, deserve some notice in this place. The Azores, the Madeiras, and the Canary Islands in the Eastern, and the Bermudas and the Bahamas in the Western Atlantic, have all been recommended as suitable residences for persons requiring a mild and equable climate, and more especially for consumptive invalids.

As our information respecting the climate of Madeira is the most complete, we shall notice it first, with the view of making it a standard of comparison in estimating that of the other islands.

MADEIRA.—The minute and careful observations of the late Dr. Heineken and of Dr. Renton, for a series of years, have afforded us sufficient data to form an accurate estimate of the climate of this island; and although our materials for enabling us to judge of the other Atlantic islands are much less complete, they leave little doubt in our minds that Madeira is superior to any of them; while it affords conveniences in other respects as a residence for invalids possessed by none of them. The height of the central ridge of mountains which compose the greater part of this island, although it may detract somewhat from its warmth during the winter, contributes

\* We refer those who desire to examine the facts upon which the above character of the climate of Malta rests, to Dr. Hennen's *Sketches of the Medical Topography of the Mediterranean, &c.*

greatly to temper the heat of its summer. It gives Madeira the advantage of a cool land-breeze during the night, which, alternating with a refreshing sea-breeze in the day, moderates the summer heat in a very material degree; while the trade-winds which prevail at this season in the latitude of Madeira, contribute also to its coolness and salubrity. The invalid, moreover, by choosing for his summer residence an elevated situation in the interior, finds a climate considerably cooler than that of Funchal, which is situated on the sea-shore and affords the best winter residence.

Comparing Madeira with the south-east of France and Italy, we find that, although its mean annual temperature is only about six degrees higher than that of these places, this temperature is very differently distributed throughout the year, the range being far less at Madeira than in the most favoured spots in the south of Europe. Thus, while the winter is twelve degrees warmer than in Italy and France, the summer is five degrees cooler; and while the mean annual range at Madeira is only fourteen degrees, it is nearly double this at Pisa, Rome, Naples, and Nice. In the equable distribution of heat throughout the year, it possesses a similar superiority over the same places; for example, while the mean difference of temperature of successive months at Madeira is only two degrees, at Rome and Nice it is four, and at Pisa and Naples five degrees.

In the progression of temperature during the day, it maintains the same superiority; the mean range for twenty-four hours being ten degrees by the *register* thermometer, while at Nice it is nine degrees, at Rome ten degrees, and at Naples thirteen degrees, by the *common* thermometer. In steadiness of temperature from day to day, (a very important quality in a climate,) Madeira excels all those places greatly. There is also a considerable difference in respect to the dryness of the two climates. Nearly the same quantity of rain falls at Madeira as at Rome; but there are only seventy-three days on which any rain falls, while at Rome there are one hundred and seventeen days. The rain at Madeira also falls at more regular seasons, chiefly in the autumn, the atmosphere being generally dry and clear for the remainder of the year.

The annual range of atmospheric pressure is very small, which is the case also at Rome and Naples.

From this comparison, the superiority of the climate of Madeira over that of the south of Europe will be at once seen. We shall have occasion hereafter to notice their comparative influence on disease.

CANARY ISLANDS.—These rank next to Madeira in point of climate. They are somewhat warmer; the mean annual temperature of Funchal, the capital of Madeira, being 65°, while that of Santa Cruz, the capital of Teneriffe, is nearly 71°. This excess of temperature, however, is not equally distributed over the whole year, the difference between the

winter temperatures at these two places being considerably less than between their summer temperatures; while Santa Cruz is 7° warmer than Funchal in summer, it is only 5° warmer in winter. The temperature is also more equable throughout the year at Madeira than at Teneriffe; the difference between the mean temperature of summer and winter being 9° at the former place, while it is 12° at the latter. The want of sufficient materials prevents us from comparing the climate of Teneriffe more minutely with that of Madeira. It seems probable, however, that when we are better acquainted with the climate and topography of Teneriffe, we may find it a favourable winter residence. But whatever may be the merits of its climate, it is at present very deficient in the other requisites necessary to render it a suitable abode for delicate invalids.

THE AZORES, OR WESTERN ISLANDS, as they are sometimes called, lie about 5° north of Madeira, and considerably more to the westward. In their external characters these islands resemble Madeira and the Canaries. We have not had the means of making ourselves sufficiently acquainted with the temperature of the Azores to speak very positively on the subject. The climate appears to be mild but somewhat humid; less warm than Madeira during the winter, and more oppressive during the summer. They certainly possess no advantages in point of climate over Madeira, while they afford few of the conveniences which that island offers to invalids.

BERMUDAS.—This numerous cluster of small islands is in the same latitude as Madeira, and differs little from it in the mildness of its winter climate. From the stormy character of the Western Atlantic, however, these islands are much more liable to high winds in the winter than Madeira, while their low character and arid rocky soil render them extremely hot during the summer, and quite improper at this season for the residence of such invalids as are likely to be sent from this country.

BAHAMAS.—This is another and much more extensive group of low islands, further south than any of those which have been mentioned, being only just beyond the limit of the tropics. The climate of the Bahamas has not much to recommend it. The winter and spring are considerably cooler than the same seasons in the West Indies, while the temperature of the summer and autumn is nearly the same as in those islands. During the winter the temperature is subject to rapid and considerable vicissitudes, and cold, harsh, northerly winds are not unfrequent. The close vicinity of the Bahamas to the North American continent no doubt has the effect of rendering the climate less equable than it otherwise would be, judging from what we know of insular climates generally in the same latitudes.

We may safely dismiss these two western groups with this brief notice; as from the character of their climates, their great distance from England, and the few local advantages which they possess, they are never likely to prove

beneficial as a residence for invalids from this country. They are better suited, in point of climate, and more conveniently situated, particularly the Bahamas, as a temporary retreat for the inhabitants of the islands which we are now to notice.

WEST INDIES.—Although these islands are not often resorted to by real invalids, yet there seems to exist, even among the profession, a vague idea that they afford a preferable climate to that of any of the places which we have noticed. That this opinion has been formed from an imperfect knowledge of the nature and effects of a tropical climate, we shall endeavour to shew.

The mean annual temperature of the West-India Islands, near the level of the sea, is about 80°, and during the six months which include the winter season the temperature is only 2° lower. Now it will be readily admitted that few invalids are likely to be benefited by so high a temperature, more particularly when continued, almost without sensible variation, night and day. The extreme annual range in the West Indies does not exceed 20°, while the mean daily range throughout the year is only 6°. But it is not so much the actual degree of temperature of a tropical climate, as its unceasing and unvarying character, which oppresses and exhausts the invalid, more especially in cases where there exists a disposition to symptomatic fever.

From this brief account of the climate of the West Indies, it is evidently an improper one, generally speaking, for consumptive invalids, who, nevertheless, are frequently sent thither. The uniformly high temperature, and almost cloudless skies, which afford no shelter from the direct rays of a tropical sun, preclude invalids from taking exercise in the open air, the principal object for which they are generally sent abroad. There is no twilight to compensate for the heat and glare of the day, and the nights are too hot to admit of refreshing repose. When we add to the foregoing evils of climate the many privations, discomforts, and annoyances which are almost inseparable from a temporary residence in these islands, and the still more weighty objection derived from the experience of medical men who have resided there, we may consider the question of the propriety of sending patients labouring under consumption to the West Indies as finally set at rest. The concurrent testimony of all the medical men whom we have consulted on the subject, and whose opportunities of judging were ample, establishes the fact that consumptive cases sent thither from this country proceed much more rapidly to a fatal termination than in temperate climates.

Notwithstanding what has just been stated respecting the climate of the West Indies and its influence on consumption, we are not prepared to say that some, nay, many cases of deranged health, of a different nature, might not be benefited by passing a few of the less sultry months (from November to February) in that climate; more especially if the invalid

possessed the means of enabling him to spend the greater part of his time on the water, merely visiting some of the more healthy islands occasionally. The remarkable revolution effected in the distribution of the circulating fluids, and the immense increase in the secretion from the cutaneous exhalents, excited and steadily maintained by a high atmospheric temperature, and this continued without intermission for many months, or even years, is unquestionably capable of producing material and very important changes in the animal economy, and may therefore be made a powerful agent in the cure of chronic diseases.

Calculous disorders are extremely rare in the West Indies, a circumstance which probably depends, in a great degree, on the abundance of the cutaneous secretion, by which the largest proportion of fluid is discharged from the system, and along with it some of those saline principles which constitute the chief ingredients of which urinary calculi are composed. A well known case has been recorded of an officer who was about to undergo the operation of lithotomy in this country: he was suddenly ordered to Jamaica, and after some time no calculus could be discovered in the bladder, nor were there any symptoms of the existence of one. Aneurisms and diseases of the heart and large vessels are also rare, and the osseous deposits, which are so generally found in the coats of the larger arteries in persons who die at an advanced age in cold climates, are said to be rarely met with in those who die at a similar age in the West Indies. Gout is not common, and rheumatism neither frequent nor severe.

Reasoning on the above facts, we should expect that the climate of the West Indies would prove serviceable to persons labouring under what has been denominated the calculous diathesis, in which there is a constant disposition to renal irritation, and the formation of gravel, upon any material change of the weather, or any trifling derangement of the digestive organs. The functions of the skin in such persons are generally imperfectly performed, and it is not unreasonable to believe that the powerful action excited, and unremittingly kept up for some months, in the cutaneous exhalents might effect a permanent change in the constitution, and if followed up by warm clothing, daily friction, and a proper diet, might entirely destroy the disposition to the formation of gravel. Upon the same principle this climate also promises benefit to persons in whom we have either positive, or strong presumptive evidence that ossific deposits are forming in the arterial system, and laying the foundation of aneurism or diseased heart. Reflecting on the powerful effect of a high temperature on the various secretions, we think it not improbable that the further progress of such a morbid process might be checked by a timely removal to the West Indies, or any similar climate, and a residence for a longer or shorter period there, according to the circumstances of the case.

What has been already stated respecting the rare occurrence of calculous disorders and diseases of the arteries in this climate, affords some grounds for such a conjecture; and it may be adduced in further support of it, that *gout*, a disease intimately related in its nature and causes to both the preceding affections, is greatly relieved, and even entirely cured in many cases, by a change from a cold to a hot climate. This effect of climate has long been known. Van Swieten mentions the case of a gentleman who had almost entirely lost the use of his hands and feet from gout, and who, after a residence of nearly three years in the East Indies, returned perfectly free from disease, and continued so; and Haller relates the case of Lord de Poincey, who, when an old man, went to the warm American islands, and got rid of his gout and other infirmities. And such instances must have come under the observation of almost every physician.

Scrofula is a very rare disease in the West-India islands, and there are many cases of scrofula in this country which we have little doubt would be greatly benefited, if not cured, by a temporary residence in that climate. The cases in which we should expect the greatest benefit are those in which the disease exists chiefly in the lymphatic glands in torpid constitutions.

We have now noticed the principal climates, both in our own and foreign countries, which have acquired the greatest reputation as places of residence for invalids, and regarding which our information is sufficiently accurate to enable us to speak with much certainty. From a residence at one or other of these places, or at several of them in succession, all that climate can effect may, we believe, be obtained by the invalid whose disease admits of benefit from a change of this kind; provided always that the climate which is best suited to his disease and constitution be selected. In making this selection we must, in the present state of our knowledge, be guided chiefly by experience; for although an acquaintance with the physical characters of a climate is highly useful in enabling us to form a tolerably correct opinion respecting the diseases in which it will prove beneficial; still, until we have had some experience of its effects, we can never be sure that our conclusions are correct; so complex is the subject of climate, and so many are the circumstances, some having reference to the agent and others to the subject, which require to be taken into account.

We shall now state briefly the effects of climate on those diseases on which it has been found to exert the greatest influence.

*Pulmonary consumption* is the disease in which, from its supposed dependence on climate, and its being found to resist all other modes of treatment, this remedy has been more particularly had recourse to, and almost as the only remaining hope. This is not the place to enter into a full detail of the circumstances under which climate promises benefit in that disease. (See the article PULMONARY CONSUMPTION.) We may, however, remark here, that climate, to

be productive of real benefit, must be tried at a much earlier period in the progress of tubercular disease than it generally is. Such is the insidious manner in which consumption, in many cases, steals upon its victims, that it has too often stamped its indelible impression on the vital organs ere the alarm is sounded, or climate or any other effectual means of treatment, have been seriously thought of. Before we can reasonably hope to cure phthisis, we must take a much more comprehensive view of the pathology of that disease than we have hitherto done: in place of fixing our attention solely on the diseased state of the lungs, we must direct it to the morbid condition of the system, —to the tubercular cachexia in which phthisis has its origin. As regards the application of climate to the disease, it is not, we believe, saying too much, when we state that consumptive patients are, for the most part, sent abroad one year at least, often several years, too late to derive any essential benefit from change of climate.

During that peculiar state of deranged health which may often be observed to precede tubercular cachexia,\* and during the existence of this morbid state of the constitution, before the disease has manifested itself in the actual development of tubercles in the lungs, change of climate forms a powerful adjunct to the other means best calculated for removing such a state of the system. When tubercles already exist in the lungs, the chances of cure are immeasurably lessened; but even then climate affords one of our most valuable resources, and one which promotes the salutary action of all our other remedies; and although our hopes of benefit under such a discouraging state of things must in general be faint, we believe the further progress of the disease may, in some cases, be thereby arrested. But such instances of success are no doubt very few, compared to the many which proceed unchecked in their course to a fatal termination, in despite of climate and every other means which we can oppose to their progress. We would therefore beg to impress upon the minds of our professional brethren the urgent necessity of directing their attention to the earliest indications of this disease, seeing how utterly inefficient all our efforts are even to stay its fatal career, when so far advanced as to manifest itself to the common observer. Until the tubercular affection of the lungs, which constitutes the essential character of what is commonly termed phthisis, is considered in its true character, as the last stage of a disease,—as the result of a morbid state of the system, which in its progress might often be cured, but which in this its termination is scarcely to be remedied,—we must still continue as heretofore, little better than idle spectators of the ravages of a disease which destroys one-fourth of our population, and numbers among its victims a large proportion of the best and fairest of our youth.

In proof of the correctness of our opinions

\* For an account of this affection see a work by the writer of this article, entitled "*The Influence of Climate*," &c. p. 315, &c. Second Edition. Lond. 1830.

respecting the influence of climate on phthisis in its early and late stages, we shall give the experience of Dr. Renton, an intelligent and observing physician, who has long practised at Madeira, and has had ample opportunities of watching the effects of that climate on phthisical invalids sent thither from this country.

This gentleman has favoured us with notes of the cases which came under his own particular observation. From these we find that between the years 1827 and 1830, *nineteen* patients labouring under confirmed phthisis arrived in Madeira, the whole of whom died; the greater number on the island, the remainder after returning to England. Of *thirty-three* cases of incipient phthisis, which arrived during the same period, *twenty-three* are now at home, (June, 1830,) apparently in good health; two remain in the island, one apparently well, the other considerably better since his arrival, but still in a doubtful state; two died, one in the island, and another after leaving it: the fate of the remaining six is not known. We consider this statement as a satisfactory reply to those who doubt and cavil respecting the influence of climate; their opinions being formed in general from a few cases sent abroad at a period of the disease when no hope of benefit could be reasonably entertained. It is only by such numerical records as the above, that we can expect to arrive at accurate conclusions respecting the influence of any means of cure in a disease, which will prove fatal in a very large proportion of cases, under any circumstances. The result in the first series of cases is nothing more than every one would expect who is acquainted with the nature of phthisis, and knows the state of the lungs in what generally passes under the name of confirmed consumption. But while Dr. Renton's experience of the effects of the climate of Madeira shews the inutility of change of climate in the advanced period of phthisis, it holds out considerable hopes from the adoption of this measure in its early stages: of *thirty-three* cases of incipient consumption, *twenty-four* were apparently cured. Such a ratio of success, we have reason to believe, has never before been observed among consumptive invalids sent to Madeira, and for this plain reason—that they were rarely sent till the disease was too far advanced to admit of recovery. Dr. Renton remarks in his communication to us, "With respect to the invalids sent out, they have been very different for the last two or three years from those sent out formerly." We have the satisfaction of thinking that we have contributed, in some degree, to this favourable result, by our appeal to British physicians in the work already referred to; and we shall be happy to find that the striking proof of the truth of our former remarks, now recorded, induces our professional brethren to pay still more attention to this subject.

Of the Atlantic Islands, Madeira; in Italy, Rome and Pisa; and in England, Torquay and Undercliff, afford the best climates for consumptive cases.

In stating these places to be the most favourable residences, we beg to be understood as referring to the winter chiefly. Italy, during the summer, is decidedly injurious to the phthisical invalid; and those who have passed the winter in the milder climates of England should in general seek a more bracing air in summer, such as that of Malvern, or even some of the more elevated and drier districts of our island; or, what would be still better, they might in the course of this season change from one place to another, taking care always that no place was visited possessing a climate decidedly hostile to their particular state of health. Such frequent changes of residence, when judiciously conducted, and combined with exercise on horseback, and a regimen suited to the particular state of the patient, are among the most effectual means which we possess for preventing consumption in persons predisposed to it, more especially in early life.

*Chronic bronchitis.*—The morbid conditions of the mucous lining of the larynx, trachea, and bronchi are greatly influenced by climate, and the change from a cold and moist to a mild and dry air seldom fails to relieve, and occasionally removes them. The situations which have been mentioned as most favourable in phthisis are best suited also to bronchial diseases generally. Of the continental climates, those of Rome and Pisa are the most beneficial in cases attended with an irritable state of the affected parts without much secretion; and that of Nice in cases attended with less sensibility, a more copious expectoration, and a relaxed state of the system generally. Madeira, as far as our experience goes, has proved more beneficial in the former class of cases than in the latter. In England, Torquay and Undercliff afford the best climates in the first class of cases, and Chifton in the latter, in which Brighton also is a very favourable residence during the autumn.

*Asthma* is often greatly relieved and occasionally ceases under the influence of a mild climate, more especially when complicated with disease of the bronchial membrane, as it almost always is when of some duration. In what has been termed humoral asthma, Nice is the best residence; but Rome is preferable when this disease is accompanied with an irritated state of the digestive organs, a complication which is exceedingly common.

*Chronic rheumatism.*—Climate produces the most decidedly beneficial effects in this disease, and that often with surprising rapidity, even in cases of long standing, which have resisted the best directed medical treatment. We would particularize Rome and Nice as the best residences for invalids suffering from this complaint. The preference to be accorded to the one or the other place will depend upon the character of the patient's constitution and the state of his digestive organs. When there exists an irritable state of these, we have already remarked that the climate of Nice will generally disagree, whatever may be the more prominent disease.

*Gout* is remarkably alleviated by a warm climate. In the selection of a residence for the gouty invalid, we must be guided by the particular state of his constitution, and the effects of the different climates which have been already pointed out. Genoa is rather remarkable for the rare occurrence of the disease among its inhabitants. But a warmer climate than any part of Italy would in many cases, we have no doubt, prove still more effectual in removing gout. We have already remarked the effects of the West-Indian climate in this disease.

*Scrofula*.—Strumous affections, especially when seated in the skin and lymphatic glands, are frequently cured, and the general health is greatly improved by a mild climate. In such cases Nice and Rome have appeared to us the most favourable residences; but in giving a preference to either, in this and all other complaints in which a residence in these places is useful, the practitioner must always keep in view the characteristic peculiarities of these climates formerly pointed out. There are cases of this disease in which the climate of the West Indies, as already remarked, would prove more effectual than any European climate; those, namely, of an indolent character with little disposition to febrile excitement.

*Dyspepsia*.—Different forms of dyspepsia, hypochondriasis, and other nervous affections, intimately connected with a disordered state of the digestive organs, all of which are aggravated by a cold and humid atmosphere, are much mitigated by a winter's residence in the south of Europe, if aided by proper regimen. Attention to the diet is particularly necessary in changing from a cold to a warm climate, and in no class of cases is this more requisite than in those of which we are now treating. (See *DYSPEPSIA*.)

The dyspeptic invalid from the north will require to be still more on his guard in the south of Europe than in his own country, particularly as regards the use of stimulants; but in nervous and hypochondriacal cases the state of the mind must always be taken into consideration in our selection of a climate and residence for the invalid. Unless we can produce an impression on the mind as well as the body, we shall make little progress in the cure of these affections. A change from one place to another will, generally speaking, be better than a long residence at any one; as much of the benefit obtained in such cases arises from a constant succession of new and agreeable impressions made upon the mind. A judicious and timely change of climate, combined with a considerable extent of travelling through a country and scenery which excite a lively interest, produces the best effects on the health of persons whose minds have been overstrained and exhausted by long continued application to the same subjects, or whose general health has been destroyed by chronic dyspepsia, and the abuse of medicines to which it too generally leads.

A single season properly spent in the south, more especially in Italy, is often productive of the most salutary effects in restoring the energy both of the mind and body; and if due attention is paid to regimen, especially as regards diet, the benefit derived will be both greater and more permanent than can be obtained, perhaps, from any other mode of treatment.

The morbid states of the mucous membranes generally are greatly benefited by a mild climate. We have already remarked its beneficial effects in the diseased conditions of the bronchial membrane, and that of the stomach, in dyspeptic affections. In similar states of the intestinal membrane, accompanied with chronic diarrhoea, a mild climate will contribute powerfully to restore the parts to a healthy state. Dysmenorrhœa, which is frequently dependent on irritation of the mucous membrane of the uterus, is often quite removed, and the healthy state of the whole uterine functions restored.

Irritable cutaneous diseases are also much alleviated by a residence in a warm climate.

It would be impossible, without extending this article to an undue length, to particularise all the disordered conditions of the system in which the change to a mild climate proves useful; but we must not omit to notice several distinct periods of life at which the beneficial effects of such a measure have appeared to us most striking, when from any cause the health has become deranged. The first is during childhood. From what has been said, in the early part of this article, of the operation of a mild climate on the various functions, it will be easily understood how beneficially this influence must be exerted at this early period of life, in favouring the growth and development of the system; and accordingly we have had abundant opportunities of observing the excellent effects produced on the health of delicate children by a residence of one or two winters in Italy.

When the health of children is naturally delicate, or when it has been rendered so by some of the diseases of childhood, such as measles, hooping-cough, scarlet-fever, &c., no measure with which we are acquainted will prove so effectual in restoring the health as a change to a dry and warm climate.

Again, about the period of puberty, or a little before this time, a change to a southern climate for one or two winters is a measure which, if judiciously advised and carefully executed, will seldom fail to improve the general health of delicate persons, and favour the full development of the system which takes place at this period of life; and when there exists a disposition to tubercular disease, it will tend materially to obviate it. We beg, however, to observe that we speak of the effects of climate in those cases, not so much as a single remedial measure, as a measure which, while it contributes powerfully of itself to improve the health, favours the operation of a proper regimen, and such other remedies as

the circumstances of the particular case may require.

The third period of human life at which we have remarked the powerful influence of a mild climate in ameliorating the health, occurs at a more advanced age. The two first occur while the body is yet in progress to maturity, the third when it has passed the zenith of its power. In the first instance, a mild climate enables a delicate frame to attain more certainly its full maturity; in the latter it prevents it from sinking prematurely into decrepitude, and enables it to prolong its existence until the period marked for its natural decay.

From about the age of fifty to that of sixty, though not unfrequently at a much earlier period, either when the system is naturally weak, or the causes of disease have been powerfully applied, the impaired condition of health now alluded to usually supervenes. This state is marked rather by anomalous disorder of various functions, indicative of a premature decay of the powers of life, than by any formal disease acknowledged in our systems of nosology. The activity of the mind and the bodily vigour have sunk many degrees, without any evident cause, and the individual, both in appearance and feeling, seems rapidly lapsing into premature old age and its accompanying infirmities. This disordered state of the health has been termed the *Climacteric Disease*; but, as we have already remarked, it occasionally occurs long before the period of life at which this change of the constitution is stated to occur naturally. (See AGE.)

The causes which lead to this condition of the health are various; as, for instance, an anxious and sedentary life, long continued and close mental application, or irregular and intemperate habits of living; and oftener still it is the consequence of the combined influence of several of these causes. From whatever cause it originates, a change for one or two years to a milder climate will prove of the greatest benefit in restoring the invalid to his wonted health.

Before closing this brief survey of climate, and of the various diseases benefited by it, there remains one circumstance to be noticed, and it is one of some importance to the invalid: we allude to the proper period for his returning to this country from the milder regions where he has been sojourning. Invalids finding a very sensible improvement in the state of their health, are too apt to consider themselves well, and become impatient to return home on the least feeling of inconvenience from the heat of the spring. Influenced by this or other causes, they frequently err by leaving a southern climate too early. A relapse of the disease, for the cure or relief of which they were sent abroad, is not unfrequently the consequence; and thus it often happens that by a little impatience, or imprudence, and occasionally from ignorance of the consequences, the advantages

obtained by passing a whole winter in a mild climate are speedily destroyed. It should be the care of the medical adviser to warn his patient, before he leaves his own country, of the risk he runs by returning home too early. If his winter residence has been Italy, the invalid should avoid recrossing the Alps till the summer is fairly established in Switzerland. He may commence his journey northwards from his winter quarters in May, but should linger in the north of Italy, or among the Italian lakes, till he finds the heat inconvenient. This will seldom happen before the first or second week of June; and whatever may be his feelings in Italy, the period we have just mentioned will be sufficiently early to arrive in Switzerland. Independently of the risk of exposure to cold while crossing the Alps, which may, indeed, be avoided by proper clothing and arranging the day's journey so as to complete it before sun-set, the invalid will find a remarkable difference between the atmosphere of Switzerland and that of Italy. He will be particularly sensible of the keenness of the evenings and nights in Switzerland. Indeed, the scenery of these two countries does not differ more remarkably to the eye than does their climate to the feelings.

When the winter has been passed in Madeira or any of the other Atlantic islands, and more particularly the West Indies, the invalid should be still more careful not to leave his quarters too early in the season. By a little care to avoid exposure to the sun, he may escape injury from the heat; but it will be difficult for him to guard against the pernicious effects of our cold north-east wind as he enters the channel, or arrives on our shores.

A delicate invalid who has passed the winter in any southern climate, should endeavour to arrange his journey or voyage so as not to reach England before the middle or rather the end of June; and his warm clothing, which he may have laid aside, should be resumed the moment his feelings tell him that he is entering a colder and more variable climate.

It is of the greatest consequence to invalids to maintain an active state of the circulation in the surface and extremities, which cannot be done in this country without the assistance of warm clothing. The increased circulation in the extreme vessels is one of the effects of a warm climate, from which the invalid derives the greatest advantage; and it should be his especial care to preserve it while in progress to and after his arrival in a colder, as to the steady maintenance of this for a considerable length of time he must mainly look for the preservation of his new stock of health.

In leaving his own country, therefore, in the early autumn, on his way to a warm climate, and in returning home in the succeeding spring, he should avoid exposure to great vicissitudes of temperature, and thus endeavour to secure the advantages, as it were, of several successive summers.

(James Clark.)

**COLD.** It is designed under this head to treat of the morbid effects of excessive cold applied to the human body, and of the means of removing them; and also of the application of cold as a remedy in diseases.

The term *cold* is relative, and perhaps, strictly speaking, ought to be restricted to that sensation which is produced in the animal body by the abstraction of caloric from it, in consequence of the application of any solid, fluid, or gas, of a lower temperature than itself. In common language, however, cold is spoken of as a positive agent, and by some men of science it has been supposed to have as distinct an existence as caloric, or the matter of heat. The result of some experiments instituted to demonstrate that cold may be radiated in the same way as caloric, appears to have confirmed this opinion in some minds; but the effects produced by those experiments are explicable on the supposition that caloric is radiated, and not an agent of an opposite character.

The sensation of cold is not always produced by the same degree of temperature, for it depends very much on the state of the body previous to its application; indeed, what may be considered a low temperature under some circumstances will cause the sensation of warmth, and a comparatively high temperature will produce that of cold. If the right hand be immersed in water at the temperature of 80° of Fah. and the left in an equal quantity of water at 40°, the former will receive the sensation of heat, and the latter that of cold; but if the two quantities of water be then mixed, and both hands dipped into the mixture at the same time, the feeling of cold will be produced in the right, and the feeling of warmth in the left; so that no fixed temperature can be called either hot or cold. The generation of animal heat, or, in other words, the internal development of caloric, is accomplished by a process continually going on in the body, more actively perhaps at some times than at others.

The abstraction of caloric from the body within given bounds may be regarded as a salutary process; on this circumstance the degree of vigour observable in the human frame, in temperate climates, so much greater than in either what are called the torrid or frozen regions, may in no small measure depend; the degree of abstraction being neither so great as to leave the system torpid, nor so slight as to render it oppressed. Instinct and reason have led to attempts to regulate, by various artificial means, this cooling effect of the surrounding atmosphere in cold climates and seasons, as well as by contrivances for cooling the air in hot regions, to protect the system against the effects of excessive heat; and it is a remarkable fact, that a provision in nature seems in some degree to be made to accomplish the same object in the animal kingdom; for in very cold climates wool and hair grow abundantly long and thick on the brutes, so as to protect them against cold, while in the hotter

climates their skin is scarcely covered; and the same animal on being removed from a cold to a warm country, or from a warm to a cold one, is found to change the length of his coat. Thus dogs taken from England to India will often lose all their hair; and in our own climate the horse is well known to have the length of the hair covering his skin regulated by the clothing in the stable.

Perhaps the temperature of the atmosphere which is most congenial to the human body is a range between 55° and 70° of Fah.; but habit has much to do with this, as with almost every thing connected with the actions of the animal economy. An extreme degree of heat may be often endured without much inconvenience by those who have been long habituated to it; and the same may be said of cold. But when the system has been making an effort, if the expression may be used, to resist the bad effects of either a very low or high temperature, a great and sudden change in the surrounding atmosphere is always productive of inconvenience. This remark refers not to a change of climate only, but to the vicissitudes which may occur in the temperature of the atmosphere in the same climate. Persons who are strong and robust, however, feel less inconvenience from these sudden changes than those who are weakly; hence the importance of regulating the quantity of clothing according to the powers of the system, and especially according to the vigour with which the circulation of the blood is carried on. A very frequent exposure to changes of temperature will often enable the body to resist the ill effects of these changes, and affords another instance of the power of habit. The fact just mentioned is illustrated by the good health often enjoyed by those persons who attend large furnaces, glass-blowers, smelters, &c. The wonderful power of the body to accommodate itself to the circumstances under which it is placed, is, in this particular, exemplified in a very striking way. Hence, undoubtedly, have originated the various modes of attempting to harden the system, and thus to prepare it to resist the morbid agency of cold. It is undoubtedly true that such means will often give tone to weakly persons, and prepare them for the vicissitudes of climate; but with such persons much care is requisite that the plan be not carried too hastily into effect. Indeed, it will be found that many cannot by any care be brought to bear it, and in such instances warm clothing must be mainly depended on as a defence from the sedative action of cold.

This leads to the more special consideration of the *morbid effects* produced on the human body by the *undue* degree of the abstraction of heat from it.

Caloric, or heat, as it is commonly termed, acts as a *stimulant* when applied to the animal body, its effects being local or general according to the extent and degree of its application: it increases, like most other stimulants, the action of the heart and blood-vessels; but (as is also the case generally with stimulants) a

secondary effect occurs, which consists in a collapse, (or in an action lower than that which is natural,) after the excitement has subsided. Effects exactly the reverse of these take place from the abstraction of caloric, or, to use the common phrase, from the application of cold. Heat is therefore a stimulant, and cold a sedative, although the exact mode in which heat or cold act on the body will probably never be determined.

The well known immediate effects of a considerable abstraction of heat are—the sensation which is called *cold*, pallor of the skin—from the absence of blood in the capillary vessels; or a reddish blue colour especially of the hands, ears, nose, lips, from a delay of blood within the capillaries, so that it becomes venous;—a shrunken state of the skin, and a contraction of it around the small glands which are imbedded in it, and around the hairs, causing it to become rough, and to resemble the surface of a plucked goose; hence the technical term *cutis anserina*. The same state of the skin of the scalp often causes the hair to rise in some degree from the head, with a feeling of tightness: this is called *horripilatio*. The extremities of the body suffer first, as the fingers, toes, ears, nose, &c., *i. e.* the parts farthest from the heart. The fingers and toes become sensibly smaller, so that rings which fitted before fall from the fingers, and shoes drop from the feet for which they were not previously too large. The action of the heart becomes diminished in force, and sometimes also in frequency—the latter being most commonly the result of exposure to a very intense degree of cold; and not unfrequently the pulsations, although weak, become more frequent than natural. These symptoms, which may be considered the moderate effects of cold, will vary greatly as to their degree in different persons exposed to the same low temperature: indeed, to some persons the abstraction of heat by the cold air of a frosty day affords a grateful feeling, and to such it may be really salutary: this will be referred to when speaking of the therapeutical effects of cold. In all persons, however, a very intense degree of cold will produce unpleasant sedative effects; and in those who have been previously debilitated, the powers of the system are depressed to an alarming, and even sometimes to a fatal extent: indeed there are very few individuals who have such vigour as to be enabled to resist the consequences of exposure, without sufficient clothing, to the severity of the winter months in the frozen regions, or to the intense cold which is met with in passing over very high mountains. The vascular system is not alone affected by the agency of cold on the body, as is proved by the symptoms which occur in the more severe cases of exposure; the brain and nervous system generally being soon brought under its influence. Perhaps it may be with propriety supposed that the nervous system primarily receives every impression from external agents, and that cold, therefore, first acts on this system, the vascular system being only

secondarily affected: this question need not be here discussed.

Numbness, or a want of the ordinary acuteness in the sense of touch, is a consequence of exposure to cold: this numbness is experienced by most persons in their fingers and toes on a very cold day, or after having been long immersed in cold water. It is worthy of remark here, that in these individuals there appears to be something very peculiar as it respects the action of cold on their extremities; the blood appears to cease to flow altogether into the vessels of the fingers and toes, which look exactly (as the common expression implies) like those of a dead person; and so torpid do they become under these circumstances, that a pin can scarcely be felt when placed between the ends of two of the fingers, and the motions of the hand are regulated, not by the touch, as is usual, but entirely by the sight. This singular idiosyncrasy has never received a satisfactory explanation: it does not appear to arise from debility of the vascular system alone, for it is found in some who have no sign of such debility: probably it may depend, as all idiosyncrasies appear to do, on an original peculiarity of structure: it is found to prevail in individuals of the same family. The very great diminution (almost suspension) of sensibility in such cases may arise in some measure from a want of the necessary supply of blood to the extremities of the nerves; as it is an undoubted fact that their sensibility is greatly regulated in its degree by the quantity of blood circulating through the capillaries. It may also in part depend on the direct effect of the cold on the nerves themselves; but that this action on the nerves is not the only cause of the torpor is rendered probable, if not proved, by the fact, that if artificial warmth be applied so as to bring the fingers to their natural temperature, the sensibility will not return until the circulation is restored.

The whole surface of the body becomes less sensible to the touch under the influence of a great degree of cold; and the sense of taste is sometimes blunted. But further, when a still greater effect is produced, the brain loses its energy, and an irresistible desire to sleep ensues. Here we may again observe that it is hardly possible to determine whether this is the direct result of the action of the cold as a sedative on the brain, or whether it depends on a want of the due supply of blood to that organ on account of the diminished action of the heart. When this overpowering tendency to sleep has commenced, much danger is to be apprehended; for it has generally been found, when indulged, to be the precursor of death. The interesting account given by Captain Cook of the excursion of Dr. Solander and Sir Joseph Banks, with nine other individuals, over the hills of Terra del Fuego, affords a very strong illustration of this effect of cold. Dr. Solander, who had witnessed the torpor and death produced by severe cold while crossing over some of the mountainous districts of the north of Europe, thought it necessary to put his companions on their guard, and requested them to

resist determinately the strong tendency to sleep which he expected some of them would feel; his words, quoted by Captain Cook, were, "Whoever sits down will sleep, and whoever sleeps will wake no more." The doctor was the first who began to experience the anticipated effect of the cold; and so irresistible was the inclination to sleep, even in him, that in spite of his judgment and fears he intreated his companions to allow him to lie down: they acted upon the knowledge he had afforded them for their own safety, and partly by intreaty and partly by force kept him for some time from indulging his destructive inclination; but at last, becoming themselves almost exhausted, they were obliged to leave him behind, together with two black servants who had also become drowsy. Dr. Solander was, however, roused, although with the greatest difficulty, after having slept about five minutes only, and carried to a fire which some of the party had succeeded in kindling, and thus narrowly escaped death, although for a time he almost lost the power of his limbs. The two poor blacks perished.

Many examples of this extreme effect of cold will be found on record in the writings of travellers and historians: the same effect is produced, to a certain extent, in this country in very severe winters. The celebrated traveller Dr. Edward Daniel Clarke, the late eloquent Professor of Mineralogy in the University of Cambridge, was on one occasion nearly losing his life by cold. Having performed divine service at a church near Cambridge in the afternoon of a very severely cold snowy Sunday, in the year 1818 or 1819, he mounted his horse for the purpose of returning home. Soon finding himself becoming very cold and sleepy, and knowing well the danger of giving way to sleep, he put the horse into a fast trot, hoping by that means to arouse himself from the alarming torpor which was coming over him: this means was unavailing; and then fearing that he should soon fall from his seat, he dismounted, and determining to use every effort to resist sleep, put the bridle under his arm and walked as rapidly as he could. This, however, did not long succeed: the bridle dropped from his arm, his legs began to falter, and he was just sinking down upon the snow, to rise, probably, no more, when a gentleman who knew him came up to him in a gig, and rescued him from his perilous situation. This account was given to the writer of this article by Dr. Clarke himself the succeeding morning; he then felt languid and feverish, after having had a good deal of reaction during the night, but the effect soon passed off entirely.

The action of cold is probably, as has been already remarked, greater on those persons who have naturally a weak circulation, or who have become weak from any debilitating cause; and this last is the reason why those are very soon affected by it who have undergone much fatigue. A moist state of the skin from perspiration or damp clothing will also accelerate the effect of cold, by superadding to the direct

effect of the cold air the further abstraction of caloric by evaporation. It is a curious but well established fact, that when the mind is deeply engaged, the body is less affected by cold; and it is perhaps on this account that maniacs will often bear exposure to extreme cold without complaining.

When the body is warm, and the circulation vigorous, provided there be no perspiration on the skin, the bad effects of exposure to cold are less likely to be experienced. The common practice, therefore, of persons cooling themselves gradually before they pass from a warm room into the open air has originated in error: the greatest protection from the bad consequences of such a change is found in a vigorous circulation, a warm dry skin, and thick clothing.

Long continued immersion of the body in cold water seems to be productive of nearly the same symptoms as those which arise from exposure to a very cold atmosphere. It has been asserted, on the ground of recorded facts, that less danger is likely to ensue from immersion in sea-water than in fresh water; and it has been alleged that this minor degree of effect is referrible to the stimulating quality afforded to the sea-water by the salts which are dissolved by it. This solution of the facts is probably in part correct; but it must be remembered that the water of the sea is rarely so cold in winter as that of rivers, the immense mass of the ocean requiring a much longer period than that of a winter to cool it down to the lower degrees of temperature of the winter atmosphere: there must besides, by means of the tides, be a continual admixture of the warm water from the southern seas with the colder water of the northern. A doubt, however, cannot be entertained of the advantage which persons who are exposed to the misfortune of shipwreck during severe cold will derive from keeping themselves immersed in the sea-water; and not only because the water is warmer than the atmosphere, but also because it will prevent the effects of evaporation. Many interesting accounts of shipwrecks have been published which show that this is not mere theory.

The complete and speedy destruction of life from exposure to intense cold may result from the general sedative effect which has been already described; but when life is not totally lost, the extremities may lose their vitality, and mortification to a greater or less extent ensue. Limbs are frequently in this way mutilated in cold seasons in northern latitudes, and in very high situations; when the surface of the nose and the ears suffer in this way, and are said to be frost-nipped or frost-bitten.

But the injury sustained from exposure to cold is not always dependent on its direct sedative action, for it may produce disease, and even cause death, by that secondary effect which is denominated *reaction*. This reaction after depression consists in the return of the action of the vascular system; if moderate, it may go little beyond the natural degree:

the pulse becomes rather more frequent and full, and the heat of the surface greater than natural, and a glow is experienced over the whole body: this soon passes off, and leaves no evil consequences. But when the reaction is great, the vascular excitement is so increased beyond its due bounds as to constitute *fever*; and perhaps there may be in reality no difference between this state of the body and fever from other causes. The symptoms are often the same, and sometimes last as long; but the feverish state in a day or two will give way, in many cases, on using very mild remedies, or even without any remedies at all: such cases are called *ephemeral fever*.

Fever is not the only consequence to be feared from reaction after exposure to cold; local inflammations may follow this general reaction, and any of the internal membranes or organs may become the seat of the inflammation; but the particular organ affected in each case may be determined by some local predisposition: thus one person will have catarrh, another cynanche tonsillaris, a third pneumonia, as a consequence of exposure to cold.

It appears, from what has been said, that it is to the excess of the reaction that such effects, both local and general, are to be attributed; and hence the importance of guarding against every circumstance which may have a tendency to stimulate the system immoderately after exposure to cold, and of employing measures calculated to subdue the action of the heart and bloodvessels when there is a threatening of sanguineous excitement. The danger of applying heat too rapidly is now generally known, as well as that of administering internally any strong stimulants. A person who has become seriously affected by cold should be placed in warm air about 65° or 70°, and should be well covered over with flannel to prevent the heat, as it becomes generated in the body, from passing off. Friction of the surface by means of the warm hands of two or three attendants, or with warm flannels, may be employed: in extreme cases the body may be wrapped in hot blankets until reaction commences; large hot poultices or fomentations may be applied with advantage to the abdomen; the warm air, vapour, or water bath, about the temperature of 98°, may be employed in those instances where the vital spark appears almost extinguished. The means already recommended must be combined with the employment of internal stimulants, alcohol, spices, ammonia, &c.: but it must be borne in mind that it is desirable to avoid the employment of internal stimulants to any great extent; indeed to avoid them altogether if possible, as, after reaction has commenced, they, by their action on the system, may cause the injurious consequences of excessive excitement. If asphyxia (or a suspension of the action of the heart and lungs) succeed to the application of cold, artificial respiration, and the other means recommended in the treatment of asphyxia, may be required. When the heat and action of the system begin to return, care is especially necessary lest the excitement rise to an im-

moderate degree. The same principle must be our guide in attempting to prevent injurious consequences after the local effects of cold. Chilblains, which are a common consequence of the local application of cold, may be prevented by warming the parts affected very gradually, and by cooling them, as soon as reaction takes place, to the extent of producing the sensation called the *hot-ach*.

Large draughts of cold fluids, taken when the body is fatigued and perspiring, are often productive of serious, or even fatal consequences: the effects are a faltering of the pulse, laborious breathing, dimness of sight, giddiness, and then general torpor and death. The proper mode of treating these cases has never been well pointed out; it appears, however, a rational practice to give, as soon as possible, some warm fluid, to apply hot fomentations or poultices to the epigastrium, and to resort to the means indicated by the principles already laid down.

The abstraction of caloric from the body may and is frequently made to conduce to the recovery of persons labouring under disease.

As a therapeutical agent, cold is employed to accomplish one of the three following purposes:—1st, to depress inordinate action of the vascular system; 2nd, to relax the muscles; 3rd, to give vigour to the body.

The sedative effect produced by cold has been already sufficiently dwelt upon to show how it may be employed beneficially to subdue high vascular action. In inflammation, therefore, and in fevers, cold may very often be considered as one of our most valuable remedies. It may be supposed by some persons, that the beneficial effect resulting from the employment of cold in inflammation and fever arises from the simple diminution of the heat: indeed it is most probable that it was on account of the augmented heat in those diseases that it was at first resorted to; but our present improved pathological views enable us to form a more correct judgment of the action of remedies; and there cannot now exist a doubt that the advantage arising from the use of cold in fever and inflammation is to be ascribed to its allaying vascular action.

When inflammation is situated in the external parts of the trunk of the body, or in the extremities, one of the means most commonly employed to subdue it is the application of an evaporating lotion. The lotion may be used cold, and then the heat is in some degree abstracted directly by the cold fluid; but the principal advantage (unless the lotion is constantly applied) is derived from the evaporation of the fluid. It is not, therefore, absolutely necessary that the lotion should be colder than the body of the patient, as evaporation will take place more speedily when it is tepid; and in some cases it is preferable to use it warm, on account of its being more agreeable to the feelings of the patient.

Although there cannot be a doubt entertained of the advantage of employing cold applications in cases of common inflammation of the surface

and of the extremities of the body, yet by many it is held to be problematical whether they are properly employed in cases of internal inflammations, as of the membranes and organs included within the skull, the thorax, and the abdomen; as by such means the blood may be so thrown upon the internal parts as to aggravate the inflammation. As it respects the brain and its membranes, this reasoning, although at first sight plausible, is evidently fallacious. The object in cases of inflammation being to lessen the flow of blood to the part affected, any means which will controul the action of the carotid arteries must be useful in inflammation within the head, as it is by those arteries that the greater part of the blood is conveyed thither. Cold applied to the scalp will be found to act as a sedative, not only upon the vessels of the integuments, but (by a sympathy which is well known to exist between the larger and the smaller vessels) upon the carotids also. It must be clear, therefore, even from theory, that cold applied to the integuments of the head will be of service in inflammatory diseases of the brain; but experience has long decided the point, and no practitioner omits this powerful remedy when he has to combat with such affections.

The immediate effect produced by a sudden dash of cold water, or by a stream of the same poured upon the face and head, is found useful in many states of the brain. This mode of using the remedy is sometimes adopted with advantage in phrenitis, in hysteria, in syncope, and in cases where narcotic poisons have been taken in large quantities, especially opium. The advantage may be owing in some degree, as in inflammation, to the sedative effect of the cold upon the bloodvessels; but this cannot account for the benefit produced in syncope, and the sudden impression made on the nerves by the cold must be also taken into the account.

It seems to remain doubtful whether or not cold may with advantage, or even with safety, be applied to the chest or abdomen when there exists inflammation of the membranes or viscera within those cavities. This practice has, however, of late been recommended by some physicians whose opinions ought to have weight, and especially so as the recommendation seems to be grounded on the result of experience: the limits of this article will not allow of a full examination of this interesting subject; the author, however, may be allowed to say that in some cases of phthisis pulmonalis, where the pleura has become inflamed, an evaporating lotion, applied over the part in pain, has often appeared to be of considerable service.

Cold applied to the body has become a very common remedy in fever, when the system is in a state of very high excitement; and it is undoubtedly a remedy of almost unequalled efficacy in such cases. It may be employed by means of cold fluids received into the stomach, or by means of water or air applied to the surface. From the time of Hippocrates the powerful effects of cold have been appreciated in controlling febrile action; and it has from

that period to the present time been occasionally lauded as an important therapeutical agent: but it was not until of late years that its applicability in cases of fever became fully understood. We are more especially indebted to the late Dr. Currie of Liverpool for our knowledge of the value of this refrigerant, and of the mode of employing it;\* although very valuable information may be found scattered through other medical works. It is not in all cases of fever that this remedy can be employed with advantage, or even with safety: it is only calculated to subdue excessive action when that action is accompanied by a temperature of the body above 98°: even among such cases there may be a few in which some other peculiarity may forbid its use,—for example, when the skin is moist. At least, if it be employed under such circumstances, it will require the greatest caution, even although the temperature of the body be high, which, however, is very unusual when the skin perspires. In measles, cold is in no case to be applied to the skin, nor are cold fluids to be drunk. Nevertheless, in scarlet fever cold is of the greatest service in moderating the action of the system. It is probable, although not clearly proved, that where fever is accompanied by some visceral disease, this remedy may act injuriously, by determining a large quantity of blood to the internal parts of the body.

The circumstances which, when combined, may justify the employment of cold as a sedative in common fever, are an increase of the animal heat above 98° of Fahrenheit, a uniform increase of temperature over the *whole* body, and a dry state of the skin over the whole surface. If there be a tendency to perspiration, it will shew itself first in a damp state of the palms of the hands, or of the axillæ. Should a sense of chilliness be felt by the patient, that also will render the employment of cold of doubtful propriety.

Several different modes of bringing the body under the influence of cold are resorted to by medical men.

First, immersion of the body in a cold or tepid bath.

Secondly, affusion of cold or tepid water over the body.

Thirdly, sponging the body with a cold or tepid fluid.

In some few cases, and in the very early stage of reaction, fever has been arrested in its progress by the cold bath or by cold affusion; but where fever is fairly established, it can rarely be suddenly put a stop to by these or by any other means: we can then only mitigate the severity of the symptoms, and thus give a better chance of the occurrence of a favourable crisis. But the practice of immersing the patient in a bath, or of throwing water over the body, has of late been very rarely adopted; and its disuse has not been without reason, for considerable inconvenience both to the patients and to the attendants is given, especially in private prac-

\* On the Effects of Water, &c. in Fever. Lond. 1805.

tion, by the employment of both these modes. But the principal objection to them arises from the impossibility of determining the precise extent to which we ought to carry the sedative effects of cold, while the body is immersed in the water, or while it is passing over it in the way of affusion. The patient may be kept too long or too short a time in the bath, or too little or too much water may be affused; so that the action of the system may be too much depressed, or not sufficiently overcome. These objections cannot be made to sponging the surface of the body with cold water: by this means the cooling process can be carried to the exact extent which is required; the criterion for judging of the effect being the feelings of the patient—a slight chilliness will mark the time to desist. Two or three attendants should be employed at the same time, with large wet sponges, passing them over the different parts of the naked body in succession, until the chill comes over the patient, who is then to be placed in a dry bed and moderately covered.

The temperature of the water when used with the sponges may not be a matter of much moment, as it is by means of the evaporation that the heat is principally abstracted from the body: tepid water (from 70° to 90°) will in general be found most agreeable to the feelings of the patient, and it will be equally, if not more speedily efficacious in reducing the morbid heat. It seems also probable, for reasons already assigned, that reaction will not so quickly occur after tepid as after cold sponging. When the desired effect is produced by this mode of refrigeration, the pulse becomes softer and slower, the skin cool and perspirable; headache, if before existing, is relieved, and frequently delirium is suspended, and the general feelings of the patient are so improved that sleep will follow. The remedy will, however, generally require repetition to derive from it its full advantage, and this should be as soon as reaction takes place to any extent; indeed the sponges may be used partially or generally many times in the day and night; but should the pulse rise very speedily, and the heat return very soon after it has been reduced by this remedy, other means must be combined with it, as bleeding, purging, &c.: but in by far the majority of cases of fever, dependance may be placed on refrigeration alone to keep down inordinate action. Vinegar, spirit, ether, &c. are sometimes used to increase the evaporation, but these are seldom required.

Cold air admitted into the patient's room, or a current of air passing over his body, will often tend to allay vascular excitement: hence poor patients, in fever, who have been lying in their own confined apartments, are often speedily benefited by removal to an hospital through the open air. It is very questionable if any medicine admitted into the stomach is worthy, strictly speaking, to be called a refrigerant, at least to be called so on account of any quality which it possesses, excepting its low degree of temperature, although many articles of the *Materia Medica* are reputed to have this effect;

but on this point the reader is referred to the article REFRIGERANTS.

When hemorrhage occurs from increased action of the circulation, or is accompanied by such increased action, it may very frequently be restrained by the sedative effect of cold. The local application of cold to the bleeding vessels, or cold so applied as to act upon the large vessels which supply those which are bleeding, will be often found of very great service; for example, in hemorrhage from the nose, (epistaxis,) cold water used to the face and head will often of itself stop the flow of blood; but in cases of bleeding from the internal organs, cold, made to act upon the system generally, will often be found of great use in helping to restrain the action of the heart. A patient labouring under hemorrhage from the lungs, (hæmoptysis,) may with great advantage be kept uncomfortably cold: of course when the hemorrhage is not active, but of the passive character, injury rather than benefit might result from the employment of this means.

The depressing effect of cold upon the energies of the animal body is remarkably exemplified in the debility which is felt in the muscles of a person who has been long exposed to a very low temperature; indeed it is very probable that the sedative action of cold on the circulating system is to be ascribed to a diminution of the irritability of the muscular fibres of the heart and bloodvessels. When, therefore, an inordinate contraction of the muscles occurs, as in spasmodic diseases, the sedative quality of cold may cause them to relax when that remedy is applied to the body to a great extent. The cold bath and cold affusion have for this purpose been frequently employed in tetanus; the relaxation, however, which often occurs immediately after the application, is generally of very short duration; and it ought to be remarked that the sudden shock experienced on the first impression of the cold water will often excite an exacerbation of the spasm, and that immediate death has ensued in a few instances. This mode of treating the disease is certainly, in general, far from being effectual; and it cannot be deemed altogether a safe one. The sedative effect of cold on the muscles has been said to shew itself in alleviating the irregular actions in chorea, hysteria, and other convulsive diseases: in these cases the cold bath or shower bath has been recommended. As an instance of the effect of cold in producing muscular relaxation, it may be stated that surgeons are sometimes able to reduce, with great ease, a dislocated limb during the temporary debility which is induced in the muscles after long immersion in a cold bath. There are, however, other remedies capable of producing relaxation of the muscles, which must be considered much more certain than cold. (See the article ANTISPASMODICS.)

The last therapeutical agency of cold which remains to be considered, is its invigorating quality when employed in cases of debility, or, in other words, its tonic property.

It has already been remarked that the direct effect of a moderately cold atmosphere is grate-

ful and refreshing to the feelings of some persons: those who have naturally a very vigorous and too rapid a circulation, those who suffer from the production of too much animal heat, and those who are liable in warm weather to have an inordinate secretion from the skin, are generally benefited by the cold season of winter: by such persons, from their feelings, a cold frosty day will be called bracing and invigorating. To those individuals, however, who have a languid circulation, either naturally or as the effect of disease, cold weather is far from being either agreeable or beneficial. It has been found on enquiry that a severe winter is in this country, and especially in the metropolis, productive of more disease than a milder season; the old and the infirm being the chief sufferers.\*

An especial reference must here be made to the beneficial effects of that moderate degree of the reaction in weakly persons which follows the application of cold to the surface. The glow which pervades the body, arising from the increase of the circulation, is often at the moment accompanied by a sensible increase of vigour and activity. The benefit appears to depend very much on the blood being thrown in greater quantity into the capillary vessels, and on a consequent increase of their action in preserving the well-being of every part of the system. Cold, therefore, in this respect, seems to act indirectly as one of the diffusible stimulants. (See the article BATHING.)

Some kinds of diseases of the skin are benefited by cold or tepid bathing. When there is much inflammatory action of the cuticular vessels, it is desirable to avoid reaction, and this is best accomplished by the use of tepid water, (about 70°,) keeping the body a long time immersed, and afterwards preventing the skin from getting hot: in other cases, where an eruption seems to depend on a torpor of the cuticular vessels, it is desirable to favour the occurrence of reaction.

On the whole, the action of cold on the human body may be regarded as very important in a therapeutical point of view; it requires, however, as all remedies do, much judicious management: but with such management it is every day made the means of alleviating sufferings and of prolonging life.

(John Whiting.)

**COLIC**, (*colica*.) This term, derived from *κόλον*, *colon*, the name given to the large intestine, is in its medical application restricted to cases in which there is pain in the bowels, obstinate constipation, and generally vomiting, but without symptoms of pyrexia. The pain which accompanies enteritis and diarrhoea is denominated tormina, or griping.

*Symptoms*.—In cases of colic, although there be no tenderness at first, the attention of the patient is soon attracted by pain which is generally felt near the umbilicus and in the lower part of the abdomen, though sometimes over the whole belly. In most cases it is relieved

by pressure, so that the patient endeavours to get relief by leaning upon his folded arms, or upon the edge of a bed, table, or chair; sometimes by lying with his weight upon the abdomen. The pain, however, may be increased on pressure. Dr. Abercrombie states that an intestine which has become rapidly distended is painful on pressure, though by attention the kind of pain can generally be distinguished from the acute tenderness of peritonitis. The pain, although constant, comes on in paroxysms, accompanied by a sense of twisting or wringing, especially about the navel. The abdomen is sometimes retracted, or drawn inwards; and occasionally the partial spasmodic action of the abdominal muscles gives an idea of the formation of balls or knots in the belly. In other instances the abdomen feels tense, elastic, and sonorous on percussion, from accumulation of flatus, which, after passing through the intestines with a rumbling noise, is expelled, temporary relief generally following its expulsion. These symptoms are usually from the first attended with vomiting, which is often so incessant, that whatever is taken into the stomach is sooner or later rejected; and in severe cases, from an inverted peristaltic action of the duodenum, the vomiting assumes a bilious character.

A variety of this disease, called flatulent colic, is very common in dyspeptic persons, more particularly in those who are ill nourished, or who are addicted to the use of spirits; and in children who are improperly fed, or whose bowels are disordered. In this form there is little sickness, and seldom constipation, but painful retention of flatus in the bowels, the colic depending principally upon debility of the muscular fibres of the intestines. Another very painful affection of a similar nature which is not unfrequently mistakenaken for the effects of gallstones, appears to depend on flatulent distention of the upper part of the intestinal canal—the duodenum and jejunum. In cases of this description the pain is felt chiefly in the right hypochondrium, often extending to the back; and in consequence of the pressure on the ductus communis choledochus, where it perforates the duodenum, the flow of bile is interrupted: hence these attacks are often accompanied or succeeded by symptoms of jaundice. In such cases, on the subsidence of the pain, there is usually a perceptible movement of air in some part of the intestines, accompanied by a gurgling noise and discharge of flatus. The pain occasionally ceases entirely, but recurs at irregular intervals, varying from an hour to a day or two. This distention of the duodenum and jejunum is occasionally observed in dyspepsia, and in these cases bilious vomiting generally takes place.

When inverted action takes place throughout the greater part of the alimentary canal, not only the contents of the stomach and small intestines are discharged by vomiting, but those also of the large intestines. The vomiting is then termed stercoraceous, and such cases are denominated *ileus*, or the *ileac passion*.

The bowels, both in colic and ileus, are

\* *Bateman*, On the Diseases of London.

obstinately constipated; so that ordinary doses of aperients do not act.

At the commencement of the attack, the tongue is white, clammy, but soon acquires a thick coating or fur. The pulse is often natural, sometimes rather slow; but when the pain is excessive, or when the symptoms do not yield to the remedies adopted, it becomes quick, and the skin hot, indicating the threatening or supervention of inflammation of the bowels: hence the occurrence of febrile symptoms in colic should never be overlooked.

Several divisions of colic, founded on the supposed causes of the disease, have been proposed by systematic writers. Thus Cullen has enumerated no fewer than seven varieties. 1. *Colica spasmodica*, characterized by retraction of the umbilicus and spasm of the abdominal muscles. 2. *Colica stercorea*, arising from accumulation of the contents of the bowels. This form occurs in costive habits, and is speedily removed by active cathartics, which often expel an incredible quantity of feces. 3. *Colica meconialis* is applied to the spasmodic pain of the bowels which infants suffer from retention of the meconium: it is evidently a modification of the last variety (*stercorea*.) 4. *Colica accidentalis* implies the origin of the disease from acrid ingesta, and is frequently induced in individuals by particular articles of diet. 5. *Colica callosa*, in which there is a feeling of constriction ascribed to some fixed part of the intestines. 6. The *colica calculosa* arises from the formation and retention of intestinal calculi. And, 7. *Colica pictorum*, produced by the poisonous effect of lead on the system, which will be afterwards particularly considered.

All writers appear to agree in the opinion that during the continuance of colic there is some cause which impedes or obstructs the passage of the alimentary contents. It is with reference to this obstructing cause that disputes among practical writers have arisen. The solution, however, of these discrepancies will be found in the fact that the symptoms of colic originate in a variety of causes. Cullen was of opinion that spasm was the essential cause of colic, and founded his varieties of the disease on the supposition that the spasm is the result of the operation of different agents on the muscular fibres of the alimentary canal. Dr. Abercrombie, on the other hand, attributes the symptoms of colic to a certain loss of the muscular power in a portion of the intestine, in consequence of which it does not act in concert with the other parts, but becomes distended by the impulse from the parts above, which in the healthy state would have excited it to contraction. He therefore infers that in colic the distended part is the real seat of the disease, and that the contracted part is not contracted by spasm, but merely collapsed, because it is empty, its muscular action being unimpaired.

It appears to us that the symptoms of colic may be referred to one of the following causes; spasm, obstruction, over-distension, inverted

action. Although Dr. Abercrombie calls in question the possibility of spasm occurring in the muscular fibre of the intestines, he cannot be said to have proved this point; he has, however, made it clear that, in many instances where colic has been supposed to arise from spasmodic contraction of some part of the bowels, it ought to have been referred to another cause. It would require numerous facts to shew that all muscular fibres are not occasionally liable to a state of spastic contraction; and it cannot be fairly doubted that, when irritating matters are passing through the bowels, such matters may cause an undue degree of contraction, so as to obstruct the passage of the contents of a portion of the tube which is above the point of contraction. We can in no other way explain the occasional production of colic from acrid ingesta. We know, however, that obstruction giving rise to colic, often arises from organic diseases, such as stricture in some portion of the intestine; various morbid growths in the intestinal canal diminishing its caliber; from hernial protrusion or internal herniæ; intussusception or invagination; twisting of the bowels, or a long band of organized lymph encircling them, forming a ligature. Colic also sometimes originates in adhesion between the adjoining portions of intestine, between the intestines and other viscera, or between the intestines and the parietes of the abdomen. Moreover, obstruction and a consequent attack of colic may arise from mechanical causes, such as collections of hardened feces, calculous concretions formed in the intestines, large gallstones, or hard substances which have been swallowed and become impacted in some part of the alimentary canal. Many of these latter causes may act in conjunction with spasm; indeed it is probable that spasm will, as Dr. Cullen supposes, often be induced by their presence, and that thus hard substances may be arrested in their progress downward by exciting a spasmodic action of the muscular fibres around them.

It is also plain, when any of the causes of obstruction just mentioned occur, that by the detention of the gaseous, fluid, or solid contents of the bowels above the point of obstruction, over-distention of the intestines must ensue, the peristaltic action become inverted, or their muscular power altogether lost, as happens in an over-distended urinary bladder. It is an interesting subject of inquiry, whether, independently of any obstruction, the muscular power of any part of the intestines may sometimes become so paralyzed as to be incapable of propelling its contents onwards; and whether from this cause over-distention can take place to such a degree as to cause colic. Dr. Abercrombie, we have seen, has pronounced it to be his belief that the muscular action is entirely destroyed, the part which has been distended falling flat when it is emptied, and presenting a broad surface like an empty bag, without any tendency to contraction. He gives a case in which the patient lived for eighteen hours, with a free external opening directly commu-

nating with the distended intestine, but without any discharge taking place, though the part contained only air and fluid faeces, and in which, notwithstanding the intestine for a considerable space above the opening must have been entirely deprived of its muscular action: on examination after death the part presented only a uniform distention, without any remarkable change either in colour or texture. Dr. Abercrombie therefore concludes that such want of power is the common, if not the constant cause of this disease. He gives also an interesting case, accompanied with painful local distention, in which, after resisting the most active purgatives, galvanism succeeded in procuring copious evacuations. Cases of colic are, no doubt, daily observed, which appear to arise from this cause; and it is probable that this debility of the muscular fibre produces, in many cases, the painful gaseous distention which often succeeds to enteritis or violent diarrhœa. Is it not probable that colic from the effects of lead is produced in this manner? Lead when applied externally does unquestionably destroy the tone of the muscular fibres of the limbs; and it would be a very remarkable circumstance, if the same agent caused paralysis in one part of the body and spasm in another. This species of colic, therefore, (*colica pictorum*;) may be adduced as a presumptive proof of the accuracy of Dr. Abercrombie's opinion, viz. that the symptoms of colic may require for their production nothing more than the loss of tone of the muscular fibres of some portion of the intestinal canal. In these cases the part of the intestinal tube which is affected will, from want of power, be incapable of propelling its contents onward; and thus by continuing to receive without being able to transmit them, the portion of intestine becomes more and more distended, and at length the whole tract above the point of the accumulation assumes an inverted action. Dr. Abercrombie thinks that, this loss of tone in the muscular fibre may be caused by rheumatism; and as it is well known that colic often succeeds to exposure to cold, this theory is plausible.

In colic arising from spasm of some of the fibres of the muscular coat of the bowels, or by mechanical obstruction, the same distention and inverted action may take place; only in such cases they are the result of the obstruction, and not of the debility. It has been asserted by some writers, that an inverted action of the whole or of part of the alimentary canal, may be produced independently of either debility, spasm, or obstruction: they adduce, in proof of this opinion, the speedy discharge by the mouth of fluids which have been thrown into the bowels by clyster. These last are called cases of simple ileus, and perhaps the evidence adduced to prove the existence of such a state is still open to controversy.

*Morbid anatomy.*—In the preceding account of the history of colic it has been shewn that the symptoms are dependent on a variety of

causes, many of which are removable; but those cases in which the colic or ileus is merely symptomatic of incontrollable organic disease in the alimentary canal, are beyond the possibility of removal. Dr. Abercrombie, to whom the profession is so largely indebted for the record of many valuable cases and pathological deductions, states that ileus may be fatal without inflammation, and gives two cases in which a large part of the small intestine was found in a state of great and uniform distention, without any appearance of inflammation. In other instances, besides distention, lividity or incipient gangrene has been found, but without any appreciable change of texture: in some cases the usual inflammatory exudation was not observed; in others there was vivid redness, and in more advanced cases gangrene, with and without exudation of false membrane. Hence the usual progress of the disease in the fatal cases is into inflammation and its consequences—the inflammation varying from a recent tinge of redness to extensive gangrene; and it should be kept in view that these changes may be going on in a latent form with every variety of symptoms. Indeed we meet with cases in which inflammatory exudation has gone on to a considerable extent before death, yet in which there was neither frequency of pulse nor tenderness of abdomen.

Various kinds of mechanical obstruction have been found in fatal cases of ileus. The obstruction is occasionally connected with disease of the intestine, with hernial protrusions, with adhesions between two contiguous portions of intestine; so that, as in a case recorded by Dr. Abercrombie, a turn of intestine insinuates itself between the two adherent portions. Various forms of internal hernia, twisting of a portion of the bowel upon itself, intussusception or invagination and calculous concretions (intestinal calculi), have also been discovered in fatal cases of ileus.

The symptoms of colic have been traced to various organic changes of structure, which diminish the caliber of the intestine. Under these, are comprehended contraction or stricture of the bowel, which are situated less frequently in the small than in the large intestines; various morbid growths or tumours having their origin in the internal surface of the bowel, and which in their progress gradually diminish its diameter, till at length even liquids do not pass through the diseased or contracted portion.

The following observations of Dr. Abercrombie are valuable from the practical inferences to which they give rise. "From a review of the whole subject, it appears that there is a remarkable variety in the morbid appearances in those cases which are usually included under the term ileus. We have seen simple distention without any change of structure, and we have seen even extensive inflammation and gangrene. We have seen in several instances the distention apparently taking place at an early period, and gradually increasing through a protracted case, and then fatal, with little or no change in the texture of the part; and in others, we have seen at a very early period, and with

much less distension, extensive inflammation and gangrene. It would therefore appear probable, that in the cases which assume the character of ileus, there is great diversity in the primary state of the affected parts; that in some it consists of simple loss of muscular power, though it may pass into inflammation at an advanced period; while in others it is at an early period connected with inflammation as a part of the primary disease. These cases seem to differ from enteritis in their symptoms chiefly by the absence of fever; and in the morbid appearances, by being fatal with simple gangrene, uncombined with the flocculent or pseudo-membranous deposition which is so prominent a character of enteritis. Now gangrene in the intestinal canal appears to be chiefly a disease of the muscular coat. A state resembling it is indeed observed occasionally in the mucous membrane; but the cases in which this occurs are accurately distinguished by their own peculiar symptoms, and they do not affect this part of the enquiry. When, in the cases now under consideration, therefore, we find gangrene uncombined with any other morbid appearance, we are perhaps warranted to conjecture that the muscular coat has been the principal seat of the inflammation. It seems to constitute a modification of disease of much practical importance, quite distinct from enteritis, and assuming simply the characters of ileus; but a modification of ileus of the most formidable kind, and very rapidly fatal. We shall afterwards see reason to believe that inflammation may be seated in the peritoneal coat alone, producing a disease which may be fatal without any interruption of the action of the canal, or that it may affect the peritoneal and muscular coat at once, giving rise to the disease which we commonly call enteritis.\*

*Diagnosis.*—It is necessary to distinguish colic—1. from enteritis; 2. from hernia; 3. from obstinate vomiting, sympathetic of disease in some distant part.

The absence of fever, the pain being generally relieved by pressure, the aspect of the countenance, and the quiet soft pulse, will generally distinguish colic from enteritis. It is however never to be lost sight of that enteritis may not only exist, but may be proceeding to a fatal termination without frequency of the pulse or abdominal tenderness. On the other hand, there may be abdominal tenderness from simple distension of a portion of the intestine, but without inflammation. The stage of the disease must also be taken into consideration: though in the primary there may be no inflammation, in the more advanced stage it may supervene, and thus prove fatal.

When the symptoms of colic arise from a hernia, the protrusion will generally lead to its detection; besides, there is no pain in the beginning at least, and when it does occur, it is more circumscribed, and the tenderness does

not extend over the abdomen until the hernia has existed some time and has become strangulated.

There are many diseases accompanied by sympathetic vomiting, which may, without sufficient care, be confounded with colic. The sympathetic vomiting may arise from renal or biliary calculi, but in these cases there are some local signs of the origin of the affection; in the former case, pain of the back, and along the groins to the testicle and thigh, and disorder of the urinary functions; and in the latter, a greater disturbance of the functions of the liver, together with pain chiefly felt in the situation of the gall-ducts; besides, in neither of these diseases is there the same obstinate constipation of the bowels as in colic.

*Prognosis.*—The prognosis in this disease must depend principally on the nature of the exciting cause. When it arises from acrid ingesta, such offensive matters will generally pass spontaneously or by proper treatment, and thus the symptoms will cease. When, however, hernia, intus-susception, stricture, or organic disease produce an obstruction, of course the danger is in proportion to the hazard arising from the disease on which the colic depends; the symptoms of colic, in such instances, being entirely symptomatic of the primary affection. But, as we have seen, it is by no means an easy task, nay, often impossible, to distinguish the cases originating in such obstructions from those which are less dangerous; and the prognosis should therefore not be formed hastily in any case.

It has been observed by Dr. Abercrombie, that ileus has been fatal while the contents of the bowels were of a natural appearance; and when obstruction has existed, its entire removal has not been followed by corresponding relief of the symptoms.

*Treatment.*—We have seen that colic may depend on causes which are capable of removal, as well as on incurable organic disease; and the symptoms in both classes of cases being nearly similar, it is impossible to ascertain whether or not the colic depend on causes capable of being removed: we must proceed on the supposition that the disease is still capable of being controlled. It is always, however, a necessary precaution to ascertain that the symptoms do not arise from hernial protrusion, as it has not unfrequently happened that hernia, which has been the cause of the symptoms, has been over-looked, and the life of the patient thus exposed to danger. When the practitioner is satisfied that there is no hernial protrusion, or that there is no evident external cause to account for the symptoms, it will be a safe practical rule in all cases of obstinate colic, more particularly if the pulse rise, and there be tenderness of the belly, and the powers of the patient do not forbid it, to abstract blood, both with the view of anticipating inflammation, or subduing that which is to be apprehended, and as a powerful means of procuring the evacuation of the bowels; the syncope, which generally follows bloodletting,

\* Pathological and Practical Researches on Diseases of the Stomach and Intestinal Canal, p. 140.

especially if performed when the patient is placed in the upright posture, being often accompanied with this effect. The bloodletting may therefore be carried to this extent in all cases where the patient is vigorous, and even repeated if the state of the pulse and other symptoms require it.

In persons who are weak, and in elderly people, however, due consideration must be given as to the expediency of bloodletting. In such cases the topical abstraction of blood may be more advisable.

It is a matter of nice practical enquiry, how far the intestines should be stimulated by purgatives: on this point Dr. Abercrombie truly observes that the adaptation of the remedies to the individual cases demands the utmost discretion: it is impossible to lay down any general rules. There are some cases which yield at first to a powerful purgative, and there are others in which an active purgative is decidedly injurious. With these sentiments our individual experience leads us to concur, as well as with the plan of administering, at short intervals, moderate doses of mild aperients. Sometimes large doses of calomel, eight, ten, or even twenty grains, will remain on the stomach, and in the course of a short time move the bowels; in other instances very small doses of purgatives in combination, and frequently repeated, answer this purpose. Purgatives will often operate best when combined with sedatives, and this is explained by the effect of the sedative taking off resistance by allaying undue contraction in the muscular fibres of the intestines, while the purgative excites the general peristaltic action, and increases the secretions from the mucous membrane. Calomel combined with opium may be given with advantage every second hour for three or four times, and then a full dose of castor-oil. If the oil be rejected by vomiting, it may be repeated with the addition of twenty or thirty drops of laudanum, and an enema, containing castor-oil and laudanum, be administered to assist the operation of the aperient. In some cases attended with most obstinate vomiting, we have seen a drop of croton oil rubbed on the tongue, and repeated six, eight, or ten times, at intervals of half an hour, procure solution of the bowels when every other purgative had been rejected as soon as it had reached the stomach.

While we endeavour to act on the bowels by aperient medicines given by the mouth, and also in cases in which they are at once rejected, it is expedient to stimulate the colon by injections: these may consist of a combination of various purgatives in common use—infusion of senna, to which may be added neutral salts, cathartic extract, croton oil, turpentine, &c. The forcible injection of a large quantity (five or six pints) of warm water, in which soap has been dissolved, has proved successful. The tobacco glyster has been administered when the ordinary remedies have failed. It should be exhibited with much caution. Dr. Abercrombie recommends that the enema should be made by *infusing* fifteen

grains of tobacco in six ounces of boiling water for ten minutes. If no effect has been produced by this injection after the lapse of an hour, it may be repeated in the strength of one scruple to the same quantity of water; and so on, until such effects are produced (slight giddiness, muscular relaxation, &c.) as show that its peculiar action on the system is taking place. It may then be repeated at intervals of one or two hours, if the case do not speedily yield. With these precautions he states that he has seldom seen any unpleasant effect from the free use of this powerful remedy. He adds, if while the tobacco injection is used in this manner, mild purgatives, such as aloes and hyoscyamus, are repeated in full doses every hour or two, the treatment is perhaps that which is most generally adapted to the ordinary cases of ileus, with the assistance of one or two bleedings if the symptoms require it, and especially if the patient be of a full habit. Opiates are very often useful in colic to allay pain. After a full bleeding, when there is tenderness, the administration of a full dose of opium, combined with an aperient, or thrown into the rectum by glyster, is often followed by relief of the pain, and evacuation of the bowels. Still, however, from the tendency of opium to diminish secretion and to suspend the peristaltic motion of the intestines, it should not be indiscriminately prescribed, but only when there are paroxysms of severe tormina. In these cases it should either be combined with a purgative, or, if given alone, it should be followed by some aperients.

There are other measures which should be put in force: the warm bath; hot fomentations, to which landanum may be added: large blisters or oil of turpentine may also be applied to the abdomen.

When the means recommended have failed, some physicians have advised the administration of crude quicksilver in doses of one or two pounds. Sometimes the sudden dashing of cold water on the extremities, and the application of cold to the belly, have afforded relief by procuring evacuation of the bowels. These are severe measures, and are only to be adopted when the disease has resisted every other plan of treatment.

In cases in which the colic depends on incurable organic disease, all measures are alike unsuccessful. The patient is generally, under such circumstances, speedily relieved of his sufferings by death; though in some instances life is protracted for an uncertain period, during which the unhappy victim endures the greatest agony. The only resource left is palliation by narcotics, and other means calculated to soothe the sufferings.

(John Whiting.—*A. Tweedie.*)

COLICA PICTONUM.—This form of colic is generally traceable to the action of lead upon the body, and is so called from its occurrence as an epidemic at Poitou. It has also received the names *Devonshire colic*, *painters' colic*, *plumbers' colic*. It seems pro-

table, from both fact and analogy, that this metal produces a specific disturbance of the animal economy, of which disturbance the symptoms of colic are only a manifestation so far as the alimentary canal partakes of the disorder. This agent, however, may produce a local disease, the effect of its morbid agency shewing itself more strongly in the part to which it is immediately applied. Persons who are employed in lead manufactories, or in smelting ores which contain lead, painters who use much white lead, and plumbers are more particularly the subjects of this disease; but it occasionally happens to patients who are employing some of the preparations of this metal for the cure of disease. Moreover this form of colic has occurred epidemically, and has been (as in the cases at Poitou) supposed to arise from the employment of the acetate of lead in clarifying wine, cider, and other liquors.\*

This affection has more largely fallen under the observation of those physicians on the continent residing where it prevails endemically. M. Ranque, Physician to the Hôtel Dieu at Orléans, has given a clear account of it, as it occurred between the years 1820 and 1826, among the persons who are employed in the white-lead manufactories at Orléans; and from this physician's account the author is induced to lay before his readers the symptoms of the disease. At first the patient loses his appetite; he feels sick, with increased discharge of saliva from the mouth; there is disturbance in the nervous system, and his nights are restless. He then vomits and discharges everything he has swallowed, mixed with bile and morbid secretions; to this succeeds pain in the abdomen, which is at first not constant, but returns at intervals, these intervals being longest at the commencement of the disease. The pain is severe about the navel, the epigastrium, the hypochondrium, the loins, and above the crest of the ileum. As the disease advances, the pain is almost constant, but is usually most severe at night, and is not increased by pressure. The abdomen is generally flat, but sometimes feels as if knotted, in other cases more or less distended. The disease is now attended with headach, pain of the limbs, especially of the inside of the thighs, knees, calves of the legs, ancles, and soles of the feet. There is no fever; the pulse, indeed, is often below 60 in a minute. Constipation of the bowels is an invariable symptom, although it does not always occur at the very commencement; the bowels are excessively obstinate, and when feces are discharged, they are dry and lumpy. The appearance of the urine is generally natural. The expression of the patient's countenance indicates distress, and there is great prostration. Symptoms of inflammation of the peritoneum occur now and then at an advanced stage of the disease, indicated by tenderness of the abdomen, frequent hard pulse, and other febrile symptoms; and in

some rare instances the cerebral functions are disturbed.

The pain of the limbs is sometimes very speedily succeeded by paralysis, but it is more frequently after the severer symptoms have passed away that the extremities become so affected.

The appearances presented by dissection after death throw but little light on the nature of colica pictonum. Inflammation of any of the textures appears to be only accidental, and is probably the effect when it occurs of the strong purges which are often used, or of the distention of the bowels, which is usually if not invariably discovered. It is particularly mentioned by those who have had opportunities of inspecting the bodies of persons who have died from the effects of lead, that the bowels appear remarkably pale, as if the quantity of blood in the vessels was less than usual. As has just been remarked, the intestines are often greatly distended in some parts, but in others they are contracted. Whether this contraction is the consequence of spasm, or (as Dr. Abercrombie would say) only the natural state of the tube when empty, it is not easy to determine; and this uncertainty about the cause of the contraction renders it very doubtful whether the distention is the consequence of spasmodic obstruction, or the effect of debility or paralysis; but as we know that the action of lead on other muscular fibres of the body is to destroy their tone, it is the most probable conjecture that those of the intestinal canal, when affected by this poison, cease to be able to propel their contents forward, and that in this way distention takes place.

The foregoing history renders it clear that the action of lead upon the system is very general; and it also seems calculated to lead to the opinion that the symptoms arise from changes in the intestines, analogous to those which are produced in other parts of the body. The primary impression made by this metallic poison is probably upon the nervous system, which secondarily causes a change in the bloodvessels and the muscular fibres. Upon the muscular and vascular system it seems to act as a powerful sedative. It is probable that it is on account of its sedative action on the capillary system that lead is found useful in some cases of hemorrhage and inflammation—may it not be from this same action upon the capillaries that the muscles become paralysed? It is a well-known fact that without a due supply of blood to their texture, the muscles lose their tone. The shrunk wasted state and the blanched appearance of the muscles of persons who have died after having been paralytic from lead, seem to favour this opinion. In explanation of the primary action of lead upon the nervous system, it is difficult to form a reasonable conjecture. The acute pains which are felt at the commencement of the disease in different parts of the body, forbid the supposition that it acts as a sedative upon the nerves; and the fact that the sentient nerves of the limbs, when the muscles are paralysed by lead, remain as

\* See the papers of Sir George Baker in the Transactions of the College of Physicians of London.

as sensitive as in health, favours the same conclusion.

It may here with propriety be observed, that after the first severe symptoms of colica pictonum have been removed by free evacuations from the bowels, there remains usually great torpor of the alimentary canal, and that it is probable that this torpor is the result of a paralytic condition more or less complete of the muscular fibres which produce the peristaltic action of the canal.

*Treatment.*—The remarks on the nature of the disease tend to shew that the treatment of colic arising from the poisonous effects of lead must be regulated by nearly the same indications as those which have been recommended for the treatment of colic from other causes. The object is, first, to procure a full discharge of the alvine contents, and afterwards to restore the bowels to their healthy condition. Purgatives, combined with sedatives, seem well calculated to fulfil the first intention; and no combination is better adapted than that of calomel and opium in the proportions already recommended. After a few doses, a large dose of castor-oil, or a drop or two of croton-oil may be given; enemata also will be found valuable auxiliaries; they should be administered about the time the purgatives may be expected to begin to act. The warm bath, the tobacco enema, and the other measures suggested as useful occasionally in the cure of colic, may here also be employed; and should there occur tenderness of the abdomen, or any of the signs of inflammation, bleeding from the arm or by leeches will be required. Emetics are employed largely on the continent. At the Hospital La Charité, at Paris, a very complicated plan of cure is adopted, but which, when analyzed, seems to be analogous to that which has been recommended in this article, although strangely pursued: it consists of emetics, cathartics, enemata, diluents, and anodynes. (See M. Andral on Abdominal Diseases.) M. Ranque, in the memoir already alluded to, recommends, on the ground of extensive evidence of its efficacy, the employment of strong counter-irritation to the abdomen and back by means of a plaster which contains cantharides and tartar emetic; and he also prescribes a liniment, made with some convenient vehicle, containing the extract of belladonna, to be rubbed on every part where pain is felt; he uses also belladonna in clysters; and the same sedative by the stomach, in the form of an ethereal tincture, (ʒi of the powdered leaves to ℥iij of sulph. ether, of which twenty drops is the dose.) The only peculiarity in this method of cure is the counter-irritation, which may probably with advantage be added to the list of curative means.

If the opinion be correct that lead acts as a powerful sedative upon the bloodvessels, no measure can appear better calculated to meet this morbid effect than powerful irritants. It is a fact well established that the paralysis which results from lead is most effectually treated by the use of blisters or other stimu-

lating applications to the parts affected; and may we not, on the same principle, (through the medium of the sympathy which is so obviously maintained between the surface and the parts contained within the abdomen,) hope to rouse the activity of the circulation of the intestinal canal by strong irritants applied to the skin! When the first urgent symptoms are overcome, and the bowels have been made to act, great attention will be required to restore completely the tone of the digestive powers. Besides those means which have been enumerated as applicable during convalescence from common colic, astringents and stimulants seem particularly serviceable when a patient is recovering from colica pictonum. Alum in doses of ℥i, with a few grains of ginger or capsicum, may be taken with decided advantage two or three times a-day, with an occasional aloetic purge. The desideratum in this stage of the ailment is to restore the tone of the weakened bowel; and this will be most probably obtained by the combined effects of external and internal stimulants and astringents, wholesome and nutritious food, and a free state of the alimentary canal.

The *dry belly-ach* of the West Indies is a disease of nearly the same description as the colica pictonum, and so is the colic of Madrid, mentioned by Dr. Pascal, (Mém. de Méd. et Chirurg. Milit. 1826.) Dr. Musgrave, of Antigua, has, in the Medical Repository, 1825, given a very good account of the former of these two diseases which is so very common among the negroes of the West-India Islands. He attributes the complaint to a morbid condition of the liver; but, in the estimation of the writer of this article, without sufficient evidence. The condition of the alimentary canal, which has already been pointed out, and especially that portion of it, the duodenum, which receives the gall-ducts, seems sufficient to explain the disturbance of the biliary function which he describes. In the West Indies the disease is attributed to the new rum which is drunk by the slaves. Dr. Musgrave depends principally on mercury for the cure of this complaint, and carries it to salivation, assisted by bleeding and purgatives. It is evident that this gentleman is influenced in his plan of treatment by the pathological views he entertains of the disorder; and it is a question which no one is better qualified, by talent and opportunities, than himself to decide, whether the cure may not be accomplished by mercury more sparingly administered.

(John Whiting.)

COMA, (from  $\kappa\acute{\alpha}\tilde{\iota}$ , or  $\kappa\acute{\epsilon}\omega$ , to lie down,) a propensity to sleep; in pathology, a suppression, more or less complete, of the powers of sensation, thought, and voluntary motion. This may occur in various degrees, from a state of slight temporary drowsiness and torpor to one of profound and permanent stupor with general paralysis both of feeling and motion. The mental powers alone may be affected, whilst sensation and voluntary motion remain

unimpaired. There may be suspension only of some of the intellectual faculties, as occurs in somnambulism and several forms of lethargy; or thought, sensation, and voluntary motion may be alike completely abolished, and life only sustained by a partial supply of nervous influence to the involuntary organs. These modifications of disease are easily accounted for by the natural divisions of the nervous system into parts having distinct functions.

Coma is a symptom not characteristic of any one condition of the brain, but may exist in connexion with morbid actions very different and even opposite in their nature. Nosologists have on this account been greatly embarrassed how to dispose of comatose affections in their classifications of disease, so as to bring them under one head. By attempting this they have introduced a degree of confusion calculated to lead to dangerous mistakes in practice; for comatose affections, decidedly connected with an inflammatory condition of the brain, have been erroneously ranged under the class *neuroses* or *adynamia*, to which classes some other of these affections, originating in debility, legitimately belong. Coma may either be a primary affection, or supervene in the course of other diseases, as a symptom. In Cullen's system, comatose affections constitute the first order of the class *neuroses*, under the title *Comata*, which order is divided into two genera, *apoplexy* and *paralysis*. Those affections which are more especially comatose, such as apoplexy, carus, cataphora, catalepsy, ecstasy, and all the varieties of lethargy, are included under the first genus. Dr. Mason Good, in his *Nosology*, classes all the affections characterised by torpor, either mental or corporeal, under the genus *carus*, having six species—*asphyxia*, *ecstasis*, *cataplesia*, *lethargus*, *apoplexia*, *paralysis*. The strong sympathy which the different parts of the brain and nervous system have with each other, establishes a close connexion between several of these forms of coma, and they not unfrequently pass into one another. In the present article we intend to confine ourselves to a brief description of the characteristic features of each of these affections; a more detailed history of some of them will be given under separate heads.

By *lethargy* is meant a torpor both mental and corporeal, with deep quiet sleep; it has a close affinity to natural sleep, differing chiefly in being more prolonged, and depending on a morbid condition of the brain. This is the slightest form of coma, and has been termed also, by some writers, *cataphora*.

*Catalepsy*, or *trance*, is a total suspension of sensibility and voluntary motion, mostly also of mental power: the pulse and breathing continue natural, the muscles are flexible, the body yielding to and retaining any given position. (See *CATALEPSY*.)

*Ecstasy* is a total suspension of sensibility and voluntary motion, mostly also of mental power; the pulse and breathing remain natural, the muscles are rigid, the body erect and inflexible. It is persons of a nervous tempera-

ment and ardent imagination, much given to reverie and deep abstraction, who are most subject to this affection. The power of attention appears wholly concentrated on one train of thought engaging only a few of the intellectual faculties, whilst the others remain in a state of complete torpor. The patient seems to experience, for the time, a high degree of intellectual enjoyment. This is the description of *ecstasy* given by ancient writers, by some of whom it has also been termed *catochus* and *catoclie*.

There is a complete abeyance of the mental faculties, of the external senses, of feeling, and voluntary motion, in the most perfect and aggravated forms of coma. The pulse is generally very slow, either full and soft, or small and hard; sometimes intermittent, at others, however, rapid, feeble, and irregular. The breathing is slow, laboured, irregular, and stertorous, the stertor arising from the relaxation and paralysis of the muscles of the internal fauces. There is sometimes dropping of the lower jaw and distention of the cheeks at each expiration, with difficulty of deglutition. The pupils are dilated and insensible to the strongest light: in some cases, however, they are either contracted or insensible, or one pupil is contracted and the other dilated. The surface of the body and the extremities are cold and clammy; the patient lies supine, and there are several other distressing symptoms indicating the rapid approach of death. This is the form of coma that generally attends diseases affecting the structure of the brain,—apoplexy, paralysis, meningitis, cerebritis, hydrocephalus, &c. It has been named by some nosologists *carus*. Others have described coma as a degree of torpor more profound than lethargy, but less than *carus*. Coma is sometimes attended with low muttering delirium, and has then been called *coma vigil*; and when resembling more a profound sleep, *coma somnolentum*.

The attack of coma is sometimes sudden, without any premonitory symptoms, and it may assume at once its most aggravated character, terminating speedily in dissolution. In other cases the loss of sense and motion is less complete, and consciousness returns in a few minutes or hours. There may be a recurrence of the attack in either regular or irregular paroxysms, as occurs in epilepsy. The invasion and progress of the complaint are, however, sometimes very slow. It commences by a tendency to drowsiness, which gradually increases until it reaches the state of complete coma. It frequently succeeds or alternates with convulsions and high delirium, and in such cases is to be considered a symptom of worse omen than delirium.

The most frequent and obvious cause of coma is pressure on the brain. A state of perfect coma can be produced artificially by applying pressure to the brain of an animal, and the coma is relieved the moment the pressure is taken off. The brain is exposed to pressure from a variety of causes. The principal of these are, congestion, inflammation, effusions of blood, pus, or serous fluid, organic tumours seated in the brain, in its membranes,

or on the parietes of the skull, fractures of the skull, with depression, &c. Coma is perhaps too frequently attributed to serous effusion in the brain, which may exist in a considerable degree without any coma, more especially when it takes place very slowly. Sudden attacks of temporary coma sometimes occur in consequence of the distended state of the stomach and bowels, compressing the large vessels in the neighbourhood of the heart, and causing an accumulation of blood in the head.

Another very important and not uncommon cause of coma is a deficiency of nervous energy of the brain. There are various ways in which this may happen. It may take place suddenly, as the consequence of a violent shock or commotion given to the brain by a fall or a blow, causing some temporary derangement of the contents of the head, and suspending the operation of the nervous principle; this is termed concussion. The same effect may be produced without any physical cause, by violent impressions made on the nervous centres, and suddenly paralysing, as it were, the action of the nervous principle, as sometimes happens after strong mental emotions, or the intense pain of severe operations. In such cases the patient sinks into a state of profound coma, from which there are instances of his never recovering; nature appearing, as is remarked by some writers, suddenly to relinquish the struggle. Intense cold acts on the brain and nervous system by producing a state of numbness and torpor which speedily passes into coma, and terminates in death.

This loss of power in the functions of the brain, or in the nervous principle of the brain, may however have occurred very gradually; and the fact of this being a cause of coma is a highly important one, which, until lately, had been too much overlooked. The profession is much indebted to the late Dr. Good and to Dr. Marshall Hall for having directed their attention to this principle in pathology. After protracted attacks of inflammatory diseases, when the patient, although considerably weakened, is considered nearly convalescent, he sometimes falls into a state of coma, preceded occasionally by acute cerebral symptoms. Children are particularly subject to this variety of coma from exhaustion; they lie in a state of insensibility, the pupils dilated, the eyes open and insensible, the face pale, the skin cold, and the pulse feeble; they may continue for a day or two in this kind of stupor, and then recover. We apprehend, however, that these symptoms have often been mistaken for those of hydrocephalus, and that death has been hastened by the active treatment employed. There are in other cases symptoms of considerable nervous irritation, headache, delirium, great frequency and irregularity of pulse, general restlessness, which are sooner or later succeeded by fatal coma. This affection has been observed in persons who had long suffered from great mental distress. Dr. Kellie and Dr. Abercrombie have attempted to give an explanation of these phenomena, which appears not unreasonable; they suppose that

when the general volume of the blood is much diminished, that balance of the circulation in the brain which seems necessary for the healthy condition of its functions is destroyed; that the arteries of the brain become contracted in their caliber, in consequence of receiving a less quantity of blood; but that, as the whole quantity of blood in the head must always continue nearly the same, a proportionate accumulation takes place in the veins and their sinuses, producing venous congestion. The considerable venous congestion observed in the heads of animals which have been bled to death, whilst the other parts of the body are blanched and drained of their blood, favours this explanation. Some of the old writers mention a form of apoplexy analogous to this affection, to which they have given the name of *apoplexia ex inanitione*. A state of high mental excitement is in some cases followed by collapse and coma. This happens in individuals endowed with a highly sensitive and irritable nervous system, possessing more imagination than judgment, and subject to alternations of great exultation and a proportionate depression of spirits. It is persons of this temperament who are generally exposed to attacks of lethargy, catalepsy, somnambulism, &c. The coma of hysteria belongs to the same class of cases.

The use of certain medicinal and other substances may be followed by coma, in consequence of their specific action on the brain and nervous system. This is the case with narcotics and spirituous liquors. The effects of spirituous liquors, and of some stimulating narcotics, may partly be accounted for by their causing an increased flow of blood to the head, and a temporary congestion; but, independent of this, they have a direct and specific action on the nervous energy, which they first highly stimulate and disturb, and next appear to prostrate and paralyse. This is what occurs in intoxication from alcoholic liquors and opium. There are other powerful narcotics, the effect of which seems to be that of at once paralysing and extinguishing the nervous energy, without previous excitement, causing thus almost instantaneous death. This is the mode of operation of the opus, tobacco, belladonna, &c. Some narcotics stimulate in small doses, and cause direct stupor in large doses.

Amongst the causes of comatose affections are to be mentioned, retrocedent gout, the suppression of exanthems or old sores, of the hemorrhoidal and menstrual flux, &c. In cases of coma, strict inquiry into these points should never be omitted.

The great practical importance of being able to distinguish accurately between the different varieties of coma must appear obvious, when we consider how widely the causes which have just been enumerated differ from each other in their nature, and that the most opposite remedies will be required for their removal. The diagnosis, however, in these affections is sometimes involved in great obscurity; and when the attack of coma is sudden, as the physician is required to act im-

mediately, he may find himself placed in a delicate and perplexing situation, for the life of the patient may depend on his selecting the right course of treatment.

The important question he will have to determine is, the exact condition of the brain to which the symptoms of coma owe their existence; whether they are to be ascribed to any of the causes of cerebral pressure, such as congestion, effusions of blood, pus, or serous fluid, fractures of the skull with depression, &c.; whether simply to the weak and torpid state of the nervous energy of the brain, or whether finally to both these causes, and in what degree they are combined. Much correct information respecting these points, and the degree of danger with which the case is attended, will be obtained by inquiring carefully into the state of the circulation and respiration, and into that likewise of the temperature and sensibility of the surface of the body and of the extremities: an accurate account of the patient's state of health previous to the attack will sometimes throw considerable light on its nature.

In the milder forms of coma, the structure of the brain is not affected; there is only a slight degree either of vascular congestion or of nervous torpor, or else a combination of both these conditions. The patient lies in a quiet sleep, out of which he can sometimes be momentarily roused by calling aloud or shaking him. The breathing is tranquil and free; the pulse soft and regular; the temperature of the body natural, and the feeling but little impaired; the pupils may be a little dilated, but retain some degree of motion. This is the usual condition of the patient in attacks of lethargy, catalepsy, ecstasy, and in the coma which follows moral emotions. When coma supervenes on gradual exhaustion, the antecedent circumstances of the case, the pallidness of the countenance, febleness of the pulse, and coldness of the surface, will sufficiently point out its true nature.

The characteristic features of the most aggravated form of coma have already been described; they are generally to be ascribed to some disease seriously affecting the structure of the brain, or else to a formidable prostration of its nervous power. Stertorous breathing has been insisted on as a sure sign of danger; its absence is not, however, to be taken as a proof of the reverse. But we may lay down as a general rule, that the danger is always in proportion to the degree in which the respiration, the circulation, and the temperature of the body are affected.

The distinction between the coma which follows simple concussion of the brain, and that arising from compression in consequence of fracture and depression of the cranium, or else effusion of blood on its inner surface without fracture, has been a point of interesting inquiry with surgical writers; having principally for its object to determine under what circumstances operations are to be performed in injuries of the head. A great deal of valuable information on this subject is to be

collected from the works of Pott, Abernethy, and Dessault. Cases of slight concussion are easily distinguished from compression, the patient still retaining some degree of consciousness and feeling, and the stupor being soon relieved. But in cases of very violent concussion, where the prostration of the sensorial power is extreme, the coma is so complete, and the symptoms so closely resemble those of compression, that the most experienced observers acknowledge the difficulty of drawing any exact line of distinction between them. The chief source of apprehension in simple concussion is the period of stupor being followed by one of inflammatory reaction.

Abernethy gives the following very graphic account of concussion, which he thinks may be divided into three stages. The first stage is that of insensibility and derangement of the bodily powers, which immediately succeeds the accident. Whilst it lasts, the patient scarcely feels any injury that may be inflicted on him. His breathing is difficult, but in general without stertor; his pulse intermitting, and his extremities are cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which he considers the *second* stage of concussion. In this, the pulse and respiration become better, and though not regularly performed, are sufficient to maintain life and to diffuse warmth over the extreme parts of the body; the feeling of the patient is now so far restored that he is sensible if his skin be pinched; but he is stupid and inattentive to slight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to his chief suffering at the time, as pain in the head, &c.; otherwise he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate; but as the former abates, the latter seldom fails to increase, and this constitutes the *third* stage, which is the most important of the series of effects proceeding from concussion. These several stages vary considerably in degree and duration. Mr. Abernethy proceeds to observe that the treatment must be different in each of them, and to caution against the very free use of stimulants in the first stage, which is too often prescribed, and particularly against their continued exhibition in the third stage, when a plan of treatment directly the reverse is required.

The coma produced by excessive intoxication has some similarity to that of apoplexy, and we have known this lead to ludicrous mistakes, not very creditable to the practitioners' discernment. The smell of the breath will in most cases supply a sure means of avoiding such errors; in some extreme, though rare instances, actual coma has, however, supervened. It is deserving of notice that impostors, who feign epilepsy with a view to extort charity, can always be detected by examining their eyes, when the pupils will be

found in their natural state as to size and sensibility. In epilepsy they are almost always contracted and insensible. In coma they are generally, though not always, dilated, and their sensibility is more or less diminished.

Syncope and asphyxia bear a close resemblance to coma in many of their symptoms; they are characterized, in common with coma, by the absence of sensation and motion, by dilatation and insensibility of the pupils, &c. They differ chiefly, however, in the state of the respiration and general circulation. The primary cause of syncope is a diminution or temporary cessation of the action of the heart; the brain being thus deprived of the usual supply of its natural stimulus, the flow of nervous influence from the sensorium, which is indispensable for the maintenance of all the actions of life, is suspended, and a general torpor with other symptoms of apparent death is the necessary consequence. In asphyxia the circulation is also stopped, through the interruption of the functions of the lungs. The primary symptoms therefore in both these diseases are a great feebleness or complete suspension of the action of the heart and lungs, and the occurrence of coma is but secondary; while, when the same symptoms occur in coma, it is only secondarily and in its advanced stages. It is not unimportant to attend to these distinctions, for we have seen a protracted fit of syncope in a fat corpulent person mistaken for apoplectic coma, and the adoption of active remedies nearly followed by fatal consequences.

As the treatment of the various kinds of comatose affections will be described under their respective heads, we intend in the present article to confine ourselves to some general observations on bloodletting in this class of diseases. When a person is suddenly deprived of sense and motion, the practitioner sent for is expected by the alarmed friends to employ instantly some active and efficient means of relief, and it is a very general rule with the profession to have recourse at once to the lancet. Should there even be any doubt in the mind of the practitioner respecting the propriety of such a course, he may still be driven to adopt it, in deference to the opinions of the public, who ignorantly conclude that, because bloodletting affords relief in some sudden fits, it is equally essential in all. If the patient recovers, the cure is attributed to the venesection; and if he dies, it is hastily inferred that nothing would have saved him. If we turn, however, to a calm consideration of the various and very opposite causes of comatose affections, it will appear a most obvious truth that nothing can be more contrary to the legitimate deductions of science, and more dangerous in practice, than this indiscriminate and empirical use of the lancet. It has been seen that among the causes of coma, some are connected with morbid conditions of the substance of the brain for the removal of which bloodletting is the only, if not a sovereign, remedy; but that on the other hand coma is frequently to be ascribed to a

deficiency or prostration of the nervous energy of the brain, in which case it is evident that the subtraction of any large quantity of the vital fluid can only have the effect of preventing the powers of the constitution from rallying, and of thus turning the scale against the patient's recovery. We have little doubt that some of the recoveries from coma after bloodletting ought to be considered as lucky escapes from death, rather than cures.

There are, as just stated, well marked cases in which there cannot be a shadow of doubt as to the propriety of venesection; as, for instance, when the coma is very profound, with a flushed face, hot skin, full and strong pulse, stertorous breathing, &c. But when in the young, the aged, or the infirm, there are evident symptoms of great debility; when the face is pale, the skin and extremities cold, the pulse feeble, the breathing not much embarrassed, &c. the propriety of general depletion to remove symptoms of coma is more than questionable; all the relief that bloodletting is capable of affording can be obtained from cupping or leeches, should even local depletion be thought necessary; and we have seen coma depending on cerebral pressure very quickly relieved by the abstraction of only three or four ounces of blood from the head; an apparently trifling cause being sometimes sufficient to destroy the balance of the circulation in the brain.

We are aware that there may be cases in which the indications both for and against general bloodletting are so nicely balanced, that it is difficult to determine which course to pursue. Under such circumstances we must proceed with great caution,—and a small bleeding may be tried for the purpose of exploring the nature of the case; we should watch the effects produced, as the blood flows; and in all doubtful cases it is preferable to take a small quantity only at first, as the operation can easily be repeated if judged advisable. In coma as well as in asphyxia, when the powers of life are sunk very low and appear to be fast ebbing, a favourable reaction is sometimes prevented from taking place by the circumstance of either the brain or the heart being completely overpowered by an excessive accumulation of blood. The timely abstraction of a very few ounces of blood has sometimes appeared to be of essential service in such cases, by relieving the mechanical oppression of the organ, and enabling it to recover a slight degree of action, sufficient perhaps to lead gradually to a favourable reaction in the other vital functions; whilst copious bleeding under similar circumstances would most probably have completely extinguished the remaining sparks of life.

The temperature of the surface of the body may be considered one of the safest guides with respect to the propriety of bloodletting, together with the state of the pulse and the action of the heart. We have never, indeed, seen beneficial effects follow venesection, when the animal heat has been very low, even although the strength of the pulse might ap-

pear to justify its being prescribed. The temperature of the body is, perhaps, a safer general criterion of the exact condition of the powers of life than even the pulse; for do we not see the arteries pulsating and throbbing with great force and frequency in cases where there is an undoubted tendency to debility and sinking? Whilst, however, a low state of the animal temperature is sufficient of itself to counter-indicate copious depletion, the opposite condition must not always be conceived to justify the use of the lancet: for a morbid pungent heat is a frequent attendant on a state of great irritability of the nervous system, characterized also by a quick throbbing irregular pulse, but indicative of a general and dangerous deficiency of the powers of life. This important point of pathology will be more fully examined in the article INFLAMMATION. We shall conclude therefore by repeating, that the practice of bleeding rashly and indiscriminately to a large amount in all cases of sudden loss of sense and motion, cannot be too strongly deprecated. A good paper on this interesting subject, by Dr. Latham, will be found in the 6th volume of the Transactions of the London College of Physicians.

(*Adair Crawford.*)

COMBUSTION, SPONTANEOUS HUMAN. When we reflect upon the difficulty with which the proximate principles of the animal kingdom are made to undergo combustion, even when exposed under the most favourable circumstances to an elevated heat, it is not to be wondered at that relations of this process having spontaneously occurred should have been received with suspicion, and ascribed for a length of time to credulity or imposture. That cases however of this kind have really taken place seems now established by indisputable evidence; but while the fact is very generally admitted, we are still, as in the instance of meteoric stones, at a loss for an adequate explanation of it. Before entering upon an analysis of the different conjectures which have been hazarded upon so obscure a subject, we shall first quote, for the purpose of illustration, a few well authenticated instances of individuals who have fallen victims to this most mysterious of all human affections.

Cornelia Bandi, Countess of Cesina, an Italian lady, sixty-two years of age, having felt drowsy one evening, retired earlier than usual to bed, and was attended by her maid until she fell asleep. When the girl on the following morning entered her mistress's apartment for the purpose of awakening her, a dreadful spectacle presented itself. At the distance of four feet from the bed there was a heap of ashes, in which the head, legs, and arms of the countess alone could be traced. The head lay between the legs, but the half of its posterior part, together with the brain and chin, were entirely consumed. The legs and arms were uninjured. The ashes, which alone remained of the rest of the body, when touched, left upon the fingers a greasy fetid moisture; and a sooty matter

was deposited upon the furniture and tapestry, and had even penetrated into some drawers and soiled the linen which they contained. There was no unusual derangement of the bed, the bed-clothes being merely thrown aside, as is the case when a person gets up. The wax of two candles placed upon a table near the bed was melted, but the wicks remained unconsumed. It is deserving of remark that it was a constant practice with this lady to bathe her body with camphorated spirit of wine. This case was first published by Bianchini, but is chiefly known to the British public in a paper communicated to the Royal Society by Dr. Cromwell Mortimer, and which may be found in the Philosophical Transactions for the year 1745.

Don G. Maria Bertholi, a friar, who lived in Mount Volere, went to the fair of Filetto, and having walked about all day, retired in the evening to the house of a relation at Fenile, to spend the night. Upon his arrival he went direct to his bed-room, and had a handkerchief placed between his shoulders beneath his shirt. In a few minutes after, having been left alone, a singular noise, mingled with cries, was heard from his room; and when the people of the house rushed in, they found him on the floor, surrounded by a lambent flame, which retired as they approached. When visited next morning by Joseph Battaglia, a surgeon of Ponte Basio, the integuments of the right arm were found loosened from the muscles, and hanging down, and those of the back, between the shoulders and the thighs, were in the same state. The part of the right arm which had sustained most injury appeared in a state of incipient putrefaction, and next day was quite gangrenous. On the third day there were thirst, fever, violent convulsions, fetid stools, vomiting, and delirium; and the gangrene had extended to all the injured parts. On the fourth day he fell into a comatose state, which lasted two hours, and then died. Battaglia observed, during his last visit, that putrefaction had commenced, and indeed had already made considerable progress. The nails had loosened and were ready to fall off. The stench was insupportable, and maggots crawled from the body at every point. The account which the patient gave of his singular attack was, that he felt a blow upon the right arm as if inflicted by a club, and then saw a spark hanging to his shirt-sleeve, which immediately reduced it to ashes. The handkerchief already spoken of, as also his drawers, were uninjured; but his nightcap was consumed, although his hair was not touched. There was no empyreumatic smell, and not a trace of fire or smoke in the room. It should also be observed that the night was calm, cool, and clear.

A detailed account of this case appeared in the Allgemeine Literatur Zeitung for 1786. It has been transcribed by most writers on juridical medicine, partly in consequence of its singularity, but chiefly because it is conceived to illustrate and support the electrical theory of the origin of what is denominated spontaneous combustion. It is also remarkable as being

the only well established instance of an individual who suffered from such a calamity having lived sufficiently long to give an account of the manner in which he was attacked.

Anne Nelis, wife to a wine and porter merchant, living in South Frederick street, Dublin, let in her husband, who had been out at a party, between twelve and one o'clock on a Saturday night. After some altercation had taken place between them, both being in a state of intoxication, Mr. Nelis went up stairs to bed, but in a few minutes came down to request his wife to accompany him, an invitation which she positively declined; upon which he took with him her candle, observing that if she was determined to sit up, she should do so in the dark. Next morning the maid servant having opened the windows of the back parlour, observed something in the arm-chair in which Mrs. Nelis usually sat, which she at first sight imagined to have been put there by young Nelis, who at the instant entered the room, for the purpose of frightening her. Upon examination, however, it turned out to be the remains of her mistress, who was found in the following state. She was seated in the chair, at a distance from the fire, which appeared to have burned out, with her head leaning upon her right hand, and bearing behind against the wall. The trunk of the body was burned to a cinder, as also the clothes which invested it; but the pelvic region, the lower and upper extremities, and such portions of her dress as covered these parts, sustained no injury. Her face had a scorched appearance; but her hair, and the papers she had put in it, had entirely escaped. The back and seat of the chair had not suffered, but its arms were charred on the inner side where in contact with the body. With the exception of the arms of the chair, the combustion had not extended to surrounding bodies. The room was filled with a penetrating and offensive odour, which was still perceptible after the lapse of several days. This woman was about forty-five years of age, of low stature, had rather a tendency to corpulence, and was a confirmed drunkard. The preceding facts may, we believe, be depended on, though we have experienced very considerable difficulty in collecting them. Strange to say, there was no inquest; and such was the anxiety of the family to hush up every thing connected with the occurrence, that a request made by Dr. Tuomy, late Professor of Physic in the School of Medicine, to be permitted to examine the body, was refused.

The following case is extracted from the Methodist Magazine for 1809, as related by a Mr. Wood, a Wesleyan minister, then residing in Limerick. "Mr. O'Neill, keeper of the Five Pounds Alms-House in the city of Limerick, was awakened about two o'clock at night by a person knocking at his room door, upon which he arose, and having inquired who knocked, he opened the door, and going with the person who had called him into his apartment, which lay under Mrs. Peacocke's room, he found a dead body lying on the ground burning with fire, and red as copper, having

dropped down from the loft, which was on fire. Examining the loft, he saw a large hole, the size of the dead body, burned through the boards and ceiling. He instantly ran up stairs, and having burst open Mrs. Peacocke's room-door, saw in the middle of the room the burnt hole through which the body had fallen. Having with assistance quenched the fire about the hole, he examined by what means the body had taken fire, but could find no cause. There was no candle or candlestick near the place, no fire in the grate but what was raked in the ashes, as is the manner of preserving fire by night; the room was examined, and nothing had taken fire but that part of the floor through which she had fallen. Even a small basket made of twigs, and a small trunk of dry wood which lay near the hole, escaped, and were not so much as touched by the fire.

"This phenomenon was the next day examined by the mayor, clergymen, and several gentlemen of the city. The impossibility of ascertaining the cause of the fire, the extraordinary circumstance of no part of the room being burnt but the centre of it, through which she had fallen, added to the well authenticated circumstance of her recent diabolical imprecations and lies, obliged every observer to resolve so awful an event into 'the visitation of God's judgment in the punishment of a daring and persevering sinner.'"—It is proper to add here, that for the leading facts of this case we do not rely solely upon the Methodist Magazine. They have been detailed to us in a letter received from Mr. Wood himself, and confirmed by an intelligent lady residing in Limerick, who personally inspected the floor through which the hole was burned; the repairs undergone by which still point out the spot at which the perforation took place. We should not omit to mention that Mrs. Peacocke was about sixty years of age, and that she indulged immoderately in intoxicating liquors.

Mrs. Stout, widow of a watchmaker, and married a second time to a man of the name of Hanna, went to bed one evening in apparent health, and was found next morning burnt to a cinder on the floor of her bedroom. When discovered, a vapour was still issuing from her mouth and nostrils, and those parts of the body the form of which had not been altered, immediately crumbled down upon being handled. Her chemise and nightcap escaped uninjured. This case occurred in 1808, at a place called Coot Hill, in the county of Cavan. The subject of it was about sixty years of age, and an inveterate dram-drinker. An inquest was held, and from the impossibility of accounting for the occurrence upon any known principle, the verdict was—"death by the visitation of God."

A. B., a woman of about sixty years of age, who lived with her brother, in the county of Down, retired one evening to bed with her daughter, both being, as was their constant habit, in a state of intoxication. A little before day some members of the family were awakened by an extremely offensive smoke which pervaded their apartment, and on going into the chamber where the old woman and her daughter

ter slept, they found the smoke to proceed from the body of the former, which appeared to be burning with an internal fire. It was as black as coal, and the smoke issued from every part of it. The combustion having been arrested, which was effected with difficulty, although there was no flame, life was found completely extinct. While the body was being removed into the coffin, which was done as soon as possible, it was dropping in pieces. Her daughter, who slept in the same bed, sustained no injury; nor did the combustion extend to the bed or bed-clothes, which exhibited no other traces of fire than the stains produced by the smoke. According to the testimony of one of the relations, who is represented as a woman of the strictest veracity, there was no fire whatever in the room. The subject of this case had been grossly intemperate for several days before her decease, having drunk at this period much more ardent spirit than usual.

For the preceding facts we are indebted to the Rev. Mr. Ferguson, of Camden-street, Dublin. They are given almost exactly in his own words. He had professional opportunities of acquaintance with the family, and he states that shortly after the occurrence he examined the room in which the old woman had been burned, and satisfied himself that the fire had not extended to the bed, bed-clothes, or furniture.

From the cases just related, and several others which might be quoted from the writings of Vic D'Azyr, Lecat, Lair, Kopp, Dupuytren, and Mare, it would appear fully proved that the human body is capable of being reduced to such a state as to undergo spontaneously, or upon the contact of flame, rapid changes analogous to those which may be effected by the agency of fire. A careful examination, also, of the histories of the several instances upon record, has enabled us to collect, at least with some probability, the circumstances which precede, accompany, and characterize this malady; for such it obviously must be considered. These we shall now enumerate, as they will serve as a guide to our inquiries respecting the immediate or proximate cause of the phenomenon.

1. Spontaneous combustion would appear to be a calamity almost peculiar to the old and feeble; for it has seldom occurred to persons of a robust constitution, or under sixty years of age.

2. Women seem particularly prone to it. Thus, of the seventeen cases collected by Kopp, sixteen occurred to females, while the subjects of the eight cases mentioned by Lair are all of the same sex.

3. Individuals who have thus suffered have, generally speaking, been remarkable for the inactivity of their habits, for corpulency, or the opposite state, great emaciation, and for their inordinate use of spirituous liquors.

Of the circumstances which distinguish spontaneous from ordinary combustion, the following seem most deserving of notice.

1. The combustion spreads with extra-

ordinary rapidity; the decomposition of the entire body being usually effected in an extremely short period of time.

2. The flame is of a lambent and flickering nature, of a blue colour, very difficult to extinguish by water, and not readily communicable to inflammable bodies placed in its vicinity.

3. A strong empyreumatic odour is usually exhaled, and there is found upon adjacent objects a fetid and moist fuliginous deposit, of a greasy nature.

4. The trunk is generally entirely consumed, but portions of the head and extremities are occasionally left uninjured.

Before examining the theories which have been advanced in explanation of spontaneous human combustion, it will be convenient to define in what *ordinary* combustion consists, and the conditions indispensable to its production. We shall thus be the better prepared to pronounce upon received hypotheses a correct and impartial judgment.

When any two forms of matter, whether they be simple or compound, combine chemically with the evolution of heat and light, combustion is said to have taken place. In order therefore to the production of these phenomena, the contact of at least two dissimilar principles, having for each other a strong affinity, is essential. Combustion may thus obviously result from the chemical action of a variety of principles; but, in all ordinary cases, one of the substances concerned is oxygen, and the other carbon, or hydrogen, or some compound of both these elements. If to these we add sulphur and phosphorus, which are associated with the preceding as component parts of animal bodies, we shall have enumerated all the elements with which we can have any thing to do in our present discussion.

But the mere contact of oxygen with a combustible is seldom of itself sufficient to determine union, much less union with the development of heat and light. Carbon and sulphur may be encompassed by oxygen, and hydrogen mixed with it, without the occurrence of any chemical action; and though this is not true of phosphorus, the union of which with oxygen takes place at the usual temperature of the atmosphere, yet the process is slow, and visible flame is altogether wanting. These observations are equally applicable to the compounds which the combustibles form with each other, with a single exception. All of these but phosphurctted hydrogen, which inflames upon mere contact with oxygen gas, require, in order to accension, the application of a somewhat elevated heat. Neglecting therefore, for a moment, this particular compound, it may be laid down that the conditions of ordinary combustion are two-fold.

1. That the combustible be in contact with oxygen.

2. That its temperature be considerably raised.

Now the human body is a combustible com-

pound, and is constantly surrounded by an elastic medium, one-fifth of whose volume is pure oxygen gas. One of the conditions, therefore, necessary to combustion, is here fulfilled; and experience tells us that the co-existence of the other, that is, of a sufficient heat, will actually determine accension. But the human body, at least in a state of health, does not spontaneously take fire; and we also know that when heat is applied to any particular part of it, the mischief done is local, and does not extend to remote organs. In reference, therefore, to the subject of this article, two questions present themselves for solution.

First, whence arises that extreme degree of inflammability of the human body, in virtue of which its combustion is so readily produced, and, occurring at any one point, is propagated with rapidity to distant parts? And, secondly, how does the combustion commence—what is the origin of the first spark!

As to the cause of the preternatural combustibility of the human body, the opinion generally entertained is, that it is to be found in the alcoholic impregnation, which, as is alleged, invariably accompanies such a state. In support of this doctrine it is affirmed that individuals who die of intoxication emit at every point a strong smell of spirits; that the colour of the flame afforded by the latter is precisely the same as that which has been observed in cases of spontaneous combustion; and, lastly, that all who have fallen victims to this calamity have been remarkable for the immoderate use of intoxicating liquors.

That the bodies of drunkards may become, as it were, soaked with alcohol, seems fully established by observation. Thus, Breschet found the different tissues of the bodies of criminals, opened shortly after their execution, to evolve a strong smell of eau-de-vie; and a similar observation has been made by Dumeril and Cuvier upon the body of a labourer, at the Garden of Plants, who had died from the effects of a large quantity of wine, which he had drunk for a wager. Dr. Marc also mentions the case of a shepherd of Laliowitz, addicted to excessive drinking, who during his last illness was constantly affected with eructations of an inflammable nature, and which emitted a strong alcoholic odour. Some indeed, adopting an ancient physiological dogma, that, however the ingesta may vary, the chyle is always the same, deny the possibility of alcohol entering the circulation unaltered. It should, however, be recollected that many substances, such as the colouring matters of madder and rhubarb, and the odiferous parts of musk, camphor, and garlic, do certainly resist the assimilating powers of the digestive apparatus, and reappear unchanged in the secretions. Nor are such facts even opposed to the opinion to which allusion has just been made. These substances may enter the blood directly by the veins, which are now known to exercise the function of absorption, instead of reaching it through the

circuitous route of the lacteals and thoracic duct.

But the theory of alcoholic impregnation is, *per se*, quite insufficient. When a healthy individual dies of intoxication, his body is found but little, if at all, more inflammable than if he had perished from any other cause; and if the flame of a candle be applied to an anatomical preparation just removed from the spirits in which it has been preserved, after the combustion of the alcohol has ceased, the surface of the preparation alone will be found burned.

From these considerations it appears pretty certain, that though the human body may to a certain extent become impregnated with alcoholic vapours, its combustibility will not, by this alone, be materially augmented; and that, therefore, when a great tendency to combustion exists, it must be the result of some peculiar pathological state. In what this state consists, it is probably impossible with any accuracy to assert in the present state of our knowledge; but every thing which we know upon the subject justifies us in inferring that the causes which produce it are such as have most influence in reducing the powers of life and enervating the system. Thus it occurs, as we have seen, almost exclusively to people advanced in years, and of constitutions broken down or enfeebled by intemperate habits.

A theory of preternatural human combustibility has been more recently advanced by Dr. Marc, which appears better sustained by facts than that of alcoholic impregnation. This learned physician, who has apparently studied his subject with great attention, contends that the combustion is owing to inflammable gases which are, in such cases, developed throughout the system.

That inflammable gaseous products are usually present in the stomach and intestines, in health as well as in disease, is a fact well known to the physiologist; but it seems difficult to admit that these can be evolved in the different tissues during life; for such an opinion would appear to involve the possibility of the occurrence of some degree of spontaneous decomposition antecedent to death. There is, however, sufficient evidence that this has occasionally occurred. Besides the case of Father Bertholi already detailed, several others to this effect might be quoted. We shall, however, confine ourselves to the following, which is of recent date, and quite to the purpose.

A man ill for fourteen days with headach and colic pains, followed by an attack of diarrhoea, which lasted three days, was taken by M. Bally into the Hôtel-Dieu. Upon entering the hospital, his left thigh and scrotum were swollen, and his respiration was short and impeded; but he complained of nothing but weakness of the lower limbs. During a fit of delirium, which lasted a few minutes, he spoke of having been bitten by a dog in the leg; but upon examination no mark of any such injury could be found. He died on the night of the day on which he had been admitted

into the hospital, and on examination eight hours after, exhibited the following appearances:—Blood had transuded from the thighs and trunk, and was also found, in a gelatinous state, in the nasal cavities. The whole of the surface of the body was emphysematous, of a violet colour, and studded with a vesicular eruption in detached spots, the vesicles being filled, some with a reddish serum and gas, others with gas alone, the latter being of a white colour. The left leg and thigh were most swollen and puffy, and evidently contained fluid. The abdomen and scrotum were also much distended, the gas in the former occurring not within the intestines, but in the cavity of the peritoneum. The brain and spinal marrow were healthy, but the vessels of the pia mater contained air. Upon cutting into any emphysematous part, a gas escaped, which was set on fire by the flame of a candle; and from a perforation made in the abdomen a gas issued, which was ignited in a similar manner, and burned with a bluish flame.

This case, which was communicated to the Académie Nationale de Médecine, excited a good deal of discussion. M. Bally considered it as illustrating Dr. Marc's theory of spontaneous combustion, while others looked upon it as proving that the putrefactive process, from which alone they conceived the gases could be derived, may set in before death. This latter opinion may appear paradoxical, but it does not seem at all improbable, much less impossible, that a spontaneous though limited decomposition may in certain states of the system take place in the living body. The elements of organized matter are, we know, combined, under the influence of vitality, into compounds very different from those which they would form if submitted to the sole agency of their mutual affinities. When released from the controlling influence of the vital powers, they enter into new arrangements; and it is but reasonable to expect that effects similar, at least in kind, may attend the diminution of those powers which is the consequence of disease, to those which are known to follow upon their extinction by death.

It is not, however, necessary, in order to account for the development of the gases, to resort to the hypothesis of putrefaction. They may be the products of depraved secretion; and this opinion seems even established by the many cases upon record of the cellular substance having become emphysematous without the occurrence of any external injury. In fact, spontaneous emphysema is at present recognized by all nosologists. (See the article EMPHYSEMA; also *Frank de Retentionibus*, and the articles *Emphysème* and *Pneumatose*, in the *Dictionnaire des Sciences Médicales*.)

But though we admit, with Marc, that inflammable gases may be developed during life throughout the different textures, yet this will not explain the completeness of the incineration which has been observed to occur, nor the rapidity with which the combustion spreads over the whole body. If a taper be applied

to carburetted hydrogen, it will burn merely at its point of contact with the oxygen of the atmosphere; and to determine the instantaneous inflammation of a given volume of such gas, it must, previously to the application of the taper, be mixed with a certain quantity of oxygen. These facts, so familiar to the chemist, suggest a necessary modification of the hypothesis of Marc. The gases evolved cannot be all of an inflammable nature, but must include a proportion of oxygen, to act the part of a supporter. On this supposition they will constitute a species of explosive mixture, and we shall be enabled perfectly to comprehend the rapidity and the extent of the destruction which must ensue from their accension.

It must, however, be admitted that, though oxygen may proceed from secretion, it is a gas not likely to be liberated by any process of spontaneous change, for it does not occur amongst the products of putrefaction. The views, therefore, which have been here advanced must, until confirmed or refuted by chemical analysis, be considered as chiefly recommended by their adequacy to explain phenomena.

Having attempted to account for the preternatural inflammability of the human body, we shall now direct our attention to the manner in which the combustion commences. In most of the recorded cases some ignited body, as a candle, fire, or lighted pipe, has been found in the immediate vicinity of those who have suffered. The consequence of this has been that some have attributed the origin of the combustion in every instance to an external cause. Such was the doctrine first taught by Vic D'Azyr, and since sanctioned by Lair, Breschet, Dupuytren, and others. Should it prove well founded, the epithet *spontaneous* will obviously cease to be applicable to human combustion.

Others, however, amongst whom may be mentioned Maffei, Lecat, Kopp, and Marc, conceived this theory inadequate to the explanation of all the cases with which they were acquainted, and to supply its deficiency, called in the calorific powers of the electric fluid.

That electricity, in the form of a spark, is attended with the disengagement of heat, and is capable of setting inflammable substances on fire, are facts which cannot be contested. But the source of the electric accumulation, in the cases under consideration, remains to be satisfactorily pointed out. And, indeed, it may be added, that the statements that have hitherto been made upon the subject rest upon mere conjecture. Some conceive that certain persons possess the power of generating within themselves a state of electric tension, and quote relations of individuals who emitted sparks at the suggestion of the will. Dr. Marc has adopted this improbable hypothesis, and coupled with it one of his own, which appears equally destitute of foundation. The gases with which the body abounds in its combustible state sometimes become, according to him, ideo-electric, from an elevation of

their temperature, whether produced by exercise, exposure to a fire, or any other cause; and hence proceeds the spark which determines their accension. Lastly, others conceive the spark when it occurs to be purely accidental, and to result from the electric fluid selecting the human body as a conductor in its passage to or from the earth. This latter supposition being the only one which in modern science is admissible, we arrive at the conclusion that electricity can scarcely ever have any thing to do in producing human combustion.

It is believed by some that cases of genuine spontaneous combustion have taken place, or that the human body has sometimes taken fire, as it were, of its own accord, without the application of external heat, or the agency of electricity. Assuming such to be the fact, can any rational explanation of it be assigned? This is almost the only question of a theoretical nature connected with the subject of this article which remains to be discussed.

Of the elementary principles which enter into the composition of the human body, phosphorus must be reckoned as one of the most abundant. It exists, in very considerable quantity, as a constituent of bones, and, in many of the secretions, in the form of phosphoric acid, united to some base; and is also to be found, in a peculiar state of combination, in the cerebral mass, and in the fat which is deposited throughout the cellular tissue. When putrefaction occurs in the dead body, experience proves that phosphorus is evolved amongst the gaseous products in union with hydrogen; and there seems little reason to doubt that this is one of the gases which are occasionally generated throughout the different textures of the living system. Now, if this be admitted, as phosphuretted hydrogen inflames upon contact with the atmosphere, we shall have a perfect and simple solution of the difficulty of *spontaneous* combustion. This theory was very early advanced, and has been particularly insisted upon by Morelli and Fanzago, and more recently by Grabner Maraschin: (*Journal Complémentaire de Dictionnaire de Médecine.*) It is, however, passed over in silence by the majority of writers.

There is another mode of accounting for the spontaneous combustion of the human body, which is entitled to a brief notice here. The chemical actions which give rise to the inflammable gases of which we have so often spoken, are attended by the development of heat; and when this rises beyond a certain point, combustion, it is alleged, must ensue.

In support of these views, the spontaneous firing of pyritic coal, heaps of chareoal, oatmeal, cotton and black wad soaked with oil, are appealed to. Whatever may be thought of this hypothesis, the records of medicine prove that the production of inordinate heat may be classed amongst the well established consequences of disease. In the Essay of Maraschin already quoted, three cases are detailed which will illustrate this position. We shall merely mention one which occurred, in 1822, to Balbiani, an Italian physician, and which

was communicated by him to Morelli, Chemical Professor at Pisa.

A farmer, twenty-six years of age, was seized, in the beginning of January, with an intermittent fever connected with gastric irritation. On the seventh day he felt in the throat a burning heat, ascending from the region of the stomach, so intense as to resemble the effects of the application to the body of red-hot coals. His breath, which smoked, could not be borne by the hand at the distance of two feet. He incessantly drank cold water, but with only temporary relief. The thirst was succeeded by a most voracious and insatiable appetite, the internal heat continuing unabated. He was treated by repeated immersion in the cold-bath, conjoined with the exhibition of draughts of iced water; and was finally cured perfectly.

From the preceding facts and arguments the following conclusions may be deduced:—1. The human body admits of being reduced to a highly inflammable state. 2. This condition is chiefly owing to the development, by perverted secretion or incipient putrefaction, of gases constituting a more or less explosive mixture, but is probably often promoted by the dispersion throughout the system of alcoholic vapours. 3. In most instances of human combustion the process has commenced in consequence of the contact with the body of external fire, or of an electric spark. 4. Cases truly spontaneous, if any such have occurred, must be referred to the disengagement of phosphuretted hydrogen, or to the caloric developed by those internal actions which determine a highly combustible state of the body.

Before concluding this article, it will be proper briefly to advert to its medico-legal bearings. The human body, in a state of perfect health, may be consumed by accident or design, and it is obviously a matter of the first moment, with a view to the protection of innocence and the punishment of guilt, that we should be enabled to distinguish such cases from those in the consideration of which we have now been engaged. The importance of the study of spontaneous combustion under this point of view is usually illustrated, in works upon medical jurisprudence, by the celebrated case which occurred at Rheims in 1725. The wife of a man of the name of Millet, who was much addicted to the use of spirituous drinks, left her husband's bed one night, and was found next morning, at a short distance from the kitchen fire, reduced to a heap of cinders. Millet, who was suspected of intriguing with a handsome servant-girl in the house, was accused of the murder of his wife, and being sentenced to death, was saved from execution by the report of a commission of medical men, who, after having investigated all the facts, declared it to be a case of spontaneous combustion.

By attending to the circumstances already enumerated as characterizing spontaneous combustion, we shall be in no danger of confounding it with that which may be produced by the ordinary artificial means. Thus, when the

subject of the calamity is a female, advanced in years, and of intemperate habits; when the destruction has been very rapidly effected, and nothing remains unconsumed but portions of the head and extremities; when the room is filled with an offensive empyreumatic odour, and a moist and fetid sooty matter is deposited upon the ashes which remain, and upon the walls and furniture;—these circumstances, or the greater number of them concurring, remove all doubt respecting the spontaneous origin of the fire. On the other hand, when the combustion is of the ordinary kind, and has been the result of accident, it will generally be but partial, and not directed in preference to any particular part of the body. In such cases, also, it will almost invariably be found to have extended to adjacent combustible substances. Lastly, when designedly produced, there will be evidence of the consumption of a large quantity of fuel.

As to the appropriate treatment of individuals who manifest a tendency to spontaneous combustion, nothing certain can be laid down: nor is our ignorance on this head much to be lamented, at least in a practical point of view; for such an affection is seldom announced by any precursory symptoms. Should, however, such a case as that which occurred to Balbiani be encountered, nothing appears more judicious than the treatment to which he resorted, namely, immersions in the cold bath, and copious draughts of cold water. Dr. Swediaur, indeed, states that spontaneous combustion is very prevalent in the north of Europe, from the excessive use of *eau-de-vie*, and that the tendency to it, when detected, is with certainty removed by the administration of recently voided human urine. Upon this statement Fodéré observes, "*credat Judæus*," and we do not hesitate to avow that we participate fully in his scepticism.

(*James Apjohn.*)

**CONGESTION OF BLOOD.**—Though this term is familiar in medical writings, and in daily use among practitioners, it appears to be employed as expressing simply an acknowledged fact, rather than as referring to any pathological exposition of the phenomenon to which it relates.

Congestion of blood and determination are terms not unfrequently used to denote the same state; yet they do not signify the same thing. By congestion is implied simple engorgement of bloodvessels, without reference to any continued increase of vascular action; while determination includes the idea of the increased impetus with which the blood is propelled into the affected part. Local inflammation is perhaps the acme of this state, combining the whole three conditions; though each of the preceding may exist independently of it, and without passing into it.

The subject, though undergoing much discussion in various works on pathological anatomy, is not yet sufficiently matured for the several facts and reasonings to be embodied in a special essay. The several local congestions will of course be noticed under the heads

of the diseases in which they respectively occur. The general principles, so far as any are deducible from such facts as are ascertained, will, perhaps, be best understood when presented in connection with the general pathology of the circulation. Simple congestion evinces over-distension of vessels, and clearly implies debility of their coats. In several tissues it seems the result rather of irritation than of pure inflammatory action. When it passes into inflammation, this seems more dependent on the general state of constitution, on the plethoric condition of the bloodvessels, with the tendency towards febrile and inflammatory excitement which this induces, than on the primary irritation, or the congestion occasioned by it. Hence congestions might be considered as passive or active; the former term applying to the simple state, the latter to that in which inflammatory action is either concomitant or superinduced.

Facts, however, are still wanted for establishing a clear and consistent theory of congestive ailments. These facts the researches of pathological anatomy, so zealously and minutely pursued at the present day, cannot fail to supply; and when sufficiently accumulated, it will not be difficult to arrange them, so as, with the aid of correct physiology and sound pathology, to deduce the principles of their occurrence, and establish on a rational basis the curative treatment of the morbid condition to which they relate. The presence of internal congestions must, for practical purposes, be of course inferred from the symptoms which indicate them; and to connect the symptoms with the structural lesions which they denote, so as to furnish practical guidance in their treatment, is the proper object of medical research. This can be accomplished only by multiplied observations of phenomena, generalised by a cautious induction. An essential part of this inquiry, however, consists of a scrutiny of those modifications or changes of structure which the morbid actions occasion, and by which the effects of these can be traced on necroscopic examination. The correctness of all theory must depend on the accuracy of the facts from which it is deduced; and as no complete theory of internal congestions can be established without the aid of numerous facts derived from actual inspection of the diseased parts after death, it is of importance that enquirers should be aware of the fallacies by which they are liable to be misled in the inspection of the structures and tissues supposed to be diseased. These fallacies are displayed by M. Andral, in his elaborate and valuable work on pathological anatomy, with a minuteness and accuracy which merit the highest praise. To render any account of his laborious researches would exceed the bounds of the present article, without sufficing for that completeness which a perfect essay on congestion would require.

It may be noticed that the different degrees of colouring observed in internal parts after death, which are so often attributed to increased vascularity, and supposed to denote

the pre-existence of congestion or inflammation, may result from various causes independently of disease. Of these M. Andral specifies several: the passive hyperæmia, which has always a tendency to take place in the last moments of life in parts abounding in capillaries;—mechanical obstacles to the venous circulation, formed a longer or shorter period before death;—the hypostatic accumulation of blood in depending parts;—the transudation of blood through its vessels;—other peculiar transudations;—various gases, &c. He also remarks that differences are presented according to the part examined, the age, the period of the digestive process going on at the time of death; with other circumstances.

Unless due allowance be made for all such sources of deception in noting the effects of morbid actions, as displayed in structural lesions, the evidences afforded by pathological anatomy, though generally regarded as the most certain which medical science possesses, must be as fallacious as medical facts derived from the observation of mere symptoms and of outward phenomena are so often alleged to be. From the industry and precision, however, with which this branch of science is now cultivated, there is every reason to hope that pathological anatomy will in no long time rest on a sure and stable foundation, furnishing in the truth and extent of its facts a basis on which a firm and abiding superstructure of pathology may be ultimately reared.

The treatment of local congestions must depend partly on the nature of their site, but principally on the cause which occasions them; whether general plethora exciting increased arterial actions and determination of blood to particular parts; simple irritation inducing an increased afflux of blood by the local excitement occasioned; or mechanical obstruction causing a retardation of blood in extreme vessels, with over-distension of their coats, and preventing its free return by the reflux veins.

Each of these states must require an appropriate adaptation of remedies; for if a just discrimination be not practised in this respect, no consistency can be preserved, nor any uniformity of success be realised. If congestions result from a plethoric habit, mere local treatment can never give effectual or permanent relief; the affection recurring so soon as the local means are discontinued. With these means depletion and abstemious diet must be combined, else disappointment and further decline of health must ensue. On the contrary, if there be no plethora, and the congestion be owing to irritation only, then general depletion is not only unnecessary but injurious, enfeebling the system, and weakening those efforts by which the congestion would be naturally relieved. In both respects are errors committed. Many congestions originating in plethora are treated as local diseases until structure becomes permanently and irremediably altered; while congestions arising from irritation are occasionally confounded with inflammation, from a delusive resemblance in some of their symptoms, and bloodletting is

injuriously resorted to. In no class of diseases is the former error of more frequent occurrence than in affections of the stomach and bowels. Increasing plethora begets almost necessarily a congestive state of the gastro-intestinal mucous membrane, the constitution endeavouring to throw off its redundancies by this and other outlets; secretions become increased, and then vitiated; digestion is impaired; appetite declines; and a condition results to which the term *dyspepsia* is usually applied. Indigestion and loss of appetite are regarded as the disease; they are imputed to weakness of stomach, and tonics are employed; some amendment may be felt by the capillaries being excited, and the appetite may improve, but the disease is not thus arrested, nor a healthy condition restored. The capillaries may contract upon their contents, and thus abate the congestion so far as they are concerned; but it is only by repelling the blood into the vessels which lead to them, and thus substituting another form of disease more mischievous and less remediable, because less within the reach of those curative processes by which the constitution so continually rectifies its own derangements. In this condition tonic treatment, subsidiary to depletory, may be and oftentimes is of service; when employed as the chief means of cure, or to the neglect of evacuations, it is invariably pernicious. The natural relief derivable from increase of secretions being arrested, the blood repelled not only overloads the larger vessels which lead immediately to the capillaries, but becomes in time congested more distantly in several of the viscera, giving rise to diseases of various kinds.

With respect to the diseases which, arising from irritation, present appearances simulative of inflammatory action, and in which congestions often occur, much valuable information may be derived from the works of Dr. Gooch, Dr. Marshall Hall, Mr. Travers, and others, who have done much to introduce greater discrimination and accuracy into the treatment of such complaints.

(E. Barlow.)

#### CONSUMPTION. (See PHTHISIS.)

CONTAGION, (from *contagium*, *contagio*, *contingo*, *con* and *tungo*, Lat.)—By this term is meant the propagation of disease from one individual to another; though it is sometimes used, both in speaking and writing, to denote the matter by which the propagation is effected. In certain cases, those of inoculation, we have perfect knowledge that this propagation is produced by the communication of a noxious matter from the individual first affected to him who receives the disease, and from analogy, and from our inability otherwise to explain the effect on the system, we infer that in all cases of contagion there is a communication of such matter. The body secondarily affected has the property of again generating and communicating to others a similar matter, the disease produced in every case being the same in kind as that existing in the body where the matter

causing it is engendered. Diseases thus produced, and possessing the power of engendering such a matter, are said to be contagious, and the matter generated is called contagious matter, or contagion.

All examples of disease produced in one human being by the application of matter derived from another do not come within the scope of this definition. For instance, in the case of certain dissection-wounds, or in the examples related by Mr. John Hunter, of disease produced by the transplanting of teeth, there is no reason to think that the individuals from whom the matter was derived, laboured under any disorder similar to that which was engendered, nor is it ascertained in either case that the disease possesses the power of propagating itself. But were it distinctly proved that either disease possesses such a property, then would it be contagious, though arising from a non-contagious source; for we are not justified in denying that a contagious disease may be generated by other morbid causes than contagion.

Contagious diseases may be divided into those whereof the contagious matter acts only by positive contact between the individuals communicating and receiving the disease, or by its transference in a visible form from one person to another by inoculation; and into those which, though communicable by contact, and in some cases by inoculation, are besides capable of transmission from individual to individual through the medium of the atmosphere. Contagion is therefore immediate or mediate—contactual or remote.

To the former division are to be referred syphilis, gonorrhœa, siveens, frambœsia, itch, porrigo, Egyptian ophthalmia, cow-pox, and probably pellagra and the mentagra of the ancients: to the latter, small-pox, chicken-pox, measles, scarlatina, hooping-cough, plague, typhus, hospital gangrene, influenza, puerperal fever, and, according to the opinion of some persons, yellow fever, and cholera of India. It has been shewn, too, by Dr. Wells, that erysipelas occasionally manifests a contagious property. There are two other diseases which were formerly considered contagious, lepra Græcorum and lepra Arabum (elephantiasis). The former is unquestionably not contagious, and from the observations made by the late Dr. Adams in the lazaret-house at Funchal, there is every reason to think the latter equally devoid of this quality. Of the two diseases communicable from inferior animals to man, hydrophobia and glanders, it is not ascertained that they may be transferred from one human being to another, which certainly would have been the case with respect to the former, had it possessed the property of remote contagion. The opinion entertained by many veterinary surgeons, that the latter is communicated by contact from horses to the human species, has been amply confirmed by the researches of Dr. Elliotson of St. Thomas's Hospital: whether it be further communicable from one human being to another is not ascertained.

Of the nature of the matter of contagion

we know nothing; but attempts have been made to ascertain the laws which regulate its diffusion through the atmosphere. The following are some of the results of these attempts which have been given to the public; although there is reason to think that they do not merit implicit confidence. Dr. Haygarth informs us that in 1777 he began to ascertain by clinical observation according to what law the variolous infection, and, in 1780, according to what law the febrile contagion is propagated. He is of opinion that the pernicious effects of the variolous miasms are limited to a very narrow sphere. In the open air and in moderate cases he supposes that the infectious distance does not exceed half a yard; and hence, he says, it is probable that even when the distemper is malignant, the infectious influence extends but a few yards from the source of the poison. He is of opinion that the contagion of fever is confined to a much narrower sphere than that of small-pox.\*

By Dr. Clark we are informed that the most malignant fever does not render the atmosphere infectious further than a few feet from the patient, or from the contagion preserved in clothes, furniture, &c.; and daily observation, he remarks, confirms the opinion that a person must remain a considerable time within the sphere of infection to receive it.†

The poison of plague has been said to be so fixed, that to be affected by it requires almost contact, unless the patient's breath be inhaled, by means of which the disease is readily communicated. We have already intimated a suspicion that these restrictions on the sphere of contagion have been imposed with more precision than sound induction warrants; but we believe it may be considered a rule that within this sphere the danger is greater, other things equal, in proportion to the proximity to the patient.

Certain circumstances influence the extent of contagious diffusion. Of these the most distinctly ascertained are atmospheric impurities; for it is ever observed, and we believe it may be predicated of every disease possessing the property of remote contagion, that its contagious matter is propagated to greater distances in a dirty, crowded, and ill-ventilated apartment than in one of which the air is pure; whilst diffused through an atmosphere of the latter description, it is speedily deprived of its noxious properties. The same principle applies to articles of dress and furniture; those which are contaminated with animal secretions and effluvia being much more readily impregnated with contagious matter than those which are clean. At the same time it must be remarked, that the neglect of cleanliness implies the multiplication of foci of contagion from the foul clothes and the presence of the discharges from the bodies of patients, and the accumulation of contagious matter from the neglect of ventilation; and hence, though filthy apartments

\* Letter to Dr. Percival, p. 8.

† Report to the Committee of the Newcastle Dispensary, 1802.

are hot-beds of pestilence, part only of their effect is to be ascribed to foul air.

Besides these auxiliaries of contagion acting in a limited district, there are others more extensively diffused, of which the influence is important. Some of these are well known, whilst others are cognizable only by their effect on the propagation of disease. The effect of those, the nature of which is ascertained, varies in the case of different contagions. The diffusion of plague, for instance, is favoured by a temperature high within a certain degree; whilst it is checked, if not altogether extinguished, by the cold of winter, and likewise by very high temperatures, such as the heat of certain parts of Africa in summer, as mentioned by Alpinus, and that of the Harmattan winds. Typhus, we know, prevails at low degrees of heat, as likewise do measles and scarlatina; and so of different contagions, we find the effect of temperature on them varies in the case of different diseases. A moist and still atmosphere may, if we mistake not, be declared favourable to the propagation of all contagious disorders; whilst it is sometimes suddenly checked by strong commotions in the air, such as storms and hurricanes.

But besides these appreciable atmospheric states, which in one way or another influence the diffusion and action of the matter of contagion, there are conditions of the air favourable to its diffusion, or otherwise, of the real nature of which we are ignorant beyond their influence over the propagation of disease. It has occurred to every medical man to see diseases, justly considered contagious, unusually prevalent in one season compared with another, though there may have been no discoverable difference in the atmospheric states to explain this variety in their prevalence; and to see them, on the other hand, decline and finally disappear long ere individuals susceptible of the contagion were wanting, without there having been any appreciable change in the state of the air to account for that in the disease. This atmospheric peculiarity, to which the name *epidemic constitution* has been sometimes applied, occasionally appears to possess a limited locality; for we find a contagious disease prevailing in a town or village, whilst places in the neighbourhood escape, though there is a constant intercommunication between the infected and healthy districts; or such a disease may spread extensively in one town, whilst in another, similar as to the habits and character of the population, and not remote in situation, it may exist, but be by no means so prevalent.

A distinction has been proposed between diseases transmissible from one human being to another, and between the terms applied to them, founded on the influence exerted by atmospheric peculiarities over their propagation. It has been suggested that the word contagious should be limited to diseases which are capable of transmission under any circumstances of the atmosphere, pure or impure, such as measles or small-pox; whilst those which are communicable only in impure or vitiated air, as some

have conceived typhus and certain other diseases to be, it has been proposed to designate by the term infectious exclusively. It will be understood that a corresponding distinction is intended between the words contagion and infection. In the first place, it may be remarked that the distinction between the diseases to which the terms are proposed to be respectively applied is hypothetical; for atmospheric impurities and peculiarities appear to have an influence on the transmission of all diseases, and it seems very questionable whether any disease, not in its own nature communicable, is rendered so by such impurities and peculiarities. Again, the words have long been used by medical men, when speaking of the transmission of disease, as strictly synonymous, and they have applied them indifferently to small-pox and typhus; and the attempt to restrict them in an unwonted manner has been productive of confusion, such limitations having the same pernicious effect as needless neologism. It may be remarked, however, that infection, though in the ordinary language of the profession strictly synonymous with contagion when employed to denote the transmission of disease, is used in a sense which the latter word does not admit, that of contamination by any thing injurious to the human frame; for which see INFECTION.

Of the diseases enumerated as contagious, small-pox, measles, scarlatina, and hooping-cough affect individuals but once in the course of their lives; at least this is a very general rule. The privilege of furnishing immunity from future attacks has been claimed, too, for yellow fever; but it seems very questionable whether the exemption afforded by it be of the general nature of that enjoyed by those who have undergone the exanthematous diseases and hooping-cough. It is indeed doubtful whether the comparative immunity furnished by attacks of that disease be any thing more than part of the general seasoning process by which the constitution becomes hardened against the influence of certain climates and their diseases. Were it unequivocally established, yet would it furnish no material evidence in favour of the supposition of this disease being contagious, unless the furnishing of exemption from second attacks were a property of contagious diseases generally, which is not the case.

A period generally intervenes between the application of contagious matter and the occurrence of the disease which it generates, varying in different diseases, and in different cases of the same disease; for instance, in scarlatina this period is said to range from three to five days, but occasionally extends to twenty-one;\* in measles from ten to fourteen; in natural small-pox from six to twenty-one; and in the inoculated disease from four to eighteen; whilst Dr. Whytt's very unhappy experiment shewed the interval for inoculated plague to be only three days. The contagion of typhus is sometimes instantly felt in the

\* Dr. Maton, Med. Trans. vol. v. art. xi.

system, as in an example which the late Dr. Gregory used to relate in his lectures, of an individual who instantly sickened and became affected with fever on kicking some chaff thrown out of a bed on which a patient ill of fever had lain; and in another mentioned by Dr. Tweedie, in his *Illustrations of Fever*, of a nurse in the Fever Hospital, who sickened whilst examining the evacuations of a patient, and passed through a most severe form of fever. Dr. Marsh's observations upon the origin and latent period of fever\* abound with striking instances of the instantaneous occurrence of the disease on the application of its cause; but the interval from the application of the poison of typhus to the production of its effect, there is reason to think, extends frequently to three weeks or a month, and even sometimes to sixty-eight days.† The latent period of the poison of hydrophobia is longer than that of any other disease we are acquainted with. This period in the case of some diseases is not one of perfect health. In that of typhus, a great degree of nervousness, inappetency, mental dejection, and debility often precede for days or weeks the symptoms which denote the commencement of the febrile movement in the system. It has occurred to the writer to observe cases in which the low but exhausting degree of indisposition attending this period has constituted the greater part of the disease which has destroyed the patient. He has visited persons who, though they had felt themselves indisposed for weeks, had persevered in their accustomed avocations in spite of this feeling, which they thought lightly of, and have then suddenly sickened with the worst symptoms of the last stage of typhus, and expired within forty-eight hours. An author already quoted, Dr. Marsh, deserves the thanks of the profession for calling their attention to the importance of this period and its proper management.

The most certain evidence we can have of a disease being possessed of a contagious property is its being communicable by inoculation. By this is meant the transference of a visible and palpable fluid, through which we must suppose the subtle matter of contagion to be diffused, from one individual to another, or from one to another part of the same individual. It is designedly practised, as is familiarly known, in small-pox and cow-pox, and also, from improper motives, in purulent ophthalmia. The application of the matter of gonorrhœa to the eye of the person affected with it is an example of the second kind of inoculation mentioned. Inoculation of one individual from another is possible in all cases in which a morbid matter, capable of being transferred by art, is engendered, of which examples in addition to those mentioned may be found in both divisions of contagious diseases. Some disorders, too, which do not during the life of the patient generate a matter which may be artificially transferred, have yet appeared to be communi-

cated in this way by dissection wounds; a description of cases very distinct from those adverted to of such wounds, in which the individual dissected did not die from a disease of the same nature as that produced in the injured individual.

The other proofs are, repeated examples of persons contracting disease from contact with persons labouring under it, or from being near to them, or from being in the same situations with respect to fomites. An inference may be drawn, too, from the exemption of individuals from a disease who sedulously avoid the sick and fomites, compared with the liability of those who neglect such a precaution. By fomites are meant matters, such as goods of any kind, clothing or furniture, which, having been near the sick, are impregnated with the emanations from their bodies. This may happen to the clothes of individuals who visit them; and in this way an attendant or visiter of patients may communicate a disease to others though he escape it himself, being secured from it in certain cases by having previously laboured under it; in others by insusceptibility of that peculiar contagion, as is frequently exemplified in puerperal fever. It is obvious that the poison may by accumulation exist in a very concentrated state in fomites which have been long near the sick or in contact with them, and consequently we find that some of the worst cases of contagious disease are produced by their means.

With respect to diseases communicable only by contact or inoculation, all doubt of their contagious nature has long ceased; and of those enumerated in the second division, some, which cannot be propagated by inoculation, especially of the exanthematous disorders, are admitted by all observers to possess this property. But respecting others the agreement on this point among medical men is by no means uniform; and controversies have hence arisen as enduring and acrimonious as any recorded in the annals of medicine. The attempts to decide this perplexed question in the case of any disputed disease, must be made in another part of the work; but it belongs to this place to point out the tests, (which owe their value to their being proofs of the circumstances already mentioned, the reception of disease by direct intercourse with the sick, and immunity from it by rigid seclusion from them,) by which any individual case should be tried, and by which alone it can be decided.

1. Contagious diseases frequently spread in places previously healthy, shortly after the arrival in them of persons from infected districts. The same remark applies to fomites. It is the more apt to occur in the case of persons, if they be sick on their arrival or become so shortly after.

2. When a case arises in a limited district, the disease spreads gradually through it as from a centre towards a circumference, but more rapidly, *ceteris paribus*, in proportion to the density of the population, and the intercourse of the healthy with the sick.

\* Dublin Hospital Reports, vol. iv.

† Bancroft on Yellow Fever, p. 515.

3. Persons whose official duties bring them into habitual and close communication with the sick, such as the medical officers and other attendants on public institutions which contain many cases of a disease, are affected with it in a greater proportion than other members of the community similarly circumstanced with themselves, the intercourse with the sick excepted. The number infected from among the different classes of such attendants bears a proportion to the closeness and duration of their communication with the sick; for instance, the nurses, and in military hospitals the orderlies, are more frequently attacked than the medical officers.

4. The contagious quality of a disease may be inferred from frequent instances of the success of measures taken to prevent its propagation, such as the early removal of the sick. The importance of the evidence to be derived from this source cannot be more clearly shown than by the following statement of Dr. Alison: "We should have little difficulty in pointing out above a hundred houses where a single case of fever has occurred, where the patient has speedily been removed and the place cleaned, and where there has been no recurrence. But we should hardly find five houses in all the closes of the old town of Edinburgh, in which a patient in fever has lain during the whole or even during the half of his disease, in which other cases of the disease have not shown themselves."\*

5. Those who seclude themselves from all communication with the sick and with those who visit them, and receive no commodities which have been in their possession or near them, escape the disease; whilst persons similarly circumstanced in all respects, the seclusion excepted, are attacked by it. The same rule applies to countries or districts secluded by quarantine or other regulations from neighbouring countries, similar in soil and climate, where disease is prevailing; though it must be acknowledged that the cases are rare in which a precise conclusion can be drawn from this latter case of exemption.

6. An inference favourable to the supposition of a disease being contagious, may be deduced from the circumstance of there being nothing in the soil or climate where it prevails fitted to engender other causes of disease, such as malaria. A similar inference may be drawn, when disease is prevailing in a limited district, from the cleanliness observed there, and the consequent exemption from infection which might be occasioned by the effluvia from decomposing animal and vegetable recrements. The previous state of health, too, of the district or country, particularly as regards the disease which is the subject of investigation and diseases of the same kind, may furnish the medical reasoner with powerful arguments.

\* On Epidemic Fever, Edin. Med. and Surg. Journ. vol. xxviii. p. 241, where the reader will find most of the tests enumerated successfully applied, to show the contagious nature of the fever of this country.

It must be remarked that, in all investigations into disputed cases of supposed contagion, as many tests as possible should be brought to bear upon the points; and that these tests should be secured by a specification of all particulars which tend to show that malaria was not an agent in the production of the disease respecting which the controversy exists. A reference to a few examples of the successful application of the tests will be the best means of putting the reader in possession of the nature of the detail required for the security of his argument.

Those of Dr. Alison have already been referred to, and the reader may be assured that he can consult none more valuable.

In Dr. Tweedie's *Clinical Illustrations of Fever* the following instance is given of the successful application of the third test, the prevalence of disease among persons officially employed about the sick.

"Every physician with one exception, (the late Dr. Bateman,) who has been connected with the Fever Hospital, has been attacked with fever during his attendance, and three out of eight physicians have died. The resident medical officers, matrons, porters, domestic servants, and nurses, have one and all invariably been the subjects of fever; and the laundresses, whose duty it is to wash the patients' clothes, are so invariably and frequently attacked that few women will undertake this duty. The resident medical officer was attacked with fever, and it became necessary to appoint some one to perform his duties. The first person who thus officiated took the precaution of sleeping at home, yet his duties were soon interrupted by an attack of fever which confined him a considerable time. He was succeeded by an individual in robust health, a disbeliever in the doctrine of contagion. He performed his duty only ten days when symptoms of severe fever appeared.

"There is no security in this narrative, striking as it is, against the favourite argument of the non-contagionists; but the following collateral circumstances present an obstacle to the intrusion of malaria, which only bigotry or the spirit of partizanship can enable it to surmount. The Fever Hospital stands in the centre of a large field, where the production of malaria is exceedingly improbable, and on the same lawn, and within a few yards of it, stands the Small-Pox Hospital; but no case of genuine fever has occurred among the medical officers or domestics of that institution for the last eight years." The relation these facts bear to the argument is sufficiently manifest.

In the case of plague, of the contagious nature of which it would be easy to accumulate proofs, the following example, selected from hundreds, of the influence of fomites, special seclusion from the sick, and close intercourse with them, illustrates well the nature of the evidence to be derived from the third and fifth tests. When the plague was prevailing in Valetta, in Malta, in 1813, the

strictest precautions were used by the inhabitants of the Augustine Convent, situated in the town, to exclude the disease. At length, however, a servant, contrary to regulations, went into a part of the town where the disease prevailed, and purchased clothes supposed to be infected. Soon after his return he confessed what he had done, and was immediately shut up, together with one of the brotherhood who volunteered to attend him. Both of them were taken ill and died, but no other person in the convent suffered. A disbeliever in contagion would attribute the disease of the servant to exposure to the malaria of the district in which he bought the clothes; but the monk's malaria must have existed in the convent:—how strange that it should have smitten only one of the brotherhood, and he the individual who alone had intercourse with the sick servant!

There can be no better exemplification of the first test than the occurrences in the Island of Ascension in 1823. This island, remote from any other land, of volcanic origin, and the surface of which consists of volcanic ashes, excepting in one point called the Green Mountain, elevated 2,500 feet above the level of the sea, where there is a thin earthy soil favourable to vegetation, but which is very dry, whilst the volcanic surface is said to be dry, arid, and barren, was uninhabited until 1815, when a few British troops were stationed there on Buonaparte's arrival at St. Helena. During the seven years which elapsed from the 7th of March, 1816, to the 7th of May, 1823, but two fatal cases of fever had occurred in the island. On the 20th of April of the latter year, the ship *Bann* arrived there from Sierra Leone with yellow fever on board, which had attacked ninety-nine of the crew, and ultimately destroyed thirty-four of them. Forty-five men, ill of fever, were landed on the island from this vessel. Eight days after the arrival of the *Bann* one case of fever occurred among the inhabitants; but eighteen days after, or on the 7th of May, fever of the same character as that which prevailed on board the ship, showed itself most decidedly; and from this time until the 16th of June, or within six weeks, fifteen persons died, of twenty-eight who were attacked with the disease, out of a population consisting of only thirty-five marines, with some women and children.\*

This case is valuable so far as a much litigated point of pathology is concerned, but it owes much of its value to the specification of collateral circumstances; such as the nature of the soil of the island, and its previous comparative exemption from fever, which render it improbable that malaria of a degree of intensity sufficient to produce such a disease, had been generated there. At the same time it must be remarked that some

cause of fever was endemial at Ascension, for twenty-three cases had taken place in its small population during the seven years preceding the arrival of the *Bann*, viz. ten cases of continued fever, eleven of bilious remittent, and two simply returned fever; and of these cases two had been fatal, one of bilious remittent, the other of continued fever. It may be observed, too, that islanders, who rarely receive the visits of strangers, are liable to be attacked with sickness of some kind on their arrival, though the visitors may not be unhealthy; as we understand is occasionally exemplified among the Shetlanders. Hence we cannot conclude *positively* that the disease was imported into Ascension; but it must be acknowledged that this case wears more the air of importation than any which has been given to the public—indeed most other attempts to prove importation have been signal failures—and that a few more cases equally striking would set the question of the contagion of yellow fever at rest for ever.

The subject would be left very imperfect if we did not bestow some attention on the question, how far contagious diseases may be produced by other causes than contagion! By admitting that the matter of contagion is the product of a diseased vital action, we are by no means forbidden the supposition that the diseased vital action required to engender such matter may occasionally owe its origin to other causes.

To commence with the simplest case,—if any member of a family becomes affected with catarrh, arising from catching cold, how constantly do we find it passing successively from individual to individual of the family, till the whole are infected, in the manner of a contagious disease, though there be no reason to think that the individual first affected received it from any other source than cold, or cold and moisture.

The itch appears to be engendered by mere filth, but when thus produced is manifestly contagious. Some forms of porrigo, too, arise spontaneously, but yet are disseminated through schools and families from the individuals in whom they have thus arisen.

Certain soldiers of a regiment may have suffered at some previous time from Egyptian ophthalmia; they may have been cured of the disease, and remained free from all symptoms of it for months, or even years; and the regiment shall consist partly of such men, and partly of men who have never had ophthalmia. If one or more soldiers who have previously suffered from the disease, have the eyes inflamed from exposure to the sun's rays, cold, or intoxication, and the inflammation is so considerable as to produce secretion from the conjunctiva, and the regiment is at the same time in barracks, so that the soldiers are brought into habitual contact, the disease will spread in the manner of a contagious disease, affecting equally those who had previously suffered and those who had not; though the individuals first affected had not been perhaps

\* Official Report of the Fever, which appeared on board his Majesty's ship *Bann*, &c. by *W. Burnett*, M.D.

for years within the reach of any supposable contagious source. The writer is not stating a mere hypothesis, but a matter which has fallen more than once under his own observation. Is it supposable that any poison had lurked inactive about the eyes of these men for so long a period? or, is it not much more probable that, the eyes being disposed to a certain form of disease, the contagious matter was really the product of the inflammation arising from the common causes mentioned?

If from over-crowding, imperfect ventilation, or neglect of cleanliness, or all conjointly, any single sore in the ward of an hospital becomes affected with the disease called hospital-gangrene, it extends to all the sores of the locality. The affection of these, it is true, may be justly ascribed to the common pernicious influence; but let the causes of this influence, over-crowding, defective ventilation, &c. cease, and cases of healthy sores be admitted, and the existence of the contagious principle diffused through the air, or adhering to fomites, is speedily manifested in the character of the sores; and this will continue till the place is evacuated and subjected to a thorough disinfecting process.

The experience of the whole profession proves that erysipelas generally arises independently of contagion; but the facts adduced by Dr. Wells leave it beyond all question that this disease is occasionally communicated by intercourse with the sick.\* Whether it owes this property, which it certainly displays but occasionally, to some peculiarity in the nature of the disease, or to extrinsic circumstances, does not appear to be ascertained.

It has already been remarked that certain circumstances of crowding, filth, and imperfect ventilation, favour the propagation of contagious diseases; but there is every reason to think that the contagious fever of this country may not only be aided in its diffusion by these circumstances, but may actually be engendered by them. We often see in epidemic seasons, fever, not traceable to any other source, springing up in the abodes of the poor, apparently produced by the concentration of human effluvia, and the decomposition of animal and vegetable recements, though possessing a contagious character when thus engendered. This mode of generation appears often to take place in seasons of scarcity, when physical privations and the depressing passions render the poor a more easy prey to disease, and by depriving them of the moral energy required to preserve order and cleanliness in their dwellings, fit these for engendering infection; whilst the want of clothing and fuel leads them to block up every chink and aperture by which fresh air might gain admittance. The same origination of a contagious disease from a non-contagious source is observed in the typhus of crowded hospitals, jails, and ships, instances

of which are so numerous and familiar to the profession that it would be to waste the reader's time to quote individual examples. It does not seem necessary to examine into the question, whether the miasmata produced by the effluvia of congregated human beings, conjointly with filth and its consequent animal and vegetable decomposition, be identical with those generated by the diseased vital actions existing in fever; for in the present state of our knowledge of the subject we have not the means of deciding it. No inference can fairly be drawn from the identity of the effect, for certain diseased states are produced by a variety of remote causes, this expression being employed in the sense usually annexed to it by medical men.

How far other diseases, which according to the very general opinion of the profession depend exclusively on a specific poison for their diffusion, may in some instances owe their origin to common causes, or such as are independent of contagion, it might appear presumptuous to say. That their diffusion is influenced by atmospheric causes is beyond all question, and there are phenomena displayed by some of them which tend to excite at least a suspicion that such causes may occasionally engender them. To select an example from the exanthemata:—scarlatina appears suddenly in the latter end of autumn; many are simultaneously attacked—so many at the commencement of the epidemic, that it is wonderful where the foci of contagion exist to contaminate them: in its course it manifests unequivocal signs of contagious power; it disappears sometimes suddenly, at others gradually, but long before subjects susceptible of the disease are wanting: no cases are seen for some months; and in the following autumn the same course is recommenced, and the same phenomena are again displayed. Where lurks the poison whilst thus in abeyance, or does it exist any where? Similar doubts and difficulties might be suggested by circumstances connected with the prevalence of measles and hooping-cough.

From the preceding observations it is manifest that the subject is one of great intricacy, and that an ample field is open to the cultivation of the diligent, ingenious, and candid. It is to be regretted that the researches into this very difficult and important subject should generally have been conducted rather with a view to support some preconceived notion, than in the spirit of honest and zealous inquiry after truth.

*Means of preventing the propagation of contagious diseases.*—These may be succinctly stated to be, the separation, as far as is consistent with humanity, of the sick from the healthy; cleanliness of the person of the patient, and cleanliness and free ventilation of his apartment; the immediate immersion in hot-water and subsequent washing of all clothes, &c. removed from his person, which might become fomites; the avoiding, on the part of the attendants, of needless and long continued

\* Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, vol. ii. p. 213, &c.

proximity to the sick, inhaling their breath, and standing in the current of air which passes over them; and the supporting of the general health of the attendants by nutritious diet and the rest which nature requires. (For further instructions, see DISINFECTION and VENTILATION.)

(*Joseph Brown.*)

**CONVALESCENCE.** This term is applied to denote the period or intermediate state between the cessation of a disease and the full restoration of health. When we speak of convalescence from disease, it is implied that there has been indisposition of a more or less serious character, and of some duration, as it is obvious it would be improper to apply this term to ailments of a trifling description. The transition from disease to convalescence, and from convalescence to health, which is seldom sudden, more especially in chronic disorders, is announced by the disappearance of the more prominent characteristic symptoms.

Convalescence is observed to be not only more slow but less permanent in chronic than in acute diseases. It is also modified, in some respects, by individual circumstances: thus, in infancy and childhood it is shorter than in the middle or advanced periods of life; it is likewise more protracted in persons of a feeble constitution, and in those who have undergone long continued rigorous antiphlogistic treatment, or who have had profuse hemorrhage. It has been asserted that convalescence is in some instances influenced by climate, and that recovery takes place sooner in temperate than in hot countries.

The changes which indicate the stage of convalescence vary according to the nature of the previous illness. They are much less remarkable in chronic than in acute disease. In chronic affections the restoration of the functions of the part affected is very slow and imperceptible: if there has been much emaciation, the flesh and bodily vigour are slowly regained, even though the local disease have been completely removed. Convalescence from acute disease, on the other hand, is more rapid and perceptible, and is announced by the cessation of the more severe symptoms, general as well as local. The frequency of the pulse abates, the heat of the skin diminishes, the thirst decreases, the various functions are gradually restored to their natural state; the tongue becomes clean, the appetite for food returns, and the patient enjoys intervals of refreshing sleep. Besides general signs of amendment, the change from disease to health is evinced in the improved aspect of the countenance: this has always been regarded as a sure criterion of returning health; indeed it may be laid down as an axiom deduced from experience, that unless improvement in the countenance accompany the amendment in the symptoms, the condition of the patient is unsatisfactory. The state of the intellectual powers also becomes improved on the approach of convalescence—there is greater mental energy—the memory, judgment, and

imagination assume their former activity, though continued mental effort sooner induces fatigue than in health. Convalescents from acute disease, however, show great sensibility to external impressions, particularly to extremes of heat or cold; they evince also a morbid nervous susceptibility, and are therefore more prone than usual to irascibility.

Another circumstance which often materially interferes with convalescence, is the supervention of some other disease during this period. It is by no means unusual to find that the original disease from which the invalid was recovering is from some cause suddenly renewed, for it should be remembered that a predisposition having been given by the previous disease, the symptoms may be reinduced by the application of less powerful exciting causes than those which produced the disease in the first instance. In other instances we find that some accidental inflammatory disease appears, and places the convalescent again in danger. This often happens in cases of continued fever; and in the eruptive fevers some accidental symptoms occasionally arise which materially interfere with convalescence. Thus, in small-pox, after the eruptive stage has passed over, secondary fever often supervenes, which may be in some cases traced to some local disturbance; and we not unfrequently observe in this disease, as well as in measles, a troublesome form of ophthalmia which is tedious and often dangerous to vision. In measles, the convalescence is very frequently interrupted by some other local inflammation, generally of the lungs, or by the supervention of glandular disease, more particularly in the advanced period of the disorder. In scarlet fever the stage of convalescence is also occasionally protracted by various symptoms, which often prove tedious and difficult to subdue. Anasarca swelling of the extremities of an acute character, with or without internal effusion; glandular enlargements, inflammation of the ear, inflammation of the large joints, irritation of the mucous membrane of the bowels, are among the more troublesome sequela which materially retard convalescence in this disease.

Besides these general circumstances which are observed in convalescence from acute and chronic diseases, there are others which characterize recovery from particular affections. It will be found to be a general rule that recovery takes place more slowly in primary than in symptomatic fevers. This slow recovery from fever, strictly so called, is owing to the more general affection of the solids, as well as to the more tedious nature of the disease, which often, in spite of the most judicious measures, runs on for an indefinite period. In inflammatory disorders, on the other hand, when the local affection is subdued, the febrile symptoms in general gradually abate, so that the patient is not only convalescent in a comparatively short time, but the stage of convalescence is also of proportionably limited duration.

In diseases of the brain the functions of this organ are seldom at once completely restored;

hence, in the stage of convalescence we often observe various imperfections either in the intellectual powers or in some of the senses, and these may continue even after the causes which induced them have been removed. When the cerebral affection has been attended with paralytic symptoms, the muscular movements often remain in some degree impaired for a considerable time after the individual may be said to be convalescent. This imperfect state of the muscular power may exist alone, or it may be associated with some defect of the mental functions, or of some of the senses. From these various morbid conditions of the nervous system the invalid may ultimately completely recover, or more or less imperfection may continue for life.

In convalescence from pulmonary diseases, some symptoms often remain which indicate the previous affection, such as cough, or slight acceleration of the breathing on any sudden or unusual exertion. When these symptoms continue, it is evident that the lungs have not regained their healthy condition; that although the progress of the malady has been arrested, it is not wholly subdued; and consequently that it is very liable to be again induced on the supervention of even a slight exciting cause. The same continuance of slight symptoms is often remarked in diseases of the abdominal viscera. In dyspepsia the digestive organs very slowly recover their tone, the convalescence being often protracted by errors in diet; and after the more prominent symptoms have ceased, the stomach remains for a long time exceedingly sensitive, and never fails to give ample evidence of displeasure, when oppressed with food of an improper quality, or with greater quantity than it can readily digest. In inflammation of the mucous membrane of the intestines too, there is often for a long time a troublesome state of the bowels, besides great tendency to renewal of the inflammatory action which may have just ceased, on the application of a very trivial occasional cause; hence the necessity of attention to minute dietetic precepts in this class of diseases.

After these general observations, we shall offer a few remarks on the management of convalescence. It is almost unnecessary to say that this must vary according to the nature of the previous disease, its intensity, and the special circumstances which each individual case presents.

In external diseases the principles of treatment are not only more obvious, but the application and the effects of remedies more nicely regulated, than in internal disorders, and for this obvious reason, that the progress of the disease can be ascertained with almost unerring certainty. The state of an internal organ can only be known by symptoms, which it must be admitted give too often uncertain and imperfect indications of its actual condition. There is, however, one among many important advantages of the knowledge of the nature and treatment of surgical diseases to the medical practitioner, that it enables him to form a pretty exact

estimate of the value of curative measures, and of the circumstances which advance or retard recovery.

In cases of ophthalmia, it is well known that it is imperative to abstain from all use of the eye, not only during the treatment, but for some time after the inflammation has been subdued. Any deviation from this obvious principle is immediately followed by such effects as are generally sufficient to bring conviction of its importance. The same necessity for caution in cases of inflamed joints comes almost daily under notice. If, therefore, such precautionary measures are necessary in external diseases, in which the various changes are evident to the senses, they are equally requisite in those of internal parts, more especially of the inflammatory kind, in which the changes which the organs undergo are almost precisely the same, while there is the same tendency to relapse, or renewal of the diseased condition, after any irregularity in the management or conduct of the convalescence.

It is quite evident that the first indication in the management of convalescence is to avoid those causes which primarily induced the disease. Another obvious principle is, that the measures to be pursued should always have reference to the nature of the previous disease, and the organ or parts which have been affected. This principle will at once suggest the propriety of abstaining from those circumstances which require such exercise of any organ which has lately been diseased, as might endanger a renewal of the morbid action. Thus, for instance, in recovery from disease of the brain, whatever entails on the patient undue mental effort, should be deferred to a more distant period. In affections of the organs of respiration or of circulation, whatever tends to excite the one or the other must be avoided. It will also be necessary to regulate not only the various functions, but the diet, exercise, and likewise the temperature of the apartment. In convalescence from diseases of the alimentary canal, the practitioner will have to attend to the state of the bowels, but more particularly to the proper regulation of the patient's food. These examples might be extended; but enough has been advanced to illustrate the principles we have endeavoured to inculcate.

Another important circumstance in the management of convalescence is the proper administration of remedies. This must be regulated by particular indications. In some instances, it may be necessary to continue for a time the employment of the remedies which were administered during the disease; for instance, after recovery from dropsical diseases, it may be useful to continue the purgatives or diuretics till the convalescence be nearly established. In other cases, the remedial part of the treatment may be entirely suspended, giving occasionally such medicines only as particular circumstances may require.

The most important department of the management of convalescence is the proper regu-

lation of diet. It is almost inconceivable how many errors are constantly committed in this respect, chiefly from want of conviction, on the part of the patient, of its important influence on his recovery, and occasionally from misconception, on the part of the medical attendant, of the principles on which the diet should be conducted. It is a common error to suppose that the debility, which is the almost invariable consequence of acute disease, and which is more perceptible when the invalid first attempts to make exertion, is to be removed by nourishing food and stimulating drinks: it is no unusual circumstance to meet with such erroneous impressions even in cases of muscular relaxation from cerebral disease. When indiscretion is committed under such circumstances, the previous disease, which had just been subdued, is very generally rekindled, and all the primary symptoms are thus reproduced.

Such errors are more liable to be committed in cases of tedious convalescence, where there is a state of undefined indisposition, attended with impaired vigour, so that the invalid does not gain strength, or perhaps loses it progressively. If the state of the organ that was primarily diseased be examined, the cause of the slow recovery will, in the majority of instances, be detected. The disease has possibly not been wholly subdued, or it may from some cause have been renewed. Under such circumstances the folly and hazard of adopting a stimulating plan of diet and tonic remedies is apparent; the only rational indication is to arrest the disease if it be not entirely subdued, or have been reintroduced.

The necessity of proper regulation of the diet is greater in convalescence from acute than from chronic diseases; it becomes the more necessary when the previous disease has been severe and protracted, or, though not protracted, when rigorous antiphlogistic measures, and especially large evacuations of blood, have been employed. The tendency, however, of chronic visceral disease to assume, perhaps suddenly, a more active form, should always be kept in view, as well as the fact that nothing is more likely to induce such excitement than errors of diet. It would lead to tedious repetition were we to point out those forms of chronic disease to which this remark is applicable: in such an article as the present, general principles only can be given, which the practitioner may apply to individual cases.

The return from the bland unirritating food which has been allowed in the active stage of acute disease, to food of a more nourishing quality, should be gradual: the first step should be to substitute another article of the same class of farinaceous food, increasing by degrees the quantity, which should be divided into portions to be taken at short intervals. Milk, particularly asses' milk, is a very suitable article of diet for delicate convalescents, and especially children. Another progression may be made by substituting a weak infusion of animal food with a moderate quantity of farinaceous admixture, either of arrow-root, prepared barley, rice, or stale bread. If the condition of the patient

admit of it, the liquid nourishment may be abridged, and a very small allowance of solid animal food allowed. Great care should be taken in the selection of and mode of dressing the animal food. In general, mutton is most easily digested, and, if it agree, may be preferred exclusively for the first eight or ten days, or exchanged occasionally for chicken. The propriety of first allowing white fish as being a more digestible kind of food for convalescents is questionable. It affords certainly a less quantity of nourishment than animal food, (though this advantage may be gained by diminishing the allowance of the latter,) but it is certainly more difficult to digest, and therefore less suited to the convalescent, besides that it affords opportunity for indulging in condiments and additions of an improper kind. In the advanced stage of convalescence from acute disease, if there be nothing to forbid it, one or two glasses of sherry, mixed with water, may be allowed. When the convalescence is completed and the health restored, a more liberal scale of diet may be gradually adopted, though for a very long time great care should be exercised, so as to avoid any articles which are likely to disagree. It should also be impressed on the mind, that the quantity as well as quality of the food is to be regulated—indeed convalescents often suffer more from too much food, even of a proper kind, than from food of an improper quality.

The due regulation of exercise forms another important part of the management in convalescence. This should not be suddenly resumed—nor at any time carried to such an extent as to induce fatigue; and should be suitably adapted, not only to the powers of the invalid, but to his previous habits and condition of life. We have already shortly adverted to the necessary precautions in exercising the functions of the organs which have been previously diseased. It must be obvious that while all undue exertion of an organ is prohibited, the bodily exercise should be so regulated as not to produce excitement, which might not only be injurious, but endanger the safety of the organ previously diseased.

The necessity of suitable clothing in convalescence is so obvious to the invalid, that it seldom requires to be inculcated by the medical attendant. In temperate places, and more especially in those situations where the temperature is variable, it is necessary to protect the surface for a time by warm clothing, and particularly by flannel under-garments. Some delicate persons suffer so much irritation from the use of flannel, that it becomes necessary to interpose a linen under-dress, or to substitute calico. It should be explained to invalids that the use of woollen garments is not so much for the purpose of affording additional heat, as to protect the surface from sudden atmospheric changes, which, by chilling the skin or exciting the circulation, might reproduce the primary disease.

The atmosphere of the chamber to which the invalid is for a time confined should be frequently renewed; and while attention is paid

to ventilation, the temperature should be duly regulated. In the winter and spring months it should be kept as nearly at from 55° to 60° Fah. as possible, while the invalid continues weak. When he has regained his strength it may be gradually reduced, so as to enable him to bear the ordinary temperature of the season, first in an airy chamber, and afterwards in the open air. When circumstances permit, nothing in general tends so much to promote and establish recovery as what is commonly termed *change of air*. In most instances, the improvement in the looks and feelings of the invalid, very soon after he has removed from a confined to a more salubrious district, is remarkably striking.

For further illustration of this subject, however, we refer to the articles CHANGE OF AIR, and CLIMATE.

(A. Tweedie.)

CONVULSIONS (*convulsio*, from *convello*, to pull together.) By the term *convulsion* is meant a diseased action of the muscular tissues characterized by violent involuntary contractions, with alternate relaxations. This diseased action is common to the muscles both of voluntary and involuntary motion, but occurs much more frequently in the former. The term *spasm* has been applied by some to the inordinate action of the involuntary muscles; the term *convulsion* being more particularly reserved to designate the irregular contraction of the voluntary muscles. By Cullen and some other writers the term *spasm* has also been applied to the fixed contraction of parts. When the contractions have been of some duration, and are not quickly succeeded by alternate relaxations, they have been called *tonic convulsion*, as is exemplified in tetanus; whilst involuntary alternate motions of contraction and relaxation have been termed *clonic convulsions*, of which hysteria affords an example. The term *convulsion* has sometimes been exclusively appropriated to clonic convulsion; but as the principal difference between *clonic* and *tonic* convulsions consists in degree, and they both originate in the same causes, it is more convenient for practical purposes to include them under the same head. Very slight and quick alternate motions of contraction and relaxation constitute what is called *tremor*.

Convulsions manifest themselves in various degrees and under various forms. They occur as a symptom in the course of many diseases, and they sometimes assume such regular and well-defined characters as to constitute distinct and separate diseases; as, for instance, in the case of tetanus and hysteria. Convulsive affections have been classed by most nosologists among the *neuroses*, or nervous diseases. Sauvages, Vogel, and Cullen include them as a genus in the order *spasm*. Cullen defines this order "an irregular clonic contraction of the muscles, bordering on but short of lethargy." The presence or absence of lethargy depends, it will be seen, on the seat of the exciting cause. This genus contains a great many species; but he has made separate genera of several convulsive affections, such as hysteria,

tetanus, and epilepsy. Dr. Mason Good's arrangement of convulsive affections is very complicated: they are included in the class *neurotica*. He makes one genus of tonic convulsions termed *entasia*, including tetanus, hydrophobia, wry neck, muscular distortions of the spine, cramps, &c. Another genus of clonic convulsions is termed *clonus*: this includes singultus, stermatio, palpitatio, niectatio, subsultus, pandiculatio. A third genus called *synclonus* comprehends tremor, chorea, shaking palsy, raphaneia, and heriberia. His last genus is called *syspasia*, or comatose spasm, in which he places convulsion, hysteria, and epilepsy.

Convulsions have also been divided into primary and secondary; acute and chronic; continued and intermittent, &c.; but these divisions are unimportant, as they lead to no practical end.

There are attacks of simple convulsion, partial and general, that cannot be referred to hysteria, epilepsy, or any of the well-defined convulsive affections which have received generic names. These varieties of simple convulsion will form more particularly the subject of the present paper; and as convulsive affections are generally entitled, by the formidable character of their symptoms and the imminent danger which frequently attends them, to the attentive consideration of the practitioner, we propose taking a general view of their pathology, and of the principles which are to regulate their treatment.

Convulsions may be *local* or *general*; each part may be separately and successively affected, or the whole frame may be convulsed at once: in some cases the convulsive movements are confined to one side of the body. We shall first consider the manner in which different parts of the body may be separately affected with convulsions.

*Local convulsions*.—When the eye-lids are affected, if the convulsion is confined to the levator palpebræ superioris, the upper eye-lid is forcibly drawn up, and cannot be closed; the eye-ball consequently remains uncovered, and is exposed to painful irritation: this occurs sometimes as a local affection, especially in neuralgia of the supra-orbital nerve. If the orbicularis muscle be affected, the eye-lids are forcibly closed, and can with difficulty be separated. Slight convulsions of the muscles of the eye cause a rotatory motion of the globe from side to side or else upwards. This is a frequent symptom of visceral irritation, especially in children, in whom it often occurs during sleep. When these muscles are more violently convulsed, there is strabismus, or a violent contortion and rolling of the globe in the socket; or else the eye is firmly fixed, staring and protruding. The iris being possessed of contractility is susceptible of convulsive action; the pupil is then either very much contracted and immoveable, or else it is alternately closed and dilated by quick and irregular oscillations. Both pupils may be differently affected, one remaining fully dilated when exposed to light, whilst the other contracts; or one may remain

stationary, the other being alternately contracted and dilated. There are in this respect great variations.

The convulsions of the muscles of the face give rise to a great variety of remarkable and opposite expressions. The whole of the features may be fixed and immoveable, or there may be a constant change of expression by the momentary contraction of separate muscles in quick succession; or the convulsions may affect only some of the features, causing, for instance, slight evanescent twitchings of the lips or distortion of the mouth; or else an elongation and drawing up of the commissures of the mouth. This last variety gives rise to a species of convulsive laughter, sometimes closely resembling the smile and laughter of health, especially in infants, but often more violent: this is the *risus Sardonicus* of the ancients. When the muscles of the jaws are affected, there may be grinding of the teeth or a violent clattering of the jaws; or else there is a permanent rigid spasm, rendering the lower jaw fixed and immoveable, as in trismus. Persons of a highly nervous temperament are sometimes affected with an habitual twitching of certain muscles of the face; these generally arise from constitutional causes, and are difficult to be remedied. Convulsions of the muscles of the tongue cause it to be violently twisted in the mouth so as to push out the cheeks, or else it is forcibly protruded; it is very liable in that case to be severely wounded by the teeth, and has in some rare cases been completely cut off. A tremulous state of the tongue when put out, is a sure sign of general nervous debility.

When the muscles of the neck are simultaneously convulsed, the neck feels hard, and the head is drawn back; if only those on one side, the head is drawn to that side or partly turned round. There may be, from this cause, either a permanent rigid contraction, or a convulsive agitation, or a simple tremor of the head and neck. These modifications are observed in wry neck and *paralysis agitans*.

Convulsion of the muscles of the pharynx impedes deglutition, and gives rise to spasmodic dysphagia. The convulsions of the muscles of the larynx cause laryngeal dyspnoea and suffocation, and either various alterations or a total extinction of the voice: these are frequently symptoms of inflammatory and spasmodic croup. The sensations of stricture and strangulation in the throat which so often attend hysteria, chorea, hypochondria, &c. are owing to a convulsive state of the anterior muscles of the neck.

Convulsive affections of the muscles of the thorax (the intercostals, diaphragm, &c.) are sometimes the primary cause of habitual dyspnoea or of violent paroxysms of cough and suffocation, constituting a variety of convulsive asthma. When the convulsions are severe, the breathing is very irregular: there are a few short inspirations and expirations; then a long intermission without any breathing, followed by several deep inspirations, with heaving of the chest and sighing: in some extreme cases the constriction of the chest has

been so violent as to stop the breathing altogether and cause asphyxia. This irregular and occasionally hurried breathing gives rise to a corresponding state in the action of the heart, which becomes violently increased; there is a sudden and considerable rise in the frequency of the pulse, which might be mistaken for fever; the circulation subsides, however, with the paroxysm to its natural standard. A convulsive state of the diaphragm gives rise to hiccup, which is sometimes a most distressing and obstinate complaint.

The convulsions of the abdominal muscles cause in some cases a violent retraction and hardness of the abdomen; in some a convulsed agitation of the parietes of the thorax, bearing the closest resemblance to irresistible laughter; and in others a peculiar undulatory motion of the abdomen frequently observed in hysteria. It is not improbable that the globus hystericus depends on a partial convulsion of the abdominal muscles extending upwards to the diaphragm, and the muscles of the thorax, neck, larynx, and pharynx. The late experiments on the causes of vomiting prove that the contractions of the abdominal muscles have as great a share at least in its production as those of the stomach. The sphincter muscles are often convulsed, as is seen in the tenesmus of dysentery, the dysuria of the irritable urinary bladder, and the retention of urine from permanent spasm of the sphincter vesicæ.

When the muscles of the trunk are affected with convulsions, the body is forcibly bent backward or else to one side: this is termed opisthotonos, and is a frequent symptom of tetanus. There is a partial and permanent rigidity of these muscles in muscular distortions of the spine. Painful cramps of the dorsal and lumbar muscles are sometimes experienced in acute rheumatism.

In convulsions of the upper extremities, the fingers are clenched on the hand and round the thumb, and the hand is turned in pronation; the fore arm is bent on the arm, or moved backward and forward as in the act of striking. There may be very slight and partial convulsions of these muscles, discovered only by the startings of the tendons (*subsultus tendinum*) on placing the hand on the wrist; these sometimes indicate the approach of a severe convulsive fit.

Convulsions manifest themselves in the lower extremities by the strong retraction of the toes inwards and downwards, the legs and thighs being rigidly drawn up or alternately bent and extended. In these cases the flexor and extensor muscles are principally affected, and the adductors or abductors but seldom.

The involuntary muscles are also liable to be affected with convulsions, although much less frequently than those of voluntary motion. The action of the heart is sometimes very much increased and irregular in nervous palpitations, and in several of its organic diseases; or its motions may be suddenly stopped by a violent spasm of some duration, as occasionally happens in angina pectoris, and in cases of retrocedent gout or rheumatism.

The muscular coat of the stomach is subject to severe and painful spasmodic contraction in gastrodynia, and in cases of obstinate vomiting. There are strong partial spasmodic contractions of the muscular coat of the intestines, in the tormina of dysentery, the gripings of colic, the borborygmi and tympanitic affections of hysteria. The muscular apparatus of the urinary bladder is often thrown into a state of spasmodic irritation in diseases of the urinary organs. That of the uterus is susceptible of a sufficient degree of inordinate and convulsive action in the puerperal state to cause occasionally a rupture of the viscus, and the regulation of its contractions both before and during labour is always an important object in the practice of midwifery.

The different varieties of convulsions which have been described may exist separately, as distinct affections; they may be variously combined; and some of them may pass imperceptibly into each other.

*General convulsions.*—General convulsions consist of various combinations of the symptoms that have been described as characteristic of local convulsions. The mode of attack and progress of the paroxysm exhibit considerable variations. Sometimes the attack is sudden and without any warning; but more generally there are some premonitory symptoms, especially in children, and in patients who have had previous attacks: of this kind are coldness of the extremities, vertigo, floating spectra before the eyes, starting at slight noises, peevishness and irritability of temper, alternate paleness and flushing of the face, disturbed sleep, irregular breathing, hiccup, cramps in the hands, legs, and feet, flatulent uneasiness of the bowels, and tension in the left hypochondrium. In some cases a sensation of creeping cold along the back, like an aura, creating shivering, is the premonitory symptom.

The paroxysm is ushered in by dull pain or a sense of weight in the head, drowsiness, flushing, vertigo, either loss of sight and a sense of complete darkness, or flashes of light and bright objects moving before the eyes, ringing of bells or the noise of roaring cataracts in the ears, sickness, pain and sense of oppression in the epigastrium, &c. These symptoms are quickly succeeded by general convulsive contractions of all the voluntary muscles and many of the involuntary, in the manner just described in the account given of local convulsions. The face is hideously distorted; the protuberant eye-balls roll rapidly in every direction with a wild stare and constant motion of the eye-lids; there is grinding or gnashing of the teeth, occasional protruding of the tongue and foaming at the mouth, with a deep hissing noise, occasioned by the hurried passage of the air in breathing through the teeth. When the respiration is laborious and very much obstructed, there is a dark redness of the face and scalp, and a purple colour of the whole body, together with a full strong pulse and violent beating of the carotids; in other cases the face is pale and the pulse small and con-

tracted. Limpid urine is frequently voided in large quantities, and sometimes evacuations by urine and stool are expelled with great violence. The muscular force exerted in the course of the convulsions is in some cases enormous, shaking the entire room, and requiring five or six attendants to control the patient. Several authors relate cases in which the contractions have been of such intense violence that the teeth have been broken, blood has burst from the nose or been effused under the skin, producing general ecchymosis, and even limbs have been luxated or fractured.\* The violence of the muscular contractions gives sometimes very severe pain. The occurrence of delirium, coma, and insensibility during or after the attack will depend altogether on the degree and manner in which the brain is affected. If the convulsions are symptomatic of organic disease of the brain, the paroxysms are likely to be attended with delirium, followed by coma and insensibility; when there is no organic affection, but merely functional disorder, as in the case of simple convulsions, the consciousness is not impaired, or only in a very slight degree.

The paroxysm may sometimes cease in a few minutes, when the patient immediately recovers; or after he has remained for some time under a sense of suffocation, the impeded circulation and all the other symptoms may be relieved by a sudden fit of sobbing and deep sighing, as in hysteria; but the paroxysm occasionally lasts for several hours, as many even as twenty-four, at the end of which the patient falls into a profound and long continued sleep, from which he awakes suddenly, unconscious of what has happened: languor, vertigo, and sickness generally succeed these prolonged attacks. The paroxysms may return again at uncertain intervals, and be thus renewed until they spontaneously subside. This is the most common course in puerperal and infantile convulsions. The fits may finally prove fatal by causing apoplexy or asphyxia, and this has sometimes happened in the first attack: not unfrequently they leave behind them paralysis, chronic epilepsy, chorea, permanent squinting, &c. In some cases the mental faculties have been destroyed, and the patient has been reduced to idiocy or imbecility. A remarkable case has been recorded in the Medical Repository, by Mr. Thompson, of Whitehaven, of loss of speech and hearing in a child six months old, who had been suddenly seized with convulsions: her vivacity remained and her health was unimpaired. She continued in this state until her sixteenth year, when, after the noise of a public rejoicing, she was observed to recover the sense of hearing, and she soon began to articulate. Convulsions sometimes terminate by critical evacuations; the paroxysm has not unfrequently subsided on the appearance of epistaxis; and there are cases on record where the convulsions always terminated by copious hemorrhage from the mouth, nose,

\* Eph. Nat. Cur. Dec. Ann. 7.

and cars. Diarrhœa or vomiting are terminations of still more frequent occurrence. A state of profound syncope has sometimes supervened on convulsions; and there are instances recorded of the patient never rallying, and of its proving consequently fatal. But in cases of this description, after the excessive nervous exhaustion which generally follows a long continued state of violent agitation of the whole nervous system, the patient may remain for a considerable time in a state of lethargy or torpor, without shewing any signs of life, and still ultimately revive. It is under these circumstances that many horrible cases of premature interment are stated to have taken place, especially of women and children. The truth of some of these cases may be called in question, but there are others which appear but too well authenticated; and there are also undoubted instances of persons having very narrowly escaped being interred, whilst in the torpid condition now mentioned.

The paroxysm just described is a delineation of the severest form of convulsion. In the majority of cases the disease is of a much milder character: there is no affection of the intellect, local congestion, or fever; the convulsions affect only a few muscles at a time, extending in succession to the others; they may be confined to one side of the body, or attack both alternately: this constitutes the *convulsio erraticæ* of Good. The paroxysms may return only after long intervals more or less regular; the ordinary period in females is menstrual or lunar: this is the *convulsio recurrens* of Good. In some cases the muscles of respiration, and those especially of the larynx, appear to be chiefly affected, and the patient emits shrill or yelling sounds, which circumstance has induced the same writer to form a separate variety with the name of *convulsio ejulans*.

An important variety of convulsions is that connected with the puerperal state; they may occur in the latter periods of pregnancy, rarely, however, before the sixth month; during parturition, or in the first few days after delivery. As a separate article is devoted to this form of convulsions, we shall merely state in general that its symptoms are in some degree modified by the close sympathy which exists between the uterine system and the sensorium; in consequence of which there is a greater tendency to oppression in the head than in any other variety of convulsions; the breathing is stertorous, and the muscular action peculiarly violent. (See CONVULSIONS, PUERPERAL.)

Convulsions are likewise of very frequent occurrence in infants, owing to their great mobility of frame. In these cases the convulsive motions, especially of the mouth, eyelids, and fingers, are so excessively rapid that it is often difficult to follow them: this constitutes the *clampsia* of Sauvages. We shall confine ourselves to this brief notice of infantile convulsions, as, in consequence of their great importance, they will also form the

subject of a separate article. (See CONVULSIONS, INFANTILE.)

Convulsions may occur in the progress of a great many diseases. There is scarcely an acute disease with which they are not occasionally combined. They sometimes manifest themselves at the beginning of inflammatory and bilious fevers, and at the invasion also of nervous and malignant fevers, especially in hot climates. The rigors of the cold fit in the severer forms of ague have assumed sometimes the character of convulsions, and the patient has sunk under them, there not being sufficient power in the constitution to bring about a reaction. When convulsions occur in the latter stages of continued fevers in combination with delirium or coma, they generally indicate some dangerous affection of the brain. It should be remembered, however, that the salutary critical terminations of fever have been observed to be ushered in by some violent perturbation of the whole system, of which convulsions are occasionally a symptom; this apparent aggravation of the fever often deceives the attendants, who mistake it for the approach of death. The writer of this article experienced on the twenty-first day of a nervous fever, a most frightful fit of convulsions, attended with laughter, hysterical sobbing, violent protrusion of the tongue, vomiting, &c. which, however, were soon relieved by the bursting out of a profuse perspiration and a complete remission of fever. Convulsive paroxysms are not uncommon in the remittent fevers of infants; and unless the progress of the disease be carefully attended to, it may be mistaken for hydrocephalus. The distinction between the two diseases is obviously of considerable moment, for the latter is always attended with great danger, whilst the former is rarely fatal.

The eruption of the exanthemata, particularly variola, rubeola, scarlatina, &c. is not unfrequently preceded by convulsions. In such cases convulsions have been considered by the majority of writers as a favourable omen; a few, however, have maintained an opposite opinion, and cases may sometimes occur that seem to justify this conclusion. When after a violent constitutional disturbance, attended with convulsions, only a very slight eruption makes its appearance, which quickly vanishes, the effort of the constitution is apparently unavailing: as the brain sympathizes strongly with affections of the skin, the irritation which should have been fixed on the skin may, in such a case, be transferred to the brain, and become the exciting cause of some dangerous cerebral disease; the convulsions will then be severe and frequently repeated, and they may ultimately prove fatal. Convulsions are also of frequent occurrence in whooping-cough and croup; in all inflammatory and organic diseases of the brain and spinal marrow; in some severe cases of organic disease of the heart, owing probably to an embarrassed state of circulation in the brain; and they have been observed, too, in calculous affections of the urinary bladder and kidneys. Acute

diseases have sometimes terminated, as if by sudden transition, in attacks of chorea, epilepsy, &c.

It is well known that the closest sympathy exists between the brain and the genital organs. The development of these organs at the age of puberty is frequently productive of considerable constitutional disturbance and nervous irritation; this is more especially the case in females: the first appearance and regular development of the menstrual discharge is attended in some cases with a great struggle in the constitution, and may be characterized by convulsive paroxysms in combination with many other painful symptoms. The susceptibility of the nervous system being considerably increased, very slight moral or physical impressions are sufficient to excite convulsions. If the struggle ends in the full and regular development of the uterine functions, the convulsions disappear, and the health will be firmly re-established. It has been observed that chorea, epilepsy, and other diseases of youth, generally subside at this critical period, if the constitutional changes peculiar to it are not interrupted; but that these diseases become confirmed and aggravated, or others make their appearance, when there is not sufficient power in the constitution to bring about the accomplishment of this important end. The spontaneous cessation of the catamenia at the usual period of life is sometimes marked, like their first appearance, by considerable disturbance of the health, and convulsions either local or general are among the occasional symptoms of the climacteric diseases of women.

The convulsive affections connected with disorder of the uterine functions do not always follow the usual regular course, but assume sometimes an infinite variety of anomalous forms; appearing in combination with other formidable diseases, resisting for years every mode of treatment, and subsiding at last without apparent cause when least expected. The following is a general enumeration of the principal symptoms of these *anomalous* cases:—convulsive affections of the limbs or muscles of the trunk, sometimes resembling tetanus, chorea, or catalepsy; permanent spasmodic retraction of some of the extremities, or weakness amounting sometimes to complete paralysis, which is often accompanied by remarkable convulsive contractions of the paralytic limbs; feeling of great weakness in the back, attended frequently with severe pain and excessive tenderness on pressure, confined to one part or extending along the whole of the spine; a variety of cerebral symptoms: intense headach, permanent or periodical; vertigo, tinnitus aurium, temporary delirium, mental alienation, or fits of lethargy; various neuralgic and convulsive affections of the face; sudden attacks of blindness; difficulty of deglutition; extinction of the voice or loss of speech. Severe paroxysms of dyspnœa, combined sometimes with violent palpitation; spasmodic affections of the ali-

mentary canal; remarkable irritability of stomach and sometimes severe vomiting, which we have seen continue with very little intermission for several months; attacks of spasmodic colic, with immense tympanitic distention of the abdomen; obstinate constipation, and an extremely vitiated state of the biliary and intestinal secretions; sometimes distressing dysuria, at others retention of urine, the urine being generally clear and very copious, in some cases very turbid and scanty.

It would be impossible to describe the various extraordinary combinations under which the preceding train of symptoms may present themselves: there may be sudden and rapid transitions from one extreme to another; we have seen in the same patient well marked symptoms of apoplectic coma and paralysis, epilepsy, catalepsy, tetanus, and maniacal delirium, succeed each other with incredible rapidity, and finally subside without any material injury to the health. The force exerted by the lady who was the subject of this case, during the paroxysms, was quite extraordinary. It frequently happened, during even the intermissions, that, when she took hold of a chair or any other object, her hand would suddenly contract upon it independently of her will, and with so firm a grasp that the utmost strength of two persons would be insufficient to loosen the fingers, and she would be obliged to wait until the spasm subsided of its own accord. In other cases the patients have laboured for a considerable time under apparent symptoms of formidable cerebral or spinal disease, such as apoplexy, hydrocephalus, paralysis, &c. and have ultimately recovered, although their condition was considered perfectly hopeless.

The pathology of these anomalous diseases is still involved in much obscurity; it is highly probable, however, that they have their origin in neuralgic affections of the brain and spinal marrow, and that the ganglionic nerves of the great sympathetic have also considerable influence in their production. Dr. Abercrombie has recorded several highly interesting cases of this description. One of the most remarkable is that of a lady aged twenty-four, who, during a period of above six years' illness, was affected in succession with hemiplegia, loss of speech, chorea, sudden attacks of blindness, convulsions of the muscles of the back, legs, and arms. These convulsions were occasionally so violent, that her body would be suddenly seized with a kind of convulsive spring, by which it would be thrown out of bed on the floor, and from the floor back again into bed; at other times she would leap on the top of a wardrobe fully five feet high; the mind remaining all the while unimpaired. Subsequent to the preceding symptoms she suffered from difficulty of deglutition, and convulsive motions of the neck, producing for weeks together a constant rotatory motion of the head. The last-mentioned symptoms continued four years, with intervals of tolerable health of only a few weeks' duration. Menstruation was all along extremely irregular and scanty, and the

bowels were torpid. The treatment during the six years previous to Dr. Abererombie's attendance, had been copious, general, and local depletion; active purging and counter-irritation. She was of a pale and bloodless aspect, though not reduced in flesh. An entirely opposite plan of treatment was now adopted; three grains of sulphate of iron, combined with sufficient aloes to regulate the bowels, being exhibited three times a day. At the end of three weeks, a severe paroxysm of the rotatory motion of the head under which she was labouring, stopped suddenly; at the same instant menstruation took place in a more full and healthy manner than it had done for many years, and from that time she completely recovered. This case affords a striking example of the anomalous nervous affections in question, and is highly interesting from the result of the treatment.

The prognosis of convulsions is very uncertain; it depends on the nature of the causes, the age, the habits of life, and preceding diseases. When the affection is purely nervous, without fever or any organic affection of the head, there is little to apprehend; but if the attack begin with symptoms of cerebral affection, or if it terminate in stupor or coma, the case is not free from danger. Acute organic disease is always attended with fever; simple nervous irritation is almost always without it. After a long continued paroxysm, arising only from nervous irritation, the patient may fall into a state of stupor bordering on coma from mere excessive nervous exhaustion: this must not be mistaken for the coma of organic disease. Convulsions towards the end of fevers, or of inflammatory diseases of the brain, are always alarming.

We have already stated what were the conclusions to be drawn from the appearance of convulsions at the invasion of fevers and of eruptive diseases. Paroxysms of long duration are attended with danger. In those cases, in which from great nervous susceptibility convulsions are very easily excited, they more readily subside, and are the less dangerous; they are thus attended with less danger in women than in men, in youth than in old age. This fact had not escaped Arætaeus, who said, *Mulieres uervorum distensionibus magis opportuna sunt quam viri, sed et frequentius etiam liberantur.*—Lib. i.

*Causes.*—The causes of convulsions are predisposing and exciting. The *predisposing* causes are either constitutional or accidental. Constitutions in which the nervous temperament predominates are the most obnoxious to convulsive affections. We know nothing of the essence of the nervous power, but one of the remarkable laws which regulate its operations is, that within certain limits its irritability increases as its energy diminishes. The nervous temperament derives its essential characters from nervous debility, combined with an increased susceptibility to external impressions. This condition of the nervous system is commonly observed in persons of relaxed,

debilitated, and delicate fibres; they are extremely sensitive to the action of all kinds of stimuli, whether physical or moral, and are endowed with great mobility of disposition and fickleness of temper; they are also frequently predisposed by their laxity of fibre to plethora; and we shall see presently that overdistention of the blood-vessels is not unfrequently an exciting cause of convulsions. The nervous temperament is, however, sometimes observed in persons of a thin and delicate habit of body, and associated at others with a firm and rigid, though spare fibre. It is evident, from what has just been stated, that women and children will be more predisposed to convulsions than men or persons advanced in life.

The accidental predisposing causes are numerous, and most of them may become exciting causes. We may state, in general, that they are to be found in all external circumstances calculated to create debility either bodily or mental.

*Exciting causes.*—It is generally admitted that the nervous power, whatever may be its nature, proceeds either from the brain singly, or the brain and nerves jointly. Although the muscles may appear to possess a certain degree of special irritability, it is incontrovertible that they derive their power of contraction from the nervous influence transmitted to them by the brain and different parts of the nervous system. The muscles of voluntary motion receive their nerves chiefly from the spinal marrow, and but few comparatively from the brain; the muscles of involuntary motion (the muscular textures of the thoracic and abdominal viscera) are mostly supplied with nerves from the ganglions of the great sympathetic, receiving only a few from the brain. The innumerable ganglia and plexuses of the great sympathetic appear to be formed principally by large and numerous branches coming from the spinal marrow. During a state of health, the contraction of the voluntary muscles is completely under the control of the brain, this organ being the seat of volition. But during convulsions the voluntary muscles are excited without the concurrence of the will, and are entirely withdrawn from its influence. Irritation in the brain alone is sufficient to produce general convulsions, in consequence of the great influence of that organ over every other part of the nervous system; but the existence of convulsions does not, on that account, always necessarily imply that there is an affection of the brain; it is easy to demonstrate by experiments that any kind of irritation applied either at the origin of the nerves in the spinal marrow, or in the course of the nerves themselves, will be sufficient to produce convulsions in all those muscular parts to which the nerves are distributed. A primary affection either of the brain or spinal marrow is not, therefore, essential to the manifestation of convulsions. Cullen, Dr. John Clarke, Brachet, and other writers have advanced the doctrine that convulsions

are always the result of cerebral irritation; but this opinion is evidently untenable. The occurrence of loss of consciousness in convulsive affections will depend on the brain being the seat of the disease, and on the manner in which it is affected; for a slight irritation of the brain, sufficient to excite convulsions, may exist without diminution of consciousness.

When the exciting cause acts on the brain, the convulsions are likely to be general, although partial convulsions are occasionally traced to some disease in the brain of very limited extent. If the exciting cause is applied to the spinal cord, all those parts receiving nerves from the portion of the cord below the seat of the irritation may be affected with convulsions; and if applied in the course of a nerve, the muscles to which that nerve is distributed will be alone affected: all convulsions produced in this manner may be considered as *primary* or *idiopathic*. But convulsions frequently occur in a very different manner, with respect to the seat of the exciting cause. Instead of its being applied either at the origin or in the course of the nerves, and the irritation being directly transmitted to their extremities, these pulpy extremities themselves receive the first irritating impressions from the various stimulating agents they come in contact with on the surfaces of organs; these morbid impressions are then transmitted along the nervous fibres to the brain and spinal marrow, which organs communicate the irritation by reflection to the whole frame. The great sympathy of several organs with both the brain and spinal marrow becomes thus a prolific source of general disturbance to the entire nervous system, of which the uterine and digestive organs afford examples in the production of hysteria, and of various other convulsive affections. The convulsions occurring in the manner just described may be termed *secondary* or *sympathetic*. It is very remarkable that pain in any part, sufficiently severe to bring on convulsions, completely disappears during the fit.

The nervous power which acts on the muscles may be produced in excess or in deficiency, or it may be irregularly transmitted. The causes of nervous irritation are extremely numerous. One of the most simple is pressure: when applied mechanically to the brain of an animal, if slight, it causes convulsion; if great, numbness, paralysis, and coma. Pressure on the brain or spinal marrow may be the effect of congestion or inflammation. An habitual determination of blood to the head in people of a plethoric habit renders them very prone to suffer from convulsions. This is frequently the case in puerperal women. Inflammation of the membranes of the brain is generally attended with very violent convulsions, much more so than inflammation of the substance of the organ.

Among the other causes of pressure and irritation are to be reckoned extravasations of blood, the serous effusions of hydrocephalus,

organic tumours, bony tumours or spiculae growing from the inside of the cranium, and injuries of the head with fracture and depression. Causes of a similar nature may affect the spinal marrow. There are other more indirect causes of cerebral irritation. It was observed by Morgagni, with respect to mechanical injuries, that the nearer they were to the head the greater was their influence on the brain; that, for instance, a very slight cut over the orbit was more likely to excite cerebral irritation than a much severer wound in a more distant part. The severe cerebral irritation which sometimes attends dentition may be accounted for on the same principle. Carious teeth are often an active source of cerebral and nervous irritation, and have not unfrequently been the occasion of slight convulsions in individuals of very irritable temperament. The laceration of nerves is a very frequent cause of tetanus, or severe convulsions. It is singular that the muscles to which the injured nerve is distributed may be the last affected with convulsive action; convulsions, however, do not always follow inflammation of the nerves. Convulsions, either local or general, are likewise frequently occasioned by tumours compressing nerves in their course;\* by contused and lacerated wounds of other parts, especially of ligaments and fibrous tissues; dislocations, compound fractures, &c. and finally, by intense pain, whatever be its source.

Gastric and intestinal irritation have always been considered among the most active causes of convulsions, especially in children; it may be sufficient to instance the convulsions occasioned by worms, and the distressing cramps so frequently experienced from the presence of acidity in the primæ viæ. We have already alluded to the great influence of the uterine functions on the brain and nervous system, and to their being a most frequent source of nervous irritation and convulsions. This arises in puerperal women from two causes—the distention and pressure of the uterus causing an accumulation of blood in the head, and the high degree of nervous susceptibility which attends the puerperal constitution.

Among the occasional causes of convulsions may be mentioned, exposure of the bare head to the heat of a burning sun; sudden transitions from heat to cold; suppressed perspiration; the suppression of eruptive diseases, such as variola, rubeola, and of many chronic cutaneous eruptions; and that likewise of old sores, and of the menstrual and hemorrhoidal discharges; the retrocession of gout and rheumatism, and of several other diseases. A strong excitement of the external senses sometimes produces great cerebral irritation. Very sensitive women have been thrown into convulsions by the scent of flowers, or by deeply impres-

\* Sir H. Hallford mentioned, in a paper read before the College of Physicians, several cases of severe neuralgia of the infra-orbitary nerve, caused by the pressure of bony tumours within the infra-orbitary canal.

sive music, or the unexpected sight of an object either of interest or aversion: the effect of the smell of paint on some constitutions is also well known.

Moral emotions may be considered among the most powerful causes of convulsions, particularly when operating upon the sensitive minds of children. This is a point of considerable importance as respects the conduct to be pursued towards them, and the regulation of their dispositions. The exciting and the depressing passions act very differently; the first, as anger and excessive joy, throw the individual into a state of high excitement, causing a determination of blood to the head: the second, as fear, occasion a sudden collapse and prostration of the nervous power. There are numerous instances of an attack of epilepsy, chorea, or even of fatal convulsions, resulting from a sudden fright. Great mental exertion, loss of sleep, excessive anxiety, the abuse of spirituous liquors, by gradually exhausting the nervous energy, create an extreme degree of irritability, which has not unfrequently induced convulsive fits.

Convulsive affections are very much under the influence of habit; so that even after the removal of the exciting cause, there may be regular repetitions of the attack, in consequence solely of the portion of the nervous system which is affected having acquired a depraved habit. Many curious instances of this description are to be found in medical writings. These habits of recurrence are sometimes not broken off without great difficulty. Another peculiarity of convulsive affections is, that they can be acquired by the mere power of imitation. In sensitive children, and young females endowed with great nervous susceptibility and a lively imagination, the influence of example on the nervous system is very remarkable; the instances of individuals so constituted being seized with an attack of convulsions, chorea, or epilepsy, merely through the shock experienced by witnessing others affected in the same manner, are by no means uncommon. In the history of the dark ages, when superstition and fanaticism had a strong hold of men's imaginations, there are recorded several instances of nervous affections, combined with various hallucinations, having spread like epidemics, from the mere contagion of example. An extraordinary instance of the influence which the strong excitement of religious fanaticism is capable of exercising over the nervous system was seen as late as 1724 in Paris, during the persecution of the Jansenists: after the death of Deacon Paris, one of the highly revered chiefs of the sect, crowds of his followers went in pilgrimage to the place of his burial at St. Medard, where they fell on his tomb, and were apparently seized with the most violent convulsions: they asserted that, after passing through this ordeal, they arose miraculously cured of any disease with which they might be affected; and this practice was continued for a considerable time. Some of his disciples were no doubt impostors; but it is well

authenticated that many credulous zealots actually worked themselves into convulsions by the mere power of their imaginations. Willis and several other writers state that convulsive affections of children have occasionally appeared as epidemics. A disease of this description carried off a great many children in Paris at the close of the last century; and it is remarkable that it attacked likewise young dogs.

Convulsions are also frequently produced by narcotic and irritating poisons. To obtain this effect, narcotics must be given in small doses; for if the dose be large, it may at once destroy the irritability, when coma and death will ensue without any struggle. The *nux vomica* seems to possess the specific virtue of exciting muscular contractility, and has on that account been successfully applied to the treatment of certain forms of paralysis. Most of the mineral poisons occasion convulsions by exciting violent inflammatory action. Exposure to the fumes of mercury and lead produces either a convulsive tremor or complete paralysis, by weakening the nervous energy. The inoculation of the rabid virus is followed by the frightful convulsions of hydrophobia; and most of the other animal poisons have a similar property, though in a much milder degree.

Several of the causes we have enumerated have a direct tendency to excite in the brain or spinal marrow various degrees of congestion or inflammation; and there can be no doubt that in some cases this is the true pathological state of these organs. We must not, however, by any means consider this as the most common form of disease, for in the majority of cases the accession of the paroxysm is not attended by any vascular excitement, and there is merely a state of nervous irritation and functional disorder.

Convulsions are sometimes produced by a state of the brain the very reverse of plethora or vascular congestion; and when it is, on the contrary, deprived of the supply of blood necessary for the continuance of its functions. This often happens after a large and sudden abstraction of blood from the arm, or profuse hemorrhage, and during the last struggles of life. It should be remembered, therefore, that convulsions arise both from an increase and a diminution of vascular action; and that *nervous debility* is the essential character of that state of the nervous system in which they originate: *a repletione aut ab evacuatione fit convulsio*, is one of the aphorisms of Hippocrates. It is also deserving of notice that many of the appearances of vascular turgescence which may be observed in the brain and spinal cord in fatal cases of convulsion, are the mere accidental effect of the violent struggles of the patient in his last moments, the same as occur in all cases of violent death.

In the description formerly given of some *anomalous* convulsive affections, we noticed a variety of disorders of the thoracic and abdominal viscera, combined with great disturbance of the nervous system, and a violent convulsive action of many of the voluntary muscles; we

stated that several of the complicated symptoms of those affections might perhaps be accounted for by a reference to the functions of the spinal marrow and of the great sympathetic or visceral nerve. Several ancient writers have conceived that many spasmodic, convulsive, and nervous diseases have their origin in affections of the spinal cord and great sympathetic. This was the opinion of Hoffmann, Ludwig, Lieutaud, Burserius, Portal, &c. The functions of these divisions of the nervous system have been more accurately investigated since by Bichat, Legallois, and Ollivier; but the subject still remains involved in much uncertainty. They have made it, however, appear highly probable that many of the diseases of the thoracic and abdominal viscera are to be attributed to morbid conditions of the spinal marrow and of the ganglionic nerves of the great sympathetic. There can be no doubt that the sympathy existing between these two classes of nerves is much greater than is generally imagined; proofs of this are afforded by the great muscular debility of the lower extremities, and the severe cramps, which so commonly attend diarrhœa or dysentery, and chronic dyspepsia; and on the other hand by the attacks of diarrhœa, gastrodynia, and cramp of the stomach, which are frequently the effect of cold and wet feet. In some chronic affections, moreover, of the thoracic and abdominal viscera, a careful examination of the spinal column has led to the discovery of one or several spots excessively tender on pressure, and by applying leeches or cupping-glasses and counter-irritants to those spots, we have seen in several instances severe palpitations of the heart, oppressive dyspnœa, gastrodynia, or great irritability of the stomach, relieved in a very remarkable manner: these are pathological considerations highly deserving of further inquiry.

*Treatment.*—In the account given of the pathology of convulsive affections, it is stated that they may originate in a variety of causes differing very widely in their nature, and that they are also considerably modified by age, sex, and temperament. The treatment adopted during the paroxysm must therefore be regulated by a careful consideration of all these circumstances. We must endeavour to ascertain whether the increased irritability of the nervous system, which is the primary source of all convulsions, proceeds from increased vascular action in the brain or spinal marrow, or from mere nervous irritation; and whether the exciting cause has its seat in the brain, spinal marrow, or course of the nerves, or the convulsions are to be attributed to the morbid condition of some other organ. If the convulsions occur in a full plethoric subject, with well marked symptoms of cerebral congestion or inflammation, fifteen or twenty ounces of blood must be taken from the arm or jugular vein; and this may be repeated in ten or twelve hours, should the symptoms continue unabated: when the strength of the patient no longer admits of general depletion, or when the symptoms of vascular excitement

are less urgent, local bleeding by cupping on the temples or nape of the neck may be employed, and in some cases may be conjoined with general bleeding.

In cases, however, depending chiefly on cerebral and nervous irritation, and characterized by a general delicacy of frame, spare habit of body, a pale face, small frequent pulse, irregular hysterical breathing, and other signs of a purely nervous temperament, copious bleeding is highly injurious, and only aggravates the symptoms by increasing the general irritability. There may be intermediate states, requiring a moderate degree of local depletion, the discrimination of which must be left to the judgment of the practitioner. We must also add, that local plethora in the brain and other organs may sometimes exist with general debility, and that paleness and languor should not in such cases deter the practitioner from having recourse to local bleeding; the treatment of such cases requires, however, no ordinary degree of tact and caution. It is very important to bear in mind that the violence of the convulsions is not to be taken as a test of the strength of the patient, for no convulsions are more violent than those which occur after profuse hemorrhage and extreme prostration; and, as convulsions arise probably from mere cerebral and nervous irritation in a considerable proportion of cases, the practice of indiscriminate copious blood-letting in every case of sudden *fits*, so much in favour with the public and a portion of the profession, cannot be too strongly deprecated; the principles we laid down on this subject when treating of *coma*, apply equally to convulsions.

The application of *cold* is often of great service in convulsive diseases. Cold applications to the head are particularly beneficial, provided they be used assiduously; they may consist of cloths dipped in water and vinegar, or pounded ice put into a bladder; or a still better method is the affusion of cold water over the head, frequently repeated. The cold bath, which has been advised by some, may be suited to robust constitutions, but would be injurious, during the paroxysm, to the weak and irritable; the cold affusion, as recommended by Dr. Currie, is less objectionable, and in cases depending on pure nervous irritation, especially in hysterical females, the shock given by dashing cold water over the body has sometimes cut short the paroxysm, and prevented its recurrence. The same effect has been obtained by free exposure to cold air, especially in children, as recommended by the late Dr. Gregory of Edinburgh. A free circulation of cool air round the patient is always most desirable.

The application of *heat*, through the medium of the warm bath, is highly beneficial and in very general use; it soothes, relaxes, and acts as a diffusible stimulus. The warm bath is therefore of great service in cases attended with a high degree of general nervous irritation, or in which cutaneous eruptions have

been repelled, and particularly when there is a dry rough skin and great rigidity of fibre. The affusion of cold water over the head, whilst the patient is in the warm bath, or stands in warm water, is an excellent practice.

*Purgatives* have always been classed among the most powerful remedies in the treatment of acute nervous diseases; the operation of a brisk cathartic during the paroxysm has the effect in many cases of immediately subduing the violence of the symptoms, and more especially where they have been induced by a disordered state of the bowels: a combination of calomel and jalap is the most active and efficacious form of cathartic; in patients of a delicate constitution and in children, a preference should be given to the milder purgatives, such as calomel and rhubarb. When cathartics cannot be administered by the mouth, they will act almost as efficaciously in the form of injection. Whilst moderate purging is decidedly beneficial, the repeated exhibition of drastic purgatives, which has been a favourite practice of late years in this country, cannot be too strongly condemned, as tending to induce a state of general exhaustion and nervous irritability similar to that which is the effect of excessive bleeding. No one can have been kept for a few days under the constant operation of brisk cathartics without feeling a considerable degree of languor and irritability. These objections are particularly applicable to the continued use of calomel and other mercurial preparations.

When the primary cause of all diseases was referred to the nervous system, and the various morbid phenomena were attributed to spasm and nervous debility, *opiates* and *stimulants* were largely administered on all occasions, and the death of the patient was often accelerated by over-excitement. In modern times, however, since the doctrines of inflammation have been so generally applied to the investigation of the nature of diseases, and their various symptoms have been referred to morbid conditions of the *vascular system*, practitioners have fallen into the opposite extreme, and laying aside all due consideration of the state of the nervous system, have employed such remedies only as tend to reduce excessive vascular action. In the class of affections under consideration, if the violent agitation of the nervous system continue, after adequate bleeding and purging, the administration of an opiate is clearly indicated, and will often be very advantageous. When prescribed under the circumstances stated, it should be given in large doses.

The external application of laudanum, in the form of frictions, combined with stimulating liniments, is an excellent mode of administering opiates, especially to children. Sometimes the direct application of opium to the skin, after the cuticle has been raised by vesication and removed, has been found a very efficacious method of exhibiting it.

The habitual use of opium creates, as is well known, an extreme degree of weakness

and irritability of the nervous system. It has sometimes occurred that after the habit had been long acquired, and the opium has been suddenly withdrawn, the most formidable attacks of convulsions have supervened in consequence of the exhaustion and sinking of the nervous power; the patient must therefore be only very gradually weaned from his indulgence in the use of opium, some other less pernicious stimulant being, if possible, substituted. We have known the spiritus ætheris nitrici and camphor mixture given in such cases with considerable advantage. The above remarks are equally applicable to the abuse of spirituous liquors.

A variety of *antispasmodics*, such as ammonia, musk, æther, camphor, valerian, and other medicines of this class, have been recommended to mitigate the violence of the paroxysm; their powers, however, are so doubtful that they are not entitled to much confidence. These remedies appear sometimes to afford relief by facilitating the expulsion of flatus from the stomach and bowels. It may also be added, that when there are symptoms of acidity in the stomach, alkaline medicines combined with antispasmodics and aromatics may be given with advantage; a teaspoonful of calcined magnesia in some aromatic water has been known immediately to relieve a fit of asthmatic dyspnoea or severe cramps in the lower extremities.

*Counter-irritation* is beneficial when applied with due moderation; large blisters to the head are decidedly injurious, preventing the application of cold, and having rather a tendency to increase the cerebral irritation; small blisters are therefore preferable, and their revulsive effect is best obtained by applying them to the feet, calves of the legs, the inside of the thighs, or along the spine. Sinapisms and other stimulating poultices may be used in the same manner, or the feet and hands may be immersed in a mustard bath: these simple remedies of former times are too much neglected in the present day.

Convulsions arising from profuse hemorrhage or after excessive bloodletting, are generally attended with giddiness, fainting, dull throbbing, pain in the head, and a tendency to coma; under such circumstances we must have recourse to the administration of diffusible stimulants in small and frequently repeated doses: brandy in warm gruel is the stimulant, perhaps, to be preferred; it may be given alternately with carbonate of ammonia or æther. Whilst the head is kept cool by evaporating lotions, great care must be taken to preserve a due degree of heat in the extremities and on the surface of the body by the usual means.

In cases of convulsions from poisons, the first object will be to evacuate the stomach by the exhibition of powerful emetics, or the employment of the stomach-pump; the subsequent treatment must vary according to the symptoms and nature of the poison, as will be detailed under the proper head. We refer to other articles in this work for the

treatment of convulsions occasioned by the action of lead and mercury on the animal economy; the modifications applicable to the treatment of puerperal and infantile convulsions are also detailed in their proper place.

The local treatment required when convulsions are occasioned by wounds of the nerves, or the laceration of any part of the body, will be specified in the article *TETANUS*. In convulsions depending on organic disease of the brain of long standing, the treatment, it is obvious, can only be palliative.

The regulation of the *prophylactic* treatment is of the highest importance in all convulsive affections, but more particularly in those anomalous, severe, and protracted cases which were described under a separate section. The paroxysms in such cases frequently resist every attempt to subdue them, and little can be done but to mitigate their severity. We stated that these anomalous affections are distinguished by considerable disorder in the functions of the uterine or digestive organs, and by a highly disturbed state of the nervous system, depending on some morbid condition of the brain, spinal marrow, or nervous apparatus of the great sympathetic; and that there is often great difficulty in ascertaining whether the disease originates in a primary affection of some portion of the nervous system, or in the morbid condition of any of the other organs. Our attention should, therefore, be directed, after the removal of urgent symptoms, to the gradual amelioration of the general health, as the most effectual means of overcoming diseased action in particular organs.

Our remarks on the injurious effects of excessive *bleeding* and purging during the paroxysm are particularly applicable to the prophylactic treatment. It has frequently happened that the dull headach and vertigo, wrinkled brow, throbbing of the temporal arteries and carotids, convulsive twitches of the features, watchfulness and restless anxiety, with alternate states of chill and morbid heat, rapid small irregular pulse, and subsultus tendinum, which are sure indications of that extreme irritability of the brain and nervous system so appropriately called *cerebral crethism* by Dr. Whitlock Nicholl, have been mistaken for symptoms of inflammation; and this serious error has led to a perseverance in those very measures which have induced and are calculated to aggravate the morbid condition in question. Instances of this description have not unfrequently fallen under our own observation; and a remarkable one is afforded in the case we have quoted from Dr. Abercrombie. Although copious and frequent bleeding may appear to afford temporary relief when there are symptoms of plethora, it increases the laxity of fibre which so strongly predisposes to a plethoric habit. A tendency to plethora in the head will be best counteracted by occasional revulsive bleeding from the lower extremities: as, for instance, the abstraction of a few ounces of blood from the feet by means of leeches, or the opening of a vein, the bleeding being encouraged by immersion

in a warm foot-bath. We have found this plan particularly useful in cases of suppressed or irregular menstruation, and by having recourse to it at the approach of the menstrual period, or on the first appearance of any of the symptoms threatening an attack of convulsions, we may often succeed in warding it off.\* Bleeding along the course of the spine by leeches or cupping, particularly when there is tenderness on pressure, will sometimes relieve very distressing symptoms of dyspnoea, palpitation, vomiting, and gastrodynia, or partial convulsions of the muscles of voluntary motion; this is a practice hitherto too much neglected. Leeches may also be applied with advantage to the rectum. It ought, however, to be made a general rule not to carry bloodletting to such an extent, with respect either to its frequency or amount, as to impair the general strength, unless there be decided symptoms of inflammation. Counter-irritation along the spine by means of blisters, tartar emetic ointment, and stimulating embrocations combined with opium, has been found a very useful adjunct to local depletion in convulsions depending on affection of the spinal marrow.

Whilst violent purging is to be deprecated, a moderate course of alterative *purgatives*, if judiciously managed, will generally form an important part of the prophylactic treatment. The function of secretion appears to be under the special control of the nervous system, whatever influence chemical affinity or galvanic agency may be supposed to have over the ultimate changes of the blood in the secreting organs: hence it is that in all cases of long continued disturbance of the nervous system, we find the secretions vitiated, and becoming in their turn sources of irritation: this is well exemplified in chlorotic women, and in chronic mental alienation. The secretions, therefore, in nervous diseases should always be carefully examined, and means adopted to restore them to a healthy state. This is to be principally accomplished by the continued exhibition of mild purgatives for a certain length of time, so as to obtain free and natural evacuations, but stopping short of the irritating and debilitating effects of active purging. We must be guided in the selection, dose, and frequency of repetition of the aperients by the habit of body of the patient, the appearance of the tongue, and state of the stomach, and the nature of the alvine and urinary discharges. We have found a combination of equal parts of the *massa pilulæ hydrargyri*, *pilula rhei comp.* and *extractum catharticum*, produce the desired effects.

*Tonic* and *antispasmodic* remedies, given either singly or in combination with purgatives, are in general remarkably well suited to that state of the nervous system which predisposes to convulsions. We would observe, however,

\* Dr. Prichard, in his able work on *Nervous Diseases*, has given an excellent account of the convulsive affections which not unfrequently accompany disordered menstruation, and of the mode of treatment; to which the reader is referred for more ample details.

with respect to this class of remedies, that if given so as to create a high state of habitual excitement, their effects will be decidedly injurious. The practice, therefore, of administering indiscriminately strong doses of ammonia, ether, or valerian, and allowing a free use of wine, to nervous and hysterical women, is often highly improper. We can only expect to do good as far as we can succeed in gradually and permanently increasing the tone of the nervous system. This effect may be fully obtained by moderate doses of some of the tonic and antispasmodic medicines, given for a considerable length of time, in conjunction with gentle aperients. The preparations of iron and bark are the tonics generally to be preferred for their great efficacy in restoring the tone of the nervous system whenever it has been gradually much impaired. Iron has also the advantage of acting as an emmenagogue, and correcting that deficiency and irregularity in the functions of the uterus which is so often the sole cause of the disordered state of the health: a striking instance of its power in this respect is afforded in the case of anomalous convulsive disease already alluded to, as quoted from Dr. Abercrombie. We have used with considerable advantage in similar cases, the carbonate of iron combined in a mixture with carbonate of ammonia and tincture of aloes; it must be given to the extent of between one and two drachms in the twenty-four hours: when carried beyond this dose it remains accumulated and perfectly inert in the alimentary canal. The preparations of zinc, the solution of arsenic, the nitrate of silver, and several of the fetid gums have likewise been strongly recommended, and may no doubt on many occasions be given with benefit. All medicines acting on the nervous system lose their effect by habit; and it is a good general rule to substitute occasionally one for another.

The cold and warm *bath* are still more valuable remedies in the prophylactic treatment of convulsions than during the paroxysm. The daily use of the cold shower-bath, with the feet immersed in hot water, and also cold sea bathing in summer, tend powerfully to increase the tone of the nervous system. The warm bath or tepid shower-bath must be ordered for delicate patients, too sensitive to bear the sudden impression of cold; but it is very desirable to lessen by degrees this extreme susceptibility, by lowering gradually the temperature of the water. We must in general be guided by the feelings of the patient and the vigour of the constitution in the choice of the cold or warm bath. There is a remarkable sympathy between the functions of the skin and those of the brain and nervous system; and it is always of first importance to excite a healthy action of the skin, which is generally dry and torpid, in persons subject to convulsive affections. The natural vapour-baths found in the caverns of the volcanic mountains in the neighbourhood of Naples were in great repute for the cure of convulsive diseases among the Romans, and are still much resorted to by the present inhabitants

of the country. We have seen the use of vapour-baths attended with the very best results in some intractable cases of convulsions.

There are few things of greater importance in the treatment of convulsions than the regulation of the *diet*; for a disordered and irritable state of the stomach and bowels frequently operates as an exciting cause. In cases attended with general plethora and a tendency to cerebral congestion, the diet must be very spare; animal food and fermented liquors are to be entirely prohibited, and a milk and vegetable diet, with light broths, prescribed. By persevering in this soothing plan, attacks of convulsions threatening to assume the character of regular epilepsy have been completely overcome. In cases, however, of an opposite description, characterised by languor and irritability, the diet, although simple, should be nourishing.

The moral management of the patient requires attention; pains should be taken to remove him from the influence of every predisposing and exciting cause, such as crowded hot rooms, late hours, sedentary habits, mental anxiety, &c. It is of consequence to provide some occupation or diversion for the idle, in order to withdraw them from the study of their own feelings; as few things tend more to increase nervous irritability than a mind preying on itself. The power of volition over the functions of the nervous system is greater than is generally supposed. When convulsions recur from mere habit, this morbid habit has in some cases been completely broken by a strong and sudden effort of the will: it is advisable, therefore, not to encourage such patients to yield to their feelings by showing them too much sympathy, but rather to remonstrate with them temperately, insisting that they have it greatly in their power to resist the first approaches of the paroxysm, if they will only resolutely determine to exert it. It is quite certain that children have been frightened *out* of convulsions as well as frightened *into* them; and it is by acting on the nervous system through the medium of the imagination, that quacks, soothsayers, and fanatics have acquired such celebrity in the cure of nervous diseases.

(*Adair Crawford.*)

**CONVULSIONS, INFANTILE.** The present article is intended to include only those convulsive diseases which are either peculiar to the earliest periods of life, or are accompanied with such circumstances as modify the symptoms, and require some peculiarity in the treatment. Convulsions are so frequent in young children, and so often fatal, that it becomes of great importance to consider whether their nature, causes, and treatment, are properly understood. Without hesitation it may be stated, that till very recently authors and practitioners were by far too apt to generalise in these cases, and the practice consequently degenerated into routine, and that often on mistaken principles. In most cases the convulsions of young children are symptomatic of

THE HISTORY OF THE  
CITY OF BOSTON  
FROM 1630 TO 1800  
BY  
JOHN B. HENNING

CHAPTER I  
THE FOUNDING OF BOSTON  
1630-1634

The first settlement in the city of Boston was made in 1630 by a group of Puritan settlers from England. They were led by John Winthrop, who had been appointed governor of the Massachusetts Bay Colony. The settlers arrived in the city on September 8, 1630, and established a settlement on the tip of the peninsula that is now the city of Boston. The settlement was named Boston in honor of the city of Boston in England.

The settlers were primarily Puritans, and they came to the city with the intention of establishing a new society based on their religious beliefs. They were opposed to the religious practices of the Church of England, and they sought to create a society in which they could practice their religion freely. The settlers were also opposed to the political practices of the English monarchy, and they sought to create a society in which they could govern themselves.

The settlers were initially met with hostility by the Native Americans, who were the dominant population in the area. The Native Americans were wary of the settlers, and they were often hostile to them. However, the settlers eventually established a relationship with the Native Americans, and they learned from them about the local environment and the ways of life of the Native Americans.

The settlers also established a relationship with the English government. The English government was interested in the settlement, and it provided the settlers with financial support. The English government also granted the settlers a charter, which gave them the right to govern themselves. The settlers used this charter to establish a self-governing society, and they elected a governor and a council to manage the affairs of the colony.

The settlement of Boston grew rapidly, and by 1634, it had become one of the largest and most important settlements in the Massachusetts Bay Colony. The settlement was a success, and it provided a model for other Puritan settlements in the New England area.

of convulsions in young children; but, as we have shown already, this is not to be defended in all cases by reason, nor does experience justify the practice. Where, however, a plethoric or too energetic condition of the vessels of the brain obtains, it is undoubtedly desirable to relieve the head by bloodletting. Very often, where there is an obstinately constipated state of the bowels, purgative medicines will not succeed in removing some offending matter from the intestines until cerebral pressure has been removed by taking away blood from the neighbourhood. For this purpose, opening the jugular vein is the readiest and perhaps the most effectual method; or, should it be preferred, cupping, or the application of leeches on the temples, or behind the ears, may be had recourse to. The quantity of blood drawn must depend on the strength of the child and the violence of the symptoms; and although on the whole, under such circumstances, children of a tender age bear the loss of a larger quantity of blood than would be supposed, very safely, yet care must be taken lest the child be brought into that state of exhaustion in which convulsions are very apt to occur from an exactly opposite cerebral condition. The writer of this article saw a plethoric child, of a year old, cupped to fainting during a severe convulsive attack, and no sooner had the faintness subsided, and the child was left bleached, with a *depressed* fontanelle, than a second and still more violent convulsion took place, from which it was with extreme difficulty recovered. Should the child be of an age at which the process of dentition would be at all likely to be going on, we should be overlooking a very essential part of the treatment if the gums were not to be freely and extensively scarified: long before a tooth is near the surface this is often of great service, and removes one of the most frequent causes of irritation. Should the case be one of great irritability of brain without plethora, after attacking the exciting cause where it is possible to remove it, should the convulsions still continue, antispasmodic medicines may be liberally administered, such as the assafetida mixture, ammonia, camphor, æther and musk, and even opium; but from the uncertain effects of the latter medicine on very young children, this must be done with great caution. Where there has been a very irritable state of the bowels, opium is particularly useful when combined with chalk and aromatics; the pulvis cretæ compositus eum opio of the pharmacopœia is a convenient form, from the small quantity of the opiate which it contains; from one to ten grains may be given, according to the age of the child, and repeated every hour or two, till the desired effect is produced. Most of the advertised *convulsive powders*, as they are termed, consist of chalk combined with musk and aromatics. In some instances, and not always in very weak and exhausted children, there is constitutionally an exceedingly irritable state of the nervous system, leading to convulsions resembling those of an epileptic nature. In these cases, tonics of a very decided character, iron for instance,

have been found by the writer sometimes as useful as they have been long known to be in a more advanced age. A child of *two months* old, large and fat, was seized with violent convulsions suddenly, the bowels having been disordered from bad breast-milk for a few days previously. The convulsions lasted for *seventeen days*, sometimes occurring three or four times in an hour, and never ceasing for more than four or five hours at a time. The fontanelle was depressed and concave always in the intervals of each paroxysm, and no blood was taken in consequence; the treatment consisting of antispasmodics, external applications, clysters, purgatives, and also of opiates, one drop of laudanum having been administered every hour for a considerable number of doses. This treatment was pursued for a fortnight with no permanent improvement. On the seventeenth day the bad success of the previous remedies induced the writer to try the carbonate of iron, of which five grains in honey were given every two hours for two days. After the second dose the face became florid, the fontanelle elevated, and the convulsions ceased. In the intervals of the fits the child took copiously of breast-milk, by means of a spoon, during the whole period. The infant remained well for a twelve-month, and then died from hooping-cough.

When the immediate paroxysm of convulsion has been subdued, its recurrence must be carefully guarded against by attentively investigating the state of the child's health up to the time of the seizure, and also avoiding and removing what may appear to have been the remote cause of the immediate attack. It is too much the fashion in all cases where fits have occurred, at once to begin a system of starvation and depletion. It is obvious that this plan can only be adapted to the cases where there are evident signs of plethora or of determination of blood to the head. Where exhaustion and emaciation already exist, a carefully graduated strengthening plan, both of diet and medicine, becomes proper, and, united with quiet, and a change to a purer atmosphere, will often answer our most sanguine expectations. It would only be useless repetition to detail the treatment proper to each of the many causes of convulsions enumerated above; we refer to the different disorders under their respective heads. It will be sufficient to recollect that when once children have been seized with convulsions, they are very likely to recur, even from causes very dissimilar to those which produced the first attack; the brain remaining more susceptible than before. Every thing which may add to this susceptibility should be carefully avoided; the bowels should be regulated, the diet narrowly watched, both as to quantity and quality, the exercise kept within bounds, heated rooms and late hours interdicted, and even the moral and intellectual education should be conducted with reference to this condition of brain,—too great and too frequent mental excitement being highly pernicious.

Before concluding this article it is proper to notice that very young infants are often affected

with what nurses call "inward fits." In these cases there is a rolling about of the eyes when asleep, a drawing down of the mouth with slight twitchings, frequent smiling during sleep, and occasionally a little blueness about the mouth. These symptoms are owing generally to distension of the stomach and to flatulence, and are easily dispelled by frictions on the stomach, back, and bowels, or a little sal volatile, or some of the aromatic distilled waters.

There is a convulsive affection of a very peculiar character which attacks very young children, and was described first by Dr. John Clarke, in his Commentaries on the Diseases of Infants. It has been named "cerebral croup," "spasm of the glottis," "the crowing convulsion," &c. The particular account, however, of this interesting disease, will be found in a separate article. (See *GLOTTIS, SPASM OF.*)  
(*C. Locock.*)

**CONVULSIONS, PUERPERAL.** In a work not professedly devoted to midwifery, a notice of this formidable occurrence must of necessity be brief.

*History of the attack.* The real puerperal convulsions can scarcely be mistaken for any other disease, and when once seen and recognised are not likely to be soon forgotten. They may occur not only during the process of parturition, but also in the latter period of pregnancy, and again in the first few days after delivery. They are generally ushered in by certain precursory symptoms; but sometimes there is no warning whatever, or one so slight as to have escaped the notice of the attendant. Usually, however, preceding the attack there is dull pain and weight in the head, constant drowsiness, flushed countenance, with a full, slow pulse, and partial or occasional failure of sight. At other times, or in other cases, the preceding symptoms are succeeded by sudden and most acute pain in the head, loss of sight, or the sensation of dark, or of bright, fiery objects moving before the eyes, ringing in the ears, and generally sickness, with pain and oppression at the pit of the stomach. The patient is then seized with twitchings of the face or a rigid contraction of the jaw, followed immediately by violent universal convulsions, resembling in many respects an attack of epilepsy. The face is distorted, the tongue protruded, with foaming at the mouth, and a peculiar deep hissing noise from breathing sharply through the closed teeth; the eyes are fixed or rolling irregularly, the pupils dilated, and the limbs are strongly and convulsively agitated. After a time the paroxysms terminate in stupor, with stertorous breathing, from which, after an uncertain interval, the patient will often awake suddenly, unconscious of any thing which has passed, and apparently well: shortly after, perhaps, the convulsions again return, and several successive fits of a similar character may recur. Apoplexy occasionally follows, and the patient may then die in the comatose stage; but this termination is not frequent where proper curative means have been employed. The occurrence of apo-

plexy may be considered rather as an accidental complication, not by any means necessarily attendant upon the disease.

*Causes.*—The immediate causes of puerperal convulsions are often very obscure. They appear sometimes to depend upon a loaded state of the vessels of the brain; at other times the brain appears to be influenced by distant irritation, either in the uterus or in the digestive organs; and again, in some cases, puerperal convulsions are induced apparently by a peculiar irritability of the nervous system. It has been remarked that there has been a greater disposition to puerperal convulsions in those patients who have been in early life subject to convulsive attacks, particularly of an epileptic character; and also in those who have suffered similarly in former labours, and have omitted those measures usually employed as precautions. That the uterine organs are in some way particularly implicated, is evident from the convulsions being of a character which may be said to be peculiar to the state of either pregnancy or parturition.

The immediate attack may be brought on by a loaded or disordered stomach, or by food, however small in quantity, of an indigestible kind. Some substances, shell-fish for instance, have been found very frequently to induce convulsions in the puerperal condition, when at other times they may have been taken by the same individual with perfect impunity. A sudden fright, afflicting intelligence, or any unexpected or depressing mental emotion may excite the paroxysm; hence it has been long remarked that unmarried women are more particularly likely to be sufferers from convulsions, from the circumstances of shame and distress under which their children are usually born. The violent straining caused by labour-pains, and even the disturbance of the frame by the earlier uterine contractions, causing a temporary rush of blood to the head, will sometimes bring on convulsions.

It must be recollected that although convulsions occur most commonly under the circumstances described, they occasionally take place also in a very exhausted state of the frame, when the system has been nearly drained of blood by excessive uterine hemorrhage, or other depletions. In these instances there is generally considerable danger, partly from the great irritability consequent upon the exhaustion, so that much slighter causes will produce more violent effects, and partly from the greater difficulty of applying remedial measures. In these cases the pulse is rapid and weak, and the countenance pale and bloodless. Half a century ago, puerperal convulsions were much more fatal than at present; for we are told by writers of the period, that upon an average, full half of the patients died; whereas now, as is well known, when properly treated, they usually recover.

*Treatment.*—This is to be regulated especially by noting the cause of the particular attack. As a general rule it may be stated, that copious abstraction of blood in a large stream is the most efficient means of shortening

the attack and securing the safety of the patient. Where the pulse is strong and full, and the frame robust, the quantity that may be taken with impunity and advantage is often very great; and where from circumstances it is difficult to procure a sufficient supply from the arm, the temporal artery may be opened, or cupping-glasses applied behind the ears or on the temples. An active purgative, as scammony, senna, or jalap, combined with calomel in a full dose, may be given; or if there is a difficulty in swallowing, one or two drops of the croton oil may be smeared upon the back of the tongue. An injection of a stimulating and purgative character may also be thrown into the rectum; and for this purpose nothing perhaps is more effectual than turpentine. Cold washes, or bladders containing pounded ice may be applied to the head, and hot mustard poultices to the feet. The propriety of repeating the bleeding, and the time of doing so, either locally or generally, must depend upon the power of the patient and the state of the pulse as well as upon the continuance of the symptoms. In the comatose state, or in what may be called a more chronic stage of the disease, blisters to the head or to the back of the neck may be of service, but they are scarcely admissible previously. In this stage a free action should be kept up from the bowels, and the turpentine enemata are especially useful. For some considerable time after the immediate symptoms are subdued, the patient must be kept perfectly quiet, all causes of irritation must be avoided, and the diet should be spare and simple.

Where the patient has been before the attack much reduced from exhausting illness, or from hemorrhage, we are not always to think it necessary to bleed, and to bleed furiously. Blood-letting must in such cases be had recourse to with very great circumspection; and if necessary at all, local bleeding, with the other remedies mentioned above, is all that we should venture upon. It is well known that dogs have been bled into convulsions, and it is probable that a similar condition of circulation in the brain exists in the cases now referred to. There has been much discussion as to the propriety of giving opium in puerperal convulsions, some having spoken very highly of its advantages, while others have decidedly thought it pernicious; but this difference of opinion has arisen solely from the want of distinction between the character of the cases to which it is or is not applicable. Experience of this fact has led the writer of this article to believe, that whilst opium is certainly injurious in puerperal convulsions of the class first described, it is often, especially when combined with full doses of camphor, most salutary in the latter, as well as in those cases of an hysterical character presently to be mentioned. From one to two grains of opium, with four or five of camphor may be given, and repeated every hour or two till the proper effect is produced; and in the exhausted cases described, the desired effect is to subdue the paroxysms, strengthen and steady the pulse, and restore colour to the counte-

nance. Another point of dispute has been, whether emetics are appropriate remedies in these attacks,—the doubt arising from the supposed bad effects likely to occur from the violent efforts to vomit causing the blood to be impelled more forcibly to the head. Where the attack has been produced by a loaded stomach or by indigestible food, spontaneous vomiting has often happened with great and sudden relief to the patient, and in such cases, but perhaps only in such, benefit will often arise from seconding the natural efforts by administering an emetic.

The last inquiry of importance is,—ought we to deliver immediately in all cases of puerperal convulsions, where the child or the placenta still remains in the uterus? This is rather a question of experience than of reason; for although it may be said that the presence of the child or the placenta in the uterus may keep up the exciting cause, yet it is well known that convulsions will often occur at a considerable interval after delivery has been completed; neither are they always relieved by emptying the uterus, where they have begun before or during labour. Many object to any artificial hastening of the birth, unless the child's head is within reach of the forceps, on account of the uterine irritation produced by the process of dilating the os uteri, to turn the child and bring it down by the feet. It may be stated generally, that the most experienced practitioners have agreed, that it is advisable to deliver, either by turning or the forceps, (whichever may be applicable,) whenever the parts are in a state to permit this to be done without much difficulty.

It may be proper to add to this account, that where convulsions have occurred in a former confinement, it is very desirable that in any future pregnancy the patient should be closely watched towards the latter part of the time: great quiet should be enjoined, the bowels should be kept regularly open, and the diet be spare; and should symptoms of general plethora appear, or of determination of blood to the head, bleeding is to be had recourse to.

There are occasionally puerperal convulsions of a less formidable character than those above described,—unless indeed they be mistaken for them,—and which consist rather of unusually violent paroxysms of hysteria than of proper convulsions; as, however, they may occur during, or shortly after parturition, they are very frequently confounded with them, and treated accordingly. The distinction may be easily recognised by the absence of stertor and perfect coma, by the great quantity of flatus discharged from the stomach and heard rolling about the intestines, by the globus hystericus, and by the rapid and remarkably contracted pulse during the fit, which becomes slower and more expanded in the intervals. The limbs, and particularly the body, are as strongly agitated as in the real puerperal convulsions, but the face is much less so. As it is too common for inexperienced practitioners to consider all convulsions connected with the parturient condition as alike, and to treat them on that sup-

position, it is important that these distinguishing marks should be accurately recognised, particularly as, although not uncommon, these cases have been scarcely noticed in works on midwifery. There is no necessity in these instances to bleed the patient, or to proceed to delivery, if that has not already taken place. All that is required is the free administration of the customary antispasmodic medicines, camphor, æther, ammonia, assafœtida, &c.; and in such cases opium or any other narcotic may be safely and beneficially exhibited. Cold water should be freely dashed upon the face, and much advantage will be obtained by warm frictions and stimulating applications freely applied to the stomach, bowels, and spine, which produce or assist the expulsion of flatus from the stomach, with great and rapid relief to the patient. Perfect quietude of mind and body is afterwards very important.

(C. Locock.)

**CORYZA**, *nasal catarrh*, *gravedo*, or *cold in the head*, as it is variously termed, is an inflammation and altered secretion of the pituitary or mucous membrane, lining the nasal fossæ, usually arising from cold. Although considered a trivial disorder, there are very few, short of severe pain, capable of producing more bodily discomfort. As this is, however, commonly but of short duration, it is chiefly on account of the coughs and bronchial affections to which it frequently leads, that coryza claims our attention.

It begins with a sense of fulness and obstruction in one or both nostrils, accompanied with the secretion of a thin colourless fluid. This flux comes on in an increased quantity from time to time, and the increase is always attended by aggravation of the uncomfortable feelings of fullness; whilst frequent sneezing, titillation in the nares and fauces, and a copious flow of tears from the full and injected eyes, shew an acrimony in the discharge as well as an increased sensibility in the pituitary membrane. This property of the humour is further proved, in the progress of the disease, by the redness and excoriation of the end of the nose and the skin above the upper lip; and it may be considered a remarkable feature in the character of the inflammation. The sense of smell is always impaired, often entirely destroyed, and that of taste usually suffers more or less. Head-ach is a very common attendant; it is principally confined to the forehead, and accompanied with a feeling of weight and heat over the brows. The partial or complete obstruction of the nasal passages, although caused entirely by the tumefaction of the membrane, gives the feeling of their being plugged up by something, which induces frequent and ineffectual attempts to remove it by blowing the nose. From the same cause the voice is rendered thick and nasal. If the attack is severe, there is frequently considerable pyrexia, with loss of appetite, and pain of the limbs, and in almost every case there is an unusual feeling of chilliness and susceptibility of cold. The disorder

is at its height generally about the third day, and then it begins to decline; the flow from the pituitary membrane becomes more scanty and viscid, the swelling and obstruction abate, while the headach and other symptoms are proportionately relieved. Between the fifth and the seventh day the disorder is entirely removed. Not unfrequently, however, fresh cold is taken from the slightest cause, and the coryza, with its attendant symptoms, is kept up for a longer time; and as long as the secretion is copious and thin, no amelioration of the other symptoms takes place. A very common consequence of the diminution of the coryza is the transfer of the inflammation to the mucous membrane of the trachea and bronchi, and, in fact, there are few cases of cold in the head which are not followed by more or less cough.

*Causes.*—The usual cause of coryza is, as we have before remarked, cold applied generally or locally, and it is the more likely to produce it, if the cold be applied to a part of the body in a state of free perspiration. But a sudden transition from cold to heat seems to be likewise capable of exciting it. A slight form of coryza may be caused by the contact of smoke or other irritating vapours with the nostrils; but this does not bear the same character. Coryza generally accompanies measles, and sometimes small-pox and scarlatina. It is likewise a principal part of the epidemic disease called *influenza*. Whether excesses of diet are really capable of exciting coryza, or whether, as is more probable, they only act as strongly predisposing causes, it is certain that a sore throat, passing into a cold in the head, is a very common sequel of a debauch. It is commonly imagined that a cold in the head is rather a sign of strong health than otherwise: this is only so far true, that, in those liable to it, the cold affects a part of less importance; whereas if the lungs, the tonsils, or the bowels are naturally delicate, the application of cold is more likely to produce disease in these parts. Liability to take cold in any way must certainly be considered as a proof of weakness of the constitution, and where it exists in a great degree, such a succession of colds sometimes attacks an individual, that for months he is not free from the uncomfortable symptoms of coryza. Such protracted cases it is proper to separate from those chronic cases of profuse pituitous secretion, or *phlegmorrhagy*, which are sometimes met with, affecting the nasal membrane in the same way that pituitous catarrh attacks that of the bronchi. In these there is no inflammation, and the diseased secretion does not possess those irritating properties that are so characteristic of acute coryza. Nasal phlegmorrhagy, as some French writers term it, attacks those of debilitated and leucophlegmatic habit, and sometimes comes on periodically. The flux is occasionally very abundant, and we have known it sufficient to wet five or six handkerchiefs in two or three hours. In the intervals there is a cessation of secretion; but, as in pituitary catarrh, (into which it is apt

to pass,) the membrane is generally left somewhat tumefied.

When coryza attacks infants, it sometimes so completely obstructs the nostrils as to interfere with the process of sucking the breast, in which nasal respiration is necessary. The child leaves off repeatedly, and becomes purple in the face, and fretful in a few seconds after each time that it takes the nipple. In such cases it becomes necessary to feed the child with a spoon.

Coryza does not lead to suppuration. Pus is sometimes secreted by the nasal fossæ, but not in consequence of the coryzal form of inflammation, which terminates by the secretion becoming viscid, and then opaque, and then of a dirty greenish or yellowish colour, after which it returns to its natural state.

*Treatment.*—The coryzal inflammation does not require bleeding or any extensive evacuation. An aperient, followed by a diaphoretic, in strength proportioned to the severity of the symptoms; the pediluvium at night, with water as hot as it can be borne, which the addition of a little mustard will render still more effectual; abstinence from all kinds of stimulating food; and confinement to bed to keep up cuticular exhalation, are the measures generally resorted to; and if they have not the effect of shortening the duration, they certainly mitigate the symptoms of coryza. It is the common practice to drink copiously of tea, gruel, or some other diluent, during a cold: as long as this promotes perspiration it is of some utility, and although it augments the flow from the pituitary membrane, it has the effect of diminishing its acrimony by dilution. It is the acrimony of this discharge which re-acts on the membrane and keeps up the inflammation and its accompanying disagreeable symptoms. On this circumstance depends the efficacy of a measure directly opposed to that just noticed, but to the success of which we can bear decided testimony,—we mean *a total abstinence from liquids*. To those who have the resolution to bear the feeling of thirst for thirty-six or forty-eight hours, we can promise a pretty certain and complete riddance of their colds, and, what is perhaps more important, a prevention of those coughs which commonly succeed to them. Nor is the suffering from thirst nearly so great as might be expected. This method of cure operates by diminishing the mass of fluid in the body to such a degree that it will no longer supply the diseased secretion. Any thing that may contribute to reduce the quantity of fluid in the body will assist in the plan of cure, and shorten the time necessary for it to take effect. It is, therefore, expedient to begin the treatment with an aperient, followed by a diaphoretic, as is usual, and this is the more necessary when any fever attends; but beyond this no further cure need be taken, and the individual can devote himself to his usual employments with much greater impunity than under the ordinary treatment. The coryza begins to be *dried up* about twelve hours after leaving off liquids; from that time the flowing to the eyes and

fulness in the head become less and less troublesome; the secretion becomes gelatinous, and between the thirtieth and the thirty-sixth hour ceases altogether: the whole period of abstinence needs scarcely ever to exceed forty-eight hours. It is then as well to return to the *moderate* use of liquids, as the first indulgence is apt to be excessive. It is not necessary to limit the solid food any more than to that which is plain and simple, except where there is acceleration of the pulse or gastric irritation, in which cases animal food should be proscribed. For the sake of comfort in mastication, the food should not be of the driest kind. Thick puddings and vegetables, with or without meat, will be the best dinner; and toasted bread, or biscuit, *merely moistened* with tea, or other liquid, for other meals. A single cup of tea is enough to bring back the coryza immediately, after twelve hours' abstinence has removed it. We doubt not that it will be said that this plan of cure is worse than the disease; and so it may be in some instances. It may be called always a choice of evils; but we do not believe that any one who is liable to severe colds, after once experiencing the amount of good and evil resulting from this method, would hesitate between them; and it is for them that we make it known. We have never witnessed any evil from this abstinence from liquids for the time prescribed; but it is not unlikely that it may do harm in persons with irritable stomachs, or in those liable to urinary disorders. Moderation in liquid food, which may be assumed as a corollary from what has been already said, is one of the best preventives against the bad effects of exposure to cold. When there is a large quantity of liquid in the system, there must be increased perspiration, and, therefore, greater risk from the effects of cold.

Chronic coryza, or nasal phlegmorrhagy, is a disorder which arises from deranged digestion, or some other functional ailment that has a tendency to diminish the tone of the fibre. It generally attacks elderly people, and in all respects resembles pituitous catarrh of the bronchi, with which it is often vicarious.

(C. J. B. Williams.)

**COUNTER-IRRITATION** (from *contra* and *irritare*). This term, which is of recent introduction, has been adopted in medicine to designate any irritation artificially established with a view to diminish, counteract, or remove some other irritation or inflammation existing in the body.

Counter-irritation is generally applied on the external surface of the body; and although some internal medicines, as purgatives, emetics, &c. probably in part owe their efficacy to the counter-irritation which they cause, we shall here restrict our attention to external counter-irritation.

To understand and determine the value of counter-irritation in the treatment of disease, it is necessary to inquire into the principles of its curative influence, and the laws of those actions on which that influence depends. Un-

happily this inquiry is restricted by the limits of our knowledge on the subject of inflammation and irritation in general; but enough information may be gathered to regulate in a general way the employment of this remedy in practice.

Nature not rarely cures diseases by counter-irritation; and it was probably from her example that art first adopted the practice. It is a common case to see an inveterate functional disease subside on the appearance of a cutaneous eruption. This more frequently occurs in sub-inflammatory affections of the mucous membranes; but examples are not wanting in which mania, paralysis, chorea, and various other diseases have been similarly cured. The exanthematous and other eruptive diseases are probably cases of a somewhat analogous description; for whether the eruption be the direct result of a curative *molimen*, or effort of the constitution, or proceed from the peculiar affinity of the skin to a virus or morbid cause wandering in the body, its occurrence is within certain limits salutary. This is proved by the relief manifestly afforded to the internal functions, and sometimes by the moderation of the fever, on the external eruption of measles, small pox, scarlatina, erysipelas, &c. Sometimes, it is true, the fever is increased by this event, and all the symptoms may in consequence assume a worse aspect. So, likewise, a chronic disease of the skin occasionally relieves a pre-existent disease of the mucous membrane; whilst in other cases it re-acts on and aggravates it.

Now such various and even opposite effects are equally produced from a new or *counter* irritation artificially established in the system; and it is, therefore, obvious that, unless judiciously administered, this remedy may prove prejudicial instead of salutary. Experience continually proves that, under certain conditions of the system, a blister or other counter-irritant aggravates the inflammation which it was applied to remove. If we inquire what these conditions are, we shall find them chiefly to consist of an excited or irritable state of the general circulation, and a susceptibility or excessive sensibility of the nervous system. We shall find, however, that the remedies employed as counter-irritants have other effects which in a considerable degree modify this qualification of their utility.

Having thus in principle limited ourselves in the expectation of advantages from counter-irritation, we may proceed to consider its effects and uses in the various forms in which practice has employed it.

Counter-irritation may with advantage be considered in relation to its degree, and to the different tissues or parts which it affects. We shall, therefore, notice successively the remedies called rubefacients; vesicants; pustular or empyematous counter-irritants; setons, issues, perpetual blisters; and cauterizing counter-irritants.

*Rubefacients.*—In the slightest degree, counter-irritation consists in an erythematic excitement of the capillaries of the skin, ter-

minating in complete resolution, sometimes with desquamation of the cuticle. An application exciting this degree of counter-irritation is called *rubefacient*. Moderate degrees of heat, (between 100° and 150°,) whether dry or with moisture, essential oils and spirits, æther, mustard, pepper, the strong alkalies and acids diluted, or weak acids in a concentrated form, and the strong counter-irritants applied for a short time or diluted, act as rubefacients on the skin, and are severally used with a view to this degree of counter-irritation. Being unaccompanied by any evacuation except an increase of the imperceptible perspiration, the action of rubefacients illustrates, better than epispastics of the severer kind, the principle of counter-irritation; and the instances of their utility are neither slight nor rare. A flask of hot water or a bag of hot sand: a poultice formed of bread-crumbs or linseed-meal and hot vinegar, with various proportions of mustard or pepper; an ammoniacal liniment or an essential oil applied by friction; pieces of cotton or flannel wetted with æther or camphorated spirit, and laid on the skin, evaporation being prevented by covering them with the warm hand, are rubefacient remedies which are often successful in removing slight internal inflammations, and in moderating those which are more intense. An incipient sore-throat is often cured by an ammoniacal liniment applied to the anterior part of the neck; a slight bronchial or a rheumatic inflammation by the same, or by the application of cajepout or other essential oil on the chest or part affected; a gastritic affection, marked by nausea, pain, and irritability of the stomach, and particularly when resulting from a powerful dose of medicine, is frequently relieved by a sinapism, or even a hot flask to the epigastrium; and a rubefacient property is joined to the derivative of a pediluvium, when, with the addition of mustard, pepper, or the strong acids, it is used to relieve the brain in fever with sleeplessness or low delirium. Some chronic inflammations of the slighter kind have likewise their more permanent rubefacient remedies. Thus a galbanum or a pitch plaster, occasionally rendered more irritating by the addition of a little cantharides, is of no small utility in chronic coughs and rheumatism. The old composition of soap plaster and muriate of ammonia, so useful for the knees of housemaids, is another example; but we may find one still more familiar in the effect of new flannel worn next the skin, which unquestionably owes some of its salutary influence to its rubefacient property. To these instances of rubefacients we may add friction and electric sparks, both of which are essentially rubefacients: the latter often produce a papular eruption; and the magnetic plates which have been recommended by some French physicians are asserted by Laennec to have a similar effect. These means, however, will be noticed under their respective heads.

Rubefacients, especially when extensively employed, are general as well as local stimu-

lants; and although their local effect is such as to counterbalance their general effect in cases of low febrile excitement, they cannot be admitted where a generally phlogistic diathesis prevails; whilst in intense inflammations they must give place to the stronger kinds of counter-irritants.

Besides the examples of slight inflammation which we have adduced as fit cases for rubefacient applications, there are others of a mixed kind in which they are not less successful.

Spasmodic affections, particularly those attacking the stomach and bowels, various pains and aches, such as tooth-ach, ear-ach, &c. which seem to partake of a nervous as well as of an inflammatory character, are often more immediately relieved by hot flasks or fomentations, a mustard poultice or pepper plaster, than by any other remedy. These affections probably have more to do with congestion, or unequal distribution of the blood, than is generally supposed; and to this circumstance we are inclined to ascribe much of the efficacy of these applications: but it may also depend on the physiological law, that if the sensibility of a part is increased, that of the adjoining parts is diminished. In great depression of the vital powers, as in typhus fever, asphyxia, &c. the general stimulus of sinapisms, stimulant frictions, and the like, is advantageous; but we shall speak of this under the head of blistering counter-irritants.

The most active kind of rubefacient counter-irritants are *sinapisms* or mustard poultices; and their action is so speedy and energetic, that they are the most eligible remedies where a sudden local irritant is required. They are usually composed of flour of mustard and bread-crumbs in equal or in various proportions, moistened to the consistence of a poultice with hot vinegar. MM. Trousseau and Blanc, in the *Archives de Médecine* (Septembre, 1830,) have detailed some curious experiments on the composition of sinapismus. They found that vinegar very much impaired the stimulant properties of the brown mustard commonly used in France, which contains the husk as well as the flour of the seeds, and they therefore recommended that sinapisms be made with water. The English mustard powder, however, which is the yellow farina separated entirely from the cortical part of the seed, is equally efficacious when mixed with vinegar and with water. Sinapisms made from mustard recently ground act more promptly than those from mustard which has been for some time kept. MM. Trousseau and Blanc tried the admixture of alcohol with sinapisms, but found it inferior to either vinegar or water. Dr. Paris recommends the mixture of oil of turpentine to quicken the operation of sinapisms; its efficacy depending on its extracting the essential oil, in which the stimulant quality of the seeds resides. Sinapisms produce, in the course of a few minutes after their application, a sense of heat, which increases to a smarting and burning pain of almost intolerable intensity. After a while this subsides, and is succeeded by a

feeling of weight and fulness, with active throbbing of the arteries. In the course of twenty or thirty minutes the burning pain again returns, and unless the patient be insensible from some cerebral affection, he can never bear the application of a sinapism beyond three quarters of an hour. The effects on the skin are remarkable. Applied for a few minutes, a sinapism does not produce a redness in proportion to the pain; but a short time after its removal the part becomes of a scarlet colour. When left on for ten minutes and upwards, the skin becomes of a deep crimson or purple colour, which remains long after all sensation has ceased. Vesication is sometimes irregularly produced after forty or fifty minutes' application, but it is imperfect, and greatly disproportioned to the degree of inflammation. The intensity of the inflammation is such that there is considerable risk of gangrene supervening, if the sinapism remain applied for more than an hour. As long as sensation is preserved, the excessive pain would be a security against its being too long applied; but in cases of stupor and insensibility it should not, therefore, be permitted to remain beyond an hour. The pain excited by sinapisms may be allayed by cold applications, or, according to MM. Trousseau and Blanc, by cataplasms of hyoscyamus, belladonna, and stramonium leaves, or by ointments containing extracts of these plants. Sinapisms are classed here because their rubefacient is their most salutary property; vesication and gangrene being their occasional or accidental rather than their desired effects. In the inflammation of organs which sometimes comes on in the progress of fever, in nervous and spasmodic disorders, and in inflammations dangerous rather from their seat than from their extent, they are remedies of the greatest value.

*Vesicants.*—The next degree of counter-irritation which we shall notice is that in which the excited capillaries throw out a serous fluid, which detaches the cuticle from the cutis, and raises it in blisters. The more powerful of those agents which we have noticed as rubefacients, if kept applied for a sufficient length of time, produce this effect; but their vesicant is not always in proportion to their rubefacient property; and others which are more certainly and exactly vesicants, are more generally preferred. Several vegetable juices produce an eruption of small blisters; as that of some kinds of ranunculus, clematis, &c. But the Spanish blistering-fly, the *cantharis*, or *melœ vesicatoria*, is the remedy which best answers as a vesicant, and is the one almost solely employed. The active property, according to the researches of Robiquet, appears to reside in a peculiar principle soluble in æther and in oil, to which is applied the name of *cantharidin*. The form, therefore, in which it is most successfully applied is in a compound of the powdered flies with hog's lard, or some such oleaginous substance, and a due proportion of wax or resin to give it the consistence of soft plaster. This spread on leather, or any other convenient substance, and applied to

the skin, soon produces a sense of heat and pricking in the part, attended, if the application is large, with some excitement of the circulation and quickness of the pulse. If it be removed in two or three hours, its effect is merely rubefacient, and no blistering is produced; but if it be allowed to remain for a space varying in different individuals from five to ten hours, the skin will be found raised in large blisters filled with a yellowish serum, which continue to rise after the blister has been removed. In some cases they do not appear until after it has been dressed; and it is, therefore, unnecessary to keep the plaster on until they are formed, or till, as it is commonly expressed, the blister rises. When the blisters are fully risen, they are snipped with a pair of scissors, which allows the serum to escape; and if it be intended that the part should heal, it is dressed with simple ointment spread on a linen rag. The serosity continues to escape, and sometimes to raise fresh blisters, for some hours after; these must be treated as before, and the dressing renewed twice in twenty-four hours.

The discharge of serum produced by blisters renders them evacuants as well as counter-irritants; and this property must be taken into account in judging of their remedial powers. Until the vesication is complete, they have all those general stimulating effects which we have noticed as belonging to counter-irritants in general. But the serous effusion greatly modifies this, insomuch that after a blister is dressed, it is common to find the pulse weaker than before its application. The first excitement of a blister often communicates itself to the mental faculties; its discharge commonly causes a general depression, with a disposition to sleep. These different effects are much more marked in some individuals than in others, and are necessarily modified by the existing disease. But cantharides have properties of a peculiar kind, which not unfrequently exert an influence on the general operation of blisters. When their active principle is absorbed into the system, it proves very irritating, and in a peculiar manner affects the urinary organs, causing strangury and even bloody urine. To obviate this, it is commonly recommended to persons during the operation of a blister to drink copiously of diluent mucilaginous liquids; but we cannot refrain from expressing our conviction that this practice defeats much of the good effect of the blister. In many inflammations, particularly in those of the thoracic cavity, a chief object of blisters is to restrain the effusion of serum internally, or to promote its absorption; and this they do by extracting serum from the mass of blood in the adjoining vessels. But if liquids are thrown in such quantities into the stomach, they are rapidly absorbed into the circulating fluids, counter-balance the effect of blisters as local evacuants, and reduce them to simple counter-irritants. In such inflammations we are convinced by experience of the advantages of abstinence from any bulk of liquid, and would, therefore,

look for other means to avoid the irritating effects of absorption from a blister. This may pretty effectually be obtained by interposing between the skin and the blistering plaster a piece of thin gauze or muslin, moistened with oil, which being a menstruum of the blistering principle, transfers its effects to the skin, whilst the gauze or muslin prevents the particles of fly from adhering to the skin, after the separation of the cuticle has rendered it an actively absorbing surface. By taking care, also, not to allow the blister to remain on longer than is necessary, we may generally avoid these unpleasant consequences: six hours is generally sufficient; for whether the blister may have risen or not, if the skin at this time appear very red and inflamed, the vesication will almost uniformly take place after its removal. It has been asserted that by boiling the cantharides their peculiar effect on the kidneys is prevented, while their blistering power is unimpaired: of this we cannot speak from experience.

Before concluding our remarks on the remedial powers of blisters, we shall add a few cautions for their management. The due contact of the blister with the skin is of importance; and this may be effected either by a bandage or by a few strips of adhesive plaster: but if too great a pressure be exercised, it will restrain the inflammation of the capillary vessels, and no vesication will ensue. It is not advisable to apply a blister to an excoriated surface, as the absorption of the aerid matter and its unpleasant consequences are very apt to ensue. When, from peculiar idiosyncrasy, blisters produce great irritation, local or general, the addition of a little powdered opium or acetate of morphia to the plaster may give relief. An excess of inflammation, which occasionally ensues after the rising of a blister, sometimes with erysipelatous or eezematous appearances around it, is best relieved by poultices, which are proper applications whenever it is desirable to moderate the irritation. When the blistered part shows a disposition to gangrene, which is not unfrequently the case with children, it must be treated on general principles, as by stimulating or other applications, solutions of chloride of lime or soda, and bark exhibited internally. To avoid this consequence in children, it is advisable never to allow the blister to remain on more than six hours; and a poultice should be substituted if the inflammation be at all high.

Simple blisters, or, as the French term them, *vesicatoires volans*, (in contra-distinction to those which are kept discharging by an after application,) are remedies much and deservedly esteemed in the cure of inflammations. As rubefacients, or simple counter-irritants, they yield to sinapisms and other remedies which we shall presently notice; but their effect as local *depletories* gives them a superiority over most other counter-irritants. In common with the other remedies of this class, they are unfit for the first stages of extensive acute inflammation; but when the general excitement of the

circulation, and the intensity of the orgasm, have been so lowered by bloodletting and other means, that the temporary irritation of the blister may be borne without risk, its action becomes highly salutary; in the first instance drawing off the irritability from the diseased part, and then removing or exhausting it by an effusion of serum. This effusion proves the means of so *deriving* to the blistered part, that the morbid exhalations in other parts are re-absorbed and drained off; and hence blisters, more than rubefacients, are adapted to inflammations of serous membranes. Besides the caution required not to apply blisters at too early a stage, it is generally necessary to beware of placing them too near the seat of inflammation; for their contiguity may greatly aggravate it, causing two inflammations, as it were, to run into one. This must be left to the discretion of the practitioner; but it may be suggested that in inflammations of the pleura,—in those superficially affecting the pulmonary substance, as indicated by auscultation,—in those attacking the membranes of the brain or the larynx, it is better to place the blister on some part adjoining rather than immediately over the affected part; and to make up by extent of the surface blistered, for any diminution of effect from distance. In fact, in all acute inflammations large blisters are to be preferred to small ones; for the irritation from the latter is nearly as great, without the same good effects. In chronic inflammations the case may be somewhat different, as it is usually necessary to apply a succession of blisters; and the weakening effects of a large discharging surface might make small ones preferable. Of chronic inflammations, those affecting the serous and mucous membranes receive the most benefit from blisters. In pleuritic and peritoneal inflammations accompanied by effusions, their evacuant effects are likewise of decided utility; and with this view they should be of large size. But in inflammation of the parenchyma of the viscera, and in that of membranes without much liquid effusion, the more powerful counter-irritants are of greater efficacy.

We have already noticed that rubefacients are sometimes valuable in continued fever, on account of the stimulus which they convey to the vital powers; and we may extend this observation to blisters, which, judiciously administered, are often doubly useful, both by the general excitement which they afford, and by their local counter-irritation and evacuation relieving the several internal organs, which almost constantly suffer in these fevers. But, equally as in the case of acute inflammations, during the stage of synocha or morbid excitement they must be excluded as injurious. It requires much nice discernment to decide on the time at which blisters may with advantage be used. Dr. Rush considered that there is a period in all fevers at which they would prove salutary; but we shall not attempt here specifically to define it. (See FEVER.) By counter-irritants or revulsives of the most prompt and powerful kind, as boiling water,

some signal cures have been effected in the worst forms of fever; the patient having been by them at once awakened to consciousness from coma or extreme collapse. M. Marjolin cites his own case as an example of this treatment; and Dr. Macintosh records one which occurred in his practice eight or ten years ago: and we have heard of other instances of its success. As there is a great risk in the subsequent effects of the local injury, which generally tends to gangrene, this practice can only be resorted to in extreme cases.

What has been said of rubefacients in spasmodic and convulsive disorders, may be equally applied to blisters, which are in fact the form generally resorted to, although full blistering is probably inferior to sinapisms repeatedly applied for a short time. There is likewise a state of general irritability of the system, accompanied with various and occasionally fugacious pains, but without hardness or fulness of the pulse, that is often greatly relieved by the application of a blister, which seems to localise the irritation, and thus relieve the system.

An exception is commonly taken to the use of blisters in the case of inflammation of the kidneys and other parts of the urinary apparatus, on account of the irritating effect of cantharides towards those organs through absorption; and although this may generally be prevented by attending to the precautions which we have before enumerated, it is acting safely to prefer some other counter-irritant. This leads us to say a few words on other vesicating remedies.

All those irritant agents which act in the most prompt and energetic manner, without destroying the cuticle, raise it at first into blisters filled with a serous fluid. Thus, boiling water, or its vapour, the concentrated alkalis, or metal heated in water, as recommended by Sir Anthony Carlisle, produce this effect. Intense heat, the strong acids and some metallic salts corrugating and destroying the cuticle, act more immediately as escharotics. But this mode of blistering is very unmanageable, as the inflammation accompanying it is of a diffuse and uncertain character, and often leads to severe sloughing. There is a method of applying the vapour of boiling water in a jet, by means of an colipile, or vessel with a narrow orifice, which might be so regulated as to produce vesication without proceeding deeper; and the liquor ammoniac triturated with an equal weight of hogs' lard may be applied, so as to produce full blistering in fifteen or twenty minutes; but unless great speed is desirable, these agents, even thus modified, are not eligible as mere vesicants.

*Pustular or empyematous counter-irritants.*—We have hitherto referred to those degrees of artificial external inflammation which terminate in resolution or serous effusion. There is, however, an important class of counter-irritants, affecting the cutaneous texture more deeply, and determining the secretion of pus. A blistered surface sometimes spontaneously takes

on this degree of inflammation; and the same effect is frequently brought on by particular applications to it; but as these methods of counter-irritation are of a mixed kind, we shall presently return to them under the head of *issues* and *setons*, and here notice particularly those applications which bring on suppurative inflammation of the skin in the form of pustules. The sulphuric and nitric acids, their escharotic power being blunted by dilution with oil or lard, produce an inflammation, which soon assumes the form of pustules, small and distinct, or large and confluent, according to the proportion and strength of the acid used. But the substance most eminently calculated to excite the pustular inflammation is tartarized antimony. We owe the introduction of this medicine as a counter-irritant to the late Dr. Jenner, who employed it in the form of ointment, in the proportion of one part of the salt to five of spermaceti ointment. It has since been extensively employed in practice, and is almost as generally used as a pustular irritant, as cantharides are to produce vesication. In our own hands we have found it so manageable as well as effectual a counter-irritant, that we consider it a remedy of equal importance with the blistering fly itself; but, as much of its efficacy depends on the method of its application, before describing its advantages we shall premise some precautions on this point.

Tartar emetic exerts no corrosive or solvent power on the cuticle; it therefore sometimes happens that considerable difficulty is experienced in making the cutis feel its effects, and this obstacle is of course greater where the cuticle is naturally dense or thick. To obviate this we recommend the part to be previously excited, either by friction with warm flannel or a flesh brush, or by some stimulating application of a penetrating quality, such as camphorated spirit or strong vinegar, or a mustard poultice applied for a few minutes. When the vascularity and sensibility of the skin have been thus exalted, the tartar emetic ointment is to be rubbed in, and it will then take a more equal as well as more certain effect: instead of having a few large and unmanageable sores produced in two or three days, as is often the case in the usual method, a vivid erythema immediately succeeds, which in the course of a few hours breaks out into a thick crop of pustules, the size and course of which vary according to the strength of the ointment and the duration of its application. On these points it is not easy to lay down any absolute rule; for, as in the operation of blisters, much depends on the individual constitution. We generally prefer an ointment of considerable strength, for instance, made with one part of tartar emetic and two of simple ointment. If the fullest effect be desired, the friction, both preparatory and with the ointment, should each be persisted in for fifteen or twenty minutes. This generally leads to the speedy formation of confluent pustules, which go on to maturation. To diminish this effect it is best to shorten the period of friction with the ointment; and where we wish for the slightest

degree of counter-irritation, it is generally sufficient to *smear* the ointment on the part previously excited by dry friction, or by some of the other applications before enumerated.

Another mode of counter-irritation by tartar emetic is, the employment of a saturated aqueous solution: the elegance and convenience of this form render it peculiarly eligible where the ointment might be considered disgusting. It is expedient to make the solution as warm as the skin can bear it, as the heat both enables the water to dissolve more of the salt, and quickens the effect on the skin. The part being previously excited as for the ointment, the solution is to be gently rubbed on it by means of a piece of flannel, and continued for a longer or shorter time, according to the degree of effect desired. The pustules thus excited are usually small and numerous, and unless the application have been continued for some time or repeated, they dry up and heal speedily. As this application leaves no marks or scars, it is particularly suited to females, who generally renounce all medicaments which may leave a trace behind. Plasters sprinkled with tartar emetic in powder have been greatly recommended; but we have found their operation very uncertain; in some cases inefficient, and in others causing a frightfully ulcerated surface, which the removal of the plaster necessarily exposes. After the application of the tartar emetic, whether in ointment or in solution, the part should be covered with a piece of rough flannel, which, if it be desired, may be made still further to promote the effect by a little ointment smeared on it. By this system of management tartar emetic may be made to produce any degree of counter-irritation, from a papular or erythematous blush to an extensively suppurating sore.

Pustular or suppurating inflammation thus excited is generally more permanent and profound in its counter-irritant influence than vesication. The formation of pus requires a greater development of vital action, a higher degree of local irritation than serous effusion, without proving more stimulant to the system. For this reason we consider the tartar emetic counter-irritant better adapted than blisters to remove deep seated parenchymatous inflammation, even of the acute kind; and although it must not supersede the free previous use of depletory measures, yet it may be employed with less hesitation than blisters, inasmuch as the absorption of the medicine into the system proves antiphlogistic instead of irritating. That such an absorption does take place is probable from the nausea which sometimes attends the use of the medicine; and we have known in a few instances violent vomiting ensue.

In the method which we have recommended for its application, counter-irritation with tartar emetic may be brought to its greatest effect of copious suppuration in from ten to twenty hours, and a full pustular eruption may be brought out in five. This rapidity of effect places it on a par with blisters; and the greater intensity of its inflammation renders it a better counter-irritant. It is perhaps inferior to them

in pleurisy, meningitis, and those inflammations in which the principal danger arises from serous effusion. In gastritis, likewise, its tendency to excite vomiting may render it objectionable. In most other acute inflammations, if its proper application be attended to, we prefer it to blisters, and in none has it proved more beneficial than in those of the lungs and air passages.

In chronic inflammation the efficacy of tartar emetic counter-irritation is more generally acknowledged. We have found it far more beneficial than either blisters or setons in chronic bronchitis and pertussis; and if we can venture no further, we may unhesitatingly assert that we have seen it retard the progress of tubercular consumption. An eruption excited and renewed on the chest, sometimes on one side, sometimes on the other, seems in these cases to act as a safety-valve to the system, letting off any incipient disposition to inflammation; and thus, without much impairing the strength, enables the body to bear tonics, and a more generous diet than it would otherwise support. It has been found of signal utility in diseases of the joints and of the bones, and is preferred by some surgeons to moxa.

Numerous cases of epilepsy, chorea, and other convulsive diseases, also cases of mania, paralysis, and neuralgia, have been recorded, in which tartar emetic counter-irritation on the nape of the neck, along the spine, or the course of a nerve, has produced relief, and even a cure. But as in these disorders the scientific physician must see pathological causes of very various nature, it would be irrational to assert that the remedy in question is universally applicable to them. As often as they arise from, or are aggravated by, some local inflammation, irritation, or congestion, we can at once perceive its utility; but we can never be reasonably confident in our expectations of success when we remember how often there are irremediable organic causes for these diseases. In these and other complaints, nature not unfrequently throws out a hint in the form of a spontaneous eruption; and the physician may with great advantage be instructed by it, and second her efforts by means of this remedy. From the facility with which this counter-irritation may be excited and kept up for any length of time by a slight fresh application, it is well adapted to remove or prevent inflammations of the eyes, ears, and fauces, which sometimes engraft themselves on the habit, and are very difficult to remove.

A remarkable effect has been observed to ensue in a few cases from the use of tartar emetic ointment; namely, an irritation, sometimes very severe, of the genital organs. We have never seen this except in cases where the ointment had been used for several days in succession, which is rarely necessary according to the method which we have recommended for its use.

When the inflammation excited by tartar emetic runs too high, it may, as in the case of blisters, be moderated by a warm bread poultice,

which does not interfere with the progress of the pustules.

*Perpetual blisters, issues, and setons.*—We have delayed to notice these counter-irritants, because they are of a mixed nature, and occasionally partake of the qualities of all those which we have already described. The inflammation which they excite is of very various degrees of intensity, and the discharge which they occasion is sometimes purulent and sometimes serous.

Blisters are kept open by removing the raised cuticle by scissors, and by applying, instead of the ordinary dressing, an ointment or cerate of an irritating quality. A small portion of cantharides is sometimes used for this purpose, but the bad effects of its absorption, which frequently ensues, raise a great objection to it. A cerate containing euphorbium and the unguentum resinosum has likewise been employed with the same view. But the ceratum sabinae is that most commonly resorted to; and, if duly managed, it is capable of maintaining a more equal degree of irritation and discharge than any other. It is, however, necessary to attend to the strength of the cerate applied; and if discharge be the principal object, it ought to be applied in a diluted form. Blisters kept open in this way, without profoundly affecting the skin, sometimes yield a copious secretion of pus, and then prove most salutary. With a continuance of the same application, however, this very commonly becomes thinner and again serous; and in time the part is habituated to the irritation, dries up, and heals. To prevent this, it is necessary to remove the films of coagulable lymph which form upon it; to keep down vegetations by touching them with nitrate of silver or burnt alum; and occasionally to cleanse the surface by an emollient poultice, or by warm fomentations with flannel. By changing the stimulating ointment, the irritation and discharge may be preserved much longer than when one only is employed. On the whole, however, this method of counter-irritation is troublesome and uncertain, and may well be superseded by a succession of blisters, or by tartar emetic.

By *issues* and *setons* irritation is applied more profoundly, being brought immediately into the subcutaneous tissue itself. The former are made by producing an opening in the skin, either by incision, by a blister, or the application of some escharotic substance, such as potassa fusa, nitrate of silver, muriate of antimony, &c. and introducing some foreign body, as a pea or a glass bead, into it, which keeps up the irritation, and forms a constant ulcer. In producing the ulcer by means of caustics, it is necessary to limit the operation, and defend the adjacent parts by a piece of adhesive plaster, with an aperture in it of the required size of the ulcer. A bit of potassa fusa placed in this aperture in the course of four or five hours forms an eschar, surrounded by an areola of inflammation. This eschar being dressed with citrine, or other stimulating ointment, begins to detach itself and to secrete pus in the course of four or five days, and after

that falls off, leaving an ulcer more or less profound.

Setons are made by passing a lancet-bladed needle, with a fasciculus of thread or silk attached to it, through a portion of the integuments (pinched up between the finger and thumb), so that the threads are left in, with the ends hanging out at each orifice. To increase the irritation, the thread is anointed daily with the unguentum resinosum, and shifted or renewed to keep the wounds open or discharging. The necessity for the renewal is superseded by substituting a long strip of caoutchouc or of lead for the threads. The inflammation at first excited by setons is sometimes so intense as to require the application of poultices to moderate it; and their dressing and management require many precautions which it is the province of surgery to teach.

Issues and setons, when in full operation, excite a phlegmonous inflammation, attended by a discharge of an abundant thick pus. This is most frequently the case with setons, and with issues formed by caustics; and these are, therefore, the most powerful and profoundly acting of their kind. But like perpetual blisters, they are apt, with the same material of irritation, to become indolent and callous, and the secretion serous and less abundant. When energetic, these remedies are of great utility in chronic inflammations of various kinds. If any distinction can be made as to the kinds in which they are most serviceable, it may be suggested that the circumscribed textural inflammation of viscera are peculiarly benefited by their use. When in a more moderate form, and secreting serum, they act rather as evacuations, and have been, not unaptly, compared to a new secreting gland in the system. They thus occasionally prove safeguards against apoplexy, palsy, and other diseases of repletion; although implicit reliance ought not to be placed on such means. For the same reason they are proper adjuncts in the cure of long-continued cutaneous disorders, preventing any ill effects from the suppression of the natural counter-irritation. So, likewise, in all cases where setons or issues themselves have been for some time used, it is proper to be cautious in suppressing them, by doing it as gradually as possible, and carefully ensuring the free action of the bowels and other secretory organs. As a means of restraining the growth or diminishing the size of tumors and bronchoceles, setons have been found of some use; and the drains which they afford have likewise checked the increase of dropsical effusions.

*Cauterizing counter-irritants.*—By this term we designate all those operations in which heat, in such degree as to cause disorganization of the part, is applied as a counter-irritant. The common effect of all these is the formation of an eschar, or dead slough, surrounded by a more or less intense inflammation, which causes the separation of the dead part and the production of an ulcerous cavity in its place. The local inflammation, thus excited, may be very intense, and the suppurative

discharge very perfect; and this kind of counter-irritation is proportionately energetic in its effects on the disease, in the same manner as others. But there seems to be another peculiar result from the application of vehement heat, namely, a strong impression, or shock, on the nervous system, which in certain diseases is not without its salutary influence.

Heat, with a view to cauterization, is applied by heated metallic instruments, burning substances, boiling water or its vapour. Instruments of iron or copper, heated to different degrees of incandescence, are sometimes used to produce local irritation and sores. This operation, which is called the *actual cautery*, produces, more than any other method, that shock to the nervous system to which we have just alluded. It has been found useful in checking violent convulsive diseases, such as epilepsy, hysteria, and local spasms. It is difficult to judge whether its efficacy depends on the pain, or on some other change wrought in the nervous system; the effect is certainly sometimes produced before such a degree of local inflammation has been excited as could act by vascular counter-irritation.

A red hot iron is sometimes used to form issues; and for this purpose it is applied with considerable pressure to the part for eight or ten seconds, and repeated if it is wished to make the ulcer deep. A portion of skin and of the cellular texture underneath is thus killed, and forms an eschar, which in the course of six or eight days is sloughed off, and the ulcer produced may be treated as an issue. The painful and formidable nature of this operation excludes it from general adoption; and, with the exception of the cases just alluded to, we do not know that it can claim any superiority over that with caustic, which is attended with little pain. The good effects of the actual cautery are, perhaps, obtained with least attendant inconvenience when the metal is heated to a white heat. Thus applied, it immediately destroys the vitality and sensibility of the part; and if the surrounding skin is protected by coverings of wetted paper or other suitable substance, in the way which has been recommended by Dr. A. T. Thomson, the suffering of the patient is much diminished, and the advantages of the remedy are with more certainty procured. The actual cautery is more frequently resorted to in surgery for the destruction of malignant productions and morbid poisons.

There is a method of cauterization, called by surgeons *transcurrent*, which partakes more than the preceding of the nature of a counter-irritant. It consists in lightly passing an iron, heated to a cherry red, on the surface of the skin in parallel lines, at such a distance from each other that an intervening space may be left free from inflammation. In this way long narrow eschars are formed, which in the course of eight or ten days are enlarged; whilst the whole surface becomes highly inflamed, and is not relieved from the painful and phlogosed state of a common burn until a copious suppuration ensues, which often

lasts for a fortnight or more. The fever and irritation which this process occasions forbid its employment in any but very chronic and indolent cases. It has proved very successful in removing chronic enlargements of the joints, and the remains of rheumatic affections.

Cauterization by substances in the state of combustion has of late years been practised to a considerable extent, in the form of what is termed *moxa*. This method is said to have been adopted from Japan, where moxas are made of a down obtained from the leaves and tops of a species of *artemisia*, made into a cone, which when lighted burns spontaneously. The pith of the stalk of the sunflower and of other *helianthi* likewise possess this property, which is owing to a small quantity of nitre in their composition. The material generally employed in Europe for moxas is cotton, rendered downy by carding, and made into a roll an inch long, and from half an inch to two inches in diameter. This is held by a forceps or wire, with one end in close contact with the skin, whilst the other is set on fire; the adjoining parts being protected by wet pasteboard or linen. The combustion is supported either by blowing or fanning, or by a slight impregnation of nitre previously given to the cotton. The sensation produced by the burning of a moxa is first that of warmth, rather agreeable than otherwise; this soon increases, as the fire approaches the surface, becoming itching, then more and more painful, and attains its acme of intensely sharp scalding pain when the combustion reaches the skin, which smokes and becomes crisp under it. The neighbouring skin is vividly inflamed, puckered, and sometimes slightly blistered. The eschar thus formed is deep, and requires a fortnight or upwards before it is separated. The ulcer formed discharges pus abundantly, and by the aid of a pea may be converted into an issue.

The gradual manner in which heat is communicated to the part in the burning of a moxa causes it to penetrate more deeply than any other form of actual cautery. Hence as a remedial agent it is well adapted to make an impression on deep-seated inflammation; and in diseases of the spine and its contents, in serofulous and rheumatic swellings of the joints, in chronic diseases of the liver, kidneys, and other internal organs, in paralysis and neuralgia, it sometimes proves more effectual than any other remedy. It is often necessary, however, to employ several moxas in succession; and if the disease be of some extent, several simultaneously, before the good effects become apparent. Moxas may be applied with greatest advantage as near as possible to the diseased part; but if their effect is intended to be deep, it would not be proper to apply them on parts where cartilage, tendon, or bone are close under the surface.

Moxas are sometimes applied with a view to counter-irritate without producing an eschar. The moxas in this case are made of sunflower pith, or of light cotton impregnated with nitre. The combustion is effected without blowing, and is not suffered to reach the skin.

Under this form, frequently applied, they have been found useful in promoting the absorption of indolent effusions in joints and cold tumours. It is probable that much of their effect in these cases depends on the stimulus which they impart to the organic sensibility of the diseased tissues which cannot be included in their counter-irritation.

A cauterizing effect may be produced by boiling water, or better by its vapour. The best method of effecting this is by an *colipile*, or vessel with a narrow tubular mouth, and kept boiling by means of a lamp. The jet of vapour issuing in full force from this is directed against the part, which is covered with thick pasteboard or linen, with an aperture of the form and size of the part intended to be cauterized. The pain caused by this operation is very severe, and the slough formed very deep. It most resembles moxa in its effects; but the wound produced by it is less manageable, and more apt to involve the surrounding parts.

(C. J. B. Williams.)

CRISIS, CRITICAL DAYS. See DISEASE.

CROUP.—(Synonyms—Cynanche *trachealis*, *C. laryngea*, *C. stridula*, Angina *polyposa*, Suffocatio *stridula*, Morbus *strangulatorius*, &c.) We prefer croup to the other appellations, inasmuch as it does not convey an erroneous notion of the nature of the disease which it designates: that disease is not a mere cynanche, or quinsy. It will be shown that inflammation, which is the characteristic of the order of diseases to which croup belongs, is not confined to the throat, but generally extends through the ramifications of the bronchi; therefore, *C. trachealis* and *C. stridula* ought no longer to be retained as nosological terms. The terms *suffocatio stridula* and *morbus strangulatorius* are indefinite, and would equally apply to the various affections in which those symptoms of croup—the *inspiratio strepens*, *vox rauca*, and *tussis clangosa*—are engrafted on other diseases; and which will be treated of under their respective titles.

This disease was honoured with the attention of the greatest man of the present age, if he can be called great who had no just sense of moral grandeur. In consequence of the general order which Napoleon issued from the head-quarters of Finkenstein,\* many essays on croup were written by foreign physicians of ability, in which nothing is omitted

\* Ce fut au quartier général de Finkenstein le 4 Juin, 1807, que S. M. I. et R. donna l'ordre d'ouvrir un concours sur la maladie connue sous le nom de croup; et c'est en exécution de cet ordre que son excellence Monseigneur le ministre de l'intérieur mit la question suivante au concours.

Déterminer, d'après les monumens pratiques de l'art, et d'après des observations, les caractères de la maladie connue sous le nom de croup, et la nature des altérations qui la constituent; les circonstances intérieures et extérieures qui en déterminent le développement; ses affinités avec d'autres maladies; en établir, d'après une expérience constante et comparée, le traitement le plus efficace; indiquer les moyens d'en arrêter le progrès et d'en prévenir l'invasion.

in illustration of that disorder which industry could collect or method could arrange.

*Occasional causes.*—In the early part of his professional life, the writer of this article lived on the coast of the Firth of Forth, where croup may be considered an endemic disease, and where every facility was afforded for cultivating an acquaintance with it. During the last twenty-two years, while practising medicine in Dublin, his opportunities of witnessing croup have not been unfavourable, especially when attending a dispensary. While discharging that duty, he had frequent occasion to observe the disease among the ragged and half-starved children of the poor who live near the canals which surround the city; or in Ringsend, near the estuary of the river Liffey; or in Sandymount, lying between Dublin and its bay: indeed the disease is prevalent, in the latter end of winter and in spring, along the whole of the eastern and northern coasts of Ireland. With respect to its prevalence along the rest of the sea-coast, no inquiries were made; his inquiries, however, sufficiently confirm the received opinion relative to the principal occasional cause of croup, viz. that in Ireland, as in Scotland, it is chiefly produced in the neighbourhood of large bodies of water, running or stagnant, fresh or salt.

*History.*—The disease may occur at any period from the second or third month after birth to puberty. The younger children are when weaned, the more liable are they to croup. After puberty it scarcely ever occurs. Some families, those especially in which the children are of a sanguineous temperament and full habit, are much more liable to the disease than others. It often attacks children who have not fully recovered from a previous illness. It is liable to recurrence, at distant intervals, upon exposure, not merely to an atmosphere which has been influenced by passing over a large body of water, but to any of the causes which produce common catarrh.

Hoarseness, in very young children, does not usually attend common catarrh; and hence when observed in a child living in a district which generates croup, this symptom is always much more deserving of attention, especially if accompanied with a rough cough, than it would be after puberty. This remark may be supposed scarcely worthy of the reader's attention; but having had innumerable opportunities of ascertaining that inflammatory affections of the mucous membrane of the larynx and bronchi in children owe their complexion to the mode of treatment adopted during the first six or eight hours of the attack, when no other symptom but hoarseness exists, we consider the observation important to parents whose children are liable to croup, and consequently to their family physician.

In the approach of an attack of croup, which almost always takes place in the evening, probably of a day during which the child has been exposed to the weather, and often after catarrhal symptoms have existed for several

days, he may be observed to be excited, in variable spirits, more ready than usual to laugh or to cry, a little flushed, occasionally coughing; the sound of the cough being rough, like that which attends the catarrhal stage of the measles. More generally, however, the patient has been for some time in bed and asleep before the nature of the disease with which he is threatened is apparent; then, perhaps without awaking, he gives a very unusual cough, well known to any one who has witnessed an attack of the croup; it rings as if the child had coughed through a brazen trumpet; it is truly a tussis clangosa; it penetrates the walls and floor of the apartment, and startles the experienced mother—"Oh I am afraid our child is taking the croup!" she runs to the nursery, finds her child sleeping softly, and hopes she may be mistaken. But remaining to tend him, before long the ringing cough, a single cough, is repeated again and again: the patient is roused, and then a new symptom is remarked; the sound of his voice is changed; puling, and as if the throat were swelled, it corresponds with the cough: the cough is succeeded by a sonorous inspiration, not unlike the kink in pertussis—a crowing noise, not so shrill, but similar to the sound emitted by a chicken in the pip, (which in some parts of Scotland is called the roup, hence probably the word croup); the breathing, hitherto inaudible and natural, now becomes audible, and a little slower than common, as if the breath were forced through a narrow tube; and this is more remarkable as the disease advances. A blush of inflammation may sometimes be detected on the fauces, and in some rare instances a slight degree of swelling round the larynx, and the child complains of uneasiness in his throat, and says he is choking. The ringing cough followed by crowing inspiration; the breathing, as if the air were drawn into the lungs by a piston; the flushed face; the tearful and bloodshot eye; quick, hard, and incompressible pulse; hot, dry skin; thirst, and high coloured urine—form a combination of symptoms which indicate the complete establishment of the disease.

Sometimes the symptoms enumerated subside about midnight, even in the absence of medical treatment; perhaps to return in the course of the following evening. From seven or eight o'clock till midnight this complaint is always at its height; but in general, unless the patient be treated with promptitude and judgment, the disease may be expected to terminate fatally; a new order of symptoms, the second stage of croup as it is called, taking place in the course of the next day.

When the first or inflammatory stage of croup just described has not subsided or received a check, the cough, from being loud and sonorous, becomes husky and suffocative; it resembles the cough which attends tracheal phthisis, and cannot be heard at any distance from the bed; the voice is whispering; the respiration wheezing; the countenance pale; lips livid; the skin motley; the eyes languid;

the iris with less colour than natural;\* the pupils dilated; the tongue loaded, and with purplish edges; thirst considerable; skin much less hot; and the stools dark and fetid. In this, the second stage, or that of suppuration, the breathing may often be remarked most free in positions which are generally least favourable to easy breathing, as, for example, when the head is low and thrown back. When the breathing is a struggle for life, the patient sometimes will suddenly obtain relief, which, however, in general is only temporary.

From the state described in the last paragraph comparatively few patients recover. The eyes now become hollow; the countenance sinks; the circulation gradually fails; the extremities are cold and swollen; jaetitation and drowsiness occur; the respiration becomes frequent, interrupted, and laborious; and, after gasping for a longer or shorter time, the child dies;—the duration of the disease being varied according to the stamina of the patient. When fatal, croup at an average occupies a period of four days. Sometimes, however, the second stage is prolonged for two or three weeks, and the patient, expectorating freely, slowly emerges from a condition which repeatedly had appeared hopeless. Along with puriform fluid, of which the sputa chiefly consist, there is sometimes expectorated a white soft tubular matter, like macaroni stewed in milk, which is called the membrane of croup.

*Prognosis.*—The danger to which a patient in croup is exposed may be easily computed by any experienced practitioner who will bestow some consideration on the first or inflammatory stage of the disease. In this stage the hoarseness and cough (unaccompanied with the pulse of inflammation), how distinctive soever of croup, do not imply the existence of danger: a hard ringing cough, followed by a crowing inspiration, will often take place during several successive nights; and these symptoms may exist without danger, so long as the breathing is free and pyrexia absent. Very active treatment may not be required, but vigilance will be necessary. The medical attendant must be within call, and see the child more than once in the course of the evening, and take care that he is under the eye of a steady and experienced nurse, by whom he may, without delay, be certified of any symptom indicative of stricture of the glottis or inflammation of the bronchi. While the breathing is inaudible and the pulse quiet, all may be considered, so to speak, as safe; but when the child crows in inspiration, when the breathing is audible, the air as if forced through a narrow tube, dry rather than wheezing—a sound which any one may voluntarily produce by contracting the glottis while he inspires,—or when the respiration is cooing or croaking, danger is present; inflammation has seized the larynx, has caused tumour and great

irritation there, and has extended into the bronchi. This is no longer a case for *expectation*, but for action. On the other hand, when the cough becomes loose, the voice more natural; when the symptoms of inflammation abate, while no symptom of the second stage exists; we may give all reasonable encouragement. In the stage of suppuration the prognostic is always unfavourable; but a prudent physician in prognosticating the issue of any disease of childhood ought not to deliver himself without reservation; he ought ever to be ready for any contingency unfavourable or favourable: his prognostication ought to be declared, to use the words of a late eminent physician, to be “subject to the uncertainty of all medical opinions.”

*Diagnosis.*—The diseases which are liable to be mistaken for croup are the following:—

1. *Measles.*—This disease often resembles croup so much, that the most experienced physician need not be ashamed of mistaking the catarrhal symptoms, which, with a ringing cough, usher in the former disease, for the latter. This he will the more readily do, unless he knows that the measles are in the neighbourhood, or that the patient, some twelve or fourteen days before, was exposed to their contagion. Upon the efflorescence taking place in the measles, the symptoms resembling croup disappear.

2. *Cynanche pharyngea.*—When inflammation runs very high in this species of quinsy, we have known it extend to the larynx, and croup thereby has been simulated; but cynanche pharyngea will not be mistaken for croup, even under such a complication, if the fauces be carefully inspected, and if it be recollected that cynanche pharyngea is attended with complete dysphagia, whereas in croup the patient can always swallow with ease.

3. *Cynanche membranacea* or *maligna.*—This disease, when the morbid action descends from the fauces into the larynx, is more liable to be mistaken for the croup than any other. In croup, therefore, the fauces, which are scarcely, if at all, inflamed, ought to be examined with care, thus to distinguish it from cynanche membranacea, or any congeneric disease. If the fauces are discovered to be spotted, as it were aphthous, encrusted with a membrane, or apparently sloughy, the disease is not croup. Moreover, cynanche maligna, being propagated by contagion, often occurs in several persons in a family or neighbourhood at the same time, and can be traced from house to house, while croup is non-contagious. When two of a family have been attacked at the same time with croup, which we have often known to be the case, it has always manifestly appeared that both had been exposed to a cold damp atmosphere, or to some other adequate occasional cause.

4. *Hysteria.*—Hysteria, which mimics so many diseases, not unfrequently assumes the character of croup. By the first case of this kind which he witnessed, the writer of this article was so completely deceived that he ordered the patient, a young lady who never

\* This paleness of the iris, which often attends the advanced stage of diseases, especially of the lungs, and which is a very unfavourable symptom, has, we think, been overlooked.

had menstruated, to be let blood, and he remained during the operation. Before she had lost more than a cupful of blood, she fell into hysteric catalepsy. The vein, of course, was immediately closed, and by means of draughts of camphor julep, Hoffmann's anodyne liquor, with five or six drops of the acetum opii in each draught, her croup was easily cured: but hysteria exhibited itself in various forms before she finally recovered. Whenever a physician is called to a young lady said to be affected with croup or inflammation of the windpipe, let him bear in mind that hysteria sometimes acts the part of croup to the very life, and even although he cannot detect any overt act of hysteria, let him look narrowly into the history of the patient, and carefully study her diathesis before he delivers his opinion. Moreover, the patient's age will always be a guide to a true diagnosis, croup not occurring in adult age or even in adolescence, and hysteria being rare before puberty.

*Spasmodic croup.*—The symptoms of croup which depend upon stricture of the glottis differ so in degree, (sometimes suffocation appears impending, sometimes the breathing is nearly natural,) as to prove in many attacks the existence of spasm; this, however, is spasm caused by inflammation, for which no antispasmodic will be equal to venesection. That inflammation in this disease often spontaneously is resolved, the spasm depending upon it subsiding at the same time, is unquestionable, and has given rise to a belief entertained by those chiefly who have overlooked the evidences of inflammation, that there is a purely spasmodic species of croup; we therefore take the opportunity which presents itself of observing that the hysteric affection just alluded to is the only species of spasmodic croup with which we are acquainted. The term spasmodic croup has been applied to affections of very different kinds, by which many discussions have been excited. We are convinced that the difficulty attending these discussions has arisen chiefly from that fruitful source of error, the misapplication of terms. The designation spasmodic croup we have reason to believe has often been applied to the hysteric affection which we have just described. It has also been applied to a well known disease of infancy, which one of our latest authors describes as follows: "Spasmodic croup occurs in very young children, and appears at the commencement of the period of dentition; sometimes earlier, and but very rarely after the child has reached its third year. The crowing noise which some infants make in respiration, and which nurses occasionally consider as a sign of thriving, is nothing more than the air rushing through the aperture of the glottis in a state of spasmodic constriction; and wherever this symptom appears, (however well the infant may seem in other respects,) it is always advisable to pay attention to it, and remove the source of intestinal irritation, which will generally be discoverable. In some in-

stances the constriction is both slight and momentary, and the spasm never produces either unpleasant or dangerous consequences: in others it is longer continued, and the infant works and struggles for breath, becomes purple in the face, and is apparently dying when the spasm begins to relax, and a long-drawn, crowing inspiration sets all things to rights again. . . . . In the fatal cases of spasmodic croup death is extremely sudden: the infant may be apparently in good health, and in a moment he makes a violent effort to inspire, which occasions something like a faint scream or cry, becomes black and swollen in the countenance, and dies before assistance can be procured." Now this is a graphic description of a disease of which an account will be found in Dr. Clarke's Commentaries on the Diseases of Children, there entitled, "a peculiar species of convulsions in infant children," which has also been sometimes called chronic croup, sometimes inward fits; and which is furthermore distinguished by a clenching of the hands upon the thumbs, and a bending of the toes downward and inward, by which the foot appears slightly clubbed. This affection, which ought never to be called croup, is not attended with cough. On dissection there is no trace of inflammation in the windpipe; the seat of the disease, it can scarcely be doubted, being in the brain.

Having repeatedly observed the symptoms which in children are supposed to constitute a non-inflammatory variety of croup, and to which most frequently the term spasmodic croup is applied, symptoms which may be found in Dr. Good's valuable work, *The Study of Medicine*, embodied under the title of Laryngismus Stridulus, viz. "sense of suffocation commencing in the night; voice shrill and croaking; countenance flushed and swollen; distressing struggle for breath;"—we were naturally anxious to determine their true nature; and as it appeared that these symptoms took place at the time of night when croup is generally at its height; that they were brought on by causes which produce croup; that they occurred in individuals and families liable to croup; that they were most certainly relieved by the internal remedy most efficacious in croup, namely, an antinomial emetic; and, on the other hand, when it was considered that genuine inflammatory croup often invades suddenly and without any catarrhal symptoms preceding, and that its most formidable attacks will often subside as the symptoms of the supposed spasmodic croup are represented to do, without remedial treatment; there appeared to us no sufficient grounds for establishing a spasmodic variety of the disease. A sounder conclusion could not be drawn relative to spasmodic croup than that with which the late Dr. Kellie ends an able letter on this much contested point. "After embarrassing myself a long time about spasmodic and inflammatory croup, and using my opportunities of observation to the best advantage of which I was capable, with the

view of establishing the diagnosis of these two diseases, I came at length to persuade myself that there was truly no essential difference between them, other than what arises from degrees of violence, and the obvious circumstance of intermission and continuance.\*

*Predisposing cause.*—There would be less difficulty in explaining the nature of the predisposing cause of croup, did we know why the disease ceases at puberty. The difference between the glottis of a child of three years and of twelve is scarcely perceptible; whereas at puberty the aperture of the glottis is quickly enlarged in the male in the proportion of ten to five, in the female of seven to five; at the same time the bronchi enlarging, and the voice undergoing a corresponding change. Upon the windpipe and bronchial system, changed in their constitution, enlarged and invigorated, the occasional cause of croup is no longer able to produce an adequate impression: it may be conjectured, then, that in the immature state of the organs affected we are to look for the predisponent cause of croup.

*Pathology of croup.*—Upon dissection, appearances are displayed which satisfactorily account for the symptoms of this disease. The symptoms, as the reader must have observed, are those of inflammation affecting the air-tubes of the lungs. The sound of the voice, the sense of strangling, (which the writer well recollects, having had a dangerous attack of the croup when he was not a very young child,) prove that the larynx is much affected; while the state of the complexion in the second stage, even when the uneasiness in the throat is relieved, the quickness of the breathing, the cooing respiration, the puriform sputa, would shew that the inflammation has extended through all the branches of the bronchial tubes. Nay, the examination of the body after death explains the sudden relief which the patient sometimes unexpectedly obtains in the second stage of the disease, as also the case which he finds in positions generally unfavourable to free breathing.

The mucous membrane is found inflamed, and, in consequence of this inflammation, the larynx, trachea, and bronchial tubes are generally lined with a membranous substance, varying in consistence, of the same sort with that which, as has been observed, is sometimes expectorated; this substance, in a fluid form, fills the bronchi. In the trachea it is soon dried, and there it obtains form and consistence; it is often partially detached. Evidences of inflammation may generally be discovered over the whole of the mucous membrane of the lungs; the cavity of the lungs is always full of fluid; the interstitial cells are sometimes filled with serum; nay, we have known parts of the lungs hepatized, and inflammation to extend not merely to the parenchyma, but to the serous membrane, in consequence of which we have seen fluid effused

into the cavity of the pleura. In many dissections the lungs have a solid feel, do not recede when the thorax is opened, and cannot be compressed.

The membrane of croup has been found partially detached, which will account for its being sometimes coughed out; and as children often swallow what would be expectorated by adults, there is reason to think that it is much oftener transferred to the stomach, upon which the struggle within the larynx ceases for a time; and this explains the gleams of hope afforded in the second stage, which, however, for the most part are gradually obscured by the steady advance of bronchial inflammation and effusion. The relief obtained in unfavourable positions may be explained as follows: the trachea has its capacity increased by being stretched to the full extent, which happens when the head is thrown backward; whereas when the patient sits, which is generally the easiest posture in difficult breathing, the head falls forward, and the membrane, especially if it be in part detached, being doubled together, fills the trachea at one point, and completely obstructs the passage of the air.

*Prophylaxis.*—When croup has once occurred in a family, it will probably renew its visits, and will attack the same child or some of the other children on a future occasion; the physician therefore should instruct parents with regard to prevention. If possible, children liable to croup ought to live at a distance from bodies of water. They ought not to occupy warm rooms, or have a superfluity of bed-clothes. Beginning in summer, they ought to be sponged with cold water every morning, and rubbed dry with a coarse towel. In winter and spring they ought to wear flannel next their skin, and to have the neck covered. They ought not to drink fermented liquor. Their diet at all times, although nourishing, ought to be light; and finally, when the weather is cold and damp, and especially during the prevalence of the east wind, they ought not to be in the open air between October and May.

*Treatment.*—When a child becomes hoarse, and begins to cough, let every kind of stimulating food be withdrawn; let him be confined to an apartment of agreeable warmth; have a tepid bath; and take a drachm of the following mixture every hour, or every two hours, if it produce sickness:—

R Vinii ipecacuanhæ ℥iii.

Syrupi tolut. ℥v.

Mucil. acaciæ ℥i. m.

and all danger will probably be averted. Whereas, if no change be made in the quality of the food, and if he be sent into the open air, he will probably undergo an attack of bronchitis or croup.

When the breathing becomes affected in croup, or when there are symptoms of inflammatory fever, an emetic should be given without delay, and blood should then be drawn from the arm, or, in very young children, from the jugular vein, unless very great relief should

\* See *Dr. Kellie's* Letter, Pathology of the Larynx and Bronchia, by J. Cheyne, M.D. p. 136.

follow the operation of the emetic.\* Next we would give the patient a powder consisting of calomel and James's powder, probably two, three, or four grains of the former, with two or three grains of the latter, and we would then have him put into a tepid bath, and supplied with diluting drinks. Every third hour, the calomel and James's powder ought to be repeated: if it should not, after a third dose, affect the bowels, a dose of castor oil may be given.

The quantity of blood drawn from a child under two years of age ought not to exceed five ounces; in a child of seven or eight it may amount to eight ounces. But one venesection will seldom suffice in a severe case of croup; it will very often be necessary, in two or three hours, to repeat the operation. When a second bloodletting fails to moderate the symptoms, we generally order leeches to be applied to the upper extremity of the sternum; three or four to an infant, ten or twelve to a child of as many years old. Leeches ought not to be applied to the region of the larynx, as children, in croup, will be found most impatient of the degree of pressure necessary to stanch the bleeding when profuse.

If manifest improvement be not produced by the application of the leeches, and if it be judged unsafe to have more blood drawn, a blister ought to be applied to the lower part of the sternum, and a solution of tartar emetic given. The dose of tartar emetic may be from a quarter to a half grain, and this may be repeated, according to its effect, and to the urgency of the attack. Sickness ought to be excited, and hence the dose, if it have no such effect, ought to be repeated in half an hour, and, if great prostration be not produced, the dose ought afterwards to be repeated hourly while symptoms of inflammation continue.

These may appear violent measures, but be it remembered that, in a vast many cases, the fate of the patient will be decided within twelve hours; nay, there are cases in which the inflammatory stage will be over in six hours from the commencement of the disease.

With respect to the treatment of the second stage of croup, or that of suppuration, little can be added to what may be found in a work on the Pathology of the Larynx and Bronchia, published by the writer of this article many years ago. In that publication it is recommended to give half a grain of tartarized antimony, dissolved in a table-spoonful of water, to a child two or three years of age, every half

\* We have adopted the following expedient, with excellent antiphlogistic effects, in violent inflammation of the lungs occurring in a robust constitution. Having ordered an emetic to be given, in eight or ten minutes after, before sickness has commenced, we have had a vein opened, and have found, before ten or twelve ounces of blood had flowed, that the patient has become sick, vomited freely, and fallen into a state of colliquation, which has lasted for a considerable time,—a powerful impression being thus made, at a small expense of blood.

hour, till sickness and vomiting are produced; and in two hours after the last act of vomiting the same process is to be recommenced, and so repeated while the strength will admit. The following case suggested this mode of treatment: a child, with disordered bowels, so delicate as not to admit of being let blood, was threatened with croup, every night, for five or six nights. Whenever the breathing became difficult, the child took as much of the antimonial solution as induced vomiting, and invariably with relief to the difficult breathing. Perceiving that in croup, then pretty generally supposed to be a disease of the trachea, every part of the inner surface of the lungs, from the larynx through the ramifications of the bronchial tubes, was in general affected, and considering that nothing could more effectually moderate the vascular action in that organ, and at the same time dislodge the exudation which fills the bronchial tubes, than the solution of tartar emetic, all reliance was placed on that remedy in the second stage of croup, more especially as it was found that bloodletting in that stage only accelerated the death of the patient. The solution of tartar emetic was prescribed the more freely, from a child having been observed to take six or eight grains of tartar emetic, without vomiting being produced. In few cases has the writer known children survive the second stage of croup; in all of these, however, they recovered while using a solution of tartarized antimony: "Emetics he had repeatedly given in the second stage of croup, but in these cases of recovery the patients were kept sick for two or three days with scarcely any interval. With the exception of tartar-emetic no medicine with which he is acquainted is entitled to confidence in the second stage of croup: calomel uncombined, as recommended by Rush, he has often given without benefit. Indeed, tartar-emetic in croup, so as to produce continued nausea, has been his sheet-anchor since 1799."\*

As there is in inflammations of the mucous membrane of the bowels a point of time, when life being rapidly on the ebb, a patient may sometimes be rescued by the substitution of opiates and cordials for the antiphlogistic regimen; so also is there, in bronchial inflammation, a time when we may with advantage lay aside all lowering remedies and give burnt brandy and ammonia, to which may be added calomel, with a minute quantity of opium, and the application of spirit fomentations to the surface. Gasping, failure of the pulse, and a clay-cold surface, show that our only faint hope is in cordials: it must be admitted, however, that a clear discovery of the point at which this change of treatment ought to take place is the reward of clinical experience alone, and cannot be made in the closet.

In the treatment of this disease we have but one point more to consider, namely, the

\* Essay on Cynanche Trachealis, or Croup, by J. Cheyne, M.D. Edin. 1801.

propriety of attempting to remove the membrane of croup by means of a surgical operation.

Considerable difficulty will attend this operation. The larynx of a child from two to twelve years of age is a very narrow tube, not more than three-eighths of an inch in diameter; consequently, to admit the introduction of a pair of forceps, the cartilages must be cut across to a considerable extent, involving bleeding from the thyroid veins, which sometimes has been productive of suffocation. But even were the larynx laid open without hemorrhage, disappointment will probably arise from the state of the adventitious membrane, which sometimes possesses so little cohesion as not to admit of being laid hold of by an instrument for the sake of detaching and removing it; nay, in some cases in which the inflammation is intense, there is no appearance of a continuous membrane, the secretion from the inflamed surface existing in the form of shreds and detached portions. "Dans plusieurs cas, et tout récemment encore, des médecins très-distingués ont pratiqué la trachéotomie sur des individus affectés de suffocation et de voix croupale, qu'ils regardaient comme dépendantes du croup. L'opération d'abord, et l'ouverture du cadavre ensuite, ont prouvé qu'il n'y avait pas de fausses membranes."—*Guersent, Dictionnaire de Médecine*, tome vi. p. 213.

Before having recourse to the operation, supposing it easy, safe, and likely to end in the extraction of the adventitious membrane, it will be proper to ask, is the false membrane in the larynx, which it is the object of this formidable operation to remove, in general the cause of the patient's death? We apprehend not. First, because in several dissections, which were long ago made with a view of determining the effect of the membrane of croup in obstructing the larynx, it so happened that within that membrane a space was left for a current of air sufficient to support life: in these bodies the cellular substance of the lungs was distended with serum, the ramifications of the bronchi were filled with puriform matter, by which the air was excluded, and the bronchial membrane was universally inflamed, thereby preventing the arterialization of the blood: the children had perished from the lungs being unable to contain a quantity of air sufficient to support the circulation, and from the bronchial membrane being unable to act upon that reduced quantity. Secondly, because when the membrane of croup, fully formed, is expectorated, the disease is generally fatal, even when all the benefits of the operation are obtained. If the disease were confined to the larynx, then, and then only, would bronchotomy be advisable. The following are the very pertinent remarks of Mr. Porter on this subject:—"But bronchotomy has in many cases of croup been successful. True; but where are the thousand instances to the contrary that might be brought against each single one of these? I have performed the operation myself on the child,

and have seen it frequently done by others, and in no one case has the life of the patient been saved. I have known and heard of it often, but never understood that it produced a recovery. Most practitioners are fond of publishing cases of successful operations, but are not so willing to make known those of an opposite description, from an idea that these supposed failures might lower them in public estimation; but these detached and solitary expositions of fortunate surgery are calculated to produce very serious injury, if they encourage others to similar attempts, in the hope of similar results. If it was possible to place a list of those cases in which bronchotomy had proved unserviceable, in array against those wherein it had seemed to be useful, it would be scarcely necessary to advance any further argument in proof of its uncertainty; and medical men would rather turn their attention to the improvement of that internal treatment, which will generally be efficacious if resorted to in time, than look for advantage in the performance of an operation from which experience holds out such slender hopes."\*

Improvement of the internal treatment of croup will, in all probability, chiefly flow from the acquisition of more clear and determinate views with respect to the nature of that disease. Some of the latest authors on nosology have formed a juster conception of croup than their predecessors did, having classed it with diseases of the lungs and not of the throat. Swediaur represents croup as a genus of the order Phlegmasiæ, and entitles it Bronchitis; Young as a species of the genus *Cauma*, or inflammatory fever, under the title of *Cauma Bronchitis*; and Good includes it under the genus *Empresina* or visceral inflammations, calling it *Empresma Bronchlemmitis*, or membrane-like inflammation of the bronchi. The latest of these authors observes that croup essentially consists in an inflammation that spreads through the whole range of the wind-pipe, from the larynx to the minutest ramifications of the bronchi.

This is a juster view of the matter than that of some of our contemporaries in France, who have endeavoured to identify croup with affections primitively of the fauces, beyond which they often do not extend; affections some of which in their constitution are the opposites to croup. MM. Bretonneau, Guersent, and others, have endeavoured to prove that croup and epidemic angina maligna are one and the same disease; that although there may be some little variety in their seat, there is none in their nature: "M. Bretonneau a démontré que l'angine maligne épidémique est une véritable inflammation pelliculaire, semblable à celle du croup. Il a prouvé ensuite, que ces deux maladies, identiques quant aux altérations pathologiques, ne diffèrent que par rapport au siège qu'elles occupent."—*Guersent*, l. c. It is strange, that among a people remarkable for their minute and patient study of disease,

\* Observations on the Surgical Pathology of the Larynx, &c. by W. H. Porter, A.M. &c.

and their refined arrangements, croup and cynanche maligna should be considered identical, because of a certain gross resemblance between them, because in both there may often be found an adventitious membrane, and because in the latter, when the diseased action is extended to the windpipe, there may arise some of the symptoms which belong to the advanced stage of the former. What real identity can there be between two diseases, the one caused by cold, the other by contagion; the one always purely inflammatory, the other generically typhoid; the one requiring a decidedly antiphlogistic treatment, the other local stimulants of the most powerful kind, tonic medicines and cordials — bark and wine, according to the procedure of our fathers? If we yield ourselves to this figment of our ingenious neighbours, we must, in the present instance, relinquish one of the great advantages which nosology affords, namely, a ready means of distinction between diseases similar in appearance but different in their essence.

If this attempt at the identification of contraries should succeed, it is obvious that the treatment of croup, which at present is simple, will hereafter be complex, difficult, and uncertain. To bear out this assertion, we shall briefly examine some parts of the chapter which Laennec has written on croup, assuming it as a fair representation of the opinions of his countrymen. I prefer an appeal to Laennec, as (although in point of practice he is often marvellously deficient) the genius of that great observer, and the ability of his translator, have obtained for his treatise on the diseases of the chest, authority in Britain as a work of pathological reference.

Laennec tells us that “sometimes croup is confined to the bronchia and their branches, there being no trace of it in the larynx and trachea.” This fact would require to be established. “More commonly, as has been shown by Bretonneau, the inflammation commences on the tonsils or the pharynx, and from thence spreads at the same time downwards to the larynx, and upwards to the cavity of the nostrils, which latter it sometimes entirely covers. Occasionally the false membrane extends to the stomach.” Again, “If the disease commences in the fauces, spots of a yellowish or greenish colour, surrounded by a deep red, are at first perceived on the tonsils, the pillars of the veil of the palate, or the back part of the pharynx; these specks gradually extend, unite, and increase in thickness, so as at last to form a complete crust, like that of inflamed blood, lining the whole entrance of the fauces, and extending in a greater or less degree into the larynx, trachea, and bronchia.” Such incrustations, proceeding from an inflamed membrane, and extending into the larynx, every experienced physician is acquainted with, in cynanche maligna. In scarlatina anginosa also, inflammation and incrustations, extending from the fauces to the larynx, may often be observed; and we doubt not that such appearances are observable in a species of angina which can be classed neither with angina maligna nor

with scarlatina anginosa;\* but in genuine croup, as it occurs in Scotland and Ireland, never.

If it be objected that the diphtherite of M. Bretonneau and the cynanche maligna of Cullen are different diseases, and that the French physician endeavours to identify with croup a form of angina, under the name of diphtherite, with which English physicians are unacquainted, or have not described in their writings; we would meet the objection by calling the attention of the reader to the following passage in Laennec, wherein a disease, which is either cynanche maligna or an ideal affection, is upon the authority of M.M. Guersent and Bretonneau termed croup. “In some cases of croup, such as occur in hospitals, the state of the system is very different, there being evident marks of a septic change in the fluids of the body: the pulse is but little accelerated, the skin harsh and dirty, the debility extreme, and the breath fetid, even when no gangrenous specks appear: this variety is, by Guersent and Bretonneau, denominated asthenic. Asthenic croup would seem occasionally to be propagated by infection.” Asthenic croup! croup with an unaccelerated pulse, fetid breath, and propagated by infection!—Laennec, after describing croup, talks of that affection resulting from a gangrenous angina, in which eschars are distinguishable before the appearance of the false membrane, and in which the gangrene is indicated by its peculiar odour. If the disease of M. Bretonneau be not cynanche maligna, let it henceforth be known as *diphtherite*, plastic angina, *angine couenneuse*, or angina membranacea, or let the next observer invent a new name more to his taste; only let him not term it croup, which is a title already applied to an affection of a very different kind, which belongs to another order of diseases.

The directions given by Laennec relative to the treatment of croup evince a judgment, in this matter, perplexed and distrustful of itself and of the resources of medicine; a disposition to temporise, arising, as we may infer, from his conception of the nature of the subject being

\* We have seen instances of membranous angina, (occurring during the prevalency of gastric fever,) which did not appear to belong either to cynanche maligna or scarlatina anginosa, and which a French physician would probably have considered as specimens of diphtherite, or, it may be, of croup. We recollect attending in one family two children who died of angina, accompanied with an exudation of concrete lymph, which from the symptoms must have lined the upper part of the windpipe as well as the fauces: this exudation, as it appeared on the fauces, we considered to be a slough, the discovery of Bretonneau not having been made. Many years after, three children, also in one family, were affected in a similar manner, during a similar epidemic constitution, two of whom died.

These cases were not attended with an efflorescence of the skin, nor were they traced to contagion, but we cannot affirm that the disease was not epidemical. At the period of the occurrence of the last three cases, a similar incrustation often covered the fauces of those who were labouring under gastric fever, to which disease we were inclined to think that this angina was allied.

clouded. "In doubtful cases," he says, "it would seem preferable rather to omit bleeding than to destroy by injudicious depletion the powers requisite for the separation and excretion of the false membrane." As to the question of bleeding in croup when the disease is once established, no doubt ought to exist, unless perhaps we may hesitate with respect to its stage. If the patient is in the first or inflammatory stage of croup, no experienced physician will omit bleeding; if in the second, or that of suppuration, no physician will propose it. If it were doubtful to which stage the symptoms belonged, it would be preferable to bleed: the *anceps remedium* ought to be preferred. Bloodletting would probably bring relief if the patient were still in the first stage, and by that measure little would be taken from our hopes were he in the second, from which so few recover. Nothing but the mingling together of incongruities and consequent misapprehensions of croup could have induced an eminent physician like M. Bretonneau to make so dangerous an observation as the following: "I am forced to declare, contrary to the received opinion, that bleeding in croup has done harm, and accelerated rather than retarded the spread of the coriaceous inflammation. I did not abandon this measure till after reiterated proofs of its injurious effects." Physicians need not be told not to bleed in *cyanche maligna*,—it never was their practice to do so, nor would they willingly bleed in any form of membranous angina; but if they renounce bloodletting in the first stage of croup, which they are taught to do by this sweeping dogma of alleged experience, they will part with the best shaft in their quiver. This is no question of nosological subtlety; if so, we would have kept aloof: it is a matter of life and death.

We shall conclude these observations with one more quotation from Laennec. "All practitioners who have had occasion to see a good deal of this disease, will readily admit that these measures, although very rational and conformable to the results of experience in the treatment of inflammatory diseases in general, are nevertheless rarely sufficient, and that very few well characterised instances have yielded to their influence." Such a conclusion naturally flows from an attempt to identify a sthenic and an asthenic disease. The reader may be assured that the practice of medicine would be much more satisfactory than it is were the nature of every disease as well understood, the principles of treatment as clear, and the results as uniform as in the instance of genuine croup. If croup is considered as purely an inflammatory disease, and, in consequence, if the treatment of it be rigidly antiphlogistic, the event, when timely aid is afforded, will be almost invariably favourable. If, indeed, the golden opportunity is lost, and the first stage is allowed to pass without proper assistance being given, while the importance of his profession in his own eyes must be enhanced, the physician can accomplish comparatively little, and the gloomy reflection of Laennec, being modified, may be

assented to, namely, that very few well characterised instances of croup, in the second stage, will yield to the influence of measures even the most rational and conformable to the results of experience.

French physicians have of late so honorably and successfully distinguished themselves by their zeal in the prosecution of pathology, that we would readily yield them our confidence, did we not know that such a disposition of mind ought ever to be resisted. The same rule ought to guide our researches into the nature of disease which governs the student in a much higher department of knowledge, viz. "Prove all things;" to which very well may be added on the present occasion, "hold fast only that which is good."

(J. Chynee.)

CUPPING. See BLOODLETTING.

CUTANEOUS DISEASES. See SKIN, DISEASES OF.

CYANOSIS, (*κύανος νόσος*), *morbus caeruleus*, *blue disorder*, *blue jaundice* of the ancients, a morbid appearance which consists in the skin assuming a blue, purple, or violet colour, especially in those parts where the cutaneous capillary vessels are superficial, as on the cheeks and lips.

This colour may be a symptom of many different diseases; but in some instances it is of so marked a purple, and the accompanying symptoms are so variable, that most physiologists have given this affection its denomination from the colour developed, in preference to one from any assemblage of symptoms; thus constituting the appearance an idiopathic disease under the appellation of cyanosis. Whether they are justifiable in so doing is questioned by others, who consider the blue colour as indicative of a cachectic or scorbutic habit, or attributable to other causes.

Cyanosis is generally accompanied by difficult respiration, palpitation of the heart with diminution of the natural temperature, an irregular or intermitting pulse, and is often attended with dropsical symptoms, the face especially, in addition to the purple colour, being bloated and œdematous: all these symptoms are much aggravated by any exertion.

When this disorder first attracted the notice of physicians, it was considered to depend on an unclosed state of the foramen ovale. A few cases where this imperfection occurred were first observed in young subjects, who survived but a short time, the blue colour being intense, and the arterial system supplied with dark venous blood, to the circulation of which through the arteries this tint was attributed. This view was confirmed by the observations of several distinguished anatomists; Senac, Morgagni, and others, reporting that they had in such instances found free communications between the right and left cavities of the heart, which should not have existed. This view appeared to be confirmed by chemical facts, with relation to the blood not having undergone that change in the lungs which vivifies

it and fits it for the general circulation; as well as from the symptoms which those subject to such affections had suffered previous to death,—dyspnœa, diminished temperature, weakness, languor, and an engorged state of almost every organ; symptoms generally associated with a want of the due oxygenation of the blood in the pulmonary circulation.

Although cyanosis is often found in connexion with an open state between each side of the heart, many cases have also occurred where this imperfection has been absent, and yet in which all the symptoms of cyanosis have presented themselves. Corvisart was one of the first who put this opinion upon record; stating that a permanent blue colour of the integuments was often connected with an unnatural communication between the cavities of the heart, but that many facts induced him to say we could not always arrive at the same conclusion. Several examinations after death occurred to him and others of his contemporaries, in which, though the blue colour had been strongly marked during life, there was no communication between the opposite sides of the heart. The writer of this article has met with some cases of this description, insomuch that for some years he began to doubt the necessary connexion between the blue colour of the skin and such a free communication. On the other hand, he has seen several cases where there was a free opening between both auricles and ventricles which must have subsisted for many years, and yet in which there was no cyanosis. In one of these cases, which is published in vol. i. of the *Medical Transactions of the College of Physicians in Dublin, (New Series,)* the communications were so large and so free that the heart might be considered single, or consisting of one auricle and one ventricle: in this instance there was no cyanosis. Nearly similar appearances occurred to Fournier, Breschet, and Bertin; and indeed have occurred to all those who have been conversant with the diseased appearances of the heart. One case in particular was met with by Breschet, in which the left subclavian took its rise from the pulmonary artery, and yet there was no blue colour in the parts supplied by the ramifications of that vessel.

It would appear, then, that the mixture of venous with arterial blood will not necessarily produce cyanosis, and that the foramen ovale may be open, allowing this admixture to take place, without the disease in question being the result.

Difficult questions, no doubt, will arise with respect to the consequences of the want of oxygenation in the blood. How is a limb deprived of arterial blood to maintain its heat? How can it preserve its vitality, or retain its colour? It is probably because the circulation is free and unembarrassed, and that there is no obstruction to the depletion of the extreme capillaries. A free and uninterrupted circulation of the blood through the capillary system appears to be necessary to the maintenance of a proper colour in that fluid:

stagnation or obstruction impairs it in proportion to their amount. John Hunter included a portion of an artery between two ligatures, thus inducing a stagnation in the intercepted fluid: the result was a change of colour from bright red to purple in the blood thus separated and brought to a state of rest. In all instances also of ecchymosis and petechial extravasation, the effused patches or points assume a purple hue.

A partial stasis, then, in the capillaries, whether venous or arterial, on the surface, should more or less exhibit a purple tinge; and such actually takes place in some morbid states not usually noticed.

Towards the close of fevers terminating fatally, and in other disorders where the functions of the nervous system are much impeded, and the circulation consequently begins to fail, we have often observed the purplish colour in the lips, cheeks, and inside of the mouth; appearances which may be evidently seen long before death. And what is this but a cyanosed state, induced by a stagnation in the capillary system, which now wants its propulsive power, when deprived of the nervous energy?

All the anatomical observations on this subject, however, confirm the fact, that in every instance of cyanosis examined after death, the right cavities of the heart have been found enlarged, dilated, or thickened, whether there was accidentally an opening or not. Corvisart, in particular, enumerates a blue or violet colour of the face and lips as appertaining to organic lesions in the right cavities of the heart, and of the whole venous system, which is in a great measure under their guidance.

In persons of an advanced age, affected with disorders of the heart, this bluish tint is not uncommon, and generally occurs in concurrence with an injected or dark colour of the mucous membranes. In these disorders, towards the close of life, there generally occurs some obstacle to the aortic circulation; this obstacle is generally connected with hypertrophy of the left ventricle; stagnation of blood in the lungs then takes place; and to this succeeds passive dilatation of the right cavities of the heart.

It has been further observed that infants at birth are often cyanosed: this may arise either from the impermeable state of the lungs, or from want of action of the respiratory muscles, especially after tedious and difficult labours. Inflation of the lungs, and other aids, frequently remove this blue tint by exciting respiration.

A want, then, of renovated arterial or oxygenated blood is not the only cause of cyanosis; it appears to depend also on obstructed pulmonary circulation, or other impediments to a free return of the blood to the right cavities of the heart.

A bluish or cyanosed appearance on the surface is known also to take place when nitrate of silver has been administered internally; and this tint has in some instances become permanent. The nitrate, in all pro-

bability, is decomposed, and oxide of silver becomes deposited in some part of the superficial cutaneous tissue.

The tinge imparted to the skin in liver diseases differs altogether from the violet hue peculiar to affections of the heart. There is a variety of jaundice described by Dr. Baillie, in the Transactions of the College of Physicians of London, which he calls the black jaundice, where the colour in some degree approximates to the blue tinge; but in the disease described by him the colour is more of a leaden or sooty character. In some few instances, where there was melanosis of the liver, the tint of the skin has appeared to the writer of this article unusually dark, and differing from the ordinary colour observed in hepatic affections. But in all these instances the distinctive characters are sufficiently striking. The state of the circulation and of the respiration is almost sufficient to afford a diagnosis; and there are other characteristic symptoms sufficiently impressive and well known, which need not be enumerated.

Bluish and bruised patches occurring in purpura, and in ecchymosed states, do not require notice further than that they are often connected with obstructed circulation in the lungs and through the heart, or with failure in the nervous energy; but for information respecting these the reader is referred to the article PURPURA.

With respect to the treatment of cyanose affections, it is obvious, when it is considered that they depend on organic lesions, that no general plan suited to cure idiopathic cyanosis can be laid down. The radical or complete removal of such disorders is quite beyond the reach of our art. The treatment must be palliative, depending of course on the precise mode of lesion in the individual instance to be treated.

In all cases it is important to maintain a healthy state of the digestive functions by suitable diet and the use of such medicines as regulate the bowels; as the functions of the liver and other organs of assimilation are principally deranged, for want, in some instances, of blood properly renovated in quality, and in others from the circulation not being sufficiently free and unobstructed through these organs.

Acute pulmonary affections often supervene in subjects of this description; and blood-letting and the other usual aids are required more promptly than in ordinary instances where there is no such complication. But it may be observed that persons advanced in life, or even at earlier periods of existence, when weakened by protracted suffering, do not bear sanguineous depletion well. It has been already remarked also, that sufferers from this disease are frequently affected with dilatation of the right cavities of the heart, and that in a passive form; in these cases blood-letting, which, except in cases of excessive sanguineous plethora, affords only momentary ease, is often followed by great prostration of strength.

When this disease is attended with dropsical

symptoms, the remedies usually resorted to in dropsical affections will afford temporary relief.

In those cyanose disorders where the strength is much reduced, the circulation languid, and the temperature below the natural standard, considerable benefit will be derived from wine, cordials, and stimulants; and opiates will control symptoms arising from tumultuous and irregular action of the heart. It is important to maintain a tranquil state of both mind and body; active exertion is nearly precluded in such disorders, but gestation in the open air is most useful in mitigating the symptoms and prolonging life.

CYSTITIS. Cystitis, or inflammation of the bladder, exists in various degrees, from that slightest form which is indicated by an increased secretion of mucus from its lining membrane, to the intensely inflamed state which runs rapidly on to gangrene. Although the several inflamed conditions of the bladder are so intermingled, and pass so gradually one into another, that they require to be viewed in close connexion in order to be clearly understood; yet it is useful, for practical purposes, to distinguish between the highly inflammatory or acute cystitis, and the mild or mucous form to which Lieutaud gave the name, now generally applied to it, of *catarrh of the bladder*.

I. *Acute cystitis*.—Acute inflammation of the bladder is known to exist by burning pain in the region of that organ, pain at the extremity of the urethra, tenderness of the hypogastrium, and frequent calls to void urine, which is expelled in small quantities and with distressing spasms. The local symptoms of inflammation are accompanied with the usual constitutional disturbance, ushered in by smart shivering, and denoted by frequent tense pulse, hot skin, thirst, loss of appetite, constipated bowels, and much restlessness. As the disease advances, the pains shoot from the bladder to the anus, the loins, down the thighs, and even to the epigastrium; complete retention of urine takes place, and the distended bladder is felt as an oval tumour rising tense above the pubes. The tenderness, which was at first confined to the hypogastrium, diffuses itself over the whole abdomen; obstinate vomiting of bilious fluid and hiccups take place; delirium comes on, coma or convulsions at length supervene, and death follows. The urine, during the progress of the inflammation, undergoes several changes. At the commencement it is high coloured, as in other inflammations; then becomes mingled with flakes of

coagulated albumen, or with blood, bloody urine being more especially observed when the disease has been induced by a poisonous dose of cantharides: as the disease proceeds, the urine acquires a highly offensive odour from its ammoniacal and putrescent condition, resembling more the washings of putrid flesh than human urine.

In this brief sketch of the symptoms of acute cystitis we may trace the progress of the inflammation from the mucous coat of the bladder, which is the most irritable and the most readily affected by disease, to the muscular tunic, and lastly to the peritoneal. Anatomists have well remarked that the first of these membranes is but loosely connected by cellular membrane to the second, and this still more loosely to the third; but they have erred in believing that acute disease is not speedily communicated from one to the other. A strong and indissoluble sympathy links them altogether, and renders them prone to follow each other in the train of inflammation.

When acute cystitis, instead of commencing within the bladder, is communicated from some of the adjacent parts, as the uterus, the rectum, or the immediately adjoining cellular tissue, the order in which the coats become successively inflamed will be different; and the muscular or peritoneal coat will then be the first affected. It is rare for the whole mucous membrane to be seized at once with inflammation: most commonly it affects the portion lining the neck of the bladder,—sometimes the upper fundus, at other times the anterior part, at others the posterior,—and involving the orifices of the ureters, it obstructs the entrance of the urine, causes the ureters to become distended, and producing pressure upon the kidneys, in this manner speedily proves fatal.

A slight degree of inflammation, or perhaps we ought to say irritation of a mucous membrane, causes an increased secretion from its surface; a greater converts the natural mucus into a puriform fluid; and a still higher degree of inflammation replaces the secretions by an effusion of plastic lymph. This progression we find in the inflammatory affection of many other mucous surfaces besides that of the bladder; of which the exudation of croup, and the false membranes discharged from the alimentary canal and the uterus, are examples. The last change produced in the mucous membrane of the bladder by inflammation is gangrene, which sometimes affects the whole surface; at other times it appears in patches; and in either case it is often found that at one spot all the tunics have become sphacelated, perforation has taken place, the urine has escaped into the peritoneal cavity, and thus destroyed the patient.

When cystitis is prolonged, the mucous membrane becomes ulcerated, and the ulcers, when small, bear no remote similitude to primary syphilitic sores, by their excavated surfaces and raised margins; a fact which we have had opportunities of verifying by dissection. Ulceration is often more extensive, for the whole

interior of the bladder has been found eroded, and in some instances the muscular fibres of the organ have been exposed as if by the knife of the anatomist. When ulceration of the mucous coat deepens and penetrates through the other tunics of the bladder, it is usually accompanied by the effusion of plastic lymph exterior to the ulcer, which thus glues the neighbouring parts together, and prevents the escape of the urine: but instances have occurred in which an ulcer of the bladder has terminated in perforation, just as from gangrene, though more slowly, and in like manner has proved fatal. The existence of ulceration of the bladder cannot be certainly known during the lifetime of the patient; but there is always reason to suspect it when disease of that organ has been of long continuance, when the pain is unceasing and excessive, and when pus is distinctly detected in the urine. We must not, however, expect to see pus in a separate state, for it is rarely discharged without a copious admixture of mucus; and this we have known to be the case when dissection revealed ulceration both of the kidney and bladder.

Inflammation of the muscular tunic of the bladder may arise either in the membrane itself, or be communicated from the adjacent textures. In some cases the inflammation of this membrane has induced circumscribed suppuration;\* in others the pus has been unfiltered extensively among the muscular fibres† of the bladder. Extensive abscesses have also been found between the muscular and peritoneal coats; and death has in this manner been produced in numerous cases of lithotomy. Chopart relates a very interesting case of large abscess around the bladder, which occurred in the practice of Moreau. In this case, that distinguished surgeon, after making an opening above the pubes, struck his bistoury into a suspected spot near the anus, and formed a counter-opening, by which he succeeded in saving his patient.

Inflammation of the peritoneal coat is often the close of a fatal disease of the bladder; but that it takes place under other circumstances, without any dangerous consequences, we have sufficient evidence from the old adhesions not unfrequently found connecting this part to the omentum, to portions of the intestine, to the uterus, or to the rectum. In a recent case of diseased prostate, the omentum was found attached to the peritoneal covering of the upper fundus of the bladder.

In all prolonged diseases of the urinary bladder, when frequent ineffectual attempts are made to evacuate its contents, the muscular coat acquires an extraordinary increase of size and firmness, separating into distinct bundles, which project on its internal surface, and leave spaces through which the mucous membrane is forced, thus forming small pouches: this is not the consequence of inflammation, but of

\* *Chopart, Maladies des Voies urinaires, t. i. p. 453.*

† *Bonetus, Sepulchretum, lib. iii. sect. 23.*

increased muscular action. There is, however, an indurated and thickened state of the bladder which is produced by inflammation, and of which Frank has given an interesting example, where he was led to conclude that the whole anterior part of the bladder was in a state of callous induration.\*

When acute cystitis is about to terminate favourably, and the violence of the disease has spent its force, the natural mucus of the bladder is increased in quantity and altered in its appearance; it separates from the urine on standing, and forms aropy gelatinous-like fluid,—the complaint passing into that milder form which has been named catarrh of the bladder.

*Causes.*—Acute cystitis is induced by direct injuries, as by wounds, contusions, severe exercise on horseback, prolonged traveling in a carriage over rough roads, the introduction into the bladder of foreign bodies, as bougies and sounds: the latter are too often incautiously used; indeed to the examinations made under such circumstances may, in some instances, be traced the fatal result of the subsequent operation of lithotomy. Calculi themselves also produce cystitis, commonly of the mild or chronic form, or catarrh of the bladder. All mechanical obstructions to the discharge of the urine, as strictures of the urethra, enlargement of the prostate gland, and calculi lodged in the neck of the bladder, may prove causes of cystitis. It is induced likewise by exposure to cold and moisture, by excess in drinking, by the internal use of cantharides, and even by their application to a highly sensitive and partly abraded surface, as in Ambrose Paré's case of the lady who was cured of an obstinate eruption in the face by blistering. (*Œuvres*, Fol. p. 777.)

Cystitis also takes place by continuous inflammation spreading along the mucous membrane from the urethra in gonorrhœa, or from the kidneys when they are diseased. It may likewise be communicated by an extension of inflammation from adjacent parts; from the translation of migratory diseases, as gout and rheumatism; or from the recession of cutaneous eruptions: these are, however, causes of chronic rather than of acute cystitis.

*Treatment.*—The treatment of acute cystitis is to be commenced by free venesection and the warm bath, which may be followed by leeches to the perineum and groins. Should the bladder be much distended, its contents ought to be evacuated without delay; but until some impression be made on the local inflammation, the introduction of the catheter will be exceedingly painful, and productive of no permanent relief. A full dose of calomel ought to be given, combined with a grain or two of opium; and after some hours the bowels may be relieved by castor oil or an emollient enema. Free perspiration ought to be kept up by Dover's powder and the cautious use of antimonials; while warm opiate fomentations

or poultices, bags of heated salt, or bladders filled with hot water, are applied to the pubes and perineum. Diluents should be freely given, and the patient restricted to a spare diet of the mildest kind of food. When cystitis has terminated in the formation of abscess, this ought, if within reach, to be evacuated as early as possible by a free and depending opening; while the tendency to hectic is checked by cool air, tepid sponging, and the mineral acids, and the strength of the patient is supported by gentle tonics and light nutritious diet. When ulceration has fairly established itself within the bladder, the resources of our art are rarely of much avail; but we are not warranted in assuming that such cases are altogether incurable; for instances are recorded, and some have come under our own observation, in which health has been restored after calculi and other foreign bodies have escaped by ulceration from the bladder. The sufferings arising from ulceration of the bladder are remarkably mitigated by the full action of calomel and opium, and by the formation of issues over the pubes. Benefit has also been obtained from the administration of *uva ursi*, *pareira brava*, and the weak saline and aerated mineral waters.

Of the practice of injecting mucilaginous diluents and mild astringents into the ulcerated bladder we cannot speak from experience; but we feel strong doubts of its efficacy, and are disposed to think that the operation would prove irritating and injurious.

When acute cystitis has arisen from calculus in the bladder, the obvious remedy is extraction, as soon as the subsidence of urgent symptoms will permit. If cystitis can be traced to the translation of gout or rheumatism, the application of irritants to the situations where these diseases previously existed, and the administration of colchicum, must be had recourse to, while the means already mentioned for subduing inflammation of the bladder are carefully put in practice.

II. *Chronic cystitis.*—This form, which has also been called *mucous* cystitis, and catarrh of the bladder, was at one period considered an uncommon disease; the laborious and accomplished Hoffmann designated it "*rarus vesicæ affectus.*" It exists either in connection with a febrile state of the body, or with simple irritation of the bladder or its adjoining and associated parts. Generally it is met with as a sporadic disease, but like the affections of some other mucous membranes, it may prevail epidemically. Gunther describes such an epidemic as prevailing in the autumn of 1782.\*

*Symptoms.*—The symptoms of chronic cystitis are, frequent calls to void urine, with more or less pain in the region of the bladder and at the extremity of the urethra, either before or during the process. There is also, in most cases, tension of the hypogastrium, which may depend either on increased sensibility of the bladder, or on distension from urine. In all cases there is discharged along with the urine an increased quantity of mucus, somewhat

\* *J. P. Frank*, *De Curand. Hom. Morb.* tom. v. Retention. Mucoso-Lymphat. Vesicæ.

\* *Sömmering*, *Über die tödtlichen Krankheiten der Harnblase und Harnröhre alter Männer.*

altered from its natural appearance. Even in health a slight mucous cloud is deposited from the urine in cooling; but in the disease we are now considering the quantity is greatly augmented, sometimes bearing the enormous proportion of more than one-half of the whole fluid discharged from the bladder.\* It is usually voided suspended in the urine, from which after a time it subsides, forming a jelly-like substance, so viscid and tenacious as to be with difficulty detached from the bottom of the vessel. At other times the mucus is discharged from the bladder in a separate state, and of so thick a consistence as to obstruct the passage of the urine, and even to plug up the catheter. The mucus, which was at first pellucid or grey, becomes in the progress of the complaint yellowish, then greenish, sometimes streaked with blood; and at length, when ulceration is established, largely mixed with pus. The character of the mucus is always alkaline, and the urine often of the same nature—ammoniacal, sometimes highly fetid.

The pathological changes discovered in cases of chronic cystitis are chiefly, injection of the mucous membrane, occasionally enlargement of the veins, and when the disease is of long standing, overgrowth and thickening of the mucous tissue. Ulceration is likewise often observed to have taken place at the close of the disease, when it has been severe and long protracted: on other occasions acute cystitis has supervened on the catarrhal affection, presenting after death the usual marks of the disease.

*Causes.*—Chronic cystitis, or catarrh of the bladder, originates in many and various causes. It has sometimes occurred at the crisis of fevers, as the mode in which solution has taken place; in other instances it has alternated with mucous discharge from the brouchi. Exposure to damp and cold, and to sudden variations of temperature, has given rise to the disease: it has also, as well as the acute form, originated from the translation of gout and rheumatism, and the repulsion of cutaneous eruptions. But its most frequent causes are calculus in the bladder and enlargement of the prostate gland. It occurs much more rarely among the young than the old, and among females than males,—circumstances which are to be explained by reference to the peculiarities of the female, and to the period at which the prostate usually becomes the subject of disease. On more than one occasion we have traced a distinct connection between mucous cystitis and a strumous habit; causes having produced it in individuals of this constitution, which would not have been sufficient to excite the disease in those of a more robust frame.

*Treatment.*—Catarrh of the bladder, though classed with inflammatory diseases, rarely requires the employment of depletion, unless when the pain in the region of the bladder is considerable, and then the application of leeches is usually sufficient. Should the disease appear in connection with other mucous discharges,

and be accompanied with febrile symptoms, the warm bath, the saline mixture, and opiates; and if it have arisen from the translation of gout or rheumatism, or the repercussion of cutaneous eruptions, free perspiration, and stimulating the part where the previous disease was fixed, will be proper. In gouty and rheumatic cases the administration of colchicum offers the best mode of cure. When the affection depends on an enfeebled constitution or scrofulous habit, the mineral acids, bitters, and astringents will be found beneficial. Of astringent remedies the best are pareira brava, uva ursi, kino, and catechu. But in this form of the disease more advantage is often derived from stimulants of the urinary organs, such as the turpentine, and above all small doses of copuba and cubeb pepper. In such cases, also, change of air and sea-bathing on a dry and open shore have been productive of much benefit. The diet ought to be mild and nutritious, consisting of milk, eggs, farinaceous substances, and a moderate proportion of animal food. In almost all instances of this disease, spirituous liquors, even in moderate quantity, are injurious; cases however do occur when a small quantity of generous wine will be found beneficial.

All irritations of the sexual organs should be avoided; and if the patient have contracted improper habits, they must be abandoned before any hope of cure can be held out. The patient ought to spend much of his time in the open air, using gentle exercise: he should reside, if possible, in a dry and elevated situation, and ought to be always warmly clothed, wearing flannel next the skin. More benefit will often be found to accrue from a careful adherence to these directions regarding diet and general management of health, than from the employment of any medicine.

The injection of the bladder with mild diluents, such as barley-water, afterwards rendered more stimulant and astringent by the admixture of some mineral water, has been practised and highly recommended by Dessault, Chopart, and others; and we are inclined to think that advantage may be derived from the mere distension of the mucous membrane under catarrhal disease; just as gleet discharges from the urethra are cured by the introduction of a full-sized sound or bougie.

When catarrh of the bladder, &c. depends on the presence of a calculus or other foreign body, no cure can be effected without extracting what causes the irritation; but after its removal we sometimes find it necessary to administer tonics and urinary stimulants, such as have been already named, before the discharge will cease. And in all cases of this nature the operation should be immediately followed by a careful attention to the state of the cutaneous surface; and warm clothing should in an especial manner be enjoined.

When the disease arises from enlargement of the prostate gland, the only remedies which can be of avail are those suited to the treatment of that disease.

\* Chopart, tom. i. p. 415.

DEATH, SUDDEN.—See PERSONS FOUND DEAD.

DELIRIUM.—The term delirium has either been employed without design in a vague and indefinite manner, or it has been purposely used in a very comprehensive sense, and made to include every mode and degree of mental disturbance, from the slight and difficultly-traced aberrations of the argumentative and almost rational monomaniac, to the muttering and dreamy stupor of a patient labouring under the delirium of typhoid fever. All the phases and varieties of mental alienation, whether degrees of melancholy or violent madness, the wild ravings of the drunkard and the intense reveries of the opium-eater, as well as the peculiar symptoms resulting from that oppressed and disturbed condition of the sensorium which exists in severe febrile complaints, are alike comprehended under the designation of delirium when thus extensively applied. But there are few common characters belonging to all these phenomena, and for the sake of distinct and accurate description they must be separated. Those which are associated with madness form a particular group, and they may all be set apart under that head. (See INSANITY.) Under *delirium* or *febrile delirium* we shall here survey the disordered states of the sensorium and intellect which occur principally in fever and inflammatory diseases, and in some disorders affecting primarily the brain itself or its investing membranes; and we shall point out the characters which distinguish these from the other phenomena, frequently though improperly included with them under the same term.

*Phenomena.*—Delirium supervenes on fever during any part of its course. It occurs in the hot stage of some intermittents, but rarely makes its appearance in typhoid or continued fever until the disease has reached its height, or until the period of strong febrile action is established. It sometimes occurs suddenly, and without any previous sign of disease affecting the head; but much more frequently it is preceded by headach, throbbing of the temples, heat of the scalp, a flushed and oppressed countenance. Occasionally a slight hemorrhage from the nostrils is the harbinger of a severe attack or exacerbation of delirium. The patient is at first delirious during the short and imperfect periods of sleep, or immediately after he is roused, becoming, when fully awakened, more clear and comparatively collected; by degrees this lucid interval is less to be perceived; the individual becomes more and more incapable of reflection and mental exertion, and gradually loses the power of recognizing the persons and objects which surround him.

The phenomena of delirium, as they appear to the observer and are remembered by the patient, are like those of a feverish and incoherent dream. When, in a state of health, all voluntary control over the course of the thoughts is withdrawn and the mind given up to reverie, there is still, during our waking

hours, a continual restraint exercised imperceptibly over the wanderings of the fancy by the lively consciousness of external circumstances and relations. This controlling influence is withdrawn in health by sleep, and in disease by the impaired state of the sensitive power which ushers in delirium, and which goes on increasing as that affection advances, until it terminates in coma or complete stupor. Delirium, then, appears to hold a relation to sleep and to the dreaming state which accompanies sleep, or to be itself but a species of dreaming more intense and profound.

Accordingly phenomena are recorded in many cases of delirium, bearing a remarkable analogy to some of the most striking peculiarities of dreams. In dreams the mind is carried back with vivid intensity of feeling to scenes long past, and recalls, with greater accuracy than in the waking moments, minute incidents and circumstances. In delirium, when the sensitive power is nearly obliterated, the memory is occasionally, under certain modifications, surprisingly powerful and active. There are accounts on record, for example, from which it appears that persons labouring under the delirium attendant on fever, or succeeding injuries of the head, have been heard to talk in languages which they had been accustomed to speak in very early childhood, but had for a long course of years disused and totally forgotten. The case of a Welshman has been mentioned, who lay ill for some time in St. Thomas's Hospital, after an injury of the head. During the course of his illness he was heard to talk Welsh very fluently, but could not utter a word of English: when he recovered, it was ascertained that he had been absent from Wales upwards of thirty years, and had entirely forgotten his native dialect, the knowledge of which was thus revived by his disease. This statement, which was first given by Mr. Tupper, has been confirmed to the writer of this article by a personal witness. A parallel case is that of a French countess, born in Brittany, who had learned the Bas Bretagne or Armorican idiom during her infancy; many years after she had forgotten it, during the delirium of a severe fever, she was heard to talk incoherently in a dialect which, to the astonishment of every body, a Welsh servant understood and interpreted. Dr. Rush, of Philadelphia, used to state that some of the old Swedish settlers in Pennsylvania, who, attaining a period of great longevity, had survived till his time, were heard in many instances during their last hours, in the almost incoherent mutterings which preceded dissolution, to talk in their native language, which, during by far the greater portion of their lives, had been entirely disused by them and forgotten.

This restoration of old and effete impressions is accompanied by another phenomenon. When the mind is thus withdrawn within itself, if we may use such an expression, and goes back to the inmost recesses in which are laid up the stores of long-concealed, but, as it seems, never to be obliterated reminiscence, it not only becomes unconscious of external circumstances,

or indisposed to the perception of surrounding objects, but even loses the recent impressions of memory. Newly acquired ideas are effaced, like the immediate impressions of sensation. The knowledge of some language but lately acquired has been thus lost. A foreigner, mentioned by Mr. Abernethy, met with an injury of the head when he was twenty-seven years of age. During the delirium which ensued on this accident he could only answer questions in French, though he had previously spoken English perfectly well. He said that he was but sixteen years old, the age at which he left his own country: it is probable that the impressions received during eleven years had been effaced from his mind. After accidents which have occasioned concussion of the brain and consequent delirium, persons have lost all recollection of events which occurred during a certain period antecedent to the injury. Two gentlemen, intimately known to the writer of this article, met with accidents which occasioned to both of them severe injuries of the head. In both, concussion of the brain was followed by stupor, and afterwards by delirium, which continued some weeks. Both of these persons recovered their faculties perfectly, but each of them had permanently lost all recollection of objects and incidents which had occupied his mind for a considerable time previously to the accident.

During the state of unconsciousness as to external impressions, there is, together with excitement of memory, sometimes a considerable degree of mental activity: the mind is exercised even in forming new combinations. Many persons have been known to compose verses and speeches, and to hold conversations on abstract subjects with individuals whom they imagined to be present.

Persons labouring under delirium are at times capable of being roused by external impressions, and, when once excited, they display unexpected muscular energy, which is followed by exhaustion, but not in every instance by a relapse into delirium. Van Swieten has twice mentioned the case of a man who, under severe delirium, was roused by hearing the noises occasioned by a fire which had broken out in a neighbouring house. His incoherent muttering, which had continued for some days, ceased, and he inquired anxiously into the cause of the alarm: his delirium was cured from that time. A patient lying ill with fever some years ago, in the Bristol Infirmary, was suddenly roused by a loud peal of thunder. He started from his bed, and in a moment leaped over the beds of the patients who lay in a row opposite to him, and before any body could lay hands on him, although in the middle of the day, when all were awake, he climbed up to an open window, twelve feet in elevation from the ground of the ward, and almost accomplished his design of throwing himself out of it. He would inevitably have been dashed to pieces if his foot had not providentially fixed upon a projecting ridge below the sill of the window, by

which, as well as by one hand grasping the window-frame, he was supported until ladders were placed on the outside of the building, by which he was taken down without injury. This man afterwards recovered.

When delirium terminates fatally, it passes into coma. Sensibility becomes more and more impaired, until all conscious feeling seems to be lost. Inarticulate moaning succeeds to delirious incoherence; the patient loses in a great measure sight and hearing; the pupils become scarcely contractile, and the evacuations escape without consciousness. Patients have recovered after remaining for some time in this state, and this has happened not unfrequently in the case of young subjects. But the symptoms above detailed are more generally followed by others, which are the sure harbingers of death. These are flocci volitantes, picking the bed-clothes, convulsions, coma, with subsultus tendinum, the eyes being turned up with a falling lower eye-lid. One of these symptoms alone denotes great danger, but the aggregate announces the speedy approach of dissolution.

*Diagnosis.*—The diagnosis between delirium and insanity is, in practice, for the most part attended with little or no difficulty. The presence of inflammatory or typhoid fever in the former case, and its absence in the latter, is in general a sufficient indication. Mad persons have many of their functions unimpaired; they walk about, eat, drink, talk. The state of a delirious person is quite different. "The insane," says M. Georget, "have frequently the external senses and the power of voluntary motion in a healthy state; they see, hear, taste; intelligence is in very few abolished; often the mental disorder is confined to a single faculty, or to a limited number of acts dependent on a single faculty; and in those cases in which it appears to be the most extended, in intense maniacal affections for example, the faculties appear to be perverted, or insulated, and without the bond of association, but are yet far from being extinguished: the most irrational maniac talks, reasons, wills, and is not always absurd in his reasonings and actions. In the delirious, on the contrary, all the cerebral functions are severely affected; there are no correct sensations, connected ideas, or passions; no regular voluntary motions; little or no intelligence or recollection: the patient is almost a stranger to every thing that surrounds him as well as to himself." We may on the other hand observe that most insane persons have the digestive or nutritive functions in a sound state, and that they display the external appearances of health, especially after the few first days from the commencement of their insanity, and before they have shown signs of the secondary disease which is destined to bring them to their end: in delirious persons these same functions are always more or less in a state of disorder. We should in fact incur no danger of contradiction from persons who are in the habit of seeing cases of insanity, if we were to venture on the assertion that a great number

of lunatics bear infinitely greater resemblance to individuals in perfect health than to patients labouring under febrile delirium.

It is of great importance not to confound these two species of mental disorder. The cerebral affection which is connected with delirium is in general severe and of short duration; it must be combated by a vigorous method of practice in order to prevent a fatal termination: madness is of long duration, and seldom or never attended with danger to existence. The latter disease seems to pursue its victims even after their recovery, by the mistrust which they inspire as well for the present as for the future; a mistrust which even extends itself to their posterity. A patient who recovers from this state is often painfully affected at finding himself in a mad-house. It would be unfortunate, on account of these considerations, to take a patient labouring under delirium for a lunatic; and in doubtful cases the physician should only describe the state of the intellectual faculties by the terms 'delirium' or 'disorder of the brain' until he has clearly recognised and is satisfied of the existence of madness.

The leading criterion between delirium and insanity is afforded by the state of the sensitive power or of the faculties of sensation and perception. Insane persons have the faculty of sensation generally unimpaired; and if they apprehend external objects to be different from what they really are, the error lies not in any disordered state of the perceptive power itself, but in the perverted judgment or false conviction of the understanding, which is so deeply rooted as even to resist the evidence afforded by the senses. An insane woman is convinced that her husband is dead; and when he actually comes to visit her, and to dispossess her of this hallucination, she insists that the devil has assumed the form of her deceased husband in order to impose upon her. A delirious person cannot distinguish one individual from another, and sometimes does not know the nurse who constantly attends him. There are, however, cases of delirium approaching somewhat to mania, in which the sensitive power is but little impaired, and some of the peculiarities of insanity show themselves. We have witnessed the display of cunning and stratagem by patients slightly delirious; artful plans laid, in order to get rid of annoyances and to gratify inclinations; a strong impression manifested by the patient that he is where he is not; a concealed suspicion that it is intended to carry him off and put him into confinement. We have known instances in which traits of this description have excited great alarm, lest what had been regarded as temporary febrile delirium might prove to be a permanent loss of reason. These fears have proved groundless. The faculties are fully restored after having been obscured under febrile delirium, with very rare exceptions. The restoration to mental vigour is, however, in some instances slow, and occupies several weeks, and even months. Facts, indeed, have occurred within our

knowledge which have seemed to indicate that the intellectual faculties have been in some instances even brighter and more vigorous than ever, or at least have been exercised with greater activity, and more displayed after a recovery from febrile delirium; and a parallel observation has been made by some of the older medical writers.

*Pathology.*—Many practical writers have been led by observation to conclude that there are two different states of the system accompanied by delirium, in one of which the brain is not the actual seat of disease, at least to any great extent, its functions being disturbed in consequence of disease, for the most part of intense degree, existing in some distant organ; while in the other form of delirium the brain or its enveloping membranes is the seat of inflammation. It is very important, in a practical point of view, to distinguish these two affections, which may be termed *sympathetic* and *idiopathic delirium*.

1. The first mentioned species of delirium was indistinctly described by Dr. G. Fordyce, in his minute detail of the symptoms of fever. Fordyce was of opinion that this form of delirium ought to be treated with slight anodynes and restoratives. M. Dupuytren has given to this species of disease the designation of nervous delirium: he has described it in the "Annuaire Médico-Chirurgical des Hôpitaux." He remarks "that it is frequently observed in highly susceptible or nervous individuals, who have received severe wounds, or have undergone painful operations; in those who have suffered greatly from the apprehension of undergoing operations, and in others who have made efforts beyond their physical strength to display fortitude and courage in bearing pain heroically; and, lastly, in persons who have made an attempt to commit suicide." According to M. Dupuytren's observation, cases of this description are never cured or alleviated by antiphlogistic remedies, but yield easily to the administration of narcotic injections. In the brain no traces of disease have been discovered by M. Dupuytren when he has had opportunities of investigating the morbid appearances in cases of nervous delirium. To this form of delirium, as M. Georget has observed, we must refer the various degrees of mental and sensorial disturbance which occur at the close of chronic, and even of acute diseases. Comparatively few persons die in the full possession of their faculties. But it may be observed that chronic affections do not in general excite delirium and febrile symptoms without passing into a certain degree of acuteness. May we not refer to the same head, as arising from a cause nearly analogous, the wanderings experienced by patients reduced to an extreme degree of weakness on sitting up or rising from bed, as well as the delirium which ensues on excessive evacuations of blood? Is there not in either case a defect of sanguineous stimulation giving rise to the disorder in the intellectual processes? If we adopt the opinion of M. Broussais on the frequent existence of gastritis, and on the

primitive or secondary causes of febrile action, "the stomach may be the organ which of all others exercises the greatest influence on the brain, and is generally, if not always, the cause of sympathetic delirium: but this opinion cannot be regarded as established."

The opinion that defective vascular action or vascular exhaustion is a frequent cause of disorder in the functions of the brain, is a conjecture not peculiar to M. Georget. But the physiology of the brain is not sufficiently known to enable us to follow this conjecture with anything like a legitimate theory. We only know the fact that long-continued irritation in the system, when the powers of life are giving way, frequently, if not generally, induces, previously to dissolution, more or less of disorder in the sensorial and intellectual functions. This is not the case exclusively in disorders affecting the stomach, or even more frequently than in complaints situated in other organs. Inflammations of the chest, phthisis, chronic ulcerations in the bowels occurring as the sequelæ of fever, and a variety of other disorders, often give rise to the kind of delirium here spoken of.

This species of disease has often been compared to *delirium tremens*. Its phenomena have but little resemblance to the symptoms of that complaint, whatever analogy may subsist between the unknown causes of both. They are alike in one respect, viz. as to the inutility of antiphlogistic remedies. It cannot be said that anodynes are equally serviceable in either; they are, however, in some instances of both diseases to be preferred to all other remedies.

2. Idiopathic delirium is a disease of greater importance than the secondary or sympathetic species, inasmuch as it denotes a specific condition of the brain, which requires a particular class of remedies, and which, unless removed by the timely and vigorous administration of such remedies, will speedily extinguish life. It is more marked in its symptoms, and more readily traced to its exciting causes: there is, therefore, not much difficulty in general in ascertaining its existence. This form of delirium, likewise, sometimes leaves behind it vestiges which may be discovered on dissection. Such are all the various phenomena produced by inflammatory action in the meninges and in some parts of the brain. These morbid changes are, however, seldom of great extent. They consist chiefly in vascular injection of the surface of the brain, increased hardness in its substance, effusion of fluid in the ventricles, injection of the vessels in the pia mater, serous infiltration of the same membrane: a similar condition of the arachnoid has been, as M. Georget observes, less frequently discovered. More important lesions than these have been traced in cases which combined paralytic or convulsive affections of the muscular system with delirium; but the latter cannot be considered as belonging to the disorder now under consideration.

To the idiopathic form of the disease belong,

a. Delirium following injuries of the head, fractures, concussions, wounds, and lesions of various kinds, which produce inflammation

either immediately or after the first effects have subsided.

b. Delirium accompanying inflammation of the brain or its membranes, brought on by exposure to heat or cold. The effects of insolation, and of exposure to heat in furnaces or heated workshops, come under this division.

c. Delirium the result of intoxication, or of excessive doses of opium or other narcotics. We allude here, not to the state of intoxication itself, but to a more severe disease which is often the sequel of intoxication. Of this cases frequently occur in practice. A theatrical performer came home to his wife in a state of intoxication. During the whole night and a part of the next day he was supposed to be merely drunk, and no alarm was taken. As he continued to be delirious on the following day, medical assistance was required. He was still in a state much resembling that of intoxication: his head hot, face flushed, eyes red, mind confused, but without coma or paralysis. His head was shaved, and the jugular veins opened. He expired in the course of the day, and the surface of the brain was found highly injected, the white substance itself presenting abundantly bloody points. A man drank by mistake a poppy-head fomentation. He was seized with violent phrenzy, but speedily relieved and cured by means of bleeding and powerful antiphlogistic remedies.

d. Delirium occurring in erysipelas affecting the head is plainly of this kind. We have repeatedly seen the morbid phenomena denoting inflammation strikingly displayed on opening the head in cases of this description. The metastasis of dropsy, of rheumatism, and of various other diseases, when apoplexy is not the consequence, gives rise to delirium, which may be termed idiopathic, whatever organ had been affected before the disease was transferred to the brain.

e. Delirium attending continued fever is of this kind, when the head is the actual seat of the most intense diseased action. When the fever has been of that kind which some writers have termed *cephalic*, when the ordinary signs of determination to the head, or of increased vascular fulness have preceded and accompanied it, delirium may be considered in cases of fever as an inflammatory complaint. The practical consideration of this subject will be entered upon more fully under the head of FEVER. We now proceed to make some observations on the treatment of delirium.

*Treatment.* The treatment of febrile delirium may be reduced to very simple principles, and these are such as are very generally understood.

Shaving the head, the application of cold water, with the admission of free air, are means often adequate to the removal of delirium as it occurs in typhoid fever. We have seen many patients, brought from close and foul apartments with typhoid symptoms and labouring under delirium, who, after undergoing these simple remedies, and passing a single night in a cool, well-ventilated ward, have been found on the next morning so much improved, and

so collected and free from mental disturbance, as to require no particular remedy directed to the state of the head.

Topical bleedings, viz. either by opening the temporal artery, by cupping on the head, or on the nape of the neck, or by the application of leeches to the head or round the neck, are well known to be among the most important remedies for febrile delirium.

Cold applications, by iced water or merely wetted cloths, by a stream of water passed by means of a funnel over the vertex, by ice pounded and put into a bladder or oiled skin, or by evaporating lotions, are next in point of importance to bleeding.

Blisters to the nape of the neck are often of great service. When the heat of the scalp is not great, or has been reduced, and especially when there is much stupor, or a tendency to coma, blisters are beneficially applied to the vertex.

Incisions in the scalp, made in the direction and over the sagittal suture, are of great service in cases of delirium combined with stupor, whether occurring in the course of fevers, or in affections of the head otherwise brought on. The incision should reach from the vertex to the anterior part of the hairy scalp, and be made down to the pericranium. The effect of this remedy is often an immediate relief by the bleeding which takes place. The subsequent inflammation and suppuration, the incision being kept open, are much more productive of benefit than the ordinary superficial inflammation excited by blisters, or the serous discharge from the surface of the cutis.

The writer of this article has now a patient who is making progress towards recovery, and is already almost convalescent. His improvement appears to have resulted from the means last described. He laboured under severe delirium with stupor, and had occasional fits of convulsion. His disorder was brought on by exposure to heat, his occupation being that of supplying with coal, and attending to the boiling apparatus of a steam-engine.

Purging is of great benefit in cases of idiopathic delirium, and is often sufficient alone to the removal of the disease. We shall not proceed further at present in the consideration of remedies required for the treatment of delirium. The morbid state of the brain, from which delirium arises, seldom forms a distinct and entire disease. When it occurs in fevers, the remedial treatment belongs to the therapeutics of fever: when it proceeds from injuries of the head, it comes under concussion of the brain, or fracture or wounds of the scalp, &c. To articles on these several subjects in the present work, or to distinct treatises, we must refer our readers for more particular details.

(J. C. Prichard.)

**DELIRIUM TREMENS.** Amongst the numerous maladies which are the results of vicious indulgence, those of which the foundation is laid in the abuse of ardent spirits, and other diffusible stimuli, form a long and fright-

ful catalogue: inflammation of the brain and its membranes; of the pleura; of the stomach; of the liver; jaundice; dropsy; diabetes; gout; mania; dyspepsia, with its manifold miseries—these are among the diseases induced by habitual intemperance; and several more might be added to the appalling recital.

Place this catalogue before the man who is beginning to acquire a taste for inebriating liquors, and he will feel alarmed; he will probably express his astonishment at the infatuation of the drunkard, and his determination to halt at once in his destructive career. Happy is it for such an one if his conviction of danger be abiding as it is powerful: unfortunately, however, it is in too many instances speedily effaced. Temptation again and again offers itself, and triumphs over repeated sober resolves, till, in the sequel, the victim persuades himself that it is absurd to forego a positive pleasure through fear of remote and contingent evils; of maladies which hundreds, more intemperate than himself, escape altogether; from many of which recovery is not uncommon; and to the visitation of which even the ascetic is liable. For some time, perhaps, he is guilty of excess only on extraordinary occasions; but, by insensible degrees, he slides into the habit of drinking deep in all companies, and, at last, of indulging even in private, and at all hours. From what is termed a pleasant companion, he degenerates into a hard drinker, and ends a complete sot.

Still he is attacked by none of the formidable diseases above enumerated, excepting dyspepsia, which he is very unwilling to ascribe to its true cause; or respecting the real source of which he is perhaps actually deceived, owing to the temporary relief which the application of fresh stimuli constantly affords him. His bane and antidote are one and the same. But he who abandons himself to incessant or immoderate potations should know, that if he escapes those diseases which once created such alarm in his mind, he is yet obnoxious to one not less formidable, which sometimes manifests itself rather suddenly, and speedily destroys the patient; sometimes creeping on by slow and almost imperceptible degrees, though it may not prove immediately fatal, may still leave him in a lamentable state of debility both of body and mind, and materially abridge the term of his existence.

This disease has received a variety of appellations. It has been called *brain fever*, a *peculiar disorder of drunkards*, *delirium et mania è potu*, *delirium ebriositatis*, *erethismus ebriosorum*, *encéphalopathie crapuleuse*, *delirium tremens*. The latter designation is here adopted, not as being altogether appropriate, for it is confessedly open to more than one objection. It is not perhaps quite correct to speak of a delirium as *trembling*; and the term is yet more faulty, inasmuch as tremor is not an invariable, though it be a very usual symptom. But the designation first employed by Dr. Sutton is that under which the disease has been commonly recognised since the publication of his valuable essay. That essay, though it was not the first

distinct notice on our present subject, was the first which seemed to attract the attention of the profession in general to a subject previously little known. The earlier labours of Drs. Pearson and Armstrong, important as they certainly were, excited less interest. It has been observed by Dr. Blake, that traces of this affection may be discovered in the writings of ancient authors, even as far back as those of Hippocrates; and it is true that, under the heads of phrenitis, mania, &c. cases are recorded by them of which the symptoms bear an intimate resemblance to those of delirium tremens; but that those cases differed materially from others of true phrenitis or mania, seems not to have entered into the minds of the venerable fathers of medicine. Their successors, from age to age, overlooked the peculiar character of the disease. Not many years ago the most distinguished lecturers offered nothing, or, at all events, nothing precise upon the subject.\* Systematic writers were silent concerning it. The first distinct account of delirium tremens was from the pen of Dr. Pearson, who, it would seem, derived his information from Dr. Young of Newcastle-upon-Tyne. Dr. Armstrong next published a paper or two upon the subject, and he was followed by Dr. Sutton. Since the appearance of his essay the disease has again been treated of by Dr. Armstrong in his lectures, and by several other authors of reputation, both of our own and of foreign countries: it has obtained a place in the works of Good and of Gregory, though unfortunately they differ as to its classification; the former placing it under nervous, the latter under inflammatory affections. It is now fully recognised as a peculiar disease, requiring peculiar treatment, and therefore one which it is of the utmost moment we should be able to distinguish from certain others to which it bears no inconsiderable resemblance, and with which it often has been, and probably often is, confounded, to the great detriment of the patient, as well as to the discredit and mortification of the practitioner.

In describing the phenomena of delirium tremens, we shall adopt Dr. Blake's division of the disease into three stages, not merely as convenient, but as founded upon a philosophic view of the subject. The advantages of considering delirium tremens under separate stages have not been overlooked by other authors, but Dr. Blake's arrangement seems, upon the whole, best calculated to obviate the obscurity and confusion in which its history was formerly involved, and to direct us as to our mode of treatment.

The approach of the first stage is announced by symptoms of general debility; the patient's appearance and manner undergo a certain change; his countenance is dejected and anxious; his spirits are depressed; there is frequent sighing, and oppression of the præcordia. All around him perceive that he is indisposed, though his most intimate friends

may be altogether in the dark as to the nature of his malady, or its cause. If the invalid be himself questioned, he will probably maintain that nothing ails him; or, if he admits that he does not feel quite well, he will not be able to explain what is the matter with him. Upon more particular inquiry it will be discovered that his nights are restless, that his slumbers are short, and disturbed by harassing dreams; that he rises in the morning unrefreshed and languid; that his appetite is impaired, or even that he loathes food; that he is annoyed by nausea and continual vomiting; that he suffers from cramps of the extremities. Vertigo and confusion of ideas are usually present. Pain of head has been reckoned among the symptoms; but it is certainly neither a common nor a leading one. The tongue is sometimes furred, but moist; often, but not in all cases, tremulous. The bowels are generally open. The pulse, according to Dr. Blake, whose opportunities of observing the disease at its commencement have undoubtedly been ample, is invariably slow; and although other writers do not mention this remarkable slowness of pulse, they all concur in representing the pulse as by no means frequent. It is, moreover, soft and compressible; often feeble and unsteady. The temperature of the body generally is not increased, while that of the extremities is considerably below the standard of health. The hands and feet are cold and clammy; the sensation they convey to the touch resembles that observed in persons labouring under enteric inflammation. Tremors of the hands occur in most instances. Such are the principal features of the first stage of delirium tremens, and beyond this stage the disease may not proceed: by timely and judicious treatment its further progress may be arrested, and by subsequent prudence on the part of the patient its recurrence may be prevented.

Generally, however, it is succeeded, after a shorter or longer period, according to the constitution, age, and previous habits of the patient, by the second stage, or that of delirium. In young and robust subjects, whose excesses have not been of long standing, the stage of re-action or excitement will come on much more rapidly than in persons advanced in years, and whose constitutions have been broken down by long intemperance. It is during this stage that the medical attendant is most liable to fall into error. The symptoms, many of them, are so similar to those of inflammation of the brain or its membranes, that, if he is not especially upon his guard, if he allows the pathognomonic signs of the disease to escape him, his diagnosis will be incorrect and his practice unsuccessful. When the second stage is coming on, the vertigo and confusion of head are more marked; there is more decided aberration of mind; the countenance gradually assumes a wild aspect; the patient is incessantly restless; there is apparent an anxiety to perform immediately whatever is desired of him; he even anticipates your wishes, or what he supposes to be your wishes; he is peculiarly sedulous in the

\* Excepting Dr. William Saunders. See Sutton's Essay, p. 4, Note.

performance of his ordinary duties, which he goes about in a hurried immethodical manner; he is very jealous of the least interference, either by advice or otherwise, as to matters pertaining to his vocation, exerting himself painfully to prove he is quite well, yet evidently mistrusting himself. Thus, if his occupation is that of a butler, he will betray a strange solicitude about mere matter of routine; he will be in a perpetual bustle; he will commit perpetual blunders, at the expense frequently of his master and his guests: his altered countenance, uncertain step, and trembling hands, will sufficiently evince his unfitness for the duties of his situation; yet he will pertinaciously repel the proffered aid of his fellow-servants; his whole manner will much resemble that of a person on the verge of intoxication, who is excessively anxious to appear quite sober. By ordinary observers he will probably be pronounced more than half drunk, and they will recommend his being sent to his bed, under the notion that sleep will effectually restore him. But such a patient cannot sleep off his malady. He is restless; his mind wanders; he rises worse than he was before, with more symptoms of high nervous irritation. By degrees mental alienation is fully established; the patient is in a constant worry about some affairs which he fancies of great importance; some business, *generally private business*, which must be attended to. He makes violent and repeated efforts to liberate himself from restraint, that he may apply himself to these affairs; but he is not, like the decided maniac, or the man labouring under the immediate excitement of an over-dose of strong liquor, disposed to be mischievous; his exertions, though vehement, are not characterized by malignity or ill nature; he quickly forgets what is past, and, if judiciously managed, is, upon the whole, sufficiently tractable. He will generally take the medicines offered him without much difficulty, and, when exhorted to endeavour to keep quiet, will manifest, for a short time, a desire to acquiesce. He will now and then recognize those of his family and friends who are near him, and will return a rational answer to a few questions; but he very speedily relapses into his erroneous train of thought. At this period of the disease the circulation is quickened, the heat of the surface becomes greater, yet still the pulse remains small, and there is a marked difference between the temperature of the extremities and that of the rest of the body, the former continuing damp and cold. If the symptoms above mentioned be not soon ameliorated, a sweat bursts out, copious and clammy, and occasionally, it is said, of an offensive odour. The mind becomes still more distressed; objects of the most appalling description sometimes present themselves to the patient's imagination; he will be possessed with the idea that he is persecuted by evil spirits, who are upon the point of carrying him away, or are preparing to destroy him; or he may fancy he is surrounded by assassins; and cases are recorded where the unfortunate

sufferers actually expired while exerting themselves to the utmost to ward off the violence they supposed was intended them. Catastrophes so lamentable are not, however, of frequent occurrence. Various other hallucinations less frightful, though still very distressing, might be mentioned; it may, however, be sufficient to observe in a general way, that the mental bias is mostly of the melancholic kind. Sometimes the most whimsical notions arise: thus a patient will imagine that rats or mice, or other troublesome vermin are running over him, or near him; that he is employed in drawing ribands from the ends of his fingers, with numberless extravagancies of a similar nature.

When delirium is completely established, there is obstinate pervigilium, and this is a very important, indeed it has been regarded as a pathognomonic symptom of the second stage of the disease. At this period, too, the countenance assumes an aspect of extreme anxiety; the tremor of the hands and tongue is greater; the latter is more furred, but still moist; the pulse is not only small but frequent, and also indistinct, partly perhaps in consequence of the tremor and unceasing workings of the tendons of the wrists; the urine is scanty and pale; the bowels are usually confined; the dejections dark coloured; the pupils are contracted, but without intolerance of light. Still there is no indication of local pain, and when the patient is asked how he feels, he will often reply that he is quite well. These symptoms either increase in violence, and others supervening, which very nearly resemble those of the last stage of typhus, the patient dies suddenly in a convulsion; or the long-continued delirium, with subsultus tendinum, picking of the bed-clothes, &c., is succeeded by a short interval of quietude, and he expires without a struggle; or, after two or three days, or it may be a week, yawning and drowsiness come on, and sleep follows, which is generally profound and of long duration, lasting from six to twelve or eighteen hours; the patient wakes collected, and greatly refreshed, and his recovery may be looked upon as almost certain.

Such are the general symptoms of the three stages of delirium tremens, which, if they be attentively considered, and viewed as a whole, will enable the medical student to perceive wherein it differs from certain other affections to which it bears a real or an apparent affinity. When he comes to the bedside, he will be in a good measure prepared to discriminate between a case of delirium tremens and one of phrenitis, mania, hypochondriasis, or typhus fever. If he be so fortunate as to be consulted early, during the first stage of the disease, he will scarcely be at a loss as to diagnosis. But it will more often happen that he is not summoned till the second stage is approaching, or until it is fully established; and then there will be more difficulty in recognising the affection. There may be certain cognate diseases where accuracy of diagnosis is not practically essential, but in very many instances it is of the utmost importance, and on no occasion perhaps more important than when we are consulted in a

case of delirium tremens. The previous habits of the patient may be unknown to the medical man; his friends may be imperfectly acquainted with them, or may endeavour to conceal them; to the superficial or the unskilful observer he may appear to be labouring under phrenitis or mania; from himself, of course, no information can be expected. Whenever, therefore, we are called to such a case, we should institute the most careful inquiry into the early symptoms of the complaint, we should endeavour to elicit from the family of the patient what has been his state, both physical and moral, for some time previous to the accession of delirium, and attentively view the previous history, so far as it may be furnished us, in connexion with existing phenomena—the pulse, the countenance, the temperature of the skin, especially of the extremities, its dryness or moisture; the appearance of the tongue; the degree and kind of alienation, whether the delirium be accompanied with pain of the head or any other part, with indications of increased arterial action, or of venous congestion, or otherwise; whether it be characterized by intractable violence, or be of a more mild and manageable nature; whether there be tremors of the hands and tongue, which almost always accompany delirium tremens from the first, and do not indicate extraordinary danger, while in phrenitis they are scarcely ever present until the last stage, and are then of most unfavourable omen.

Having thus detailed the symptoms of the disease, we proceed to say a few words respecting its causes. Now the principal features which mark its first stage so commonly exhibit themselves in intemperate subjects early in the day, when they are in the state of exhaustion which is the usual consequence of a debauch, and have so frequently been observed to arise in soldiers and others, when for a time deprived of their daily quantity of liquor; that the sudden subtraction of accustomed stimuli has been regarded, by respectable authorities, as *invariably* the immediate cause of the disease. The habitual and excessive indulgence in strong liquors, or in other diffusible stimuli, has been considered as the predisposing, and the privation of them as the occasional or exciting cause of the affection.

To a somewhat whimsical theory of M. Leviellé,\* that delirium tremens consists in exaltation of the vital powers of the brain, excited by alcoholic molecules absorbed from the surface of the stomach and bowels, and carried into the current of the circulation, it is objected by Dr. Blake, that he never saw an individual attacked with delirium tremens so long as he continued to indulge in his accustomed alcoholic potations; but that it invariably came on when old drunkards ceased for a given time (either from the effects of an excessive debauch, or from any other cause

whatever, such as a wound, a fracture, or a fever,) to take their usual inebriating draughts. To overthrow M. Leviellé's theory would perhaps cost little labour, but we do not consider that it is in the least degree shaken by the objection just stated; for that delirium tremens may manifest itself in individuals who have never been deprived of their accustomed stimuli, even for an hour, is most certain; as, for example, in publicans, who live in an atmosphere charged with alcohol,—who, though seldom absolutely intoxicated, are always more or less under the influence of intoxicating liquors—who are sipping from morning to night. Instances of well-marked delirium tremens occurring in such persons have fallen under our observation. Interesting cases might be cited, where, upon the patient's being at once removed beyond the sphere of temptation, recovery was rapid and complete; and others might be adduced in evidence that the habitual stimuli being obstinately persisted in, or, after a certain interval of abstinence, foolishly resumed, the disease will proceed to a fatal termination.

The delirium which comes on in persons addicted to hard drinking, several days subsequent to a wound or fracture, the traumatic delirium of M. Dupuytren, the symptomatic delirium tremens of M. Barkhausen of Bremen, and which is relieved by ardent spirits or strong liquors of one kind or other, though it be doubtless very nearly allied to the affection which is the subject of our present inquiry, does not seem to be identical with it. In such cases the system receives a sudden and violent shock; an individual, previously perhaps in the enjoyment of robust health, accustomed to strong exercise, engaged in a laborious occupation, requiring much support, is at once confined to his bed; his habits are in a moment broken off; and no wonder that, in a few days, he falls into a state greatly resembling that of a patient in typhus—a state which absolutely requires the stimuli to which he used to resort previously to the reception of the injury. But in delirium tremens, unconnected with other disease or injury, we recognise no such immediate and overwhelming shock. The general health is first perceived to fail; it becomes more and more impaired; then come on the characteristic symptoms of the affection; and, if the habitual stimuli be continued, those symptoms progressively increase. From the first the patient passes into the second stage, from that into the third stage of the disease, and he dies. Upon the whole, it would appear that the predisposing cause of the delirium which in intemperate persons supervenes to a wound, a fracture, a fever, &c. is habitual indulgence in strong liquors, or certain other diffusible stimuli, while the sudden abstraction of such stimuli is its immediate cause. But in delirium tremens, unconnected with specific disease or accidental injury, the predisposing cause is to be sought in peculiarity of temperament, combined with other circumstances, such as mental anxiety, great and continued fatigue, &c. while habi-

\* Mémoires de l'Académie Royale de Médecine, tom. i. Sur la Folie des Ivrognes, ou sur la Délire Tremblante.

tual intemperance must be regarded as the immediate or exciting cause.

We have stated that delirium tremens is caused by the intemperate use of strong liquors, or of certain other diffusible stimuli. Of these latter, opium, either alone or in its various combinations, is the chief. The long continued and free use of opium may certainly induce true delirium tremens. We have known it to be so produced, and this fact is sufficient to overthrow the theory of M. Leviellé, before referred to, which would make the absorption of alcoholic molecules the exciting cause of the disease. It has also been asserted that the poison of lead, that malaria, that long fasting, will produce it; but we think, with Dr. Blake, that where delirium tremens follows emanations from lead, malaria, hunger, &c. it is only in subjects in whose constitutions the *ebriositatic diathesis* has been established by frequent excesses. When delirium from such causes occurs in persons of temperate habits, it will not present the other pathognomonic symptoms of the disease of which we are speaking.

We now arrive at an important question, one which we would gladly dispose of in a satisfactory manner, but which, we fear, must be left in obscurity—What is the pathology of delirium tremens? Dr. Armstrong, in his lectures, fairly confessed he could not satisfactorily answer the question. The affection, he said, appears to depend principally upon some condition of the nervous system with the nature of which we are unacquainted; and so he left the subject. By Dr. Gregory it is dismissed in terms sufficiently expressive of his doubts respecting it. "It appears," he says, "to have for its proximate cause a peculiarly excited state of the nervous system; but the occurrence of such symptoms in cases of extreme inanition would lead to the belief that *exhaustion of nervous power* expresses, perhaps, more accurately its intimate nature." It were easy, in this place, to descend learnedly upon cerebral irritation and disorganization; we might throw additional darkness over what is already obscure; we might pretend to explain what is unknown, by something completely unintelligible. In the absence, however, of just information, either by means of examination after death, or from any other source, we prefer acknowledging that we are very ignorant as to the pathology of delirium tremens: we do not know in what its intimate nature consists; but we do know enough to direct us as to practice; to enable us to state that in delirium tremens, uncomplicated with other serious disease, such as inflammation of some important part, unless circumstances are peculiarly unfavourable, unless the patient's constitution is extremely shattered, or he is very ill-managed, he will recover from the immediate attack. In simple delirium tremens, occurring in a subject neither far advanced in years, nor completely broken down by excess, our prognosis would be favourable.

We may now proceed to the treatment of the disease. And here we would once more

strongly insist upon the importance of minute attention to its several stages; since, as each stage presents some difference with respect to symptoms, each will require modification as to the plan of treating it. It may be assumed that the disease is one of debility. Blood-letting, as a general remedy, is no longer thought of. In its first stage, of which the symptoms are entirely those of diminished energy, no practitioner would dream of bleeding, either general or topical. In this stage, (we speak, be it remembered, of delirium tremens uncomplicated with other accidental affection,) there is absolutely nothing but what would contra-indicate abstraction of blood. The employment of laxative medicines will however be needed. The bowels may not be, and indeed they usually are not, constipated, yet the stomach and collatitious viscera may fail in the due performance of their respective offices; the alvine evacuations, though not deficient, may be unhealthy. In so disordered a state of the nervous system, as Dr. Gregory observes, the secretions will probably be vitiated. Mild purgatives will commonly suffice; but if, as sometimes happens, the bowels are actually constipated, recourse must be had to more active remedies, and amongst these croton oil perhaps is entitled to especial regard, since, beyond its purgative quality, it appears to exercise a peculiar influence upon the nervous system.

While in this stage of the disease we deprecate bloodletting, and would, under ordinary circumstances, employ only mild laxatives, we would not, on the other hand, advocate a highly stimulant plan of treatment. Under such treatment patients may now and then recover; but, generally speaking, the liberal exhibition of accustomed stimuli will be likely to render the supervention of the second stage more certain, to induce more violent reaction, and to place the patient in extreme jeopardy. The accustomed stimuli should be withdrawn without hesitation. Neither wine, nor spirits, nor strong malt liquors, should be allowed at all; or at all events they should be administered only in very moderate quantities. Opium should be regarded as our chief remedy; but at this period it is not to be given in full doses, but in small ones, repeated at short intervals. If nausea is present, with disposition to vomiting, or actually vomiting, about ten drops of laudanum, or of Batley's solution, may be given every other hour in an effervescent draught; and anodyne enemata, should the stomach be very irritable, may be employed. If the stomach is retentive, and there be no nausea, the above mentioned quantity of the opiate, with a few drops of Hoffmann's ether, or (should ether disagree, as it sometimes will, producing a distressing sense of coldness in the stomach,) a few drops of the aromatic spirit of ammonia, in camphor mixture or some other grateful vehicle, will be found more advantageous than any of the stimuli to which the patient has been accustomed. The warm-bath or tepid affusion should not be neglected.

Even cold affusion has been recommended upon highly respectable authority; but, when we reflect upon the train of symptoms which manifest themselves in the first stage of the disease, we should scarcely, even in a young and healthy subject, venture upon the adoption of so bold a practice. Anodyne frictions may be employed to the epigastrium; the head may be shaved, and the scalp stimulated by strong volatile liniment; and a blister be applied to the nape of the neck. Emetics have been recommended by American physicians; but, as they do not appear to recognize the several stages of the affection, they leave us in ignorance as to the exact period when emetics should be given: they can scarcely be deemed applicable during its first stage; and in the second they would seem to be a doubtful remedy.

By the judicious employment of the means just pointed out; by the adoption of what may be termed a stimulo-narcotic plan of treatment, modified according to the intensity of the symptoms, and the age, constitution, &c. of the patient; the second stage may be averted; the depressed nervous power being gently raised, the necessity for a great remedial effort of nature, for violent reaction, may be superseded; sleep may be induced, and the patient awake free from complaint.

While upon the subject of treatment in this stage of the disease, we have not touched upon diet, and for this plain reason, that the state of the stomach is usually such as not to admit of any thing beyond what is essential in the way of medicine. Should, however, this stage be protracted, and the patient seem to require, or express a wish for food, any mild nourishment, such as arrow root, sago, or broth, may be allowed him.

Should the second stage come on, depletion is, for the most part, still to be avoided; it is a remedy not to be employed but with the utmost caution. In young and vigorous subjects, and where there exists evidence of local determination, a single moderate bleeding from the arm, or the application of leeches to the temples or behind the ears, may prove useful; but the bleeding should never be large, and very seldom will it be proper to repeat it; while, generally speaking, it should be rejected as a practice which has too often done mischief, and has not unfrequently destroyed the patient. Opium is, at this period, our sheet-anchor, opium in full doses; all other remedies are of inferior importance. The object is to get down, and that speedily, what experience has proved to be generally effectual. We would recommend laudanum, say sixty minims, every hour or two; such a quantity of liquid may almost always be given without difficulty, while opium in substance may be refused, or its tincture in combination with other medicines may be obstinately rejected.

The medical attendant should watch by his patient during the exhibition of opium, and steadily persevere for several hours,—not so much regarding quantity, as the effect produced. While, however, we thus strongly

insist upon the bold and free employment of opium in the second stage of delirium tremens, we would not be understood as advocating its excessive or indiscriminate exhibition. Should the remedy, after some hours, fail to produce the desired effect, we must proceed with caution, lest by pushing it too far we add to the intellectual disturbance, and to the danger of our patient. The probability, however, is, that in a few hours there will be a remission of symptoms; that tranquillity will succeed gradually to high excitement, and there will be a disposition to sleep. This disposition will sometimes be attended with slight rigors, which may alarm those who are unaware of their nature and consequences. We should then be more sparing in our administration of opiates, and allow some time to intervene between the doses. The inclination to sleep should be promoted by every means in our power: every thing calculated to excite, as light, noise, &c. should of course be studiously guarded against. The first slumber may perhaps be interrupted by startings, and the patient may soon awake alarmed and distressed; but a moderate dose of opium, with some warm stimulating drink, and a kind encouraging manner on the part of the attendants, will generally be followed by a sleep more profound and of long duration, from which the patient will awake perfectly collected.

Anxious not to divert the attention of the practitioner, at this so important a period of the disease, from the one great and principal remedy, we have hitherto said nothing of other curative means; of calomel with the compound ipec. powder, in the proportions of two grains of the former to six of the latter, every two hours, till the system is affected or the disease yields; of the warm bath; of cold applications to the head; of purgatives; among which we may once more notice croton oil, either given internally, or used in the way of friction to the abdomen. These are not to be overlooked; they are valuable auxiliaries; and should opium, after a fair trial, fail us, as it occasionally will, camphor, musk, ether, ammonia, with hyoseyamus, are succedanea not to be neglected. The cautious administration, too, of alcoholic liquors may, in such cases, be of service.

During this stage we must pay particular attention to the moral management of the patient. We must strive to obtain his confidence, to gain an ascendancy over his mind without having recourse to coercive measures. As patients in delirium tremens are not usually disposed to be mischievous or malignant, physical restraint should be generally avoided: if a man is very uneasy and unquiet in bed, he may be permitted to get up; and if he is very importunate to go over his house, or is possessed with the idea that he must absolutely examine letters or papers, it will be the part of prudence to yield to his wishes, at least to a certain extent, for by so doing we shall be most likely to gain an empire over his mind; and the satisfaction of his desires, when they are not clearly improper, will probably obviate

a long and painful scene of impatience and contention, and will favour the return of tranquillity, and the accession of that sleep so much to be wished for. On no account, however, should the patient be left for a moment without an experienced attendant; and it should be remembered, that although the delirium in this disease is not generally characterised by intemperate violence, instances *sometimes* occur where it very closely resembles true mania.\* Where the unhappy patient manifests a strong disposition to offer violence to himself, or to those about him, every offensive weapon should be removed, and two male attendants be employed to keep the patient within bounds. We say *two* attendants, because thus the strait-waistcoat may be avoided, which, as Dr. Armstrong has observed, should never be resorted to but at the last extremity.

In one word, the treatment of patients in delirium tremens should be according to Pinel's directions in other cases of mental alienation.

To cut short the disease at this period is beyond our power; our efforts must be steadily directed towards the mitigation of urgent symptoms. Nature is now actively engaged in the work of restoration, and it is the part of the sound physician to be her discreet minister. He may direct her efforts, but he must not pretend to "give them pause." If left to herself, her operations will probably be fearfully energetic: we should endeavour to regulate the efforts she is making towards a good end.

It may, however, happen that all our exertions during the second stage of the disease will prove unavailing; that the third stage, that of tranquillity and sleep, will not be induced by any of our remedies; and that all the untoward symptoms formerly enumerated will supervene. How are we then to act? We must persist in the same general mode of treatment. We may shave the head, and apply blisters or antimonial ointment; we may apply blisters, or mustard cataplasms to the extremities; we may employ mercurial frictions; we may give powerful stimulants. It is incumbent upon us not to omit these remedies, though there exists little chance of their proving efficacious. The last symptoms are those of effusion into the ventricles, or on the surface of the brain; and such effusion to any considerable extent is almost always the forerunner of death.

When the event is more fortunate, when the immediate danger is averted, we should support the strength by moderate and frequent supplies of mild nourishment, and the judicious exhibition of diffusible stimuli, gradually diminishing the latter, and after a short time subtracting them wholly.

Having thus far conducted the patient,—having placed him in present safety,—the merely professional duty of the physician may be considered as terminated. Something, however, yet remains for him to do

if he would be deemed the *neighbour* of the individual whom he has just succeeded in rescuing from extreme peril. The physician should not lose sight of the convalescent until he has seriously advised him as to future conduct. He should avail himself of the *molliora tempora faudi*;—gratitude, confidence in the talent of his medical attendant, a vivid sense of the danger he has escaped, a present conviction that he has nearly perished through his own folly, will probably incline the patient to listen attentively to counsel earnestly and forcibly urged, yet without the semblance of harshness or the tone of reproach. What the nature of this counsel should be, the medical man need not be informed: the prophylaxis in the disease before us is sufficiently obvious. The complete abandonment of previous habits must be inculcated; but to produce a lasting impression, the adviser must speak from the heart. He must, to adopt the language of one who was truly an ornament to his profession, "evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom his counsels are addressed." Such honest counsels may be productive of an indelible impression; they may conduct to the happiest results, to moral as well as physical restoration; or should they be offered in vain, the physician will retire with at least the pleasing reflection that he has to the best of his ability fulfilled his duty.

(H. W. Carter.)

DENTITION, Disorders of. Under this head we shall endeavour to collect, not all the affections which hereditary errors and popular prejudice have marshalled under it, but such as careful and unbiassed observation has demonstrated to be occasionally induced by the process of cutting the teeth. By adhering to this resolution, a subject, once of interminable length and exaggerated importance, may be brought within comparatively narrow bounds, and if it be curtailed somewhat of its mysterious interest, it will not, we trust, lose in respect of practical utility.

The operations of nature are usually conducted in so skilful and complete a manner as should inspire all reasonable minds with large confidence in her powers, and lead them strongly to doubt all those hypotheses which would make disease a necessary adjunct to the evolution of our corporeal frame. That artificial modes of life, on the other hand, together with injudicious management, an excess of nutriment, with deficient exercise, impure air, and the other causes which tend to derange the general health, must greatly increase the difficulty and danger of the process of dentition, is indubitable; but that the mortality fairly traceable to it should, under any circumstances, have been rated so high as one-tenth and even one-sixth of all the children who undergo it, cannot fail to excite our surprise.

Children, as well as adults, are liable to numerous diseases of the three great cavities; but the difficulty of accurately recog-

\* A medical friend of the writer very nearly lost his life by the violence of a patient labouring under delirium tremens.

nizing them in early infancy too frequently causes their true nature to be overlooked, and disorders which are really idiopathic to be considered merely sympathetic affections depending on the process of teething.

Dentition, though often difficult and painful, is not in itself, properly speaking, a disease; yet the excitement which it produces is favourable to the development of such complaints as there exists a tendency to at this time of life. It is indeed the most critical period of childhood, and the supervention of any serious disease, as small-pox, measles, &c. during its progress, is, from the increased sensibility of the whole system, attended with more than ordinary danger.

*The first dentition.*—The rapidity with which the first set of teeth is developed necessarily causes a considerable determination of blood to the head, a circumstance which assists us in explaining many of the morbid tendencies which at this time occur. The rapid evolution which the brain, also, is at this period undergoing, concurs in a still more powerful degree to heighten the nervous susceptibility. This stage of existence is, indeed, remarkably characterized by a tendency to cerebral affections; and diseases of the chest, abdomen, and other parts, often become complicated with them, or towards their termination merge into them. The irritable constitution and extensive sympathies which distinguish infancy, help us to account for the severity of the symptoms which sometimes occur from teething. As the child grows older, though the local affection may be equally violent, the intensity of the constitutional effects is generally much diminished, and accordingly we find that the cutting of the large double teeth occasionally gives rise to much less disturbance than that of the smaller teeth which preceded them.

Any unusual obstacle to the coming forward of the teeth, such as may be caused by a disproportion between their rate of development and that of the jaw; or even their too rapid progress and the consequent appearance of several of them simultaneously, must greatly augment the disturbance produced by this process.

The rudiments of the teeth are visible in the fœtus about the second or third month. As they increase in size, they are found to consist of a double membranous sac, from the bottom of which rises a pulp composed of a vascular and nervous substance, and surrounded by a colourless fluid of a mucilaginous consistence. This fluid is gradually absorbed as the pulp enlarges, and ossific matter becomes visible on the summit of the latter about the end of the third month. The enamel is subsequently formed, but whether by deposition from the fluid, or by secretion from the inner and vascular membrane of the sac, is a disputed point. The jaw at first presents only a channel along its edge; but by the growth of transverse bony septa, this is subdivided into cells, and the alveoli are thus formed. The germs of most of the permanent teeth are visible even in the

fœtus, and are situated behind and below the milk teeth.

At the period of birth the ossification of the teeth is already far advanced, the crowns of the incisors being usually completed, and a considerable part of those of the double teeth formed. The ossification of their roots is a subsequent process, and in proportion as it advances, and as the alveoli become developed, the crown of the teeth is propelled towards the surface of the gum, and by the gradual absorption of this, and of the apex of its own enveloping sac, at length makes its appearance externally. The pressure on the membrane and gums, and the consequent irritation which accompanies this stage of the process, give rise to the painful symptoms of dentition.

The milk teeth are twenty in number: they usually appear in pairs, and those of the lower jaw generally precede the corresponding ones of the upper. They succeed each other commonly in the following order: first, the middle incisors; next, the lateral incisors; then either the canine teeth or the anterior molars,—perhaps more frequently the latter,—(but not invariably so, as M. Serres would have us believe;) and lastly the posterior molars.

The first incisor is generally cut about the sixth or seventh month, although occasionally not for many months later; the canine teeth commonly appear about the fifteenth month; and the posterior molars at various periods from the twentieth to the thirtieth. Thus, the whole period occupied by the first dentition may be estimated at from a year and a half to two years.

Such is the usual process of dentition; but it varies considerably in different individuals, both as to its whole duration, and as to the periods and order in which the teeth make their appearance. In scrofulous children, according to Gardien, the first incisors are occasionally cut so early as the third or fourth month; but such teeth are apt to decay and soon drop out. Underwood, on the other hand, has known weakly and rachitic children to be still without a tooth at twenty-two months old; and in such subjects analogy would certainly lead us to expect the ossification of the teeth to be tardy and imperfect. The premature and rapid development of the teeth has occasionally appeared to Guersent to be, not the effect, but the exciting cause of rachitis and tubercles: and, in general, it may be stated that the greater the number of teeth coming forward simultaneously, the greater the danger: those who have them late usually suffer least.

Numerous instances are on record of children who were born with some of their teeth already cut; of which Richard III., Louis XIV., and Mirabeau, were notable examples. In the case of Louis it was brought forward, but fallaciously, as an argument to establish his legitimacy, on which the lateness of his posthumous birth had thrown suspicion. Such premature dentition is neither a proof of

protracted pregnancy, nor yet of a strong constitution in the infant, as it has been observed that such children are often unusually small, and most frequently die early. Indubitable instances are mentioned by authors, of individuals who never had any teeth: Borelli knew a woman of sixty years of age in this predicament: certain diseases of the jaw affecting the germs of the teeth may be occasionally the cause of this singular phenomenon. Soëmmering and Fox each saw a case where several of the teeth were consolidated into one mass; and we have met with a similar instance in the Museum at Leipzig, of two incisors grown together by their crowns, whilst the roots are separate.\* Such abnormal appearances depend, no doubt, on the deficient evolution of the alveolar septa.

The natural symptoms of dentition in its mildest form are an increased flow of saliva, with swelling and heat of the gums, and occasionally flushing of the cheeks. The child frequently thrusts its fingers, or any thing within its grasp, into its mouth. Its thirst seems to be increased, for it takes the breast more frequently, though, from the tender state of the gums, for shorter periods than usual. It is more fretful and restless, and sudden fits of crying and occasional starting from sleep, with a slight tendency to vomiting and diarrhoea, are not uncommon. Many of these symptoms often precede the appearance of the tooth by several weeks, and indicate an increased activity in the process of ossification and development, or what in common language is called breeding the teeth. In such cases the symptoms subside in a few days, to recur again when the tooth approaches the surface of the gum. In the first period the pressure of corals and other hard substances on the gum seems to be agreeable, by numbing the sensibility and dulling the pain. A better form than that of the ordinary coral is an ivory ring, as it obviates the danger of its being thrust into the eyes or nose. Rousseau, in his *Emilius*, objects to the use of hard substances for this purpose, and refers us to the instinct of the young of other animals, which leads them to exercise their budding teeth, not on bone or stones, but on softer substances, on which they can make some impression. In accordance with this view a stick of marsh-mallows or of liquorice root, a piece of wax-candle or a crust of bread, have been recommended instead of the coral; and in France they often dip them into honey or a sweet decoction of barley, in order to render them more agreeable to the child, and more relaxant to the gums. In some parts of Germany we frequently see infants sucking a small bag containing a mixture of sugar and

spices, which is given to them whenever they are fretful or uneasy. It reacts sufficiently on the gums, and certainly seems a very successful expedient for occupying the child and keeping it quiet: it thus saves the nurse some trouble; but the injury which the constant use of these sweet and stimulant ingredients must do the stomach, renders their employment very objectionable.

Gentle friction of the gums by the finger of the nurse is pleasing to the infant, and seems to have some effect in allaying irritation and altering the mode of the sensibility.

Pain appears to be the chief cause of all the morbid sympathies accompanying dentition, and is attributable partly to pressure on the membranous sac and on the gum, and partly, or, as some think, principally, to the pressure made by the root of the tooth on the dental nerves.

In feeble and delicate children dentition is usually, as we should naturally expect, more tedious and difficult than in the healthy and robust; but to this there are numerous exceptions; and it is certain that when disorder does occur in the latter, they suffer much more severely, and are more apt to be cut off suddenly by superinduced inflammatory affections, as was long ago remarked by Hippocrates. Puffy infants, on the contrary, are more prone to a wasting diarrhoea and marasmus; and those reared in a crowded city generally suffer much more than those who have been brought up in the healthy air of the country. In a word, the two extremes of debility and high health, or rather that appearance of it which is induced by over-feeding, are both exposed, and nearly in an equal degree, to danger;—the former from a low wasting fever and bowel complaints; the latter from acute fever, determination of blood to the head, and convulsions. Those who have asserted that robust children always suffer most, have perhaps been misled by external appearances, forgetting that every the slightest change of condition in the fat and florid child will be more obvious and striking to the eye, than in one which was already pallid and thin.

The management of infants during teething, when the process is going on in a favourable manner, is very simple, and rarely calls for the interference of the physician. The child should be much in the open air, and well exercised, and the bowels kept free. The employment of the cold bath or cold sponging daily, followed by gentle friction over the surface of the body, is very useful; and all means should be taken to support the tone of the system at a just medium. The breast should be given to it often, but not long at a time, and thus the attendant thirst will be quenched, and the gums kept moist and relaxed, and their irritation soothed, without the stomach being overloaded. The health and diet of the nurse should at this period be particularly attended to, and all stimulant food and drinks avoided.

Dr. John Clarke, in his *Commentaries on the Diseases of Children*, ascribes most of the

\* In the same museum, which is very rich in preparations illustrating malformation and diseases of the teeth, there are examples of ankylosis of the teeth with the jaw, occurring in rachitic subjects; and others exemplifying the fragility of these organs in individuals of a similar constitution, and explaining their consequent liability to break in extraction.

disorders which accompany dentition to overfeeding and consequent plethora; to improper kinds of food, which produce irritation; and to keeping the head too warm. He asserts that coolness of the head, and washing it daily with cold water, renders children much less liable to illness during this period. Spontaneous salivation and moderately lax bowels are always to be considered favourable, as they tend materially to diminish irritation; and when absent, their place should be supplied by gentle aperients, especially in the case of plethoric children, or those with cutaneous eruptions.

When dentition is difficult and tedious, the treatment is more complicated, and consists in allaying local irritation, moderating urgent symptomatic affections, and when protracted and productive of much exhaustion, in supporting the general strength. But, in order to treat of this part of our subject more satisfactorily, we shall divide the phenomena of difficult dentition into the idiopathic or local, and the sympathetic or secondary. These latter might again be divided either according to their nature, into spasmodic and inflammatory; or according to the organ or texture which they affect: as this latter subdivision appears more conducive to accurate diagnosis, we mean to adopt it.

Of the local symptoms, or those occurring in or near the mouth, painful inflammation and swelling of the gum, which is hotter, of a deeper red than natural, and intolerant of the slightest pressure, are the most usual, and the cause of all the rest. There is often great determination of blood to the head, the cheeks being red, hot, and swollen, the eyes irritable and watery, the salivation profuse, and the salivary glands occasionally enlarged and painful. Aphthæ sometimes occupy the mouth and fauces, and abscesses have, in some rare cases, been observed at the root of the tongue. The symptomatic fever is often great, and is remarkable for its sudden rise and declension, intermitting and recurring frequently in the course of a few hours. The thirst is extreme, and the child is at one time restless and irritable, and at another heavy and oppressed. The sleep is broken, and the infant frequently awakens suddenly and in a fright from its short slumbers. The urinary secretion is usually much diminished, though cases do sometimes occur, as has been mentioned by Whytt, when it is increased, and in such the accompanying symptoms will generally be found to be more of a nervous than an inflammatory character.

As all these symptoms are induced by the painful tension of the gum, the most rational mode of attempting their relief is by freely lancing the swollen part. Of the practical utility and perfect safety of this operation, notwithstanding the prejudices which exist against it in some other countries, we have ample proof in its daily performance with impunity, and in the instant relief which it often affords to all the symptoms. To give it a chance of success it must be done effectually,

and both the gum and the capsule of the tooth laid fairly open. An assistant holds the head of the infant firm, whilst the operator, with a gum lancet or a narrow bistoury having three-fourths of its blade guarded, separates the jaws, and keeping the tongue and cheek out of the way with the fingers of his left-hand, cuts down firmly in a longitudinal direction on the inflamed and swollen gum; and if it be a double tooth which is coming forward, he should convert the incision into a crucial one. In Paris they often dissect out the flaps, but this seems to be an unnecessary addition to the pain of the operation. The slight bleeding which occurs is highly beneficial, acting as a local depletion, and thus conspiring to take off tension. The fears of an excessive or debilitating loss of blood from this source, may be considered, as to all practical purposes, unfounded and chimerical. We do not usually recommend the performance of this operation till the tooth be already so far advanced that we can be pretty sure of succeeding in laying open the capsule; for slight scarifications of the gum can afford no effectual or permanent relief. Cases may, however, occur, where even the temporary ease which superficial scarifications are capable of affording should not be renounced; but here we must take care to explain to the child's friends the object of their performance, else the speedy return of the symptoms and the non-appearance of the expected tooth may tend to bring the operation of lancing the gums, or our own skill, into disrepute. The old apprehension that the scars which ensue, oppose, by their hardness, the subsequent progress of the tooth, though repeated in one of the latest French works on the diseases of children, is quite groundless; for cicatrices, like all other new-formed parts, are, as Hunter long since pointed out, much more easily absorbed than the original structure. Slight ulcerations of the gum have in some rare instances succeeded to the incisions; but this is a very unusual occurrence, and may be generally prevented by taking care to have our lancets perfectly clean; they are besides of very little consequence, as they readily heal under slightly astringent applications. Both Underwood and Hamilton enumerate ulceration of the gums amongst the occasional effects of teething, and the former thinks they occur even more frequently in cases where lancing has not been performed.

When the pain, determination of blood to the head, and fever, persist after the gums have been freely lanced, laxatives, mild diaphoretics, the warm bath, and slightly stimulating pediluvia must be employed, and if these be insufficient, one or two leeches should be applied behind the ears. When by the above means the fever has been in some degree reduced, the bowels continuing free, if the pain be still very severe, the cautious use of anodynes, as a drop or two of tincture of opium, or minute doses of hyoscyamus may be tried. But perhaps as a general rule, seeing that infants are so very susceptible of the influence of narcotics,

their external use, in the form of anodyne frictions to the spine, is preferable. When very restless at night, the infant should be frequently taken up and carried about in an airy room: by the cool air and the nearly erect posture, the feverishness will be alleviated, and the tendency of blood to the head counteracted.

Such are the measures which modern experience has found the most effectual in moderating the pains of dentition. Very different was the practice of our forefathers, who, misled probably by the fanciful doctrine of signatures, were in the habit of applying to the gums specific ointments made of the brains of hares, or of the combs of cocks, which, as old Hartman would have us believe, "cause the production of teeth without difficulty and free from accidents." Whilst we smile at the credulity of former generations, we must not forget that the anodyne necklaces and other charms still in use in our own day are in no wise more trustworthy or less absurd.

With regard to the affections of distant organs occurring during teething, we must not forget that they may originate as primary or idiopathic diseases at this period as well as at any other. Still, after making every allowance on this score, certain disorders manifest themselves so much more frequently during this process, and often subside so rapidly on the appearance of a tooth, as to leave us no doubt with regard to their occasional connection with the business of dentition.

Of the disorders which may be thus called into action by the irritation of teething, very formidable lists have been made out by authors. The following is a specimen of these, and of the confused manner in which symptoms and diseases are often jumbled together: vomiting, anorexia, diarrhœa, cholera, costiveness, increased or diminished urine, urethral or vaginal discharge, with painful micturition; dry cough, dyspnoea, catarrh, pneumonia, spasmodic affections of the face, limbs, glottis, &c.; insomnia, agitation and fright on awaking, epilepsy, somnolence, stertor, coma, transient palsy of the arms and legs; ophthalmia, hydrocephalus, marasmus; eruptions, especially about the head and face, swellings of the hands and feet, enlargement of the cervical, femoral, and mesenteric glands, and other scrofulous affections.

From this enumeration it appears that the chylipoietic and respiratory organs, the brain and nervous system, the skin and the lymphatics, are the chief seats of the sympathetic affections occasionally induced by dentition.

Of these secondary affections, those of the mucous membranes are the most frequent, and they may be either inflammatory or not. Inflammation of the conjunctiva, of the mucous membrane of the air-passages and lungs, or of the stomach and intestines, will be characterized by the usual symptoms, and require the same kind of treatment as idiopathic inflammation of the same parts, though it will rarely be necessary to push it so far. Incision of the inflamed gums should always be premised, and will sometimes, without the employment of

almost any other measures, be followed by the speedy resolution of the disease.

Far the greater number, however, of these affections are not truly inflammatory, but depend on a peculiar state of irritation kept up in these remote organs by sympathy with the inflamed gum. Such, usually, is the nature of the accompanying cough, vomiting, or diarrhœa. When the vomiting and purging are not attended with pain on pressure, redness of the tongue, loss of appetite, or great oppression and fever, we have no reason to believe in the existence of inflammation, either in the stomach or intestines. Such symptomatic vomiting may usually be restrained by diminishing the quantity or varying the quality of the child's milk or other food; and if there be evidence of excessive determination of blood to the head, by the application of one or two leeches behind the ears. Should it prove very obstinate, and debility, and loathing of food be induced by it, narcotic frictions and fomentations of the abdomen, and a small blister applied for three or four hours to the epigastrium or to the upper part of the spine, may be requisite.

In severe and protracted diarrhœa interfering with the sleep and nutrition, and accompanied by debility, emaciation, pallid skin, a dull eye, and sunken expression of countenance, in addition to some of the above measures, tonic and alterative aperients are called for, such as rhubarb combined with ipecacuanha or hydragryrum cum creta. Absorbents will be necessary if there be acidity in the primæ viæ, which is a frequent symptom in the derangement of the digestive organs induced by teething, and is evidenced by griping and by green and sour-smelling stools. If the discharges are of a bad quality, being fetid, blackish, or very pale, an occasional dose of calomel to modify the intestinal secretion should be exhibited. In very obstinate cases the cautious use of Dover's powder, opiates alone, or in combination with minute doses of calomel, and given at short intervals, or opiate enemata may be indispensable. But in the latter mode of exhibiting opium, especially in the case of children, we must never forget that its action is sometimes, as has been pointed out by Dupuytren, even more energetic than when given by the mouth. The diet must be particularly attended to, the nurse changed if her milk seem to disagree, and the strength supported by beef-tea, rice-milk, arrow-root, &c. In many of these cases quinine in small doses will be found a very useful auxiliary. We are not advocates for the premature use of medicine in this affection: as on the one hand neglected diarrhœa is a frequent cause of death in dentition, and as on the other a lax state of the bowels has a great influence in moderating the dangers of this period, it requires a very nice discrimination on the part of the practitioner to know when to interfere. Perhaps no attempt should be made to check the intestinal secretion so long as the appetite, sleep, and strength continue unaffected. It is certain that bowel complaints, which would be thought very alarming at any other time, are often well borne when they depend merely on

the irritation of teething. We should therefore, in most cases, content ourselves with watching their progress as long as they keep within the limits stated above.

Vomiting and purging often coexist, and in their combination frequently constitute a very formidable affection. M. Cruveilhier has described under the title *Maladie gastro-intestinale des enfans avec desorganization gelatiniforme*, a very violent and fatal disease of the stomach and intestines of this kind, which is characterised by excessive thirst, urgent vomiting, and frequent, very fetid, green stools, like chopped spinach. After repeated vomiting the child becomes cold, and falls occasionally into a state approaching to syncope. The pulse is slow and irregular; the intellectual faculties continue clear to the end. The infant is extremely irritable and cries incessantly, except whilst being carried about in the nurse's arms. A state of drowsiness and oppression soon supervenes, the face assumes a cadaverous appearance, and the eyes are half closed and turned up. The coldness of the body, and especially of the extremities, goes on rapidly increasing, and in the course of twenty-four or forty-eight hours, a state of extreme prostration and fatal collapse are sometimes induced. By a superficial observer this disease might be mistaken for a cerebral affection, as there is somnolence and screaming, with slowness and inequality of pulse in both; but in the peculiar disorder under consideration the somnolence is interrupted by the slightest touch, the sensibility of the skin is morbidly increased, the intellectual faculties are entire to the last moment, and the respiration is not unequal, as in disease of the brain. On dissection, the mucous membrane of the stomach, and generally that of the small and great intestines, is found in a state of softening, being reduced to a soft and disorganized pulp, but without any appearance indicative of inflammation. Cruveilhier's treatment consisted in confining the diet entirely to milk, and giving even that in the very smallest quantities, together with baths and fractional doses of opium administered at short intervals, both by the mouth and in enemata. The chief causes of the disease seem to be improper food, premature weaning, and dentition. It may run on for many days, or even weeks, and when it proves fatal, terminates at last either by an acute attack or by gradual sinking. It is evidently closely allied to cholera morbus, and is in no degree an inflammatory affection.

M. Guersent, physician to the Children's Hospital at Paris, has given a description of the above disease, differing in some respects from that of Cruveilhier's. He remarks that this peculiar combination of vomiting and purging occurs only in young infants from three or four months old to the end of the period of dentition, and is most common when they are getting the canine and double teeth. The diarrhœa is extremely abundant, and the stools are sometimes yellow, but oftener green, like flocculi of confervæ floating in a transparent serous fluid. Vomiting is soon superadded,

first of a serous fluid, and at a later period of a porraceous matter. A dry cough and irregular febrile exacerbations usually occur in this affection: the prostration of strength and emaciation are extreme. Towards the close, slight convulsive motions are observed, chiefly about the face and eyes. The voice becomes excessively feeble, the features become relaxed, and the child sinks at length either in a state of agitation or of extreme exhaustion, whilst the consciousness to surrounding objects continues unimpaired to the last. There are some varieties of the disease: thus the diarrhœa may precede the vomiting many days; or they may both commence nearly at the same moment, and the child then dies with symptoms of cholera in the space of three or four days, or occasionally even within twenty-four hours. The affection sometimes, however, assumes a more chronic form, lasting thirty or forty days;—but here there are frequent suspensions and renewals of the symptoms. On dissection, the mucous membrane of the stomach and intestines has usually been found pale, colourless, and almost transparent, as if it had been macerated in water, and the mucous follicles are in their natural state. In some rare cases slight redness has been evident in the cæcum and colon, but this so seldom, that it could only be considered as a casual complication; and the same may, according to Guersent, who is here at variance with Cruveilhier, be said of the softening of the mucous membrane of the stomach and intestines, which forms no essential or constant part of the disease. The treatment which he has found to succeed best in this peculiar affection, as well as its morbid anatomy, tends to prove that it is much more nearly allied to cholera than to gastro-enteritis: this treatment consisted in the very lowest diet, mucilaginous drinks, emollient injections, fomentations and narcotic cataplasms. Leeches are almost always useless or injurious. As the disease advances, baths and the very cautious use of opiate enemata are proper; and when the prostration is extreme, sinapisms and blisters should be applied to the limbs, nucha, or abdomen. Tonics and stimulants have usually seemed to do harm. In the acute or cholera form it mostly proves fatal in spite of all kinds of treatment. It is here from opiates internally that we can alone expect any benefit.

Mr. Parrish, of Philadelphia, has described a spasmodic affection of the intestines, or a species of flatulent cholera, which he thinks is often dependent on the irritation of teething. The belly swells up rapidly and becomes extremely tender to the touch, the child cries much, the muscles of the face and limbs are spasmodically contracted, and the stools are suspended. The only thing which gives relief is the expulsion of flatus, and the consequent reduction of the tympanitic state. The appropriate remedies, after lancet the gums, seem to be draughts or enemata, containing a few grains of assafœtida, and two or three drops of laudanum, friction of the abdomen and spine with an anodyne liniment, and the induction

of a free state of the bowels by some gentle aperient, or a soap suppository. Mr. Parrish has recommended, as an immediate mode of relief, the extraction of the air from the rectum by means of a syringe.

Having already alluded to disorders of the chest, we shall here only add that a susceptibility to catarrhal, and even peripneumonic affections, seems to be occasionally induced by teething. When the presence of inflammation is indicated by fits of coughing so painful as to make the child cry, and by soreness of the chest, dyspnoea, anorexia, and feverishness, after lancing the gums, repeated purgatives, emetics, and diaphoretics will often afford much relief; but in severe cases leeches and blisters must never be omitted.

The dry nervous cough of irritation is, however, by far the most frequent species, and may occasionally be much alleviated by anodyne frictions of the spine and abdomen, though it often resists all treatment till after the tooth is cut, and then ceases spontaneously. Cough at this period seems sometimes to depend on an intermediate derangement of the digestive organs, as is indicated by the state of the tongue, tension of the abdomen, unnatural stools, and the absence of fever: here emetics and purgatives are the appropriate remedies.

Affections of the brain and nervous system may occur in every degree from a slight and passing determination of blood to those organs, up to the most violent irritation, congestion, or even inflammation. The pain in the gums keeps the nervous system in a state of constant excitement, which is favourable to the development of spasmodic affections.

When there exists considerable plethora and drowsiness, the use of purgatives and leeches, with blisters to the nape of the neck, is indispensable. On the other hand, a state of insomnia is occasionally induced; or the sleep is much interrupted, and the infant often awakes with a start, frightened and crying. This should never be overlooked by the physician, as it indicates a condition in which the occurrence of epilepsy or convulsions is by no means improbable. It seems sometimes to depend on cerebral congestion, and sometimes on derangement of the digestive organs, though occasionally it is purely nervous; and according to whichever of these may be its cause, it will require the use either of leeches and purgatives, or of antispasmodics and warm baths.

Where much fever accompanies dentition, convulsions often occur, especially if the bowels be in a constipated state. Neither feeble and irritable, nor large and fine infants are exempt from their attacks; but the latter are the most apt to be cut off suddenly by them. It is with the protrusion of the anterior molars, or of the canine teeth, that they most frequently come on; and they are occasionally preceded by grinding of the teeth, trembling of the lips, and other premonitory symptoms. They are not always so dangerous as is commonly imagined, and are least so when confined to spasmodic motions of the eyes, face, and arms. But if,

on the other hand, the fits are very general and violent, and succeed each other rapidly, they are then always very alarming. They occasionally terminate in apoplexy or paralysis. As very formidable convulsions have been known to cease immediately on the gums being lanced, this operation should never be neglected where they appear swollen and painful. Tepid baths, leeches, purgatives, narcotics, and antispasmodics, are severally useful in different states of the system. Thus, if pain be the predominant symptom, we should avail ourselves of the soothing influence of tepid baths; if the sleep be lost, the cautious use of narcotics will be justifiable, provided there be no fever; otherwise, and especially if the child be plethoric, purgatives and leeches must be premised. In weakly children, assafetida and some other medicines of the antispasmodic class have been occasionally found useful. Sprinkling cold water in the child's face while in the bath will often cut short the fit; and when the recurrence of the disease is very frequent, an issue at the back of the neck, or the production of an artificial eruption, is to be recommended. (See CONVULSIONS, INFANTILE.) Underwood speaks of a transient palsy of the arms and legs occurring as each tooth is coming out, and which does not require any particular treatment beyond attention to the gums and to the bowels. The paralysis after convulsions is often permanent and hopeless: leeches and counter-irritation to the spine should, however, have a trial in such cases.

Of the convulsive affections occurring during dentition, one of the most formidable is *spasm of the glottis*, sometimes, but improperly, termed spasmodic or chronic croup. Dr. John Clarke has described it under the title of "*a peculiar Convulsion of Infant Children*;" and it has also been noticed by Dr. Hamilton, of Edinburgh, and Dr. Cheyne, of Dublin. Dr. Monro has alluded to it where he speaks of a peculiar species of hydrocephalus, attended with spasm of the glottis. It has been written on by Mr. Pretty, in the *Medical and Physical Journal*, under the name of *cerebral croup*, and has been described, in France, by M. Guersent, under the title *Pseudo-croup nerveux*, and still better by Gardien, under that of *Spasme du thorax et de la glotte*; and by Richter, Raimann, Schmalz, Wichmann, &c. in Germany. But the latest, and much the most satisfactory account of this disease is that by Dr. Marsh, in his paper in the *Dublin Hospital Reports*, vol. v. to which, and also to the article *GLOTTIS, SPASM OF*, in the present work, the reader is referred.

A peculiar swelling of the hands and feet has been mentioned by Underwood as an occasional symptom of painful dentition. It was considered by him as in itself, if not decidedly beneficial, like a slight diarrhoea, at least unimportant, as he found it to cease spontaneously when the tooth came up. If any feverishness co-existed, he attributed it not so much to those tumours, as to the casual coincidence of derangement in the bowels or some other organ.

Dr. Kellie, of Leith, who has described this singular affection more at large, asserts that though it be sometimes thus slight and transient, yet in many cases it has appeared to constitute a part of a disease of a more striking and serious nature. The swelling, which is situated on the back of the hand and on the dorsum of the foot, has a considerable degree of roundness and elevation, such as might be produced by a blow. It seems to arise suddenly, and is of a mottled, somewhat livid, or purplish colour, feeling rather cold, and exhibiting no sign of inflammation or increased sensibility. It is firm, and does not pit on pressure. It will occasionally continue for weeks, gradually becoming softer or assuming somewhat of a leucophlegmatic hue, to which occasionally, but very rarely, œdema of the whole limb has been known to supervene. Usually, however, it disappears more suddenly, without passing into the leucophlegmatic stage. It is generally connected with a symptom of a more formidable character than itself, viz., the spastic contraction of the flexors of the thumb and toes. The thumb is rigidly contracted and permanently bent downwards, and laid flat upon the palm of the hand; and in like manner the toes are bent down to the plantar aspect of the foot. The carpus is also sometimes drawn down by its flexors, so as to increase the sphericity of the metacarpal bones. The child is peevish and restless, but does not seem to suffer much pain in the affected parts. In some cases only there is pyrexia towards the evening; the bowels are commonly torpid, and the stools procured by laxatives are fetid, clayey, green, sour, and slimy. Its duration is from a few days to several weeks, and its termination usually favourable. General convulsions have, however, sometimes supervened; in one of Dr. Kellie's cases fever made its appearance, and two others died with what Dr. Armstrong calls symptoms of "hectic teething." It is a disease of the epoch of dentition, and as the symptoms have occasionally ceased immediately after the cutting of a tooth, we may conclude that teething is, at times at least, its exciting cause. The treatment recommended by Dr. Kellie consists in scarifying the gums, removing plethora if it exist, restraining vascular excitement and local determination, and regulating the alvine discharges.

Of the cutaneous eruptions connected with dentition little need be said, as they seem, by their derivative action, like a lax state of the bowels, to be rather useful than otherwise. The principal varieties are, an erythematous efflorescence behind the ears (intertrigo); crusta lactea; the different varieties of strophulus (the red gum or toothrash of the vulgar); small phlyctenæ, like those of a burn, and evanescent red spots appearing upon the face and other parts. But as most of these may occur also quite independently of dentition, we can be certain of the connexion in those cases only when they make their appearance, or undergo an exacerbation, just before the

cutting of a tooth, and become milder or disappear after it. Should they run to such an extent as to become troublesome, laxatives are the best means of keeping them down. During their existence exposure to cold should always be avoided.

Disease of the lymphatic system is an occasional result of the debility often induced by teething, and is manifested in the enlargement of the cervical, inguinal, and mesenteric glands, &c. In these, as in all other serofulous affections, our chief attention should be turned towards the improvement of the general health by good air, nutritive food, regular exercise, attention to the digestive organs, and other measures to which we have alluded in a preceding paragraph.

*The second dentition.*—The milk-teeth generally begin to fall out about the seventh year, or somewhat earlier, and are replaced in the course of five or six years by the permanent teeth, which usually come up with little or no pain. Cases do, however, occasionally occur in which there is considerable local irritation, and consequent enlargement of the glands about the jaw and neck, ophthalmia, cutaneous eruptions, &c. The wisdom-teeth, which are cut about the twenty-seventh year, or occasionally much later, are often productive of considerable uneasiness and swelling. The pain being sometimes periodically intermittent, has been mistaken for an aguish or rheumatic affection, and treated with bark and similar medicines. Cases are mentioned where, from the imperfect development of the jaw, there has not been room enough for the dentes sapientiæ to come easily forward; and hence much pain and swelling of the face, together with violent headach, inflammation of the eyes, pain in the ear, and abscess near the angle of the jaw, have resulted. Free incision of the gum, or even extraction of a tooth, may, in some of these cases, be necessary, along with leeches, fomentations, and poultices to the external swelling.

The second set of teeth occasionally come up before the first have fallen out, and we have then the singular appearance of a double row of teeth: on the other hand, there are instances on record of individuals who did not begin to get the second set till they were forty or fifty years of age. The cases in which very old persons have cut a third set of teeth\* are so extremely rare, that we only allude to them because their development has been sometimes accompanied with excruciating pain and other circumstances, which might be extremely puzzling to the practitioner if not aware of the possibility of such an occurrence.

(*W. B. Joy.*)

DERIVATION (from *derivare*). This term may be received in two acceptations: it may apply to an effect produced on any morbid condition of parts by an artificial irritation or determination elsewhere, which removes or diminishes

\* See Ed. Med. Comment. vol. iii.

the primary one; or to the removal or diminution of a morbid condition, consequent on the occurrence of a new irritation or excitation of action *not* artificially produced. Thus when a blister is applied in a case of pneumonia, with relief of the pulmonary disease, we have an example of the first acceptation; and when a disease of the lungs subsides on the occurrence of a cutaneous eruption, or of a diarrhœa, we have an instance of the second. In either case the principal pathological phenomenon is the change of the seat of irritation or excitement.

The term *revulsion* is one better adapted to express this phenomenon, but it matters little which phrase we adopt. The older authors entered into many arguments respecting the difference between revulsion and derivation, but as their ideas on these subjects were founded on false physiological views, we shall pass them by here.

The circumstances under which derivation, as taken in its first acceptation, is observed, may be thus enumerated.

First, the application of agents to the two great surfaces of relation, namely, the skin and mucous membranes, calculated to irritate or merely increase the normal action of these tissues; and secondly, the use of stimulants calculated to excite the secretions of various of the parenchymatous organs. Under these heads may be enumerated all the irritating applications which we make to the skin, such as cantharides, ammonia, tartar emetic, &c., and also the use of friction and heat. When we employ purgatives to cure a dropsy, or a disease of the skin or of parenchymatous organs, when we use diaphoretics to relieve a mucous inflammation, or diuretics to remove serous effusions, we act on the derivative or revulsive system, and the remedies are in all cases derivatives or revulsives. In some of these cases, we cure or alleviate the original disease by the production of a new inflammation in the part acted on, as in the case of blistering; in others, the part acted on is not made the seat of a new inflammation, but its normal secretion is excited and increased, as in the case of warm bathing producing diaphoresis.

The second example of artificial derivation is the production of irritation in tissues deeper seated than the skin, but still exterior to the viscera. Of this, the use of setons and issues is an example.

But, as we have already shown, derivation or revulsion is often found to occur independently of any artificial excitation, and the consideration of this subject comes to be of the highest interest in medicine. As, however, it is more immediately connected with metastasis, we shall in this place merely sketch the leading physiological facts connected with this species of derivation. One of the most interesting of these is, that this revulsion often occurs between analogous tissues; thus, in cases of inflammation of the synovial membranes, the sudden subsidence of the disease is commonly followed by inflammation of some of the serous membranes, such as the pericardium, peritoneum, pleura, or

arachnoid. Again, a patient has diarrhœa; this suddenly subsides and is succeeded by violent bronchitis; he has a disease of the skin, which is repressed, and the mucous membranes become engaged, or *vice versa*. But this rule is by no means so general as to form a law in pathology, for we find very many instances of exception; for example, the occurrence of ascites after suppression of the perspiration, hemorrhage from the kidneys after the desquamation of measles; the alternation of catarrh and liemiplegia; of gout and gastro-enteritis, or bronchitis; of mania and œdema of the lower extremities.

We shall not here examine the relation of cause and effect in these examples of conversion of disease; it may suffice to remark, that in some cases the subsequent or secondary disease appears to arise from the cause so well illustrated by Broussais, namely, the predominance of the sympathetic over the primary irritation; while in others it seems to result from a morbid condition of the whole system, consequent on the subsidence or removal of some local irritation, which, from its chronic duration, has apparently become necessary for the proper balance of the constitution.

Two modes of revulsion are used in medicine. In the first, we endeavour to change the seat of irritation or excitement from the viscera to the surface; in the second, we change it from one viscus to another. The first may be called the exterior or peripheral revulsion; the second, the interior or visceral. To the first of these we shall in this article principally direct our attention.

The *modus operandi* and therapeutic application of the exterior derivatives are questions of great interest in medicine. In some cases the application of a blister to the surface is followed by great relief of the internal disease, while in others the reverse occurs. To determine the cases in which the favourable or unfavourable results may be reasonably expected, comes to be a great desideratum. Here experience is our chief guide. It has been long known that blisters will relieve local inflammations of the internal parts under three circumstances; *first*, where the disease is of the acute character, but modified in its intensity by active antiphlogistic measures; *secondly*, where it is acute, as respects the time, but occurring in cases where the powers of life are low, as in typhoid inflammations; and, *lastly*, in chronic diseases. In all these cases, the activity of the capillary circulation in the diseased part is weak, and revulsion taking place with ease, a rapid removal of the local disease is often the effect of our treatment. On the injurious effects of external revulsives in acute inflammations, before depletion is used, most authors are agreed. Rostan, in his *Clinical Medicine*, says, "Revulsions are generally contra-indicated in the early stage of acute diseases when there is fever and the subject is young and strong." The same author, in another place, says that although a derivative effect is often obtained, yet that in many cases excitation will follow

the use of revulsives, and an effect directly contrary to that expected will be produced. Mr. Porter, in his 'Surgical Observations, on the Diseases of the Larynx and Trachea,' expresses himself strongly against the use of blisters in acute laryngitis, particularly when applied to the neighbourhood of the part. He says, they cannot be resorted to at an early period without considerable risk of doing mischief. A case is related, where, in acute pneumonia, the application of a blister was followed by an aggravation of the symptoms and death. On dissection, a portion of the surface of the lung, exactly corresponding to the size and shape of the blister, was found in a more advanced stage of inflammation than the remaining pulmonary tissue. Many other authors might be quoted to the same effect. Our own experience is decidedly in favour of these views. We have often seen a distinct exacerbation follow the application of a blister in the acute pneumonia, bronchitis, or gastro-enteritis of children, in cases where bloodletting was not used; and many medical friends have informed us of similar occurrences in their own practice. Even in a few chronic cases we have observed the same effect where local bleeding has not been premised.

We must, then, admit that external derivatives have two modes of action; the one derivative, the other directly stimulant on the diseased part. We find them, as we stated before, generally useful in three sets of cases, namely, acute inflammations where general and local bloodletting has been premised, typhoid inflammations, and chronic diseases: and it becomes probable that a *part* at least of their utility is owing to the direct stimulus conveyed to the capillaries of the diseased tissue. A state of these vessels, analogous to Andral's *asthenic hyperemia*, in all probability exists, and we know that stimulation is often the best mode of removing this morbid condition. This will account for the injurious effects of external revulsives in acute cases before depletion has been used, and is not inconsistent with their good effects in cases of a different description. They are all essentially stimulants. If the irritability of the system is great, an increase of fever will be the result of the sympathetic irritation of a blister, and in this way the local inflammation will be aggravated. Whether the increase of the local disease be always owing to this cause, or whether it may occur without the intervention of sympathetic fever, are questions of difficulty, but happily not of great practical importance.

We often find, in cases of intense irritation of internal organs, that blisters will not vesicate the skin, but that, as soon as the disease has been modified, they will produce their usual effect. Can this be explained by supposing, that in consequence of the intense inward determination, the surface has lost a portion of its vitality? In such cases, the vesication of the surface is often not the cause, but the consequence of the diminution of diseased action.

The means generally employed to produce external revulsion are the application of blisters, sinapisms, or the tartar emetic ointment; and the use of setons, issues, the moxa, heat, and friction. In this country the most common mode is the application of blisters, either immediately over the diseased organ, or at some distance from it. Unpleasant consequences often follow even this simple proceeding; of which the principal are the infliction of great pain, the production of a too violent inflammation, and the occurrence of strangury. All these bad effects appear frequently to arise from the practice which commonly prevails of allowing the blister to remain on for twelve or even twenty-four hours; a mode of proceeding totally useless, and constantly injurious.

Dr. Leahy, the learned Professor of the Practice of Medicine in the School of Physic in Ireland, has long inveighed against this practice. His mode is to remove the blister as soon as decided pain is produced, although the part be not vesicated. Simple dressings are then applied; and free vesication subsequently occurs; and in the majority of cases none of the distressing effects alluded to are produced. We can speak from our own experience of the superior efficacy of this mode, and feel strongly disposed to believe that were it more constantly pursued, we would see fewer cases of the aggravation of internal disease from the use of blisters.

These views are also much insisted on by M. Bretonneau, in his *Traité de la Diphtérie*. His mode of using blisters is peculiarly elegant, being founded on the experiments of Robiquet, which show that the vesicating principle is soluble in fatty substances. A piece of extremely thin paper is inserted between the blister and skin, through which of course the oily solution penetrates. Many of the inconveniences of the common mode of blistering are avoided, such as the long-continued irritation that portions of the cantharides produce by sticking to the part; the unsightly marks which blisters leave, &c.: and M. Bretonneau states that during six years' practice in his hospital, there did not occur a single case of ischuria after blistering performed in this way.

Some practitioners, particularly on the continent, prefer applying blisters always at some distance from the seat of disease; in this way, according to their opinion, avoiding the danger of direct stimulation. Facts are still wanting to enable us finally to determine on the relative merits of these two modes of proceeding; but if the use of a blister over a part affected with acute inflammation is avoided until its capillary irritation has been modified by antiphlogistic treatment, we believe that the practice will generally be found safe.

The use of the tartar emetic ointment, as recommended by Jenner, has now become very common. In some cases, however, it is productive of great distress, in consequence of the formation of large and angry pustules; a circumstance in most cases arising from the use of too great a quan-

tity of the salt in forming the ointment. A drachm to the ounce of lard is the usual proportion; but if we employ a diminished quantity, the remedy will act much better, and frequently with little or no distress to the patient. From a scruple to half a drachm of the salt, finely pulverized, is generally sufficient; and in this way an extensive eruption of minute pustules will be produced, from which we have never seen any unpleasant consequences to follow. An extraordinary effect of this mode of counter-irritation has been several times observed, namely, the supervention of violent irritation about the parts of generation. At first it was supposed that the irritating substance was directly conveyed to the parts by means of the patient's hands; but this opinion is untenable, as the eruption has occurred in cases where the greatest caution was used to prevent any direct conveyance of the ointment to the genitals. This circumstance is noted by Dr. Mackintosh, in his *Practice of Physic*; and both Dr. Graves and the writer of this article have had frequent opportunities of observing it in the Meath Hospital. In a case which occurred in private practice, the inflammation about the genitals in a young female was so severe as to threaten mortification. Another unpleasant result of this mode of counter-irritation is the occurrence of violent and obstinate vomiting, particularly where the ointment has been rubbed over the epigastric region.

We shall now proceed to consider the use of external revulsion in cases of visceral disease. Authors appear to agree as to the impropriety of using revulsives in cases of disease of the brain when it is acute, and particularly where bloodletting has not been premised; thus fully bearing out the doctrine which we have endeavoured to support in this article.

In diseases of the brain and spinal marrow, all the different modes of revulsion have been practised with great success. Indeed, with the exception of the first stage of acute irritations, it may be said that revulsives are of the highest utility in all cerebral diseases, whether functional or organic: where coma supervenes, and in chronic affections, the best results often follow this practice. Thus in all the forms of paralysis depending on disease of the brain and spinal marrow, the various revulsives have long been recognised as among our best remedies; and they may be often employed as prophylactics, as in cases where an apoplectic disposition decidedly exists, and where the life of the patient may be prolonged by the timely use of a seton in the neck.

Dr. Jenner, in his letter on the influence of artificial eruptions, speaks in the highest terms of the utility of the tartar emetic ointment in the cure of insanity, declaring that in all his cases (eighteen in number) this treatment succeeded in removing the disease. Dr. Burrows, however, is by no means so sanguine; but states that in cases where insanity has ensued on the subsidence of a cutaneous eruption, or is connected with gastric irritation, this

treatment will ameliorate the symptoms. He prefers the use of the tartar emetic ointment to that of blisters.

In Lallemand's "*Lettres sur l'Encéphale*," a case is recorded highly illustrative of the effects of powerful revulsion under the most unfavourable circumstance. A patient, upwards of sixty years of age, became affected with symptoms of encephalitis, in consequence of an injury of the head. The prominent symptoms were stupor, paralysis with convulsions of the right arm, embarrassment of speech, and loss of memory. The circumstance of the injury of the head being unknown to his medical attendants, the case was considered as an example of idiopathic fever, until the tenth day, when the patient was seen by M. Lallemand for the first time. The patient had then frequent and long-continued fainting fits; the limbs on the right side were contracted, with complete paralysis of sensation; the eyelids closed, the eyes divergent and insensible to light; there was complete loss of hearing and intelligence; the body was covered with a cold sweat; the respiration frequent and stertorous; and the pulse imperceptible. In this desperate state, Lallemand applied boiling water to the legs of the patient. The first application produced a sudden motion of the whole body; the left arm was agitated, the eyelids were raised, and the pulse became perceptible in the arm. In the course of half an hour the boiling water was applied to the thighs with still more remarkable effects: the face became red, and the pulse full and frequent. Ice was now applied to the head, and in two hours the sensibility was so much restored that the patient frequently attempted to remove the cold application. Under this treatment, with the occasional application of a few leeches to the head, the patient was nearly restored in the course of eight days; and in two months all paralysis had disappeared. The eschars produced by the boiling water were very deep, and suppurated abundantly, seven weeks elapsing before cicatrization took place. Dr. Mackintosh, in his *Practice of Physic*, details a case of severe cerebral affection in fever, where the best results followed a similar practice. In this case, however, neither paralysis nor coma had taken place.

In the employment of revulsives in diseases of the brain, it appears most proper to select for the place of stimulation some part remote from the cranium. In this way the action of the revulsive can be powerfully assisted by the application of cold to the head, as by the use of ice, or, what is still better, the cold affusion, used in the manner directed by Dr. Abercrombie.

We may here notice the practice of counter-irritation along the spinal column, as proposed by Mr. Teale for the cure of hysterical affections; and which, according to him, has been followed by the best effects. It would appear, however, that as yet a sufficient number of observations has not been made to establish the pathological views on which this practice is founded. Doubtless, cases of spinal irritation do occur

where the use of revulsion may be followed by the best results. In veterinary practice we have known good effects obtained, in cases of tetanus, by the use of severe counter-irritation along the spinal column.

In diseases of the respiratory organs, whether of the mucous membrane, parenchyma, or serous investment, revulsions have long been employed by physicians. The same principles which guide us in the use of revulsives in diseases of the brain are found to apply here:—improper in the acute stage, and even dangerous when the irritation has not been reduced by antiphlogistic measures, they are found generally of the highest utility in cases where the lancet has been used, and where the inflammation is of an asthenic or chronic character. In simple acute laryngitis, the best authors agree as to the impropriety of using blisters to the anterior portion of the neck. Guersent and Porter express themselves most strongly on this subject; the former, however, admitting that they may be useful in the *asthenic croup*; but he prefers employing them at a distance from the affected part. Indeed, there are few diseases where so much caution should be used in any mode of treatment which would have a chance of increasing irritation; as we know that a momentary spasm of the glottis may suddenly extinguish life. In an irritable patient, then, we must be extremely cautious in the employment of the revulsive mode. But in chronic laryngitis we find the best effects from counter-irritation in the neighbourhood of the part; repeated blistering, frictions with the tartar emetic ointment, and the use of the seton, being among our most successful modes of treatment in this obstinate disease.

The good effects of severe counter-irritation in a case of chronic laryngitis of long standing, and which threatened the life of the patient, were strikingly exemplified some time ago in the Meath Hospital. The symptoms were extremely urgent, and were not alleviated by local bleeding. Two blisters, of about two inches wide and five in length, were applied along the course of the sterno-mastoid muscles, and the vesicated surface sprinkled with finely powdered tartar emetic. A most severe counter-irritation was thus produced; the patient suffered extremely; but the laryngitis was completely removed, and we believe the cure was permanent.

In diseases of the lungs we find the same general principles equally to apply. We have seen many instances where the symptoms of acute pneumonia or pleuritis were clearly aggravated by the empirical use of blisters; but in the second stage of acute bronchitis, in most of the forms of chronic catarrh, in whooping-cough, in hepatizations, or passive congestions of the lung, and in the advanced stages of pleurisy, the revulsive practice is almost always followed by the best effects. The utility of the same practice in cases of chronic phthisis is so well known that we need not comment on it here.

One of the most distressing circumstances in the progress of a case of hypertrophy of the

heart, is the occasional increase of palpitations and præcordial distress: this is frequently relieved by the application of a blister; a circumstance which, combined with our knowledge of the efficacy of local bleeding in similar cases, adds greatly to the probable correctness of Andral's opinion, that in many such cases the cause of these symptoms is an irritation of the internal membrane of the heart.

In the examination of the effect of external revulsion in diseases of the digestive system, we must consider its employment in affections of the mucous and serous membranes. Broussais, in his *Phlegmasies Chroniques*, endeavours to establish that in inflammations of the mucous membrane, both acute and chronic, such practice is always improper, and that those cases of altered function which are relieved by vesication of the surface, are not in reality examples of inflammation of the mucous membrane. This assertion, however, appears too general; both analogy and experience lead to the conclusion that in acute gastro-enteritis the use of revulsives to the surface will be probably followed by bad consequences, but this is far from applying to the chronic affections, where we know that this practice is constantly productive of the best effects. In scirrhus of the stomach, in chronic diarrhœa, or dysentery, in tabes mesenterica, the great utility of external revulsives has long been established; so that, as far as the affections of the gastro-intestinal mucous membrane are concerned, the general principle which we have been endeavouring to establish is also borne out. In point of fact, Broussais does not seem to be sufficiently aware of the utility of stimulation in the internal as well the external chronic inflammations.

The same conclusions are to be drawn in the case of peritonitis. In the violent acute disease, and particularly before general and local bleeding has been freely premised, a blister often aggravates the symptoms; but in the chronic and asthenic forms of the disease, as in the low puerperal peritonitis described by Dr. Cusack and Dr. Gooch, it is found that blistering the abdomen is often followed by the happiest results.

We are indebted to Mr. Crampton for the particulars of a remarkable case of chronic abdominal disease, where a powerful and extensive revulsion was followed by the greatest relief of symptoms. A lady, who had laboured under ovarian disease, with severe symptoms of chronic inflammation of the mucous membrane of the intestines, as evinced by diarrhœa, bloody stools, tenderness of the abdomen, and emaciation, was severely burned in consequence of her clothes taking fire; the neck, arms, and throat were the seats of the injury. On recovering from this accident, the greatest improvement became manifest in her general health; the bowels became regular, nutrition went on, the ovarian enlargement subsided greatly, and the patient has since enjoyed a state of good health which could never have been anticipated.

For information on the employment of re-

vulsives in diseases of the urinary organs, and in affections of the generative system, we beg to refer to the articles on these subjects. We shall merely remark that many practitioners avoid the application of a blister to the loins in acute irritations of the kidney, such as nephritis or renal calculus, fearing that strangury would be certainly produced. We believe that this fear is quite unfounded, and that the application of a blister to the loins may be constantly had recourse to with the best effect in these cases. There is no evidence to shew that strangury is more liable to be produced by a blister to the loins than to any other part; but it is almost certain that in the majority of cases the strangury is owing to the mismanagement of the blister.

The last class of affections in which we shall examine the utility of revulsives is that of fevers. Louis has investigated this subject with his usual precision, by comparing the effects of blisters in cases of typhoid fever which have proved fatal, and in those where recovery took place. In the first class, he found that the mean duration of the disease was not altered by the practice; that no effect, either upon the temperature of the body, or the state of the circulation, could be connected with the action of the blister; that in two-thirds of the cases the cerebral functions underwent no alteration; and that in the remaining third but a very small proportion presented alleviation of symptoms. The examination of the digestive functions shewed the same results, so that he concludes that in his cases the action of blisters produced no effect, either on the duration of the disease, or the progress of its symptoms. In those cases where recovery took place, he concludes that blisters had no appreciable effect on the disease, and that they perhaps but slightly retarded the convalescence: so that, connecting these facts with the inconvenience of blisters, he holds that they should be banished from the treatment of typhoid fever.

It is to be remarked, however, that in these cases the blisters were applied, not over the splanchnic cavities, but to the extremities; the conclusions therefore only apply to this particular mode, and afford no reason for banishing the use of blisters from the treatment of typhoid fever. We know, indeed, from experience, that in certain cases their utility is most remarkable. In the majority of cases of fever the attention of the physician is principally directed to remove inflammation or congestions in some of the great cavities, and revulsion is often the only mode left to him of accomplishing his object. Thus in certain cases of coma occurring at an advanced stage of the disease, the greatest advantage is derived from the application of a blister to the head. In catarrhal fever, when copious secretion sets in, and the powers of life are low, we have found, in the Meath Hospital, the most striking advantage from free blistering on the chest, and have never seen any unpleasant result. So, also, where pneumonia occurs in the course of a typhoid fever, the application

of a blister, after depletory measures have been used, or where the skin is cool and the powers of reaction are slight, has been frequently successful in ameliorating or removing the disease. Our experience in the Meath Hospital leads us to the conclusion that, as far as the utility of blisters in fever is concerned, we may use them for the relief of the secondary inflammations which occur, with great benefit; always, however, acting on the principles which we have maintained in this article.

(*William Stokes.*)

DERIVATIVES. See DERIVATION.

DETERMINATION OF BLOOD.—This term is used to denote an afflux of blood to a particular part, impelled by increased arterial action. When such afflux exists without any obvious increase of impelling power, it is denominated congestion. Both may coexist; that is, congestion may first take place, and, on vascular action becoming excited, determination may ensue, increasing still further the congestion, and superadding those lesions which determination more especially occasions; or congestion may be produced by determination, and may continue after this has subsided.

Congestion is more or less a passive condition; determination is always active. On determination subsiding, congestion may yield to the sanative powers of the constitution, unaided by medicine; or it may continue, and require special means to be resorted to for its removal.

When congestion takes place in any part, its origin must be ascribed to some weakness of the vessels of the part, causing them to yield to the ordinary force of circulation; in determination, vessels which would resist the ordinary force of vascular impulse may become over-distended by increase of momentum; yet here there must be some relative weakness to cause them to give way. The relative facility of yielding to distension, thence arising, whether natural or acquired, may influence the locality of the determination; or this may be directed by various sympathies and nervous connexions, and also by some peculiar property of the stimulus which produces the vascular excitement. Some determinations are solely attributable to nervous sympathy, as those which occur in health under mental emotion. In blushing, for instance, there is obvious determination of blood to the cheeks; nay, when intense, to the whole neck and breast. Similar instances might be adduced, but it is needless to advert to them, morbid determination being the condition under consideration. It is, perhaps, from the influence of nerves in giving direction to local determination, that certain stimulants determine blood more particularly to certain organs, some causing blood to flow more particularly to the brain, while others tend to induce vascular fulness in the liver or in other parts.

Determination admits of being inferred from the symptoms which denote it, these varying according to its seat, and to the func-

tions of the part affected; the fact of its occurrence is amply verified by necroscopic examination when opportunity for this is afforded.

As determination may ensue upon congestions, so may it be followed by, or pass into, inflammation, of which indeed it seems to be an essential constituent. But as congestion does not necessarily produce determination, neither does determination pass necessarily into inflammation. Such determination, though an advance towards inflammation, and prone to pass into it, may yet exist so as to constitute formidable disease, and thus continue for an indefinite time without inflammation ensuing. Congestion of blood, kept up by determination, may take place in the brain, lungs, liver, or any other organ, without evincing the peculiar phenomena of inflammation, and may, in each, cause appropriate disturbance of function to a formidable extent. When such cases are treated as subordinate degrees of inflammation they yield readily, and to practice less active than inflammation would require; but when, from the absence of purely inflammatory symptoms, they are referred to debility or some unexplained nervous derangement, and are in consequence treated with stimulants, they rather become aroused into inflammatory action, which perhaps is in such cases the happier result, as they are then treated aright; or they lead insidiously to disorganisation of structure, thus laying the foundation of some of the most irremediable of human diseases; for though medicine can do much to correct functional disturbance, and can to a certain extent promote even restoration of structure where the organic change has been slight, it cannot supply new organs, nor give to a scirrhous and disorganised mass the efficient energies of a healthy viscus. On which account the study of determinations, and of the causes both local and constitutional from which they arise, is of the highest importance, as a just conception of their nature and tendencies may enable the practitioner to avert, by very gentle means, lesions of the frame which, if suffered to advance to a certain extent, the utmost efforts of his art may be unable to remedy. In this instance the maxim "principiis obsta" cannot be too forcibly inculcated. The special determinations, however, belong not to this place; they either constitute, or are connected with, special diseases; under each of which they will of course be found respectively noticed.

(Edward Barlow.)

DIABETES. Some of the earlier writers on medicine have given different names to the disease which forms the subject of the present article. Thus it has been styled *diarrhœa urinosa*, *hydrops ad matulam*, *hyderus*, *dipsacus*, *morbus sitibundus*, *fluxus urinæ*, *nimia uriniæ profusio*, *polyuria*.

Owing to the excessive secretion and frequent evacuation of urine in this affection, it has also been named *diabetes*, from the Greek verb *διαβαίνω*, which signifies to pass through: and from the circumstance of the urine having

generally a smell of honey, and a sweetish taste, the adjective *mellitus* has been employed to denote this character. M. Renauldin, in an able article on diabetes in the *Dictionnaire des Sciences Médicales*, and afterwards Dr. Prout, insist upon defining diabetes to be "a disease in which a saccharine state of the urine is the characteristic symptom," although the etymological import of the word extends to any affection accompanied with an immoderate discharge of the urinary secretion. It is not the best logic, however, to found a definition upon an hypothesis; and as there are several instances on record of patients dying under all the symptoms of diabetes, yet without the slightest indication of sugar in the urine, we cannot fairly dispose of these by assuming its presence in the latent state; for it may be latent in the most incidental case of hysterical enuresis, and then how could Drs. Renauldin and Prout refuse the name of diabetes to this fortuitous symptom? We make no unfair extension of their hypothesis; and to speak truth, chemists have as yet discovered no good test of either sugar or urea when in small quantities; nor, were they perfect, ought medical men to take their results as defining disease. Diabetes, like every other malady, must not be defined by symptom *a* or symptom *b*, but by the aggregate and concatenation of the leading symptoms. Of these, immoderate excretion of urine and cachectic emaciation seem much more characteristic than sweetness, however general, and which it must be allowed is at times undistinguishable. All the modes of analysis hitherto devised for indicating the vegetable and animal oxides are extremely imperfect, especially when these are intermingled with other oxides; and the most delicate of them seem to consist, not in demonstrating the presence of these oxides themselves, but in generating new bodies, which are supposed to result from the re-union of the primary elements into which the former had been supposed to be reduced by the operation. In every genuine case of diabetes, however, Dr. Prout contends that a careful analysis of the urine will detect more or less saccharine matter, even when the sensible qualities of this fluid fail to point out the least saccharine impregnation; for, as Dr. Watt has observed, sugar may be present, but so covered with other substances that it cannot be at all detected by the taste.

Hippocrates seems to have been altogether ignorant of this affection, for we find no allusion to it in any of his writings; but Celsus, Galen, Aretæus, and Alexander Trallianus, have left us histories of diabetes. The description of it given by Aretæus is particularly clear and minute. These writers, however, looked upon the disease simply as an increased flow of urine, and as proceeding from renal irritation. Galen thought that this affection bore the same relation to the kidneys and bladder as the lientery does to the stomach and intestines. Aretæus considered it a colligation of the flesh and limbs into urine. He has observed,

“ that it has the usual urinary course, *namely*, the kidneys and bladder, for the patients never cease voiding their urine, but as from the openings of the water-ducts, the stream is perpetual.” Trallianus adopted much the same view of the complaint. No further light seems to have been thrown upon the nature of diabetes until the time of Willis, who first pointed out the saccharine taste of diabetic urine. “ The subjects of this affection,” that able writer has remarked, “ pass more urine than the whole quantity of fluids taken into the body; they have besides a constant thirst, and a slow kind of hectic fever always on them. It is very far from true, as some authors affirm, of the drink being again discharged with little or no alteration, for the urine in all that I have seen, (and I believe it will universally be the case,) differed not only from their drink, and from every other fluid in the animal body, but was like as if it had been mixed with honey or with sugar, and had a wonderfully sweet taste.” Willis has ably investigated the principal phenomena of the complaint, and endeavoured to point out its seat; but he confesses his ignorance of its causes and true nature. He has enumerated a variety of remedies adapted to the removal of the disease, but he admits the difficulty of ascertaining what are the true purposes which ought to be kept in view in its cure. At the commencement of the diabetic tendency, he found a cure by no means difficult; but in the advanced stage of the disease such a result very seldom occurred. This he supposed was owing to the crisis of the blood being only a little loosened, and thus readily brought back again into its former state; but when so much dissolved as to have most of its parts separated from each other, it could seldom, if ever, be restored. The treatise of Willis upon diabetes has been translated by Dr. Latham, and published in his “ Facts and Opinions” concerning that affection.

Sydenham, who lived for several years after Willis, and was cotemporary with him, has not alluded to the sweetness of the urine in diabetes, though he has left an extremely accurate description of its causes and the indications of its cure. We shall not attempt to account for this silence of Sydenham, by supposing, with Dr. Latham, that it arose from any other cause than mere inadvertency. Experiment was then but a new branch of science; and the practice of tasting the urine of a diabetic patient was probably first adopted by Willis, of all men, from the beginning of time; nor would the practical mind of Sydenham consider the announcement of more importance than if he had been told that the urine of hydrophobia was bitter; for what, in his time, was to be learnt from either? After Sydenham, we meet with notices of this affection in the writings of Cullen and Heberden; and since their time many attempts have been made to elucidate its real nature, and to establish a successful mode of cure. Dr. Rollo, however, strongly roused the attention of the profession to the subject by the

publication and extended circulation of Captain Meredith's case, in which he proposed a new and important plan of treatment. To that author every praise is due for having enabled us to form more correct notions of the nature and cure of this complaint. The names of Cruikshank, Girdlestone, Fothergill, Dobson, Latham, Baillie, Lubbock, Bostock, Wollaston, Warren, Henry, Bardsley, Watt, Satterley, Prout, and Marsh, may be mentioned as those of valuable contributors to the general fund of information which we now possess concerning this formidable malady.

It has been supposed that diabetes is a disease of more common occurrence at the present time than formerly, because we meet with so few notices of the complaint in the writings of authors from Willis to Rollo, compared with the numerous authentic records of diabetic cases since the valuable publication of the latter physician. The fact seems to be that the disease is now better understood, and its symptoms are more generally known, so that not a few cases which would formerly have been classed under the head of phthisis or tabes, are now ascertained to be genuine examples of diabetes. Dr. Storer, of Nottingham, states, in a letter to Dr. Rollo, that he had not seen a single instance of diabetes during sixteen years in which he had the care of an infirmary, containing upon an annual average fifty-two in-patients and three hundred out-patients. In the Manchester Infirmary, diabetic patients not unfrequently present themselves for admission, and it generally falls to the lot of each of the medical officers of that institution to receive several cases under his care during the year. On inquiry, we have found that the same holds true with other extensive public hospitals. In private practice too, instances of this disease are by no means uncommon; for we believe there are few medical men who have a fair share of professional employment, to whom cases of diabetes have not somewhat frequently occurred. Diabetes occurs in early as well as in advanced life. Heberden erroneously supposed that it exclusively attacked the aged and infirm. We have witnessed two instances of this disease in children under six years of age; and Dr. Venables has also recorded several marked cases of infantile diabetes. A very distinct example connected with the process of dentition, and in which the urine was sweet, is related by Morton. More than half of the cases seen by Dr. Watt, and he believed the same observation would hold with regard to all that have been published, occurred between the ages of thirty and forty-five; and of the other half a greater number were below the former of these ages than above the latter. “ Of the whole,” he says, “ the best marked and most rapid in their progress have occurred in the very prime of life, and when the constitution was supposed to be in its full vigour. There is, perhaps, no period of life completely secure from the disease, though few instances have been recorded under the age of puberty. I have met with

one instance in a boy of three years of age. It was most distinctly marked; the urine amounted to six or seven pints daily; the voracious appetite, urgent thirst, and arid skin were very remarkable. He had also phymosis, and afterwards suppression of urine. The disease terminated in a fatal dropsy."

This disease not unfrequently makes its approach insidiously; and it unfortunately happens that the first symptoms are often disregarded, and the complaint is allowed to advance for some time uncontrolled by medicine. The increased flow of urine is merely regarded as the necessary effect of the thirst, and the discovery of the saccharine condition of this fluid is also mostly accidental; but when hectic, emaciation, and debility have supervened, a more strict inquiry into the symptoms is generally instituted, and the real nature of the complaint becomes fully ascertained. The almost constant desire to make water, and the insatiable thirst, particularly during the night, are two most distressing symptoms; the patient being obliged to be supplied with a large quantity of fluid near his bed-side, and having to rise six or seven times or oftener to evacuate the bladder. The urine has a slight straw colour, and sweetish taste, and yields on evaporation a considerable quantity of saccharine extract. The amount of this secretion passed during the twenty-four hours is sometimes very considerable. It has exceeded, in more than one instance, seventy pounds. In the case of Smith, detailed in the writer's "*Hospital Facts and Observations*," thirty-six pints of urine were voided in the course of twenty-four hours; and in that of Johnson, thirty-two pints. The discharge, generally speaking, is less than the liquid ingesta; but it has been found in one or two cases, that the liquid egesta have considerably exceeded the whole amount both of the solid and liquid ingesta. This fact, though denied by some writers, has been satisfactorily established by Dr. Bardsley, who has shewn that the excess of the former cannot be accounted for solely on the supposition of its being derived from a general wasting and diminution of the solid and fluid parts of the system; for in two or three instances during the period in which the register clearly pointed out almost a regular daily excess in the amount of the urine compared with that of the liquids and solids taken, the patients had gained an accession to their weight of many pounds. "To what law or process of the animal economy," the author just named observes, "is the supply of this superabundant quantity of urine to be attributed? Is it derived from cuticular or pulmonary absorption, or from a colliquation of the humours of the body? Each of these modes has been insisted on by different writers." We receive the fact without framing any hypothesis to account for it. The researches of modern physiologists, particularly those of Klapp and Dangerfield, do however render it extremely probable that this superabundant quantity of fluid is absorbed by the lungs from the mois-

ture of the atmosphere. Numerous observations demonstrate that almost every kind of matter in the state of fluid or vapour, introduced into the cells of the lungs, is rapidly absorbed from thence into the circulation, and, generally speaking, presents itself at the kidneys; thus the oil of turpentine manifests itself in the urine within a few minutes; and the amount of these facts goes to prove that there is a free and rapid absorption always taking place on the surface of the lungs. On the other hand absorption through the cuticle, if it exists at all, cannot be demonstrated; while it is admitted by almost every one, that nine-tenths of the copious exhalation of the pulmonary surface, which, according to proportion, must at least be ten times as great as that by the skin, or twenty pounds daily, is constantly in the act of being re-absorbed by the pulmonary surface: and since the avidity of the absorbents is known to be greatly augmented, as in dropsy, by an increased diuresis, while the pulmonary exhalation must be proportionally diminished, it is easy to conceive that the absorption of the fluid excreted from the bronchi will be considerably increased, and thus augment the quantity of fluid egesta above the ingesta. There will, moreover, be absorption of part of the residual air in the lungs, and this will again supply itself from the now moister air brought in from the atmosphere by inspiration, to what extent it is not easy to compute; nor can we reasonably expect that any such computation will correspond very exactly with the weights of the ingesta and body at different times, the means of taking which are often much more fallacious than is generally believed.

The mouth is mostly dry and parched, the taste is perverted, and the secretion of saliva altered; a tough viscid phlegm occupies the fauces; the tongue has a brownish fur on its centre, with florid edges; the gums are soft, spongy, and bleed on the slightest pressure of the tongue against them, being mostly ulcerated about the roots of the teeth; the appetite is usually keen, and sometimes ravenous; uneasiness about the stomach and bowels is experienced, chiefly after eating, and the contents of the former are not unfrequently discharged in an acid and undigested state; the skin is rough, dry, and unperspirable; the bowels are generally costive; there is frequent pain and a constant sense of aching and weakness across the region of the kidneys, particularly on the least exertion; itching and excretion, with phymosis of the prepuce, occurs in males, and an uneasiness about the meatus urinarius in females; the semen is discharged involuntarily, chiefly after voiding urine; and there is a total loss of the sexual propensities. Headach, impaired hearing, giddiness, and indistinct vision, are mostly present. When these symptoms continue only for a short time, they are followed by serious disturbance in the general health, such as extreme debility, languor, and great emaciation. The pulse, which is at first quicker than natural, becomes

slow and feeble. The legs and ancles swell; and a tickling cough, with shooting pains in the chest, mostly harasses the unfortunate patient in the last stage of his disorder. The mind is extremely peevish, irritable, and somewhat suspicious; the spirits are low and depressed.

By attention to the above symptoms, it is not, we conceive, difficult to distinguish diabetes from every other disease. There may be a preternatural discharge of urine in other affections; but *in this only* is a saccharine condition of that secretion present. Most of the more severe symptoms of this disease are attributable to the immense amount of solid matter which is constantly draining off from the body; and indeed some diabetic patients seem to sink merely from the debility occasioned by the continued secretion of an unnatural quantity of urine containing so large a proportion of animal extractive matter. The appetite, though voracious, is inadequate to the supply of nourishment sufficient to balance the immense and rapid waste which is daily taking place. "The loss of so much matter," Dr. Elliotson observes, "from the system, sufficiently explains the hunger, the feeling of emptiness and sinking in the stomach, the emaciation, debility, anaphrodisia, coldness of the legs, pain both of them and of the loins, the depression of spirits, &c. without attributing the disease to the stomach or the kidneys exclusively. The excessive escape of fluid, or when this does not take place, the feverishness, equally explains the thirst and dryness of the skin."

It will be shewn, when we come to the consideration of the pathology of diabetes, that it is mostly complicated with disease in some important organs. Dr. Willan observed that he never met with a confirmed case of this disease in which there was not some considerable disorder of the constitution, or a defect in some organ essential to life. Our experience leads us to hold this remark as not far removed from truth; although it may be said that the constitutional affections are more frequently the effects of the progress of diabetes, than the concomitants of its commencement. Pulmonic affections, we know, not unfrequently precede or accompany diabetes. Dr. Bardsley remarks that he scarcely recollects an instance of the disease where a slight affection of the chest did not more or less prevail. In several instances, too, on record, a connexion between phthisis pulmonalis and diabetes is strikingly marked. The phthisical symptoms existing previously to the attack of the latter disorder are often suspended by its influence; but on the partial removal of the diabetic complaint, the tubercles pass rapidly through their several stages, and the patient's sufferings are terminated by death. A similar suspension of the progress of disease in the lungs is sometimes noticed in females who become pregnant whilst labouring under the symptoms of confirmed phthisis. The cough, expectoration, and hectic fever,

almost entirely disappear, pregnancy advances, and labour ensues; when in the course of a few weeks (sometimes days) the pulmonary symptoms return with aggravated severity, the strength rapidly declines, and life is soon extinct. In the more confirmed cases of this disease which have fallen under our notice, there has been generally present a teasing tickling cough, sometimes attended with purulent expectoration, and mostly with dyspnoea, and shooting pains in the chest.

The most common exciting causes have been, according to our experience, frequent exposure of the body to sudden alternations of heat and cold, and an indulgence in copious draughts of cold fluid when the system has been over-heated by labour or exercise. In twelve cases that have come under our observation, the patients have attributed their ailment to one of these causes; hence, we have observed this affection chiefly amongst that class of artisans whose occupations expose them to sudden changes of temperature, or who reside in damp and low situations. The intemperate use of spirituous liquors, poor living, and distress of mind not unfrequently operate, too, in the production of this disorder. It is a curious analogous fact, that dogs and rabbits fed upon rye-meal, or on decoctions of wheaten flour, have a species of diabetes produced; as has been ascertained by the experiments of Dr. Krimer of Hallé. The secretion of urine becomes much increased; the urea and uric acid almost or altogether disappear; the animal becomes emaciated; and, in place of sugar, the urine is found loaded with albumen and mucus. The origin of the complaint has been traced by some patients to sleeping out the whole of the night in the open air, in a state of intoxication. The subjects of this disease have been mostly liable to profuse sweating upon any ordinary exertion, and at such times have been accustomed to abate thirst by drinking freely of cold liquids, or by eating immoderately of acid fruits, thus suddenly checking perspiration. The state of the mind seems to have a more intimate connexion with this affection than has been generally supposed. In several cases on record, mental anxiety and distress have been assigned as its chief cause. Indeed, a temporary diabetes insipidus is a very ordinary effect of such a state, and the despondency of mind throughout the disease is distinctly alluded to by Aretæus, and by many other eminent writers.

We have not observed the characteristic odour, compared to that of hay, from the persons of diabetic patients, to which Dr. Latham has particularly alluded. It has been supposed that the phymosis before noticed as a symptom of diabetes, proceeds from the extreme sensibility of the urethra, which subjects it to the general irritation of the system so frequently present in the complaint, and thus renders it morbidly sensible to the stimulus of the urinous fluid.

With respect to the emaciation, it may be

remarked that Dr. Lubbock considered it a leading circumstance in this affection; for in his experience it came on slowly, the subject of it not perceiving much deviation from health. "I have at this time," he observes, "two patients who, excepting a slight and very gradual wasting of the body, some increase of thirst, with occasional uneasy sensations about the stomach, to which may be added, feebleness of sight at times, and an habitual tendency to phymosis, possess that degree of apparent health and strength that would mislead a common observer." He conceived that the emaciation claimed the first attention of the physician; as without the removal of this symptom, neither the reduction of the urine, the alteration of its quality, nor the appearance of considerable remaining muscular power, could prove that the disease had yielded to any curative process.

Diabetes frequently occurs in the scrofulous habit, but is not confined to it alone. Some authors are of opinion that the disease may be hereditary; thus Dr. Prout observes, he cannot doubt but that a predisposition or tendency to this affection exists in some families, as he has witnessed four distinct instances of such a circumstance. The first was that of a young man whose mother and uncle had died of the disease; the second was that of a lady about fifty years of age, whose brother or sister had sunk under the complaint; the third was that of a girl about ten years of age, whose father two or three years before had died of the same affection; the fourth instance was that of a gentleman, aged fifty-four, who died of this affection, and whose father had laboured under the same disease for several years. Dr. Storer has noticed the occurrence of three cases of diabetes in one family, in the persons of a brother, sister, and her daughter. The father of the two elder died of that affection. In another instance, related by Mr. Leigh Thomas, three brothers in one family laboured under diabetes. Morton has also alluded to the hereditary nature of the disease. We believe that a tendency to it is occasionally inherited; but further experience and a more extended inquiry on this point are necessary, before diabetes can be correctly arranged like scrofula, phthisis, mania, and apoplexy, under the head of *family* diseases; for in not a few instances no hereditary origin can be traced. Yet, it must be observed, that even of these diseases, no two have exactly the same hereditary influence, nor are any two of them modified exactly in the same degree by circumstances; while all of them are seen to spring up every day in cases where no hereditary taint can be suspected; so that, if a comparatively rare disease like diabetes has been found by Dr. Prout hereditary in four times out of twenty, it seems fair to admit, that, as in the case of a great many other diseases, its supervention is often greatly favoured, if not determined, by hereditary conformation; and little more can be said even of scrofula or mania.

Various opinions have been formed con-

cerning the *proximate cause* of diabetes. Thus some authors of eminence, like Mead, have supposed that it depends on a "morbid state of the liver and bile;" some, as Dobson, Home, Cullen, and Rollo, believed that it proceeds from a defect in the assimilatory organs; whilst others, as Dupuytren and The-nard, have attributed the principal phenomena of the disease to a "morbid action of the kidneys." Dr. Baillie also thought it probable that diabetes was owing to a deranged action of the secretory structure of the kidneys, by which the blood there is disposed to new combinations; and that the effect of these combinations was the production of a saccharine matter. He at the same time imagined that the chyle might be so imperfectly formed as to cause the blood to be more readily changed into a saccharine substance by the action of the kidney. The ingenious author of the *Zoonomia* conceived that diabetes was produced by a retrograde motion of the absorbent vessels, owing to which chyle passed from the lacteal into the lymphatics of the kidneys or the bladder. Cawley thought that in this disease the tubuli uriniferi were enlarged or relaxed, by which the chyle escaped into the urine. Willis concluded that diabetes depended upon a dyscrasy or intemperament of the blood, resulting from a morbid action of the assimilating powers. "Thus," he observes, "diabetes is rather and more immediately an affection of the blood than of the kidneys, and it thence has its origin, inasmuch as the mass of blood becomes, as it were, melted down, and is too copiously dissolved into a state of serosity, which indeed is very manifest from the quantity of urine so immensely increased, which cannot arise from any other cause than from this solution and waste of the blood: whence also the blood, which is left in the body, the serum being thus copiously abstracted from it, becomes much thicker and more apt to coagulate, as we may infer from the quick and laborious pulse; for on that account the heart acts with more rapidity, that the blood, which it thus agitates more than is usual, may be preserved from coagulating." The two hypotheses, however, which refer the seat of the disease to a morbid action of the stomach, and a morbid condition of the kidneys, have been most generally adopted. "Were I to give a theory," says Dr. Home, "to explain the nature and symptoms of this wonderful disease, I would say that it arises from a defect of the animal or assimilatory process, by which the aliment is converted into the nature of our body."

Dr. Home considered the excess or defect of this process as the source of many disorders. Rollo, too, observes that the immediate cause of diabetes mellitus is a morbid condition of the stomach, forming or evolving from vegetable substances saccharine matter, which is quickly separated as a foreign body by the kidneys. "But, to be more particular," he continues, "we allege that this disease consists in an increased morbid action of the

stomach, with too great a secretion, and an alteration in the quality of the gastric fluid, producing saccharine matter by a decomposition of the vegetable substances taken in with the food, which remains unchanged." It has been urged, and with reason, as a very serious objection to the theory of Dr. Rollo, that no sugar has been detected in the blood of diabetic patients; a fact which we shall shortly shew to be established by the interesting experiments of Wollaston, Marcet, Nicholas, Gueudeville, Thenard, Bostock, Vauquelin, Segalas, and other able chemists.

In several instances of the disease which have come under our own examination, there certainly has been ample evidence of preceding stomach derangement; but admitting that the stomach is generally in a state of morbid activity, as may be inferred from the increased and almost insatiable appetite which accompanies the disease, still we are ignorant of the particular condition of the *primæ viæ* which leads them to favour the extraction of sugar. Dr. Henry thinks that the theory must be modified by assuming that the blood which reaches the kidneys contains the elements of sugar, and is deficient in those of urea. He supposes, however, that it is necessary to a just pathology of the disease that some morbid condition of the kidneys should be admitted, though of a kind which has not yet been explained by anatomical investigation.

Dr. Mason Good conceived that a morbid and highly irritable state of the kidneys was sufficient to account for every other derangement that marks the progress of the disease. He saw no necessity for supposing an idiopathic affection of any other part, whether the stomach or the nerves, the digestive or the assimilating powers; but decides, from the attention which he has paid to the nature of diabetes, both in theory and practice, that the whole of its phenomena may be traced to renal mischief, and consequently that it is a far less complicated affection than has hitherto been supposed. That the kidneys are frequently in a state of irritation is evident from the pain, heat, and weakness, experienced in those organs, and the augmented urinary secretion.

Dr. Lubbock seems to have noticed the coincidence of the parched and dry skin with the saccharine quality of the urine, from which he was induced to believe that in this affection the want of perspiration or excretion from the surface is connected with sweetness of the urinary fluid; and this belief was supported by an examination of the nature of the perspirable fluids, and of the component parts of saccharine matter. On this view he has formed a theory of diabetes. "It has been proved," he observes, "that sugar is, for the most part, composed of carbon, oxygen, and hydrogen, united in a certain ratio; and it appears, by the experiments of Cruikshank and Abernethy, that, besides the occasional aqueous fluid discharged daily from the surface of the body, about three gallons of carbonic acid are also lost to the system by the per-

spirable matter. Now supposing, as happens in diabetes, this perspirable excretion, or carbonic acid, is suppressed and retained in the system, it is probable that the carbon and oxygen of the acid so retained, by entering into a due combination with some portion of the hydrogen of the animal body, may tend to the production of the saccharine matter of the urine; and as the carbonic acid is the general product of the vegetable world, it would follow that its retention in the animal body may produce the phenomena of the defective animalization, characterising diabetes as exhibited in the formation of sugar."

Dr. Latham has broached a very fanciful hypothesis concerning the proximate cause of diabetes, founded chiefly on the dyscrasy of Willis, and the selecting power of the kidney. As it is impossible to condense it, we shall be satisfied with merely mentioning that it is quite as untenable as some of its ancient predecessors. Dr. Ferriar has also given a very vague opinion in explanation of the phenomena of this disease. He supposes that if the extreme vessels should from any cause take on a morbid action, and, instead of supplying nutritious matter, should form a substance which cannot be applied to renew the waste of the system, the diseased secretion must either accumulate in the intermediate passages of the circulation, where it would produce hectic fever, (by absorption,) and subsequently death; or it must be carried off by some of the excretories, to which its stimulus must cause an increased determination of fluids. Thus he conceives to be precisely the case in diabetes. He afterwards refers the secretion of saccharine matter in the kidneys to metastasis, and supposes it to arrive there by the circuit of anastomosing branches.

In a reply to some strictures of the reviewer in the *Medical and Physical Journal*, on a case of diabetes related in the *Sixth Volume of the Edinburgh Medical and Surgical Journal*, the editor observes that the discharge in diabetes may be a diversion of a profuse secretion from the skin to the kidneys; that besides being morbidly profuse, it is, like other secretions, susceptible of a change, and may become stimulating even to the skin itself, and consequently much more so to the kidney, where it then must certainly act as a foreign body exciting the organ to extraordinary action; and that in the enlarged and excited state of the vessels of the kidney, time is not allowed for the secretion of urine to be perfect, and that chyle may pass off with it, or it may be called the urine of digestion or of the chyle, which in the healthy state is passed two or three hours after a meal, and cannot be considered a natural secretion. M. Dezcimeris supposes that the proximate cause or essence of diabetes consists in irritation of the kidneys; that this irritation is rarely primitive, being mostly the result of chronic gastritis. In the course of the latter affection there is extreme thirst; the patient drinks freely, and the urine is in proportion: this

state is prolonged; the activity of the kidneys increases every day at the expense of that of the other excretory organs; they remove from the body those fluids which require constant renewal, and thus again contribute to augment the thirst.

Such are only a few of the hypotheses which have been framed to explain the nature of diabetes; but they are sufficiently numerous to shew how little is really known respecting it. One great cause of this diversity of opinion is, as we shall hereafter shew, the defective aid afforded by pathological investigation. "Pathological anatomy," as the late celebrated Laennec justly remarked, "is incontrovertibly the surest guide of the physician, either in the recognition of maladies, or in the cure of those which are susceptible of cure." We have no theory of our own to propose; but from all the attention which we have been able to pay to the subject, and from what we have seen of the disease itself, it appears to us proper to admit that the natural and healthy action of *both the stomach and kidneys* is materially disturbed; the former perhaps primarily, and the latter secondarily; and that the *dry and unperpirable condition of the skin* is much more intimately connected with its production than is generally supposed: this diabetes is an affection not proceeding from a morbid action of one particular part, but of several important organs. This statement is sanctioned by facts, and seems to derive confirmation from the symptoms, the remote causes, the effects, and analogy with other diseases. We have used the word *perhaps* in the above allusion to the primary derangement of the stomach, because in several diabetic cases on record the increased secretion of urine preceded every other symptom. So constant is the sympathy between the kidney and the stomach, that Sydenham himself has declared there is no other mean of distinguishing between nephritis and hzmorrhoe than the expression of this sympathy in the former case by vomiting. It is possible that increased action of the kidney may very early, though not primarily, call the stomach into sympathy. In a communication from our friend Dr. Miligan of Edinburgh, he remarks that the famous Peter Petit asks, in his Commentary upon Aretæus, if the excess of sugar is furnished by an error of the digestive process, why does it not pass off by the bowels, the lungs, or the skin, as well as by the kidney? "But this very profound and philosophical question is very early answered by the practical observation, that we know, as a matter of experience, that any excess of fluid introduced into the circulation does not readily pass off by the skin, lungs, or bowels, but seems naturally and designedly in almost every instance to be carried away by the route of the kidneys and urinary passages; and that, therefore, we have a right to expect that it will be so here. But it does not follow from this that the *first* profusion of urine in diabetes is saccharine, nor yet that the initial steps of the malady are to

be traced to errors in the action of the stomach or the skin: nay, so great is the number of persons who at all times labour under disease of the two latter organs, that on diabetes commencing we should require very strong proofs that some aggravation of the morbid condition of these parts, unconnected with any suddenly inter-posed cause, took place at the time, before we admitted that they were instrumental in producing diabetes."

We must next allude to the *prognosis* to be generally formed in this malady. It has been satisfactorily proved that a saccharine condition of the urine may exist during several years without the general health being materially affected, or the power of the stomach much impaired. Diabetic patients, whose mode of living has been on the whole temperate, have been known, in not a few instances, to reach advanced age. It is in those cases, chiefly, where the constitution has been previously injured by long-continued and frequent irregularities that the disease under consideration proves rapidly fatal. Whilst the digestive organs continue to perform their functions with tolerable vigour, the supply of nutritious matter will be found nearly adequate to balance the waste which is daily taking place from the increased quantity of the urinary secretion. We have at this time two diabetic patients, who, excepting some increase of thirst and urinary discharge, and occasional disturbance of the digestive organs, enjoy a fair share of apparent health and strength, and are fully equal to the various exertions that devolve upon them in the ordinary intercourse of life. The disease, however, ought to be viewed with much concern, for it is too apt to pursue its fatal progress in defiance of all the resources of our art. It is difficult to establish a perfect cure when the characteristic symptoms of the affection have been once fairly developed. We find that even Aretæus alluded to its fatal nature. He has remarked, "that the disease is chronic, and generated by length of time; but short is the life of man when its establishment is fully completed." The perfect recovery of the patient depends upon the removal, not merely of one, but of the whole of the symptoms; for one may be relieved by the aggravation of another. Though there may be a considerable reduction in the quantity of the urine, still if there be no alteration in its quality, and the saccharine impregnation continues, the disease cannot with propriety be said to have yielded to any curative process. It is by close attention to, and an early discovery of the premonitory symptoms that we must hope to prevent a fatal termination. The disease unquestionably may be controlled at its commencement by the employment of the means hereafter to be pointed out; but it unfortunately happens that the malady has in most instances made considerable progress before the patient's attention has been called to its real nature. Rollo, Beddoes, Cleghorn, Watt, Bardsley, and others have related cases of diabetes in

which a cure has been effected; but this happy result is by no means of common occurrence. When the disease is complicated with phthisis, scirrhus, or other organic mischief in any important organ, all hope at once disappears.

With regard to the perfect cure of diabetes, it is certainly necessary to speak with much caution; for, like some other formidable diseases, it is for the most part only capable of being relieved, and not of being effectually removed. "Within the last six or seven years," says Dr. Prout, "nearly twenty cases of diabetes have fallen under my observation; and among these, I have never but in *one* instance, and in that *for a very short time only*, seen the urine of a diabetic patient rendered quite natural." Dr. Lubbock, too, never saw this disease yield to any curative measures; the emaciation continued to increase more or more, until, after a lingering and protracted state of suffering, the unhappy subjects of it at last gradually sunk. Of twenty-nine diabetic patients who have been under our care, sixteen have eventually died, strongly evincing the fatality of the disease; eight out of the remaining thirteen have perfectly recovered; and of the other five we have received no account. The chances of restoration to health are frequently diminished by the irregularities of the patients themselves, in deviating from the prescribed modes of treatment, notwithstanding the strongest promises on their part to comply strictly with the wishes of the practitioner.

Previously to enumerating the *morbid changes* which have been observed after death in diabetes, it may be well to inquire what light has been thrown upon the pathology of this disease by chemical analysis of the urine and blood of diabetic patients.

*Sensible properties and chemical analysis of the urine in diabetes mellitus.*—Several distinguished chemists (amongst whom may be mentioned the highly respectable names of Cruikshank, Fourcroy, Nicolas and Gueudenville, Thenard, Vauquelin and Segalas, Dalton, Bostock, Henry, and Prout,) have sedulously occupied themselves in investigating the properties of diabetic urine, and have performed a variety of interesting experiments, with the view of determining the precise nature of that morbid secretion. The sweet taste of diabetic urine seems, as before observed, to have been first distinctly pointed out by our countryman Dr. Willis. Since his time, the existence of sugar in the fluid has been satisfactorily determined. It is worthy of remark, however, that the saccharine impregnation of diabetic urine is not at all times discoverable by the taste; for that secretion has been found to vary at different intervals during the twenty-four hours. In the case of a young lady, related by Mr. Shirreff, the urine voided at one o'clock was free from sweetness and perfectly insipid; some time after it appeared natural, but two hours after dinner was sweet, and in the evening again perfectly natural.

The urine in this disease has, it has been already said, a pale straw-colour. It is mostly clear when first voided, but on standing some time in the vessel, not unfrequently deposits a white flaky precipitate. Its smell at first strongly resembles that of new hay, but in the course of a short time a faintish acid odour may be perceived. It has been stated that the temperature of diabetic urine, when recently voided, is lower than that of the healthy secretion; but this is a point which we have examined with much care, and we have found that no marked difference exists between them. An important circumstance connected with the consideration of the peculiar character of diabetic urine is its *specific gravity*. The profession is under obligations to Dr. Henry for having satisfactorily shewn that the specific gravity of the urine in diabetes mellitus is higher than in healthy urine; a circumstance which had been overlooked by some of the most eminent writers on the chemical history of that disease. In ten cases of diabetes where he had an opportunity of determining this property, it never fell short of 1028 nor exceeded 1040; 1000 parts of water at 60° Fahrenheit being taken as the standard; whereas in healthy urine he never found the specific gravity, under any circumstances, to exceed 1020. Dr. Henry has recently informed us that subsequent trials of the specific gravity of the first morning's urine of healthy persons lead him to believe that this is understated, though perhaps a fair average for the whole day. Dr. Henry considers the specific gravity as a most useful test of the existence of diabetes in doubtful cases, and, when taken along with the actual quantity discharged, as furnishing a tolerably correct idea of the degree of morbid action. "It may be objected, perhaps, (he observes,) to the employment of this test, that it requires more familiarity with the method of taking specific gravities than falls to the lot of the greater part of medical practitioners. By means, however, of an hydrometer, which is well known to practical chemists, and which may be readily procured at a small expense, the specific gravity of the urine may be taken in a few moments, and with the greatest accuracy, by a person wholly unaccustomed to experiments of this kind." Deeming it desirable to establish a connexion between the quantity of extractive matter and the more certain character of specific gravity, Dr. Henry engaged in a series of carefully conducted experiments, and from them constructed the following *table*, which exhibits at one view the quantity of solid matter in diabetic urine of different specific gravities between 1050 and 1020. The scale may be extended, however, by the rule of proportion, to any case in which the urine may be found to have a specific gravity above the former or below the latter of those two numbers. In the experiments which furnished the above data of the table, the urine was evaporated by a steam heat till it ceased to lose weight, and

till it left an extract which became quite solid in cooling.

| Specific gravity of urine compared with 1000 parts of water at 60°. | Quantity of solid extract in a wine pint, in grains and tenths. | Quantity of solid extract in a wine pint, in |     |          |
|---|---|--|-----|----------|
|   |   | oz.  | dr. | scr. gr. |
| 1020  | 382.4   | 0  | 6   | 1 2      |
| 1021  | 401.6   | 0  | 6   | 2 1      |
| 1022  | 420.8   | 0  | 7   | 0 0      |
| 1023  | 440.  | 0  | 7   | 1 0      |
| 1024  | 459.2   | 0  | 7   | 1 19     |
| 1025  | 478.4   | 0  | 7   | 2 18     |
| 1026  | 497.6   | 1  | 0   | 0 17     |
| 1027  | 516.8   | 1  | 0   | 1 16     |
| 1028  | 536.  | 1  | 0   | 2 16     |
| 1029  | 555.2   | 1  | 1   | 0 15     |
| 1030  | 574.4   | 1  | 1   | 1 14     |
| 1031  | 593.6   | 1  | 1   | 2 13     |
| 1032  | 612.8   | 1  | 2   | 0 12     |
| 1033  | 632.  | 1  | 2   | 1 12     |
| 1034  | 651.2   | 1  | 2   | 2 11     |
| 1035  | 670.4   | 1  | 3   | 0 10     |
| 1036  | 689.6   | 1  | 3   | 1 9      |
| 1037  | 708.8   | 1  | 3   | 2 8      |
| 1038  | 728.  | 1  | 4   | 0 8      |
| 1039  | 747.2   | 1  | 4   | 1 7      |
| 1040  | 766.4   | 1  | 4   | 2 6      |
| 1042  | 804.8   | 1  | 5   | 1 4      |
| 1044  | 843.2   | 1  | 6   | 0 3      |
| 1046  | 881.6   | 1  | 6   | 2 1      |
| 1048  | 920.  | 1  | 7   | 1 0      |
| 1050  | 958.4   | 1  | 7   | 2 18     |

By referring to this table, we can readily ascertain the quantity of solid matter voided by a diabetic patient in a given time. Thus, as Dr. Prout has noticed, suppose ten pints are passed in twenty-four hours, of the average specific gravity 1040, it is evident that this will contain  $10 \times 10 \dots 4 \dots 2 \dots 6 = 15 \dots 7 \dots 2$ , or upwards of a pound and a quarter of solid extract.

The quantity of extractive matter obtained from diabetic urine is liable to considerable variation; but it is for the most part in proportion to the violence and severity of the disease, especially when the patient is not confined to any rules of diet. It has amounted in a few instances to more than two ounces from one pint (wine measure) of the fluid; but the medium quantity in even very aggravated cases of diabetes mellitus may be fairly estimated at not more than ten drachms of solid extract. The specific gravity, too, sometimes changes in a very remarkable manner. In the case of a patient lately under our care, it was reduced in the course of two days from 1033 to 1022, and very shortly afterwards it reached 1042. In another instance, alluded to by Dr. Prout, the specific gravity was reduced in about sixty hours after the patient had commenced with the use of opium, from 1038 to 1.1074. The saccharine matter had apparently disappeared, and was afterwards superseded by urea, the quantity of which had become excessive.

The able author just mentioned has shewn that an excess of urea frequently precedes the appearance of saccharine matter in the urine. "Now it is a remarkable fact," he adds, "that

in diabetes, in proportion as the saccharine matter diminishes under the above plan, that of urea generally increases; and in such instances the presence of the former principle cannot only be no longer distinguished by the sensible properties of the urine, but scarcely be demonstrated by the utmost skill of the most experienced chemist, though the specific gravity of the urine may at the same time be nearly 1040." Sometimes sugar is wholly wanting in diabetic urine even when the urea has altogether disappeared. Dr. Young met with an instance of this kind. After evaporating the fluid in a gentle heat, a brown substance was dissolved in abundance in alcohol, and afforded a stiff extract, which contained the lactic acid, with a little trace of lactate and muriate of ammonia, but consisted almost entirely of the animal extract which accompanied the lactates, was precipitated by tannin, and left after combustion a little muriate of soda, which showed a slight trace of uncombined alkali.

It has been matter of dispute whether urea is contained, in any proportion whatsoever, in diabetic urine. Whilst Cruikshank, Dalton, Foureroy, Nicolas and Gueudeville, Thenard and Bostock contend for the non-existence of urea in the urine of patients labouring under diabetes, Henry and Prout maintain that, although the quantity of that substance be very much diminished, still it is never entirely absent. Dr. Bostock published a highly valuable paper on diabetes in the 6th volume of *Memoirs of the Medical Society of London*, in which he stated that he had procured nitrate of urea in abundance, along with oxalic acid, from the extract of diabetic urine. He was afterwards induced to repeat his experiments at the request of Dr. Bardsley, who sent to him several pure specimens of saccharine extract for examination, having himself failed in several instances to detect any urea in diabetic extracts. The result was, that Dr. Bostock found his former inference to be erroneous, and, with a candour very honourable to himself, acknowledged that we have no evidence of the existence of urea in diabetic extract.

In the experiments of the seven first named chemists, the test employed to detect the presence of urea was the addition of nitric acid to the extract of urine dissolved in a small quantity of water. On treating extracts obtained by slow evaporation from healthy urine in this manner, they found that a copious precipitation of nitrate of urea always ensued; whereas in their trials with diabetic extract they seem to have failed to discover any traces of urea. Dr. Henry, however, has satisfactorily shewn by several experiments conducted for the purpose, that the action of nitric acid on the urea may be prevented by its agency on the greater proportional mass of sugar. He has stated that urea cannot be made apparent by nitric acid in the extract from any mixture of diabetic and natural urine, when the former exceeds the latter in a greater proportion than that of six to one; or when the solid urea is less than one-twentieth of the weight of the mixed

extract. It is on the ammonia which comes over *early* in the distillation of diabetic urine, that Dr. Henry seems disposed chiefly to insist, as establishing the presence of urea, because there is no other animal substance which can give origin to the volatile alkali under such circumstances. "Another proof (Dr. Henry observes) of the existence of some portion of urea in diabetic urine, may, in many instances, be obtained by a careful observation of the phenomena attending its spontaneous decomposition. At a temperature exceeding 60° Fahrenheit, diabetic urine passes rapidly to the acetous state. But if the succession of changes be carefully watched, it will be found that there is a point at which, before it becomes acid, it exhibits, to sufficiently delicate tests, distinctly alkaline properties." "The deficiency of urea in diabetes," he adds, "may be stated as being very considerable. In those cases where I have attempted to estimate it, from the quantity of ammonia evolved by the destructive distillation of the urine, the urea has not appeared to exceed from 1-40th to 1-60th the quantity contained in an equal measure of concocted healthy urine. One specimen of diabetic extract, with which I was favoured by Dr. Bardsley, approached so near to perfect whiteness, that there appeared to me little reason to expect any evidence of its containing urea. Yet even in the product of the distillation of this extract, after being rectified with the addition of potash, ammonia was found. On distilling, also, a portion of the urine itself, the condensed liquor gave manifest traces of carbonate of ammonia. This urine, however, contained a far less proportion of urea than I had ever before ascertained; not exceeding, as nearly as I could estimate, 1-80th of the natural quantity. Making every allowance, then, on account of the increased flow of urine, it will appear that the quantity of urea discharged by persons labouring under diabetes, in any diurnal interval, falls considerably short of the quantity voided in a state of health." We have repeated these experiments with great care on an extensive scale, and are satisfied with their accuracy. Dr. Prout also considers the absence of urea as by no means characteristic of diabetes. He admits that in this, and some other affections of the urine, very little urea is sometimes present; but the same he shews to hold with respect to the other principles, many of which are deficient in such urine as well as urea. He never met with a specimen in which it was entirely absent. It may in fine be correctly stated that there exists a *deficiency*, though *not a total want of the urea*, in the urine discharged in well-marked cases of diabetes mellitus.

It may be proper to notice the effects produced by certain *re-agents*, and by *evaporation*, on diabetic and healthy urine, according to the experiments of MM. Nicolas and Gueudeville. 1. Tincture of turnsol added to diabetic urine received a reddish violet tinge; with healthy urine it assumed a deep red. 2. Nitrate of silver occasioned in diabetic urine a curdy precipitate, of which the colour, at first white, soon changed to violet, and the liquor became limpid

with a slight tinge of yellow; it was altogether inodorous. With healthy urine the same re-agent afforded an abundant precipitate of a deeper violet colour, and the liquor preserved a yellowish red colour, and emitted a strong urinous odour. Each precipitate consisted of nitrate and phosphate of silver. 3. Lime-water produced a milkiness in diabetic urine, immediately rendering it turbid, and affording a faint ammoniacal odour. After some time a flocculent precipitate occurred, of which a part remained on the surface of the liquor, which became as limpid as water: this precipitate was phosphate of lime. The same test also rendered healthy urine opaque, and the precipitate was white and extremely buoyant; but the liquid preserved a fine lemon-colour: the precipitate, a phosphate of lime, was also more abundant by one half. 4. Concentrated sulphuric acid added to diabetic urine afforded a beautiful rose colour, occasioning at first a slight effervescence. The surface of the fluid became covered with a light froth, which remained for a long time, and there was scarcely any precipitate: the liquor was inodorous. At the instant of mixing sulphuric acid with healthy urine the effervescence was scarcely perceptible, and the foam was slight. The liquor assumed a reddish brown colour, and preserved the odour of urine: at the bottom of the vessel was observed a small quantity of a darkish red precipitate. Dr. Henry has mentioned to us that on adding nitric acid, moderately diluted, to diabetic urine, he has often observed a change of colour to a red, resembling that of a weak acidulated infusion of rose leaves, and an immediate and very sensible increase of the saccharine odour. 5. Muriate of barytes rendered diabetic urine somewhat turbid; and in a short time a slight precipitation took place of a white salt, which was sulphate of barytes. The same re-agent produced a like effect upon healthy urine; but the precipitate was rather more abundant, and of a brownish red colour. 6. Oxalic acid afforded with diabetic urine a light rose-coloured flocculent precipitate, of which a considerable part was held in suspension in the liquor. The same acid threw down a precipitate with healthy urine, but it was heavier and of a deeper colour. 7. Sulphate of mercury rendered diabetic urine slightly turbid, and gave it the appearance of a white salt. A precipitate of a reddish tinge gradually occurred, one half of which remained suspended in the liquor. Treated by the same re-agent healthy urine assumed a brownish red tinge: the precipitate resembled a lilac-coloured salt, and was wholly deposited at the bottom of the vessel. It was the phosphate of mercury. 8. Pure potass rendered diabetic urine turbid, and afforded a small portion of ammonia; a white precipitate was afterwards procured in small quantity. The precipitate afforded by the same re-agent with healthy urine was on the contrary abundant, and the disengagement of ammonia very considerable. 9. Muriate of lead communicated to morbid urine a milky colour; the precipitate which ensued was that of a white salt, slightly tinged with red; it was a phos-

phate of lead: the liquor remained transparent. Muriate of lead imparted to healthy urine a violet colour, and produced a red precipitate; the liquor remaining of a brownish red colour. 10. Diabetic urine precipitated nitrate of mercury of a rose colour, and the liquor became as limpid as water. The precipitate of nitrate of mercury by healthy urine was also of a rose colour, but more abundant; and the liquor preserved a brown tinge.

*Analysis by evaporation.*—1. After exposure to the air during six weeks, (from 10° to 12° Reaumur, 54° to 59° Fahr.,) diabetic urine became turbid within the first six days, and gradually deposited a white flocculent substance, which was found to be albumen. The liquor afterwards became limpid and slightly coloured, having a sour odour and acid taste exactly resembling vinegar made with milk. Healthy urine, after like exposure to the air during the same period, soon exchanged its natural odour for one that was strongly ammoniacal; its colour became brown, and in the end it putrefied, affording a very fetid and offensive smell. The precipitate was pulverulent, and composed of phosphate of lime, soda, and muriate of soda. 2. Diabetic urine became acid, and turned blue vegetable tinctures red; whereas healthy urine, when putrid, rendered the same tinctures green. 3. This acid urine combined perfectly with carbonate of potash in solution, without marked effervescence: the liquor, after filtration and evaporation, furnished acetate of potash, mixed with a small quantity of phosphate of potash; the precipitate obtained was scanty, of a white colour, and composed of lime and a small portion of magnesia. 4. Four pounds of diabetic urine afforded, on evaporation carefully conducted, four ounces and a half of extract, of the consistence of honey, of a brown colour, like to treacle, and having the odour of burnt sugar; whereas only three ounces six drachms of an extract of the consistence of honey, of a very brown colour and urinous odour, were obtained from four pounds of healthy urine. 5. Ten parts of diabetic extract were mixed with four of muriate of lead and one of powdered charcoal, and after being dried they were submitted to distillation in a retort. Little or no ammonia was afforded, but carburetted hydrogen and a black fetid oil. The residue in the retort, on being subjected to an intense heat, gave no traces of phosphorus. The extract of healthy urine, treated in the same manner, furnished ammonia and a fetid oil; the residue contained some muriate of ammonia, and when thrown upon ignited charcoal, emitted the odour of phosphorus. 6. One ounce and two drachms of diabetic extract being treated with four ounces of alcohol, at 35° Reaumur, afforded a yellow fluid resembling Spanish wine; the solution of the matter was nearly complete, and the liquor deposited, in the space of twenty-four hours, a light, flocculent, grey substance, which, when washed and dried, weighed only twenty grains; its taste was saline and slightly sweet. Lime-water, added to one portion of the residue, afforded a feeble ammoniacal odour; sulphuric

acid, applied to the other portion, changed it to a black colour, and produced the odour of sulphurous acid gas, indicating the presence of albumen. An equal quantity of the extract of healthy urine, treated with alcohol, afforded an abundant precipitate, composed of the phosphates of magnesia, lime, soda, and ammonia, uric acid, benzoic acid, and albumen. Urea and the muriates of ammonia and soda were held in solution in the liquor. In order to obtain these different substances separately, the fluid was evaporated, and the residue being dissolved in water, nitric acid was added to it, which occasioned a copious precipitate. This precipitate was found to be a nitrate of urea. 7. On submitting diabetic extract to distillation with nitric acid, nitrous vapour was disengaged; the residue being dissolved in distilled water afforded, on evaporation, oxalic acid, and a small portion of phosphoric acid. 8. Four ounces and a half of diabetic extract, of the consistence of honey, being dissolved in a pound of distilled water, with half an ounce of yeast added to it, and exposed to a temperature of 15° Reaumur during twenty-four hours, readily fermented, and afforded a considerable quantity of carbonic acid gas. After the fermentation was over, the whole being submitted to distillation yielded ten ounces of a spirituous liquid. Such were the chief methods employed by MM. Nicolas and Gueudeville, with the view of establishing the peculiar nature of diabetic urine. Dr. Bostock also submitted portions of diabetic urine to the action of different re-agents. His experiments, as well as those of Cruikshank, Nicolas, and Gueudeville, satisfactorily prove that the different salts exist in diabetic urine, nearly in the same proportion to each other as in the healthy state of the fluid, but that they amount only to about one-third of the absolute quantity. Sometimes diabetic urine has been found to contain a small portion of blood, (as in the case of Stevenson, related by Dr. Watt,) and occasionally a white milky-like fluid resembling chyle. Having thus noticed the principal circumstances connected with the *urine* in diabetes, it may be proper to allude to the state of the *blood* in that disease.

*Analysis of the blood in diabetes.*—Nicolas and Gueudeville, Wollaston, Marcet, Henry, and some other eminent chemists, have performed many experiments to determine the existence or non-existence of sugar in the blood of persons labouring under diabetes mellitus. Dr. Rollo stated (in the case of Captain Meredith) that the patient was bled, and the blood was kept for several months without undergoing any putrefactive process; while a portion of healthy blood, taken at the same time and placed in the same room, exhibited evident marks of considerable putrefaction in four days, and was obliged to be thrown away on the seventh. Nicolas and Gueudeville ascertained that the blood of diabetic patients afforded some serum, a small quantity of fibrine, and was less animalized than that of persons in good health, but that it contained no saccharine matter. Having satisfied himself how the

albuminous part of healthy serum could be most completely coagulated, and by what appearances the presence of sugar that had been added to it would be most easily discerned, Dr. Wollaston added half a drachm of muriatic acid, previously diluted with one drachm and a half of water, to six drachms of serum, and immersed the phial containing them in boiling water during four minutes. In the course of a few hours a drachm or more of water exuded from the serum that had been so coagulated. A drop of this water being evaporated, the salts which it contained were found to crystallize, so that the forms of the crystals could be easily distinguished; they were principally common salt. If any portion of saccharine matter were added to the serum previous to coagulation, the crystallization of the salt was impeded, or wholly prevented, according to the quantity of sugar present. By the addition of ten grains to the ounce, the crystallization of the salts was entirely prevented, and the degree of blackness and disposition to deliquesce was of course more manifest than with smaller quantities. As a further test of the absence or presence of sugar, Dr. Wollaston added a little nitric acid to the salts that remained after crystallization of the drop. He found that when the serum had been successfully coagulated without any addition of sugar, the nitric acid merely converted the muriatic salts into nitrates, and nitrate of soda was seen to crystallize without foam or blackness. But when sugar had been added, a white foam rose round the margin of the drop, and if further heat were applied it became black, in proportion to the quantity of sugar present. On applying the above tests to diabetic blood and serum, Dr. Wollaston failed to detect any traces of sugar. Dr. Henry performed some interesting experiments on diabetic blood, as noticed by Dr. Ferriar, which confirm the results of Dr. Wollaston's analysis. Dr. Prout has also made a comparative examination of the blood of a person labouring under confirmed diabetes, with healthy blood. He states that he was induced to undertake it with the intention principally of determining whether the quantity of azote was the same in each. The diabetic blood presented the usual appearances of healthy blood. The following were the results of his experiments:—

|  |        |
|--|--------|
| Specific gravity of the serum of diabetic blood .....  | 1029·5 |
| ————— of the urine of the same person, voided at the same time.....  | 1044·8 |
| One hundred grains of the diabetic serum, evaporated and dried to the standard formerly mentioned, left ten grains of solid matters, which upon analysis were found to consist of albumen..... | 8·7    |
| Laetates and animal matters usually existing in the blood .....  | ·6     |
| Salts.....   | ·7     |
|  | ————   |
|  | 10·    |
|  | ————   |

“ Which very nearly coincide,” says Dr.

Prout, “ with the proportions ascertained by Dr. Marcet and Berzelius to exist in the serum of healthy blood. One hundred grains of the diabetic urine, evaporated and dried as before, left 11·7 grains, nearly the whole of which was sugar. Portions of albumen from the serum of this diabetic blood, dried and analysed as before, yielded *precisely the same results* as albumen from the serum of healthy blood.”—“ To ascertain,” Dr. Prout continues, “ the relative proportions of azote present in the diabetic urinous extract and the extract from healthy urine, portions of them were burnt with the oxide of copper. The results were, that one hundred parts of the diabetic extract (abstracting alkaline and earthy salts) yielded only 6·5 parts of azote, while the same quantity of extract from healthy urine yielded from thirty-five to forty parts of the same principle. To obviate the objection that the saccharine matter of the urine might be formed from the other principles of the blood and not from the serum, comparative experiments were made with the *cruur* of healthy and of diabetic blood. The results were precisely similar as to the quantity of azote in both, and at the same time the quantity of azote did not differ much from that found to exist in the serum above mentioned.” From these experiments of Dr. Prout's, it may be safely inferred that the blood of diabetic patients contains an equal quantity of azote with that of healthy persons.

We may observe here, that Dr. Wollaston thought that, in order to account for the presence of sugar in the urine, we must either suppose a power in the kidneys of forming this new product by secretion; or, if we admit that the sugar is formed in the stomach by a process of imperfect assimilation, must then allow the existence of some channel of conveyance from the stomach to the bladder without passing through the general system of blood-vessels. He conceived, that if prussiate of potass could be taken with safety, its presence would be discerned by a solution of iron in as small a proportion as almost any known chemical test. Finding that a solution of this substance might be taken without the least inconvenience, and that in less than one hour and a half the urine became perceptibly impregnated with it, although the quantity employed had not amounted to more than three grains of the salt, he administered to a healthy person, about thirty-four years of age, a dose corresponding to three grains and a half of the dry salt, and repeated it every hour to the third time. The urine being examined every half hour, was found in two hours to be tinged, and to afford a deep blue colour at the end of four hours. Blood was then taken from the arm, and the coagululum, after it had formed, was allowed to contract so that the serum might be fully separated. He then endeavoured to ascertain the presence of the prussiate by means of a solution of iron, but without effect. Dr. Marcet also performed several interesting experiments at the request of Dr. Wollaston on this point. In one experiment he administered five grains of prussiate of potash dissolved in water, to a

young woman labouring under diabetes mellitus; and the proportion was repeated every hour till she had taken thirteen or fourteen such doses. After the fifth dose, her urine, by the addition of a drop or two of a solution of sulphate of iron, turned blue instantly. At this period of the experiment, a blister was applied to her stomach, and after a few hours, whilst still taking the prussiate of potash, and whilst the urine strongly indicated its presence, the blister was cut and the serum collected. This serous fluid being, in the same manner as the urine, subjected to the action of a solution of sulphate of iron, did not suffer any change of colour in the least indicative of the presence of prussic acid. Yet the urine still remained capable of imparting a blue colour to solution of iron, fifteen hours after taking the last dose of the prussiate of potash. Dr. Mareet afterwards repeated Dr. Wollaston's experiments on the serum itself, and with a similar result. He also found that the susceptibility of the passage by which prussiate of potash is transmitted to the bladder seems to vary in different individuals; for in five trials he failed to discover any vestige of that salt in the urine of persons who had taken it in quantities sufficient to produce its appearance in others.

These experiments, though highly interesting and ingenious, still fail to establish the fact of a direct communication between the digestive organs and the kidneys or bladder, by which sugar may be conveyed from the former to the latter without its entering the general circulation. It is known that other substances are also met with in the urine, such as urea and lithic acid, which have never been detected in the blood or other fluids of the body. We have ourselves also carefully analysed the blood taken from several diabetic patients, but never could detect the existence of sugar in it, nor indeed any marked difference in its chemical composition from blood in the healthy state. Hence, it may be concluded that saccharine matter does not exist ready formed in the serum of diabetic blood; unless, indeed, we suppose with some modern continental writers, that sugar, like mercury, upon entering the blood, unites itself intimately with the albumen, and constitutes a new compound of unknown properties, and which consequently sets our tests at defiance, although easily decomposed by the glands, of which organs this species of separation seems the natural office. It is not more difficult to conceive how a kidney strongly excited by a redundant efflux of blood to its tissue, should convert part of the elements of the latter into sugar, than that the mammary glands of a woman should be found to perform the same thing in the sugar of the milk which it secretes upon a similarly sudden determination of blood to it after parturition.

*Pathology of diabetes.*—It is matter of regret, that hitherto the most careful anatomical research has afforded no satisfactory information concerning the origin of this complicated malady. Various morbid changes

have been detected on the post-mortem examinations of diabetic patients, but these, in not a few instances, may more properly be considered as the effects than as the causes of the disease. The kidneys are more frequently met with in a morbid state than any of the other abdominal viscera; their size is occasionally much augmented. In four fatal cases under our own observation in immediate succession, these organs were greatly enlarged, and the ureters were considerably dilated. Dr. Duncan has related a case of diabetes in the Edinburgh Clinical Reports, in which the kidneys were much larger than common; and Dr. Rutherford and other pathologists have noticed an unnatural increase of their size. The texture of the kidneys in some instances is firmer, in others more flaccid than usual; their vessels are also occasionally preternaturally enlarged; and their surrounding cellular membrane has more than once been found filled with a gelatinous substance. In the case of Robinson, mentioned by Dr. Rutherford, the kidneys were much augmented in bulk, soft, and their surfaces painted with numerous vessels; the vessels were uncommonly dilated. The emulgent vein of the right-side was not under three-fourths of an inch in diameter, as it appeared distended with blood. The ureters also were considerably dilated; the bladder seemed capacious, its coats thickened, and it was half filled with liquid. In the dissection, too, of Ann Laidlow, given by the same author, the kidneys were found somewhat enlarged, and on cutting into them the tubuli uriniferi were more distinct than usual, and the pelvis of each was also considerably increased; but no other morbid change of structure was perceived. Mr. Brodie, on examining the kidneys of a patient of Dr. Warren's, who died of diabetes, found them to possess an unusually firm and grisly texture. In order to ascertain the state of the bloodvessels, he injected one of the kidneys with size and vermilion previously to examination; the other was allowed to remain in its natural state. On cutting into the substance of the injected kidney, the cortical part appeared unusually red, and the cryptæ were seen more numerous, larger, and more distinct than ever occurs under circumstances of the most fortunate injection. The bloodvessels of the cortical substance of the kidney which had not been injected were unusually turgid; the ureters, emulgent artery, and vein, were of natural dimensions; the renal capsules were firmer and harder in their texture than usual, and seemed to partake of the grisly structure of the kidneys: the bladder was sound. M. Dezeimeris noticed the increased bulk of the kidneys in three cases of diabetes, which occurred at the Hôtel Dieu in one year. "In all the cases the volume of the kidneys was much enlarged; all their vessels were considerably developed, and their tissue, which was gorged with blood, and of a deep red colour, could be torn with the greatest facility." It appears from an interesting and extremely

minute examination of a case of diabetes conducted by Dr. Monroe, that all the glands of the absorbent system were either enlarged or morbidly altered in structure. Upon dividing the right kidney into two equal portions by a longitudinal incision, it seemed as if it had been very successfully injected. Many blood-vessels, both in the cortical and medullary part, were filled with florid blood, owing to which the distinctions between these parts was not well defined. A transparent yellow-coloured substance was found effused on the outer side of the pelvis and infundibula.

Dr. Beer met with a very remarkable degeneration of both kidneys in the body of a young man, who had for a long time laboured under diabetes. They were extended by hydatids, contained in their interior substance, to such an enormous size that each was one foot long and seven inches broad, and the ureters were of the size of the thumb.

The ureters and bladder are sometimes considerably dilated. In one instance, Dr. Duncan found the bladder capable of containing five pounds of urine, and he states that about that quantity remained in it after death. It had its natural form, and its parietes were rather thinner than usual, although the muscular fasciculi were very well marked. Its inner coat presented a perfectly healthy appearance, and the ureters were about one-fourth of an inch in diameter: the sympathetic and splanchnic nerves were also enlarged to nearly three or four times their usual size. In the dissection of a diabetic patient of Dr. Pearson's, mentioned in Dr. Rollo's work, the kidneys were found to be in a perfectly sound state, and so were the ureters; but the urinary bladder was much thickened, and the urethra was dilated to three or four times its usual width; in another, related by Dr. Marshall, the kidneys had assumed a chocolate colour, were large, and the texture soft and flaccid, particularly that of the portion comprehending the tubuli uriniferi: the bladder exhibited nothing unusual. In the case of Oliver Orinrod, detailed by Dr. Clark, the ureters were very much dilated, and through their whole course measured full half an inch in diameter. In two cases, we have found the bladder much contracted and thickened. In one instance the capacity of this viscus was so much diminished as not to admit more than a small egg; in the other, the parietes of the bladder were even more thickened.

As post-mortem examinations in cases of death from this disease are always interesting, we shall detail the following one which recently occurred in our own practice. The external cutaneous veins were distended with fluid blood. On detaching the scalp, some ounces of blood issued from the cut surface: the pericranium was redder than usual. The encephalon, and its containing membranes, appeared free from disease. On raising the sternum from the pleura, there were exhibited no traces of recent inflammation, but exudations of coagulable lymph appeared on the surface of the pleura pulmonalis, which had

formed pretty strong bands or partial adhesions to the pleura costalis, particularly on the right side. Lungs sound. Nine ounces of fluid were found in the right cavity of the thorax, and eight ounces in the left; the quantity of liquor pericardii was about half an ounce. Gall-bladder distended with bile. Liver larger than usual, and of a firmer consistence. Spleen of natural size, though rather denser than common. The urinary bladder was full. The left kidney had undergone a remarkable diminution in bulk, being not more than one-third of its usual size. After the removal of fat, &c. it weighed ten drachms (troy weight); it was otherwise healthy, with the exception of some small *hydatids* on its surface. The right kidney weighed five ounces six drachms (troy weight); its surface was a little irregular. The stomach was inflamed on its posterior side and next the cardia; the inflammation only affected the inner membrane, which was also slightly corroded by the gastric juice. It contained five ounces of half digested cream-like fluid. In this instance, the diminished size of the left kidney formed the most singular feature in the dissection.

MM. Dupuytren and Thenard, on the examination of a diabetic patient, met with the stomach in a very much enlarged state; its vessels were greatly dilated, and forming upon the internal membrane of the organ a red network. It also contained a considerable quantity of uninflamable gas, and a small portion of a greyish liquid, in which were floating seven or eight small, yellowish, round, fatty substances. The duodenum, and upper part of the jejunum and ileum, were somewhat redder and thicker than natural; no appearance of disease was discoverable in any other part of the intestinal canal. The liver, spleen, and pancreas were sound. The gall-bladder was moderately filled with healthy bile. The kidneys were at least one-third larger than usual; their structure was soft and of a grey colour, but in every other respect natural. The other organs connected with the urinary apparatus were free from disease, though the bladder was very small. The abdominal lymphatic system, and the thoracic duct, were more than ordinarily developed. The arterial and venous systems had undergone no morbid alteration. The lungs adhered to the sides of the chest by loose cellular tissue. In the right lung there were some small *voniceæ* containing pus; in the left, several cysts completely filled with an elastic fluid. The muscles were pale and flaccid, but otherwise in structure quite healthy.

Dr. Baillie has also left an account of the post-mortem examination of a person who had been long affected with diabetes, and had been a patient under his care in St. George's Hospital. The state of the kidneys is very minutely noticed. "Both were of the ordinary size and shape. When the proper capsule was removed from each, the veins on the surface were much fuller of blood than usual, and had an arborescent appearance. When the substance of both kidneys was cut into,

it was observed to be every where much more crowded with bloodvessels than in a natural state, so as in some parts to approach to the appearance of inflammation. Both kidneys had the same degree of firmness to the touch as when healthy, but they were hardly so firm as kidneys usually are the vessels of which are so much filled with blood. A very small quantity of whitish fluid, a good deal resembling pus, was squeezed out from one or two of the infundibula in both kidneys, but there was no appearance of ulceration in either. The artery and vein passing into the cavity of each kidney presented exactly the natural appearance. After separating, a good deal, the cellular membrane which joins together the bloodvessels, was discovered a lymphatic passing from one of the kidneys: it was of the usual size, had the common valvular appearance, and was empty. There were doubtless several others belonging to both kidneys, but they were so small as not to be distinguishable. The nerves of the kidneys were of the usual size, and the ureters of both were perfectly natural. The renal capsules appeared quite healthy. The structure of the liver, stomach, spleen, pancreas, intestines, and urinary bladder, was perfectly natural, but one or two of the mesenteric glands contained a considerable quantity of earthy matter."

Organic changes are sometimes discovered in the internal structure of the kidneys in diabetes. We may state as a pathological fact of some importance, that in three instances of this disease we have detected the peculiar granulated or mottled condition of these organs, so well described by Dr. Bright as occurring in dropsical affections accompanied with albuminous urine. The cortical part had lost all appearance of its natural structure, and presented a tolerably uniform yellowish color with many yellowish-grey spots. The mesenteric glands in two cases were much enlarged and indurated; and in the other, several vomices were detected in the right lung. There was no evidence of organic disease in the liver or in any of the other abdominal viscera in the latter instance.

Besides these morbid conditions of the kidneys and their appendages, a diseased state of the stomach and lungs has also been noticed in this affection. The former organ has been found to exhibit marks of inflammation, and the latter have been studded with tubercles in different stages of their progress. In a fatal case of diabetes, which occurred in the Manchester hospital a few months since, both lungs were tuberculated; and except dilatation of the pelvis of the kidneys and of the ureters, there was no perceptible disease of the urinary organs. The pulmonary affection was subsequent to the diabetes, therefore it cannot be said that this affection was excited by the former. In most of the dissections on record, the mesenteric glands have afforded evidence of structural derangement; and from our own observation we should say, that next to the enlarged and flaccid state of the kidneys, this is the most uniform morbid appearance in diabetes. We not unfrequently meet with

similar disease of structure, however, in diseases very different both in their nature and symptoms from the one under consideration; hence, it is not singular that such an infinity of hypotheses should have been advanced to account for the phenomena of this malady. In some examinations of diabetic patients no trace of organic disease has been discoverable. An intelligent practitioner informed us during the last year, that he had recently examined the body of a young man, twenty-one years of age, who had died of this disease, without being able to detect the least deviation from healthy structure in any of the cavities.\* The different morbid appearances in the stomach, liver, and lungs, noticed above, are undoubtedly in some instances merely accidental attendants; and indeed the diseased state of the kidneys themselves is, we conceive, mostly the consequence of long continued morbid action. The ureters, too, become dilated, and the bladder contracted and thickened, from the constant passage of such an increased quantity of urine. From these observations, it is evident that the information regarding the nature of diabetes derived from dissection is very unsatisfactory, and that up to the present period we are ignorant of the *essential pathology* of the disease. With so defective a pathology, the treatment must necessarily be vague, and in a great measure empirical.

The *treatment* of diabetes mellitus comes now under consideration. The statements respecting the cure of diabetes furnished by the ancient writers on this disease are altogether unsatisfactory. This cannot be matter of surprise when it is considered that they regarded only the unnatural quantity of the urinary discharge, being entirely ignorant of any morbid alteration in its qualities. As it would answer no useful purpose either to enter into an examination of the comparative value of the whole of the modes of treatment that have been proposed, or to dwell at any length upon the particular remedies which have been recommended, on various authority, for its removal, we shall first merely notice the four branches of cure, *animal diet, venesection, opium, and astringents*, which of late years have been chiefly adopted; and then point out those principles of treatment which seem to us to be best calculated to arrest the progress and remove the symptoms of the complaint. Dr. Hoine first suggested the employment of animal diet and alkalies, with a view to their specific operation as septics; but Dr. Rollo is entitled to the high merit of having put into practice the rigid use of an animal regimen as the most effectual mode of curing diabetes. The employment of this plan is founded on the principle of preventing the introduction of the materials of which sugar is formed into the system, and of thus destroying the saccharine impregnation of the urine. Dr. Rollo also combined with an entire abstinence

\* In a dissection of a diabetic patient of Dr. Forbes, no morbid lesion could be detected except slight enlargement of the kidneys, and a remarkably hypertrophied state of the duodenum. It was simple hypertrophy, without any mark of inflammation or alteration of tissue.

from vegetable food the exhibition of the hepatic ammonia, and the occasional interposition of narcotics and emetics. Dr. Rollo's practice has long since enjoyed a fair trial in the hands of many distinguished practitioners, and consequently sufficient time has been allowed to admit of a correct inference being drawn respecting its real claims to the high character bestowed upon it by so able an advocate. Without particularising individual cases in support of the efficacy of a strict adherence to animal food in removing some of the more formidable symptoms of diabetes, it may be stated that its power of abating thirst, diminishing the unnatural quantity of the urinary secretion and rendering it more animalized, of relaxing the skin, and of increasing the bulk and strength of the body, rests on the incontrovertible evidence of facts and experience. Its influence upon the urine is in general speedy and favourable, and though perhaps when employed *singly* it may prove on some occasions inadequate to the perfect cure of the disease, still, under almost all circumstances, it will be found to act as a powerful auxiliary to venesection, opium, or the other means which may be adopted. Dupuytren and Thenard have contended that diabetes may be as readily subdued by animal diet as an intermittent by the use of the cinchona bark. Dr. Baillie, in alluding to Dr. Rollo's method of practice, observes that it has been much more successful than any other hitherto adopted. Dr. Bardsley has also shown the advantages derived from confining diabetic patients to animal food. Several of his cases strongly exemplify the reduction in the quantity of the urinary secretion, and the disappearance of its saccharine properties, which speedily followed the use of this regimen. Dr. Willan states that this disease has been relieved, and the saccharine quality of the urine removed, by animal diet and the general plan recommended by Dr. Rollo. Were it necessary, other respectable authorities might be adduced in support of the curative value of the same method. We have adopted the animal regimen in several instances with the most marked and unequivocal benefit, and have known patients, who have had sufficient means and resolution to persevere in its use for some length of time, not merely to recover their wonted health, but overcome the tendency to the disease. Owing to the high price of meat, but few of the poorer classes of persons who have the misfortune to labour under this complaint are capable of a strict compliance with this plan of treatment, for the amount of their daily labour is mostly insufficient to procure such a supply as the appetite demands. This is not the only obstacle to the employment of animal food as a remedy in diabetes; for there is often considerable difficulty in keeping the patients for any length of time exclusively confined to such a regimen; and many failures with this method of treatment may be attributed to a secret indulgence in variety of aliment. In some instances there is an insuperable disgust at the taste, smell, and even sight of animal food. With the ordinary class of hospital patients it is extremely difficult to prevent a deviation from the prescribed plan

of diet. Dr. Rollo himself laments that the mode of cure which he proposed is so contrary to the inclinations of the sick. "Though perfectly aware," he observes, "of the efficacy of the regimen, and the impropriety of deviations, they commonly trespass, concealing what they feel as a transgression to themselves. They express a regret that a medicine could not be discovered, however nauseous and distasteful, which would supersede the necessity of any restriction of diet." This aversion, however, to the animal regimen is by no means general, for in some instances it has been adopted with little or no inconvenience, and even been continued by the patients from choice, when a certain allowance of vegetable food has been permitted by the physician. Dr. Marsh rather overrates the loathing of animal food on the part of diabetic patients, when he asserts that the adoption of the animal regimen, during even fourteen days, is, in his opinion, more than questionable. In some of the cases published by Dr. Bardsley, the exclusive use of animal food was continued for more than two months. We occasionally visit a lady who has laboured under diabetic symptoms for more than nine years, and during the greater part of that time she has adhered, with scrupulous exactness, to the use of animal food.

It must be recollected, however, that there is a certain period at which it is necessary to combine vegetable with animal diet. When the more urgent and characteristic symptoms of the disease are subdued, and at the same time the strength and bulk rather diminished than increased, and the appetite is feeble and impaired, it is proper to allow a small proportion of vegetable food. The salutary effects of this change are soon rendered visible in the improvement of the appetite, and the acquisition of flesh, strength, and spirits. It has been remarked, also, that whenever a return to vegetable diet is allowed not only with impunity but advantage, it forms the surest criterion of the restoration of the assimilating powers of the system, and consequently of the removal of the disease. It is necessary, however, to caution patients against indulging too freely at first in the use of vegetable diet after a long and rigid adherence to animal food, as they are apt, from the agreeable nature of the change, to relinquish the latter regimen altogether, and thus favor a reproduction of the disease. At this stage, the state of the digestive organs requires particular attention in order to establish on a firm footing the benefit obtained; for if the stomach and bowels are permitted to become deranged by irregularities in diet, the danger of a relapse may be apprehended. Bitter tonics, mild aperients, chiefly rhubarb and magnesia, and sea air, prove eminently useful in promoting the tone of the system. It is by no means intended to recommend animal diet as the only mode of subduing this obstinate disease, but to shew that no other, without its aid, will have the same influence in arresting the progress of the diabetic symptoms.

Previously to commencing with the sole use of animal food, it is of the first importance to have the stomach and bowels brought into as

natural a state as the character of the complaint will allow. Costiveness must be obviated by the regular use of mild aperients, and for this purpose castor oil is preferable to the saline class of purgatives. The first effects of this plan of treatment should be very carefully watched, as there is considerable risk of the sudden occurrence of acute inflammation of the thoracic or abdominal viscera when it is adopted shortly after an entire abstinence from vegetable food. We have more than once been obliged to modify the practice on this account. The liability to inflammation under the animal regimen is strikingly exemplified in the case of James Ridens, aged 26, who was admitted into the Manchester hospital on the 2d of August, 1824, labouring under the ordinary symptoms of diabetes. The quantity of urine passed in the twenty-four hours amounted to nearly two gallons. One pint yielded, on evaporation, 1 oz. 4 drs. and 8 grs. of a thick sweet syrup. He had lost all venereal appetite, and his semen was involuntarily discharged. Animal diet was prescribed, and the nitric acid mixture was ordered for common beverage. His bowels were opened by the aid of castor oil. On the 5th the urine was diminished more than four pints, and the patient said that it was somewhat less sweet to the taste. He had no aversion to animal food. Early on the 8th he was suddenly seized with a severe pain in the epigastric region, which was much aggravated under the pressure of the hand. The stomach rejected every substance received into it. The pulse was small and frequent, and the countenance indicated great uneasiness. Twenty leeches were instantly applied to the epigastrium, sixteen ounces of blood were removed from the arm, and a purgative enema was injected. In the evening the patient seemed somewhat relieved by the bleeding, but the pain of the epigastrium was still present. A copious evacuation followed the enema. The serum of the blood was milky, and the crassamentum firm. Pulse 120, and weak. A vein was again opened, and eighteen ounces of blood were abstracted; twelve leeches were applied to the epigastrium, and a pill with two grains of calomel, and two of extract of hyoseyamus, was directed to be taken every third hour. The pulse after the bleeding was 106. On the morning of the 9th, we found the patient much worse, and evidently sinking very rapidly. He could with difficulty reply to the questions put to him. The pain of epigastrium was diminished, but the pulse was tremulous and intermitting, and his extremities were cold. His bowels had been moved twice during the night. Anodyne fomentations were applied to the epigastrium, weak wine and water was administered, and bottles of hot water were applied to the feet. He expired in the course of the afternoon. The friends, though urged by frequent solicitations, obstinately refused to allow an inspection of the body. From the above reports, however, it is highly probable that Ridens died of inflammation of the stomach, induced by an unlimited use of animal food. At first, it was imagined that the sudden attack which

proved fatal might have been owing to over-repletion; but he had retired to rest as well as usual, and even complained of severe pain of epigastrium before breakfast, which was generally with him a very hearty meal. In the case, too, of John McLean, related by Dr. Cleghorn, it appears that, although his diabetic symptoms were much relieved by the use of animal food, still the pneumonia which destroyed him was induced by strict adherence to this regimen.

It may be remarked here, that M. Roehoux prescribed urea to a diabetic patient, (whose blood was analyzed by MM. Vauquelin and Segalas without finding in it any trace of sugar,) and it was continued for several days; but the urine, which was increased in quantity, afforded, on careful chemical examination, no urea.

Very opposite to the above plan of treatment recommended by Dr. Rollo, is that of depletion, by *copious* and *repeated bleedings*. Dr. Watt was first led to try venesection from the circumstance of his patient expectorating blood, and from having in mind the case of Captain Meredith, (related by Dr. Rollo,) who, on the evening after bloodletting, "felt lighter, cooler, and more cheerful, and had less pain about the kidneys." On the following day Dr. Watt's patient seemed much relieved, the quantity of urine had diminished, the crassamentum of the blood was black, and void of tenacity. Finding so much relief from the first bleeding, he resolved on a second, and eighteen ounces were accordingly taken from the arm; an animal diet was enjoined, and carbonate of ammonia prescribed to obviate acidity. By repeated bleedings and a similar diet and medicines, in about four months this patient was restored to health. The following is the statement of Dr. Watt's mode of treatment. "The treatment according to my plan is to reduce the quantity of blood already in the system, to diminish the supply of new materials, and to afford a certain proportion of stimuli. The first is accomplished by venesection; the second, by abstinence; the third, by blistering, mercury, &c. The effect of this treatment on the system is increased reaction, indicated by some degree of fever, and terminating in the restoration of all the secretions." It is to be regretted that the same result has not attended the employment of bleeding in cases of diabetes occurring to other practitioners.

Dr. Watt appears to have tried venesection in one or two instances under the most untoward circumstances, the pulse being slow and feeble, the strength reduced, and the lower extremities oedematous; and still with benefit. Even the first bleeding sometimes produced an evident improvement in the symptoms. In the case of Stevenson, the fifth bleeding acted like a charm. "The recovery after this was instantaneous and striking. The painful sensation in his bowels left him; the power of virility returned; the gums became sound; the skin soft and perspirable; the saliva, the urine, and the alvine discharge natural; in six

days he returned to his work: in two months he was restored to his original health."

Dr. Watt found that the blood first drawn in diabetes was thin and destitute of buffy coat; the coagulum being so soft and weak that it could not support its own weight. As the operation was repeated, the blood assumed more and more an inflammatory character, and often exhibited ultimately a thick buffy coat, and a strong, firm, and tenacious crassamentum. "The improved texture of the blood," he observes, "as venesection was repeated, the increased hilarity of mind, and general renovation of the living functions, warrant the conclusion, that, however weakening it may be in particular circumstances, bloodletting is a most important mean of disburdening the system, and of preparing the way for the final re-establishment of health and vigour." Mr. Murray has also related a case in the 8th volume of the Edinburgh Medical and Surgical Journal, in which the blood improved simultaneously with the health. Some other instances have been recorded, illustrative of the salutary change produced in the constitution of the blood itself by repeated venesections. Dr. Ayre found bleeding useful in one example of this disease. The appearances of the blood strongly resembled those observed by Dr. Watt; and indeed, so close was the relation betwixt the state of the blood and the relief afforded, that the amount of the one was almost determinable by a view of the other. It is mentioned that during the first month the patient lost eighty-eight ounces of blood, and took at least only half the usual food, yet he gained nine pounds in weight, and acquired sufficient strength to follow a laborious employment. The marked good effects of venesection in two cases of diabetes have been ably shewn by Dr. Satterly. His experience fully confirms the safety and efficacy of the practice in some species of that complaint.

We are enabled to speak of the *real* value of venesection in diabetes from a careful and fair trial of its influence upon the symptoms on several occasions. It is a remedy of the first importance during the acute stage of the disease, for it has the power of abating the thirst, reducing the quantity of the urinary discharge, and restoring the natural secretion of the skin. Under no other circumstances have we employed venesection with advantage, though blood has been abstracted from the system at regular intervals and to a considerable amount. The practice, indeed, on the contrary, has been attended with a diminution of the patient's strength without relief to the diabetic symptoms. Taking Dr. Watt for our guide, we have followed his plan of treatment with scrupulous exactness, with a view of determining its true claims to confidence, but we have had too often to lament the want of success which has followed its adoption. The experience of the profession at large would seem to confirm the statement just made; for the practice of venesection, so generally employed shortly after Dr. Watt's publication, is now, comparatively speaking, only partially

pursued. We venture to recommend the employment of bloodletting during the early stages of the disease in persons of somewhat plethoric habit; and where the strength is not much reduced, and particularly when pulmonary irritation, as indicated by difficulty of breathing, slight cough, and shooting pains in the chest, may be present. The propriety of repeating the operation, and the frequency of the repetition, will be best determined by the effects produced upon the symptoms; for in some instances it may not be prudent to open a vein more than once, whereas in others no such restraint is necessary. There is sometimes an objection on the part of the patients to allow a fair trial of venesection, for feeling great debility and lassitude on the least exertion, they complain more of the want of a supply than of a superabundance of blood, and thus cannot be convinced of the benefit likely to accrue from such practice.

When general bleeding cannot with safety be adopted, the local abstraction of blood may occasionally be substituted with advantage. It has been our uniform custom in cases of this disease, to direct the application of leeches to the loins, when much pain and uneasiness have been experienced in the region of the kidneys, and always with good effect; and we have also found, with Dr. Marsh, that leeches on the epigastrium have been highly useful in removing the feeling of internal heat and tenderness so much complained of in that part. Indeed, patients have requested the repetition of leeches to the epigastrium on more than one occasion, being fully convinced of the benefit derived from them. This local bleeding has not materially reduced the strength, even when employed more than once. It should never be omitted under the circumstances we have pointed out, for though possessed of no curative efficacy, it is valuable in relieving painful and unpleasant symptoms, and is seldom, if ever, attended with harm, which is more than can be truly said of some other remedies proposed in this disease.

In a case of diabetes, under the care of Dr. Forbes, the first application of leeches to the epigastrium was *immediately* followed by a change in the urine to the healthy appearance. It was also much diminished in quantity. But the benefit was temporary, and although the same effect followed subsequent leechings, but in a less degree, the general result did not seem very beneficial.

Cupping is preferable to leeches when it is desirable to fix the precise quantity of blood to be removed, on account of the weakened state of the patient. Great benefit sometimes attends the application of blisters to the loins in cases of this disease. We have preferred the frequent repetition of blisters, to keeping the excoriated surfaces open by means of irritating dressings.

With the view of diminishing the nervous irritability of the system so generally present in this disease, the narcotic power of *opium* has been freely tried, and in many instances much benefit has attended its exhibition. It has also been prescribed with the intention of

opening the skin, and exerting an astringent effect upon the kidneys, similar to that which it usually induces on the intestinal canal. Dr. Warren published two cases of diabetes mellitus treated with opium, in the fourth volume of the Medical Transactions, which afford satisfactory evidence of the influence of that valuable drug in restraining the quantity, and moderating or removing the saccharine quality of the urine. In one of the patients this desirable effect was produced after gradually increasing the proportion of opium to six grains twice a day; the sweetness of the urine returned on the diminution of the dose, but was again removed by increasing it. The other patient died, (although the original disease was subdued,) of phthisis pulmonalis. The dose was gradually augmented to five grains of solid opium four times a day. Dr. Elliotson has since exhibited opium in four cases of diabetes, in which the good effects of this remedy were satisfactorily established. He has administered it in large doses, but it appears more advisable not to push the quantity to any great extent. Dr. Prout also found opium useful in this affection. "All the beneficial effects," he observes, "to be really expected from opium, may in most instances be obtained by moderate doses only; and when thus judiciously exhibited, and when no peculiarity of constitution forbids its use, I believe that it will be found one of the most powerful remedies that we possess in this disease." Dr. Marsh, too, considers that amongst the remedies hitherto employed, opium in very large doses ranks highest, for it possesses the property of checking and restraining the flow of urine, and depriving it of many of its morbid qualities. Our experience accords with that of the above named authors, but we have rarely found it necessary to administer more than six grains in the day, though on some occasions this proportion has been considerably exceeded; and when continued, during any length of time, in rather large quantities, this drug has produced alarming and pernicious effects. We are decidedly of opinion, that it proves most beneficial in moderate doses. Of late we have given the preference to the acetate of morphia, as it appears to exert an equally powerful influence upon the disease, without occasioning the pain of head and constipation which almost invariably accompany the free exhibition of opium. On the whole, opium is unquestionably entitled to be considered as a remedy of much value in diabetes, for it not merely diminishes the quantity of the urinary secretion, but also proves useful in removing uneasy sensations and calming mental agitation. *Astringents* constitute another line of practice which is very ancient, and is still resorted to by a considerable number of practitioners. They are recommended by Celsus, and from their natural tendency to correct every excess in secretion, have obtained considerable notice in the writings of almost every author since his time. That they prove beneficial by constricting the relaxed extreme vessels through which the

urine filters into the papillæ of the kidney in diabetes, is the general opinion; but they may probably act also by an inherent sedative power, on which their astringent virtue seems almost entirely to depend. It is sufficiently proved by observation that they lessen the quantity of urine thrown off by the diabetic patient, up to a certain limit; but this they seldom can be made to pass; and they scarcely ever diminish the saccharine impregnation of the urine. By acting as tonics, however, and by lessening the sensibility of the stomach, they become useful auxiliaries in several modifications of the disease, and are chiefly objectionable when they are found to increase constipation. Celsus, however, trusted chiefly to a constipating diet, and strong rough wines. Sydenham used the rind of the pomegranate; Morton rhubarb, which was afterwards repeated by Professor Rutherford with advantage. Lime water, decoction of oak bark, infusions of kino and catechu, uva ursi, and diosma crenata, with many others, have lately been employed with the same intention as the above: but it may be fairly questioned whether alum, the vitriols, or indeed any astringent that ultimately stimulates, can safely be put in action for the cure of diabetes. Dr. Grahame, of Dalkeith, has lately published an ingenious method of directing the sulphate of zinc to the kidneys, by combining it with turpentine in the form of a pill; but even this mild preparation should be tried with caution.

Thus it appears that each of the four modes of cure mentioned above has strong claims to confidence and adoption, in certain forms and stages of diabetes. Before laying down what appear to be the correct principles of treatment, it may be proper very briefly to enumerate some of the individual remedies that have been employed for the removal of this disease. The phosphoric acid and its salts, as recommended by Dr. Latham, the phosphate of iron as used by Dr. Venables, in doses of one or two grains, gradually increased to a scruple or half a drachm, three or four times a day; the phosphate of soda, on the authority of Dr. Sharkey, who has published two cases of cure attending its exhibition; ammonia; calcined magnesia; tonics, such as the mineral acids, cinchona, myrrh, &c.; various bitters; mercury pushed to the extent of inducing salivation; chalybeates; cold bathing; and the colchicum autumnale, have been severally used in diabetic cases, and with various success. We have been informed by an intelligent medical friend, that he has of late exhibited the meadow saffron in two instances of this disease, and with a highly satisfactory result; but further evidence of its efficacy is required before it can be entitled to rank as a remedy in diabetes. Dr. Ferrar has detailed three cases of confirmed diabetes, in which a cure is said to have been effected by a combination of Peruvian bark, uva ursi, and opium, in the proportion of one scruple of each of the former to half a grain of the latter, administered four times daily, with the

use of lime water for common drink. He treated this disease as one of debility. A case has also been related by Dr. Bateman, where the same practice was successfully adopted; but the disease returned after discontinuing the medicine, and did not so speedily yield to a repetition of it. In other hands this treatment has altogether failed. Dr. Shee has published a case, in the progress of which, after the ineffectual administration of astringents and opium, paralysis with convulsions of the whole of the right side supervened. In the course of ten days the patient was restored to health, (the diabetic symptoms yielding first, and afterwards the paralysis and spasm,) by a combination of camphor, kino, and oxide of zinc, with tonic infusions. Dr. Alley effected a cure of diabetes by animal diet and cinchona; and Dr. Fraser mentions an instance in which the urine lost its saccharine property in a month after commencing the use of animal diet and the sulphate of iron.

Of late the aid of iodine has been sought in the treatment of this affection; and it has been stated to us, on highly respectable authority, that it is a remedy of superior efficacy to any of the numerous substances that have been proposed for the removal of the diabetic symptoms. The experience of the profession, however, is as yet required to establish its real remedial virtues in diabetes.

The nitric acid diluted with water, (in the proportion of about three drams of acid to three pints of water,) is generally productive of benefit, mitigating the thirst and heat, and thereby diminishing the quantity of the urinary secretion. In the majority of diabetic cases it may be taken with advantage; but when there is any tendency to diarrhoea it ought to be omitted, as the bowels are apt to be disturbed by its use. Under these circumstances, lime water, or soda water, will be found excellent substitutes, as they are palatable to the taste, and quench the thirst.

The Bristol water was considered by Dr. Baillie as the best kind of drink in diabetic affections; indeed it has long been celebrated in such complaints. Dr. Marsh states that he has known a patient, labouring under confirmed diabetes, drink very largely of the Leamington saline waters without increasing the quantity of his urine, and even apparently with some advantage to his general health.

It has been shown that animal diet, opium, and venesection may be adopted *singly* with advantage in some instances of this disease; but we have found from experience that the *conjoint employment* of the two former remedies, with the occasional aid of the latter, is attended with much greater benefit. Animal diet forms the first and most important part of the treatment; for it possesses by far the most powerful influence upon the urinary secretion; and until the unnatural quantity of that fluid be considerably reduced, it is in vain to hope for any material change or improvement in its quality. Unless the disease be first of all much changed by perseverance in the animal

regimen, very little benefit is to be expected from any other remedy whatever. It is proper during its adoption to bear in mind the *probable* occurrence of inflammation in some organ or part of the body, and to be prepared to meet it early by antiphlogistic measures. Opium is also extremely serviceable in allaying nervous irritability, and in restraining the urinary discharge. Indeed, few cases of this disease occur, in which the use of this valuable narcotic is not indicated, or can even be omitted without disadvantage. It does not interfere with the animal regimen, but proves a powerful auxiliary in the removal of the complaint. Venesection, too, when employed with vigor during the early and acute stages of the disease, before the constitution has become seriously affected or much debilitated, occasionally arrests the progress of the diabetic symptoms, and sometimes completely subdues the malady.

Thus it is obviously improper to trust the cure of diabetes to any one remedy. In the selection of remedies, the symptoms form the safest guide. In obscure diseases, of the known varieties of treatment, that is to be held the best from which most benefit has been obtained; a principle which by no means precludes the trial of new remedies. Having ascertained the individual effects of several, it is often desirable to employ them *together*, as by their combined operation they prove more powerful in promoting restoration to health. Though much advantage often attends the united employment of animal diet, opium, and venesection, still we believe that the warm bath will generally be found more useful than the latter mode of cure. This opinion has been confirmed by the experience of several respectable practitioners. Warm bathing is generally agreeable to the patients themselves, and when aided by flannel clothing proves serviceable in removing the harsh, dry, and shrivelled state of skin which accompanies almost every genuine case of diabetes. It may be correctly affirmed, that in every instance of this disease it is of the first importance to employ such means as are best calculated to restore the natural functions of the skin. Our experience entirely coincides with that of Dr. Marsh on this part of the treatment. As early as 1765 "a case of incontinency of urine complicated with diabetes," was published in the third volume of the *Medical Observations and Inquiries*, by Dr. A. Fothergill, of Northampton, illustrative of the good effects of antimonial sudorifics assisted by the warm pediluvium. Under this treatment all the symptoms improved; the patient's strength and appetite gradually increased; his skin became moist; and his urine was less in quantity than his drink. His recovery was at length perfect. Dr. Marsh, however, has the merit of having enjoined a more minute attention to the improvement of the state of the skin in diabetes. "Medical assistance," as Dr. Watt has justly remarked, "is seldom required where it is not more or less affected, and we have no security of the disease being

removed, though apparently local, till the skin assume a healthy appearance. An excess or deficiency in the cuticular discharge never fails to produce some derangement in the rest of the system." When the functions of the skin are restored, and a free and equable perspiration is re-established, a favourable change in the more urgent symptoms soon becomes manifest; the distressing thirst and sensation of internal heat are mitigated, and the quantity of the urinary discharge rapidly decreases. In diabetes, with the exception of the kidney, there is indeed, (as Dr. Bostock observes,) no obvious exit by which the contents of the stomach can be evacuated; the perspiration is checked, the alvine discharge is in general not increased, and the weight of the body is daily diminishing; hence the necessity of directing remedies to the relaxation of the skin. With a view of producing a more direct action on the skin, Dr. Marsh was induced to employ the vapour bath in a well marked case of diabetes placed under his care, and the impression made upon the disease by the frequent use of this remedy surpassed his expectations. Its salutary effects in promoting diaphoresis were immediately perceptible. He also kept up the perspiration by means of warm clothing and continued bodily exercise; and with daily improvement to the patient, who was dismissed from the hospital in a convalescent state. "The warm bath has been used," (says the author just named,) "but it has been used only occasionally: it has been employed as a secondary remedy, as one of minor importance, and not as one which, if properly managed, is of itself sufficient to effect a cure. Its daily employment for weeks, nay months, may be requisite to bring about that relaxed and freely perspiring state of the skin, without which, whatever temporary abatement in the symptoms, or diminution in the flow of urine, may have taken place, not one step has in reality been made toward the accomplishment of a cure." We are satisfied, with Dr. Watt, that it is upon the skin the first impression of disease is generally made, and that we have no security of the system being fully restored till it becomes natural in its appearance, and resumes its functions. In the case of Gosling, already before the public, and in two other instances of subsequent occurrence, we have employed the sulphur in preference to the warm bath, as it possesses the power of stimulating the cutaneous vessels more forcibly than the mere vapour of water. The result on each occasion has been the re-establishment of a healthy cutaneous discharge with an amelioration of the symptoms of the complaint. Owing to the great debility and frequent pulmonary irritation present in the disease, much muscular exertion is not practicable, though it is particularly desirable to obtain moderate exercise without inducing fatigue. In conjunction with the warm and sulphur baths, the pediluvium, bodily exercise, friction, as recommended by Celsus, and flannel clothing, remedies which act *directly* upon the skin, diaphoretics may

be exhibited internally with great advantage. The pulvis ipecacuanhæ compositus, in the proportion of eight grains every five hours, often succeeds in promoting free perspiration, and also proves useful in allaying nervous irritability. It is certainly entitled to rank very high as a remedy in diabetes. In cases of a chronic kind, and accompanied by much debility and nervous irritation, Dr. Prout says that he has seen the very best effects from a combination of the pulv. ipecac. comp., and full doses of carbonate of iron, exhibited in the form of an electuary made with the albumen ovi. The tartarized antimony, in the dose of a sixth of a grain every three hours, also determines freely to the skin, and at the same time keeps up a slight degree of nausea, which is rather desirable than otherwise. When the salt acts upon the bowels, the proportion must be diminished. Having succeeded by these means in re-producing cutaneous secretion, it is indispensably necessary, in order to insure the good effects of the amendment, to avoid sudden changes of temperature, and to endeavour to maintain healthy perspiration by the aid of warm clothing and daily gentle exercise. We are enabled to speak from our own experience of the efficacy of what may be called the *diaphoretic plan of treatment*. In some instances, where every other means have proved unsuccessful, it has operated in a manner most decidedly beneficial. The patients have regained both flesh and strength, and recovered their wonted spirits and activity. We have found it most advantageous in the incipient state of the disease; but it has also been of service where the complaint has been long continued, and the patient's constitution much debilitated.

We are led to draw the following inferences from the preceding facts and observations.—1st. That no satisfactory explanation of the real nature of diabetes has, as yet, been presented to the profession; hence, its proximate cause is still involved in obscurity. 2d. That it is probable that in most instances the stomach is primarily deranged, and that the kidneys are rendered morbidly active by the percolation of saccharine matter. 3d. That the employment of an exclusively animal diet proves chiefly useful by cutting off the supply of those materials which lead to the formation of sugar; and thus, if persevered in for a time, a favourable change mostly occurs in the assimilation. 4th. That the *animal regimen*, *opium*, *diaphoretics*, and the *warm bath*, constitute the most effectual means of arresting the progress of the diabetic symptoms, and of effectually removing the complaint; and that cupping and blistering the region of the kidneys, venesection in recent cases of an acute character, lime-water, or nitric acid for common drink, prove useful auxiliaries to the preceding remedies. 5th. That no individual remedy or method of treatment is applicable to every case of the disease: for in some instances an entire abstinence from vegetable food is highly useful; whilst in others, venesection, opium, or diaphoretics are found

most beneficial. 6th. In commencing with any plan of treatment in this disease, it is proper to ascertain the quantity of solids and liquids daily taken, in order to be enabled to institute a comparison with the urine and its contents afterwards. A chemical examination of that secretion ought never to be omitted before the trial of any remedial measures, and during the progress of the complaint; as it enables the practitioner to determine with accuracy one most important point, namely, the quantity of saccharine matter it contains, and to ascertain the gradual advances towards recovery. The urine may assume nearly a natural colour, and lose all its diabetic properties to the taste and smell, when, on being evaporated, its residuum is found to afford a saccharine impregnation, shewing that the disease is not completely subdued. From inattention to the evaporation and analysis of this fluid, medical men occasionally overlook the real nature of the disease. The specific gravity of the urine ought also to be very carefully ascertained, for it is impossible to pronounce with any degree of accuracy respecting the removal of this disease, or the beneficial change produced by any curative method upon the urinary secretion, without making occasional examination of the specific gravity of that discharge. So long as the specific gravity of the urine remains beyond the natural standard, the cure cannot be considered perfect, although the patient may be capable of resuming the ordinary duties of life.

(James L. Bardsley.)

**DIAGNOSIS.** This term is derived from *διά* and *γίνωσκω*, to know, and signifies *distinction* in general; in medicine it is employed to designate the distinction of diseases.

It is necessary, before giving a detailed view of the diagnostic arrangement of diseases, to enter upon the general consideration of symptoms, as the principal source on which the distinction of diseases depends; and as symptomatology, or the doctrine of symptoms, cannot properly be considered under *diagnosis*, we propose to treat of the symptoms and diagnosis of diseases under the term **SYMPTOMATOLOGY**.

(Marshall Hall.)

**DIAPHORETICS**, (*διαφορητικὰ φάρμακα*, from *διαφορέω*, *différo*, *discutio*, from *διά*, *per*, and *φέρω*, *fero*, *porto*,) are medicines that augment the function of perspiration. In order to understand the mode in which they operate, we ought to possess an accurate idea of the manner in which the cuticular function is performed in a state of health.

The importance of perspiration for the preservation of health is well understood, but the laws to which it is subjected are still imperfectly determined. It is a function of the whole of the skin; but whether it is possessed equally by every part of it, has not been ascertained: it is, however, probable that some parts perspire more freely than other parts.

The perspiral matter passes off either in the form of a thin, invisible vapour, as *insensible perspiration*; or in a liquid form, as *sweat*. Various attempts have been made to ascertain the quantity of the cuticular discharge. From the time of Sanctorius, who first endeavoured to determine it experimentally, to that of Lavoisier and Seguin, little confidence could be placed on the results of the experiments, as the amount of the pulmonary exhalation was not deducted in calculating the loss which the body sustained in a given time. Lavoisier and Seguin overcame this difficulty, by enclosing the whole body in a silk bag, varnished with caoutchouc, having a small opening carefully cemented round the mouth, which permitted the person to breathe. The quantity of the cuticular discharge was thus determined to be one pound fourteen ounces in twenty-four hours;\* and, as this was the result of repeated trials, we may regard it as the average quantity in a state of health.

Many circumstances tend to vary the loss by perspiration, not only in different individuals, but in the same person at different times, and under a diversity of circumstances; as, for instance, the vigour of the frame, the nature and quantity of the ingesta, the temperature of the atmosphere, and many external relations. Thus perspiration is diminished immediately after a meal, but augmented during the process of digestion: it is also promoted during sleep; in a dry state of the atmosphere; in a current of air; and under a diminished barometrical pressure. But these circumstances are supposed to promote perspiration independent of vitality; and therefore Dr. Edwards has divided perspiration into that which results from ordinary physical influences, and that which is dependent on vitality or secretion; or into *exhalation* and *secretion*. Both are liable to be affected by external agents. In low temperatures, the loss by evaporation exceeds that by secretion, because cold suppresses secretion more than it impedes evaporation. It may, indeed, be maintained that even in a low temperature the cutaneous capillaries are still stimulated; and, consequently, that the portion of the insensible perspiration, which is the result of vital energy, must still be supplied: but it is in the ratio only of the stimulus which excites the vessels that furnish it: whilst the evaporation is less diminished, because the air being heated by contact with the body, is enabled to hold more moisture in solution than the air farther removed from the body; and thence evaporation is favoured.

One evident intention of perspiration is to prevent the temperature of the body from rising above that degree which a state of health requires, and to operate as a balance to the heating influence of increased arterial action. It also counterbalances other secretions; as for instance that of the kidneys, which is

\* Mémoires de l'Académie des Sciences, 1790, p. 610.

diminished as the perspiration is increased, and augmented when it is checked—a physiological fact of much practical value.

Many experiments have been made to ascertain the chemical nature of the perspired matter. From all that is known, it may be concluded that it consists chiefly of aqueous fluid, containing in solution some free lactic acid, lactate, muriate, and phosphate of soda, and an oleaginous principle: but there is also reason to believe that gaseous fluids are perspired by the skin with bases of nitrogen,\* carbon,† and hydrogen;‡ and to the presence of the latter, variously modified by the accession of other constituents, some physiologists attribute the odour of perspiration. This odour, however, seems rather to depend on the secretions of the mucous follicles mingling with the perspiration, than to be a quality of this fluid, as it differs in different parts of the body.

Contemplating the nature of the perspiratory function, we may conclude that it is intended to answer two purposes:—1. to convey caloric from the body, and thereby to moderate and regulate its temperature; 2. to carry off a large quantity of carbon and hydrogen from the circulating mass.

Disease is frequently the consequence of a sudden check to the perspiratory function; means, therefore, have been sought for to restore it; and substances which have the power of effecting this are termed *diaphoretics*. Let us now inquire in what manner they produce their effects.

Diaphoretics may operate in two ways:—1st, by stimulating generally, and so augmenting the force of circulation as to propel the blood forcibly through the minute vessels of the *corium*, by which both the secreting power of the skin, and the excretory function of the exhalants, is increased; 2dly, by the absorption of the diaphoretic substances taken into the stomach, and the direct application of these to the cutaneous capillaries.

In the healthy state of the system, perspiration is, probably, always the result of stimulating, either directly or indirectly, the cutaneous exhalants; and sweating follows increased vascular action, whether this arise from muscular exertion, or from substances taken into the stomach. But in disease, when the temperature of the body is augmented, the pulse is often frequent, indicating increased excitement of the general circulation, yet the skin remains dry. In this state there is evidently diminished action of the exhalents, whilst the cutaneous capillaries have their

secreting power impeded; and, therefore, this condition must be overcome before diaphoresis can be produced. Those substances which augment the force of the general circulation, whilst at the same time they excite the cutaneous exhalants, will effect this desired change; few substances produce this double effect, alone, but it is readily induced by some combinations.

Those diaphoretics which operate by augmenting the force of the vascular system, increase the frequency and the power of the pulse, and raise the temperature of the body, previous to the flow of perspiration: on the other hand, those which act by stimulating the cutaneous exhalants without augmenting the force of the general circulation, exert a primary influence on the nervous energy of the stomach, and the skin responds by that inexplicable connexion to which the term *sympathy* has been applied.

As the primary effect of diaphoretics is the evacuation of a large portion of the aqueous part of the blood, it might be supposed that this vital fluid would in consequence become thicker; but various circumstances concur to prevent such a result. Amongst others, thirst always accompanies sweating; and as this forces us to take fluids into the stomach, the waste of the aqueous matter thrown off by the skin is rapidly supplied. At this time, also, other fluid excretions are diminished, the urine for instance; so that the watery matters which would be carried off by them are diverted to the surface, and even several substances, which naturally find other outlets, are expelled by the skin. This is clearly demonstrated in some diseases. Thus, in cases of ischuria renalis, the perspiration has been found to contain uric acid and other traces of urine. Dr. Percival relates a case in which the perspired matter was so saturated with the salts of the reflux urine, as to crystallize on the surface of the body, in the form of a white powder. Such a condition of circumstances is, indeed, not surprising, when we consider that the suppression of one secretion induces an unusual action in the vessels of some other organ, and a changed condition of the secretion.

One unquestionably beneficial effect of diaphoretics is the determination of the blood from the interior to the surface, thereby relieving congestions, and maintaining that due balance of the circulation which appears to be essential to the preservation of health. Their salutary influence is also displayed in the increased power which they bestow on the absorbents, and in their relaxation of the surface in febrile affections. The relaxing effect of diaphoretics is indeed the most important property they possess as remedial agents, as it is on this power that their utility in inflammatory affections depends. Were it, however, attempted to induce diaphoresis in inflammatory or febrile affections by stimulating diaphoretics, the desired effect would not only be prevented from taking place, but the hazardous symptoms would be aggravated. Several circum-

\* Vide Ingenhouz's Experiments; Expériences sur les Végétaux, tom. i. p. 152; and those of Trousset, Annales de Chimie, tom. xlv. p. 73.

‡ Experiments on Insensible Perspiration, by W. Cruickshanks; Jurine's Experiments, Histoire de la Société Royale de Médecine, tom. x.; and those of Abernethy, detailed in his Surgical and Physiological Essays.

stances, therefore, are requisite to be attended to, in the administration of this order of medicines: we shall mention those most important in a practical point of view.

1. Whenever diaphoretics are indicated, the patient should be confined to bed, but not overloaded with bed-clothes. If the pulse be full, hard, and quick, and the skin hot, blood-letting, if not contra-indicated by some peculiar circumstance, should preface the use of the diaphoretics; and the bowels should also be freely opened. It is a correct opinion, that free perspiration is not consonant with a quick hard pulse, and a temperature of the skin exceeding 102° of Fahrenheit: in this state, if sweating occur, it is generally partial, and rather injurious than salutary. Even after the reduction of the phlogistic diathesis, the diaphoretics to be selected are those which nauseate and relax the surface.

2. The free use of diluents is necessary during the operation of diaphoretics, unless the stomach be in a highly irritable state. If antimonial diaphoretics, however, be employed, acidulated fluids should not be taken soon after the dose of the antimonial, as vomiting would be induced. When the temperature of the surface is high, the diluents should be cold; but when it is moderate, they should be tepid. So important, indeed, is dilution in promoting the action of diaphoretics, that the mere introduction of cold or tepid fluids into the stomach during the hot stage of fever, often produces diaphoresis.

3. During the operation of diaphoretics, it is essential to use bad conductors of caloric as coverings: both the body clothes and the bed clothes of the patient should be flannel, which, being of a light spongy texture, not only preserves an uniform temperature, but also absorbs the moisture as the perspiration flows. When linen is employed, the moisture accumulates in it, and aiding its conducting power, carries of the heat too rapidly from the body, and chills the surface. Attention to this circumstance is most essential, if it be requisite to keep up the sweating for ten or twelve hours or longer, and especially if sleep become necessary during the continuance of the sweating. The older practitioners invariably resorted to the use of flannel during diaphoresis; a custom which has been too hastily condemned by modern practitioners, who recommend, instead of flannel, frequent changes of well aired linen, asserting that this is more refreshing to the patient; that, from its comfortable feel, it has a tendency to allay irritation, consequently to aid in subduing the restlessness and inquietude of fever; and that it is essential for carrying off the fomes of the disease. The last part only of this opinion is well founded; and few practitioners would place a patient labouring under an infectious fever in flannel: indeed, under such circumstances, perspiration to the extent which requires the use of flannel is neither necessary nor desirable.

4. Attention must be paid to the *state of the*

*bowels and kidneys.* If perspiration be requisite in a low stage of fever, purging must be studiously avoided, and should be checked if it occur spontaneously whilst the sweat is flowing; as it is almost certain to stop the sweating and to aggravate the disease, by diverting the blood to the interior, and exposing the patient to cold. The utmost caution, indeed, is requisite to prevent the admission of cold air to the surface; and no cold liquids should be taken into the stomach whilst the sweat is flowing, and for some time after it has ceased. During the administration of diaphoretics, every thing which has a tendency to promote the secretion of the kidneys should be avoided. The avoiding a frequent change of linen is in conformity with this rule, as, in affecting these changes, the surface must be necessarily exposed.

5. The morning, directly after sleep, is the best period of the day for administering diaphoretics, as the system is then easily excited, and the surface is relaxed: experience has demonstrated that many persons in whom perspiration cannot be induced at any other period of the day, may be readily made to sweat at that time. When perspiration accompanies diseases, it generally happens in the morning; there is then, also, a natural decline of febrile excitement; thence it is the most favourable time for the action of diaphoretics: and besides, as the administration of diluents is necessary to maintain the diaphoresis, this is the more convenient period for their administration.

6. When sweating is to be checked, the skin should be dried with soft warm towels; the patient should be carefully moved into dry flannels, and the coverings gradually lessened, allowing the arms to be cautiously exposed to the air. By these means, the injurious consequences, which might follow a sudden revulsion, are avoided.

Before entering upon the examination of those substances and means which are usually employed to promote diaphoresis, it may be proper to state why we arrange them under the two following heads:—

1. Diaphoretics, which cause a copious, watery, cutaneous excretion, or flow of *sweat*.

2. Diaphoretics, which only augment the *ordinary perspiration*.

The first set excite the cutaneous capillaries and exhalants to a degree sufficient to increase both the secretory and the excretory functions of the skin beyond that point at which the perspired matter is carried off in the insensible form; thence it appears as sweat, and the substances inducing it ought to be distinguished from other diaphoretics. They are properly termed *sudorifics*. The second set operate in the same manner, but so moderately that they merely augment the ordinary insensible perspiration. It is true that both these results may be obtained by modifying the dose of the substances employed, and the circumstances under which they are administered; but nevertheless there are substances which, all circumstances being equal, produce a more pow-

erful diaphoretic effect than others; and, therefore, this division is useful.

1. *Sweating* may be produced in two ways: by substances taken into the stomach; and by applications to the surface.

a. The substances capable of producing sweating when taken into the stomach—*sudorifics*—belong both to the *organic* and the *inorganic* kingdom of nature. Among the first, *ipecacuanha*, the root of the cephaelis *ipecacuanha*, which has been long known as a valuable sudorific, owes its properties to a peculiar alkaline principle, discovered by M. Pelletier, in 1817, named *emetia*.\* Separate from the *ipecacuanha*, *emetia* has not yet been introduced into general practice in Great Britain, although it is much employed on the continent. *Ipecacuanha* in moderate doses, one grain or less, is well calculated to produce sudorific effects; but it is seldom administered alone for this purpose, being generally combined with opium, the narcotic influence of which it moderates, whilst its own diaphoretic powers are augmented by the combination. It exists in this state in the compound powder of *ipecacuanha* of the British Pharmacopœia, ten grains of which, a full dose for an adult, contain one grain of *ipecacuanha* and the same quantity of opium. In prescribing this powder, or *ipecacuanha* itself, or its infusion in wine, although it may be advantageously combined with camphor or with nitrate of potassa, yet it ought not to be prescribed in conjunction with astringent decoctions or infusions, as the tannin unites with the *emetia*, forming an insoluble tannate, which is inert. Its sudorific effects, when once begun, should be maintained by copious dilution with tepid fluids; but tepid drink should never be taken immediately after the powder, otherwise it may be rejected by vomiting. It should, also, be recollected that the diluents should not be acidulated, as the combination of vegetable acid with *emetia* is more likely to run off by the bowels than to exert a diaphoretic influence; at the same time, as it is advisable to add something to the tepid water to prevent the nausea extending to vomiting, lemon-peel may be infused in toast-water for that purpose.

*Mezereon*, the inner bark of the roots of *daphne mezereum*, is also supposed to owe its sudorific property to an alkaline principle, *daphnina*,† which was first procured by Vau-

\* The *emetia*, in its separate state and pure, is white, pulvulent, and unalterable in the air, of a slightly bitter taste, inodorous, sparingly soluble in cold water, but soluble in hot water and in alcohol and ether. It is seldom obtained in this state, but is usually of a reddish-brown colour and deliquescent. One hundred grains of good *ipecacuanha* contain sixteen of *emetia*. MM. Majendie and Pelletier suppose that it is taken into the circulation, and exerts a specific effect on the lungs, and on the mucous membrane of the intestinal canal.

† *Daphnina*, when pure, is a colourless, inodorous alkaline salt, which crystallizes in transparent brilliant crystals, soluble in water, alcohol, and ether. The alkalies, lime water, and barytic water tinge its solution of a golden hue; nitric acid converts it into oxalic acid.

quelin from the *daphne alpina*; but this is uncertain. *Mezereon* is a stimulant sudorific, exciting, powerfully, the heart and whole arterial system: it is apt to cause vomiting and purging. It has been found very useful in chronic rheumatism, and, in conjunction with the liquor arsenicalis, in obstinate cases of lepra, and some other chronic cutaneous affections. It is probably to its sudorific property that we are to ascribe its beneficial influence as an ingredient in the compound decoction of sarsaparilla, in secondary syphilis and many chronic diseases. We are aware that Mr. John Pearson states, that he had "very seldom found it possessed of medicinal virtue, either in syphilis or in the sequelæ of that disease, in scrofula or in cutaneous affections."\* Our experience prevents us from according with this opinion. Its sudorific powers may be secured by administering an infusion, made with two drachms of the bark in a quart of hot water, in doses of  $\mathfrak{f}\mathfrak{ʒ}\mathfrak{i}$ . every four hours.

*Guaiacum*, the concrete juice of the *guaiacum officinale*, was known as a diaphoretic so early as 1508, and was used by the natives of St. Domingo as a specific in syphilis; but although, when administered alone, it possesses no influence over lues venerea, yet it is a powerfully stimulant sudorific, and proves useful in impetigo and some other cutaneous eruptions; in ozæna, and in scrofulous affections of the membranes and ligaments. Its utility in these cases may depend on its power of augmenting the energy of the absorbents and the cutaneous capillaries, thereby improving the state of the cuticular function. In chronic rheumatism, a solution of *guaiacum* in aromatic spirit of ammonia, the tinctura *guaiaci ammoniata*, given in doses of from  $\mathfrak{f}\mathfrak{ʒ}\mathfrak{ss}$  to  $\mathfrak{f}\mathfrak{ʒ}\mathfrak{i}$ . at bed-time, and its sudorific powers aided in the morning by copious dilution with tepid fluids, has been productive of much benefit; and it is equally serviceable in atonic gout: but its boasted efficacy as a gout medicine has never been realised; and even in chronic rheumatism the remark of Dr. Ferriar, that although in some forms of the disease it proves serviceable, in others it produces no effect whatsoever, is no doubt correct. Dr. Chapman makes the following remarks on the efficacy of *guaiacum* in a morbid affection of the eye:—"There is a morbid affection of the eye of gastric origin, hitherto not sufficiently noticed, where, although no external inflammation exists, or so slightly as hardly to be perceived, there is great intolerance of light; sometimes very acute lancinating pains through the ball, although more generally the sensation is that of a dull obtuse ache, attended with much heat and aridity of surface, which, whatever may be its nature, is very successfully treated by the *guaiacum*."† Dr. Chapman appeals to his own experience of the efficacy of this

\* Pearson's Observations on the Effects of various Articles of the Materia Medica, in the cure of Lues Venerea, Lond. 1800, p. 49.

† Chapman's Materia Medica.

medicine, and affirms that he never saw the disease cured by any other.

As a sudorific, guaiacum acts freely only when the surface is kept warm; otherwise, it excites the urinary discharge. The more minutely the guaiacum is divided, the more certain is its sudorific power; and, therefore, the tincture, decomposed by water, if the precipitated guaiacum be rubbed up with mucilage to suspend it in the liquid vehicle whatever it may be, is the best form in which it can be prescribed. The dose of either of the tinctures is from ℥ʒi to ℥ʒiii. The ammoniated tincture is to be preferred in atonic gout.

It is unnecessary to enter into any details respecting those sudorifics which owe their powers to volatile oil. They are all too stimulant to be employed as sudorifics, except in diseases of diminished energy. In the low and sinking stage of typhus, serpentaria often proves beneficial; when, although the dry hot skin indicates the necessity of a sudorific, yet the nauseating and relaxing diaphoretics would prove injurious. It has also been found useful in dyspeptic affections accompanied with a dry skin, and is an excellent adjunct to cinchona or its salts in protracted cases of intermittents, and in atonic gout.

The only *inorganic* substances of value as sudorifics are the preparations of *antimony*. All of them may be so managed as to produce sudorific effects, but the most manageable and certain is the tartrate of antimony and potassa; and, in small doses, of from one-sixth to one-fourth of a grain, it seldom fails to procure copious sweating. The experiments of Dr. Elliotson have completely demonstrated the inert character of the pulvis antimonalis of the London Pharmacopœia; and the writer of this article has satisfied himself, by an experimental investigation, that it bears no resemblance to the true James's powder, the place of which it is intended to supply. The antimony in James's powder is in the state of a soluble *protoride*; in the pulvis antimonalis it is usually\* in that of an insoluble *peroxide*; and as it is undoubted that the more soluble the salts of antimony are, the more certain and powerful is their sudorific influence, it is easy to explain the general inefficacy of the antimonial powder, 130 grains of which have been given, three times a day, without producing even nausea.† But, at the same time, it must be admitted that no medicines are so much modified in their effects by idiosyncrasy as antimonials: in one person, small doses of tartar emetic will induce only moderate sweating; in another, the same dose will cause alarming vomiting and purging, extreme depression of bodily strength, and excite a degree of nausea which cannot be allayed.

\* We say usually, because no preparation used as a remedial agent is so variable in its nature. In a few specimens we have found a small proportion of the protoxide: but in far the greater number of the specimens examined, the antimonial is in the state of a peroxide.

† London Medical Gazette, December 1831, p. 463.

The influence of antimonials is much augmented by combination with other substances, as camphor, calomel, and opium; but, in prescribing tartar emetic, it should be recollected that it is decomposed by alkaline carbonates, by the medicinal soluble salts of zinc, lead, bismuth, and mercury; and that an insoluble tannate is formed with the protoxide of antimony, when tartar emetic is added to any of the astringent vegetable infusions or decoctions, with the exception of those of oak-bark. The tannate thus formed is inert; on which account decoction of yellow cinchona is the antidote of tartar emetic. In acute rheumatism and other inflammatory affections, a combination of one grain of calomel, one-fourth of a grain of tartar emetic, and from one to two grains of opium, administered every fourth or fifth hour, produces every thing that can be expected from a sudorific: indeed, when the intention is to determine powerfully to the surface, the tartrate of antimony and potassa, in small doses, repeated at proper intervals, and aided by warmth and diluents, is, as we have already said, more manageable and certain in its effects than any other of this order of remedial agents.

*b.* Those agents which, applied to the surface, produce sweating by directly stimulating the cutaneous capillaries, are warm and hot baths, vapour-baths, hot air-baths, and the cold affusion. For the *modus operandi*, and manner of administering these, we must refer to the article BATHING.

2. The diaphoretics which merely augment the ordinary perspiration produce their effect in three ways:—1. through the medium of the stomach; 2. by entering the circulation, and acting directly on the skin; 3. by application to the surface.

Among the substances of this division of diaphoretics which operate through the medium of the stomach, we think it unnecessary to say any thing either of *musk* or of *castor*. With respect to *dulcamara*, (the twigs of the solanum *dulcamara*), which owes its efficacy to a peculiar alkaloid, named *solanina*, either diaphoresis or diuresis may be produced by it, according to the extent of the dose or the manner in which the surface of the body is managed during its administration. It generally produces nausea, and not improbably much of its diaphoretic influence depends on this circumstance; and on this account the dose should be gradually increased during its administration. Two fluid ounces of the decoction, made with ℥i. of the bruised twigs boiled in a pint and a half of water down to a pint, given three times a day, seldom fail to induce and maintain a gentle breathing perspiration. *Camphor* certainly produces a tendency to diaphoresis, without increasing the velocity of the pulse; and, therefore, it forms a useful adjunct to more decided diaphoretics; but with respect to sarsaparilla, even this is doubtful; and we are disposed to think that the diaphoresis which it is supposed to produce is due to the tepid diluent regimen which is generally prescribed during a course of it.

Among the inorganic substances belonging to this division of diaphoretics, we find the carbonate and citrate of ammonia, citrate of potassa, and acetate of ammonia. The first stimulates the nervous energy, and produces diaphoresis when aided by external warmth and plentiful tepid dilution; it is indicated in the sinking stage of typhoid fevers, and other debilitated conditions in which diaphoresis is still desired; but otherwise its place can be much better supplied by many other substances. In combination with guaiacum and opium, considerable advantage has been obtained from it in obstinate cases of chronic rheumatism. To produce its diaphoretic effect the dose should not be less than twelve grains, nor more than twenty: the best vehicle for administering it is the almond emulsion. The *citrate of ammonia*, which is generally prepared at the moment of its administration by saturating recent lemon-juice with carbonate of ammonia, possesses very moderate diaphoretic powers; but it is less nauseous than the acetate, and forms an excellent vehicle for tincture of opium, when it is desirable to promote its diaphoretic influence. The same remarks apply to the *citrate of potassa*, which is more frequently employed than the former preparation, especially when the stomach is in a highly irritable state. The old method of administering the saline draught—first swallowing the solution of the alkali, and immediately afterwards the lemon-juice, although now seldom recommended, yet had its advantages. The alkaline solution allays the irritability of the stomach, whilst the close application of the carbonic acid, extricated in the stomach, to the nerves of that viscus, affords a certain degree of tone without interfering with the diaphoretic operation of the neutral salt formed by the union of the two bases. The best of the neutral salts, however, for inducing diaphoresis is the *acetate of ammonia* in solution, the old *spiritus Mindereri*. The common solution of this salt, the *liquor ammoniæ acetatis*, is generally very carelessly prepared, and little pains taken to produce a strictly neutral solution: when the alkali predominates, the solution of tartar emetic, occasionally prescribed with it, is decomposed; when the vinegar is in excess, the usual dose of the antimonial excites vomiting. The crystallized salt, formed by saturating strong acetic acid with ammonia, being always neutral, should be employed in solution in preference to the usual preparation. When perfectly neutral, the solution is an excellent vehicle for soluble antimonials and opium, aiding considerably the effect of both on the skin: it is also easily retained on the stomach, and frequently allays the irritability of that organ when administered in doses of  $\mathit{f}\mathit{3}\mathit{i}\mathit{i}\mathit{i}$ . to  $\mathit{f}\mathit{3}\mathit{x}\mathit{i}\mathit{i}$ . in any bland fluid.

The last of the substances necessary to be noticed in this section of the second division of diaphoretics is *water*. The greater part of the fluid perspired by the skin is water; and if the surface be kept warm, so as to check the action of the kidneys, the proportion is generally in the ratio of the quantity of fluid

taken into the stomach. But besides this cause of the diaphoretic influence of water, it is also well known that the sudden impression of a draught of cold water upon the nerves of the stomach acts most forcibly in promoting diaphoresis. A person who awakes in the night with the tongue feverish and parched, a quick pulse, and a dry, hot skin, finds immediate relief from swallowing a large draught of cold water: the cutaneous capillaries immediately consent with the stomach, and copious perspiration often ensues. By imitating this practice in fevers a similar result is occasionally obtained. When water is to be employed as a diaphoretic, much depends on the management of the patient during its administration. If the surface be kept warm, and the body surrounded with bad conductors of caloric, a moderate quantity of water will produce the effect required. Under these circumstances, cold water is to be preferred to warm; but it must be kept in remembrance that in delicate constitutions, even in fever when the excitement is high, a sudden reduction of temperature is hazardous, and, therefore, tepid drinks are necessary; and small quantities of aromatics may be added to the aqueous fluid to moderate the nausea which tepid water always produces.

Besides being diaphoretic itself, water is the general auxiliary of all other diaphoretics; nor can the influence of the best of them be maintained without ample dilution. In this case the fluid employed should always be tepid, at least of a temperature not under 65° Fahrenheit. The same rule, indeed, is necessary for the administration of diluents as for the external employment of water: when the temperature of the body is under 96°, cold drink should not be ordered. Nature points out the best indications for using water, both as to its administration at first and its continued employment, by the sensation of thirst which accompanies every state of febrile action: when this is present, we cannot err in prescribing water, the temperature being determined by that of the body and the state of the skin.

Among those substances which enter the circulation and operate as diaphoretics by their direct influence on the skin, the first which we have to notice is *sulphur*. When this substance is taken into the stomach, it passes off through the cutaneous exhalants united with hydrogen; a fact demonstrated by silver, worn in the pockets of those taking it, assuming the same dark hue as if it had been exposed to a stream of sulphuretted hydrogen gas; and as it thus passes off, it excites diaphoresis. As a diaphoretic, sulphur is employed in cases of chronic rheumatism and some other skin diseases; and in combination with oil, the *oleum sulphuratum* of the London Pharmacopœia, in chronic catarrh: but this is an acrid, nauseous preparation, and consequently seldom administered. In combination with potassium, sulphur forms a solid preparation, *hepar sulphuris*, which by solution in water is converted into a hydro-sulphuret of potassa. Both of these preparations have

been employed as diaphoretics in chronic affections of the chest, and in several cutaneous diseases.

The action of the salts of *mercury* upon the capillary system has been long known; and in having the cuticular discharge promoted by them, it is probable that the skin only shares, as a secreting organ, in the general influence which they exert on the glandular system; but although their influence on the cutaneous function is demonstrated by daily experience, yet they are only employed as auxiliaries in promoting diaphoresis. Calomel, the protochloride of mercury, is the preparation usually selected for obtaining the effect of mercury on the cuticular exhalants; and it is generally conjoined with tartar emetic or James's powder, ipecacuanha, guaiacum, or opium; to which it imparts additional sudorific power. In these combinations, calomel is given with advantage in all inflammatory diseases; and, in the form of Plummer's pill, in cutaneous eruptions and in chronic rheumatism. In this pill the antimonial is the antimonii sulphuretum præcipitatum of the London College, a preparation possessing more certain sudorific properties than the pulvis antimonialis: whether an influence can be ascribed to the guaiacum, considering its small proportion to the more active ingredients in this pill, seems doubtful. As a diaphoretic, the dose of calomel should not exceed one grain, frequently repeated.

c. Whether sweating or mere diaphoresis be produced, the cause of both, as far as they are the result of the substances to which we have already referred, is the augmented action of the whole vascular system; but diaphoresis may be procured by the excitement merely of the cutaneous capillaries. The natural insensible perspiration is, indeed, apparently the effect solely of the cuticular system of vessels; and although means exist by which this may be carried to sweating, yet still the cause is confined solely to the cuticular vessels. *Friction* operates in this way, acting on the surface, in a manner equivalent to muscular exertion on the whole habit, in augmenting diaphoresis. The tepid bath produces its effects on the same principle, although both the degree and the nature of the stimulus be different. When the tepid bath is employed, it is necessary to continue the application for a considerable time to produce the desired effect. The first result of its application is emollient, the second diaphoretic.

In remarking on the practical employment of diaphoretics, we should say that they must be selected according to the nature of the disease, and the object to be accomplished. Those that operate by augmenting the force of the general circulation are well adapted for relieving internal congestions; those which produce nausea and unload the oppressed capillaries, are adapted for diminishing febrile action, and reducing the morbid temperature of the body.

With respect to the diseases in which diaphoretics are beneficial, we must refer to the various

articles which are devoted to their consideration.

(A. T. Thomson.)

DIARRHŒA, (*Διάρροια*, from *διάρρῆω*, *perfluo*, primarily from *διὰ*, *per*, and *ῥῆω*, *fluo*); looseness, flux, lax. This is a very common and well known disease, characterised by frequent and imperative calls to go to stool, the evacuations being more liquid than the usual healthy discharges from the bowels. Pain or griping is occasionally an attendant, but not necessarily so. This disorder is frequently a matter of trifling importance; at other times it is productive of serious consequences.

*Causes.*—Diarrhœa may originate in very various causes. One of the most common is the direct application of stimulants to the interior of the digestive tube. Errors in diet, either in quantity or quality, will often act in this way. When a great mixture of different kinds of food and drink is taken at the same meal, a sudden attack of diarrhœa is no uncommon occurrence, and need not be matter of surprise. In some constitutions a draught of cold water, beer, milk, &c. immediately affects the bowels, especially if the individual is heated at the time; and ices are often productive of the same effect. Unwholesome articles of diet operate in a similar manner on many individuals. Of this kind are, animal food approaching to a putrid state, raw vegetables, cucumbers, melons, mushrooms, certain salads, &c.\* Diarrhœa is also a very common occurrence in infants when the nurse's milk disagrees, or when other food is given too stimulant for their digestive powers, or in too great quantity.

Diarrhœa occurs as a sympathetic disorder in many diseases, as in the dentition of children; and there are many affections of a more general kind where it is a frequent attendant. Measles, scarlatina, and other exanthemata, afford examples of this. In such cases there is little doubt that an excited or hyperemic state of the mucous membrane takes place: some have even supposed that an eruption analogous to that on the surface may be present. In gastric and enteric fevers, also, diarrhœa is a frequent symptom. It is often the initiatory state in cholera and dysentery; and in some diseases, as fevers, it occasionally shews itself as a critical discharge. The diarrhœa which attends the latter stages of phthisis, and other forms of hectic and atrophic affections, is universally known.

Many causes give rise to diarrhœa in a less direct manner, such as exposure to cold, cold and wet feet, an atmosphere simply cold and

\* We have the personal testimony of no less a man than Cicero, that the substances last mentioned are productive of this complaint.—Dum volunt isti laui terra nata, quæ lege excepta sunt, in honorem adducere, fungos, helvellas, herbas omnes ita condiunt, ut nihil possit esse suavius. In eas quum incidissem in cana augurali apud Lentulum, tanta me *διάρροια* arripuit, ut hodie primum videar consistere. Ita ego, qui me ostreis et murenis facile abstinēbam, a beta etiam et a malva deceptus sum.—*Epist. Fam. lib. vii. 127.*

damp, or impregnated with putrid exhalations, &c. With some persons exposure to warm and damp air is productive of the same consequences; and alternations of temperature are often equally effective, as in the case of a hot day being succeeded by a chilly evening. Suppressed evacuations, as interrupted sweat, checked menstruation, the disappearance of abscesses, retrocession of the eruption of small-pox, measles, or scarlatina, are occasionally succeeded by diarrhœa. Many persons of a nervous temperament are subject to similar attacks on the least agitation of mind, anxiety, or surprise; and when such mental states are present, the slightest errors of diet will be followed by liquid discharges from the bowels, although the same persons are exempt from any such attacks when no such disturbing causes are in operation, even when they indulge in a great variety of food. Morbid secretions from the liver and other glands that open into the intestinal canal, as well as irritating secretions from the mucous membrane itself, are also causes of diarrhœa. So likewise are worms generated there; but less frequently than might be expected.

Gout in many instances appears to maintain a tendency to loose discharges from the bowels, and to expend itself by this outlet. We have known several cases of persons who were accustomed to have three or four loose motions daily while in health; and when the least interruption to this ordinary habit took place, a fit of regular gout came on, the diarrhœa reappearing when the gouty attack had subsided. One gentleman had his first attack of gout on giving a check to a loose state of the bowels which he considered troublesome; and for many years afterwards diarrhœa and gout constantly alternated. This is the *diarrhœa arthritica* of Sauvages, and is noticed by many practical writers, as Sydenham, Baglivi, Musgrave, &c.—Many persons are liable to diarrhœa on visiting certain cities, as London, Paris, Cork, Limerick, Galway, &c. The waters of such places are commonly accused as producing the complaint, but there are probably other causes. Diarrhœa often prevails epidemically without our being able to trace the precise cause; but in such cases it is commonly accompanied by catarrhal affections of other mucous membranes.

*Symptoms and different forms of diarrhœa.*—An attack of diarrhœa is, in most instances, from whatever cause it may proceed, preceded by feelings of indigestion, nausea, flatulence, &c. It is usually attended by more or less pain or uneasiness in different parts of the abdomen, more especially before the bowels are called upon to act. In the more severe forms the abdomen is often swelled, hot, and painful to the touch, and the discharges are announced by searching pains of various degrees, sometimes slight, sometimes very severe, and attended occasionally by fainting, and frequently by nausea, or even vomiting. The pain seems to follow the transit of the alimentary mass, and to be connected with the peristaltic contractions of the muscular coat of

the intestines. The discharges take place without effort, and in some instances are involuntary. The patient feels weaker after each evacuation, yet experiences some relief from the pain, tension, and flatulent working in the bowels.

The number of stools is very uncertain; they may amount to ten, fifteen, twenty, or even twice that number, in the twenty-four hours. In the commencement of the attack they are abundant in quantity; afterwards they become more scanty, and, whatever may have been their original condition, consist chiefly of a serous fluid mixed with mucus, with or without bile, and often with fibrous threads. The discharges are more fetid in proportion to the quantity of proper excrementitious matter contained in them. Paleness and wasting of the body accompany the severer attacks; likewise a sense of chilliness, dry skin, a loaded tongue, and a diminution of the urinary secretion. The patient becomes often so enfeebled as to be forced to keep his room or even his bed.

The nature of the evacuations in diarrhœa has of course attracted the attention of physicians in a very particular manner, and in most cases they have been considered as constituting the very essence of the disease. The discharges vary extremely in colour, consistence, and other physical characters; and although this variety is often observable in individual cases, either at one and the same instant, or at different periods of the attack, still, generally speaking, different cases commonly preserve throughout their course one predominant character of the evacuations. On this fact has been founded the most common classification of diarrhœa which we possess, and which, variously modified, has obtained from the earliest times up to the present period. This classification is, no doubt, as we have just observed, founded in nature; still it must be strongly impressed on the mind of the student and young practitioner, that the nature of the stools alone cannot be admitted as affording a true indication of the pathological condition of the parts which constitute the seat of the disease, and much less as a guide in practice. Constant attention to their character, however, can never be dispensed with on the part of the practitioner.

For a full account of all the appearances of the discharges which have been considered as characterising different species or varieties of diarrhœa, we must refer to nosologists and systematic writers. We can only notice a few of the most remarkable.

*Fœculent diarrhœa.*—The evacuations in this variety are of the ordinary fœcal character, but more liquid and more frequent than natural. This may be said to be present in the commencement of all the other forms, inasmuch as the fœcal contents of the bowels must be evacuated either before the morbid secretions take place, or in conjunction with them. What, however, has been usually termed fœculent diarrhœa, is that in which the evacuations retain this character through the greater part of

their course. This is the *D. stercorea* of Sauvages, the *D. crapulosa* of Cullen, and the *D. fusa* of Good. It is apt to occur to those who have large appetites, and who have overloaded the stomach with a variety of food. It often comes on without warning and without pain. It is sometimes attended with dyspeptic symptoms, but sometimes not. It generally ceases of its own accord; and though it leaves the patient somewhat debilitated, the healthy functions of the bowels are soon restored, provided the patient or his attendants are not too anxious prematurely to arrest the discharges, or again to overload the stomach with improper food.

*Bilious diarrhœa.*—This is not a very uncommon form of bowel disorder, yet we believe it is often said to be present when the affection is merely that last described. In the proper bilious diarrhœa, the stools, at first fœcal, are loaded with a morbid proportion of bile, and are, in consequence, of a bright yellow or greenish colour. It is supposed to arise from an excited condition of the liver producing a superabundant secretion of bile, or bile of a morbid character, which acts on the mucous membrane of the bowels as a stimulant. This state of the liver is frequently produced, we believe, by a primary affection of the duodenum, of an inflammatory kind, which either simply excites the gland to increased action, by what has been termed continuous sympathy, or produces in it a like condition with itself. In either case the result is an augmented flow, and probably a depraved state of the bile. This species of diarrhœa is often met with in those who live intemperately, or whose hepatic organs have suffered in warm climates. Intense moral emotions, such as a violent fit of anger in sanguine temperaments, or grief and disappointment in melancholics, have been observed to give rise suddenly to it. The connection between the manifestation of the passions of the mind and the secretion of bile, so familiar to our classical readers in the writings of the ancient physicians as well as poets, is founded in accurate observation, and no doubt originated in the supervention of the form of diarrhœa now under consideration, to strong mental emotions. All our nosologists agree in terming this variety *D. biliosa*.

*Mucous diarrhœa.*—In the true mucous diarrhœa, the stools contain little or no proper fœcal matter, but consist chiefly of mucous or watery fluids, the former being predominant. The stools sometimes consist entirely of mucus, which is passed either in large continuous masses, or in separate flakes, intermixed with more liquid matters; it is often found, particularly in the commencement of an acute attack, or rather, after this has lasted a few days, quite transparent, and of the consistence of jelly; at other times it lies at the bottom of the pan like semi-transparent mucilage. The stools are of very various colours, depending chiefly on the degree of admixture with bile, but the characteristic features of the variety are to be sought for rather in the consistence and tenacity than in the colour. This form of diar-

rhœa is usually acute, and often reigns epidemically in conjunction with mucous fevers and catarrhal affections of the other mucous membranes, with some of which it occasionally alternates. It is often unaccompanied with fever, even when of considerable severity; sometimes, however, there is a very marked febrile state. It sometimes assumes a more chronic or sluggish course in old delicate valetudinarians, who suffer from dyspeptic, hypochondriac, and other chronic ailments. In such cases, both the stomach and bowels are often loaded with depraved mucus secreted in great quantity, and which appears to be the cause of the diarrhœa. In cases of this kind the mucous membrane is sometimes found thickened and congested, and the mucous follicles are erected and patulous; and unless a suitable treatment is adopted, the disease degenerates into a permanently chronic state, probably with atrophy or dropsy. This is the *D. mucosa* of Cullen and Good, the *Caliaca mucosa* of Sauvages.

*Serous diarrhœa.*—In this form the discharges are quite serous or watery, and hence it has been termed *diarrhœa aquosa* by many authors. The stools may be coloured variously, or they may be nearly colourless; they may be almost limpid, or intermixed with minute flakes or shreds. Sometimes they are intermixed with mucus, but their characteristic feature is their being copious and watery. In some cases the quantity of fluid passed is very great, and speedily induces extreme debility. It is not always easy to distinguish this variety from cholera.

Serous diarrhœa may be produced under the same circumstances as the mucous variety, and then it must be considered as an acute disease, and as being, in many cases at least, dependent on an excited or inflamed state of the mucous membrane of the bowels. At other times it would appear as if the serous discharge originated in an opposite condition of this part, the exhalents pouring out their contents rather from loss of tone, and passively, than by an active organic process. It sometimes succeeds profuse perspirations suddenly repressed, or the imprudent use of acids and cold drinks when the body has been heated. It is sometimes the mode in which nature relieves herself from other diseases, as in dropsy, which has been known entirely to disappear on the supervention of a profuse diarrhœa of this kind. In very severe cases the discharges are so copious, and the emaciation and exhaustion so great, that it would appear as if almost the entire contents of the exhalent system were thrown upon the intestines. A marked form of this species is the diarrhœa of infants, termed *watery gripes*, in which the stools are often purely serous. This is the *D. serosa* of Sauvages and Good: it is included under the last variety (*mucosa*) by Dr. Cullen.

There is a variety of diarrhœa termed *tubularis* by Dr. Good, and which may be more properly named flaky or membranaceous. It is more entitled to notice as throwing some light on the pathology of the disease than as a dis-

tinet species of diarrhœa. In this variety there is a discharge of coagulable lymph, generally in the form of shreds or bands of more or less extent, and sometimes retaining the tubular shape of the bowel, whence Dr. Good derived his specific epithet. Such discharges are certainly met with in relaxed states of the bowels, but they are still more generally, perhaps, observed in cases where constipation is the habitual state. The fact is, that the peculiar inflammation of the mucous membrane, which gives rise to this morbid secretion, may produce either constipation or diarrhœa; and it is probable that when the former state exists, the seat of the disease is in the small intestines, and when the latter, in the large intestines. We have frequently observed these fibrinous discharges in cases of temporary diarrhœa supervening to a long-continued state of constipation, whether excited by improper diet, purgative medicines, or occurring without any obvious cause. Such cases are, in fact, examples of chronic enteritis, and not of diarrhœa.

The *chylous* or *milky* diarrhœa of authors, and that termed *gypscous* or *chalky* by Dr. Good, are both denominated from false notions of their nature. We believe that the whiteness in the one case is no more owing to the presence of chyle, than in the other it is produced by lime, as Dr. Good supposed. The chief cause of the white colour in both these varieties is, no doubt, the absence of bile of the natural character or quantity; but as this may occur in very different states, and when the discharges are in other respects very different, there is no sufficient reason for establishing any distinct form of disease on these grounds. It is proper to observe, however, that in chronic cases when the stools are of this colour, and more particularly if they resemble an admixture of chalk and water, as described by Dr. Baillie (*Med. Trans.* vol. v.), they for the most part indicate a disease of a serious, often of a dangerous character.

The variety termed *lientery*, in which undigested aliment appears in the stools, has no claim to be considered as a distinct form of diarrhœa, as the circumstance supposed to characterise it may occur in every species of the complaint.

*Nature of the disease.*—The foregoing account of the principal phenomena and more marked varieties of diarrhœa has necessarily anticipated much that might be said under this head. We shall therefore content ourselves with a few additional observations. "It is with difficulty," says Dr. Cullen, "that I have arranged this genus, as it is not very consistent with our plan to let it stand in our nosology. Diarrhœa is universally symptomatic of a great variety of diseases, many of which are different from one another; so that a genus formed from all these is a very complicated one, and comprehends many dissimilar affections and diseases." (*First Lines*, Dr. Thomson's edition, vol. ii. p. 470.) This observation of Dr. Cullen is very just; but he might have gone even further, and stated that in a perfectly philosophical system of medicine, what is commonly termed diarrhœa

would be regarded merely as a symptom of different pathological states, and would, therefore, be banished from the list of individual diseases. We are, however, far from having attained to this perfection of pathology even in theory; and it is more than questionable if the adoption of such a view of the ease in practice would ever be beneficial. The safer plan to follow is to consider *the flux*, termed diarrhœa, as a distinct disease, but to regard it as the consequence of various morbid states in different cases; the practitioner only taking care, before he applies his remedies, to ascertain the particular state which exists in the individual case before him, as far as his observation and pathological knowledge enable him to do so. If he does not do this, but regards *the flux* only, without reference to its cause, he will be liable to commit grievous errors in his treatment.

As a general rule, we may consider diarrhœa as having its seat in the intestinal mucous membrane; and it is the state of this membrane, and not the discharge, which is to be regarded as the great object of attention to the pathologist and practitioner. The only exceptions to this rule are the cases where the disease is excited by fluids poured into the intestinal tube from the annexed glands, or by irritants of a temporary kind, as food or medicines, applied directly to the membrane. Even in these cases the secondary affection of the membrane is often of much more importance than the cause producing it.

In the class of cases just mentioned, the mucous membrane of the bowels can scarcely be said to be diseased; and the functional disturbance speedily subsides on the removal of the offending cause. But in the great majority of the cases of diarrhœa the membrane is affected in a more permanent manner, although the degree of this varies extremely.

In the mildest form of the affection there seems to exist merely a morbid degree of irritability, or a morbid sensibility, in the mucous membrane, which scarcely exhibits any indication of disease, except when excited by something applied to it. What, however, in a sound state would produce only the proper and natural degree of peristaltic action, now produces a morbid degree of action incompatible with perfect health. In another form of the affection there exists, perhaps in conjunction with the foregoing state, a morbid degree of excitement or of increased action in the membrane, considered as a secreting and exhaling organ, whereby it throws out its fluids in a morbid state or in a morbid quantity, or both. In a third class of cases it is supposed by some that the exhalents, in place of being excited to increased action, are in a state of atonic relaxation, and thereby allow their fluids to escape in a condition no less deviating from that of health.

But in a still more numerous class of cases there exists a more permanent deviation from the healthy condition of the mucous membrane, namely, some form or degree of that pathological state to which we give the name of inflammation. In diarrhœa this state may exist in

every degree, from the slightest shade of congestive irritation up to well-defined alteration of the normal structure of the membrane: it may be confined to a small portion of the intestinal tube, or it may extend over a large portion. In this form of diarrhœa, the evacuations deviate greatly from the character of health, and consist principally of fluids secreted by the inflamed membrane, being mucous or serous, or flaky from admixture of coagulable lymph, and very variously coloured according to the condition of the liver, the ingestion of food, the previous treatment, &c. In almost all cases the inflammation is confined to the large intestines; but in some it extends to the small, and it may even originate there.

The form of diarrhœa just noticed, and which may almost always be regarded as present in recent cases of much severity and in which the stools are not fecal, can be considered as differing from the disease termed dysentery only in degree. When the inflammation is strongly marked, no doubt there supervene some peculiar symptoms—particularly the intermixture of blood with the mucous discharges, and fever—which do not exist in diarrhœa; but still the essence of both diseases is the same. Both are inflammations of the mucous membrane of the large intestines; but in the one the affection is slight, in the other it is severe. There is the same difference between them as there is between a mild pulmonary catarrh and bronchitis, but no more.

The diarrhœa which almost always attends the latter stage of phthisis depends on ulceration of the mucous membrane. The ulcers in this case are often extremely numerous, being spread over the whole extent of the bowels, but they are most common near the extremity of the ileum. Many other organic affections of the mucous membrane of the bowels, for the most part the consequence of inflammation, give rise to diarrhœa; but cases of this kind do not come properly within the scope of the present article.

The state of the mucous membrane found on dissection in simple diarrhœa, varies greatly in different cases. In recent examples, not connected with other diseases, opportunities for examination after death will rarely occur, as almost all such cases are cured. When opportunities of examination have been found, the membrane, in recent cases, has been observed more or less red and congested, or extremely pale and anæmic, the redness being disposed in patches or in continuous stripes, leaving the intervening portions very pale. In cases of more severity and long standing, although still short of the degree constituting the dysentery of nosologists, a great variety of morbid appearances have been found. In these the membrane presents every variety of colour, from the most intense red, purple, or brown, to the blanched or anæmic state above mentioned, in which there is nothing to be seen in the vessels but colourless fluids. In other cases there is an enlarged and patulous condition of the mouths of the mucous follicles, which look erected, and sometimes inflamed, and as if excoriated. The whole mu-

cous membrane is also found thickened and œdematous, as in certain forms of dropsy, and is often greatly softened. The intestinal tube is frequently much contracted in its caliber. In some cases coagulable lymph is found adherent to the inflamed spots; but this is not of frequent occurrence: very tenacious mucus of an inspissated character is common. In many instances dissection detects scarcely any deviation from the state of health; and then we may reasonably suppose that the exhalents and mucous glands merely afford a rapidly increased supply.

The termination of diarrhœa, when unattended by other, and especially visceral diseases, is for the most part favourable. But when the inflammatory state of the membrane becomes considerable, the disease then, under the name of dysentery, may lead to very serious results, ulceration taking place in the different tissues of the intestine, sometimes followed by perforation and fatal peritonitis. In some cases the inflammation of the mucous membrane extends or is transferred to the serous coat, giving rise to ascites. In this way diarrhœa and dropsy have been observed to alternate, according as the morbid action chiefly occupied the internal or external tunic of the bowel. When it assumes the chronic form, diarrhœa is sometimes a most obstinate disease, resisting in many cases, for months or years, every variety of treatment. When, however, it is not immediately dependent on great organic changes in the bowels or connected viscera, the general health is often much less affected, even in severe cases, than might be expected. We have known chronic diarrhœas of considerable severity continue through the greater part of a long life.

*Treatment.*—In undertaking the cure of a case of diarrhœa, it is often of as much consequence to consider its degree of severity and its duration as its precise nature. Slight cases of every kind are in general easily removed; and in recent cases, even when severe, the mode of treatment is almost always simple, and generally successful.

*Acute or recent diarrhœa.*—1. In the common form of feculent diarrhœa recently produced by some known cause of irritation, as from improper food or otherwise, it is seldom that any other treatment is necessary except abstinence from food, with rest, and simple dilution. In such cases the offending matter is commonly itself speedily evacuated, and occasions at the same time a complete discharge of the whole fecal contents of the bowels. When this is effected, the morbid action usually subsides of its own accord, and health is at once restored. Sometimes, however, the offending matter is either not thrown off, or only partially, and a degree of excitement is kept up sufficient to irritate the bowels without unloading them; the stools, partly fecal, partly mucous or serous, are scanty, and are accompanied with more or less of griping. The indication here evidently is to unload the bowels thoroughly; and it is best fulfilled by an active but not irritating purge, such as castor oil, rhubarb, and mag-

nesia, or the common senna draught of a moderate degree of strength. When the evacuations are free and complete, the irritation is commonly at an end. But sometimes, in place of being insufficient, the evacuations are too copious; the irritating matter has acted like a drastic purge; or the ineffectual efforts produced by the primary cause have been raised beyond the healthy degree by the purgative, and the same result of hypercatharsis ensues. In cases of this kind the obvious and appropriate remedy is an opiate; and few cases will resist the effect of this when combined with quiet, a warm bed, and abstinence.

In feculent diarrhœa coming on without any very obvious exciting cause, in persons who are great eaters, or whose bowels are generally in a confined state, it will likewise be proper in most cases to administer a purgative, as the probability is that the cause of the diarrhœa is some irritating matter lodged in the bowels, and not any primary source of irritation in the intestinal membranes; and it may be stated, as a general rule, that in recent cases, if the motions are fecal, this practice will always be safe, and generally beneficial. Even in cases where the stools are altogether without proper fœces,—mucous or serous,—if there exists any reason to expect an accumulation of fœces in the bowels, a purgative will still be proper. The previous health of the patient, his habits as to eating and alvine excretion, the nature of the stools at the very commencement of the attack, and the degree of tension and hardness of the bowels, will, if duly weighed, in most cases lead to a just conclusion as to the point in question. Where there remains any doubt, the safest plan will be to give a moderate dose of a mild purgative, particularly castor oil, and be guided by its effects. If by its operation fecal stools are brought away, and the irritation still continues, a repetition of the dose or a still more active form of medicine will be proper. In persons whose bowels have been costive for some time before the attack, and also in those who are large feeders, and particularly if they lead sedentary lives, a dose of colocynth with calomel and antimonial powder may be proper, followed up after a few hours by the saline senna draught; the after treatment being the same as before.

2. If the feculent diarrhœa is complicated or caused by a superabundant secretion of bile, it will be necessary to restore the liver as well as the bowels to its healthy functions. The unloading the bowels by purgatives may be at first necessary; but when this is effected, the treatment of the hepatic affection may be a work of some time. It is obvious that the consideration of this subject belongs rather to another place, (see HEPATITIS, and LIVER, DISEASES OF); but we may be allowed to say a few words on it in reference to diarrhœa. If the augmented flow of bile or its depravation has been produced by a mere temporary excitement, little specific treatment will be requisite, as the disorder of function will in most cases be removed on the removal of the

cause. What is more commonly called bilious diarrhœa is, however, in general, an affection of a more fixed character, depending, as we had occasion formerly to remark, either on an inflammatory state of the liver itself, or an excited condition of this gland transmitted through its ducts from an inflamed duodenum. In both cases the disease is usually of an acute character, and requires nearly the same treatment. If the inflammatory state is considerable, or is attended with fever, venesection will be proper; but this will not often be the case in any state which can be classed under the head of diarrhœa. Local bleeding with leeches, or cupping in the hepatic and præcordial region, will, however, always be proper, and must be carried to such an extent as the urgency of the symptoms may seem to require. The repetition of this measure several times, after the interval of one or two days, may be requisite; and its effects will be greatly promoted by the frequent use of warm fomentations to the same parts. Mild mercurial preparations, the best of which is the hydrargyrum eum eretâ, will also be proper in cases of this kind, more especially if the affection of the liver is primary; they should be given in small doses at bed-time, and followed up next morning by a moderate dose of castor oil or other mild purgatives; but care must be taken that the inflammatory condition of the duodenum (if it exists) is removed, or at least mitigated by other means, before the administration of purgatives. Calomel will then have a much more beneficial effect in restoring the healthy condition of the liver. Cooling, saline, and demulcent pitans constitute the best general remedies in this kind of diarrhœa, and commonly suffice, in conjunction with the means above mentioned and a proper diet, to restore the patient to health. The proper diet in these and other cases will be mentioned hereafter.

3. In the acute or recent diarrhœa, distinguished by the discharges being chiefly mucous or serous, with little or no admixture of proper fœces, all these having been previously evacuated either by the natural efforts or by purgatives administered with this intent, we are no longer to look for relief from the employment of cathartics, but from means calculated to allay the irritation which exists in the mucous membrane, and which constitutes the disease. These means consist of a proper diet, or the abstinence from all food, the internal use of refrigerants, diluents, demulcents, diaphoretics, and opiates, the local detraction of blood, warm baths or fomentations, and other measures of analogous tendency. The treatment will vary considerably according as the attack is slight or severe, and also according to the nature of the exciting cause. In very mild cases, keeping the patient in bed, and restraining him from the use of all kinds of food, with the exception of barley-water,—in small quantities, and this only if there is thirst,—will very often put an end to the attack in twenty-four hours, without any other means. If the attack appears to have originated in cold or obstructed

perspiration, it will be proper to apply the general means found most useful in catarrhal affections, of which the most effective are confinement to bed, in a warm room, and mild saline diaphoretics. If the case is somewhat more severe, the application of warm fomentations to the abdomen, by means of flannel bags filled with bran and dipped in hot water, will be proper, (they will indeed be proper, though perhaps not absolutely necessary, in the very mildest cases,) together with small doses of mucilage, with or without nitre or the liquor ammoniæ acetatis, and an equally rigid system of diet. If the diarrhœa does not speedily yield to these mild measures, or if it be accompanied with much griping or painful tenesmus, a small dose or two of laudanum, or of the pulv. ipec. comp. in chalk mixture, will be proper; or a glyster may be administered, consisting of not more than a couple of ounces of starch mucilage, and a proportion of opium varying according to the severity of the case.

Where the irritation is not very considerable, these means will almost invariably put an end to the attack in a very short time. But should they not do so, or should the severity of the symptoms at the commencement announce the invasion of a more formidable disease, previously to the use of opiates, six, eight, ten, or twelve leeches, according to the violence of the attack, should be applied to the anus, and the glyster be afterwards given. The leeches may be applied a second or even a third time, if the complaint proves obstinate. In some cases general bloodletting may be proper; but this is a measure rarely necessary while the disease remains of such moderate severity as still to justify the application to it of the term diarrhœa.

The internal remedies we are accustomed to employ in the cases where opiates are improper or unnecessary, or in conjunction with these, consist almost entirely of the blandest fluids given in small quantities, such as the mucilage of acacia or tragacanth and water, with or without nitre; the chalk mixture with the same substances, small doses of the liquor ammoniæ acet., and the like. Indeed, were it not that it is often necessary, for the satisfaction of the patient or his friends, to administer some medicine internally, the case would often be better left to nature, after the employment of the more active remedies; but if medicines are given, they should be such as are at least harmless. We will venture to assure the inexperienced that they will find such means infinitely more conducive to the recovery of the patient, in the cases now under consideration, than either purgatives, or astringents, or opiates, which we regret to say are so often lavished by those who in their pride of *bold practice*, as it is termed, are accustomed to regard with scorn the treatment we are now recommending. When the disease is prolonged beyond the space of twenty-four or forty-eight hours, or even during this period, if desire for food is urgent, more nutriment may be allowed; but this must be in very small quantity, and either liquid or of

the softest deliquescent solids. Of this kind are barley-water, rice-water, arrow-root, sago, weak tea with milk, rice-gruel, weak chicken or veal broth thickened with rice or barley, &c.

In the variety of mucous diarrhœa which occurs in certain epidemic constitutions, and in persons of a sluggish phlegmatic habit, and in which the intestinal tube is rather irritated secondarily by its own morbid secretions than primarily, a different kind of treatment is necessary. Both emetics and purgatives are here indicated; the first to evacuate the contents of the stomach and to stimulate its coats to more healthy action; the last to produce a similar effect on the bowels. Ipecacuan is the best emetic in such cases, and the same medicine, in small quantity, will be very properly combined with rhubarb as a purgative. A useful purgative will also be found in small doses of castor oil combined with a few drops of the oil of terebinth. When by these means the bowels are unloaded of their morbid secretions, and the membrane stimulated to more healthy action, if the diarrhœa still continues it must be checked by mild astringents and tonics, or by small doses of opium. In these cases catechu and kino are found useful; but when such means are necessary, the disease will come under the head of chronic diarrhœa, the treatment of which we shall now notice.

*Chronic diarrhœa.*—This form of diarrhœa is that which the practitioner is most frequently called upon to treat, and which he finds by far the most difficult to cure. In addition to the intrinsic severity of the disease, sufficiently evidenced by its long duration, and perhaps in spite of proper treatment, he has probably to contend against many obstacles to recovery which did not exist, or existed in a much less degree, in the acute disease. The patient may have probably an excellent appetite, and cannot or will not refrain from food calculated to keep up his complaint; neither can he be restricted in many other particulars which obstruct recovery, but which the violence of the acute disease either forced him to attend to, or its brevity rendered but little irksome.

Chronic diarrhœa may assume all the forms of the acute variety as far as regards the nature of the evacuations, and most of them may successively appear in the same case; although, generally speaking, the motions preserve one predominating character, as in the acute disease. It is chiefly in the chronic form, however, that the food appears undigested in the stools; a circumstance readily accounted for both by the nature of the two cases and the diet respectively used in them. In many cases of diarrhœa which are chronic both as to time and the moderate severity of the symptoms, the disease is found, on close examination, to consist rather of a frequent return of slight attacks of the acute kind, than to be strictly chronic, in the usual sense of that term. This is an important distinction, and deserves the best attention of the practitioner.

In respect to the treatment of chronic diarrhœa, it may be stated generally, that

when the symptoms assume the general character of any of the forms of the acute disease formerly noticed, the treatment to be had recourse to must be similar in kind, but modified by the degree of severity and other circumstances of the particular case. Other modes of treatment will, however, be often necessary, and which would have proved injurious in the acute affection. It is here where the medicines properly termed astringents, and also tonics, are applicable, and which are so seldom proper in any of the acute forms. In numerous cases of the chronic disease such remedies are likewise very improper, and we believe that the great art of treating chronic diarrhœa successfully, consists principally in the practitioner having the skill to discriminate such cases as are benefited by purgatives and astringents, from the very large proportion which are injured by them.

We think it will not be disputed by any practitioner of experience, who has been accustomed to consider diseases more according to their pathological relations than as mere subjects of empirical prescription, that the greater number even of chronic diarrhœas depend not so much on any foreign matter applied to the intestinal mucous membrane, as on some intrinsic irritation of this membrane itself; and, consequently, that the treatment in all such cases is founded not on the indication of evacuating irritating matters, but on that of allaying organic irritation. In a certain proportion of cases, no doubt, such irritating matters are present, and their evacuation is essential to the cure of the disease. Great mischief, however, has arisen from the false notion entertained by many practitioners in this country, that *most* diarrhœas are occasioned by such extraneous sources of irritation, and which can only be relieved by purgatives. We cannot too strongly enter our protest against such a principle as a general rule of practice. The circumstances under which purgatives may be used in recent or acute cases were formerly pointed out; and when similar circumstances exist in the chronic stage, the same treatment will be proper. The accumulation of feces in the bowels in conjunction with diarrhœa, will always indicate the propriety of purgatives, and they may, in a general way, be considered as not likely to be injurious as long as the stools are feculent. The same observation is equally applicable to those cases in which there appears to be a morbid accumulation of mucus or other secretions in the intestinal tube.

We do not mean to deny that even when the disease consists essentially in an irritation of the membrane, a purgative may not lessen or relieve it; indeed, we know by experience that this is actually the case, and it is only what might be expected from the known effect of stimulant applications to chronic inflammations of other mucous membranes; but we wish the young practitioner to understand that this practice is to be considered as the exception, not as the rule in the treatment of diarrhœa, and

that even when a purgative has relieved the symptoms, it is not to be hastily or often repeated. The repetition of purgatives in all bowel complaints requires much judgment and discretion. Aperients may be considered as fairly applicable in cases in which the irritation is of an inactive kind, or where the disease has proved rebellious to remedies of a different class. In such cases rhubarb is perhaps the best purgative.

Another notion, no less false, and perhaps even still more prevalent among practitioners, is, that a great proportion of chronic diarrhœas depend on debility or loss of tone of the intestinal membrane, and are only to be relieved or removed by astringents, tonics, &c. Such a state may undoubtedly exist; but we are well assured that the number of chronic diarrhœas which originate in this cause is extremely small compared with the cases which depend on an irritated or inflamed state of the membrane.

On the whole, we wish the young practitioner to understand that he is to proceed to the treatment of chronic diarrhœa on the only rational principle of endeavouring to ascertain the precise nature of each individual case before he prescribes for it; that he is to give emetics or purgatives where there is evidence that the bowels are oppressed or irritated by fecal accumulations or morbid secretions; that he is to give astringents and tonics where the flux seems to be the consequence of a debilitated and relaxed state of the mucous membrane; that he is to soothe excessive irritability by opiates; and that he is to remove congestive irritation and inflammation by the means best calculated to effect this object in other parts of the system, namely, by removing all causes calculated to keep up irritation, and by the employment of such means as have the power of directly diminishing the local disease. Our limits will not permit us to enter into the consideration of the characteristic features of each of these different kinds of diarrhœa; but their discovery will not be very difficult to any one who is well grounded in the general principles of pathology, and who will take pains to investigate with attention the history and phenomena of the different cases that come before him.

We shall conclude this article by some further observations on the principal remedies used in diarrhœa.

*Diet.*—In all the forms of diarrhœa, acute or chronic, and whatever be the other kind of remedies which are proper, there is one mode of treatment which is universally applicable, and which is the most important of all: this is a proper system of *diet*. This is so important a part of the treatment, that we have no hesitation in stating that the majority of cases of diarrhœa, both acute and chronic, that are curable, may be cured by it alone. In all cases of acute diarrhœa, and in the large class of chronic cases which depend on irritation of the mucous membrane, the food should be very sparing in quantity, of the mildest quality,

and such as to leave, after the process of digestion, as little excrementitious matter as possible. In recent attacks of the acute diarrhœa, it is often proper to take no food for the first day, or only mild drinks, containing a small quantity of unirritating nutriment, such as barley-water or arrow-root. During the subsequent days, the same general kind of diet must be continued, but may be given in larger quantity or of greater strength. When the irritation is somewhat allayed, on the third or fourth day perhaps, but not earlier, broths may be allowed, but no solid food of any kind, and, least of all, solid animal food is to be permitted until the disease is removed or greatly allayed.

The following may be stated as the order in which the articles of diet will generally be found most proper in such cases: barley-water, arrow root made with water, sago or tapioca, rice-gruel, oatmeal-gruel carefully strained, light broths, with some of the preceding ingredients. In some cases, more especially of the chronic kind, a drier diet is found more suitable,—the liquid food appearing to keep up the diarrhœa; but in all cases the ingesta must be of the mildest quality. Rice is one of the most valuable articles of diet in such cases. It should be well boiled and merely moistened with a little broth. While it is extremely mild and unirritating, rice scarcely leaves any remains to be transmitted along the intestines, and this is the reason why it is generally regarded as astringent. As soon as it can be borne, a *small proportion* of the highest animal food may be taken with the rice. Tender chicken is the best to begin with; then white game boiled; and then roast mutton. The meat of young animals, as lamb and veal, should be avoided. Beef is too stimulant, and fish is bad on account of the large quantity of excrementitious matter it leaves in the bowels. Animal jellies are generally allowable in the cases where meat is found to agree; but they often are more irritating to the bowels than the muscular flesh of animals.

In chronic diarrhœa attention to diet is no less necessary, and in general it will be found that the same kind of food is alone proper. It constantly occurs to us to meet with cases of diarrhœa of many months' standing, or which have lasted even for years, and which are speedily removed by the substitution of a mild unirritating diet for the ordinary food of healthy persons. We will here give the outlines of a recent case of this kind, extracted from the out-patients' journal of a public institution to which the writer is attached, and we introduce it the rather because it is *not* an uncommon case.

May 4, 1831. J. G., gardener, æt. 35. Has been affected for two years with his present complaints, which constitute that form of diarrhœa commonly termed *lientery*. During the whole of the above mentioned period he has had five or six loose stools daily. He has a good, often a craving appetite, but unless he is very particular as to what he takes, he

suffers pain, sometimes severe pain, shortly after eating, and a relaxed motion speedily follows. The stools are in general liquid, slimy, dark, and offensive, and frequently contain masses of undigested food. All sorts of hard or solid food disagree, such as tough meats of every kind, pork, cheese, &c., and when taken, appear unchanged in the subsequent motions. More fluid food agrees, such as arrow-root, gruel, rice, broth if not fat, &c. He is much troubled with flatulence, but is never sick at stomach so as to vomit, nor is he thirsty. The tongue is white, with considerable tenderness on pressure, and also distension of the epigastrium; the urine is clear. There is no particular dryness of skin, and he perspires easily on exertion. He has occasional headach, giddiness, and slight palpitation, and the feet are often cold, especially at night. He sleeps well, except when pain is present in the bowels. He has lost eighteen pounds in weight during the last twelve months. Notwithstanding the avowed inconvenience produced by certain kinds of food, he does not usually debar himself from them. He also drinks beer, about two pints daily.

This man was directed to alter his diet entirely; to give up all kinds of solid food, and to live on broth, jellies, light puddings, rice, and liquid farinaceous food; to give up drinking beer; and, in a word, to take nothing which he knew to have the effect of irritating his bowels. He was directed to put his feet in warm water every night. The only remedies prescribed were, ten leeches to the pit of the stomach, and a powder consisting of pulv. tragacanth c. ʒij potassæ nit. ʒj, to be dissolved in half a pint of cold water, and taken daily in divided portions.

The effect of this change of regimen, (to which the man adhered faithfully) was, that the diarrhœa ceased within three days, and never returned. He was not, however, discharged from the books of the infirmary until the end of July, although he had for some time returned to the use of animal food without suffering any inconvenience: indeed, he said his bowels were then in a better state than he ever remembered them to have been. This man continued well many months after his discharge.

In some cases of chronic diarrhœa, however, particularly those in which astringent medicines are found useful, a solid diet of a more stimulating quality, with a moderate proportion of wine, is found much more useful than the bland unirritating food above mentioned. In such cases the dry and tonic diet has the effect of producing motions of a more solid kind; while at the same time it tends at once to restore the lost tone of the bowels and the general strength. In practical medicine we must never follow our pathological principles so far as to be blind to the results of experience; and in diarrhœa, as in every other disease, however we may allow to science the initiatory in prescription, it is the observation of a favourable result alone that can justify perse-

verance in any kind of regimen or medicinal treatment.

*Leeches.*—In the case above detailed we are disposed to attribute nearly all the good effects to the change of diet; but the application of leeches, even for a single time, was probably of benefit. We judge so from the marked benefit we constantly find from their use in this complaint, whether in the acute or chronic form. When the diarrhœa is evidently complicated with a state of irritation or slight inflammation of the mucous membrane of the stomach and small intestines, the treatment should begin with the application of leeches to the epigastrium. If this and the appropriate diet fail, then leeches must be applied to the anus, or to this part in the first place, if the diarrhœa is uncomplicated with gastric irritation. For the relief of the inflammatory irritation of the large intestines, there can be no doubt that leeches applied to the anus are greatly more efficient than when placed on the abdomen. This remedy is indeed possessed of remarkable powers in the disease, often working, according to the common expression, "like a charm," even in cases of very long standing and of different external characters. Combined with proper diet, indeed, we are persuaded that the greater number of diarrhœas, both acute and chronic, will yield to this method, with little or no aid from other medicine. We have repeatedly known a diarrhœa of long standing, more particularly in the case of infants, cured by a single application of two or three leeches only; and in more obstinate cases it will be found that an instantaneous and marked remission of the symptoms follows every repetition of the remedy. Although, in our own practice, we always combine with the use of leeches, in the cases where they are indicated, a proper diet, yet we have had ample evidence of their unassisted powers in checking or removing diarrhœas of great severity and obstinacy. We would add one caution which may be useful to those not in the habit of making much use of this remedy:—to ensure the full effect, the leeches should be applied immediately to the anus, that is, as close to the mucous membrane of the extremity of the rectum as possible. Unless accurate directions are given, nurses will be apt to mistake our meaning. It has frequently happened to us to find the prescription of *hirudines ano* carried into effect by their being applied to the buttock, perineum, or even sacrum.

*Bathing.*—In most of the cases in which an unirritating diet and the local detraction of blood are beneficial, the employment of some form of the tepid or warm bath will be useful. Although the general bath is often indicated, and is the best form of the application, yet in the majority of cases we find that the frequent use of warm fomentations to the bowels by means of flannel bags of bran, with the foot-bath at bed-time, answers completely in promoting the removal of the intestinal irritation. (See BATHING.)\*

\* Riverius gives his own case in testimony of the efficacy of the warm bath in diarrhœa. "Corruptus

*Opiates.*—Of the means calculated to assist in the cure by affording temporary relief from pain, as well as by directly allaying the irritated condition of the bowels, no remedy equals the use of opiate injections. In all cases where there is tenesmus with pain and frequent stools, this remedy is to be had recourse to as a means of temporary relief, whatever other plan may be pursued for the permanent cure of the disease. Solid opium, or extract of poppy, carefully rubbed down into mucilage, or the pulvis opii, Battley's liquor, or the common tincture, may all be used. Perhaps the pulvis opii is, on the whole, the most convenient form, of which one, two, or three grains may be administered in a couple of ounces of starch mucilage. This may be repeated according to the urgency of the case; but the student is to be earnestly cautioned not to be seduced by the relief often produced by this application, into the neglect of means of more permanent efficacy.

*Astringents.*—It will not, we trust, be imagined, from the manner in which we have recommended the use of the foregoing remedies, that we consider the treatment of diarrhœa by the use of astringent medicines, properly so called, as generally either useless or improper. On the contrary, we know that cases of this disease are every now and then met with, that can only be cured by such medicines; and that they are very often necessary, at least as palliatives, in the chronic form of diarrhœa. Sometimes nothing else affords relief. All that we labour to impress on the mind of the young practitioner, or on those who have unfortunately been taught to treat diseases as mere collections of symptoms, without reference to pathology, is, that there are many kinds of diarrhœa which can be best treated without astringents and without purgatives; and that the presence of frequent fluid dejections does no more necessarily indicate the use of such remedies, than any other single symptom necessarily indicates a peculiar treatment, without reference to the whole disease of which it is but a part.

In all cases, before we have recourse to astringents, the state of the patient must be carefully examined into, the nature of the evacuations, the state of the abdomen, &c.; lest some inflammatory affection should still remain and keep up the diarrhœa. Astringents are a class of remedies which seldom fail to do mischief when they do not do good. They are indicated in the cases where the diarrhœa appears to be kept up by loss of tone, or by a morbid degree of irritability, not dependent on vascular orgasm or inflammation, in the mucous membrane of the bowels; and they are properly used in all chronic cases which have resisted the means calculated to relieve active irritation, or other known pathological conditions, as noticed above.

sum diarrhœa biliosa, tanta acrimonia prædita ut anum eroderet, ardoremque urinæ concitaret. Dysenteria erat in prociectu. Ingressus semicupium tepidum, illico liberatus sum."—River. Op. Univ. p. 599.

For the particular forms of astringents most useful in such cases we must refer to writers on *Materia Medica*, and to the article *ASTRINGENTS* in the present work. We can only afford space here for a few observations.

The astringent substances from the vegetable kingdom that have been used in alvine fluxes are extremely numerous; and it is probable that some of those not now included in our pharmacopœias, or, if included, not much employed, are not the least useful. Catechu and kino are now in most common use, probably not so much because they are in reality the best remedies, as because they are the strongest astringents. They are, however, often very useful in the cases of diarrhœa wherein remedies of this class are indicated. Both these substances may be given separately, or in combination with opium or other astringents. One of the most usual forms of prescription is the tincture of catechu in chalk mixture, combined with equal parts of the tincture of cinnamon. In other cases the watery infusion of catechu answers better, in the form of the *infus. catechu comp.*, and may be given in doses of one or two ounces after every loose motion.

Dr. Pemberton had an idea that kino had some peculiar virtues as an astringent; that it did not act as such except diarrhœa were present. He therefore gave it the preference to other astringents. His mode of administration was in doses of a scruple made into a bolus with opiate confection.\* More recently an extensive series of experiments on the effect of kino in diarrhœa, were made in the hospital of *La Pitié*, in Paris, by M. Bally. In chronic diarrhœa, unaccompanied by fever or marks of inflammation in the mucous membrane, the continued use of the remedy, even for a short time, was found almost invariably effectual in stopping the diarrhœa. In one case of three years' standing it effected a cure. But the most remarkable result of M. Bally's experiments is the alleged fact—that the kino, given in doses of twelve or fourteen grains for several days in succession, succeeded in curing diarrhœas attended by febrile and inflammatory symptoms.† We confess we are surprised at such a result.

Logwood, tormentil, and bistort were more employed formerly than at present as astringents. We believe the former to be a valuable remedy: the best form of using it is decoction, which may likewise be made the vehicle for more active remedies. The plantain (*plantago*) was much used by the older authors; and it and many other vegetables were taken boiled in broths and demulcent ptisans—a form of medicinal administration too much fallen into disuse in this country. Unripe medlars were formerly famous for their occasional effects in diarrhœa; but we apprehend the cases are few in which they can be recommended.‡

\* Treatise on Diseases of Abdom. Visc. pp. 112 and 149.

† Med. Gazette, vol. v. p. 700.

‡ Forestus relates a case of diarrhœa which seems to have been most particularly obstinate, since he informs us that the poor patient “ omnem

Among the mineral astringents, lime and its carbonate deserve attention, as being in most common use, and as being perhaps not the less useful because they are possessed of only moderate astringency. In certain mild forms of diarrhœa, particularly after the use of purgatives, the *pulv. eretæ comp.*, with or without opium according to circumstances, is a very mild and valuable remedy; and the *mistura eretæ*, it need hardly be said, is the common and one of the best vehicles for other more powerful astringents. In the more chronic forms of diarrhœa lime-water has been found occasionally useful, taken in large quantities as a beverage; and it is very properly combined in such cases with gum, and often with milk. Equal parts of lime-water and milk, with acacia or tragacanth, is a favourite remedy with many old practitioners. Alum is a medicine given frequently in a somewhat similar form, under the name of *alum whey*, which is made by adding two drachms of the alum to a pint of boiling milk: of this whey a glassful or three or four ounces may be taken as a dose. Alum is also given in a solid form, in bolus or pill, combined with kino, catechu, or opium. The stronger mineral astringents, the acetate of lead and sulphates of copper and zinc, are occasionally useful, particularly the sulphate of copper; but this remedy is chiefly applicable in a form of the disease which does not come properly under our notice in this article, the diarrhœa of phthisis.

In this and other forms of diarrhœa depending on disorganization of the bowels, opiate clysters are commonly found most effectual. A simple form of injection recommended by Van Swieten is also found occasionally beneficial in this distressing complaint: it consists simply of an ounce of treacle or juniper-rob in three or four ounces of warm milk.\*

In every form of chronic diarrhœa, warm clothing with flannel next the skin, and an additional quantity on the abdomen, in the form of a belt or swathe, is highly useful. In many cases, also, warm galbanum plasters and other warm external applications to the abdomen are very beneficial. This mode of treatment was much used by the older authors. (See *Forestus passim*.)†

It is hardly necessary in all such cases to dwell on the propriety of the patient being lodged in a dry well-ventilated chamber; or of the advantages of a mild and dry climate.

suam substantiam frustra in medicorum opo consumpserat, consilii causa, ut ab hoc malo liberari posset,” but which he (Forestus) cured in a few days by giving him a great quantity of unripe medlars to eat. The same author tells us of a patient of Spirinchius, who was cured of an equally obstinate diarrhœa by the same means; but Spirinchius was more fortunate in a richer patient, “ qui medico trecentos aureos pro sola mespilorum præscriptione numeravit.” *Forest. Op. tom. iii. p. 47.*

\* Comment. vol. ii. p. 394. *Diarrhœa Febrilis*.

† Quibus adjungenda sunt *topica*, olea, unguenta, linimenta et foveæ, unguenta et irrigationes, ex oleo omphac. rosaceo, myrteo, cotoneorum cum vino adstringente, cerata, &c. *Forest. vol. iii. p. 58.*

Chronic diarrhœa is, indeed, one of the diseases in which a change to a warmer and drier climate than ours is found most beneficial, (see CLIMATE); and this leads us to notice the fact well known to travellers, and to physicians who have had much to do with travelling invalids, that a journey is almost specific in arresting diarrhœa.

(John Crampton.—John Forbes.)

DIETETICS.—An organised body, whether of the animal or vegetable kingdom, cannot sustain the functions of life without a certain expenditure, or consumption of the materials of which it consists; and it is evident, therefore, that every living being, in order to continue its existence, must possess the means of receiving and assimilating to itself foreign matter for the repair of its diurnal waste. It is upon this necessity that the want of food is founded; its judicious administration must be directed upon principles the knowledge of which can be alone derived from the sources of physiology and chemistry.

The possession of a receiving canal, or internal cavity of some kind, would appear to be exclusively characteristic of the animal creation; and Cuvier has distinctly stated that he knows of no animal unprovided with such an apparatus. In plants, on the contrary, which never contain any organ analogous to an internal stomach, the fluid supplies are absorbed by pores on their surfaces; and although some physiologists have questioned the propriety of so sweeping a generalization, minute investigation has shewn, that so far from being real, the instances adduced by them in support of their objection are only apparent exceptions to this general law of nature. To enter upon this wide field of inquiry would be altogether foreign to the practical objects of the present article; nor can we undertake to examine the great diversity of means which Nature employs in the different orders of animals for the conversion of food into nourishment or into blood; we shall only observe that with such nicety are the processes of waste and supply adjusted, that whatever may be the quantity of food taken, or however the circumstances under which it is consumed may vary, the same individual, after having augmented in weight in proportion to the quantity of ingesta, will return in the space of twenty-four hours to nearly the same standard, provided the development of growth, or the existence of disordered function, does not interfere with the result. During this period, the food has been decomposed, and re-combined into compounds analogous to those which constitute the organs to which it is carried; and this would appear to take place, however remote its composition may be from that of the structures with which it is assimilated. It is, however, important to notice that the extent of the digestive cavity bears a relation to the nature of the food it is destined to receive, and by which the animal is designed to be nourished; for the more

dissimilar its composition to that of the body it is to recruit, the longer must it remain in its alimentary cavity, and the more complicated must be the changes which are to perfect its transmutation. We thus find that carnivorous animals have generally less capacious and complicated organs than the herbivorous tribes; and that amongst the latter, those that feed upon seeds or fruits, with the exception of the *ruminantia*, have them less so than those which live upon leaves or the entire vegetable. The digestive canal of man is less capacious and complex than that of other mammalia which live entirely on flesh; whence we may infer that in a state of nature he may be capable of subsisting either on animal or vegetable food, and that he is not only qualified for every diversity but for every admixture of it. Thus do we see that, while many savage tribes exist almost entirely on fruits and roots, others are as exclusively fed on raw animal flesh. The Hindoos, for instance, live upon rice; the Lombard peasants upon maize; the West Indian negroes fatten upon sugar, those of Senegal upon gum; while the Esquimaux gluts himself with the blubber of the seal. It would appear, however, that although man may subsist upon almost every variety of food, he cannot bear with impunity a sudden transition from one species to another. This circumstance was well exemplified in the eastern part of France in the year 1817, where the failure of the crops occasioned such a famine that the poor were compelled to feed upon whatever vegetable productions could be found: the consequences are stated to have been general anasarca, interruption of the menstrual discharge, a diminution of the ordinary number of conceptions by at least one half, and a permanent injury to the health. Even the sudden return to the use of barley-bread, after the continuance of this miserable regimen for three months, M. Gaspard informs us, was not unattended with danger. Spallanzani has satisfactorily shewn that animals may be brought to live on food of the most opposite kind, provided the change from their usual diet be *gradually* accomplished,—such, for example, as a pigeon on flesh, an eagle on bread, &c. We know that in certain maritime districts of the East, horses are not unfrequently fed upon fish, while on the coast of Coromandel they are fattened upon balls of boiled flesh mixed with grain; and it is on record that a lamb kept on ship-board was fed with flesh until it refused the grass when afterwards turned into a meadow. Such facts have induced some physiologists, amongst whom we may mention the distinguished name of Dr. Bostock, to consider it probable that all the anatomical varieties in the structure of the stomachs of different animals may be resolved into their *mechanical* effects upon the aliments submitted to their action; and that, whatever may be the chemical composition of the food, provided it be sufficiently comminuted or triturated, it will be equally acted upon by the gastric juice. We might here ask whether the nature of the

digestive solvent itself may not at the same time vary with that of the food which excites its secretion, and whether in this way Nature, if not abruptly called upon, may not adapt her measures to her necessities?

Although it is not our intention to discuss, at any length, the question as to whether Nature originally intended that we should feed on animal or vegetable food, nor to follow the train of those speculative authors who have endeavoured to prove that animal food was not eaten before the deluge, but was introduced in consequence of the deterioration which the herbage sustained on that occasion,—there are, nevertheless, several points connected with the first of these questions which we consider as deserving some notice. Reasoning from the data afforded us by the researches of the comparative anatomist, we are undoubtedly authorised in pronouncing man to be an *omnivorous* animal, and this is perhaps the only generalisation of which the subject is susceptible; Broussonet, however, has ventured so far to refine upon this proposition as to decide upon his being more herbivorous than carnivorous in his nature; and, from the proportion which the different teeth bear to each other, he concludes that his mixed diet should consist of animal and vegetable food in the proportion of twenty to twelve. It is, however, quite clear that no rule of this kind can possibly be established. We have only to consider the different effects produced upon the body by these two species of food, to perceive that the circumstances of climate, season, exercise, habit, age, and individual peculiarity must at once oppose such an admission.

As every description of food is converted into blood, and since the flesh and blood of carnivorous and herbivorous animals do not differ very materially from each other, it may be inferred that the ultimate effect of all aliments must be virtually the same; and that the several species can only differ from each other in the quantity of nutriment they afford, in the comparative degree of stimulus they impart to the organs through which they pass, and in the proportion of vital energy they require for their assimilation. Now were the degree of excitement which attends the digestion of a meal commensurate with the labour imposed upon the organs which perform it, it is quite clear that less irritation and heat would attend the digestion of animal than of vegetable food; for in the one case the aliment already possesses a composition analogous to that of the recipient, and requires little more than division and depuration; whereas in the other a complicated series of decompositions and recompositions must be effected before the matter can be animalised, or assimilated to the body. But the *digestive fever*, (if we may be allowed to apply such an expression to a healthy process,) and the complexity of the alimentary changes, would appear in every case to bear an inverse relation to each other. This must depend upon the fact of animal food affording a more highly animalised chyle, or a

greater proportion of that principle which is essentially nutritive, as well as upon the immediate stimulus which the nerves receive from its contact. In hot countries, therefore, or during the heat of summer, we are, as it were, instinctively led to prefer vegetable food; and we accordingly find that the inhabitants of tropical climates select a diet of this description. The Brahmins in India, and the people of the Canary Islands, Brazils, &c. live almost entirely on herbage, grains, and roots, while those of the north use little beside animal food. On account of the superior nutritive power of animal matter, it is equally evident that the degree of bodily exertion, or exercise, sustained by an individual, must not be overlooked in an attempt to adjust the proportion in which animal and vegetable food should be mixed. Persons of sedentary habits are oppressed, and ultimately become diseased, from the excess of nutriment which a full animal diet will occasion; such a condition, by some process not well understood, is best corrected by aesculent vegetables. It is well known that artisans and labourers, in the confined manufactories of large towns, suffer prodigiously in their health whenever a failure occurs in the crops of common fruits. This fact was remarkably striking in the years 1804 and 1805. Young children\* and growing youths generally thrive upon a generous diet of animal food; the excess of nutritive matter is consumed in the development of the body, and if properly digested imparts strength without repletion. Adult and old persons comparatively require but a small proportion of aliment, unless the nutritive movement be accelerated by violent exercise and hard labour.

Those who advocate the exclusive value of animal food, and deny the utility of its admixture with vegetable matter, adduce in support of their system the rude health and Herculean strength of our hardy ancestors. The British aborigines, when first visited by the Romans, certainly do not appear to have been conversant with the cultivation of the ground, and according to the early writers, Cæsar, Strabo, Diodorus Siculus, and others, their principal subsistence was on flesh and milk; but before any valid conclusion can be deduced from this circumstance, the habits of the people must be compared with those of their descendants. The history of later times will furnish us with a satisfactory answer to those who deny the necessity of vegetable aliment. We learn from the London bills, that scurvy raged to such an excess in the seventeenth century as to have occasioned a very considerable mortality; at that period the art of gardening had not long been introduced. It appears that the most common articles of the kitchen-garden, such as cabbages, were not cultivated in England until the reign of

\* The aliment of almost every animal, in its first stage of life, is composed of animal matter; even the graminivorous birds are nourished by the yolk of the egg for several days after being hatched.

Catharine of Arragon; indeed, we are told that this queen could not procure a salad until a gardener was sent for from the Netherlands to raise it. Since the change thus happily introduced into our diet, the ravages of scurvy have been less severely experienced.

It follows, then, that in our climate a diet of animal food cannot with safety be exclusively employed. It is too highly stimulant; the springs of life are urged on too fast; and disease is the necessary consequence. There may, nevertheless, exist certain states of the system which require such a stimulus, and there may also exist a condition of the digestive organs which renders them incapable of assimilating vegetable food; the physician, therefore, may occasionally confine his patient to an animal regimen with as much propriety as he would prescribe opium or any other powerful remedy. By a parity of reasoning, the exclusive use of vegetable food may be shewn to be inconsistent with the acknowledged principles of dietetics, and to be incapable of conveying a nourishment sufficiently stimulating for the active exertions which belong to our present civilized condition. At the same time, it must be allowed that an adherence to a vegetable diet is usually productive of far less evil in sedentary habits than that which follows the use of an exclusively animal regimen.

A very curious chapter might be written upon the adverse opinions which the physicians of different ages have maintained as to the importance of dietetic observances for the preservation of health and the cure of disease. Hippocrates was the first who attempted to establish any general principles upon the subject of dietetics; but accurate as he was in all his observations of the phenomena of disease, and admirable as are his precepts for its management, so warped were his notions with regard to the nature of aliments, by an absurd and predominating theory, that, instead of gathering from the stores of his experience any useful information, we find nothing but a mass of the most extraordinary conceits. Assuming as the directing principle of all his researches, that living bodies contain two elements, differing in power but agreeing in purpose, viz. *fire* and *water*, which, with their consequences, heat and dryness, moisture and cold, he considers as necessary and sufficient for the maintenance of all the functions,—the water nourishing and the fire setting in motion,—he proceeds, after shewing that disease arises from the deficiency of one or the other of these elements, to enumerate the different articles of diet which, from their heating, drying, moistening, and cooling tendencies, are best calculated to counteract such morbid states. He tells us, for instance, that fowls of every kind are drier than quadrupeds, because they have no bladder, and neither secrete urine nor saliva; thereby shewing that the heat of the body dries up its moisture. Their eggs, he says, are strong, nourishing, and inflating; strong, because they contain the germ of an animal,—nourishing, because they nurse it, as

it were, with milk,—and inflating, because they become dilated from a tiny particle to a large size. But it was not to be expected that, anterior to the discovery of the circulation of the blood, or to the existence of chemistry as a science, any rational views could be entertained upon a subject so entirely dependent upon such knowledge for its explanation. There exists, however, a connection between a class of phenomena which the ancient physicians recognised, and which the moderns appear to have too hastily disclaimed,—we allude to what they termed *non-naturals*; so called from their not being essential to the mere nature or constitution of living animals, and which, besides the different aliments, included air, exercise, sleep, the excretions, and the passions of the mind. In the second part of this article it will be the endeavour of the writer to point out and enforce upon the mind of the practitioner, the very important relations which obtain between the different stages of digestion and the non-naturals above enumerated.

In modern times, the multiplied resources of pharmacy, and the discovery of new chemical agents, have naturally enough led practitioners to depend upon such remedies for the cure of chronic disease rather than upon a modified plan of diet; while, in the circle of the profession, a certain degree of distrust, or we might even add of opprobrium, has fallen upon such practitioners as have insisted upon its paramount importance. This circumstance easily admits of explanation. In physic a remedy or a practice has never been discarded by the regular practitioner but it has immediately found a patron in the empiric, who seizes upon it with avidity, in order to convert it to his own advantage, just as the rabble dress themselves in the cast-off clothes of their superiors.

The minor writers who have swarmed within the last half century have greatly contributed to throw discredit upon the subject. Nothing cherishes the public scepticism, with regard to the efficacy of the medical art, so much as the publication of the adverse and contradictory opinions of its professors upon points so apparently simple and obvious, that every superficially informed person constitutes himself a judge of their merits. If a reader is informed by one class of authors that a weak stomach is unable to convert *liquid* food into aliment, and by another that *solid* food is injurious to feeble stomachs, he at once infers that the question is one of perfect indifference; and ultimately arrives, by a very simple process of reasoning, at the sweeping conclusion that the stomach, ever kind and accommodating, indiscriminately converts every species of food into nourishment, and that he has therefore only to consult his own inclination in its selection. On the valetudinarian, incapable of healthy reflexion, and ever seeking for causes of fear and anxiety when they do not choose to come uncalled, such works may have a contrary tendency, and lead him to sus-

pect the seeds of disease in every dish, and poison in every cup.

It appears to us that authors have in general laid far too great stress upon the quality of the different species of food, and have condemned particular aliments for those effects which should be attributed to their quantity, and still more perhaps to the circumstances under which they were taken; their dietetic precepts have therefore frequently assumed the air of ascetic austerities, and they have thus represented the cure far more formidable than the disease. It has been sarcastically observed by a popular writer, more remarkable for the playfulness of his style than for the soundness of his logic, that there exists a more intimate connexion between the doctrine of Tertullian and that of many a dietetic practitioner, than is generally supposed; that he is the ascetic intrenched in gallipots and blisters, preaching against beef and porter; terrifying his audience with fire and brimstone in one age, and in the other with gout and apoplexy. Now, while we must all deeply lament that the severity of this sarcasm should have been in some measure sanctioned by the theoretical absurdities of many of our writers, it is impossible that any reasonable person can seriously contend that numerous diseases do not arise from an improper management of diet; much less that a judicious regulation of it cannot be rendered subservient to their cure. To those, however, if such there be, who do question the importance of dietetics, we have only to observe that they may as well deny the utility of the medical art altogether, and assert that, in all disorders of function, Nature is sufficiently powerful to rectify and cure them, without the intervention of art. Unless this be granted, it is absurd to say that beneficial impressions may not be made as well through the medium of the *materia alimentaria* as through that of the *materia medica*; or, to borrow the language of Dr. Arbuthnot, that what we take daily by *pounds* must not be, at least, as important as what we take seldom, and only by grains or tea-spoonsful.

To get rid of such a difficulty, a class of philosophers admit the salutary influence of particular aliments in rectifying disorders of function, but deny the necessity of reason or philosophy for the selection or management of them, since they consider that Nature has implanted in us instincts sufficiently strong and intelligible to direct us, under all circumstances, to what is salutary, and to warn us from such food as may be injurious. We may observe in reply, that man has so long forsaken the simple laws which Nature had instituted for his direction, that it is to be feared she has abandoned her charge, and left him under the controul of that faithless guide and usurper, to which civilization has given birth. Appetite, which expresses the true wants of the system, can no longer be distinguished from that feeling which induces us to prefer one species of food to another, and which is the offspring of habit, and the consequence of artificial asso-

ciations. Nor must it be forgotten that, during disease, the senses frequently lose their tact, and the invalid experiences an appetite for things that would be prejudicial.

That the natural relations which subsist between the qualities of food and the impressions made by them on the senses, are changed or destroyed by the refinements of artificial life, is a fact supported by many powerful arguments. How many kinds of aliment, originally disagreeable, become pleasant by habit? and how many substances, naturally agreeable, become disgusting from the creation of certain prejudices? We are acquainted with a lady who is always made sick by eating a green oyster; the cause of which may be traced to an erroneous impression she received with respect to the nature of the colouring matter. Dr. Fordyce has urged a still more serious and conclusive objection to that hackneyed maxim, "that we ought to live *naturally*, and on such food as is presented to us by nature," viz. that *man has no natural food*. It is decreed that he shall earn his bread by the sweat of his brow; or, in other words, that he shall by his industry discover substances from which he is to procure subsistence; and that, if he cannot find such, he must cultivate and alter them from their natural state. There is scarcely a vegetable which we at present employ that can be found growing naturally. Buffon states that our wheat is a factitious production, raised to its present condition by the art of agriculture. Rice, rye, barley, or even oats, are not to be found wild, that is to say, growing naturally, in any part of the earth, but have been altered, by the industry of mankind, from plants not now resembling them in such a degree even as to enable us to recognise their relations. The acrid and disagreeable *apium gravecolens* has been thus transformed into celery; and the *colewort*, a plant of scanty leaves, not weighing altogether half an ounce, has been improved into cabbage, whose leaves alone weigh many pounds; or into a cauliflower of considerable dimensions, being only the embryo of a few buds, which, in their natural state, would not have weighed many grains. The potato again, whose introduction has added so many millions to our population, derives its origin from a small and bitter root, which grows wild in Chili and at Monte Video. If any of our readers, in the face of such facts, still remain sceptical upon the subject of these metamorphoses, let them visit the fairy bowers of horticulture, and they will there perceive that her wand has not only converted the tough, coriaceous covering of the almond into the soft and melting flesh of the peach, but that, by her spells, the sour sloe has ripened into the delicious plum, and the austere crab of our woods into the golden pippin; that this again has been made to sport in almost endless variety, emulating in beauty of form and colour, in exuberance of fertility, and in richness of flavour, the rarer productions of warmer regions and more propitious

climates. If cultivation can ever be said to have left the transformation of vegetables imperfect, the genius of cookery is certainly entitled to the merit of having completed it; for whatever traces of natural qualities may have remained, they are undoubtedly obliterated during their passage through her potent alembic.

After all then, experience can alone supply the want of instinct, and form the basis of a rational system of dietetics. Experience, dearly bought experience, has taught us that headach, flatulency, hypochondriasis, and a thousand nameless ills, have arisen from the too prevailing fashion of loading our tables with a host of *entremets* and *hors d'œuvres*, which have too frequently usurped the place of the roast beef of old England. The theorist, in the true spirit of refinement, laughs at our terrors: he admits, to be sure, that the man who eats round the table, "ab ovo usque ad mala," is a terrific glutton, but that, after all, *he has only eaten words*; for, eat as he may, he can only eat animal matter, vegetable matter, and condiment, either cooked by the heat of water or by that of fire, figure or disfigure, serve, arrange, flavour, or adorn them as you please. There is not a physician of any practical knowledge who cannot, at once, refute such a doctrine by a reference to facts; every old nurse knows from experience, that certain mixtures produce deleterious compounds in the stomach, although the chemist may, perhaps, fail in explaining their nature, or the theory of their formation. What would such a reasoner say, if he were invited to a repast, and were presented only with charcoal and water? Would he be reconciled to his fare by being told that his discontent was founded on a mere delusion,—that the difference between them and the richest vegetable viands was merely ideal,—*an affair of words*,—as, in either case, he would only swallow *oxygen, hydrogen, and carbon*? And yet we will venture to assert that the presumption in such a case would not be more violent, nor more opposed to the just principles of physiology and chemistry, than is the argument by which the sciolist attempts to defend a practice which converts our refreshments into burdens, and our food into poison.

I. MATERIA ALIMENTARIA.—Those bodies which have possessed life can alone be strictly considered as affording aliment to animals; and yet there exist a certain number of inorganic substances, such as water, common salt, lime, &c. which, although incapable by themselves of nourishing, appear, when administered in conjunction with the former, to contribute essentially to nutrition. The consideration, therefore, of the *materia alimentaria* necessarily embraces, not only the *substantive* agents above stated, but those accessories which from their *modus operandi* might properly enough be entitled *alimentary adjectives*. Under the former division will be arranged all the varieties of animal and vege-

table food; under the latter, the class of *condiments* will merit our attention.

The arrangements which different authors have proposed for the classification of alimentary substances will be found to vary according to the particular theory by which each may have been influenced. The chemist investigates the composition of an aliment, and arranges it either according to the ultimate elements of which he supposes it to consist, or according to the proximate principles which he considers to predominate in its composition. The naturalist, on the other hand, merely inquires to what division in his zoological system each article of diet belongs, and assigns to it a corresponding place in his arrangement; while the experienced practitioner is disposed to distribute the *nutrientia* in an order which answers to his notions of their relative nutritive value, or to the supposed facility with which they are dissolved in the stomach: thus, for example, as he finds from experience that the darkest coloured flesh generally contains more nourishment, while it stimulates the system more powerfully than the whiter kinds, he distributes venison, beef, mutton, hare, &c. into one group, while lamb, veal, and the white meats, such as that of turkey, partridge, pica-sant, chicken, &c. he considers as constituting a different class.

Chemists have been ever anxious to reduce all nutritious substances to some one or more proximate principles. Haller attempted to resolve them into one elementary jelly. Cullen was of opinion that the matter of nutrition is, in all cases, either oily or saccharine, or what seems to be a combination of both these principles. Fordyce reduced all nutritious matter to mucilage; but since he admits of a *farinaceous* mucilage, a *saccharine* mucilage, &c., Dr. Bostock very justly remarks that the inaccuracy with which he may be charged is but of a verbal description. Richerand attempted to shew that the nutritive principle is in all cases either gummy, mucilaginous, or saccharine. Dumas is disposed to regard 'mucus' as the "*principe eminent nutritif*," by which he probably means albumen, since he observes that it forms the basis of our organs. Dr. Prout, whose researches in organic chemistry claim our highest attention and respect, has stated that he considers that there exist three great natural classes or groups, which essentially constitute the groundwork of all organized beings, which he denominates the *saccharine*, the *oleaginous*, and the *albuminous*.

M. Majendie has distributed the nutrientia into nine classes, according to the predominance of one or more of those proximate principles, upon the presence of which modern science has assumed that the nutritive qualities of substances mainly depend.

The following is his arrangement:

I. FIBRINOUS ALIMENTS.—Comprehending the flesh and blood of various animals, especially such as have arrived at puberty;—venison, beef, mutton, hare.

II. ALBUMINOUS.—Eggs, &c.

III. GELATINOUS.—The flesh of young animals; veal, chickens, calf's foot, certain fishes.

IV. FATY AND OILY.—Animal fats, oils, butter, cocoa, &c.; ducks, pork, geese, eels, &c.

V. CASEOUS.—The different kinds of milk, cheese, &c.

VI. FARINACEOUS.—Wheat, barley, oats, rice, rye, potato, sago, arrow-root, &c.

VII. MUCILAGINOUS.—Carrots, turnips, asparagus, cabbage, &c.

VIII. SACCHARINE.—The different kinds of sugar, figs, dates, &c.; carrots.

IX. ACIDULOUS.—Oranges, apples, and other acescent fruits.

If there be any truth in our dietetic experience, and any natural affinity between the objects of our classification, the theory of their arrangement will be unimportant; for, however greatly the roads of our pursuit may vary, we must all ultimately arrive at the same end. The danger of relying upon chemistry alone as our guide arises from the uncertainty in which the elementary nature of matter is involved. There can be but little doubt that the supplies by which the bodily waste is recruited are solely derived from the food, for experiments of the most refined nature have shown that no part of the air we breathe is absorbed by the lungs; but it is more than doubtful whether those substances which are considered as the ultimate, or even the proximate, principles of our frame, are supplied to them ready formed by the aliments; or in other words, whether the powers of life do not analyse the matter submitted to them, and by recombining its elements, with which we are probably as yet unacquainted, produce those compounds which the chemist has been induced to suppose have been merely transferred from the ingesta, in order to be incorporated with the living structure. This is not only a highly curious, but a very important question in dietetics. If the views of the chemist be true, we have only to ascertain what principles may be excessive or defective in any state of disease, and at once to adopt a diet that may restore the healthy balance: but plausible and encouraging as such a theory may appear, an appeal to experience will at once prove it to be a delusion. The emaciated invalid can no more be restored to his plump contour by oleaginous ingesta, than the rickety child can be cured of a *mollities ossium* by the administration of phosphate of lime. "Nature," says Dr. Prout, "will not permit the chemist to officiate as her journeyman, even in the most trifling degree; or in other words, he is as little able to remedy or supply, in a direct manner, what is amiss or wanting in organic action, as he is to remedy or supply an injured nerve or muscle; and the only way in which, for the most part, he can hope to influence her operations, is through the indirect agency of those circumstances which naturally possess the power of influencing

them, and the management and controul of which are, to a certain extent, within his power."\* This admission, however, by no means invalidates the utility of chemical inquiries with regard to the nature of the different articles of diet; for as long as the composition of our diet possesses the power of influencing the constitution of our bodies, it is essential that we should be acquainted with its most minute details.

Amongst the numerous chemicophysiological questions which have arisen in connexion with the subject of dietetics, the late speculations of M. Majendie are not the least curious. It has been asserted by this distinguished physiologist that the azote or nitrogen of all the different tissues of the animal body can only be supplied by our food, and, consequently, that no substance which does not contain this principle can support life. In order to acquire some more exact notions on this subject, he submitted several animals, during a necessary period, to the use of food of which the chemical composition was accurately ascertained. We shall present our readers with a short abstract of these experiments, and then explain the different, but not less important, conclusions which we are prepared to deduce from their results. He took a dog of three years old, fat, and in good health, and put it to feed upon sugar alone, and gave it distilled water to drink: no restrictions were imposed as to quantity. It appeared very well in this way of living for the first seven or eight days; it was brisk, active, ate eagerly, and drank in its usual manner. It began to get thin in the second week, although its appetite continued good, and it took about six or eight ounces of sugar in twenty-four hours. Its alvine excretions were neither frequent nor copious; that of urine was very abundant. In the third week its leanness increased, its strength diminished, the animal lost its liveliness, and its appetite declined. At this period there was developed, first upon one eye, and then on the other, a small ulceration on the centre of the transparent cornea; it increased very quickly, and in a few days was more than a line in diameter; its depth increased in the same proportion; the cornea was very soon entirely perforated, and the humours of the eye ran out. This singular phenomenon was accompanied with an abundant secretion of the glands of the eyelids. The dog, however, became weaker and weaker; and, though it ate from three to four ounces of sugar per day, it became so weak that it could neither chew nor swallow; for the same reason every other motion was impossible. It expired the thirty-second day of the experiment. M. Majendie opened the animal with every suitable precaution. He found a total want of fat; the muscles were reduced to less than five-sixths of their ordinary size; the stomach and intestines were also much di-

\* Gulstonian Lecture, 1831.

minished in volume, and strongly contracted. The gall and urinary bladders were distended by their proper fluids, which M. Chevreul was called upon to examine. That distinguished chemist found in them nearly all the characters which belong to the urine and bile of *herbivorous* animals; that is, that the urine, instead of being acid as it is in *carnivorous* animals, was sensibly alkaline, and did not present any trace of uric acid, nor of phosphate. The bile contained a considerable portion of *picromel*, a character considered as peculiar to the bile of the ox, and in general to that of herbivorous animals. The excrements were also examined by M. Chevreul, and were found to contain very little azote, whereas they usually furnish a considerable quantity. M. Majendie considered that such results required to be verified by new experiments; he accordingly repeated them on other dogs, but always with the same conclusions. He therefore considered it proved, that sugar by itself is incapable of supporting dogs. This want of the nutritive quality, however, might possibly be peculiar to sugar; he therefore proceeded to inquire whether other substances, *non-azotised*, but generally considered as nutritive, would be attended with the same consequences. He fed two dogs with olive oil and distilled water, upon which they appeared to live well for about fifteen days; but they afterwards underwent the same series of accidents, and died on the thirty-sixth day of the experiment. In these cases, however, the ulceration of the cornea did not occur. Gum is another substance that is said not to contain azote, but which is considered as nutritive. To ascertain whether it acted like sugar and oil, several dogs were fed exclusively upon it, and the phenomena did not sensibly differ from those above described. An experiment was then instituted with butter, an animal substance which, like the preceding, is considered as not possessing any azote in its composition. The dog was supported by it very well at first; but in about fifteen days it began to lose flesh and to become weak: it died on the thirty-sixth day, although on the thirty-fourth he gave it as much flesh as it would eat, a considerable quantity of which it took for two days. The right eye of this animal presented the ulcerations of the cornea. The opening of the body exhibited the same modifications of the bile and urine.

In order to make the evidence furnished by the above experiments as complete as possible, after having given to dogs separately, oil, sugar, or gum, he opened them, and ascertained that these substances were each reduced to a particular chyme in the stomach, and that they afterwards furnished an abundant chyle; whence he argues that, if these different substances are not nourishing, it cannot be attributed to the want of digestion.

We are anxious to give all due credit to the accuracy with which these experiments were performed, but we deny the conclusions which this eminent physiologist has deduced from their results. We meet him at once, by

questioning the truth of his very first proposition, that sugar, oil, and gum cannot furnish azote. Is there a chemist of the present day who does not believe, although he is unable to prove it by direct experiment, that azote is a compound? The sugar therefore may furnish its elements, although we cannot detect azote during its decomposition in our laboratories. But let us waive this objection; we are quite prepared to impugn his conclusions on other grounds. What do his experiments prove? In the first place, the fact which we have before stated,—that an animal cannot bear a sudden and permanent change in its diet without injury; and in the next place, that a highly concentrated diet, or food which does not contain an intermixture of innutritive parts, is always injurious.

M. Majendie has himself, by subsequent experiments, furnished evidence against his own theory; for a dog confined on a diet of white bread, the gluten of which contains an abundance of azote, perished like those fed on sugar or gum. Animals, moreover, which were kept upon cheese, and even upon hard boiled eggs, became diseased, and yet *casein* is a highly azotised principle, while albumen is considered by Berzelius as the peculiar source of all the animal secretions.\*

We have said that a certain volume or bulk seems to be a necessary condition of wholesome food;—does not the capacity of the digestive organs sufficiently show that Nature never intended them for the reception of highly-concentrated food? This truth is still further exemplified by the very sparing manner in which she produces concentrated aliment; the saccharine matter of esculent fruits is generally blended with acidulous and mucilaginous ingredients, and the oleaginous matter is thus combined with the farinaceous, in seeds, kernels, and other substances of this description. The evils arising from the use of a too concentrated diet is well known to the physician; and, if we extend our observations to the domestic animals under our care, we shall derive further evidence of this important fact. A great number of our horses are fed with oats and beans, the nutriment of which is condensed into a much smaller space than it could generally be in natural provender; and these animals, when supported on such food, are consequently liable to various ailments originating from diseased action in the stomach, or from general plethora; in short, it need scarcely be remarked that horses so fed, and unnaturally confined in stables, require to be bled and purged to preserve their lives. The animal thus abused evidently suffers from acidity, as we find him frequently eating absorbent earths with avidity.† The extraordinary exertions often required of horses render it necessary that

\* The ingenious experiments of Mr. Hatchett also show that albumen is the *parent* fluid from which other principles may be formed; he found, for instance, that it was convertible into gelatine and fibrine.—*Phil. Trans.* 1800.

† The habit of crib-biting may perhaps be attributed to such a source.

they should be better fed than when existing in a more natural state; and since they do not travel so well with a full stomach, it is also necessary to adopt the use of food in which the nutriment is reduced into the smallest compass. Post-horses and others, whose motion must be rapid, are therefore chiefly fed with corn alone; but what is the effect!—fermentation instead of digestion; as the intolerable odour which assails us in the stable, under such circumstances, and the decomposed glass of its windows from the sulphuretted hydrogen acting upon the lead contained in it, sufficiently testify. Did it never occur to the physiologist, that had Nature intended animals to feed only upon the concentrated aliment of gramineous and leguminous vegetables, she would have supplied them with an apparatus by which they might separate the chaff and straw from the grain!

These remarks may be applied to man: we shall have occasion to show hereafter that the use of chocolate, butter, cream, sugar, and rich sauces, without a due admixture of bread, potatoes, and other less concentrated aliment, is invariably attended with disordered digestion. Unless the taste be vitiated, there exists an instinctive aversion to such food—

—————“ the prudent taste  
Rejects, like bane, such loathsome lusciousness.”

The Kamtschatdales are frequently compelled to live on fish-oil, but they judiciously form it into a paste with saw-dust, or the rasped fibres of indigenous plants.

*Nutritiveness and digestibility of different kinds of food.*—Before we attempt to appreciate the value of the different articles of the materia alimentaria, it will be necessary to caution the reader against the popular error of regarding the terms digestible and nutritive as synonymous and convertible. A substance may be highly nutritive and yet be digested with difficulty; that is to say, it may require all the powers of the digestive organs to convert it into chyle, and yet, when so converted, it may afford a principle of highly-restorative energy: this is the case with the fatty and oily aliments.\* On the contrary, there are substances which apparently pass out of the stomach with sufficient readiness, but afford but little comparative support to the body.

Writers on dietetics have descanted very learnedly upon what they please to term the *perspirability* and *alkalescency* of certain aliments. To the former we are quite unable to attach any precise meaning; with respect to the latter, we apprehend that it is intended to express a highly-nutritive quality, with a certain degree of indigestibility. *Heavy* and *light*, as applied to food, are terms equally vague and indefinite, and ought never to be introduced into writings which aspire to the character of philosophical precision. The observation may be extended to the epithet *bilious*.

It is only necessary to reflect upon the chemical and mechanical processes by which chy-

mification is performed in the stomach, to perceive that the digestibility of a substance may depend upon other circumstances than that of its chemical composition. Its mechanical state, with regard to texture and consistence, is of the highest importance; and if we attempt to deduce any law upon this subject, from the known solubility of a substance out of the body, we shall fall into several fatal errors. It will be necessary to investigate this question with some attention; for it not only explains the relative digestibility of aliments, but furnishes the only true basis for a system of skilful cookery.

The healthy stomach disposes most readily and effectually of solid food, of a certain specific degree of density, which may be termed its *digestive texture*; if it exceed this, it will require a greater length of time and more active powers to complete its chymification; and if it approaches too nearly to a gelatinous condition, the stomach will be equally impeded in its operations. It is, perhaps, not possible to appreciate or express the exact degree of firmness which will confer the highest order of digestibility upon food;\* indeed this point may vary in different individuals; but we are taught by experience that no meat is so digestible as tender mutton: when well conditioned, its fibre appears to possess that degree of consistence which is most congenial to the stomach; and in this country it is perhaps more universally used than any other animal food. Wedder mutton, or the flesh of the castrated animal, is in perfection at five years, and is by far the sweetest and most digestible. Ewe mutton is best at two years old. Beef appears to be not so easy of digestion; its texture is firmer, but it is equally nutritive; much, however, will depend upon the period which has elapsed since the death of the animal, and more upon the method of cookery; in short, it would be worse than useless to attempt the construction of any scale to represent the nutritive and digestive qualities of the different species of food: the observations here introduced are merely noticed for the sake of illustrating those general principles whose application can alone afford us any rational theory of diet.

It will not be difficult to understand why a certain texture and coherence of the aliment should confer upon it digestibility or otherwise. Its conversion into chyme is effected by the solvent power of the gastric juice, aided by the *churning* which it undergoes by the motions of the stomach; and unless the substance introduced possesses a suitable degree of firmness, it will not yield to such motions: this is the case with soups and other liquid aliments; in such cases, therefore, nature removes the watery part before digestion can be carried forward. It is on this account that oils are digested with so much difficulty; and it is probable that jellies and other glutinous matters, although

\* Some experiments were instituted for this purpose by Gosse, of Geneva; but the conclusions deduced from them are by no means satisfactory. He confounds solubility with digestibility, which in itself is sufficient to vitiate his reasoning.

\* It has been calculated that an ounce of fat meat affords nutriment equal to four ounces of lean.

containing the elements of nourishment in the highest state of concentration, are not digested without considerable difficulty; in the first place, on account of their evading the grappling powers of the stomach, and, in the next, in consequence of their tenacity opposing the absorption of their more fluid parts. For these reasons the addition of isinglass and other glutinous matter to animal broths, with a view to render them more nutritive to invalids, is a questionable custom.

The texture of animal food is greatly influenced by the age, sex, habits, condition, diet, and description of death of the animal which furnishes it. In proportion generally to the age, its flesh is coarser and more firm in texture, as every one must have noticed in eating birds. If the flesh of mutton and lamb, beef and veal, are compared, they will be found of a different texture; the two young meats are of a more stringy, indivisible nature than the others, which makes them harder of digestion. It has been also justly observed that young animals differ from old ones in the distribution of the fat, which in the latter is chiefly collected in masses or layers, external to the muscles; whereas in the former it is more interspersed among the muscular fibres, giving the flesh a marbled appearance, which is always a desirable property of butchers' meat. The texture of food will also vary according to the wild or domesticated state of the animal; that of the former is more dense, although highly nutritive. The sex also modifies the quality of the flesh, that of the female being always more delicate and finer-grained than that of the entire male, whose fibres are denser. The influence of the genital organs upon this occasion is very extraordinary; it is generally believed that the flavour of the female is even improved by removing the ovaries, or *spaying* them, as it is called. Every day the testes are permitted to remain, even though totally inactive with regard to their proper functions, injures the delicacy of the veal of the bull calf; and an animal which is not castrated until after puberty always retains much of the coarseness of the entire male. The mode of killing an animal has been considered, from the remotest ages, as capable of affecting the quality of its meat. The flesh of hunted animals is characterized by peculiar tenderness; the same effect is produced by any lingering death. This fact probably explains the policy of those old municipal laws which ordained that no butcher should offer or expose any bull-beef for sale unless it had previously been baited; and it is upon the same principle only that the quality of pig's flesh could be improved by the horrid cruelty of whipping them to death, as said to be practised by the Germans. The action of vinegar, administered to an animal some hours before killing it, is also known to be capable of rendering its flesh less tough. It is a common practice in the country to give a spoonful of this acid to poultry, when they are intended for the immediate service of the table.

Nothing, however, tends more effectually to ameliorate the rigidity of the animal fibre than incipient putrefaction. The length of time that meat ought to be kept after it is killed will necessarily depend upon its tendency to undergo the putrid fermentation, and the prevalence of those circumstances which are inclined to favour it.

The circumstances which have been just enumerated, as being capable of influencing the texture of our food, and consequently its degree of digestibility, are, however, unimportant when compared with the modifying powers of cookery, which we shall now proceed to examine.

*Cookery.*—By cookery, alimentary substances undergo a twofold change; their principles are *chemically* modified, and their textures *mechanically* changed. The extent and nature, however, of these changes will greatly depend upon the manner in which heat has been applied to them; and if we inquire into the culinary history of different countries, we shall trace its connexion with the fuel most accessible to them. This fact readily explains the prevalence of the peculiar species of cookery which distinguishes the French table, and which has no reference, as some have imagined, to the dietetic theory or superior refinement of the inhabitants.

By the operation of *boiling*, the principles not properly soluble are rendered softer, more pulpy, and, consequently, easier of digestion; but the meat, at the same time, is deprived of some of its nutritive properties by the removal of a portion of its soluble constituents: the albumen and gelatin are also acted upon; the former being solidified, and the latter converted into a gelatinous substance. If, therefore, our meat be boiled too long or too fast, we shall obtain, where the albumen predominates, as in beef, a hard and indigestible mass, like an overboiled egg; or where the gelatin predominates, as in young meats, such as veal, a gelatinous substance equally injurious to the digestive organs. Young and viscid food, therefore, as veal, chickens, &c., is more wholesome when roasted than when boiled, and is easier digested. Dr. Prout has very justly remarked that the boiling temperature is too high for a great many of the processes of cooking, and that a lower temperature and a greater time, or a *species of infusion*, are better adapted for most of them. This is notorious with substances intended to be *stewed*, which, even in cookery-books, are directed to be *boiled slowly*, (that is, not at all,) and for a considerable time.\* The ignorance and prejudice existing on these points is very great, and combated with difficulty; yet, when we take into account their importance, and how intimately they are connected with health, they will be found to deserve no small share of our attention. The loss occasioned by boiling partly depends

\* Hence it is that beef-tea and mutton-tea are much more calculated for invalids than the broths of these meats.

upon the melting of the fat, but chiefly from the solution of the gelatine and osmazone; mutton generally loses about one-fifth, and beef about one-fourth, of its original weight. Boiling is particularly applicable to vegetables, rendering them more soluble in the stomach, and depriving them of a considerable quantity of *air*, so injurious to weak stomachs. But, even in this case, the operation may be carried to an injurious extent: thus potatoes are frequently boiled to the state of a dry insipid powder, instead of being preserved in that state in which the parts of which they are composed are rendered soft and gelatinous, so as to retain their shape, and yet be very easily separated. On the other hand, the cabbage tribe and carrots are frequently not boiled long enough, in which state they are highly indigestible. In conducting this process it is necessary to pay some attention to the quality of the water employed; thus, mutton boiled in hard water is more tender and juicy than when soft water is used; while vegetables, on the contrary, are rendered harder and less digestible when boiled in hard water.

By the process of *roasting*, the fibrine is corrugated, the albumen coagulated, the fat liquified, and the water evaporated. As the operation proceeds, the surface becomes first brown, and then scorched, and the tendinous parts are rendered softer and gluey. Care should always be taken that the meat should not be *over-done*, nor ought it to be *under-dressed*; for although in this latter state it may contain more nutriment, yet it will be less digestible, on account of the density of its texture. This fact has been satisfactorily proved by the experiments of Spallanzani,\* and Mr. Hunter observes that "*boiled, and roasted, and even putrid meat, is easier of digestion than that which is raw.*"† Animal matter loses more by roasting than by boiling; it has been stated above, that by this latter process mutton loses one-fifth, and beef one-fourth; but by roasting, these meats lose about one-third of their weight. In roasting, the loss arises from the melting out of the fat, and the evaporation of the water; but the nutritious matter remains condensed in the cooked solid; whereas, in boiling, the gelatine is partly abstracted. Roasted are, therefore, more nutritive than boiled meats.‡

The process of *frying* is, perhaps, the most objectionable of all the culinary operations. The heat is applied through the medium of boiling oil, or fat, which is thus rendered empyreumatic, and therefore extremely liable to disagree with the stomach.

By *broiling*, the sudden browning or hardening of the surface prevents the evaporation of the juices of the meat, which imparts a peculiar tenderness to it. It is the form selected, as

the most eligible, by those who seek to invigorate themselves by the art of *training*.

The peculiarity of the process of *baking* depends upon the substance being heated in a confined space, which does not permit the escape of the fumes arising from it; the meat is therefore, from the retention of its juices, rendered more sapid and tender. But baked meats are not so easily digested, on account of the greater retention of their oils, which are, moreover, in an empyreumatic state. Such dishes accordingly require the stimulus of various condiments to increase the digesting powers of the stomach.

*Articles of diet.*—Were we to follow the steps of preceding writers on dietetics, we should present a catalogue of the nutrimenta, and introduce under each article a history of its composition and qualities; but the utility of general principles is to abbreviate labour, and to class under distinct heads those remarks which were previously scattered and unconnected.

We have seen that the nutritive qualities of a substance depend upon its composition; but that its digestibility may be influenced by various mechanical causes. It is by such tests that we have now to examine the several classes of food, and to assign to the individual bodies which they embrace their relative value as articles of diet.

*Milk* is the only nutritive fluid with which nature has presented us; but if we examine its chemical composition, we shall soon discover that it possesses an ingredient which is instantly coagulated in the stomach; so that, in fact, it must be regarded as a mixture of solid and liquid aliment; the latter, however, considerably exceeding the former in quantity, and thereby demonstrating the necessity of a greater portion of fluid than of solid matter; for the reparation of that habitual waste, upon which the necessity of alimentary supplies is founded.

Although recent milk appears as a homogeneous liquid, it may be resolved, partly by standing, and partly by agents that do not essentially alter the nature of its components, into three proximate ingredients, the *cream*, *curd*, and *whey*.

1. The *cream* rises to the surface of the milk, after it has stood for some hours, and may be skimmed off, and thus separated from it. It appears to possess many of the properties of oil, is smooth and unctuous to the touch, and stains cloth in the same manner as other unctuous substances. By standing for some days it becomes gradually thicker, and at length forms a soft solid, in which the flavour of cream is no longer perceived, and that of cheese is substituted in its place. According to the experiments of Berzelius, cream is a compound body, consisting of butter, 4·5; cheese 3·5; and whey, 92 parts: but since the whey holds certain salts in solution, we may consider the whole of the solid matter contained in cream as amounting to 12·5 per cent. When cream is agitated, as is done by the common process of churning, it is separated into two parts; a thick

\* Spallanzani on Digestion, vol. i. p. 277.

† Hunter on the Animal Economy, p. 220.

‡ It has been computed that, from the dissipation of the nutritive juices by boiling, one pound of *roasted* contains as much nourishment as two of boiled meat.

animal oil, well known by the name of butter, and a fluid which possesses exactly the same properties as milk that has been deprived of its cream. This change has been supposed to be owing to the combination of the cream with the oxygen of the atmosphere; but it takes place, though perhaps not equally well, in vessels from which the air has been excluded.

2. When milk, either deprived or not of its cream, is mixed with certain substances, or allowed to stand till it becomes sour, it undergoes a change which is called coagulation, consisting of its separation into a solid substance termed *curd*, and a fluid called *whcy*. This change may be effected by several agents, such as alcohol, gelatine, and all astringent vegetables; by acids, and many neutral salts; by gum, sugar, and more particularly by the *gastric juice*. The effect is supposed to arise from the affinity of the coagulating substance for water, the curd, being principally albumen, having very little affinity for the same; but this theory can hardly explain the operation of the gastric juice: the infusion of a piece of calf's stomach, not larger than a half crown, will coagulate a quantity of milk sufficient for making a cheese of sixty pounds weight, although the quantity of coagulating matter cannot in this case exceed a few grains.

3. *Whey*, or the liquid which remains after the separation of the curd, is a thin and almost transparent fluid, of a yellowish-green colour, and a pleasant sweetish taste. It still contains, generally, a portion both of curd and of butter; the former of which may be separated by a boiling heat, in the form of coagulum. The buttery matter also separates by heat, especially if the whey be previously allowed to become sour. Whey contains, indeed, in its recent state, some acetic acid. When whey, which has been deprived as much as possible of the butter and curd, is slowly evaporated, it yields the peculiar substance termed "*sugar of milk*," which may be obtained, by clarification with whites of eggs, in the form of crystals. The presence of this saccharine matter held in solution in whey enables that fluid to undergo the vinous fermentation; and it is accordingly employed by the Tartars for making a sort of wine, which is called *Koumiss*. For this purpose mare's milk is selected, as containing a larger portion of sugar than that of the cow. Whey also contains several saline bodies, viz. *auriate of potass*, *phosphates of lime and of iron*, and *sulphate of potass*; and a peculiar *animal matter*, which gives a precipitate with infusion of galls, and affords carbonate of ammonia by distillation.

Although nature has presented us with this compound fluid for the purposes of nourishment, and although it is evident that its several ingredients are wholesome, and designed for the various objects of aliment, yet, when separated by art, they are frequently unwelcome to the stomach; that viscus would appear to dislike the interference of the cook, in the performance of an analysis which its own powers are so well calculated to effect. We are well assured that the first process which takes place in the

stomach for the chymification of milk, is its separation into curd and whey; and yet the former of these substances, when obtained by art, frequently proves highly oppressive to the stomach, and sometimes occasions obstructions in the bowels. *Cheese*, again, which is nothing more than the coagulum of milk, pressed, salted, and partly dried, with a portion of butter, which, having been enveloped in the curd, is not afterwards separable, is one of the least digestible of our aliments, and is only adapted to strong stomachs, and to such persons as use great and constant exercise. When *toasted*, it is still more injurious, from acquiring a tenacity of texture highly hostile to the digestive function of the stomach. *Butter*, from its oily nature, is apt to disagree with delicate stomachs, and when rendered empyreumatic by heat, produces heartburn and other distressing symptoms. Whey differs considerably in its dietetic value, according to the method employed for its separation. When this is effected by *rennet*, it always holds a portion of cream and curd suspended in it, besides its quantity of sugar. It is, therefore, considerably nutritive; but it is, at the same time, more accecent than milk, and hence it is liable to produce flatulence in those whose stomachs are disposed to encourage fermentation. Whey that has been produced by spontaneous coagulation always contains less nutritive matter, is more acid, and consequently more objectionable, unless, perhaps, as a drink in certain states of fever.

From this account of the composition of milk, several properties of the entire fluid may be understood. By boiling it, its albuminous part is not coagulated into a mass like the white of an egg, on account of the large quantity of water through which it is diffused; but a thin pellicle forms on the surface, which, if removed, is immediately replaced by another; and thus the whole of the albumen may be separated in successive portions. The effect of this process is therefore to diminish the nutritive quality of the milk; but it may at the same time render it more easily digestible. We have known many invalids who could take boiled milk, but were unable to bear that fluid in its natural state.

Milk, in its dietetic relations, may be considered as intermediate between animal and vegetable food; it is easily assimilated, and therefore affords a quick supply of aliment to the system, while it does not excite that degree of vascular action which is produced by other animal matters. Its nutritive powers may be increased by various additions, which have also, on some occasions, the effect of correcting its natural tendency to acidity, and on others, that of obviating the costiveness which it is liable to occasion; such objects are sometimes fulfilled by adding oatmeal gruel to it. In certain states of organic disease, we have found that milk, impregnated with the fatty matter of mutton suet, is a valuable article of diet: such a repast is best prepared by inserting the suet in a muslin bag, and then simmering it with the milk.

Before quitting this subject, it is necessary to observe that there exists some difference in the

composition of the milk of different animals. That of the human subject is much thinner than eow's milk; is of a bluer colour, and contains much more saccharine matter. It also yields a larger proportion of cream, but from which the butter cannot be separated by agitation. It deposits a part of its curd by mere repose. Asses' milk bears a stronger resemblance to human milk than to any other; it contains more sugar than that of the eow, and the proportion of curd is so considerable as even to separate on standing, before the milk becomes sour. Goat's milk yields a remarkably thick and unctuous cream, and abounds also in curd.

*Eggs*, in point of nutriment and digestibility, may be classed next to milk; but their qualities will greatly depend upon the manner in which they have been cooked. When raw, they are certainly not so easily digested as when lightly boiled, so as slightly to coagulate their albuminous principle: but if this process be carried too far, they are converted into a hard mass, which requires a long period for their digestion: but this is much accelerated by the use of vinegar as a condiment. They are distinguished by the peculiar quality of singularly affecting some stomachs, even in the smallest quantity; while they do not produce any uneasy impressions on others. We are acquainted with a person who constantly finds an egg to produce uneasiness when his stomach is in the least deranged, but who can eat them with impunity at all other times. It is a notorious fact that eggs, when raw, are laxative, and when cooked are apt to produce costiveness.

*Fish* has been generally considered as holding a middle rank between the flesh of warm-blooded animals and vegetable food. It is certainly less nutritive than mutton or beef; but the health and vigour of the inhabitants of fishing-towns evidently prove that it is sufficiently nourishing for all the purposes of active life: but in order to satisfy the appetite, a large quantity is requisite; and the appetite returns at shorter intervals than those which occur during a diet of meat. Nor does this species of food produce the same stimulus to the body; the pulse is not strengthened as after a repast of flesh; and that febrile excitement which attends the digestion of the more nutritive viands is not experienced. Hence fish affords a most valuable article of diet to invalids labouring under particular disorders; for it furnishes a chyle moderately nutritive, but, at the same time, not highly stimulant. From the nature of its texture, it does not require a laborious operation of the stomach; although it is sufficiently solid to rescue it from those objections which have been urged against liquid or gelatinous food. From the observations just offered upon the nutritive powers of fish, it must follow that such a diet is not calculated to restore power to habits debilitated by disease, and should never be directed under such circumstances, but from the conviction that the digestive powers are unable to convert stronger aliment into chyle. The jockeys who *waste themselves* at Newmarket in order to reduce

their weight, are never allowed meat when fish can be obtained. On account of the low stimulant power of fish, it requires the assistance of condiment; and on this account salt appears to be an essential accompaniment.

Fish have been arranged under three divisions, viz. *fresh-water fish*, *salt-water fish*, and *shell fish*; but, since the value of these animals as articles of food has an intimate relation to the colour and texture of their muscles, and to their gelatinous or oily qualities, it will be expedient to consider their several varieties with reference to such conditions. Turbot, cod, whiting, haddock, flounder, and sole, are the least heating of the more nutritive species; and the flakiness of the fish, and its opaque appearance after being cooked, may be considered as true indications of its goodness; for when the muscles remain semi-transparent and bluish, after sufficient boiling, we may reject it as inferior in value, or not in season. When the fish is in high perfection, there is also a layer of white curdy matter, resembling coagulated albumen, interposed between its flakes. The whiting is well adapted for weak stomachs, on account of the little visciduity which it possesses; it is, at the same time, tender, white, and delicate, and conveys sufficient nutriment with but little stimulus to the system. The haddock much resembles it, but is firmer in texture. Cod has a more dense fibre than the two former, and contains also more glutinous matter: it is an excellent aliment, but upon the whole is not quite so digestible as whiting or haddock. It is generally preferred when large; but such fish are frequently coarse. The haddock is certainly better when it does not exceed a middling size. Turbot is an excellent article of food; but it is usually rendered difficult of digestion by the quantity of lobster sauce with which it is eaten. Sole is tender, and yet sufficiently firm; it is therefore easy of digestion, and affords proper nutriment to delicate stomachs. It is necessary to state that every part of the same fish is not equally digestible; and it unfortunately happens that those which are considered the most delicious are, at the same time, the most exceptionable: the pulpy, gelatinous skin of the turbot, and the glutinous parts about the head of the cod, are very apt to disagree with invalids. Salmon may, perhaps, be considered the most nutritive of our fish; but it is heating and oily, and not very digestible: and persons, even with strong stomachs, are frequently under the necessity of taking some stimulant to assist its digestion. The addition of lobster sauce renders it still more unwholesome: the best condiment that can be used is vinegar. As connected with the time of spawning, the season of the year has the most decided influence upon the quality of salmon. It is in the highest perfection, or *in season*, as it is termed, some time previous to its spawning; the flesh is then firm and delicious; whereas, after this event, it is for some time unfit for food. Salmon trout is not so rich and oily as the salmon; although, therefore, it is less nutritive, it is at the same time

less heating and more digestible. Eels are extremely objectionable, on account of the large proportion of oil which they contain. From these observations, the value of fish may be appreciated, and the qualities which entitle them to election easily understood. Firmness of texture, whiteness of muscle, and the absence of oiliness and viscosity, are the circumstances which render them acceptable to weak stomachs.

*Shell fish* have been greatly extolled by some physicians as nutritive and easily digestible articles of food. It will be necessary to examine this question by the application of those principles which we have endeavoured to establish. Oysters would appear to enjoy a reputation which they do not deserve: when eaten cold they are frequently distressing to weak stomachs, and require the aid of pepper as a stimulant; and since they are usually swallowed without mastication, the stomach has an additional labour to perform, in order to reduce them into chyme. When cooked they are still less digestible, on account of the change produced upon their albuminous principle. It is, however, certain that they are nourishing, and contain a considerable quantity of nutritive matter in a small compass. It is equally clear that oysters have occasionally produced injurious effects;\* these have been attributed to their having lain on coppery beds, but this idea is entirely unfounded, and arose merely from the green colour which they often acquire, the cause of which is now generally understood, being sometimes an operation of nature, but more generally produced by art, by placing them in a situation where there is a great deposit from the sea, consisting of the vegetable germs of marine *confervæ* and *fuci*, and which impart their colour to the oyster. For this object the Dutch formerly carried oysters from our coasts, and deposited them on their own. Native oysters, transported into the Colchester beds, soon assume a green colour. Where this food has produced a fit of indigestion, it has evidently arisen from the indigestible nature of the oyster, and the state of the individual's stomach at the time; and had such a person indulged to the same amount in any equally indigestible aliment, there can be no doubt but that he would have experienced similar effects. Oysters cast their spawn, which the dredgers call the *spat*, in the month of May, after which they are sick and unfit for food; but in June and July they begin to mend, and in August they are perfectly well. We therefore see the cause of their going out of season, and discover the origin of the old maxim, that an oyster is never good except when there is an *r* in the month. Lobsters are certainly nutritive; but they are exposed to the same objection on the ground of indigestibility; and such has been their effect upon certain stomachs, as to have excited a suspicion of their containing some poisonous principle: they have been known to occasion

pain in the throat, and, besides eruptions upon the skin, to extend their morbid influence to the production of pain in the stomach, and affection of the joints. As found in the London market, they are generally underboiled, with a view to their better keeping; and in that case they are highly indigestible. The same observations apply to the crab. Shrimps are a species of sea crab, which vary in their colour and size, and are considered easier of digestion than the preceding articles. The mussel is a species of bivalve which is more solid, and quite as indigestible as any animal of the same tribe. The common people consider them as poisonous, and, in eating them, take out a part in which they suppose the poison principally to reside. This is a dark part, which is the heart, and is quite innocuous: the fact, however, is sufficient to prove that this species of bivalve has been known to kill; but probably not more frequently than any other indigestible substance. Our annals abound with instances of the deleterious properties of melon, cucumbers, &c. and yet no one will contend that any poison, properly so called, resides in such vegetables. The peculiar cutaneous efflorescence which is produced by the imperfect digestion of shell fish, has been observed to occur more frequently in cases where the fish has been stale or tainted, although it also happens where no such error can be suspected.

It has been usual to attribute all the cutaneous affections which follow the liberal use of fish as depending upon the sympathy of the skin with the stomach. This, we believe, is in general the true explanation, since the effect is merely temporary; and when the process of digestion is finished, it departs. Its departure may even be hastened by the operation of an emetic removing the noxious aliment. At the same time the fact must not be overlooked, that the oily principle upon which depends the odour of certain fish, is absorbed from the alimentary canal, and carried into the blood; this is evident from the peculiar flavour of the flesh of certain birds who live upon fish. It is also well known that persons confined for any length of time to a diet of fish secrete a sweat of a rancid smell. It is not therefore improbable that certain cutaneous diseases may be produced, or at least aggravated, by such diet; and in hot climates this effect may be less questionable. The priests of Egypt may therefore have been prohibited from eating fish upon just principles, in order that the leprosy might be averted; and the great legislator of the Jews was, no doubt, influenced by some such belief, when he framed his celebrated prohibition.\*

It is usual to add various condiments to fish, and many kinds of fish are doubtless thus rendered more digestible, by a necessary stimulus being afforded to the stomach; but rich sauces are ever to be avoided by the valetudinarian. Vinegar and salt, perhaps, form the best additions.

The mode of cooking fish is another circum-

\* Medical Transactions of the College of Physicians, vol. v.

\* Leviticus, xi. 9—12.

stance of some importance. Frying them in lard or oil is an objectionable process: in general, the process of boiling is best adapted for rendering them wholesome. Stewed fish, with all the usual additions of glutinous and stimulant materials, are extremely injurious to dyspeptics.

*Birds.*—There exists a great variety in the qualities of the food which is furnished by this class of animals, with regard to nourishment, stimulus, and digestibility: the whiter meat of domesticated birds, as the wings and breasts of chickens, contains less nutriment and is less digestible than that which is furnished by wild birds, as the partridge, &c.; but the former is, at the same time, less stimulant and heating than the latter. These are the circumstances which are to direct the medical practitioner in his opinion. No general rule for the choice of either species can be established; it must be determined by the particular condition of the patient, and the effect which the aliment is intended to produce. The same observation will apply to the flesh of quadrupeds; that which is dark-coloured and contains a large proportion of fibrin, as venison, &c. is easily disposed of by the stomach, and a large quantity of highly-stimulating chyle is produced from it. The whiter meats are, on the contrary, detained longer in the stomach, and furnish a less stimulant chyle. The former, therefore, will be more easily digested by weak persons, while the latter will frequently run into a state of acetous fermentation; but they may, nevertheless, be preferable on many occasions, inasmuch as they impart less stimulus to the general system. We see, therefore, the folly into which many popular writers have fallen, of stating such or such an article as being wholesome or otherwise; as the wholesomeness of an aliment must depend upon its fitness to produce the particular effect which the case in question may require. Van Swieten has justly said, that “to assert a thing to be wholesome, without a knowledge of the condition of the person for whom it is intended, is like a sailor pronouncing the wind to be fair, without knowing to what port the vessel is bound.”

*Farinaceous aliments.*—The flour of wheat contains three distinct substances; a *mucilaginous saccharine matter*, *starch*, and a peculiar substance, possessing many of the properties of animal matter, termed *gluten*. It is to the quantity of this latter ingredient that wheat flour possesses so decided a superiority over that of barley, rye, or oats, for from these latter grains much less gluten can be extracted. It furnishes by far the best ingredient for making that important article of diet, *bread*; although it may also be made of all the various sorts of grain, as well as of chesnuts, of several roots, and of the potatoe. We shall first describe the nature of wheaten bread, and then compare it with that produced from other substances. The first process for rendering farinaceous seeds esculent, is to grind them into powder between mill-stones: the *meal* thus produced is purified from the husk of

the seed, or *bran*, by the operation of sifting or *bolting*; and it is then denominated *flour*. This, when mixed with water or milk, undoubtedly possesses the power of nourishing the body; but in this raw state it would not be sufficiently digestible; it would clog the stomach, and oppose those actions which are essential to chymification. The application, however, of heat renders the compound more easy to masticate as well as to digest; whence we find in the earliest history a reference to some process instituted for the purpose of producing this change, although the discovery of the manufacture of bread, simple as it may appear to us, was probably the work of ages. It has been just stated that wheaten flour is the best adapted for making bread, that is to say, *loaf* bread; this depends upon the greater quantity of gluten which it contains, and which operates in a manner to be presently explained. The first stage of this process of *panification* consists in mixing the flour with water, in order to form a paste, the average proportion of which is two parts of the water to three of the flour; but this will necessarily vary with the age and quality of the flour: in general, the older and the better the flour, the greater will be the quantity of water required. This paste may be regarded as merely a viscid and elastic tissue of gluten, the interstices of which are filled with starch, albumen, and sugar. If, then, it be allowed to remain for some time, its ingredients gradually react upon each other, the gluten probably performing an important part; by its action on the sweet principle, a *fermentation* is established, and alcohol, carbonic acid, and lastly acetic acid, are evolved. If the paste be now baked, it forms a loaf full of *eyes* like our bread, but of a taste so sour and unpleasant that it cannot be eaten. If a portion of this old paste, or *leaven*, as it is called, be mixed with new-made paste, the fermentation commences more immediately, a quantity of carbonic acid is given off, but the gluten resists its disengagement, expands like a membrane, and forms a multitude of little cavities, which give lightness and sponginess to the mass. We easily, therefore, perceive why flour, deficient in the tenacity which gluten imparts to it, is incapable of making raised bread, notwithstanding the greatest activity may be given to the fermentative process by artificial additions. Where, however, *leaven* has been employed, the bread will be apt to be sour, in consequence of the great difficulty of so adjusting its proportion, that it shall not by its excess impart an unpleasant flavour, nor by its deficiency render the bread too compact and heavy. It is for such reasons that in this country we employ *barin*; a ferment which collects on the surface of fermenting beer. It appears that we are indebted to the ancient Gauls for this practice. In Paris it was introduced about the end of the seventeenth century; the Faculty of Medicine, however, declared it to be prejudicial to health, and it was long before the bakers could convince the public that bread baked with *barin* was superior to

that of *leaven*. A great question arose among chemists as to the nature of this *barm* that could produce such effects, and elaborate analyses were made, and theories deduced from their results; but all these ingenious speculations fell to the ground, when it was found that *barm*, dried and made into balls, would answer every purpose: the bakers imported it in such a form from Piardy and Flanders, and when again moistened, it fermented bread as well as the recent substance. The presence, therefore, of carbonic acid, water, acetic acid, and alcohol, could not be essential, for these ingredients were separated by the process of its preparation. At length it was discovered that gluten, mixed with a vegetable acid, produced all the desired effects; and such is the nature of leaven, and such is the compound to which *barm* is indebted for its value as a panary ferment. After the dough has sufficiently fermented, and is properly raised, it is put into the oven previously heated, and allowed to remain till it is baked. The mean heat, as ascertained by Mr. Tillet, is 448°. When the bread is removed, it will be found to have lost about one-fifth of its weight, owing to the evaporation of water; but this proportion will be varied by the occurrence of numerous circumstances which it is not easy to appreciate. Newly-baked bread has a peculiar odour as well as taste, which are lost by keeping: this shews that some peculiar substance must have been formed during the operation, the nature of which is not understood. Bread differs very completely from the flour of which it is made, for none of the ingredients of the latter can be discovered in it; it is much more miscible with water than dough; and on this circumstance its good qualities, most probably, in a great measure depend. It is not easy to explain the chemical changes which have taken place. It appears certain that a quantity of water, or its elements, is consolidated and combined with the flour; the gluten, too, would seem to form a union with the starch and water, and thus to give rise to a compound upon which the nutritive qualities of bread depend.

*Unleavened* bread consists of a mixture of meal and water, formed into a firm and tough cake, made as thin as possible, to favour its drying, and sometimes with the addition of butter, to render it more soluble, friable, and porous; but it renders it sourer, and more apt to produce acidity on the stomach. Of the unleavened sorts of bread, biscuit is by far the best; and in all cases where leavened or fermented bread does not agree, its use cannot be too strongly advocated.

The different sorts of bread to be met with in this country may be considered under three classes: viz. *white*, *wheaten*, and *household*. In the first, all the *bran* is separated; in the second, only the coarser; in the third, none at all: so that *fine bread* is made only of flour, *wheaten* bread of flour and a mixture of the finer *bran*, and *household* of the whole substance of the grain, without taking out either the coarse *bran* or fine flour. It is necessary for

the medical practitioner to understand these distinctions; for it will be proved that an important dietetic fact is connected with them. The tendency of starch upon the bowels is astringent. Bread, therefore, which is made of the whitest flour is apt to render them costive; but this is counteracted by the presence of *bran*, the scales of which appear to exert a mechanical influence upon the intestines, and thus to excite them into action.

The French have many varieties of bread, in which eggs, milk, and butter enter as ingredients. They are also in the habit of adding ammonia to the dough; which, during its evaporation in the oven, raises it, and thus adds to its sponginess.

*Barley-bread* has a sweetish but not unpleasant taste; it is, however, rather viscid, and is less nutritive, as well as less digestible, than wheaten bread. It is common to mix peas-meal with the barley, which certainly improves the bread. *Rye-bread* is of a dark brown colour, and is apt to lie heavy on the stomach; it is also liable to create aceseeny and purging; but it appears to be highly nutritive. In some of the interior counties of England, where their bread is often manufactured from oatmeal, there is a mode of preparing the meal by making it sour; the bread, instead of being hard, is thus rendered of a soft texture, and from its moderate acidity is wholesome to strong persons: but invalids should, if possible, avoid it. In bread, however, this grain is more usually in an unfermented state, or it is made into flat, thin cakes, which are baked or roasted. It is evident, from the health and vigour of the people who use this grain as a principal article of diet, that it must be very nutritive; but the stomach will require some discipline before it can digest it. In those unaccustomed to such food, it produces heartburn; and it is said to occasion, even in those with whom it agrees, cutaneous affections. In times of scarcity, potatoes have been made into bread; but they contain too much mucilage in proportion to their starch to afford a good article: the bread thus produced is heavy, and apt to crumble into powder; effects which are obviated by mixing a certain quantity of wheat-flour with the potatoes. Rice will also serve the purpose of making very good bread; but, like the potatoe, it requires the addition of some flour. It is said by some that bread made of different kinds of grain is more wholesome than that made of only one sort, as their qualities serve to correct one another. This is certainly the case with that which is commonly called *brown bread*, and which is made of a mixture of wheat and rye flour; the former, being of a more starchy nature, and apt to produce costiveness, while the latter often proves too laxative: a due proportion of each, therefore, must furnish a desirable compound.

The importance of bread, as an article of diet, will be easily deduced from the principles upon which the digestion of food in the stomach is explained. In addition to its nutritive qualities, it performs a mechanical duty of some

importance. It serves to divide the food, and to impart a suitable bulk and consistence to it; it is, therefore, more necessary to conjoin it with articles containing much aliment in a small space, than where the food is both bulky and nutritive. The concentrated cookery of the French is rendered much more wholesome from the large quantity of bread which that people use at their meals. Bread should never be eaten new; in such a state, it swells like a sponge in the stomach, and proves very indigestible. Care should also be taken to obtain bread that has been duly baked. Unless all its parts are intimately mixed, and the fixed air expelled, it will be apt, in very small quantities, to produce acescency and indigestion.

After stating the advantages of bread, it is necessary to make a few observations upon the evils which it may occasionally produce. In certain diseases it evidently produces a tendency to acidity; we have daily instances of this fact in children, in whom acidity and much alimentary disturbance follow its use. Shebbeare goes so far as to say that the rickets are so common in France only because the quantity of bread given to children is excessive; which, by its acidity, destroys the calcareous substance of the bones, and reduces them to a state of cartilage. This is mere idle speculation, which is in direct variance with the received opinions upon the subject. Where acidity occurs, the bread should be toasted, or well-prepared biscuit substituted.

Much has been said and written upon the subject of the adulteration of bread; but we are inclined to believe that the evils arising from such a practice have been greatly exaggerated. It is certain that the inferior kinds of flour will not make bread of sufficient whiteness to please the eye of the fastidious citizen without the addition of a proportion of alum. It has been also found that unless this salt be introduced into the flour, the loaves stick together in the oven, and will not afterwards separate from each other with that smooth surface which distinguishes the loaf of the baker. This circumstance is probably owing to the action of the alum upon the mucilage of the flour, which it coagulates. It has been said that the smallest quantity that can be employed for these purposes is from three to four ounces to two hundred and forty pounds of flour. It cannot be denied that the introduction of a portion of alum into the human stomach, however small, may be prejudicial to the exercise of its functions, and particularly in dyspeptic invalids. It was found by Mr. E. Davy, of Cork, that bad flour may be made into tolerable bread by adding to each pound from twenty to forty grains of the common carbonate of magnesia.

Besides bread, several other preparations are made by the solidification of flour, such as pudding, pancake, &c. The most digestible pudding is that made with bread or biscuit and boiled flour: *batter* pudding is not so easily digested; and *suet* pudding is to be considered as the most mischievous to invalids in the

whole catalogue. *Pancake* is objectionable on account of the process of frying imparting a greasiness to which the dyspeptic stomach is not often reconciled. All *pastry* is also objectionable: we believe that one half at least of the cases of indigestion which occur after dinner-parties may be traced to this cause.

Many persons entertain a strange prejudice in favour of *pudding*; and appear as if they considered it to possess a balsamic virtue, or some property by which the digestion of other aliment is expedited. If ever such a diet has served the valetudinarian, it must have been by excluding less stimulant food, and not by any virtue inherent in the *pudding* itself.

Amongst the farinaceous aliments, the *potatoc* holds a distinguished rank; but its digestibility greatly depends upon its kind, and the nature of the cookery to which it is subjected. That species which is known by the name of *waxy* potatoe should be shunned by the dyspeptic, for it is so indigestible as to pass through the intestines in an unaltered state. The same objection applies to the young or new potatoe. The mealy kind more readily yields to the powers of the stomach, and affords a healthy nutriment: but to the dyspeptic, we have generally found this vegetable, in all its states, to be injurious; if ever allowed to such patients, it is worthy of remark that *roasting* is preferable to every other form of cookery. The process of *washing* certainly does not contribute to its digestibility. If boiled, care should be taken that it is not over-done; for in such a case it is deprived of its nutritious qualities.

*Rice* is the general aliment of the people of the East, with whom it answers the same purposes as bread does with us. As it is not much disposed either to acescency or fermentation in the stomach, it furnishes a wholesome aliment when mixed with other food; but if taken in large quantities by itself, from its low degree of stimulant properties, it is apt to remain for a length of time in the stomach: this effect is greatly increased by protracted boiling. Where the stomach is in a state of relaxation and debility, it ought not to be taken without condiment; it is, for this reason, found necessary in the warmer climates to conjoin it with a considerable quantity of warm spices. There formerly existed a prejudice against its use, from a belief that it had a tendency to produce blindness. It is scarcely necessary to state that such an idea has no foundation in truth. It is generally considered as astringent, and is, therefore, a popular remedy for diarrhœa; no astringent principle, however, has yet been discovered in its composition, and it is probable that it owes its virtues on such occasions to the mild and bland mucilage, with which it abounds, shielding the intestines from acrimonious humours.

There are various other aliments in domestic use which owe their qualities to starch, such as *sago*, *tapioca*, *arrow-root*, &c. From the mucilaginous form in which they are usually administered to invalids, they are not so digestible as is generally supposed; but where

the stomach rejects more substantial food, they are useful in themselves, as well as proper vehicles for the administration of vinous stimulants.

The leguminous productions, or *pulses*, may be considered as constituting the second division of farinaceous aliment. They differ little from grains, except in affording a more unctuous flour, which forms a milky solution with water, owing to the presence of an oily matter. Although they are highly nutritive, they are certainly more indigestible than seeds, and the bread they afford is apt to occasion flatulence, and to lie heavy on the stomach. The use, therefore, of this species of food is more circumscribed than that of the farinaceous seeds; it is principally confined to the lower classes, and to those possessing strong powers of digestion. In dyspeptic habits they ought on no account to be allowed; the symptoms of uneasiness which they produce in such persons is often alarming: flatulence and colic are the common consequences of their action. Pulses are employed in two very different states; in an early stage of their growth, when they are succulent; and when all their parts have reached maturity: in the former condition they are frequently acceptable to the stomach; but in the latter they are only calculated for those who have strong digestive powers.

*Peas* form a wholesome and light food when green and young, but when full grown and dry they are very indigestible: in this latter state they contribute, in a remarkable degree, to the generation of gas in the intestines. In the form of pudding they are, if possible, still more objectionable; for, to the bad qualities which depend upon their composition, are thus added those which arise from tenacity of texture. *Beans*, like peas, are comparatively wholesome in their immature state. The *kidney-bean*, being eaten with its pod, is not so flatulent as other pulse: when well boiled it is easy of digestion, but not very nutritive.

*Nuts* are generally supposed to have constituted the earliest food of mankind; and they still furnish, in some countries, a considerable source of food. In this country they are principally known as an article of the dessert, although on some occasions they are eaten with our food. With regard to composition, the chestnut may perhaps be considered as more nearly allied to the pulse than to the nut tribe, since it affords no oil by expression, and from its farinaceous qualities it may even be made into bread, although it is heavy and indigestible. Its nutritive power must be considerable, since it forms the chief food of the lower orders of the plains in Lombardy; and it has been conjectured that it was the *acorn* so frequently mentioned in ancient history and tradition. When eaten after dinner, an indulgence which can only be conceded to the most robust, it ought to be previously roasted; its digestibility is also increased by being kept for some time after it has been gathered. It is at the same time thus rendered more pa-

latable by the greater evolution of its saccharine principle.

The evils which may arise from the use of the chestnut are still more likely to occur after the ingestion of nuts, for they are more oily, as well as more viscid and glutinous: when eaten, they should always be accompanied with salt; but it would be wise to banish them entirely from our tables.

*Esculent roots*.—These are of two kinds: those used as food, and those which principally answer the purposes of condiment or seasoning. Under the first division may be classed *turnips, carrots, parsnips, Jerusalem artichokes, radishes, &c.*, many of which, it will be seen, are seldom used solely for aliment, but are rather brought to our tables to qualify our animal food. Under the second division may be arranged *onions, garlic, horse-radish, &c.* It will be necessary to offer a few observations upon the qualities of these several roots.

The *carrot*, from the quantity of saccharine matter which it contains, is very nutritive and slightly laxative; but it also possesses a large proportion of fibrous matter, which in some stomachs prevents the digestion of the root, and it passes through the bowels with but little change: to obviate this effect, it ought to be very thoroughly boiled, and it should be eaten when young. It appears to have been introduced by the Flemings, in the reign of Elizabeth. The *turnip* is a very excellent vegetable, and, although it has the character of being flatulent, it is less liable to disagree with the stomach than the carrot; it ought, however, to be well boiled, and the watery part separated by pressure. Lord Townshend, secretary to Charles I., was the person who introduced its use into England; but it appears that the ancient Romans, in the best period of their republic, lived much upon this root. The *parsnip* is nutritive and digestible, although many persons dislike it on account of its sweet flavour. The *Jerusalem artichoke* is agreeable, but watery and flatulent; it ought, therefore, never to be eaten without a proper accompaniment of salt and pepper. All the varieties of *radishes* have a pungent and acrid taste, in consequence of a peculiar stimulating matter, which resides in the cortical part of the root. They may be said to contain little else than water, woody fibre, and acrid matter, and cannot, therefore, be very nutritive; they may act as a stimulant, and thus prove useful, but they ought never to be eaten when old, as the quantity of inert matter in such a condition is apt to disagree with the stomach. From the consideration of radishes we pass, by an easy transition, to that of onions, &c., for they appear to form the connecting link between alimentary roots and those used principally as condiment. The *onion*, however, although classed under this latter division, and must be considered as valuable on account of its stimulating matter, certainly contains a considerable proportion of nourishment. This appears evident in its boiled state, by which process its acrimony is exhaled, and a sweet muc-

lage separated. Sir John Sinclair says that it is a well-known fact that a Highlander, with a few raw onions in his pocket, and a crust of bread, or some oat-cake, can travel almost to an incredible extent, for two or three days together, without any other sort of food. The French are fully aware of the quantity of nourishment this plant affords; hence the soup à l'oignon is considered by them as the best of all restoratives. As a stimulant to the stomach and bowels, the onion, in a raw state, is certainly of value, and this is much enhanced by its diuretic qualities. The leek, garlic, shallot, are of the same species, and possess qualities of the same nature. *Horse-radish* is a warm and pungent root, and is highly valuable to the dyspeptic as a stimulant; it is, perhaps, the best of all condiments for the prevention of flatulence.

*Esulent herbs.*—In this class are arranged the leaves and stalks of such vegetables as are eaten at table in the form of “greens and salads.” Herbs eaten in a raw state are far less digestible than when cooked. During the heats of summer they are refreshing, and are well calculated to assuage that febrile state which full meals of animal food are known to occasion. Of all these herbs the *water-cress* is the most beneficial; for, by operating in some degree as an aromatic, it promotes digestion, and corrects that tendency to flatulency which other raw vegetables are apt to produce. According to Xenophon, the ancient Persians lived upon water-cresses, which they considered the most wholesome of vegetable productions. The *lettuce* is generally eaten with other herbs, in the form of a salad, dressed with oil and vinegar. Some difference of opinion has arisen with respect to the propriety of such additions. Gosse, of Geneva, found that vinegar retarded its solution in the stomach, and oil has been stated by others to render it less digestible. We have generally found such condiments useful, and that dressed lettuce is less likely to ferment in the stomach than that which is eaten without them. Oil is known to have such an effect in checking fermentation, and the vinegar is not found to promote it. The lettuce contains a narcotic\* principle; and the effect of this is, in a great measure, obviated by a vegetable acid: those persons, therefore, who eat lettuce with a view to obtain such effects, ought to take it without vinegar. The digestibility of celery is greatly increased by maceration in vinegar. *Cucumbers* are by far the most unwholesome of all raw vegetables, and should be avoided as poison by dyspeptics.

The vegetables which require to be boiled are the different species and varieties of *colewort*; the value of which does not depend so much upon their nutritive quality as the tenderness of their texture. On this account, the

cauliflower and brocoli are the species to be preferred, particularly the younger sprigs of the former. Of the kinds where the leaves only are employed, the Savoy is of a sweeter and more tender texture than the others, particularly its central and upper leaves. The cabbage tribe appear to contain a peculiar essential oil, whence the unpleasant odour of cabbage water; this matter is liable to produce offensive effects on the stomach: the vegetable should therefore be boiled in two successive waters, in order to free it entirely from the noxious ingredient, and at the same time to render its texture soft and digestible. *Asparagus* is quickly dissolved in the stomach, and, when sufficiently boiled, is not disposed to create flatulence or acidity: along with its mucilage it frequently contains some sweetness, which affords a proof of its nutritive quality. From the peculiar odour which it imparts to the urine of those who eat it, it appears to possess some active matter distinct from its mucilage; and it is generally considered diuretic. *Asparagus* is only wholesome when in an intermediate state between root and plant. When older than this, it is remarkably acid.

*Fruits.*—These are generally regarded as articles rather of luxury than of food; and were we to form our opinion of their value from their abuse, we should certainly be rather disposed to class them under the head of poisons than of aliments. Nothing can be more mischievous to the invalid than large quantities of apples, pears, and plums, in the form of dessert, after the stomach has been already loaded. But, when taken under other circumstances, they contribute to health, and appear to be providentially sent at a season when the body requires that cooling and antiseptic aliment which they are so well calculated to afford.

Fruits may be arranged under the following heads: stone fruits, the apple species, small-seeded fruits, small berries, and farinaceous fruits.

The stone fruits have been denounced as the least digestible species by popular acclamation, but much of the mischief that has been attributed to their use has arisen from the unripe state in which they were eaten. They are, however, certainly less digestible than other species, and more liable to undergo fermentation in the stomach. The hard pulp of certain plums remains also in the alimentary canal for a long time, and is frequently passed without having been materially changed. The ripe peach is the most delicious, as well as one of the most digestible of the stone fruits; the apricot is equally wholesome, but the nectarine is liable to disagree with some stomachs. Cherries are far less digestible; their pulpy texture and skins are not easily disposed of by the stomach; and as the sweetest species contain a considerable excess of acid, they may be objectionable in some cases, and desirable in others. The apple species is not so dilute and watery as the foregoing fruits, and is less apt to pass into a state of noxious fer-

\* We are told that Galen, in the decline of life, suffered much from morbid vigilance, until he had recourse to eating a lettuce every evening, which cured him.

mentation; but its texture is firmer, and on that account it is retained longer in the stomach, and often proves indigestible. The same observations apply to pears, except that, their texture being in general less firm, they are less objectionable. The orange, when perfectly ripe, may be allowed to the most fastidious dyspeptic; but the white, or inner skin should be scrupulously rejected, for it is not more digestible than leather. The small-seeded fruits are by far the most wholesome. Of these the ripe strawberry and raspberry deserve the first rank. The grape is also cooling and antiseptic, but the husks and seeds should be rejected. The gooseberry is less wholesome on account of the indigestibility of the skin, which is too frequently swallowed. The fruits to be classed under the head of small berries are the cranberry, the bilberry, and the red whortleberry. These are rarely eaten, except when baked, and in that state their aescency seldom proves injurious. The farinaceous fruits are universally unwholesome. The melon, which is the principal one, is very apt to disagree with weak stomachs, and should never be eaten after dinner, even by persons in health, without a plentiful supply of salt and pepper.

By cookery, fruit, otherwise unwholesome, may be converted into a safe and useful aliment. Apples, when baked, afford a pleasant repast, and from their laxative properties are well adapted to certain forms of dyspepsia. Dried fruits, from the quantity of sugar which generally enters into their composition, are very much disposed to ferment and occasion heartburn.

OF DRINKS OR LIQUID ALIMENTS. — As the introduction of solid aliment into the stomach is for the purpose of furnishing materials for the repair of the different textures, so is a supply of liquid matter essentially necessary to replace the fluids which are constantly ejected from the body, during the exercise of its numerous functions. In this point of view, therefore, the drinks ought to be considered as real aliments. The chyme and the chyle may also require the assistance of some liquid medium to increase the fluidity of the mass, or to favour the absorption of its finer and more nutritive parts. In every point of view, therefore, dilution is an essential operation; and an animal will not only endure the sensation of hunger with more tranquillity than that of thirst, but he will survive longer under the privation of solid than of liquid aliment.

Before we enter upon this part of the subject, it will be necessary that we should offer a few remarks upon the nature of the changes which liquids undergo when introduced into the stomach, and which would appear to be determined by the nature of their composition. The subject teems with curious facts, and is one of much importance to the physician, as it will enable him to appreciate the utility of liquid diet, and to understand the circumstances which should decide its preference.

It was long supposed that liquids, like solids, passed through the pylorus into the intestines, and were absorbed together with the chyle, or rejected with the excrement. It is not asserted that this never occurs; but it is evident beyond contradiction that there must exist another passage, although its nature remains obscure, by which liquids can be conveyed to the circulation; for it has been shown that, if a ligature be applied round the pyloric orifice, in such a manner as to obliterate the passage into the duodenum, the disappearance of the liquid from the cavity of the stomach is not so much even as retarded. In order to discover whether drinks are absorbed along with the chyle, M. Majendie made a dog swallow a certain quantity of diluted spirit during the digestion of his food; in half an hour afterwards the chyle was extracted and examined: it exhibited no trace of spirit, but the blood exhaled a strong odour of it, and by distillation yielded a sensible quantity.

If a liquid, holding nutritive matter in solution, be introduced into the stomach, it is either coagulated by the gastric juice, or its watery part is absorbed, and the solid matter deposited in the stomach; in either case the solid product is converted into chyme. Milk, as we formerly observed, appears to be the only liquid aliment which Nature has prepared for our nourishment; but it seems that she has, at the same time, provided an agent for rendering a certain portion of it solid, and hence we are led to infer that this form is an indispensable condition of bodies which are destined to undergo the processes of chymification and chyfication; and that, unless some provision had existed for the removal of fluids from the stomach, the digestive functions could not have been properly performed. When the broth of meat is introduced into the stomach, the watery part is carried off, and the gelatine, albumen, and fat are then converted into chyme. Wine and fermented liquors undergo a similar change; the alcohol which they contain coagulates a portion of the gastric juice, and this residue, together with the extractive matter, gum, resin, and other principles which the liquid may contain, is then digested. Under certain circumstances these liquids may observe a different law of decomposition, which will, perhaps, in some measure explain the different effects which such potations will produce; for example, the spirit may undergo a partial change in the stomach, and be even digested with the solid matter, or, on some occasions, be converted into an acid by a fermentative process; this will be more likely to occur in vinous liquors, which contain ingredients favourable to the production of such a change, and hence the deleterious property of fermented liquors does not bear an unvarying relation to the absolute quantity of their alcohol. Oil, though possessing the fluid form, does not appear to observe the law which governs the disposal of such bodies; it is not absorbed, but is entirely transformed into chyme by the stomach. To

effect this change, however, it seems essential that the stomach should be in a state of high energy, or the fluid will undergo chemical decomposition; nor will the stomach, unless it be educated, as it were, to this duty, like those of some northern nations, digest any considerable quantity of it; and since it cannot be absorbed, it must find its exit through the alimentary canal, and consequently prove laxative.

In classing the different species of drinks, we may, as with solids, arrange them according to their chemical composition, thus—

I. WATER.—Spring, river, well-water, &c.

II. THE JUICES AND INFUSIONS OF ANIMAL AND VEGETABLE SUBSTANCES.—Whey, tea, coffee, &c.

III. FERMENTED LIQUORS.—Wine, beer, &c.

IV. THE ALCOHOLIC LIQUORS, OR SPIRITS.—Alcohol, brandy, rum, &c.

*Water.*—The qualities of water differ essentially according to the source from which it has been obtained; and those accustomed to this beverage are sensible to differences which wholly escape the observation of less experienced judges. How far the existence of foreign matter injures its salubrity has been a subject of much controversy. That the presence of very minute quantities of earthy matter can become a source of disease sounds strangely to the ears of the philosopher; and yet we have known patients, after drinking a glass of water, from a sense of weight and oppression at the stomach, at once pronounce the existence of foreign ingredients. Animals would appear to be generally more sensible of such impurities than man. Horses, by an instinctive sagacity, always prefer *soft*\* water; and when, by necessity or inattention, they are confined to the use of that which is *hard*, their coats become rough and ill-conditioned, and they are frequently attacked with gripes. Pigeons are also known to refuse hard, after they have been accustomed to soft water. We are informed by Cleghorn that on the eastern side of the island of Minorca, the sheep, on account of the hardness of the water, are subject to a disease in the spleen. But the most dangerous sources of impurity exist in the animal and vegetable kingdoms; putrescent matter poisons our beverage, and becomes the secret cause of numerous complaints. The usual varieties of common

\* An important practical distinction has been founded upon the fact, that the water of some springs will dissolve soap, while that of others decomposes and curdles it; the former has been denominated *soft*, the latter *hard* water. Sulphate of lime is generally the salt which imparts this quality of hardness; and it appears that the proportion of five grains to the pint is sufficient for the purpose. Soft water is a more powerful solvent of all vegetable matters, and is consequently to be preferred for domestic as well as medicinal use. The brewer knows well, from experience, how much more readily and copiously *soft* water will dissolve the extractive matter of his malt; and the housewife requires not the chemist to inform her that *hard* water is incapable of making good tea.

water were classed and defined by Celsus, and modern chemists have not found any reason to reject the arrangement. “*Aqua levissima pluvialis est; dein fontana, tum ex flumine, tum ex puteo; posthac ex nive aut glacie, gravior his ex lacu, gravissima ex palude.*”

We may remark of river water, that, as it is derived from the conflux of numerous springs and rain water, the proportion of its saline constituents ought to be small, since various precipitations must necessarily take place from the union of different solutions. It is, however, liable to hold in suspension particles of earthy matter which impair its transparency, and not unfrequently its salubrity. It may also, in the vicinity of a large town, hold dissolved, as well as suspended, a considerable portion of animal and vegetable matter: this is unquestionably the case in the water supplied from the Thames by the Grand Junction Water-Company.

For the purification and preservation of water, numerous ingenious methods have been adopted. The mechanical impurities may be easily enough removed by filtration, a process which is suggested by Nature herself, for all springs arising through sand, gravel, &c. must undergo such an operation, but it will not remove a particle of that matter which is held in solution, and hence the filter is only of partial utility. As that peculiar property which constitutes what is termed *hardness* generally depends upon *sulphate of lime* in solution, it cannot be removed by filtration, but the addition of an alkaline carbonate, in the proportion of from ten to fifteen grains, to every pint, twenty-four hours before it is used, will be found to soften it; or, if it should be found to depend upon *super-carbonate of lime*, which is sometimes the case, long ebullition, without any addition, will be found sufficient for its cure. Another mode of improving water, and one which has been lately adopted by Mr. Robins in his patent filters, is by the application of charcoal, a substance which possesses in an eminent degree the property of preserving water from corruption, and of purifying it after it has been corrupted; hence the filtration of water through alternate layers of sand and charcoal offers the readiest and most effectual mode of abstracting its impurities with which we are acquainted.\* Where we have reason, however, to suspect much injurious contamination, the process of boiling should never be omitted; after which it may be strained and filtered, and lastly agitated in contact with the atmosphere, in order to restore to it its natural proportion of air. In China, water is never drunk until it has been boiled. The mischievous effects of impure water, where it cannot be corrected by any chemical process, are said to be best counteracted by some bitter

\* The great desideratum has ever been to remove *soluble* matters from water; it is by no means impossible that a simple voltaic apparatus will hereafter be contrived for such a purpose.

vegetable. Virey supposes that this circumstance first induced the Chinese to infuse the leaves of the tea-plant.

Water is unquestionably the natural beverage of man; but any objection against the use of other fluids founded on their artificial origin, may be at once met by the same argument which has been adduced in defence of cookery. We are to consider man as he is, not as he might have been had he never forsaken the rude path of nature. We are ready to admit that the more simply life is supported, and the less stimulus we use, the better; and that he is happy who considers water the best drink, and salt the best sauce; but how rarely does a physician find that his patient has regulated his life by such a maxim! He is generally called upon to reform stomachs already vitiated by bad habits, and which cannot, without much discipline, be reconciled to simple and wholesome aliment. Under such circumstances, nothing can be more injudicious than abruptly to withdraw the accustomed stimulants, unless it can be clearly shown that they are absolutely injurious,—a question which it will be our duty to investigate.

The juices and infusions of vegetable and animal matter constitute the second division of drinks.

*Toast water.*—By impregnating water with the soluble parts of toasted bread, we shall obtain a liquid which will frequently agree with those stomachs which rebel against the use of the more simple fluid. It is thus also rendered slightly nutritive, holding a certain portion of gum and starch in solution. Sir A. Carlisle recommends that it should be prepared with hard biscuit, reduced by fire to a coffee colour. “This drink,” says he, “being free from yeast, is a most agreeable beverage. Much depends upon the water, employed for its preparation, being at a boiling temperature, and it ought to be drunk as soon as it has sufficiently cooled; for, by being kept, it acquires a mawkish and unpleasant flavour. Infusions of other kinds of bread, especially those of toasted oat-cakes, and dried or toasted oatmeal, have been recommended; but the taste of such infusions would not be palatable to any one who has not been accustomed to oat-bread.

*Barley water.*—The decoction of barley is a very ancient beverage; it is recommended by Hippocrates, and preferred by him to every other aliment in acute diseases. Barley has the advantage over other grains, in affording less viscid potations. The invention of *pearl barley* has greatly increased the value of this grain; it is prepared by the removal of its husk or cuticle, and afterwards by being rounded and polished in a mill. These well-known granules consist chiefly of fecula, with portions of mucilage, gluten, and sugar, which water extracts by decoction; but the solution soon passes into the acetous fermentation. The bran of barley contains an acrid resin, and it is to get rid of such an ingredient that

it is deprived of its cuticle. The addition of lemon juice and sugar-candy greatly improve the flavour of this drink.

*Gruel.*—Oats, when freed from their cuticle, are called *groats*; in which state, as well as when ground into meal, they yield to water, by ection, the fecula they contain, and form a nutritious gruel, which has also the property of being slightly aperient. It should never be kept longer than forty-eight hours, as it becomes acescent after that period. Gruel may be made of a different degree of consistence, according to the object of its potation. If it be used as a demulcent drink, it should be thin; and may be made, as Dr. Kitchener, our culinary censor, informs us, by mixing well together, by degrees, in a pint basin, *one* table-spoonful of oatmeal with three of cold water, and then adding carefully a pint of boiling water, which is to be boiled for five minutes, stirring it all the time, to prevent the oatmeal from burning at the bottom of the stewpan; then strain through a hair sieve, to separate the undissolved parts of the meal from the gruel. If a more substantial repast is required, double the above quantity of oatmeal must be treated in a similar manner. To increase the nutritive quality of this aliment, broth or milk may be substituted for water. Some persons are in the habit of introducing a piece of butter into gruel; but the propriety of this practice is questionable, where the stomach is supposed to generate acidity.

*Sage tea.*—The virtues of sage have been so extravagantly praised, that, like many of our remedies, the plant is fallen into disuse from the disgust which its panegyrists have excited. We are convinced, however, that in the form of infusion it possesses some power in allaying the irritability of the stomach,\* and that, on many occasions, it will furnish a salutary beverage. The same observation will apply to the infusions of *balm* and *rosemary*. A drink extremely agreeable to the stomach of invalids may also be made by infusing lemon-peel in boiling water, and adding a small quantity of sugar.

*Tea.*—There is no subject that has occasioned a greater controversy amongst dietetic writers than that of tea. By one party it is decried as a poison; by another it is extolled as a medicine, and a valuable addition to our food; while some refer all its beneficial effects to the water thus introduced into the system, and its evil consequences to the high temperature at which it is drunk. In order to understand the value of the different arguments which have been adduced in support, or to the disparagement, of this beverage, it will be necessary to inquire into its composition. Two kinds of tea are imported into this country, distinguished by the epithets *black* and *green*. Both contain astringent and narcotic principles, but in very different proportions; the latter producing by far the most powerful in-

\* It is frequently used by the Chinese as a tonic for debility of the stomach.

fluence upon the nervous system. As the primary operation of every narcotic is stimulant, tea is found to exhilarate and refresh us, although there exist individuals who are so morbidly sensible to the action of certain bodies of this class, that feelings of depression, accompanied with various nervous sensations and an unnatural vigilance, follow the potation of a single cup of strong tea; while others experience, from the same cause, symptoms indicative of derangement of the digestive organs: but these are exceptions\* from which no general rule ought to be deduced. The salubrity of the infusion to the general mass of the community is established by sufficient testimony to outweigh any argument founded on individual cases. It must, however, be admitted, that if this beverage be taken too soon after dinner, the digestion of the meal may be disturbed by the distension it will occasion, as well as by its influence as a diluent; the narcotic and astringent principles may also operate in arresting chymification; but when a physician gives it his sanction, it is with the understanding that it shall be taken in moderate quantities, and at appointed seasons. In enumerating the advantages of tea, it must not be forgotten that it has introduced and cherished a spirit of sobriety; and it must have been remarked by every physician of general practice, that those persons who dislike tea, frequently supply its place by spirit and water. The addition of milk certainly diminishes the astringency of tea; that of sugar may please the palate, but cannot modify the virtues of the infusion.

*Coffee.*—The hostility which has been manifested against the use of tea has been extended, with equal rancour, against that of coffee, and, probably, with equal injustice. The principle upon which its qualities depend is more stimulant than that of tea, and certainly exerts a different species of action upon the nervous system, although it is very difficult to define the nature of this difference. If taken immediately after a meal, it is not found to create that disturbance in its digestion which has been noticed as the occasional consequence of tea; on the contrary, it accelerates the operations of the stomach, and will frequently enable the dyspeptic to digest substances, such as fat and oily aliment, which would otherwise occasion much disturbance. The custom of taking coffee immediately after

dinner, so universally practised by the French, no doubt must counteract the evil effects which the peculiar form of their diet is calculated to produce. Coffee, like tea, has certainly an antispasmodic effect on many individuals; it imparts an activity to the mind which is incompatible with sleep; but this will rarely occur if the heverage be taken for several hours before our accustomed period of repose. It seems to be generally admitted that it possesses the power of counteracting the effects of narcotics; and hence it is used by the Turks with much advantage, in abating the influence of the inordinate quantities of opium they are accustomed to swallow. When our object is to administer it as a promoter of digestion, it should be carefully made by infusion; decoction dissipates its aroma. The addition of milk is one of questionable propriety; that of sugar, or rather sugar-candy, may be allowed. Some persons can never take this beverage without suffering from acidity in the stomach: where this happens, the practice must be abandoned.

*Chocolate.*—In consequence of the large quantity of nutritive matter which this liquid contains, it should be regarded rather as food than drink. It is prepared by reducing the cocoa-nut into paste, with sugar, milk, or eggs: it is also frequently mixed with different aromatics, the most common of which is the *vanilla*, a substance very liable to disagree with the stomach, and to produce a train of nervous symptoms. As a common beverage, chocolate is highly objectionable; it contains an oil which is difficult of assimilation; it therefore oppresses the stomach: this effect is of course increased by the application of too much heat in its preparation. Another objection against its use is to be found in the observations which we have already offered upon the subject of too great concentration.

*Cocoa* is usually considered as a substitute for chocolate. As it contains less nutritive matter, it is not so objectionable; and, as the oily matter exists only in small quantities, it is less likely to disagree with the stomach.

There are certain saline solutions which are frequently employed as drinks, and deserve some attention in this place: such are *imperial* and *soda water*. *Imperial* is a solution of cream of tartar flavoured with lemon peel. It ought never to be used except as a medicine. If employed as an ordinary drink, it is apt to retard digestion. If ever useful as an article of diet, it will be under circumstances of robust health, and where a large quantity of animal food has been taken. The modern custom of drinking *soda water* during, or immediately after dinner, has been a pregnant source of dyspepsia. By inflating the stomach at such a period, we inevitably counteract those muscular contractions which are essential to chymification. The quantity of soda thus introduced scarcely deserves notice: with the exception of the *carbonic acid gas*, it may be regarded as water, more mischievous only in consequence of the exhilarating quality in-

\* The reader is referred to a pamphlet entitled "*Observations on the Medicinal and Dietetic Properties of Green Tea*," by W. Newnham, Esq. There is a great deal of sound sense in this little production. The author refers the different effects produced by green tea to the different states of the system in which it is taken. He maintains that in a state of what he calls *sthenic excitement* of the brain and nervous system, as that produced by alcoholic stimulants, or by intense and long-continued application of the mind to any particular object of literary research, green tea will act as a salutary remedy; whereas, on the contrary, in states of diminished excitement, morbid vigilance and nervous disturbance will follow its potation.

ducing us to take it at a period at which we should not require the more simple fluid.

*Fermented liquors.* Volumes have been written to prove that spirit, in every form, is not only unnecessary to those who are in health, but that it has been the prolific source of the most painful and fatal diseases to which man is subject; in short, that Epimetheus himself did not, by opening the box of Pandora, commit a greater act of hostility against our nature than the discoverer of fermented liquors. This is a striking specimen of the fallacy of reasoning against the *use* of a custom from its *abuse*. There exists no evidence to prove that a temperate use of good wine, when taken at seasonable hours, has ever proved injurious to healthy adults. In youth, and still more in infancy, the stimulus which it imparts to the stomach is undoubtedly injurious; but there are exceptions even to this general rule. The occasional use of *diluted* wine has improved the health of a child, by imparting vigour to a torpid stomach: we ought, however, to consider it rather as a medicine than as a luxury.

Without entering further into the discussion of a question which has called so many opponents into the field, it may be observed, that whatever opinion we may have formed as to the evils or advantages consequent upon the invention of wine, we are not called upon, as physicians, to defend it; our object is to direct remedies for the cure of those diseases which assail man as we find him in the habits of society. And as these habits, says Dr. W. Philip, are such, that more or less alcohol is necessary to support the usual vigour of the greater number of people even in health, nothing could be more injudicious than wholly to deprive them of it when they are already weakened by disease, unless it could be shown that even a moderate use of it essentially adds to their disease, which, in dyspeptics, is by no means the case. Our own experience coincides with that opinion. In cases where the vinous stimulant has been withdrawn, we have generally witnessed an aggravation of the dyspeptic symptoms, accompanied with severe depression of spirits.

The term wine is more strictly and especially applied to express the fermented juice of the *grape*; although in common language it is used to denote that of *any* sub-acid fruit. The presence of *tartar* is perhaps the circumstance by which the grape is more strongly distinguished from all the other sub-acid fruits that have been applied to the art of wine-making. Its juice, besides, contains within itself all the principles essential to vinification, in such a proportion and state of balance as to enable it at once to undergo a regular and complete fermentation; whereas, the juices of other fruits require artificial additions for this purpose: and the scientific application and due adjustment of these means constitute the art of making domestic wines.\* It has been re-

marked that all those wines that contain an excess of malic acid are of a bad quality: hence the grand defect that is necessarily inherent in the wines of this country, and which leads them to partake of the properties of cider; for in the place of the *tartaric*, the malic acid always predominates in our native fruits.

The characteristic ingredient of all wines is *alcohol*; and the quantity of this, and the condition or state of combination in which it exists, are the circumstances that include the more interesting points of inquiry, and explain the relative effects which different wines produce upon the system; we shall therefore proceed to investigate the various species, with reference to such conditions.

Wines may be at once resolved into two great divisions; into those which are coloured, and commonly called *red* wines, and into those which have a yellow tinge, more or less deep, termed *white* wines. This colouring matter is not derived from the juice, but from the husk of the grapes. If, therefore, the fermentation be not permitted to take place in contact with the hulls, and sometimes even with the stalks of the fruit, a *white* wine is in all cases produced. This colouring matter is highly astringent, and consequently the red wines differ from the white in their effects upon the stomach; and yet it is difficult to explain the well-known extent of this operation, by the presence of so small a proportion of active matter. It must, however, be remembered that irritable stomachs are frequently impatient of astringent matter. Many persons are incapable of drinking port wine in consequence of the heartburn it occasions; while others, on the contrary, appear to derive advantage from the tonic influence of its astringency. This is a circumstance of idiosyncrasy which no theory can explain. Every physician must be practically aware of the caprice which the stomach displays in its morbid conditions; but as a general rule, it may be stated that *white* deserve a preference over *red* wines, because the latter, being pressed, and subjected to a stronger fermentation to extract the colouring principle from the husk, are necessarily more loaded with extractive and astringent matter; and as this remains in the stomach after the liquid portion of the wine is absorbed, it will be liable to occasion disturbance.

The odour, or *bouquet*, and flavour which distinguish one wine from another, evidently depend upon some volatile and fugacious principle not hitherto investigated by the chemist: this, in sweet and half-fermented wines, is immediately derived from the fruit, as in those from the *Frontignan* and *Muscato* grapes; but in the more perfect wines, as in *Claret*, *Hermilage*, *Rivesaltes*, and *Burgundy*, it bears no resemblance to the natural flavour of the fruit, but is altogether the product of the vinous process. Some wines are artificially flavoured by the introduction of foreign ingredients, as

\* For an account of which, the reader is referred to a most ingenious and interesting essay by Dr. Macculloch, entitled, "Remarks on the Art of mak-

ing Wine; with Suggestions for the Application of its Principles to the Improvement of Domestic Wines."

by almonds in Madeira wines, as well as in those of Xeres and St. Lucar; and hence their well-known nutty flavour. Among the ancients, and in modern Greece, it is at this day the fashion to give a resinous flavour, by the introduction of turpentine into the casks. These wines were supposed to assist digestion, to restrain morbid discharges, to provoke urine, and to strengthen the bowels; but Dioscorides informs us that they were known to produce vertigo, pain in the head, and many evils not incidental to the potations of the same vinous liquor when free from such admixtures.

The quantity of acid contained in wines has been supposed capable of diminishing their salubrity, and in some cases of rendering them eminently noxious. There can be no doubt, that where there exists a considerable excess of gallic or malic acids, or where acetic acid has been generated during a protracted fermentation, such wine will be obnoxious to the stomach; but where the acid arises from the nature of the fruit, it surely cannot merit the odium which popular opinion would assign to it. What, for instance is the acid contained in Madeira, and against which so many objections have been urged? an atom merely of tartar! And yet the person who fancies that his digestion can be deranged by its action, will swallow twenty times the quantity of the same ingredient in some other shape with perfect indifference and impunity.

Before we quit the subject of vinous acidity, we must add a few words upon its supposed influence in exciting paroxysms of gout. That such attacks have followed particular potations we do not mean to deny; but a slight excess of any kind, whether in diet or in exercise, will excite the disease in those predisposed to it. Where this predisposition exists, an additional glass of claret may excite the disease; but in all such cases any other exciting cause would have a similar effect.

It has been already stated that the characteristic ingredient of all wines is *alcohol*; and that its quantity, and the condition or state of combination in which it exists, are the circumstances in which the medical inquirer is principally interested. The late experiments of Mr. Brande have thrown considerable light upon this subject; although, as in most instances of discovery, they have raised up new doubts and difficulties. Daily experience convinces us that the same quantity of alcohol applied to the stomach under the form of wine, and in a state of mixture with water, will produce very different effects upon the body, and to an extent which it is difficult to understand. It has, for instance, been demonstrated beyond the reach of doubt, that port, madeira, and sherry contain from one-fourth to one-fifth of their bulk of alcohol; so that a person who takes a bottle of any one of them will thus take nearly half a pint of alcohol, or almost a pint of pure brandy! And, moreover, that different wines, although containing the same absolute proportion of spirit, will be found to vary very considerably in their intoxicating powers. No

wonder, then, that such results should have staggered the philosopher, who is naturally unwilling to accept any tests of difference from the nervous system, which elude the ordinary resources of analytical chemistry. The conclusion was therefore drawn, that alcohol must necessarily exist in wine in a far different condition from that in which we know it in a separate state; or, in other words, that its elements only could exist in the vinous liquor, and that their union was determined, and, consequently, alcohol produced, by the act of distillation. That it was the *product*, and not the *educt* of distillation, was an opinion which originated with Ronelle, who asserted that alcohol was not completely formed until the temperature was raised to the point of distillation. More lately, the same doctrine was revived and promulgated by Fabbroni, in the Memoirs of the Florentine Academy. Gay Lussac has, however, silenced the partisans of this theory, by separating the alcohol by distillation, at the temperature of 66° Fahrenheit; and, by the aid of a vacuum, it has since been effected at 56°. And to complete the demonstration, Mr. Brande has shown that, by precipitating the colouring matter, and some other elements of the wine, by the *sub-acetate of lead*, and then saturating the clear liquor with *sub-carbonate of potass*, the alcohol may be separated without any elevation of temperature; and he has accordingly, by this ingenious expedient, been enabled to construct a table, exhibiting the proportions of spirit which exist in the several kinds of wine. No doubt, therefore, can any longer be entertained upon the subject; and the fact of the difference of effect produced by the same bulk of alcohol, when presented to the stomach in different states, is to be explained on the supposition that, in wine, it is not only more intimately mixed with water, but that it exists in combination with its extractive matter; in consequence of which it is incapable of exerting its full effects before it becomes altered in its properties, or, in other words, partially *digested*; and this view of the subject may be fairly urged in explanation of the fact, that the intoxicating effects of the same wine are liable to vary in degree in the same individual, from the peculiar state of his digestive organs at the time of its potation.

We have hitherto only considered alcohol as it exists in a combined state in wine; but it is essential to state that the stronger wines of Spain, Portugal, and Sicily, are rendered marketable in this country by the addition of *brandy*, and must consequently contain more or less *uncombined* spirit; but the proportion of which will not bear a ratio to the quantity added, because, at the period of its admixture, a renewed fermentation is produced by the scientific vintner, which will assimilate and combine a certain portion of the foreign spirit with the wine: this manipulation, in technical language, is called "*fretting in*." It is to the quantity of *free*, not to that of *combined* spirit, that the injurious effects of such wines are to be attributed. "It is well known," ob-

serves Dr. Macculloch, "that diseases of the liver are the most common and the most formidable of those produced by the use of *ardent spirits*." It is equally certain that no such disorders follow the intemperate use of *pure wine*, however long indulged in: to the concealed and unwitting consumption of spirit, therefore, as contained in the wines generally drunk in this country, is to be attributed the excessive prevalence of those hepatic affections, which are comparatively little known to our continental neighbours.

Much has been said about the effects of *new wine* upon the stomach, compared with those produced by that which has been long kept. It will be necessary to consider the changes produced in this liquor by being kept. In the first place, red wine gradually deposits a quantity of cream of tartar, in combination with extractive and colouring matter, forming what is commonly called the crust; so that a considerable portion of that matter which is likely to disagree with the stomach is thus removed; but when kept in a cask, in addition to this change, a quantity of water is evaporated, and the wine becomes comparatively stronger. The custom of exposing Madeira to motion, and a certain elevation of temperature, by sending it a voyage to the East Indies, unquestionably improves the flavour, and produces some internal change in the composition of the wine, which the chemist is unable to explain.

In a dietetic point of view, wines may be arranged into four classes; viz. 1. *sweet wines*; 2. *sparkling or effervescing*; 3. *dry and light*; 4. *dry and strong*.

1. *Sweet wines* contain the greatest proportion of extractive and saccharine matter, and generally the least ardent spirit, though this is often rather disguised than absent. Since a proportion of sugar has remained unchanged in these wines during the process of vinification, they must be considered as the results of an imperfect fermentation, and are, in fact, mixtures of wine and sugar; accordingly, whatever arrests the progress of fermentation must have a tendency to produce a sweet wine. Thus, boiling the *must*, or drying the fruit, will, by partially separating the natural leaven, and dissipating the water, occasion such a result as is exemplified by the manufacture of the wines of Cyprus, the *Vino Cotto* of the Italians, and the *Vinum Coctum* of the ancients; by that of *Frontignac*, the rich and luscious wines of *Canary*, the celebrated *Tokay*, *Vino Tinto* (Tent of Hungary), the Italian *Montefiascone*, the Persian *Schiraz*, the *Malmsey* wines of *Candia*, *Chio*, *Lesbos*, and *Tenedos*, and those of the other islands of the Archipelago. On account of the sugar contained in such wines, they are liable to become acescent on weak stomachs; but where this is not the case, they are, in small quantities, frequently beneficial to invalids.

2. *Sparkling or effervescing wines*.—These are indebted for their characteristic properties to the presence of carbonic acid: they rapidly intoxicate, in consequence of the alcohol which

is suspended in, or more probably, in chemical combination with the gas, being thus applied in a sudden and very divided state to a large extent of nervous surface: for the same reason their effects are generally as transitory as they are sudden. Independently of the alcohol thus held in solution in the carbonic acid, it is probable that some active aromatic matter is volatilised together with it, and which may account for the peculiar effects produced on some persons by champagne.

3. *Dry and light wines*.—These are exemplified by the more esteemed German wines, as hock, rhenish, mayne, moselle, neckar, and elsass; and those highly-flavoured wines, burgundy, claret, hermitage, &c. The former of these wines combine the effect of an acid with that of the spirit. They do not contain any uncombined alcohol, and on that account are to be greatly preferred. *Genuine* claret must be considered as the most beneficial of all our vinous liquors; it is well fermented; and, on account of the small proportion of spirit, as well as of extractive, which it contains, it is more salubrious than port. It has been already observed that burgundy appears to hold dissolved some unknown principle of great activity; upon no other supposition can we explain its stimulant properties. A few glasses of this wine will produce heat and headach, which the relative quantity of alcohol in its composition will not account for.

4. *Dry and strong wines*, as madeira, port, sherry, &c. The name *sec*, corruptly written sack, signifies dry. The *sec* wine, prepared at Xeres, in Spain, is called, according to our orthography, sherris, or sherry. In the manufacture of this wine, *lime* is added to the grapes; a circumstance, observes Dr. Macculloch, apparently conducive to its well-known dry quality, and which, probably, acts by neutralizing a portion of *malic* or *tartaric* acid.

It is a fact not easily explained, that the stomach is frequently outraged by a wine to which it has not been accustomed; and it is equally true that a mixture of different wines is a common source of indigestion. The custom of mixing wine with water has its advantages as well as its evils. By dilution it frequently proves too little stimulant to the stomach, and runs into a state of acescency. An invalid is also thus liable to deceive himself, by taking more wine than may be consistent with his welfare. Much, however, depends upon the quality of the wine taken; the lighter wines cannot require dilution, while port is certainly rendered less injurious by the admixture.

Home-made or domestic wines may be generally considered as injurious to delicate stomachs; they are apt to ferment and produce indigestion. Cider and perry are grateful drinks in hot weather; but as they do not contain a sufficient quantity of spirit to prevent their passing into the acetous fermentation in the stomach of an invalid, they should be avoided by those who have any predisposition to indigestion.

*Beer*.—This is an article of beverage in

almost every country. The Chinese prepare it from rice, and the Americans from maize. We are also informed by Herodotus, that, in very early history, the art of making a fermented liquor from barley was discovered by the Egyptians. As the climate of England is not congenial to the growth of the vine, this species of liquor is perhaps more universal than in any other country; and it has therefore been denominated *vinum Britannicum*. In the higher walks of society, it has indeed, of late years, been nearly excluded: but whether this revolution has been attended with advantage, we shall presently have occasion to inquire. Malt liquors differ from wines in several essential points: they contain a much larger proportion of nutritive matter, and a less proportion of spirit; while they contain a peculiar bitter and narcotic principle derived from the hop. It would appear that the extractive matter furnished by the malt is highly nutritive; and we accordingly find that persons addicted to such potations are in general fat. Where, however, they are indulged in to any extent, without a corresponding degree of exercise, they induce a plethoric state of the body, and all the diseases consequent upon such a condition. In order to understand the process by which they furnish nourishment, we must once more refer the reader to the observations which are offered on the important subject of the digestion of liquids; from which it will appear that a highly-concentrated extract will be left in the stomach after the removal of its watery part. This extract is, for reasons already stated, not very digestible; and will therefore require the presence of less inspissated food to promote its chymification. Ale, therefore, when taken without such precautions, is liable to disturb the digestive organs. The addition of the hop increases the value of the liquor, by the grateful stimulus which it imparts, and in some measure redeems it from those vices with which it might otherwise be charged. To those therefore whose diet is not very nutritive, ale may be considered not only as an innocent but as a salubrious article; and happy is that country whose labouring classes prefer such a beverage to the mischievous potations of ardent spirit. These remarks, however, cannot apply to the classes of the community who "fare sumptuously every day." They will not require a nutritive potation of such a character; and light wines have accordingly, in these days of luxury, very properly superseded its use: but we are not disposed to extend this remark to its more humble companion, "*table beer*." We regard its dismissal from the tables of the great as a matter of regret; its slight but invigorating bitter is much better adapted to promote digestion than its more costly substitutes. But it should be soft and mild; for when stale and hard it is likely to disturb the bowels, and occasion effects the very opposite to those it is intended to produce. Nor ought it to have too great a proportion of hops, but should be thoroughly fermented and purified. Sydenham always took a glass of small beer at his meals,

and he considered it as a preservative against gravel.

The great division of malt liquors is into small beer, ale, and porter.

The liquor called *Ale* was originally made of barley, malt, and yeast alone. There existed for a long time a strong prejudice against hops, which were considered as "pernicious weeds;" but it is now generally admitted that they constitute the most valuable ingredient in malt liquors. Independently of the flavour and tonic virtues which they communicate, they precipitate, by means of their astringent principle, the vegetable mucilage, and thus remove from the beer the active principle of its fermentation: without hops, therefore, we must either drink our malt liquors new and rosy, or old and sour. There are several varieties of ale, distinguishable by their colour: when the malt is slenderly dried, the ale is *pale*; or *brown* when the malt is more roasted or high dried.

*Porter*.—This is made from high-dried malt, and differs from other malt liquors in the proportions of its ingredients, and by the peculiar manner in which it is manufactured. Much has been said upon the fraudulent adulteration of this article; but we are inclined to believe that these statements have been exaggerated.

*Ardent spirits*.—The art of extracting alcoholic liquors by distillation from vinous liquors, must be regarded as the greatest curse ever inflicted upon human nature. The fatal effects of dram-drinking have been vividly depicted by numerous writers; and the awful truth has been too frequently illustrated to render any remarks in this place necessary. In a medical point of view, however, spirit may be considered as occasionally useful. Where it is taken in a diluted state, the mixture should always be made twelve hours before it is used. Spirit and water do not easily combine; and much of the force of the former is blunted by intimate incorporation with the latter, as we have already observed under the history of wine. We throw out this hint to those who are in the habit of drinking weak brandy and water at their meals; although the propriety of such a practice is questionable. There are cases of dyspepsia in which wine and beer equally disagree with the stomach, producing acidity and other distressing symptoms: very weak spirit may, perhaps, in such cases, be taken with advantage; but its strength should be uniform, and no circumstances should induce the patient to increase the proportion of the spirit. The habit of drinking *liqueurs* cannot be too much reprobated: many of these *cordials* are impregnated with narcotic substances, which add to the noxious qualities of the spirit.

OF CONDIMENTS.—These may be defined substances which are, in themselves, incapable of nourishing the body, but which, in concert with our food, heighten its flavour, promote its digestion, or correct some of its deleterious properties. The existence and necessity of such agents are more general and important than is generally supposed, and a philosophical examination of their *modus ope-*

*mandi* would disclose views of great and novel interest to the physician. The bitter principle which exists in the composition of grasses and of other plants, appears to be essential to the digestive process of herbivorous animals, for when deprived of it they become diseased; and yet we are assured, by repeated experiment, that it passes through the alimentary canal without undergoing the least change; it can therefore only act as a stimulant *in transitu*, and affords an excellent example of a natural condiment. We are ourselves conscious of the invigorating effects of slight bitters upon our stomach, although civilization has, to a great degree, destroyed our natural taste for them, while, by improving our vegetable food, it has probably rendered such a stimulus unnecessary. The Swiss peasant cheers himself amid the frigid solitude of his glaciers with a spirit distilled from *gentian*, the extreme bitterness of which is relished with a glee that is quite unintelligible to those who are not accustomed to it.

From the different nature of condiment, it has been usually divided into three classes; viz. the *saline*, the *spicy* or *aromatic*, and the *oily*.

*Salt* appears to be a necessary and universal stimulus to animated beings; and its effects upon the vegetable as well as animal kingdom have furnished objects of the most interesting inquiry to the physiologist, the chemist, the physician, and the agriculturist. It appears to be a natural stimulant to the digestive organs of all warm-blooded animals, and they are instinctively led to immense distances in pursuit of it. This is strikingly exemplified in the avidity with which animals in a wild state seek the salt-pans of Africa and America, and in the difficulties they will encounter to reach them: this cannot arise from accident or caprice, but from a powerful instinct, which, beyond control, compels them to seek at all risks that which is salubrious. We are all sensible of the effect of salt on the human body; we know how unpalatable fresh meat and most vegetables are without it. One of the ill effects produced by an unsalted diet is the generation of worms. In Ireland, where from the bad quality of the food the lower classes are greatly infested with worms, a draught of salt and water is a popular and efficacious anthelmintic. Lord Somerville, in his Address to the Board of Agriculture, gave an interesting account of the effects of a punishment which formerly existed in Holland. "The ancient laws of the country ordained men to be kept on bread alone, *unmixed with salt*, as the severest punishment that could be inflicted upon them in their moist climate. The effect was horrible; these wretched criminals are said to have been devoured by worms engendered in their own stomachs." The wholesomeness and digestibility of our bread are undoubtedly much promoted by the addition of the salt which it so universally receives.\*

\* A pound of salt is generally added to each bushel of flour. Hence it may be presumed, that every adult consumes two ounces of salt per week, or six pounds and a half per annum, in bread only.

If the utility of salt be thus established, it may be asked how it can happen that salted provisions should ever produce those diseases which experience has shown to arise from their use. In explaining the operation of *salting* meat, and in appreciating the effects of such meat as food, it will be necessary to advert to a chemical fact, which has not hitherto attracted the attention which its importance merits. The salt thus combined with the animal fibre ought no longer to be considered as condiment; a chemical combination has taken place; and although it is difficult to explain the nature of the affinities which have been brought into action, or that of the compound to which they have given origin, it is sufficiently evident that the texture of the fibre is so changed as to be less nutritive as well as less digestible. If we are called upon to produce any chemical evidence in support of such an assertion, we need only relate the experiment of M. Eller, who found, that if salt and water be boiled in a copper vessel, the solution will contain a notable quantity of that metal; whereas if, instead of heating a simple solution, the salt be previously mixed with beef, bacon, or fish, the fluid resulting from it will not contain an atom of copper. Does not this prove that the process of salting meat is something more than the mere saturation of the animal fibre with muriate of soda?

*Vinegar*, in small quantities, is a grateful and wholesome stimulant; it will often check the chemical fermentation of certain substances in the stomach, and prevent vegetable matter in its raw state from inducing flatulence; but its use requires caution, and in some morbid states of the system it is obviously improper. Fatty and gelatinous substances frequently appear to be rendered more digestible in the stomach by the addition of vinegar, although it is difficult to offer either a chemical or physiological explanation of the fact. The native vegetable acids may also be occasionally substituted: the addition of lemon juice to rich and glutinous soups renders them less liable to disagree with the stomach; and the custom of eating apple-sauce with pork is, undoubtedly, indebted for its origin to the same cause. We shall take this opportunity to observe that vinegar, if taken in considerable quantities, as is not unfrequently the case with young persons, to prevent the accumulation of fat, is highly injurious to the digestive organs; and, if the habit be long continued, produces fatal marasmus.

*The aromatic condiments* comprise the foreign spices, as pepper, cayenne pepper, cinnamon, nutmeg, cloves, ginger; and the indigenous herbs and roots, such as parsley, thyme, sage, garlic, leek, onion, horse-radish, mustard, &c. The former of these were not intended by nature for the inhabitants of temperate climes: they are heating and highly stimulant. We are, however, not anxious to give more weight to this objection than it deserves. Man is no longer the child of nature, or the passive inhabitant of any particular region: lu-

ranges over every part of the globe, and elicits nourishment from the productions of every climate. It may be therefore necessary that he should accompany the ingestion of foreign aliment with foreign condiment. If we go to the East for tea, there is no reason why we should not go to the West for sugar. The dyspeptic invalid, however, should be cautious in their use; they may afford temporary benefit at the expense of permanent mischief. It has been well said that the best quality of spices is to stimulate the appetite, and their worst to destroy by insensible degrees the tone of the stomach. The intrinsic goodness of meats should always be suspected when they require spicy seasoning to compensate for their natural want of sapidity. But, mischievous as the abuse of aromatic condiments may be, it is innocent in comparison with the custom of swallowing a quantity of brandy or an increased libation of wine to counteract the distress which supervenes on a too copious meal.

*Oil.*—This, with butter, constitutes what are called the oleaginous condiments. Melted butter is, perhaps, the most injurious of all the inventions of cookery: oil, when used in extremely small quantities, as a seasoning to salads, appears to prevent their running into fermentation, and consequently obviates flatulency.

II. ON THE PERIODS BEST ADAPTED FOR MEALS, AND ON THE INTERVALS WHICH SHOULD ELAPSE BETWEEN EACH.—Having offered a history of alimentary substances, and pointed out the general characters by which each species may be distinguished, we shall, in the next place, proceed to inquire into the various circumstances which may be capable of modifying the effects of food upon the human body, so as to promote, retard, or altogether to suspend the digestion of it; and, first, with regard to the periods best adapted for meals. It is not extraordinary that a discrepancy of opinion should exist upon a question which involves so many fluctuating circumstances. Controversy upon this, as upon many other subjects of diet, has engendered a disbelief in its importance, and this scepticism has given a plausible pretext for indulgence on the one hand, and protracted fasting on the other, as the wishes or habits of mankind may have rendered most agreeable. We have been told that the best time for dining is, "*for a rich man, when he can get an appetite, and for a poor man, when he can get food.*" But appetite in health is regulated by habit, and in disease it acts but as an imperfect monitor. Certain general principles, therefore, deduced from observation and experience, must be laid down for our guidance, and these again in their application must be modified and adapted to the circumstances of every particular case; but before we enter upon this part of our subject, we must offer a few remarks upon the phenomena of *hunger* and *thirst*.

To account for the well-known sensation of hunger, various hypotheses have been framed, which it is not our present purpose to examine.

The physiologists of the present day would appear to incline to the belief that it arises from the stimulant action of the gastric juice upon the nerves of the stomach; and to support this opinion Dr. Wilson Philip relates the following experiment. A person in good health was prevailed upon to abstain from eating for more than twenty-four hours, and during that interval to increase the appetite by more than ordinary exercise. At the end of this time he was extremely hungry; but, instead of eating, he excited vomiting by drinking warm water and irritating the fauces. The water returned mixed only with a ropy fluid, such as the gastric juice is described to be. After this operation, not only all desire to eat was removed, but a degree of disgust was excited by seeing others eat. He, however, was prevailed upon to take a little bread and milk, which in a very short time ran into the acetous fermentation, as indicated by flatulence and eructation. Now, if this experiment proves any thing, it merely shews that disturbance of the stomach, or of the nervous arrangements which are subservient to it, will destroy appetite for food; the existence of nausea, short of vomiting, will produce the same effect, and yet in this latter case the gastric juice is not removed: so, again, if a narcotic be applied to the nerves, their power is paralyzed, and the sensation of hunger ceases. Such an effect is produced by the juice of tobacco, although by long habit the stomach may become indifferent to its operation. Whenever the Indians of Asia and America undertake a long journey, and are likely to be destitute of provisions, they mix the juice of tobacco with powdered shells in the form of small balls, which they retain in their mouths, the gradual solution of which serves to counteract the cravings of hunger. Sir Walter Scott tells us that "General Monk, not being able to procure any supper at Coltstream, was fain to have recourse to chewing tobacco to appease his hunger." In like manner we may explain the operation of spirit in taking away the appetite of those who are not accustomed to it; while those who indulge the habit receive its stimulant without its narcotic impression. Lord Byron entertained a great dread of becoming corpulent, and on that account frequently abstained from food for several days together, appeasing his hunger by a wafer and a glass of brandy.

Although we do not mean to deny that the presence of a portion of gastric juice does not contribute to the sensation of hunger, it is quite evident that the phenomenon is intimately connected with an energetic state of the nerves, occasioned by an interval of inactivity, during which, when the organs are in a healthy condition, the vital powers may be supposed to accumulate. We might even venture to question the agency of the stomach so far as to contend that the sensation of hunger is seated in the ganglionic system; for we know from actual experiment that *nausea* is wholly independent of the stomach, since that sensation, as well as the spasm of retching, may be produced by the

injection of tartar emetic into the veins of an animal, from which the stomach has been previously removed. Nausea, then, although, like hunger, it be referred to the stomach, is evidently independent of it; and if nausea can exist, why may not the opposite sensation of hunger, even though the animal should have lost its stomach by excision?

Natural appetite, which is only the first degree of hunger, never appears to recur until the aliment previously introduced has been duly assimilated. It cannot, therefore, strictly speaking, be said to have an immediate reference to the state of the stomach; for although all the chyme may have long before passed out of that organ, if any delay or embarrassment occur in its ulterior changes, appetite will not return, since the nervous energy being engaged in their completion cannot accumulate in the stomach: on the contrary, in certain diseases, as in *tabes mesenterica*, notwithstanding the presence of alimentary matter in the stomach, the appetite is never pacified, the subsequent processes being imperfect. These views are not introduced in this place for the purpose of encouraging fruitless speculation, but in order to establish a proposition of the highest importance in its relations to the theory of diet; viz. *that the several processes by which food is converted into blood cannot be simultaneously performed without such an expenditure of vital energy as weak persons are unable to sustain without mischief*. Thus, chylification would appear to require the quiescence of the stomach, and sanguification to be still more incompatible with the act of chymification. If, therefore, the stomach be set to work during the latter stages of digestion, the processes will in weak persons be much disturbed, if not entirely suspended. Certain circumstances cause hunger to return at nearer intervals by accelerating the nutritive process; while others, by producing an opposite tendency, lengthen such intervals.

It is a well known fact that if a person be interrupted in his meal for a quarter of an hour, he finds on resuming it that his appetite is gone, although he may not have eaten half the quantity which he required: this probably arises from the food having entered upon those ulterior changes which are incompatible with the energy of the stomach.

The feeling of thirst announces to the individual the necessity of introducing a certain quantity of liquid into the system, in order to repair the waste which the body has sustained in the exercise of its functions, or to impart a due degree of solubility to the aliments which have been taken. We accordingly find that excessive perspiration increases the demand for it, and that dry food is followed by the same effect. The sensation is usually referred to the throat and fauces, but its intensity does not bear any relation to the dryness of those parts; for in some cases, where the tongue, to its very root, is covered with a thick and dry crust, there is little thirst; while, on the other hand, it is frequently intolerable at the very time the mouth is surcharged with saliva.

We are inclined to refer the sensation to the cardiac or splenic portion of the stomach.\* Dr. Gardner has remarked that, in the case of a person who had cut through the œsophagus, several buckets-full of water were swallowed daily, and discharged through the wound, without quenching the thirst, which was afterwards found to abate by the injection of diluted spirit into the stomach.

All physicians advocate the necessity of regularity, both as it regards the number of meals and the periods at which they are taken. Those who have weak stomachs will, by such a system, not only digest more food, but will be less liable to those affections which arise from its imperfect assimilation; because, as Dr. Darwin has justly observed, they have in such a case both the stimulus of the aliment they take, and the periodical habit to assist the process. The periods of hunger and thirst are undoubtedly catenated with certain portions of time, or degrees of exhaustion, or other diurnal habits of life; and if the pain of hunger be not removed by taking food at the usual time, it is liable to cease until the next period of time or other habits recur. As these periods must vary according to circumstances in each individual, it frequently becomes necessary in civilized life to have recourse to intermediate meals, or luncheons; but to the dyspeptic patient such indulgences are rarely to be permitted. It is the more necessary to impress this precept upon the minds of invalids, as the anxiety of friends and the popular errors which exist upon the subject are too apt to establish the mischievous though specious aphorism of Sir William Temple, that "the stomach of an invalid is like a schoolboy, always at mischief unless it be employed." By such a system the natural process of digestion must, if our preceding views be correct, be constantly disturbed, and the healthy action of the stomach, as evinced by the return of moderate appetite, entirely prevented. But though the advantage of regular meals at stated periods is desirable, it has been much disputed how many ought to be allowed in the day: some physicians have considered one, others two, three, or even five necessary. It is, perhaps, impossible to lay down a general rule that shall apply to every particular case. In some persons the food rarely remains longer than three hours in the stomach; in others four, five, or even six hours. It is evident, then, that the repetition of the meals ought to be regulated by this circumstance; always avoiding the extreme of

\* Although the stomach is a single bag, it may be considered, with respect to its functions, as divisible into two distinct cavities; and these portions are, during the activity of the stomach, separated from each other by a peculiar muscular contraction. These chambers evidently appear to perform different offices in the process of digestion. The splenic portion would seem to separate from the food the superabundant water, and then to transmit the former to the pyloric division, where it undergoes its first great change. In the horse the mucous membranes of the two extremities of the stomach present even a striking difference in structure.

long fasting and repletion. Celsus recommends the healthy to take food rather twice than once in the day, and Sanctorious says, "that the body becomes more heavy and uneasy after six pounds taken at once than after eight taken at three meals," and that he who makes but one meal in the day, let him eat much or little, is pursuing a system that must ultimately injure him." When Plato returned that memorable answer to the philosophers who inquired whether he had seen any thing remarkable in Trinacria, "*vidi monstrum in natura, hominem bis saturatum in die,*" he referred rather to the quantity than to the repetition of the meal of Dionysius. In our opinion, where the individual takes moderate exercise, three frugal meals may be allowed. It is reported that, when Alexander the Great turned away his cooks on proceeding upon a march, he observed that he had no further occasion for such assistants, as he carried with him superior cooks—a long morning's journey to create an appetite for his dinner, and a frugal dinner to give a relish to his supper.

*Breakfast* is, perhaps, the most natural and not the least important of our meals; for, since many hours must have intervened since the preceding repast, the stomach ought to be in a condition to receive a fresh supply of aliment. As all the food in the body has during the night been digested, we might presume that a person in the morning ought to feel an appetite on rising; this, however, is not always the fact; the energies of the stomach, although invigorated by repose, are not immediately called into action, especially in debilitated habits; it is therefore frequently advisable to allow an interval to pass before the meal. A question of some interest has arisen as to the propriety of taking a solid or liquid breakfast. We seem to have greatly departed from the custom of our hardy ancestors in this respect. A maid of honour in the court of Elizabeth breakfasted upon beef, and drank ale after it; while the sportsman and even the day-labourer of the present day frequently breakfasts upon tea. The periods of their meals, however, were so generally different from those of modern times, that we cannot establish any useful comparison between them without taking into consideration the collateral circumstances which must have influenced their operation. It will not be difficult to shew that liquids at this meal are essentially necessary. To say nothing of the instinctive desire we all feel for them, it is evident that there is a certain acrimony and rankness in all our secretions at that time; the breath has frequently a peculiar taint in the morning, which is not perceptible at subsequent periods of the day. The fluids of the body must have sustained a loss by perspiration, which experiments have shewn to be double during sleep, a fact which in itself shews the propriety of a *liquid* breakfast.

*Dinner*.—Among the Romans this was rather considered as a refreshment to prevent faintness, than as a meal to convey much nourishment; but in modern times we need scarcely say that it is regarded as the principal meal, at

which every species of luxurious gratification is indulged in. With regard to the proper period at which invalids should dine, physicians entertain but one opinion. This period is the middle of the day, or at about two or three o'clock, in order to afford a timely replenishment before the evening waning of the vital powers, and which naturally precedes the hour of rest. The exact period, however, of dinner must in some measure be directed with reference to the necessary habits of the patient, the nature and time of his breakfast, and, above all, to the rapidity or slowness of his digestion.

*Ought we to take liquids at our dinner?*—This question has been a fruitful source of controversy; but it appears to us to be very easily settled. By drinking *before* a meal, we place the stomach in a very unfit condition for the duties it has to perform. By drinking *during* a meal, we shall assist digestion if the solid matter be of a nature to require it, and impede it if the quantity taken renders the mass too liquid. It is evident that if the stomach be distended with fluid, the digestion of its solid contents must meet with impediment; its bulk will stimulate the muscular fibres to contract too rapidly, and thus to expel the food before it has undergone the necessary changes; while at the same time, if the solid matter be diffused through a large quantity of liquid, it cannot be so easily acted upon by the gastric juice; nor can it be readily converted into that pulvaceous mass which appears to be a preliminary step to its digestion. On the other hand, if the food be too hard or dry, its necessary change by the *churning* of the stomach cannot be accomplished. It therefore follows that different aliments will require different quantities of liquid to assist their chymification. Animal food will demand, of course, a greater quantity than vegetable food; roasted than boiled meat, &c. The best, and perhaps the only test of the necessity of liquid during dinner is to be found in the sensations of the individual, which ought never to be disregarded because they appear in opposition to some preconceived theory. If our food possess that degree of succulence which characterises digestible aliment, there will seldom be any occasion for drink; but, on the contrary, where the mass is too dry, the stomach will give us notice of it by the creation of thirst. But, under any circumstances, the quantity taken should be small; it is during the intervals of our solid meals that the liquid necessary for the repair of our fluids should be taken: and this brings us to the consideration of the next repast.

*Tea*.—Theory and experience both conform in demonstrating the advantage which attends a liquid repast a few hours after dinner. At this period the chyle has entered its proper vessels, and is flowing into the blood, in order to undergo its final changes. Then it is that the stomach, having disposed of its charge, receives the wholesome draught with the greatest advantage; then it is that the blood, im-

pregnated with new materials, requires the assistance of a diluent to complete their sanguification, and to carry off the superfluous matter; and it is then that the kidneys and the skin will require the aid of additional water to assist the performance of their functions.

*Supper.*—In the time of Elizabeth, the nobility and gentry were accustomed to dine at eleven, to sup between five and six, and to retire to rest at ten. It is therefore evident that any argument in favour of this meal, founded upon the healthy condition of our ancestors, cannot avail. By supper, in modern times, we mean a meal just before bed-time; but as sleep is not favourable to every stage of digestion, it is very questionable whether retiring to rest with a full stomach can, under any circumstances, be salutary. During the first part of the process, or that of chymification, a person so situated may perhaps sleep quietly, unless, indeed, the morbid distention of the stomach should impede respiration, and occasion distress; but when the food has passed out of the stomach, and the processes of chymification and sanguification have been established, the natural propensity of the body is for activity, and the invalid awakes at this period, and remains in a feverish state for some hours. Upon this general principle, then, suppers, that is to say, *hearty suppers*, are to be avoided. The same objection cannot be urged against a *light repast*, which is often useful to dyspeptics; and it has been truly and facetiously observed, that some invalids need not put on their night-cap if they do not first bribe their stomachs to good behaviour.

*On the quantity of food that ought to be taken at different meals.*—Nothing can be more absurd than to establish a rule of weight and measure upon such occasions. Individuals differ from each other so widely in their capacities for food, that to attempt the construction of a universal standard would be little less absurd than the practice of the philosophical tailors of Laputa, who, the reader will remember, wrought by mathematical calculation, and entertained a supreme contempt for those humble and illiterate fashioners who went to work by measuring the person of their customer; but Gulliver tells us that the worst clothes he ever wore were constructed on abstract principles. How then, it may be asked, shall we be able to fix the proportion of food which it may be proper for an invalid to take? By desiring the patient to attend carefully to the first feeling of satiety. There is a moment when the relish given by the appetite ceases; a single mouthful taken after this oppresses a weak stomach. If he eats slowly, and carefully attends to this feeling, he will never overload the stomach; but, that such indication may not deceive him, let him remember to *eat slowly* and to *masticate* thoroughly. This is an important condition; for when we eat too fast, we introduce a greater quantity of food into the stomach than the gastric juice can at once combine with; the consequence of which will be, that appetite

may continue after the stomach has received more than it can well digest.

ON THE CONDUCT TO BE PURSUED PREVIOUS AND SUBSEQUENT TO MEALS; AND ON THE RELATIONS OF DIET TO THE NON-NATURALS.—We do not intend to assert that Nature ever contemplated the necessity of confining men to a certain routine of habits; nor did she ever contemplate, as far as we can learn, the existence of those diseases which may render such discipline necessary. We have in this place only to inquire into the habits which are most favourable or hostile to the process of digestion, and then to form a code for the direction of those who may stand in need of such artificial assistance. We have therefore to consider the influences of air, exercise, sleep, and the passions of the mind.

Exercise in the open air is essential to the well-being of every one; but its degree must be regulated by circumstances. The interval between breakfast and dinner is the period for active exertion, and the enjoyment of it, when not attended with severe fatigue, will strengthen and invigorate all the functions of the body; but it is important to remark that *the valetudinarian and dyspeptic should never take his principal meal in a state of fatigue*: and yet what habit is more general! Every body is impressed with the belief that after the sedentary occupation of the morning, to take a long and fatiguing walk will sharpen the appetite and invigorate the digestion: the consequence is obvious; instead of curing, such a practice is calculated to perpetuate and even to aggravate a dyspeptic malady; for the powers of digestion will be thus summoned at a period when the vital energy of the body is exhausted. We are anxious to be clearly understood upon this point: let it not, therefore, be supposed that we decry the use of moderate exercise before dinner; it is only the abuse of it we are so anxious to prevent. No person should sit down to a full meal unless he has previously inhaled the open air, and taken a quantity of exercise proportionate to his power of sustaining it without fatigue.

If exercise be necessary previous to a meal, there is also a certain period after it at which the accomplishment of the last stage of digestion will be accelerated by it.

When the chyle enters the blood, the body becomes enlivened; while the stomach and small intestines, having been liberated from their burthen, oppose no obstacle to the free indulgence of that desire for activity which Nature has thus instinctively excited for our benefit. Then it is that animals are roused from that repose into which they had subsided during the earlier stages of digestion, and betake themselves to action; then it is that civilised man feels an aptness for exertion, although he mistakes the nature and object of the impulse, and is inclined to regard it as nothing more than a healthy sensation, by which he is summoned to that occupation to which inclination or duty may prompt him. Thus, instead of being *bodily* active, the studious man receives it as a summons to

mental exertion; the indolent man, perhaps, merely to sit up and enjoy himself; the libertine to commence his libations; and the votary of fashion to attend the crowded circles of gaiety and dissipation. In short, this feeling of renovated energy is used or abused in a thousand ways by different individuals, without their ever dreaming that *bodily exercise*, and *that alone*, is implied by it. The result of this mistake is, that imperfect assimilation and all its train of evils follow. In this respect our ancestors enjoyed a great advantage from their early hours; they were enabled by them to take exercise at the most advantageous periods of the day; even the ball-room, which in our days might be termed Death's ante-chamber, was not injurious;—with them the dance commenced at six and terminated at eleven; with us it begins at eleven and ends at six!

If exercise be useful during the period of sanguification, pure air is not less so; and we may take this opportunity of protesting against the custom of frequenting crowded and ill-ventilated apartments at the very hour when the body requires the purest air for the sanguification of the aliment which has been recently taken into it.

Sleeping after dinner is a practice of very questionable propriety: it is true that the inhabitants of many southern climates indulge in it with impunity; but it does not appear essential in this country, where animal food is used in such considerable quantities. Its effect is to hurry on the different stages of digestion; and hence the fever and state of excitement in which the person not unfrequently awakes. In states of disease it may occasionally be useful, and the recumbent posture may expedite the passage of the aliment out of the stomach; but we should recommend those who indulge in such a habit to remove all ligatures from the body.

Passions of the mind, such as fear, anxiety, and rage, are well known to affect the nervous system, and, through that medium, the stomach and functions of the digestive organs; and so immediately are their consequences experienced, that a person receiving unpleasant intelligence at the hour of repast is incapable of eating a morsel, whatever might have been the appetite before such communication.

“ Read o'er this ;  
And after this ; and then to breakfast  
With what appetite you may.”

In directing our attention to the *excretions*, we must not overlook the sympathy subsisting between the skin and stomach. If the cutaneous vessels be universally excited, and this excitation be long continued, they will at length fall into a state of indirect debility, whence a sense of faintness, loss of appetite, and the inability of digesting solid food will be experienced. This fact explains the diminished appetite of which persons complain in hot weather, and that universal custom in tropical climates of combining the food with large quantities of aromatic stimulants. One of the most striking instances indicative of this con-

sent between the skin and the stomach is to be found in cases where cold or wet has been applied to the lower extremities. The following is an extract from a letter received by the writer of this article from Dr. John Badeley of Chelmsford:—“ A gentleman who consulted my father, complained that on getting out of bed in the morning, and putting on his leather breeches, he constantly vomited, from the sensation of cold thus occasioned. My father recommended him to take a glassful of cold water before he commenced dressing, and it was found effectual. The gentleman never afterwards vomited upon these occasions.”

But it is necessary to conclude this essay. We have endeavoured, in the shortest possible compass, to develop the philosophy of the subject of dietetics, and, as far as our present knowledge extends, to point out the chemical and physical varieties of structure and composition which confer upon different articles of nourishment, their relative, nutritive, and digestible qualities. In the article *REGIMEN* we shall endeavour to apply this knowledge to the treatment of individual diseases. No general rule can be given for the guidance of the physician in such cases. Every such attempt must be a failure: it may foster quackery, and perpetuate popular error, but it can never advance the progress of that pure and simple science which it is the object of these pages to inculcate.

(J. A. Paris.)

DILATATION OF BRONCHI. — See  
BRONCHITIS, CHRONIC.

DILATATION OF THE HEART.—The disease commonly known by this name consists of an amplification of one or more of its cavities. The ventricular parietes may be thickened, natural, or attenuated. The disease accordingly resolves itself into three varieties, corresponding with these states.

1. *Dilatation with thickening*, in which the cavity is enlarged and the walls are thickened.

2. *Simple dilatation*, in which the cavity is enlarged and the walls are of their natural thickness.

3. *Dilatation with attenuation*, in which the cavity is enlarged and the walls are attenuated.

The first variety is identical with that variety of hypertrophy called hypertrophy with dilatation, different names being employed for the two, in order to express, in dilatation with thickening, a predominance of dilatation, and, in hypertrophy with dilatation, of hypertrophy. The second variety is perfectly identical with hypertrophy by increased extent, with natural thickness of the walls; but the term simple dilatation is preferable when the dilatation is so great that its symptoms predominate over those of hypertrophy. Two, or all three of the forms of dilatation are sometimes found together in different parts of the same cavity.

The anatomical characters of simple dilatation and that with thickening will be described in the article on *HYPERTROPHY*. To dilatation with attenuation we here direct our atten-

tion. It seldom affects one ventricle without the other. The emaciation may be such as to reduce the most substantial part of the left ventricle to two lines in thickness, and the apex to a mere membrane, of which we have seen more than one instance. Extreme attenuation is more common in the right than in the left ventricle. In either, the columnæ carneæ appear stretched and spread. The inter-ventricular septum is proportionably much less attenuated and softened than the other parts. Dilatation takes place more in the transverse than in the longitudinal direction of the ventricles, and it accordingly communicates to the heart an unusually spherical form, so that the diameter of the organ near the apex is almost as wide as at the base, the apex itself being often scarcely distinguishable. This alteration of shape is the best criterion for determining whether a heart be dilated or not when the enlargement is so inconsiderable as to render the question doubtful. When both the auricle and ventricle are much dilated, it is not unusual to find the intermediate aperture widened, and its valve sometimes not large enough to close it. The muscular substance, sometimes healthy in every form and degree of this affection, in general is not so. For, when the organ is considerably enfeebled, its parietes are usually more or less softened and flaccid, and in some cases of a deeper red, (a consequence of venous engorgement,) in others paler or more fawn-coloured than natural.

Dilatation may give rise to rupture of the heart, especially as it is so often attended with softening. We witnessed a case of this kind a few years ago, and are acquainted with others.

In order to judge accurately of dilatation of the auricles, it is necessary to have distinct ideas respecting their natural form and dimensions. The four cavities of the heart are very nearly equal in capacity; but, as the parietes of the auricles are thin, and those of the ventricles are comparatively thick, the auricles, when merely full, and not distended, form only about one-third of the total volume of the organ; or, what is the same thing, the volume of the auricles equals about half that of the ventricles.\* The right auricle being of a more elongated, flattened form than the left, and being generally found in a state of distension, has the appearance of being considerably larger, though in reality it is only a little so.

Distention, taking place during the last moments of life, and observable, though more rarely, in the left auricle as well as in the right, constitutes the great source of fallacy in determining, after death, whether these cavities are really dilated or not; for the engorgement, though only of a few hours' duration, may stretch them to a magnitude almost equalling that of the ventricles.

M. Laennec has given good criteria by which a dilated may be distinguished from a distended auricle. An auricle simply distended is tense, and through its thinnest parts distinctly shews the dark blood within. One

dilated does not present the same appearance of tension, and its parietes are more opaque. When the blood is evacuated through the vessels without cutting into the cavities, the latter, if merely distended, return at once to nearly their natural size; whereas, if dilated, they maintain almost the same size as they had when full. Dilatation of the auricles is almost invariably accompanied with more or less thickening of their parietes.

The method of distinguishing distention from dilatation is much the same in the ventricles as in the auricles: namely, when merely distended, they are found enlarged, firm, and tense; but these conditions almost entirely disappear when the blood is pressed out through the natural apertures. On the contrary, when truly dilated, they have no appearance of tension, are more or less flaccid, and the enlargement persists after the blood has been evacuated.

Dilatation of the heart is a purely mechanical effect of over-distention. Blood, accumulated within its cavities; exerts a pressure from the centre towards the circumference, in every direction; and when once it surmounts the resistance offered by the contractile and elastic power of the parietes, these naturally yield and undergo dilatation. The rapidity with which this process takes place, and the extent to which it is carried, depend on the degree in which the distending exceeds the resisting force; and as the latter bears a direct ratio to the volume of the muscle, supposing it to be healthy, it follows that those cavities which have the thinnest parietes are, *ceteris paribus*, the most susceptible of dilatation. Accordingly, we find that the right ventricle is more frequently and promptly dilated than the left, and the auricles than either.

In order to produce permanent dilatation, the operation of the exciting cause must either be prolonged for a certain time, or frequently repeated at brief intervals. Contraction of an orifice, for instance, acts in the former manner; and nervous palpitations, or occupations requiring constant reiteration of muscular efforts, produce their effect in the latter way. When the operation of the cause is only brief and transitory, the result is merely a temporary *distention*, from which the muscle recovers itself by its own elastic and contractile reaction so soon as the distending force is removed. This cannot be regarded as a pathological state, and it must, therefore, be carefully distinguished from genuine dilatation.

The exciting causes of dilatation are, 1st, deficient power of the heart, whether congenital or acquired, in proportion to the system; 2d, in general terms, all obstructions to the circulation, whether situated in the orifices of the heart, or in the aortic or pulmonary system. The latter class of causes are, in fact, essentially the same as the exciting causes of hypertrophy; for it depends on the proportion which the resistance of the muscle bears to the distending force, whether the one affection or the other is produced. When, therefore, dilatation occurs in one of the cavities

\* *Laennec*, de l'Auscult. tom. ii. p. 523.

with naturally thick walls, in which we should more properly expect hypertrophy, it must be ascribed either to a congenital disproportion of the heart, in consequence of which the cavity in question is thinner, and therefore more disposed to dilatation, than natural; or it must be attributed to the obstruction, from its nature or situation, bearing more in proportion on that particular cavity than on any other. It is from having overlooked these considerations respecting the relations of the resisting and distending forces to each other, that some have excluded dilatation from the catalogue of mechanical diseases, and supposed that it takes its rise in any cavity of the heart either by chance or by some vital predilection—some vague, unintelligible predisposition.

Dilatation occasionally affects only a single ventricle, and it is generally the right; but much more commonly it attacks both. The auricles, being protected by their valves from the direct influence of the numerous causes of pressure which operate on the ventricles, are far more exempt than they, both from dilatation and hypertrophy. But when the auricular valves are diseased, whether their state be that of contraction, which impedes the transmission of the auricular blood, or of permanent patency, which allows a regurgitation of the ventricular, the auricles, suffering unnatural distention, become dilated.

It is seldom that dilatation of the auricles occurs under any other circumstances than those of disease of their valves; so seldom, indeed, that Laennec does not recollect to have seen an instance, though he does not deny the possibility of the occurrence. More instances than one, however, have fallen under our own observation, and we have generally found the dilatation connected with some circumstances incapacitating the ventricle from freely evacuating its contents. It is natural, indeed, to suppose that when such is the case, the stagnation of blood in the ventricles must, for the time, have an effect in distending the auricle equivalent to that produced by contraction of the auriculo-ventricular valve; and considering the frequency of stagnation in the right ventricle, we might at first expect dilatation of the corresponding auricle from this cause to be frequent. But it must be remembered that, for the production of the disease, it is necessary that the operation of the cause be permanent, or at least very prolonged. Such, however, is seldom the case with the stagnation in question; for a ventricle, though so feeble in itself, or so encumbered by an obstacle before it in the course of the circulation, as to become gorged during an accelerated state of the heart's action, will, when tranquillity is restored, transmit its contents with a facility that could scarcely be anticipated. During such intervals, therefore, the muscular fibres of the auricle recover their contractile power, and restore the cavity to its natural size.

M. Bertin contends that dilatation is never a *primitive* malady, but merely a consecutive effect of a pre-existing lesion of an obstacle to the course of the blood; and that the symptoms

produced by such obstacles, viz. vascular engorgement, dropsy, passive hemorrhage, &c. have no other relation to dilatation than as being results of the same cause—the obstruction of the circulation.

We cannot concur with M. Bertin in these opinions. It is true that, in order to produce dilatation, there must exist a weight or pressure of the circulation upon the heart greater than the organ is capable of sustaining; and it is true that such pressure may be occasioned by the mechanical obstacles to which M. Bertin ascribes it, namely, contraction of the orifices of the heart, diseases of the aorta, and all maladies which impede the course of the blood, whether in the lungs or in the system of the great circulation.\* But it is equally true that the same pressure on the heart may result, not from increased weight of the circulation, but from deficient power of the heart; and such is its cause in those who, by original conformation, have the organ thin in proportion to the size of the body. Another class in whom debility of the heart exists as a cause of dilatation, comprises those who have had the organ softened or otherwise enfeebled by disease; an effect not unfrequently produced by typhoid fever, and by inflammation of the substance and membranes of the heart.

Dilatation, then, occurring under the circumstances described, is as justly entitled to the rank of a *primitive* disease as hypertrophy; for as in both the disease depends, not on the pressure of the circulation, but on the manner in which the heart resists that pressure, in both the organ itself is the part where the disease originates; the only difference being, that in the one case the effect is produced by deficient, in the other by superabundant, power of the muscle.

In the next place, M. Bertin has, in our opinion, attributed far too much to the lesion of which he considers dilatation to be the effect, when he says that this lesion is the sole cause of all the symptoms which authors have been in the habit of ascribing to dilatation. It is true that when the lesion is so great as to constitute an extreme obstacle to the circulation, it may produce the symptoms in question; but it does not produce them, or produces them only in a very slight degree, when the obstacle is not extreme. We have repeatedly witnessed cases in which a well-marked if not a considerable obstacle, as a contracted valve, or a dilatation or aneurism of the aorta, had subsisted for a long period, even for years, without producing any material symptoms of an obstructed circulation; but the moment that dilatation of the heart supervened, the symptoms made their appearance in an aggravated form. We apprehend, therefore, that the heart is the part mainly concerned in their production; nor do we think this opinion less tenable because the symptoms are more severe when enlargement of the heart co-exists with an obstacle than when the enlargement exists alone; for it is natural to suppose that when two causes con-

\* Bertin, p. 380.

spire to produce the same effect, that effect will be greater. But this is not all; for not only does each produce its own effect, but one increases the effect of the other; namely, the obstacle adds so much to the pressure of the circulation on the heart, that this organ labours under a double disadvantage, first, from its own diminished power, and, secondly, from a preternatural pressure upon it. Thus the resulting effect of the obstacle and the dilatation of the heart combined, is greater than the sum of the two taken separately.

In further invalidation of M. Bertin's opinion, we may add that we have seen numerous instances in which all the phenomena of an obstructed circulation were occasioned by dilatation alone, as no other obstacle capable of accounting for them could be detected in the course of the circulation.

According to the foregoing arguments then, it appears, first, that dilatation may be a *primitive* disease, and that, as such, it is capable of producing all the phenomena of an obstructed circulation; secondly, that when it is consecutive to another lesion, it plays a prominent, and perhaps even, in some cases, a more important part than that lesion in producing the phenomena of an obstructed circulation.

In order to ascertain the *real* effects of dilatation, it is necessary to confine ourselves, in studying them, to the simple uncomplicated form of the disease.

Taking into consideration this form alone, and admitting, on the foregoing grounds, that it is capable of producing all the phenomena of an obstructed circulation, we have next to inquire how, or by what mechanism, it produces them. To answer this question,—it produces them by putting the muscular fibres of the heart preternaturally on the stretch, whereby their contractile power is diminished; they lose, as it were, in force what they gain in length; and it is this deficiency of power in the main spring of the circulation which constitutes the obstacle, if it may be so called, to the circulation, in the same way that weakness of the spring of a time-piece retards its movements.

*Diagnosis of dilatation.—General signs.*—We have shown that the effect of dilatation is to enfeeble the heart, and thereby occasion the phenomena of an obstructed circulation. We have now to examine these phenomena as signs of dilatation.

The heart, when dilated, is subject to palpitations of a feeble oppressed kind, and more or less distressing, frequent, and prolonged, according to the extent of the malady. The attacks are provoked by any over-exertion or mental excitement. The pulse is soft and feeble, and if the debility of the heart be very considerable, it is small. Irregularity and intermittence are rare, except during severe dyspnoea, or when the vital powers are much exhausted, as in the extreme stage of the disease.

The languor of the arterial circulation causes the extremities and surface to be chilly, the disposition to be melancholy, and the character to be deficient in energy. The blood, not being freely transmitted by the left ventricle,

accumulates by retardation in the lungs; whence difficulty of respiration; cough, sooner or later attended with copious expectoration of thin, serous mucus; œdema of the cellular tissue of the lungs, greatly aggravating the dyspnoea; terrific dreams, with starting from sleep; and passive pulmonary hemorrhage of dark, grunous blood in small quantities, forming sanious sputa, and generally the precursor of death when it occurs in individuals affected with extreme difficulty of respiration. The lungs being obstructed, the engorgement is propagated backwards to the right side of the heart, to the great veins, and finally to all their ramifications. From this venous engorgement arises a series of striking phenomena, which we shall review successively.

1. *Serous infiltration.*—This generally makes its appearance first in the lower extremities, because it is in them that the circulation is most languid, the return of the blood being opposed by its gravity: while about the feet and ankles it is little promoted by the action of superincumbent muscles. Increased serous exhalation takes place in the serous membranes also; hence hydro-thorax, hydro-pericardium, and ascites, one or other of which is almost invariably present when there is much external dropsy.

2. *Discoloration of the face.*—If the complexion was originally florid, it becomes purple or deep violet, principally on the cheeks, the end of the nose, and the lips, with intumescence of the latter. If originally pale, it becomes cadaverously exanguious, and has a dusky, leaden cast, especially about the eyes. The lips are either livid or totally colourless. Lividity sometimes shows itself in the extremities as well as in the face.

3. *Congestion of the brain.*—This produces sub-apoplectic symptoms, as dull headach, felt principally along the course of the great sinuses; hebetude of the mental faculties; stupor, convulsions, and eventually complete coma. It is not unusual for these symptoms to supervene a few days before the fatal termination. Sometimes they depend not on congestion alone, but partly also on serous effusion into the ventricles. This, however, is not always the case, as we have ascertained by several dissections.

4. *Injection of the mucous membranes.*—It is common to find them after death so vascular as to present the appearance of inflammation. This is especially the case in the stomach and intestines, and it is necessary to be aware of the circumstance, in order to guard against the error of attributing the redness to inflammation.

5. *Passive hemorrhage.*—This takes place from the lungs, as already stated, from the nose, the stomach, the intestines, and more rarely from the bladder. It results from engorgement of the mucous membranes. The effusion consists of dark blood exuding in small quantities. When from the stomach, it has occasionally the appearance of coffee-grounds.

6. *Congestion and enlargement of the liver.*—

This is so common a consequence of retardation of the circulation on the right side of the heart, that few persons so affected in any considerable degree are exempt from it. By the obstruction which it occasions in the system of the vena porta it leads to ascites.

The sign which, with Laennec, we think the most constant and characteristic of the equivocal signs of dilatation of the right ventricle in particular, is permanent turgescence of the external jugular veins *without sensible pulsation*. This turgescence does not disappear when the vein is compressed at the upper part of the neck.

Dilatation of the auricles presents no general signs distinguishable from those of disease in the corresponding ventricle or valve, to which it owes its origin; but its existence may be inferred when the valve in question is either much obstructed or permanently open, or when, from any cause, there is great retardation of blood in the ventricle.

*Physical signs.*—The signs of the two first varieties of dilatation, namely, that with a thickened, and that with a natural thickness of the walls, are given in the article on hypertrophy. It only remains for us to describe the signs of the third variety, or dilatation with attenuation.

*The impulse.*—In this variety the impulse is diminished, and in extreme cases entirely absent, even during palpitation. When felt, it is only a brief percussion of the thoracic parietes, not elevating the ear. When the dilatation is great, the impulse is a little lower down than natural. It sometimes happens that, of several beats of the heart that are heard, one only is felt; and if this be vigorous, it warrants a conclusion that the parietes are little attenuated. Though Laennec does not make this observation, we have assured ourselves of its accuracy by numerous post-mortem examinations.

*The sounds.*—When the walls of the ventricles are merely thin without being dilated, the first sound (the sound produced by the systole of the ventricles) is louder, shorter, and clearer than natural; it approximates in its character to the second sound, (that produced by the diastole of the ventricles,) which is analogous to the flapping of a pair of bellows. When there is dilatation, even in a moderate degree, the first sound becomes almost the same, and nearly as strong as the second; and finally, when the dilatation is considerable, the two sounds cannot be distinguished either by their nature or intensity, but solely by their respective relations of synchronism or anachronism with the arterial pulse. The pulse in remote arteries, as the radial, often being, in dilatation and various other diseases of the heart, later than the ventricular systole, the pulse of the carotid or subclavian should be felt.

In proportion as the sounds of the heart are louder, they are audible at a greater distance over the chest: accordingly, M. Laennec has proposed a scale by which the extent is made an index of the degree of dilatation and attenuation. Before describing this scale, it

is necessary to acquaint the reader with the range of the sounds in the natural state.

In a healthy man, of medium stoutness, and whose heart is in the best proportions, the sounds, according to Laennec, are audible in the præcordial region alone; that is, in the space comprised between the cartilages of the fourth and seventh left ribs, and underneath the inferior half of the sternum; also, if the sternum be short, in the epigastrium. We have generally thought that they may be heard a little beyond this range. The sounds are similar and equal on the two sides of the heart, those of the right being most audible under the sternum, and those of the left under the cartilages of the ribs. When audible beyond the limits mentioned, they are heard successively in the following places, constituting the scale alluded to:—viz. 1st, along the sternum and on the left superior anterior part of the chest as high as the clavicle; 2d, over the same extent on the right side; 3d, on the left side of the chest, from the axilla to the region of the stomach; 4th, on the right side over the same extent; 5th, on the posterior left side of the chest; 6th, on the posterior right side. The intensity of the sound is progressively less in the succession indicated, provided the parts around the heart are in the same states. But there are so many diversities in these states, which may interfere with the order described, that we have found the scale of M. Laennec of little practical utility in estimating the degree of dilatation. Thus, in very fat subjects, in whom the impulse of the heart is not perceptible to the hand, the space over which its healthy sounds can be heard by the cylinder is much more limited than natural: Laennec has even found them confined, in some instances, to a square inch, though we cannot say that this has occurred to ourselves. On the other hand, in meagre persons, in those who are narrow-chested, and in children, the sounds are audible much further than ordinary: namely, over the two inferior thirds, or even three-fourths of the sternum, sometimes even over the whole of that bone, and at the left anterior superior part of the chest as high as the clavicle; often, also, though less distinctly, below the right clavicle. In very meagre subjects, we have heard them over the whole chest, both posteriorly and anteriorly. Now, as it is almost impossible to make an exact estimate of the degree in which stoutness limits, and leanness, &c. extend the range of the sounds, this range is not a sure criterion of the degree of dilatation.

Again, a lung in any way consolidated, whether by hepatization, tubercles, or compression by fluid in the cavity of the pleura, transmits the sounds of the heart more readily than a lung that is sound and permeable to air—a phenomenon explicable on the principle that dense bodies are the best conductors of sound. The effect is the same, though there be cavities in a tuberculous lung; for the sound is transmitted, not through the cavities, but through their walls, which are denser than healthy pulmonary tissue.

Under these various circumstances then, the sounds are irregularly propagated, and the progressive scale of Laennec is interfered with. For instance, if the right lung be consolidated, the sounds will be more audible on that side than on the left.

Our own mode of estimating the degree of dilatation is, by observing how far the first sound resembles the second, and comparing the intensity of the first, heard immediately over the ventricle affected, with what we believe, from experience, would be its intensity in the same subject if the heart were healthy. We then corroborate the estimate, if necessary, by the scale of Laennec, making allowance, as far as is practicable, for stoutness, leanness, youth, pulmonary condensation, &c. The manner in which we judge of attenuation by the first sound, is less by its loudness than by its remarkable shortness and clearness; for we think it is often louder in dilatation with hypertrophy, or even with a natural thickness of the parietes, than with attenuation. This opinion is opposed to that of Laennec, who "thinks he may regard it as constant, that the extent over which the beats of the heart are audible, is in the direct ratio of the feebleness and thinness of its walls." So far is this from being perfectly true, that we have met with cases in which the heart was dilated and attenuated to the extreme, yet the first sound was feeble: nor should we expect it to be otherwise in such cases; for when the heart, from extreme dilatation, is too feeble to contract smartly, its sounds must necessarily be weak. Hence they are so in ramollissement, and in the moments preceding dissolution.

*Resonance on percussion.*—The resonance of the præcordial region on percussion is diminished by dilatation. The dulness is situated rather lower down than natural, and as it is always in proportion to the increase of volume of the heart, it is greater in hypertrophy with dilatation than in mere dilatation. Dulness of the præcordial region on percussion may exist independent of enlargement of heart; namely, when the anterior borders of the lungs are hepatized, and extend in front of the heart. On the contrary, dilatation sometimes does not occasion deficient resonance when the lungs are emphysematous, and their anterior margins are forced between the organ and the sternum.

*Physical signs of dilatation of the auricles.*—Auscultation has not hitherto supplied any direct signs of dilatation of the auricles; but as this affection is in general the consequence of disease of the valves, and of enlargement of the ventricles impeding the circulation through the heart, its existence may be inferred from the presence of signs of these affections.

*Prognosis.*—In many persons the heart, without being dilated, has naturally thin walls: those of the left ventricle, for instance, are not, at the utmost, more than twice the thickness of those of the right. This state presents the same signs as dilatation, but in a less degree: namely, the impulse is diminished, the first sound is loud, short, and clear, and both sounds are more extensively audible than natural. Individuals so affected may live for a great number

of years,—even to an extreme old age, in a state of tolerably good health: it is only to be remarked that this conformation is in general accompanied with a delicate constitution, a slim stature, and small muscles. In fevers and diseases of the respiratory organs, the individuals in question experience, *cæteris paribus*, greater dyspnoea than others. If such a conformation augment, even slightly, a dilatation of the heart is the result.

A slight degree of dilatation is not a very formidable affection. The dyspnoea is sometimes not so great as to deserve the name of *morbid*; but the patient has merely a shorter respiration than most men, he more readily loses breath, and experiences palpitations from much slighter causes. With these slight symptoms, however, he generally exhibits some traces of the cachexy proper to organic disease of the heart. The state described, which is that of a great number of *asthmatics*, may subsist very long without occasioning any disorder of a serious nature; it may remain without making progress for a great number of years, and it does not always prevent the patient from attaining an extreme old age.

When dilatation has advanced so far as to occasion *morbid* dyspnoea, it has a constant tendency to increase unless the circulation be kept tranquil by a very quiet life, and by judicious medical treatment when necessary. With these precautions the disease may be kept stationary, sometimes for an indefinite period, if not exasperated by fevers or inflammatory affections, which, by hurrying the circulation, are eminently prejudicial.

When dropsy comes on, and, after having been removed by remedies, constantly shows a disposition to return, we may know that the dilatation tends to its fatal termination; and although the patient may sometimes rally from five, six, or even more attacks, he generally sinks in the course of one or two years, or less. The progress of dilatation with hypertrophy is much more rapid, as explained in the article on **HYPERTROPHY**.

The general prognosis is founded on the above considerations, and is favourable so far as life is immediately concerned. The particular prognosis depends upon the degree of severity of the symptoms and on the constitution of the patient.

*Treatment.*—The treatment of dilatation with *increased* power of the heart, that is, with hypertrophy, is described in the article on hypertrophy. In this place we have only to speak of the treatment of dilatation with *diminished* power, that is, with attenuation, and sometimes even with a natural degree of thickness of the parietes.

The first indication is, to remove, if possible, the exciting cause of the dilatation; and if this be done before the disease has proceeded to such an extent as entirely to deprive the muscular fibre of its resilience and elasticity, these faculties come into operation and restore the organ to its natural size. Accordingly, if the cause be an obstruction in the pulmonary circulation, as that produced by peripneumony,

hydro-thorax, or pneumo-thorax, emphysema, the use of wind-instruments, ventriloquism, tubercles, &c., the attention must be primarily directed to the removal of these affections and the prohibition of these habits. If the cause be, too violent exercises or passions, inebriety, occupations which, by placing the patient in a constrained posture, prevent the free circulation of the blood, as in shoe-makers, tailors, &c., the pernicious exercises, habits, or occupations must be abandoned, and the passions calmed. All the causes enumerated being of a temporary nature, the dilatation resulting from them, if not inveterate, can often be removed. But when the cause is permanent, as the contraction of an orifice of the heart, or a natural or acquired feebleness of the organ in proportion to its function, a cure of the dilatation is scarcely to be expected; but it may often be prevented from increasing, and the life of the patient may sometimes be prolonged even to its extreme limits. In such cases, therefore, the practitioner should steadily and perseveringly pursue a palliative and prophylactic treatment, having first discarded from his mind the impression, no less erroneous in itself than detrimental to the progress of medical science, that organic diseases of the heart are necessarily fatal, and that, therefore, all treatment is unavailing.

The circulation should be kept as tranquil as possible by a quiet life and a moderate unstimulating diet. The food, however, should be rather nutritious, comprising a little animal food or soup twice a-day, in order to keep the muscular system in general, and that of the heart in particular, in good tone. The same object may be promoted by a clear, dry, bracing air, (as that of Brighton,) and by the shower-bath; from both of which we have seen the best effects result. Neither of them, however, have we found to suit those patients who have great pulmonary congestion with copious expectoration; as such require a warm humid atmosphere to favour expectoration and the cutaneous function, and they cannot bear the shower-bath on account of its determining too much from the surface to the heart and great vessels: neither can they well bear opiates, as these remedies partly occasion diminished mucous secretion, and partly accumulation of that already secreted; both of which circumstances increase the dyspnoea. The general health and strength may likewise be improved by the occasional exhibition of biters, mineral acids, and chalybeates, with aromatics. The stomach, in particular, should be kept in good order, as its derangements—even a little flatulence or acidity—have a surprising effect in disturbing the action of the heart. The same may be said of the biliary secretion. When there is an unequal distribution of nervous power, indicated by hysterical symptoms, &c., antispasmodics, particularly the *pilula galbani composita* and valerian, are very useful adjuncts to other remedies.

Febrile and inflammatory affections of every kind, but particularly inflammation of the lungs and bronchi, should be sedulously guarded against, and, when occurring, should be

promptly treated. Even a slight pulmonary catarrh should be viewed as a serious affection. To prevent colds and relieve the heart by keeping up the circulation on the surface, flannel next to the skin is almost indispensable; and, if the patient be chilly, as is frequently the case in dilatation, a jacket of wash-leather should be worn over the flannel during winter.

Attacks of dyspnoea are best relieved by immersing all the extremities in warm water, a blanket being thrown round the patient to promote perspiration, and fresh cool air being admitted to satisfy the craving for breath. While this is being done, he should take an antispasmodic draught composed of ether, laudann, camphor, ammonia, and assafoetida, combined according to circumstances. (See treatment of VALVES, DISEASES OF.) It may be repeated two or three times, at intervals of from half an hour to an hour according to circumstances.

Bloodletting should not be resorted to in dilatation with deficient power of the heart, *during the paroxysm*, and merely for the purpose of relieving it. The abstraction of a small quantity has not the effect, and that of a large quantity is inadmissible, as it does more injury by increasing the debility of the heart and the system, than it does good by lightening the circulation; and consequently, an ultimate aggravation of dyspnoea ensues. More than once have we seen a large and indiscreet bloodletting fatal, as the patient could not rally from the exhaustion produced by the attack of dyspnoea to which that from the depletion had been superadded. If there be an absolute necessity for bloodletting—that is, if the dyspnoea be constant, and cannot be relieved by any other means—the quantity drawn should not exceed six ounces at one time; and it should be drawn very slowly, in the recumbent position, and during the intervals or remissions of the fits. In this way the bleeding may be repeated, if necessary, every one, two, or three months, provided it does not diminish, but rather increases, the strength of the patient.

For the treatment of dropsy, cough, &c., we refer the reader to the article on VALVES, DISEASES OF.

(*J. Hope.*)

**DISEASE.** Disease is disordered action of any part of the machinery of the body. Its primary effects, or perhaps we should say, its primary palpable phenomena, are impeded or disordered functions; and of these the results are alterations of structure, and various symptoms or signs indicative of functional and of structural changes.

There is a state of the different systems of which the body is composed, in which all the functions of life are performed with comfort and ease, and a sense of well-being. This is the state of health. Whenever any bodily or mental function is not performed thus harmoniously, there is an interruption of this state, however slight the departure from the condition of health may be. The first symptom of this slight disease, for such it is, is mere discomfort. As the disorder proceeds, if it does pro-

eed, from this slight beginning, the discomfort is succeeded by pain and various other circumstances, which are all, consequently, so many symptoms of disease. Thus the slightest disordered action may produce only inconvenience; as nausea, vertigo, pruritus: and increased disordered action will produce increased inconvenience; vomiting, loss of sense, cutaneous inflammation, with the additional symptom of pain. On this aggravated state changes of structure supervene. It occasionally happens that functional disorders, because they in such cases affect parts of a low degree of sensibility, proceed far, even to structural alteration, with nothing more than symptoms of occasional discomfort; but these instances are not frequent.

Compatible with the state of health, also, are considerable varieties in the performance of certain functions. They do not interrupt health so far as to produce even discomfort. The pulse of some individuals is never beyond 50, and of others never below 110. In some the function of digestion is more rapidly and actively performed than in others: and the intellectual alacrity of different persons is well known to be widely different, yet without disease. But when the food is not digested without discomfort or pain, or the circulation not carried on, or the mental movements not made, without similar results; when the appetite is lost, when there is fainting, when there is privation or other affection of any of the sensations or mental faculties; then there is disease.

The least consideration shews us that man is exposed to various circumstances capable of disordering his functions, and all these circumstances are so many *causes* of disease. They are found in the elements by which he is surrounded; in the food on which he subsists; in excess or defect of voluntary exercise; and in the nature of his mind, sensations, and affections, which subjects him to various kinds of risk by prompting various actions and enterprises, and which is susceptible of impressions as well as capable of originating such actions. Man is also liable to connate and inherited defects, and to diseases resulting from the natural decay of his bodily frame.

The element to which man is chiefly and at all times exposed, is the air. Its variable temperature, dryness, and moisture; its alternations of calmness and commotion; and probably, also, its variable electrical states; not only immediately affect the surface and the respiratory organs, but through the latter the blood, and through that fluid the energy of all parts of the system. Some of the variations seem to have a direct influence on the nervous system; and there are presumable properties in the air, yet unknown save in their destructive effects, which are largely concerned in the production of our common continued fevers, the yellow fever, the plague, the intermittents of fenny countries, cholera, and what is called influenza. No doubt can be entertained of the agency of such atmospherical influences in the production of the common eruptive disorders; and of one at least of the disorders

characterised by irritation of a particular portion of the nervous system (the respiratory), and by spasm,—circumstances exemplified by the whooping-cough. The direct influence of the air on the nervous system is not easily proved, but to this, or to some effect produced on the fluids or solids of the body, together or separately, must be ascribed the variations of feeling and spirits experienced by so many individuals in variable states of the weather, and the suicidal despondency which medical travellers have found to be induced by the sirocco. (Dr. J. Johnson.) The condition of certain structures of the body, and perhaps of their nerves, is seen in the course of the seasons to be materially affected by certain states of the atmosphere: the effects being sometimes, apparently, merely the result of temperature, as in the catarrhs, and disorders of the respiratory and circulating apparatus in the cold weather of severe winters; but at other times more obscure, as in the irritability of the mucous membrane of the stomach and intestines in the summer and autumn, of which the consequences are periodical dyspepsia, gastric fevers, diarrhoea, dysentery, and cholera. Of diseases thus obscurely arising, some, peculiar to particular localities, are called endemic; others, appearing and disappearing at particular seasons with some regularity, are called epidemic, and many of the latter become under certain circumstances communicable from one individual to another.

Several of the occupations of man in civilised countries are carried on in confined and ill-ventilated places, where the mere assemblage of many persons deteriorates the quality of the air: the effect of breathing this is very injurious to health, and a very common cause of disease. The influence of a high temperature, combined with excessive moisture, has been abundantly experienced in the diseases incidental to tropical climates. There are also occupations in the course of which light particles of foreign matter are mingled with the air and inspired; as needle-pointing, grinding of corn, and mason's work; and these particles cause irritation and disease.

In the quality and in the quantity of food are found also the causes of disease. Some kinds of food produce disorder by their stimulating properties, and some by otherwise inducing departures from healthy processes, as in the example of calculous formations in the kidneys. Man is equally disordered by excess and defect of nutrition.

Excess or defect of voluntary exercise and rest affect him no less. It is the rule of nature that voluntary muscular action cannot be neglected with impunity; and its excess produces direct exhaustion.

Many familiar facts, not uninteresting to the medical observer, illustrate the effects of certain species and measures of diet, and peculiar kinds and degrees of exercise, upon the human body. The corpulence and fatness of coachmen and farmers, and the thinness of students and of foot-soldiers, may afford him instruction. But the effects of what is termed *training*, both in increasing and decreasing the bulk and

strength of the body, and the vigour of the mind, are more especially deserving of attention. By the administration of dry and very nutritious food; by a certain degree of exercise in the open air; by allowing a moderate portion of sleep; and by avoiding every kind of excess; assisted, however, it should be said, by great attention to the state of the surface, and by a little preparatory purgative medicine; the athletes of old, and the prize-fighters of modern times, have been accustomed to attain such a corporeal condition in the course of six or eight weeks as to endure great fatigue, to breathe freely and fully under extreme exertion, to bear violent blows on the head without giddiness, and to incur severe wounds without danger or long inconvenience. The appetite, after such a system of training, becomes great; the skin becomes of a better colour; and the shape of the body improves. A man thus disciplined can not only run twenty or thirty miles with ease, or walk a hundred, but can face dangers which would before have appalled him; and wrestle or contend advantageously with an assailant by whose strength he would previously have been overpowered. It is said, too, that the perceptions become more acute, and the mental faculties more active; but such consequences are of course not always observed among those who are commonly the subjects of training, although in their gaming devices they not infrequently shew great acuteness and power of calculation. These effects of training are commonly very transient, and repeated or excessive training seems to shorten human life. It is a question, however, how far this supposed hurtful effect of training is to be ascribed to the intemperate habits of the persons usually submitting to training. Race-horses and game-cocks, which are also subjected to particular training, are not found to be shorter-lived than other animals of the same species.

By methods entirely opposite, the reduction of strength and of bulk may be effected in a very short space of time. The boys employed as jockeys at Doncaster and Newmarket are sometimes reduced twelve or sixteen pounds in weight in the course of ten days, in order to ride a particular race. They are not allowed during this preparation to have meat, or wine, or ale; but live on fish, and puddings, and bread and butter: they have tea at night, but nothing to eat with it. With this slender diet is conjoined strong exercise in thick and heavy clothing. After the race is run, the jockey is allowed to indulge himself; and it is said that as much as nine pounds in weight have been regained in eighteen hours. The effects of this reduction of weight and strength on the brain, as exemplified in the intellectual manifestations, have not been noticed; but it is said that the constitution is often ruined by these vicissitudes. Many jockeys may be observed to be stunted in growth, and to have, even in the prime of life, the dry and withered appearance of premature old age.

It is worthy to be remarked, that not only do excess in diet and extreme abstinence, too

much rest and excessive fatigue, extremes of heat and extremes of cold, disorder the body; but that they all seem, when carried to the utmost, to affect the body in the same, or nearly the same manner. All (perhaps by impairing the functions of the nervous and vascular systems) eventually induce those disturbed actions which constitute febrile disorder. In fact, what is called *reaction*, under most circumstances, consists of the establishment of actions tending to febrile or inflammatory processes; and probably the converse, namely, that inflammations and fevers are commonly intended to rid the body of some inconvenience, is not far from the truth.

The great gift of the mind, also, by which man is so greatly raised above the lower animals—by which he inquires, improves, records his improvements, and looks beyond this life,—is a gift that his imperfect nature cannot bear without the tribute of occasional inconveniences, from which the less privileged animals are exempt. Its inordinate exertion, and the vehement impressions of which it is susceptible, exhaust the nervous energy, or impair the nervous actions, or alter the actual condition of the nerves; and thus deprive the physical part of the system of some of its power, increase its susceptibility, disturb the processes which should be performed in the different bodily organs, and bring on disease, or gradually enfeeble the whole system. From such causes we perceive, in different cases, various irregular actions, chiefly exemplified in the muscles,—agitation, tremor, faltering voice, unsteady gait, spasm, hysteria, epilepsy;—or exemplifications of diminished power, as in the various shades of paralysis.

By sloth and negligence, or by irregularity and prodigality of application, the powers of the mind itself are equally impaired in some cases, and in others disturbed. Sudden and excessive joy exhausts the mental and nervous power at once; and sudden and overwhelming sorrow oppresses both beyond recovery, producing a state which is sometimes followed by that deep sleep which restores the capacity of endurance, and sometimes by that sleep which ends all worldly suffering.

The influence of sudden mental impressions on the circulation, in whatever way this is exerted, is evident enough in numerous instances. Their power in the production of that unequal distribution of blood called *determination* is conspicuously seen in the simple act of blushing. Violent anger, or a sense of shame, causes the smaller vessels of the face and neck to be instantaneously injected with blood. By similar, but more violent effects, anger has led to apoplexy; and this passion is seen to render the face red in some individuals and pale in others. Fear commonly produces paleness, and extreme fear may induce death. The functions of the lungs may be affected, or at least the respiratory exertions are quickened, by surprise or other emotion; and simultaneous palpitations shew that the heart responds to the same influences; or its sympathy may produce some suspension of its actions, and syncope

ensue: the faltering speech and the trembling limbs on some occasions, and the increased speed and strength exhibited on others, equally shew how much the muscular energy may be influenced by temporary states of the mind. The gushing of tears in states of sorrow; the diarrhœa and copious renal secretion under the action of fear or vexation; the sudden appearance of gout and of cutaneous eruptions in circumstances productive of great mental disturbance; the profuse perspirations, and the altered colour of the hair sometimes induced; are all illustrations of the operation of the same class of causes.

Long continued depression of mind, or long anxiety, produces effects which are deeper and less immediately visible. The nervous and the vascular system seem equally to suffer; and habitual disorder of some of the functions, going on to the structural alteration of some organ, is the consequence. Chronic determination to the vessels of the stomach or lungs; or to the liver, or intestines; or to the heart, or to the brain itself, are common results. Obstinate dyspepsia, attacks of asthma, permanent mischief to the hepatic and intestinal functions, or some variety of mental disorder, are among the modes in which such results are manifested: as is also a slow increase in the size, or change in some part of the structure, of the heart itself; curiously according with that strong and melancholy expression, that the person thus destroyed has "died of a broken heart."

On the other hand, need any one be informed of the happy effects of a tranquil state of mind, or of the improved health which is brought by complete relief from heavy anxiety! The amended appetite, the better sleep, the improved complexion, the increased nutrition, which follow in the train of cheerfulness, must be familiar to the most superficial observation.

The diseases produced by a disordered imagination require only to be mentioned.

There is a principle in the human body which enables it, when not previously disordered, to support and resist the influences of all the agents of disease up to a certain point. By this principle, which has been called the conservative principle, it is enabled to endure great and even sudden changes of temperature, and is secured for a time against noxious atmospheric influences. Great variety of food can not only be borne without inconvenience, but appears to be salutary; and occasional imprudences, as regards both excess and fasting, will, in a state of perfect health, produce no permanent uneasiness. So also exercise may be taken, even to the production of extreme fatigue, or we may devote ourselves to long-continued sedentary study, and yet remain well for a time; and it is familiarly seen that neglect of proper rest often passes unpunished. It is the same with respect to the mind. When we are in perfect health, the various trials met with in the world; the joys, the sorrows, the anxieties, which by turns affect us, are met with steadiness and fortitude, and pass away without disturbing the equanimity

of that part of the system on which they make their transient impression. Leisure or complete idleness may also be interchanged with severe or varied mental application, and the health of the mind still be maintained.

But when, by the prolonged or inordinate impression of some of the causes of disease already enumerated, or by other causes of disease which remain to be mentioned, the vital power is impaired in any one organ; when, for instance, the gastric, pulmonary, or cutaneous functions, or the faculties of the mind, begin to show a little interruption of vigour and regularity, even the ordinary objects with which the especial function is habitually concerned become exciting causes of disease. Not only extremes and sudden varieties, but the common air, the ordinary kind and measure of food and drink, the customary exercise, and the daily excitements and depressions of social life, become so many sources of irritation: all those things which have occasionally been defined the sources of vital motion,—all external stimuli, all ideas of the mind, and volition,—then become causes of actual disease.

Besides the causes of disease to which man is by his position constantly exposed, there are others incidental to his frame itself. A heart naturally feeble, or disproportionately small, is inconsistent with health. In every part of the globe, although more in some parts than in others, the species is subject to occasional deformities, some of which, as a contracted cranium or thorax, interfere with the most important functions, and impede their just performance. Very serious diseases arise also, in the course of life, from disordered actions, of which the causes are often entirely unknown; such are those departures from healthy deposition denominated cancer, tubercle, fungus hæmatodes; as well as the production of parasitic animals in certain structures.

It is also very often seen that one disease will produce a second, not unfrequently more severe and dangerous. In this way some of the morbid formations just spoken of are occasionally induced; as that of pulmonary tubercle after a severe attack of catarrh, or after hooping-cough, or fever, or the measles. There is so close a connexion between the different functions of the body, and between these and the mind, that no function can be long or very severely disordered without involving the disorder of another. This is particularly observable in affections of the respiratory and circulating systems, but is existent, in a greater or less degree, with respect to all the rest. As fever is a disease which most deeply affects all the functions of the body, it more than any other leaves a disposition to various forms of disease; sometimes to disease in the organs of locomotion, sometimes to disease of the lungs, and very often to diseases dependent on serious impairment of the nervous system, as paralysis or fatuity. The most numerous instances, however, of disease following disease, are furnished by irritations, various in kind and in degree, of the intestinal mucous membrane;

which are so largely concerned in fevers as by some pathologists to be considered as their sole cause, and which doubtless induce every variety of irritation in the vascular apparatus of different tissues, from simple determination to common or to specific inflammation; aggravating also, and often alone producing, all the varieties of nervous and spasmodic affections; and being most widely concerned in the establishment of local disorders of every description, from a simple papular eruption to erysipelas, or to ulceration and deep destruction of parts. The sympathies subsisting between the liver and the brain, and, more remarkably, between the uterus and the whole nervous system, produce phenomena from which the list of illustrations might be greatly swelled.

Some diseases, chiefly such as exclusively affect glands, will in succession attack various parts. When tubercles exist in the lungs, they often also exist in several other situations, as in the mesenteric glands, in the glands of the intestines, in the uterus, in the liver, in the kidneys, even in the heart. The term malignant has been, although with no very settled meaning, applied to such affections, and most frequently to cancer and fungus hæmatodes, which, when once existing in any part, are imagined by some pathologists to spread to other parts, and especially to other glands, by absorption. It is at least certain that such diseases seem to extend themselves in succession from the structure first attacked. The cause is not so clear as the fact is certain. It may be, that a general predisposition existing to a specific form of disease, the absorption, which unquestionably takes place, of diseased matter, acts only by applying an irritant or exciting cause to other parts, as sufficient as other irritants, but not more sufficient than they, to disorder the glands through which it passes; and which glands, when irritated and disordered, run into the disease to which they are by original constitution predisposed. Or the disease may be simultaneous in many parts, although unequally advanced. With respect to tubercles, however, when they exist in other parts of the body than the lungs, it may, we believe, be always predicated that they will also be found in the lungs themselves, and in a more advanced state.

It is not to be forgotten, moreover, that the means employed to cure diseases are not always guiltless of producing others. Nearly every kind of medicine induces a temporary state which is really a state of disease, of which the intention and effect is to relieve diseases more serious or less controllable. The excessive employment, therefore, of any kind of medicine may induce permanent or at least serious disease. Thus drastic purgatives will bring on hemorrhoids; mercury will hasten the progress of phthisis; alkalies will irritate the digestive mucous membrane; and all the narcoties will obtund the sensations and cloud the intellect. There is the strongest reason to believe that many nervous affections are exasperated by the habitual employment of mercurial purgatives; iodine has sometimes caused more obvious nervous irritations; the nitrate of silver pro-

duces a permanent disease of the skin, limited, however, to an affection of its colour.

Old age, naturally impairing the vigour of every function, necessarily exposes every function to disorder from common causes. In the best constricted body, the failure of the human frame must begin somewhere. Even in those rare cases in which extreme old age seems to be borne without disease, there is commonly particular impairment of some function or other for some time before all the functions cease. Long before death, the diminution of muscular power generally becomes evident. A marked failure in the powers of the stomach is still more common. The inconveniences of this time of life have, however, been eloquently enumerated in the article AGE.

The terms applied to all these different causes of disease, and the arrangement of them, have occasioned much very useless dispute. It is time that such scholastic trifling should be abandoned. What was defined, we believe first by Gaubius, as the *proximate cause*, which when present constituted the disease, when taken away removed it, and, when changed, changed it, either means nothing, or means the first of the effects of the cause of disease.

Two things are plainly necessary for the production of disease; a cause which acts on some organ, and a disposition in the organ to be acted upon. Two kinds of causes, then, and two only, are plainly concerned in the production of disease: a cause which predisposes, and a cause which excites. This may be illustrated by the single instance of typhous fever. One man is affected with typhous fever, and his neighbours escape. The exciting cause of the fever is supposed to be something peculiar in the air. But his neighbours have been exposed to the same peculiarity, and are not affected with fever. We explain this by saying that his health was not previously good; that he was not in a state to resist the influence of the cause. This presumed disorder of his health was in this instance, then, the cause which predisposed him to the influence of the exciting cause of the fever. In the same way we see, of half a dozen persons simultaneously exposed to cold and moisture, one becomes affected with sore throat, one with pleurisy, and one with rheumatism; and the rest may continue well. The exciting cause was present to all, but a predisposing cause existed only in some, and was different in each of those in whom it did exist.

If we retain the term proximate cause, it signifies, in these cases, the pathological condition of the throat, the pleura, or the joints; but we think the term may be advantageously banished from medicine.

The chances and the characters of disease are always in proportion to the force of the exciting cause, and to the degree of the susceptibility to its operation. Of several persons suffering from what is called determination of blood to the head, one may have vertigo, another pain; one may have a fit of epilepsy, and one die apoplectic. The difference in the

effect may be occasioned by a difference in the power of the exciting cause, or in the violence of the determination; or, the determination being equally violent in all, the different effect may depend on the peculiar susceptibility of each.

There are certain cases in which disease appears to be produced simply by the application of an exciting cause, without the existence of a cause predisposing. There are others in which an exciting cause often seems to be wanting. These inconsistent phenomena, however, are to be ascribed to our imperfect knowledge of some of the causes. A violent burn, a wound, or other accident, will produce inflammation of various tissues, with no other predisposing cause than the nature of the human constitution. A child, in a particular condition of atmosphere, will become affected with whooping-cough or measles; and the predisposition is here also inherent in the constitution of the body. When the predisposition is removed, as in ordinary cases it is, by the occurrence of these disorders, the child may be exposed to the exciting cause, the peculiar condition of the air, with complete impunity. The cases in which disease seems to arise without an exciting cause are chiefly those of morbid formations, in which such cause exists in the supervention of certain actions not yet understood.

**FORMS OF DISEASE.**—Diseases, however various or complicated, or whatever are their terminations, admit of a division into two great primary classes; the first comprehending all *disorders of function*; the second all *morbid products*.

*Disorders of function.*—The view taken of this class by the general pathologist is one which is continually enlarging with the progressive improvement of physiology. Its leading features may be spoken of in connexion with the two most important systems of the body, the vascular and the nervous. Nearly every disordered action which can be conceived to exist must be intimately connected with some irregularity in one or both of these systems.

1. In the *vascular* system we observe, *a.* local determinations or local accumulations of blood, productive of an excess of supply, with excitement of the part supplied in excess; or congestion, with oppression of the part congested. *b.* Local defective supply of blood, producing or contributing to produce defective secretions, defective energy, external discoloration, and a tendency to other disordered actions. Of these may be mentioned as examples, defective supply to the breasts or uterus in feeble women; to the hair in old or sickly persons; to the brain and other organs in those convalescent from fever; and to the feet in diseased or aged persons, with a tendency to mortification. *c.* General excess of blood, or plethora; the results of which are very various: *e. g.* increase of natural secretions, exhalations, and the vigour of different functions; irregular actions; excessive growths; and, perhaps, other morbid formations. *d.* General defect of blood, or anæmia.

*e.* The state of the bloodvessels in inflammation, whether common or specific, as in croup, &c. *f.* The state or actions of the bloodvessels in misplaced and new formations, including altered conditions of the blood contained in them.

2. In the *nervous* system we equally observe excess, defect, and irregularity of distribution.

*a.* Local excess of nervous power; a state often accompanied with excessive sanguineous supply, but not invariably. To this excess of nervous power we cannot but attribute some of the instances of increased sensations and increased muscular actions in maniacal and hysterical persons. In the cases of increased secretions, increased absorption, increased nutrition, and increased evacuations; comprising the unusual flow of tears, or bile, or urine; the sudden disappearance of dropsical accumulations; hypertrophy of organs; diarrhœa, and excessive perspiration; a mixed explanation must be admitted: and in most of these circumstances, or perhaps in all except that of increased absorption, there appears to be a simultaneous excitement of the nerves and the bloodvessels.

*b.* So, also, the general excess of nervous power, or general nervous excitement, is not often seen distinct from excitement of the vascular system.

Either, first existing, seems to induce the other. The nervous excitement may, however, exist first, and therefore separately.

*c.* The general defect of nervous power is shown in the weary and exhausted, and in some forms of incipient paralysis. It is observed in many other instances, but generally coexisting with defective power of the vascular system. *d.* Local defect of nervous power is seen in persons affected with tremors, chorea, and partial paralysis; in idiots and lunatics, whose intellectual actions are weak, impeded, or disordered, whilst their digestive powers are often unimpaired or even increased. It is observable also in the sick, the feeble, and the aged, and is one of the most ordinary precursors of death.

The instances of deficient secretions, deficient nutrition, and deficient evacuations, are, as the reader will suppose after what has already

been said, to be viewed generally as the consequences of a simultaneous defect in the nervous and vascular actions.

If it be admitted that the action of the absorbents depends on the nerves, deficient absorption would in some instances appear to depend on defective nervous supply to the absorbent vessels.

It is highly probable that some of the disorders of the function of respiration depend on deficient actions in the respiratory nerves.

In some of the instances of chorea, as in tetanus, and in hydrophobic convulsions, the disorder of the nervous system probably consists of excess, or of irregularity, rather than of defect.

*c.* There is, apparently, a morbid condition of the nerves in all inflammations, and evidently in some, as in gout.

*f.* There are probably disordered nervous actions, in no degree yet understood, concerned in misplaced and in new formations, including altered states of the blood itself.

One very important example of general disordered action has been left out of this enu-

meration.

One very important example of general disordered action has been left out of this enu-

meration.

One very important example of general disordered action has been left out of this enu-

meration.

One very important example of general disordered action has been left out of this enu-

meration.

One very important example of general disordered action has been left out of this enu-

ration, namely *fever*. Its place must depend on the yet undecided question of its actual nature. The vascular and the nervous depression, and the subsequent excitement of both the bloodvessels and nerves, are sufficiently evident. But not only is the order of these phenomena yet undetermined, but their relation to a primary impairment of the vitality of the blood at least not disproved. For this reason we pass on to the *second* great class of diseases, or morbid products.

*Morbid products.*—These may exist in the solid or in the fluid components of the body. They probably seldom arise from disorder of one of the great systems without coexisting disorder of the other. In their characters they vary exceedingly, as will be made apparent by the following, which is still an imperfect enumeration of them.

*a.* The effects of simple determination of blood, or local excess, which seem to be not only in many cases an increase of natural discharges, but alterations in their properties. These have not been very closely investigated. The sudden, profuse, and watery discharge from the mucous membrane of the nostrils incidental to some individuals from slight causes, and distinct from common coryza, affords an example of this class; and sudden evacuations from the skin, or bowels, may be also mentioned. The redundant growth, or hypertrophy of organs, demands, for one of its accompaniments, or rather one of its causes, this increased determination of sanguineous material; but such departures from the natural state should perhaps be classed in another division (*c*). Active hemorrhages are another consequence of increased determination to particular parts.

*b.* The effects of inflammation;—serum, lymph, false membranes on serous surfaces, pus, thickenings of parts by intestinal depositions, gouty concretions, the diphtheritic formations on mucous membranes, as in croup, and in inflammation of the mucous lining of the intestines or the vagina; and the peculiar matter found in scrofulous glands.

*c.* Natural secretions or formations misplaced;—bone in soft parts, as in the membranes of the brain, in the heart, in the bloodvessels; fat about the heart, or in the substance of the liver; misplaced fibrous tissue, cartilage, cellular tissue, hair, nails, serous tissue (in certain tumours, *Bichat*), mucous tissue (in fistulæ, *Hunter*), enamel (in some diseases of the joints), synovial membrane (in false articulations), arteries, veins, and nerves (in some tumours). These misplaced productions are often imperfect. They do not necessarily endanger life, although they are often inconvenient, and sometimes dangerous, in consequence of their situation or the size to which they attain. In certain cases they are formed for the preservation of life; as in the case of the fibrous masses formed in aneurism, and of the cysts or boundaries of abscesses.

*d.* Altered secretions;—soft or fragile bone; acrid bile; the disorders of the urine accompanying calculous formations.

*e.* New formations, not the product of inflammation. In this class may be placed the various tumours—common, adipose, pancreatic, mammary, and tuberculated sarcoma; and encysted and osseous tumours; all of which are of a local character, and many of which coexist in some instances, as in certain enlargements of the ovaria. To these must be added the more serious formations connected with some taint or fault in the constitution; as scirrhus, tubercles, scrofulous enlargements, encephaloid tumours or fungus hæmatodes, and melanosis. Hydatids, worms, diseased exhalations, (as ascites, in disorder of the liver,\*) and changes in the nature of the blood itself, belong also to this class; and also the calcareous productions found in the lungs and bronchial glands. Many of the products under this head are dangerous to life. Reacting on the imperfect constitution in which they have originated, they occasion fever, various functional irregularities, emaciation, and death. They are frequently accompanied by inflammation, the supervention of which appears to accelerate their progress; but in their origin, in their first symptoms, and in the wide difference existing between them and the ordinary products of any of the forms of inflammation which are the results of accidents, or can be excited by artificial means, we have so many reasons for ascribing them to processes quite distinct from the inflammatory process.

*THEORIES OF DISEASE.*—These observations bring us immediately to the great question of the *origin* of these important departures from health; not only as regards the new products of disease, but the misplacements and excess and deprivation of some of the natural products; the solution of which cannot precede the determination of some unsettled questions, in physiology. When the laws and processes of secretion are clearly demonstrated, the next step will be an accurate knowledge of the diseased actions in which morbid products originate.

The alterations occurring in the fluid parts of the body, but particularly in the blood, which once attracted so much attention as to be the general basis of a pathological system, have recently, after experiencing the capricious neglect to which many doctrines containing much truth have at different periods been subjected, again drawn towards them the anxious attention of philosophical physicians. (See the article *BLOOD*.) The vital and, as it were, independent properties of the blood are no longer overlooked, and the important office performed by this fluid in relation to the secretions, an office extending beyond the mere supply of a material for their formation, directs the inquiries of the pathologist towards those intimate changes which, taking place within the arteries, or even in organs contributing to the unexplained function of the hæmatisis,

\* In a case of hypertrophy of the heart, the patient's perspiration tinged his linen, and the lining of his hat, of a red colour.

are the real causes of the singular and abnormal products presented by various diseases. Thus we may in the present time perceive the dawn of a new humoral pathology, more correct, and at the same time less exclusive, than that which from the age of Hippocrates down to nearly the end of the seventeenth century prevailed throughout all the schools and doctrines of medicine. Without reverting to the dreams of the mathematical physicians, the doctrine which ascribed so many of the phenomena of disease to the *moving powers* will not be discarded; and even the first changes traceable in the blood itself may be acknowledged to depend upon irregularities in actions of which the very existence is yet in the utmost degree obscure.

When it is considered that five-sixths of the materials of the body are fluid; that all the materials even of the solid parts primarily exist in a fluid state, and are again reduced to fluidity before their ultimate removal; it is quite in vain to deny the importance of paying attention to diseased states of the fluids. But physiology teaches us that the formation of the fluids depends, no less than that of the solids, on certain preceding actions, and that the disturbance of these actions is often known to be, and may probably always be, antecedent to the diseased condition of the fluid parts.

In some circumstances the blood is seen to be so suddenly deprived of its vitality, that the primary impairment of that vitality in other cases where there is a long series of morbid phenomena, becomes exceedingly probable. When death is occasioned by lightning, by a violent blow, or by the poison of a rattle-snake, and sometimes even by the unknown poison which produces a sudden and violent attack of fever, in which the patient dies without reaction; the most palpable disorder is effected in the blood itself, which is found to be deprived of its natural and vital properties. The change in these cases is so instantaneous, that even if we admit an antecedent change in the nervous actions, we admit what we are at least unable to demonstrate. Recent observations have made it highly probable that in a severe attack of the spasmodic cholera, the serum and some of the saline constituents of the blood are forcibly separated from the red globules.

In the instance of melanosis, some pathologists have considered the black formation to be a deposit from the blood, which has previously undergone some peculiar change. The growth of polypi may perhaps be attributed to some change by which the fibrine is separated from the blood.

In other cases, where the duration of less violent phenomena is more prolonged, as in the case of eruptive fevers, we have every proof of the action of the first cause of the disease upon the fluids. In the small-pox we are enabled to communicate the disease directly through the blood to the whole system.

The great respectability of the authorities which might be ranged on one hand as supporters of the doctrine of fever being pro-

duced by an atmospheric poison acting upon the blood;—and, on the other hand, as supporters of the doctrine which, admitting the sanguineous changes and their consequences, assert the primary action of the febrile poison on the nervous system;—very forcibly shews the difficulty of determining the question by observation, and in the present state of physiology, of unravelling the intricate implications of the nervous and vascular systems in the performance of healthy, and consequently of diseased actions. Any one acquainted with the present state of medical science, and possessed of some share of ingenuity, might construct a plausible theory by attaching himself to either one or the other of these great systems. The more palpable indications of disorder, although that disorder is often but reaction, would probably cause the number of those espousing the *vascular* theory to be the most considerable; whilst the undefined limits of nervous influence would give to the *nervous* theory all the advantages to be derived from bold and unrestrained conjecture. In the mean time, a true and permanent doctrine would still be eventually found to lie between these extremes, and to be founded on the triple basis of cotemporaneous disorders of both the great systems, and on the occasional primary affection of either one or the other.

At no period since the first cultivation of medicine have physicians ever been so free from any predominant and absorbing theory of diseases as at the present time. So great, indeed, has been the zeal with which facts and cases have been collected, that the age is somewhat open to the reproach of having reasoned upon them too little. Yet, when it is considered how indispensable to a correct system of pathology is a previous enlargement of certain parts of physiological science, it ought to be matter of praise rather than of censure that the physicians of the present day so much abstain from premature conclusions. When the physiologist can explain the formation of the several secretions from the blood, and the workings of the fine apparatus by which these formations are effected, and new parts formed, while old parts are carried away;—when the relative dependences of the nervous and the vascular systems are determined, and the chemistry of the animal fluids in disease as well known as is that of their normal state, then, and then only, will the doctrine of the intimate nature of diseases become exact.

One or two of the general theories of disease, however, which have been prevalent since the commencement even of the present century, may be alluded to. A great majority of the pathologists of this country, who ascribe disease to disordered actions, for a time adopted the views of the late Dr. Parry, of Bath. He was a physician of great talents and great industry. Amidst the fatigues of a large practice, and many interruptions from ill health, he found time to make observations upon almost every form in which disease presents itself; and he proceeded a considerable way towards forming these observations into

a great system. Perceiving the error of the older practitioners, who, in their attention to nervous phenomena, overlooked their frequent dependence on vascular disturbance, he rejected, most certainly in terms too positive and unqualified, all idea of a nervous theory, and looked for the origin of almost all diseases to some irregularity in the powers which move the blood. This theory was actually applicable to so many and such severe affections, not a few of which had been previously misunderstood and very erroneously treated in practice,—and it was moreover so specious and so convenient, that it promised fair at one time to be universally adopted. There were few forms of disorder in which it seemed very difficult to admit, either that the impetus of the blood in the organs chiefly affected was morbidly increased, or, without general disturbance of the circulation, the tonicity of the arteries proceeding to such organs was diminished, their elasticity preponderant, and their resistance to the usual momentum of the current of blood morbidly decreased. In either of these cases, one of which was often capable of demonstration, whilst the other always admitted of supposition, and not unfrequently existed, the morbid phenomena present in each case were ascribed to undue determination of blood.

Of many diseases the first palpable phenomena are affections of the vascular system. But that there are morbid actions in which, even when visibly increased or disordered vascular action is present, it is but an accompaniment, however inconvenient and even hurtful, is sufficiently evident. The mere disorder in the circulation will not account for the various morbid processes incidental to the serofulous constitution, or for many of the affections of the digestive, respiratory, mental, and other functions. With all our respect for Dr. Parry, and there are few authors for whom we entertain a respect more sincere, it is impossible to go along with him, when, as if to shew his theory in the most disadvantageous point of view imaginable, he speaks of “that increased determination of blood to the lower extremities which constitutes gout.”\*

We cannot, in short, possibly exclude the idea of a peculiar constitution of nervous substance, or modification of nervous action, although such constitution and modification are only perceived by certain effects for which no other satisfactory cause can be assigned. If such a pathology be still imperfect, it is only so because physiology is circumscribed. When the nature of that nervous power or influence is understood, which in one part of the nervous substance effects motions in other structures, in another part permits sensation, in another volition, in another the internal sense which governs some of the most important animal processes, and in another all that we call intelligence, then may the pathologist presume to hold a bolder language,

for he will then advance to facts with which he is at present quite unfurnished and unaided.

In the mean time, the pathological connexion between the two great systems, of which illustrations have been already given, are even now not neglected in practice. The relief of some nervous disorders is attempted, and often effected, by means acting primarily on the vascular; as in the case of hysteria, in which venesection is so frequently more serviceable than any of the means which are considered to act immediately on the nerves. There are cases of inflammatory disorder in which the best auxiliaries of bloodletting are sedatives, which seem simultaneously to allay nervous and vascular irritation. Attempts are alternately made to check the progress of morbid formations, as of scirrhus, by lessening the supply of blood to the part affected, and by soothing the nervous system. In phthisis pulmonalis, we endeavour to decrease the general momentum of the blood, or the irritability of the heart and arteries, without repeatedly lessening the general quantity of the blood; and the means employed, as, for instance, the digitalis or the hydrocyanic acid, seem to act on the whole vascular system by first acting on the whole nervous system. These are so many exemplifications of a liberal and philosophical theory of diseases, which, without being formally avowed, appears to us to have been acted upon for many years past, in this country, in a variety of disorders. It is not displeasing to observe with how little pomp such a system has gradually spread its rational influence over British practice; its unpretending character arising apparently from its being little more than a reflection of undeniable facts.

The strong disposition of the human mind to rest and generalize after the fatigue of acquiring or observing a limited number of facts, has even divided into at least two sects those who ascribe disease to disordered actions; and these, adopting a nervous or a vascular theory, are only distinguished by the particular position they have selected, by the particular facts or phenomena on which they take their stand, and which they believe in every case of disease to precede all the rest. A few, and but a few, of the distinguished teachers on the continent yet cling to the assertion that all disordered actions must be preceded by organic or structural change; an assertion implying too complete a reversal of the order of observable phenomena to require any discussion. But a much larger sect is composed of those who ascribe all morbid phenomena, all disease, all structural change or new formation, all disordered action, to some shade or other of inflammation; rather, it is to be apprehended, from a misapplication of language, and the too licentious extension of the term inflammation, than from a real and unqualified proselytism to so sweeping and unphilosophical a generalization. Another sect, the followers of M. Broussais, whose talents, unbounded confidence in himself, and vehe-

\* Elements of Pathology and Therapeutics, cccclvi.

ment eloquence, have attracted some and scared others to swell the number of his disciples, acknowledge no other origin of the most remote diseases than disordered action, irritation, or sub-inflammation of the mucous lining of the intestinal canal; a plausible doctrine, resting on numerous facts, and largely intermingled with truth, but which becomes useless or unsafe when it is made universal.

But whilst almost all the schools of Europe, and we may add of America, have been distinguished by a calm and philosophical spirit, averse to mere hypothesis, and little addicted to implicit adoption of the tenets of any single master—*nullius addictus jurare in verba magistri*,—a sect has arisen in Germany, chiefly consisting of men whose enthusiasm far outruns their powers either of observation or of reasoning, and embodied under the appellation of Homœopaths. To omit all notice of this sect might be considered improper in so general an article as the present; yet to speak of their opinions and practice without departing from the ordinary style of medical discussion is somewhat difficult.

Not without the credit of having pointed out some unnoticed circumstances connected with the administration and effects of medicines, and even deserving of some praise for having enforced a few salutary maxims of diet and of regimen; the founder of this sect, Dr. Samuel Hahnemann, surpasses all the heads of all the sects that ever flourished, or that have been forgotten, in the boldness of his assertions, the careless extravagance of his deductions, and the scorn with which he regards all whom he fails to persuade.

According to the doctrine thus presented to the hitherto deluded followers of physic, the art of curing diseases consists of the employment of medicines in each case, which, in a person in good health, would produce a similar disease. There is, we think, an ancient proverb which comprehends the grand principle of homœopathie, "what will cause a fever will cure a fever;" a doctrine which appears, at first sight, hardly more reasonable than if one were to say, what will make a man drunk will make a man sober; or, what will break a man's leg will set it. Although, as is the case with any assumed general principle, a few specious facts may be quoted in support of it, or its truth may be admitted in a very limited number of instances, no one who reflects on the methods now, by universal consent, adopted in the treatment of the large and important classes of febrile and acute inflammatory disorders, can fail to perceive that a principle from which these and all surgical diseases must be excluded, has no claim to be looked upon as general. It can be no matter of surprise that a mind which can calmly entertain such a delusion, should believe that medicines daily used with the effects desired in using them would be more useful, nay, more energetic, if employed in doses a million, a trillion, or a decillion times more minute. Even of this extraordinary diminution of dose,

and of its good effects, some examples may be adduced, which all must admit—that of mineral waters, for instance, although we are not sure that Hahnemann has availed himself of it. But, in this case, small doses are useful where larger doses of the ingredients of the water would be positively hurtful; and there is something, too, in the chemistry of nature not yet perfectly imitated by art. In many of the cases appealed to by the homœopathist, (mercury, henbane, &c. being employed,) larger doses are given daily and with the best consequences, and in the same description of cases in which the followers of Hahnemann would divide a single dose into portions sufficiently numerous for all the patients in all the hospitals in the world. Still the narrow principle is again admitted, as universal, undeniable, and now first revealed to mankind. Precisely the same kind of reasoning pervades the homœopathic doctrine of *chronic* diseases, *all* of which are ascribed to syphilitic taints or to some form of cutaneous disorder: thus adding another to a thousand previous instances, that in the circle of diseased actions any separate portion may be fixed on as the universal beginning by those whose defective sight is confined to that portion.

The reception of such doctrines, even by a few individuals, in any country where the reasoning powers are not utterly neglected, can but be regarded, to use an expression which the late Dr. James Gregory used to apply to such follies, as a pitiable proof of the ignorance and credulity of mankind. No one will think such censure unjustly applied to the Homœopaths, if he recollects, that without disputing concerning the examples which they bring to support their great principle of curing by resemblances, its absolute admission would dictate that ardent spirits should be given in phrenitis, in gastritis, and in cystitis; opium in lethargy and coma; turpentine in irritable states of the urethra, and aloes in painful hemorrhoids; and that the only defence to be made against the accusation of merciless and even fatal practice in such cases, rests on the tenfold greater, although less dangerous, folly of giving the ardent spirits in doses of five hundred parts of a drop, and the turpentine and aloes in doses of the millionth part of a grain.

#### RELATIONS AND CONVERSIONS OF DISEASES.

—Dismissing the subject of general theories of disease, it belongs to the general view of the laws which govern morbid actions, to notice the singular relations which exist between affections of different parts of the body, and also the conversions of diseases which are sometimes found to occur.

These may be viewed in connection with the vascular or the nervous system. The relation and conversion of diseases dependent on a state of plethora are so commonly observed as to be known to all practitioners. Such a condition not only disposes to all inflammatory disorders, but may induce the especial embarrassment of any single organ without inflammation; as, in the lungs, asthma or pulmonary apoplexy; in

the brain, lethargy or cerebral apoplexy. Combined with a predisposition or susceptibility of the nervous system, it may concur to the production of gout or of mania.

As regards the relation of affections of the nervous system, we see whole families—every member exhibiting the family susceptibility, but each in a different manner, either from different portions of the nervous system in each being inadequate to healthy actions, or peculiarly affected by the circulating system. Eccentricity, excessive shyness or timidity leading to seclusion, chorea, epilepsy, amaurosis, mania, and other nervous affections are very commonly observed thus associated by the bonds of relationship, giving as distinct a character to large families, as the most peculiar external features of resemblance transmitted by inheritance.

New directions given to certain portions of the blood, together, probably, with a transference of morbid actions in the nerves, may cause not only the conversion of gout to mania, already mentioned, but of erysipelas of the scalp to phrenitis, or of erysipelas of the trunk to sub-inflammation of the intestinal coat with diarrhoea. The sudden repulsion of some of the disorders of the scalp in children, as of porrigo, is not unfrequently followed by meningitis. The sudden recession of the cutaneous efflorescence and inflammation in rubeola, scarlatina, or variola, is commonly followed by inflammation of the lungs, or the bowels, or the brain. The supervention of an affection of a new organ, or the subsidence of a similar disorder of an organ primarily affected, is usually termed *metastasis*; among the most familiar examples which may be mentioned, is that of rheumatism, in which the articular affection, when it suddenly ceases, is not unfrequently followed by inflammation of the pericardium, and even of the heart itself.

Irritations of the nervous system, of which the actual nature is very obscure, but the effects are very serious, may now and then be observed to succeed each other either by natural conversion, or in consequence of means employed for the cure of that which first existed. The most striking case of this kind which we ourselves have witnessed was that of a lady, who had been for several years affected with melancholia without any discoverable cause. When all the resources of ordinary means and medicine had been unavailingly exhausted, she was persuaded to try the prescriptions of an irregular practitioner. By his advice she persevered for some time in the use of the corrosive sublimate, together with large doses of the sulphuric acid. The mental depression gave way whilst she was taking these medicines, somewhat, as may be supposed, to the discomfiture of those who had vainly attempted to produce the same good effect. In a very short time the same patient began to complain of pain referred to the back and loins, of a burning character, at first occasional and not very severe, but which gradually became heightened to the extreme of human agony. Medical and surgical skill were fruitlessly exerted even to give tem-

porary relief, and no means seemed for a moment to suspend the malady, or to give the faintest hope even that the principle of transition or conversion could be brought into operation for the patient's benefit. Her sufferings were unintermitting, except during short and broken intervals of sleep, for nearly two years: the lower extremities became powerless, then contracted, then inflamed by contact; and these complicated afflictions only ended in death.

The most singular transitions of nervous irritation are exhibited in hysteria, in the course of which the most severe inflammatory affections are sometimes simulated in succession.

The inconveniences following the removal or cure of chronic diseases are often such as to make the propriety of endeavouring to put an end to them somewhat doubtful. After the cure of a chronic diarrhoea by metallic astringents, we have noticed the re-appearance of scrofulous ulceration of the skin; and in a case in which this had occurred, and the ulceration was healed by a desperate quack, symptoms indicative of pulmonary tubercles immediately appeared, and death ensued. The same phenomena have often been known to follow measures calculated to repel enlargements of the cervical glands. We have many times observed the supervention of various inconveniences on the disappearance of chronic or habitual coughs. The cessation of gout, or the suspension of hemorrhoids, has often been followed by epilepsy or by asthma. These accidents, of which a long list might be given, prompt a very important indication to be observed in the treatment of all such affections, which will be dwelt upon in the article *MEDICINE, PRACTICAL, PRINCIPLES OF*.

Occasionally there is a translation of diseased exhalations or effusions. Anasarca will subside, and œdema of the lungs will follow. Hydrothorax or ascites are sometimes much relieved by dropsical swellings occurring in the extremities. General dropsy has come on after the cure of ephidrosis, both affections seeming frequently to be meant for the relief of plethora.

Some affections are suspended during pregnancy, apparently in consequence of a converted determination from the part disordered to the uterus. The instance of phthisis has frequently been observed; and we have noticed remarkable examples of it in obstinate and extensive psoriasis. It is curious that the determination to the mammae during lactation does not prolong the benefit; a fact which common observation confirms as regards consumption, and which we have equally noticed in the example of eutaneous disease. The object of the law of nature here exemplified seems to be the preservation of the species, which after parturition may be vicariously performed.

*MODIFICATION OF DISEASE BY TEMPERAMENT.*—Other modifications of disease arise from what are called *temperaments*: they modify the predisposition to receive disease from the several *causes* which have been mentioned; and they modify the course of disease when it is excited by any cause. The term temperament, however, founded on an ancient doctrine of four

humours supposed to temper each other, but long employed without reference to the theory in which it arose, and often with a vague and unsettled signification, is among the inconveniences of medical nomenclature, which so many have prided themselves on deforming by new additions of barbaric jargon, and so few have attempted to purify and improve. The *sanguine* temperament (indicative of the predominance of the sanguineous system), the *choleric* (or bilious), the *phlegmatic* (or pituitous), and the *melancholic* (or atrabilarious), are designations which, however frequently and familiarly employed, convey little precise meaning, and that little not always correct. The sanguine temperament is supposed to be characterized by a full habit, a soft skin, a ruddy complexion, red or auburn hair (the *flavus* of the Romans, and what the Scotch still call yellow-haired), a frequent pulse, large veins, and vivid sensations. The melancholic, on the contrary, is described as existing in a firmer frame, and thinner, with a dark skin, black hair, and a slow circulation: the nervous system is less easily moved; the disposition is grave and meditative (*meditabundus*, Gregory, in *Conspect. cap. xxiii.*), and the affections are fervent and steady. Intermediate between these is the choleric. But the phlegmatic differs from all in the laxity of the skin, the paleness of the face, the lighter colour of the hair, and the greater sluggishness of the faculties of the mind.

It is unquestionable that this ancient division must have been the product of extensive and delicate observation. It is even possible that when the varieties of men were less mixed, the temperaments, some of which continue the characteristics of nations, were less frequently blended. At present, all attempts to limit the inexhaustible varieties of temperament, compounded, it may be, of so few and such simple elements, is as unsuccessful as to comprehend within the bounds of a few descriptions all the variety produced by the different associations of the few features of the human face. However interesting, therefore, a recollection of the temperaments may be to him who speculates on the varieties of human character, it now affords little help to the practitioner of medicine, and a consideration of their divisions may advantageously give place to one which has the recommendation of being at once more simple, not less comprehensive, and more easily admitting every diversity.

There is an evident difference in the susceptibility of different individuals to external and internal, to bodily and mental impressions; and this susceptibility, to the expression of which we would in medical language limit the word temperament, may be, and doubtless sometimes is, uniform throughout the whole individual frame of body and mind. But it is so often irregularly distributed, and so often variously limited in different individuals, so liable also to transitory and permanent increase or diminution from various accidental causes, that it requires, for any useful pathological or therapeutic end, to be regarded with little or no reference to an arbitrary division admitting only

of complete individual varieties. From the original or constitutional excess or defect of susceptibility to one or more, or all the impressions which the mental and bodily frame is intended to feel, arise various diseases, and the diseases affect, for the same reason, a particular course. The susceptibility may be so increased, that common light, common air, common sounds, common food, common occurrences, cannot be tolerated: it may be so diminished that these circumstances do not affect the senses on which they are intended to act. But the susceptibility may be partial; increased at one time, diminished at another—increased in one organ, and not in others; diminished in some organs, and in others increased.

To this kind of susceptibility the practitioner is required to pay much attention, in order to discover the tendency in his patients to particular forms of disease, and the consequent propriety of pursuing particular methods of cure. The occurrence of disease in any organ commonly, for a time, increases or diminishes its susceptibility to ordinary impressions. Thus, after fever, the brain and the intestinal canal occasionally remain for some time irritable and intolerant of all impressions, and in other cases for a long time inert and torpid. The disease of some organs induces or is connected with peculiar states of susceptibility in others. During the progress of tubercles in the lungs, the irritability of the heart is very conspicuous, and that of the bowels is not unfrequently fatal. In morbid states of the brain the stomach is sometimes irritable, and vomiting is a symptom; and sometimes in a state so completely opposite that powerful emetics will not rouse it, and food is obstinately refused. In the same individual we may see the mind excited, or exhibiting, if we revert to the old terms, the peculiarities of the sanguine temperament, and the stomach, bowels, and skin decidedly phlegmatic; and to such cases no general term can correctly be applied. All these varieties of susceptibility undergo modification by climate, by diet, by excessive evacuations, by the neglect of exercise, by exclusion from pure air, by mistaken habits as regard clothing, and by other causes of which the importance is fully shewn in the article *EDUCATION, PHYSICAL*, to which the reader is referred for many particulars which could not properly be here introduced. Modifications, both as respects the whole body and particular parts, are effected by age, and are noticed in the article under that head already referred to.

Generally speaking, there exists in women a greater degree of susceptibility to impressions than in men; and this is very often observed in that degree of excess which constitutes what Dr. Cullen called *mobility*, and which is the affliction of the greater number of those who are termed nervous patients. These are the individuals who feel all the impressions of sense with almost painful acuteness: they long retain, and vividly recal, the impressions of music and of painting, except when new objects excite them, and therefore longest in the dark; and they are prone to hysterical affections, as va-

rious as the sensations and actions can be which may be associated with morbid conditions of all the various parts of the nervous system. (See Hysteria.) The importance of being acquainted with the modifications of disease in a temperament of this kind is very great indeed. Such patients are not only more readily affected by disease, but by remedies, than other patients. Soon reduced to apparent weakness, the same facility of being acted upon by various stimuli occasions their recoveries to be often equally sudden, and to the inexperienced practitioner surprising. Both the prognosis and the treatment must be regulated by these circumstances. Violent medicines will do the patient harm and him discredit. The pale, languid, feverish, irritable, complaining patient of to-day may before to-morrow be converted, by the unexpected visit of a friend, into a patient no longer submissive to physic, or mindful of slight ailments, but anxious to return to all the amusements of a dissipated life. In proportion as there is in the male sex an approach to this mutable susceptibility, the practitioner must expect the same results, and observe the same caution.

*VIS MEDICATRIX.*—The signification and value of the different symptoms and signs of diseases are treated of in the articles *PROGNOSIS* and *SYMPTOMATOLOGY*. There is, however, one view of symptoms in general which especially belongs to the general subject of disease; namely, their frequent indication of that power in the system to which has been given the appellation of a *vis medicatrix natura*. This curative power or property, although the idea of it may have been pushed needlessly far, and rendered somewhat too material, is an undoubted existing property of the living animal body. It is this which Van Helmont personified as the archæus, or grand regulator, whose throne was the stomach. It is what Wepfer called the president of the nervous system: and we do not see that Stahl went beyond them when he referred the government of the body “directly and entirely to the rational soul,” diffused, however, over the whole body.\*

The truth is, that we have daily proofs of there being a power in the constitution to repair injuries and restore lost parts; and that several actions which we call disease are instituted to get rid of the causes producing them. Nor is there any necessary extravagance in the supposition that the possible intention of all may be so. The law may perhaps be said to be analogous with, or conformable to, the law of which natural philosophers have gained a knowledge by induction from various phenomena; that all *action* is followed by *reaction*, equal to, but different from, the primary action.

If a bone is broken, if a muscle, or tendon, or even a nerve is divided, the divided ends are reunited. If a portion of substance, as of the skin and cellular membrane and muscle, is lost, or cut out, the deficiency is repaired, and

the cavity built up by granulations from the bottom, and at last covered in by new skin. If a part removed is without much delay re-applied—a tooth, the tip of the ear, a finger, a part of the nose,—it becomes firmly united in its original situation. So anxious, if we may so speak, is nature to preserve the life she has given, that wounds of the most important organs will cicatrise; wounds of the lungs, of the heart, of the intestines, of the bladder, of the uterus, even of the brain.

Dr. Parry enumerates among salutary processes, reaction, shivering, convulsions, bodily exercise, tears, sighing, gout, dyspepsia, fornicatio, vertigo, convulsions, fever, loss of appetite, and wasting. The propriety of including some of these may appear questionable; but illustrations of the salutary effects of the greater number will so readily present themselves to those familiar with pathological phenomena as to require no further observation. Many cases of conversion of disease are, of course, to be referred to the same head.\* Viewing the principle in its widest extent, it may be said to be first exemplified in the convulsions of infancy; and it is exhibited for the last time, and ineffectually, in the convulsions so often preceding death.

There is a kind of consolation, not unattended with a hope of the final extension of medicine far beyond its present powers, to be derived from observing that even diseases of a most fatal character evince a conformity, as it were, to the same great curative and preservative law. The whole series of changes in the tubercle are but so many efforts to dislodge and eliminate it from the lungs; the process is attended with irritation, and by long continuance, or rather by constant repetition, it generally ends in death. A similar process prevails in cancer, and is sometimes, although rarely, more happily effected. Calculi in the bladder occasionally become enveloped in pouches of the lining membrane, and irritate the patient no more; and sometimes escape by ulceration into the rectum or vagina, or through the abdominal integuments.

There can be no difficulty in admitting these indications of the *vis medicatrix nature*, without referring them to anything more than an internal sense, which the preservation of existence did not require to be of the same nature as what are called the external senses. It would be hardly necessary to allude to the more material character given to this power, if the physicians who were most disposed to invest it with personal properties and dignity, had not, as a natural consequence, become too scrupulous about opposing it, even to the extent of curing all diseases by what the French have called *expectation*.

The proper advantage of acknowledging such a power is, that it prevents indiscriminate and officious meddling,—that *medicina perturbatrix* which incessantly contradicts even the best

\* See *Hoffmann*, *Commentarius de differentia inter Hoffmanni doctrinam medico-mechanicam et G. E. Stahlii medico-organicam*.

efforts towards a natural cure. In the modern practice of medicine and surgery, the *vis medicatrix naturæ* is seldom disregarded; but its suggestions are not followed without discretion. Seeing the intention of its working, it is yet often seen by the practitioner to work in a dangerous manner, and too much by a general rule; sometimes too abruptly, and sometimes after too lingering a manner. The object of art is to adapt the rule to particular instances; and the greatest wisdom of the practitioner is shewn in determining when to wait upon nature, when to rouse her to exertion, when to moderate those exertions, and when to put an absolute stop to them.

When a bone is broken, the body being previously in full health, the *vis medicatrix naturæ* is soon in full activity; the whole restorative force is called out. The vascularity, the heat, the vitality of the surrounding parts is increased; and inflammation ensues. But it is often necessary to moderate this zeal and haste of nature; to lessen the superfluous excitement, leaving only that degree of it without which the repair cannot proceed. Among savages the natural power of healing is so perfectly exercised, that it is said the most frightful wounds will heal without surgical aid. On the other hand, a patient of infirm constitution or disordered health becomes subject to some local congestion; or some accidental and trifling injury brings a part of the integuments into a state of chronic and inactive disease; and the *vis medicatrix naturæ* is not exerted until the obstacle to its exertion, the disordered state, perhaps, of the digestive organs, is removed by alterative medicines: but that done, and a wound or abrasion, which had remained stationary for weeks, instantly puts on a new character; secretory and absorbent processes are at once commenced, and the cure is soon completed.

We see, too, in the case of a patient alarmingly lowered by an attack of fever, the nervous energy sunk, the power of the heart diminished, the digestive function almost annihilated, the respiration laborious and feeble. Nature, unassisted, will undoubtedly try to make this patient rally: but if the trial is successful, it can only be so in the course of many weeks, perhaps many months; and the body and the mind will long continue to suffer, or perhaps never wholly recover. Often, after a succession of attempts, the patient sinks at last. But we know, that by stimulants and tonics judiciously administered, we can rouse the powers of digestion, and reanimate the whole frame, in less than half the time and with less than half the danger.

Whilst, however, we seriously consider the design of nature in any malady,—whether she is working, and how she is working, and how the machinery will endure the process she has set up—we should still, having to treat diseases as they occur in civilized life, never trust entirely to the *vis medicatrix naturæ*, except in the case of the most trifling injuries, where a process of very small extent is all that is required for the cure.

The natural powers of healing and recovery are in many cases strongly influenced by peculiar mental states. The same emotions and passions which redden or blanch the cheek, which affect the cutaneous and renal functions, or those of the stomach and bowels, can also promote or retard the activity of the *vis medicatrix naturæ*. Confidence of recovery often conduces to recovery; and extreme despondency concerning the tendency of a disease sometimes leads to a fatal result. This is very conspicuous in some affections, as in fevers; and has often been asserted to prevail in malignant disorders, particularly in cancer: and some practitioners are consequently inclined to place implicit reliance on the prognostics in which their patients are disposed to indulge. But the example of phthisis, which is in that respect not singular among chronic disorders, may serve to shew that confidence may be even a part of the disease, arising from a morbid condition of the sensorium: and we have attended patients in lingering forms of fever, which ended happily, yet throughout the whole course of which it was impossible to excite a ray of hope in the mind of the patient. In some cases the cessation of the fever induces a deep but temporary despondency of recovery. Even with these exceptions, the influence of the mind over disease should never be overlooked by the practitioner; nor should he forget to inculcate that this influence of the mind, like all the mental actions, may by firm endeavours be to a great extent subjected to the will.

ACUTE AND CHRONIC DISEASES.—The different period required by different disorders, unassisted by medicine, for the production of a natural cure, or, in fatal cases, for the destruction of life, has long been the occasion of a general division of diseases into *acute* and *chronic*. Acute diseases are commonly attended with severe and obvious symptoms; whilst chronic disorders are usually less marked, and attended with less suffering. To these distinctions there are, however, exceptions. Diseases of short duration, and in their effects destructive, are sometimes attended with few symptoms of the mischief they are effecting in the brain, in the lungs, or in the intestines; and diseases slow in their progress are often accompanied with sufferings of a very severe kind.

In acute disorders there is, except in rare instances, warning sufficient to guide the practitioner; but in chronic diseases the most extensive injury sometimes proceeds undiscovered until the discovery is useless. Acute inflammation, for instance, can seldom be overlooked; but chronic inflammation is frequently unnoticed until some of its worst effects on structure have been wrought by long continuance. It is no less essential to the physician than to the surgeon to be especially mindful, in all obstinate maladies, of the possibility of serious disorder.

PERIODICITY AND CRISES OF DISEASE.—But there are also diseases, acute as regards their severity, and chronic as regards their

duration, which are what is called *remittent* and *intermittent*. The symptoms arise and decline in a certain series and in a certain time; then disappear, and after a certain interval are renewed. The class of fevers remarkably exhibits all the peculiarities of remission and intermission; and these will be described under the head of FEVER. In this general view it may be sufficient to mention, that in our common continued fevers there is generally once, and sometimes twice, in the space of twenty-four hours, an observable remission or marked alleviation of the febrile symptoms. It is, however, in many cases not very striking; and it is always less striking in this country than in those fevers of warmer climates to which the observers have agreed to give the name of remittents. In one class of fevers, sufficiently familiar to the practitioners of marshy countries, the remission is so marked and of such continuance as to be denominated an *intermission*. Each paroxysm of an intermitting fever or ague has a precise beginning, middle, and end, with an unquestionable cessation for a time, after which a new paroxysm is commenced. The intermission is never of less length than some hours; it is often twenty-four, and not unfrequently forty-eight.

Not, however, in fevers alone have these well-known but unexplained circumstances of intermission and remission been observed; diurnal remissions are distinguishable in every attack of inflammation. There are periods of the day or night in which the symptoms are less severe, and other periods in which there is an exacerbation. Even some inflammatory affections are intermittent, of which, perhaps, rheumatism is the most frequent example; although pleuritic and other inflammations have been described as assuming the same character.

An intermittent form of attack may very commonly be observed in many of the disorders usually called nervous or spasmodic; as in hysteria, epilepsy, and nervous asthma. Close observation will occasionally detect regularity in the attacks of epilepsy, where slight inquiry would not cause it to be suspected. We have sometimes found the alternate fits corresponding in point of time, and the paroxysms very nearly observing two distinct periods; so as to be somewhat analogous, only with much longer intermissions, to what is called a double tertian. The same intermission, more or less regular, and often with considerable intervals, prevails in a great number of cases of maniacal affection.

The intermissions in these instances appear sometimes to be associated with periodical changes, not appreciable except in their effects, in the nervous system itself. At other times there is a manifest periodical excitement of the vascular system; but whether a primary excitement or not, the progress of physiological and pathological knowledge will alone discover. The ancient cultivators of medicine attached considerable importance to the periodicity of inflammatory affections, even of the slightest kind; believing that whatever measures were employed, they would run a certain course,

mitigated perhaps, but not prematurely brought to a termination. Both with respect to these and to the febrile disorders, certain days were believed more favourable to a termination of the malady than others, or even to its amelioration. These were called *critical* days. If the disorder did not begin to decline, or altogether decline, on one of those days, the hope of the practitioner was transferred to a future critical day, overleaping one or two days, and sometimes a greater number. Unfavourable changes were alleged to occur on the same days in bad cases. For a belief sanctioned by the acute observation of the Greeks, and more or less cherished by almost every sect up to the present day, it must at least be said that there must be some strong foundation. Yet on few points are modern authorities more at variance; some retaining the old faith pure and unmixed; some admitting it with reservations; and some regarding it as a venerable but a groundless prejudice. We are not afraid to confess that our individual observation inclines us to rank among the believers; although at the same time we acknowledge the insufficiency of individual observation on a question of this nature.

There is some analogy between these periodical movements of disease, and the periodical performance of certain of the healthy functions, although, as regards several of the latter, the effect is commonly ascribed to habit. The desire for food, however, and that for sleep, which may be looked upon as indications of an approach to a state of exhaustion in some part of the system, are found to recur within a certain period in all; whilst in the instance of the uterine functions in the female, and in the frequent examples of inconveniences resulting from a plethoric state of the blood-vessels, there is a certain effect produced within a given and exact time, and with which habit can have nothing to do. Again, in almost all slight but not very transient disorders, there is an alternation of excitement and depression, "a good day and a bad day;" and, during convalescence, particularly from fever, we have often noticed the great distinctness of this intermittent or periodical character.

As from the earliest cultivation of medicine it was observed that some peculiar circumstance or state of the body accompanied the solution of many diseases, or preceded and, as it were, announced their favourable issue, or, on the other hand, their termination in death; these circumstances or states came to be spoken of as constituting what was called a *crisis*, (from κρίσις, judgment,) and the days on which they were most generally found to take place were termed *critical days*. This language still prevails, even among those who are less inclined than ourselves to credit the ordinary restriction of such occurrences to distinct periods.

Certain changes, often noticed as preceding death, more especially in chronic diseases,—hiccough for instance,—and which are therefore considered and called *critical*, do also, if any faith may be reposed in popular obser-

vation, sometimes recur, increase, or alternate with other critical changes, at periods answering to that when the first warning of that kind appeared. If physicians place no reliance on such testimony, we are inclined partly to attribute it to their being seldom long engaged in watching maladies at the bed-side, where the senses and thoughts naturally become concentrated on the events of the sick chamber alone. Our own observation in the course of country practice, and in cases where circumstances have occasioned our attendance to be close and protracted, has, we must candidly own, gone some way to corroborate the popular evidence on these points, which are certainly not of a nature to be made familiar to those whose chief knowledge of disease is acquired in formal consultations, or in daily visits to the wards of public institutions. No harm can arise, at all events, from directing the practitioner's attention to a subject which can only be investigated by a close attention to all the phenomena of ordinary sickness.

In the progress of a fever, the recovery or the fatal termination are doubtless often preceded by some new action exemplified in the state of the bowels or of the skin. The sweating stage of an intermittent will occur to every reader as an example; but analogous phenomena often characterise those fevers which are denominated continued. Some are also distinguished by critical eruptions, of which the appearance relieves the febrile state. Certain conditions of the cutaneous or respiratory functions, productive of a peculiar odour of the breath or perspiration, are well known to practitioners as indicative of an aggravated malady.

Inflammatory disorders sometimes suddenly and happily terminate on the super-vention of catharsis; whilst the common termination of inflammation in abscess is itself often spoken of as critical; so that to this day we hear of crude abscesses, of the digestion of the pus, and, among the older members of the profession, of the coction of the matter. Nervous affections, dependent probably in such cases on a plethoric state of portions of the nervous system, often for a time disappear immediately after an attack of epistaxis, or, in females, on the appearance of the catamenia after suppression. The accession and the departure of a paroxysm of hysteria or of asthma is sometimes marked by a copious flow of limpid urine; and a very free excretion of mucus from the bronchial membrane forms the common and true crisis of the asthmatic fit. Countless illustrations might be accumulated, but no one conversant with disease can have failed to remark them.

According to doctrines now very little regarded, these and numerous other phenomena acquired an additional importance from being considered indicative of the successful or unsuccessful results of a supposed struggle in the system for the expulsion of a morbid matter; a supposition which, in many cases, is so far from being in any degree unphilosophical, that it rests on facts too plain and of

too frequent occurrence to admit of the least dispute. The terms crudity, digestion, and coction, have however been conveniently laid aside, as communicative of a sense which was not sufficiently exact.

The days on which the critical events are to be expected have been variously named by different observers. This discrepancy, and, indeed, the chief difficulty in ascertaining, by actual observation at the bed-side, the truth or incorrectness of the ancient belief, arise from the same cause, namely, the uncertainty so often existing respecting the day on which any given disease actually commenced. In fevers, the first day is sometimes sufficiently marked, but not uncommonly it is impossible to determine when the general disorder was really advanced to the febrile condition. We should ourselves venture to direct the attention of those anxious to investigate this curious subject, to the third, fifth, seventh, eleventh, fourteenth, and twentieth days of our common fevers; and we think their attention will not go quite unrewarded.

The physician will, perhaps, find, that in a considerable proportion of cases of continued fever, his services are first deemed necessary on the third day of fever, in consequence of symptoms indicative of a serious disorder then first becoming observable to the friends of the patient. Judicious treatment will often assist in bringing about a favourable change on the fifth or seventh; or a decided improvement will occur between the eleventh and the fourteenth day; or be postponed until about the twentieth. Without affecting rigid exactness in respect to these days, or attaching extravagant importance to them, we have certainly thought ourselves justified in these conclusions respecting them, by observations made in circumstances not unfavourable to precise and undisturbed observation. The principle assumed is one which in numerous cases of disease is perfectly undeniable—that certain morbid processes are for the most part effected in definite periods of time.

It is not the object of the present work to collect the curiosities of medical literature; and we have therefore briefly dismissed this, among other subjects, on which it would be easy to prolong ingenious discussion. The practical application of the doctrine of a crisis is obvious. Its observation may conduce to exact prognosis; an art so difficult and deep-tious, that all prudent physicians advise that the prognostic should be guarded with a care that may, in all cases, cause it “to quadrate with the event;” but at the same time an art in which the observant practitioner wonderfully excels those whose notice of the turns and changes of maladies is less diligent. Moreover, if a disease ordinarily terminates in some specific way, or in some specific crisis, the induction of that particular crisis becomes a wise indication for the guidance of the practitioner, although it will often be found that art cannot accomplish more than an ineffectual imitation of those critical evolutions which nature wants the power to perform.

Besides the property inherent in the body which may be assumed in many instances of periodicity to be the primary cause, there is an evident periodical influence exerted over many maladies by certain combinations of temperature, moisture, electricity, and other atmospherical properties, at different seasons of the year. There are individuals who in the the spring of each year become maniacal; others in whom the heat of the summer seems to produce the same unhappy effect, and who are well in the winter. A tendency to vernal fever is very common in delicate women; and an aggravated dyspepsia, arising from gastric and intestinal irritation, is the frequent precursor, and apparently the exciting cause of many of the fevers of autumn, which are so commonly termed bilious; and with which some individuals are regularly attacked every year.

The influence of the heavenly bodies on the corporeal actions of the beings inhabiting this planet, the *lunar* and *sol-lunar* influences, once so reverently regarded, have been for some time past so often the subject of ridicule, as to make almost any allusion to them liable to the same reception. It would, however, be difficult to shew, in the first place, any very good reason why animal bodies should be exempted from the operation of masses capable of acting on large portions, or on the whole of the globe on which they live; and abundant testimony, although not always, it must be confessed, very conclusive, might be collected in favour of views which have been too entirely discarded. That a lunatic should be under lunar influences is an opinion now seldom mentioned but to afford an opportunity for complacently contrasting the wisdom of the present time with the credulity of the past. Yet of those who have the charge of lunatics we have, we think, found the majority disposed to believe as their forefathers did. The determination of all questions of this kind requires such long and patient observation; there are so many collateral sources of deception, and the exceptions appear to be so frequent; that it is to be feared mankind will long continue to content themselves with unweighed assertions on the one hand, and indolent and contemptuous incredulity on the other.

**NOSOLOGY.**—It was our intention to conclude this article with a view of the different *arrangements* of diseases which had been made by successive physicians since Aræteus first divided them into acute and chronic, unless, as is sometimes stated, Asclepiades is to be considered as having been the first deviser of nosology, many of his definitions being retained by Cælius Aurelianus. Galen, however, mentions Mnesitheus, who lived after Hippocrates, as having distinguished himself by the classification of maladies.

Conceding that the use of all nosological studies is really limited to the schools, and that to the practitioner they afford no immediate aid, it is yet not uninteresting to see the way in which some of the greatest men who have

ever cultivated physic have attempted to reduce the innumerable diversities of disease into something like order. Not to dwell on their divisions into those of the solids and fluids; into internal and external; into idiopathic and sympathetic; into protopathic and deutero-pathic; into hereditary, congenital, and acquired; into those of infancy, childhood, adult, and old age; into those attacking men and women; into the salutary, the benign, the malignant, and the pernicious: and without insisting vehemently on the importance of the divisions into curable, incurable, and fatal; or, with regard to the seasons, into the vernal, those of summer, the autumnal, and those of winter; or into the sporadic and popular; or into febrile and non-febrile; or sthenic, or asthenic; or general and local: and passing over many other refinements of a like kind, too often based on erroneous theories;—it would be most unjust to forget the eminent services of Sauvages, the first of the modern nosologists, (1731,) and the frequent references to whose writings in this work sufficiently shew the estimation in which he is yet held. The celebrated Linnaeus also, in 1763, endeavoured to arrange diseases with the same regularity with which he classed the objects of botany, but with less success. Among the classes of Sauvages were anhelations, weakness, pains, and discharges, all of which are usually but the *effects* of disease. In the arrangement of Linnaeus, fevers and syphilis are placed together, on the ground that both are contagious.

In the more complete attempt of Dr. Cullen, praised, and justly praised, as an estimable work by his successor, Dr. Gregory, eatarrh and dysentery are placed together, because both are profluvia, or discharges. Dr. Cullen's nosological arrangement was succeeded by that of M. Pinel, which became as general in the French schools as that of Cullen had been in England. The arrangements of Sagar, Macbride, Bang, Daniel, J. P. Frank, Sprengel, Hufeland, and many others, in whatever estimation they were once held, or whatever merit they possess, are now seldom referred to except by the curious. Even Cullen's nosology is almost unknown in the schools of London; and Swediaur, who tried to improve it, is no better remembered. Among the nosologists who have pushed the science to extremes, Vitet is sometimes alluded to, as placing in his sixth class, or diseases of *evacuation*, and in its fourth order, *of organised bodies*, accouchement, avortement—making pregnancy a disease, “beginning in conception, and ending in delivery.”

The name of the celebrated John Brown demands, at least, a passing attention. Dividing all disorders into sthenic and asthenic, he established on that bold foundation a superstructure of physic so ingenious, that, great as its defects were, and great the practical errors into which they led, they long attracted the regards and admiration of many of the most famous schools of Europe.

With more attention to the natural pheno-

mena of the human body, with more practical experience and wisdom, but at the same time with a freer indulgence of fancy, Darwin attempted a new arrangement of diseases in the *Zoonomia*; a work in which, amidst a great variety of matter of very various value, the student will find many practical observations indicative of the penetration and genius of its distinguished author.

Dr. Bartholomew Parr, the author of the *London Medical Dictionary*, a work of great merit, and full of practical information, attempted to improve the nosology of Cullen, but little was gained by the attempt. Inflammations constitute his second class, and in it we find phthisis. In the profluvia we meet with cholera and diabetes. In the suppressorii, or suppressed functions, we find constipation, and asthma, and jaundice, and thirst.

These obvious inconveniences of artificial classification, which so many able persons have been so little able to avoid, shew in an unanswerable manner the inutility of such divisions. If we were disposed to ridicule the science of nosology altogether, we might dwell on the nosology of Dr. Parkinson, who divided all diseases into hyperbiosis and catobiosis, and hoped "to obliterate the term fever from nosological language;" or we might turn to the *chemical* nosology of M. Baumes, of Montpellier, who classified maladies as calorinised, oxygenised, hydrogenised, azotinised, and phosphorenised. But any farther consideration of the subject would be of little use to readers of any class.

If any arrangement is likely to be useful in a practical point of view, it would seem to be either that of diseases according to the *parts*, or the *functions* which they respectively most affect. The former is the arrangement followed by the present professor of the practice of physic in the London University; and the latter was followed by the writer of this article in the same chair. By observing either of these methods, the student's practical knowledge seems most likely to become conveniently and usefully arranged, so as to be retained with the greatest certainty, and referred to with the greatest facility; the first inquiry of a practitioner who is investigating the case of a patient, being concerning the part or function affected. Some affections, as fever, being of a general character, are conveniently placed in a distinct class. The specious exactness of an arrangement proposed by Dr. Young, the learned author of the *Introduction to Medical Literature*, never sufficed to bring into general notice a system which was seen, at the first glance, to be without any practical utility; and the same general objection may well excuse our dwelling upon or detailing any particular system in a work like the present. The functional arrangement adopted by Dr. Mason Good might deserve particular notice, on account of the reputation of its author, were it not that his incredible prodigality of barbarous medical terms has made his nosological arrangement, if not quite confused and unintelligible, at least such as to defy the efforts of

the strongest and most retentive memory. Having ourselves attempted a plan much less ambitious, and, as we believe, much more useful, it affords us no small gratification to find that the principle of that which is followed by a teacher of so high and deserved a reputation as Dr. Elliotson, is as nearly as possible the same. The only object of any consequence which it was ever pretended that nosology could effect, is the accurate discrimination of diseases. This cannot be taught by short definitions, but by full, and careful, and collated descriptions: and in order that such descriptions may be readily made and remembered, we believe that arrangement of diseases to be the best which causes those which affect the same organ to be brought close together. Their resemblances may thus be best compared, and their differences best observed; of which the result will be, that facility and accuracy of diagnosis which so greatly contribute to distinguish one practitioner from another; and, indeed, without which, no man, be his learning or his science what they may, can ever practice physic with success or satisfaction.

(J. Conolly.)

**DISINFECTION.**—This word, being in some degree new to our language, is here used to express the operations by which we attempt to clear the air and other bodies from the contamination of certain minute particles, some perceivable by the sense of smell, others not to be thus recognised, but all producing deleterious effects on the human system. Of those perceptible to the sense of smell the chemical qualities are in general more or less known to us; of those too, which are not to be thus perceived, we possess some chemical knowledge; but of others we know nothing excepting their deleterious effects on the human system, and occasionally on that of inferior animals. (See **EXCRETION**.)

However various the sources of contamination, the means which have been resorted to for their correction are reducible to three heads: first, diluting, with pure air, the atmosphere of the infected apartment or place; secondly, the admixture of certain gaseous matters with such an atmosphere, in order to decompose the infecting particles; or attempting to divest the atmosphere of them by substances which have an absorbing power; thirdly, clearing, by washing, cleansing, and exposure to the air and to disinfecting agents, the solid matters, such as bed and body clothes, the walls of apartments, &c. of the noxious matters with which they might infect the atmosphere by slowly giving them out to it.

1. Diluting with pure air (for the means of accomplishing which see **VENTILATION**) is the measure which, in all cases admitting of correction, merits the most confidence, and without which all other means are nugatory. It is the sole proceeding resorted to in cases in which the atmosphere of any place is rendered deleterious to life by the admixture of considerable quantities of noxious

gases, as of carbonic acid produced by vinous fermentation, the combustion of charcoal, or the decomposition of vegetable matters in a close place; or of carburetted hydrogen, which is occasionally so copiously evolved in coal-mines; or where the wholesomeness of the air is impaired simply by the destruction of its oxygen, as occurs in the acid fermentation; or where great numbers of persons are assembled in a place comparatively small.

2. The decomposition of the infecting particles has been attempted from an early period. Large fires were formerly kindled in the streets of a town where pestilence was prevailing, with this view; but it seems more than questionable whether they can in such a situation produce any beneficial effect whatever, and by enlightened people they are now entirely abandoned. In a limited quantity of air, however, as in an apartment, or the hold of a vessel, they may be useful, not by acting chemically on miasmata, but as a ventilating process, by causing a current of air in such situations; the heated and consequently light air ascending through the chimney or any aperture which may exist, and being replaced by a portion of that from the exterior. The firing of gunpowder in the open air, which has been occasionally resorted to, seems destitute of any effect, for we cannot expect any beneficial chemical action from the azote, carbonic acid, sulphate and sulphuret of potash, which are its products; neither can there be hoped from it any movement of the atmosphere sufficiently general to be of service; but in a limited space, by expanding the air, it may certainly cause it to be replaced by a portion of the cooler and more condensed external air. Fumigations with certain aromatic substances, as camphor, benzoin, &c., have enjoyed a degree of reputation probably unmerited, and founded solely on their property of disguising unpleasant odours; but they are now superseded by measures deemed more scientific, which we shall proceed to consider.

*Quick-lime.*—This substance, besides its well-known property of absorbing carbonic acid, which is copiously evolved from putrefying masses, appears, too, to absorb other gases which are the result of putrefaction; at least it has the quality of correcting offensive odours. From its power in this way, and probably from a supposition that it decomposes or absorbs miasmata, it is usual to pour it into privies or drains which emit offensive odours; and when pestilential diseases are prevailing to an extent to cause great mortality, it is customary to throw a thick bed of this substance over the corpses in the grave or trench in which they may be deposited. It is applied, too, in the form of whitewash to the walls of apartments, in which persons ill of febrile disorders have lain, as a security against any contagious matter which may have adhered to them.

*Charcoal.*—This substance, as is well known to chemists, possesses the property of absorbing gases, and might, on this account, be advantageously employed to rid a limited portion of air of hydrogen or other offensive matters with

which it was impregnated. It has not, however, been employed in this way; but the utility of charcoal filters in divesting water of any gases, the products of animal or vegetable decomposition with which it is contaminated, has long been recognized.

*Acids.*—These have long been supposed to have the power of decomposing contagious matter, or in some mode depriving it of its virulence. The well-known *thieves' vinegar* owed its popularity to this supposed property; and it is still the custom to dip into vinegar letters and papers which arrive from places where pestilence is prevailing. Clothes and goods of all kinds, coming from lazarettos, are exposed to the vapours produced by the slow combustion of sulphur (sulphurous acid). But the former being thought too feeble, and the latter having been found exceedingly irritating to the lungs, they are rarely employed for general disinfecting purposes; and when acids are used, either the muriatic, the oxymuriatic (chlorine), or the nitrous is resorted to, though the employment of any of them in an inhabited apartment is not unattended with serious inconvenience to patients and attendants.

Muriatic acid was first employed by Guyton Morveau, in 1773, to disinfect the principal church of Dijon, the air of which had become so contaminated by the emanations from the vaults below, from which, on account of their too crowded state, the bodies had been removed, that it was utterly unfit for divine worship. Vinegar, aromatics, and the deflagration of nitre had been tried without effect; but the vapour arising from the decomposition of six pounds of common salt by two of concentrated sulphuric acid deprived the air in one day of all unpleasant odour, and in four days afterwards worship was performed. This distinguished philosopher, towards the close of the same year, used fumigations of muriatic acid with complete success for disinfecting the prison of Dijon, whither fever had been imported from other gaols, of so malignant a nature that thirty-one prisoners had perished from it in a very short space of time.

The proportions recommended are twelve parts of sulphuric acid of the specific gravity 17 to fifteen parts of muriate of soda, which should be slightly moistened before the acid is poured upon it. If employed for disinfecting an uninhabited place, flat earthen dishes, containing the mixture, may be placed on a sand-bath, and the whole of the acid may be added at once. If in one occupied by patients or others, all heat should be dispensed with, and the acid should be added gradually. The latter rules should be considered imperative in all cases where acids are employed to disinfect inhabited places.

Nitrous acid fumigations were first employed in this country; and a liberal parliamentary grant was bestowed on Dr. Carmichael Smyth for their application to disinfecting purposes, which was regarded as a discovery. A prior claim was subsequently set up for Dr. Johnstone, of Worcester. The fumigations were successfully employed by Dr. Smyth in 1780,

for checking the progress of a fever which prevailed among the Spanish prisoners at Winchester, of whom it had destroyed a seventh part in three months. Several other examples of their utility in disinfecting ships and hospitals might readily be quoted. Nitre and sulphuric acid are the substances employed in this mode of fumigation, and equal parts of both ingredients are found to be the best proportions. The combination of the salts producing a considerable evolution of heat, none should be employed to aid the decomposition. It is calculated that half an ounce of each ingredient will suffice to disinfect an apartment of ten feet in each dimension, comprising of course a thousand cubic feet; and it is advised, in case of our having to apply the method to larger apartments, that we should multiply the cups or saucers which contain the ingredients, rather than introduce a larger quantity than that mentioned into one vessel, as the red fumes disengaged might seriously incommode the operator.

Oxygenated muriatic acid (chlorine) was first proposed as a disinfecting agent by Fourcroy in 1791. It was soon after employed by Cruikshank, of Woolwich, and by Guyton Morveau, who thought it preferable to all other acids; and it has since united most suffrages in its favour. There is an excellent and concise account, in the eighteenth volume of the *Journal of Science and the Arts*, of the disinfection of the Milbank Penitentiary by Mr. Faraday. To this the reader is referred, as it comprises all that is necessary to be known of the mode of applying fumigations of chlorine to uninhabited places. The following are the material points of the process adopted by Mr. Faraday. He found that one part by weight of common salt, and one part of oxyde of manganese, when acted upon by two parts of oil of vitriol, previously mixed with one part by weight of water, produced the best results. The salt was bruised down with a mallet previously to being mixed with the manganese; and the acid and water were mixed in a wooden tub, and allowed to stand for some hours, that the heat produced by their combination might be dissipated before they were poured on the other ingredients. Common red pans, of a flat form, were used for the fumigation. The evolution of chlorine commenced a few minutes after the ingredients were mixed in the pan, and continued for four days, no extraneous heat being employed in the operation. The quantity of materials used was 700lb. of salt, 700lb. of oxyde of manganese, and 1400lb. of sulphuric acid; whilst the space requiring fumigation amounted to nearly 2,000,000 cubic feet, and the surface of the walls, floors, and ceilings was about 1,200,000 square feet. The able arranger of the process is of opinion that from one-half to one-fourth of the chlorine, and consequently of the ingredients employed for its production, would be quite sufficient in a building of the same extent, for any of the usual cases where fumigation is required. The proportions recommended by Guyton Morveau differ from those employed

by Mr. Faraday. The former philosopher advised that two parts of powdered oxyde of manganese should be mixed with ten parts of muriate of soda, and that the mixture should be acted upon by six parts of sulphuric acid previously diluted with four of water; and in an uninhabited room, forty feet by twenty, he thought two ounces of oxyde of manganese, ten ounces of muriate of soda, six ounces of sulphuric acid, and four ounces of water, sufficient for perfect disinfection; the doors and windows being closed for ten or twelve hours.

Chlorine is so powerful an irritant to the bronchial lining, that its rapid evolution in the processes described above is quite inapplicable to inhabited apartments or wards, unless the quantities of the ingredients employed are so small in proportion to the space to be disinfected that we cannot expect any beneficial result from them. Guyton Morveau endeavoured to surmount this difficulty by means of his permanent apparatus of disinfection, which consisted of a glass vessel encased in wood, having its mouth very accurately closed by means of a ground-glass stopper, acted on by a vice. A slight turn of the vice allowed the vapours, by their expansive force, to raise the stopper and mingle with the atmosphere. One-third of the apparatus was occupied by four parts of oxyde of manganese, finely powdered and sifted, ten parts of nitric acid of sp. gr. 1.40, and ten of muriatic acid of sp. gr. 1.134. From this combination the chlorine is disengaged much more slowly than by the action of sulphuric acid on a mixture of muriate of soda and manganese; and by means of the vice the issues of gas are regulated at pleasure, whilst the lightness and closeness of the apparatus enable us to remove it readily from one place to another. The disinfecting hottle, arranged in the manner described, may be opened twice a day, and still retain its disinfecting power for three or four months. However ingenious the plan of M. Guyton Morveau, this, and perhaps all disinfecting processes—certainly all for occupied wards or apartments—are superseded by the agents more recently introduced by M. Labarraque. This gentleman, an apothecary in Paris, was the first to suggest the employment of chlorine in a liquid form for disinfecting purposes. He recommends two solutions. One, the chloride of lime (a solution of bleaching powder), is prepared by passing chlorine gas over hydrate of lime: this, when dissolved in water, forms Labarraque's liquid; or the liquid may be formed directly by passing the gas into water which holds lime in suspension. Two methods are recommended for forming chloride of soda, one by M. Labarraque, and the other by M. Payen. The former passes chlorine gas into a solution of carbonate of soda; the latter decomposes chloride of lime by the carbonate. Both processes are easy, the latter the most so; and it has been so arranged by M. Payen as to make the resulting compound identical with that prepared by the former method. No carbonic acid is expelled on passing the chlorine into

the solution of carbonate of soda; the solution has a faint smell of chlorine; when heated, scarcely any chlorine is evolved; it first acts as an alkali on turmeric paper, and then bleaches it; on the addition of acid, chlorine and carbonic acid are expelled.

Chemists do not seem fully agreed as to the precise nature of these compounds, but in a practical work we do not feel called upon to enter into controversies on this point. (See Granville in *Journal of Science*, &c. vol. xxiii. and R. Phillips in *Philosophical Magazine*, vol. i. of New Series.) It is material to know that they are most powerful disinfecting agents, and that since their introduction by Labarraque they have been applied to every kind of case in which the operation of such agents is requisite, by innumerable scientific persons of various nations, whose testimony is loud in their favour. They appear to act, as the experiments of Gaultier de Claubry tend to prove, by the evolution of chlorine, from the action of the carbonic acid contained in the atmosphere on the compounds, so that a gradual fumigation by chlorine takes place; and where atmospheric impurities abound, the proportion of carbonic acid being generally greater, the fumigation will be more rapid. The following is an abstract of these experiments.

Well saturated chloride of lime being dissolved in water was submitted to the action of carbonic acid gas; chlorine was quickly disengaged, and by continuing the operation a sufficient length of time, the whole was expelled, the liquor no longer possessing bleaching powers, and carbonate of lime having been precipitated.

Air, passed slowly through a saturated solution of caustic potash, to deprive it of carbonic acid, was then made to traverse a solution of the chloride of lime; no chlorine was liberated, no effect of any kind produced.

The chloride of soda is equally decomposed by carbonic acid, only more slowly, in consequence of the solidity of the salt produced.

A filtered solution of the chloride of lime was exposed to air on the 13th of August; on the 10th of October it no longer contained chlorine; did not affect litmus; and the precipitate from it proved to be carbonate of lime. A stronger solution of the same chloride, exposed to the air on the 16th of August, was found in the same state as the last on the 10th of October.

Air was passed through blood, which had been left to putrify for eight days; being then passed through a solution of the chloride of lime, carbonate of lime was deposited, and the air was rendered inodorous and completely purified. In a second similar experiment the fetid air was passed through a saturated solution of caustic potash before it arrived at the solution of the chloride; the latter then had no effect upon it, and the air retained its insupportable odour. Another experiment was made with air left twenty-four hours over putrescent blood; the portion of it which was passed directly through the chloride was perfectly purified, but when previously freed from

carbonic acid, the chloride had no effect upon it. (*Annales de Chimie*, xxxiii. 171, and *Journal of Science*, vol. xxiii.)

These experiments of Gaultier de Claubry seem very conclusive, yet a fact is mentioned by Labarraque and Partou, in their report to the Council of Health of Paris on the removal, from the church of St. Eustache, of the bodies which were deposited there during "the three days" of July, 1830, which tends to shew that carbonic acid is not uniformly the agent which decomposes the chlorides and calls into action the disinfecting power of the chlorine. These individuals found this process go on very rapidly indeed, though a bed of lime thickly spread over the floor must necessarily have absorbed the carbonic acid; and hence were led to conclude that an exact theory of the phenomenon still remains to be discovered. (See Report, &c. or abstracts of it in the *Medical Gazette* for January 1, 1831, which also merits perusal as shewing the mode of applying the disinfecting liquid on a large scale.)

The chloride of lime is the preparation which M. Labarraque recommends for disinfecting apartments, while that of soda is especially employed, in topical and external application, to foul wounds and ulcers, &c. It were needless to enlarge on what is so familiarly known, their power of delaying the occurrence of putrefaction, of arresting it when it has already commenced, and of purifying the tainted air of hospitals, prisons, lazarettos, ships, sick-chambers, sewers, drains, and manufactories in which animal substances in a state of putrefaction are used, and their consequent utility to the anatomist, physician, and, we may say too, police-officers and magistrates.

If an uninhabited place is to be disinfected, troughs or pans, which expose a considerable surface to the air, and containing the chloride of lime, are placed in various parts of the building; the same liquid is poured over the floor, and sheets wet with it are suspended in various situations. If an inhabited ward or apartment is to be kept clear of impurity, the floor must be frequently and freely sprinkled with it, and portions of linen moistened with it should be attached to the bed-curtains, window-hangings, &c. If a putrefying body is to be preserved, it should be kept wrapped in a cloth steeped in it; or, if one is to be exhumed, the same plan should be adopted, with a copious affusion of the liquid into the vault the moment it is opened. It may be poured freely into drains, privies, or night-chairs which emit an offensive odour; and foul sores may be frequently washed with the liquid chloride of soda, diluted, if necessary, with rose-water. The only inconvenience connected with their use is the unpleasantness of the smell of chlorine, which some patients declare to be worse than that which it is employed to correct; but they should be reminded that there is nothing pernicious to life in the smell of the disinfecting liquid, whilst the bad smell of the apartment betokens unwholesomeness.

The subject would be left imperfect did we

not inquire into the extent of the power and the mode of action of acid fumigations, in which class we include chlorine, either directly applied or furnished by the chlorides, though not ignorant that the title of chlorine to be considered an acid is disputed by chemists, and though there may be still some doubt as to the mode in which the chlorides affect atmospheric impurities.

It will be at once understood that these agents can produce a beneficial effect only on a limited quantity of air, and that no epidemic constitution existing in the atmosphere of a district or country can be corrected by them. If they are to have any beneficial effect in checking the propagation of febrile diseases, the miasmata which engender such diseases must be existing in a limited space; for if the air which will necessarily replace that which has been disinfected partake of a general contamination, it is manifest that their employment can be attended with no good effect but that of correcting obvious nuisances, such as bad smells. Hence, when these vapours have been employed to prevent the diffusion of a widely spreading epidemic malady, they have uniformly proved inefficacious, as was shewn by M. Nysten and Professor Arejula regarding yellow fever, when it was prevailing in the south of Spain during the years 1800, 1801, 1803, and 1804. Cabanellas, it is true, who was sent by the Spanish government into Andalusia to employ them, thought favourably of their merits, but the weight of testimony is against him; and, besides, he did not employ them till the month of November, when the heat having abated, the intensity of the epidemic must, according to its known laws, have been diminishing. That, employed in a limited atmosphere, they have some effect in checking the spread of typhus, appears to rest on competent authority. Ignorant as we are of the nature of contagion, we are of course ignorant of any specific chemical power they possess of acting upon or decomposing it. All the stronger acids, as we know, possess the property of corroding the animal texture; and their power of acting on contagious matter which is of animal origin, may depend on this property, or on their quality of absorbing or decomposing the noxious gases, which are probably powerful vehicles of contagion, as it is ever found to be least active in the purest atmosphere. That in some way they act on the contagion of typhus rests on the testimony of Guyton Morveau, Carmichael Smyth, and a host of persons of note and character; but the feeling of the profession at large, and we believe that feeling to be a correct one, is that their power over it is limited, and does not supersede the necessity of avoiding needless approximation to the sick, and of adopting every measure of ventilation and cleanliness which art can supply.

That, in a limited atmosphere, they promptly destroy bad odours, is well ascertained, and of all modes of fumigation that with chlorine is the most efficacious in this way: but on what this property depends does not seem very well

understood in the case of all of them. Chlorine combines readily with hydrogen, and combines with or decomposes its compound gases; it decomposes, too, ammoniacal gas, and hence there is not much difficulty in understanding how an agent which acts promptly on those gases, the result of putrefaction, and affecting strongly the sense of smell, should be powerful in correcting the more obvious nuisances of infected apartments. But it is not so clear how certain of the other disinfecting agents, muriatic acid for instance, the affinity of which for septic gases is less general than that of chlorine, remedy such nuisances, though the experience of Guyton and many others places the fact that they do so beyond all question.

3. It is obvious that the solid matters which are in the infected apartment will receive the beneficial influence of the fumigations employed to purify the air. In addition to this, they should be washed with soap and water, or an alkaline ley; the walls should be white-washed, and air be freely admitted for some time previously to the room's being again inhabited. All body and bed-clothes withdrawn from patients labouring under fever should be thrown at once into hot water, and after remaining there for some time, should be thoroughly washed with soap or an alkaline ley. They should then be hung up in the air for a considerable length of time, and they may be occasionally sprinkled with the chloride of lime.

The ordinary mode of preparing the liquid chloride of lime is as follows:—Introduce into a common retort fourteen parts of black oxide of manganese, six parts of muriate of soda, the same proportion of sulphuric acid, and twelve parts of water. The chlorine gas will rise without the application of heat, (though, if it is thought desirable to accelerate the operation, heat may be employed,) and should be transmitted through a tube attached to the neck of the retort to the bottom of a vessel filled with a saturated solution of lime. When this is saturated with chlorine, the test of which is the cessation of the evolution of gas from the materials in the retort, it contains about twenty per one hundred of this principle, and may be diluted with forty parts of water for ordinary disinfecting purposes. It is desirable to add the water shortly before employing it, as an extrication of gas commences rather rapidly immediately on the water being added.

The liquid chloride of soda is prepared in the same manner, a solution of one part of subcarbonate of soda in twenty parts water being substituted for the saturated lime-water. The absorbing power of this solution over the chlorine is less than that of the lime-water: hence, when used for disinfecting purposes, the liquid chloride of soda should be diluted with only thirty parts of water.

The materials employed for impregnating one or the other of these liquids with chlorine may be frequently made to evolve more of this principle by the addition of more sulphuric acid, and thus successive quantities of the

chlorides may be formed from the same ingredients.

Dr. Henry, of Manchester, has recently performed a series of experiments, which seem to prove that the fomites, or materials impregnated with the infectious principles of various contagious diseases, may be rendered totally inert by exposure to elevated temperatures. Dr. Henry first ascertained that raw cotton, and various kinds of piece-goods manufactured from that or other materials for clothing, are injured neither in texture nor colour by exposure for several hours to a dry temperature of nearly  $212^{\circ}$ , or even  $250^{\circ}$ , Fahrenheit. He next ascertained experimentally, that vaccine matter, though capable of communicating the disease after exposure to  $120^{\circ}$  Fahrenheit, is rendered inert by a temperature of  $140^{\circ}$ . In the third place, he found that a flannel shirt, which had been worn by a patient in well-marked typhus between the tenth and eleventh days of the disease, was, after exposure for an hour and three quarters to a temperature of  $204^{\circ}$  Fahrenheit, incapable of communicating the disease to a person, below whose nostrils it was placed for two hours; that a second flannel waistcoat worn on the night between the eleventh and twelfth days, and heated in the same manner, and worn for two hours by the same individual, did not communicate the disease; and that a third worn by the patient on the night between the twelfth and thirteenth days, after exposure to heat and seclusion in an air-tight canister for twenty-six days, was equally incapable of communicating fever. In the fourth place, he found that a series of eight flannel waistcoats worn for several hours by patients in distinctly marked scarlet fever, afterwards exposed to heat varying from  $200^{\circ}$  to  $204^{\circ}$ , and eventually worn for several hours by children not having had scarlet fever, did not communicate the disease to these children.

Dr. Henry expresses himself with a degree of caution respecting a positive conclusion being deduced from his experiments on the contagious principle of typhus; but thinks his experiments sufficiently numerous to prove, that by exposure to a temperature not below  $200^{\circ}$ , during at least one hour, the contagious matter of scarlatina is either dissipated or destroyed. He is more inclined, however, to the latter than the former supposition, because cow-pock matter, though completely deprived of its volatile portion at  $120^{\circ}$ , is not rendered inert by temperatures much below  $140^{\circ}$ .

As a disinfectant of articles which are capable of imbibing and retaining contagion, heat, the author suggests, is greatly superior to the vapours or gases used for the same purpose; inasmuch as the transmission of the latter may be stopped by a few folds of compressed materials; while heat, if time enough be allowed, finds its way in spite of all obstacles. He limits the application of the method to the destruction of contagion existing in substances technically called "susceptible;" for instance, to infected clothing of every description; to infected bedding and bed-furniture of

every kind that would be spoiled in washing; to trunks and other packages brought by travellers from infected places, and to merchandise whenever it can be shown or rendered highly probable that such merchandise has been in the way of imbibing contagious matter. The apparatus recommended by Dr. Henry is simple, and seems well calculated for the object he has in view. It consists principally of two vessels of copper, or tinned iron, between which steam, the agent employed for transmitting heat to the infected materials, is introduced: but for a full description of the apparatus, and for the plate in which it is represented, we must refer to the Philosophical Magazine and Annals of Philosophy for January, 1832.

In a matter of so much importance, and, we would add too, of such extreme difficulty, it appears desirable that a more ample series of experiments should be performed on the contagious principles of typhus and scarlatina; and that we ought not to rely on mere analogy as a reason for extending to other contagious the procedure recommended, but that these ought likewise to be made the objects of experiment.

(Joseph Brown.)

DIURETICS, (*Diuretica*, Φάρμακα διουρητικά, from διὰ and οίγω, *meio*: *Th. ούρον, urina*.) medicines which augment the urinary discharge. This definition might be considered defective, as being too general, but it is the only one that can be admitted; for the excretion of urine, under the influence of diuretics, does not always arise from a direct application of the diuretic substances to the kidneys; but, frequently, from circumstances connected with the state of the stomach, and other organs, under which the kidneys act only a secondary part.

Diuretics are supposed to operate in four distinct ways: 1, by passing into the circulation, and, being conveyed to the kidneys without undergoing any decomposition *in transitu*, acting directly as stimulants on the urinary organs; 2, by suffering decomposition *in transitu*, and acting on the kidneys by one or more of their constituents; 3, by acting primarily on the stomach and primæ viæ, communicating their action to the kidneys by sympathy; and, 4, by stimulating the disordered capillary system to more healthy action,—thereby preventing the undue effusion of fluids into the serous cavities, and permitting the absorbents to convey those already effused into the circulation, to be discharged by their natural excretories the kidneys.\*

1. In the healthy and ordinary condition of the body, the blood which is sent to the kidneys is divided into innumerable streams, each of which, entering the glandular glomerules of which these organs are principally

\* This plan of the mode in which diuretics operate is a modification of that of Dr. Paris, (*Pharmacologia*, vol. i. p. 167,) which in its turn is a modification of that suggested by Dr. John Murray, (*Materia Medica*, vol. i. p. 366-8.)

composed, supplies the pabulum from which the urine is secreted; whatever, therefore, is conveyed to the kidneys through the medium of the blood must, more or less, affect the natural function of these organs. Thence the inquiry, in what manner is this effected?

If we analyse the urine, we find that it consists of water; urea, a peculiar compound of nitrogen, oxygen, carbon, and hydrogen; small proportions of sulphates of soda and potassa; phosphates of lime, soda, and ammonia; muriates of soda and ammonia; lactate of ammonia and fluuate of lime. Knowing that these are the components of urine, it is not difficult to ascertain what substances have passed through the kidneys, and whether these have undergone decomposition. Thus, if free potassa or nitrate of potassa be taken into the stomach in moderate doses, and be afterwards detected in the urine, we may conclude that they have been conveyed to the kidneys through the blood, as they could not otherwise be found in the excretion of these organs. The excretion, however, of these salts, does not take place without the kidneys experiencing the influence of their stimulating qualities, and consequently having their natural action so much augmented that a larger than usual supply of urine is the result. On the knowledge of this truth, the first division of the preceding arrangement is constituted. It is nevertheless a curious fact that, although these substances can be readily detected in the urine, yet they cannot be discovered in the blood; neither can colouring matters, which are easily displayed in the urine, be rendered evident, either in the blood or in the chyle. A doubt was suggested as to the medium through which such matters are conveyed to the kidneys, by Sir Everard Home, who imagined that they found their way through the spleen; but he afterwards properly abandoned this opinion, on finding that, after removing the spleen and tying the thoracic duct, the colouring matter of rhubarb injected into the stomach of a dog could be detected in the urine. It is sufficient, however, for our purpose, to know that substances taken into the stomach are conveyed to the kidneys;\* and that, if they are of a nature to stimulate these organs, provided the stimulus be short of that necessary for exciting inflammation, an increased secretion of urine must follow. It is indeed perfectly obvious that the stimulant influence of diuretics must be within a certain limit; for were the excitement of the kidney sufficient to induce inflammatory action, the urine, instead of being augmented in quantity, would be scanty, high-coloured, and acrid; a fact of great practical importance.

It may not be improper to remark, in this

\* Alkalies are detected in the urine by testing it with turneric paper; nitre by dipping a piece of bibulous paper into it, then drying the paper, and applying it to the flame of a candle; if it deflagrate, nitre is present. The odour of asparagus, garlic, turpentine, cubebs, and many other substances, is detected in the urine an hour or two after these substances have been swallowed.

place, that the chief intention of the renal secretion is, probably, the excretion of urea. When both kidneys are taken away from a dog, the animal dies before the ninth day; but, previous to death, the serosity of the other secreting organs affords traces of the presence of urine in it. In reply to this mode of reasoning, it is stated that, in a healthy condition of the body with the kidneys entire, urea has been detected in the perspiration; and that there are instances of persons having passed no urine for many years together, and who yet have suffered no inconvenience;\* but these are exceptions to a general rule.

Much of the fluid ingesta passes off by the kidneys, and the quantity of urine excreted is generally proportionate to the quantity of fluid taken into the stomach; thence the necessity of dilution to promote the operation of diuretics. None of the substances possessing diuretic properties require the aid of dilution so much as those in the first division of our arrangement. Without this they would scarcely be conveyed to the kidney, and, if they were, the over-excitement which would be induced would check rather than promote the increase of the urinary secretion.

The action of diuretics is, also, much modified by the function of the skin. When a diuretic is administered, the surface should be kept cool; for if the cutaneous exhalents be stimulated by heat, the medicine determines to the surface, by that law of the system which regulates the balance between the skin and the kidneys as excretories, and sweating supervenes with a diminished discharge of urine; just as in the healthy state, in cold weather, when the surface is chilled, the urine is abundant and pale, whilst in warm weather, when perspiration flows freely, it is scanty and high-coloured. On this account the season of the year, and all circumstances influencing the function of the skin, modify the operation of direct diuretics.

2. Many vegetable bodies and some salts which operate as direct diuretics, undergo digestion, to a certain extent, and only one or more of their constituents reach the kidneys. It is a curious fact, however, that the saline bodies which undergo decomposition in transitu are those into which the vegetable acids enter as components. The acid, which is separated, is decomposed and resolved into its primary elements as if it had been swallowed in its free state; and the alkali being taken into the circulation, is conveyed undecomposed to the kidney, and excites that action in it which promotes the secretion and excretion of the urine. This remark however, as we shall afterwards prove, is not generally correct; for some salts, compounds of vegetable acids with alkalies, bitartrate of potassa, for instance, operate in a manner which cannot be explained upon the supposition that its alkali only is conveyed to the kidneys,

\* Dr. Richardson, in a paper published in the Philosophical Transactions of 1713, mentions a lad of seventeen, who had never made any urine.

The neutral salts containing the mineral acids are not decomposed, but operate as direct diuretics, as has been already described. Dr. Paris seems inclined to believe that the *bitter principle* is the active ingredient of the vegetable diuretics, which are decomposed by the digestive organs: we are not prepared to deny the accuracy of this opinion; but, if we may reason from analogy, we should be disposed to ascribe the effect to some alkaline principle, which it is probable all of them contain. That other principles of vegetable bodies are separated during digestion, and carried to the kidneys, is evident from the odour which garlic, turpentine, asparagus, and some other vegetable matters impart to the urine; and as these are diuretics, it is not improbable that they possess this quality from the principle, whatever it is, which is combined with or constitutes the odorous matter.

Salts containing vegetable acids in excess, are more diuretic than those which contain the same acids in proportions only to neutralize the alkaline bases with which they are united, in proportion as they are more susceptible of decomposition. Thus, whilst bitartrate of potassa is diuretic, the neutral tartrate is purgative, and exerts no action on the kidney. Something, however, is due to the extent of the dose in which the salt is administered; many substances in small and moderate doses operating as diuretics, which, in large doses, operate as cathartics. This is the case with bitartrate of potassa. Oil of turpentine in doses of ten or fifteen minims up to a fluid drachm, stimulates the kidneys so powerfully as to cause bloody urine, yet a fluid ounce purges and produces no perceptible effect on the urinary organs; and in the same manner, when nitrate of potassa has been taken in large doses by mistake for sulphate of magnesia, the symptoms do not indicate any affection of the kidneys.

3. With regard to the third description of diuretics, those which augment the flow of urine, without acting directly on the kidneys, we find that they are substances which, augmenting the nervous energy, give an impulse to the general vigour of the habit, and produce tone. In a weakened state of body the fluids in the serous cavities and cellular texture accumulate; and when the cutaneous system shares in the general debility, anasarca also is the consequence. In such conditions of the body, by augmenting the general tone, the urinary organs also acquire additional vigour; and thence diuresis and the absorption of effused fluids follow the administration of vegetable bitters and other tonics.

4. The fourth division of diuretics is one of great importance, and contains, besides mercury, many diuretics, the action of which has been erroneously supposed to depend on their influence on the absorbent system. We shall examine this subject in detail, when we have occasion to speak of the substances that are arranged under this division.

Diuretics, from the increased discharge of urine which they induce, operate as evacuants;

but, at the same time, they also exert a stimulant influence. As evacuants, they remove the general plethoric state of the system, and diminish excitement without inducing much debility; for, as the abstraction of fluid from the circulating mass is slowly effected, the vessels contract and gradually accommodate themselves to the lessened quantity of their contents. As evacuants also, diuretics are supposed to carry off acriminous matters contained in the blood; but the existence of such matters in the circulating mass is very doubtful. As stimulants, diuretics act both on the general and the capillary systems, even when they exert a direct influence on the kidneys. As far as their effects depend on their stimulant properties, they are contra-indicated in all inflammatory states of the kidneys; in which states, and where much irritability is present, the simple diluent diuretics are to be preferred. Water is the best of these; how far it acts a part in all diuretics is not accurately known, but it has undoubtedly an influence in modifying their effects. There is no doubt that copious draughts of water, or any mild aqueous fluids, if not determined to the skin by external warmth, pass freely off by the kidneys, and thus produce an increased discharge of urine.

Among the diuretics which act primarily on the kidneys, without undergoing decomposition in transitu, we find some volatile oils. The *oil of turpentine*, one of these, in whatever manner it may be taken into the habit, rapidly displays its presence in the urine by the odour of violets, which it communicates to that secretion. Its effects, however, as we have already stated, are greatly influenced by the extent of the dose. In some idiosyncrasies it causes a cutaneous eruption closely resembling eczema, in which case it ought not to be prescribed. During its employment neither wine nor spirits should be indulged in, and the ordinary quantity of food should be diminished. *Cajeput* oil, and that of *cubeb*s and of *juniper*, operate in every respect in the same manner. They are all employed to excite the action of the kidneys in hydropic diseases; but in effecting this, it is probable that they also influence, generally, the capillary system. The oil of turpentine is the most useful of the three; thence the reason why good English gin is a superior diuretic to Hollands, being rectified on oil of turpentine instead of juniper berries. These volatile oils may be combined with sugar as an oleo-saccharum, and given in any bland fluid, the best of which is the bitter almond emulsion.

Among the inorganic substances belonging to this section of the direct diuretics, *iodine* stands foremost. The alcoholic solution or tincture is the form of the medicine most commonly employed. When administered internally in doses of from ten to thirty minims of the tincture, in a glass of water, twice or three times a day, iodine stimulates powerfully the whole of the glandular system, and, in a special manner, the kidneys. The diuretic effects of iodine, in combination with its general in-

fluence on the glandular system, renders it a most useful remedy in ascites connected with diseased states of the liver and the mesenteric glands. Like foxglove, it does not act beneficially when the abdomen is tense; but after tapping and reducing the excitement by a judicious employment of the lancet, it rapidly displays its influence on the kidneys. It seems to be the only decided agent which we possess for stimulating the absorbents, and this extends even to their influence over healthy glands: both the mammæ and the testicle free from disease have in several instances nearly disappeared during its administration. The writer of this article has had occasion to remark its powerful influence on the absorbents most satisfactorily demonstrated in a case of diseased ovarium, which, after tapping, and a course of alteratives with tincture of iodine, carried to the extent of sixty minims for a dose three times a day, was completely cured. In this instance, it is probable that the great advantage arose from the rapidity with which the iodine was thrown into the habit after the tapping, and whilst the flaccid sac remained as a kind of extraneous body in the abdomen. It has never proved useful in similar cases when administered during the turgidity of the ovarian tumor, the growth of which seems to be little connected with the general system, and to depend solely on the local action of its own vessels; the state of tension, therefore, being its natural state, it may be regarded in this condition beyond the sphere of action of agents affecting the general system,—a circumstance, however, which is set aside as soon as the fluid is discharged, and thence it is brought within the sphere of the influence of the iodine.

Some inconveniences arise from the employment of iodine in irritable habits. It causes febrile excitement, which is often accompanied with nausea, vertigo, and headach, and, occasionally, with dysenteric symptoms, and, at other times, symptoms resembling those of paralysis agitans. It, also, in some instances excites perspirations and gripings. Under such circumstances the use of the medicine must be suspended.

A milder diuretic than either pure iodine or its tincture is the *hydriodate of potassa*. Owing to its solubility, it is administered in a saturated solution, in doses of *mxx.* to *ʒi*. It is incompatible with salts of copper, of lead, mercury, or silver.

The only oxide which has a direct diuretic influence is *potassa*. In the form of the liquor potassæ of the British pharmacopœia, it may be administered in very large doses in bland, demulcent fluids. Its primary influence is exerted on the stomach: if any acid be present, it is neutralized; but if the alkali predominate, or no acid be present, it first acts as a sedative, allaying the morbid irritability of the stomach, and then entering the circulation, is carried undecomposed to the kidney, upon which it acts, and can be readily detected in the urine.\*

As a diuretic, potassa is not extensively prescribed, owing to an erroneous opinion that it is injurious in large doses. The writer of this article, by gradually increasing the dose, has given one hundred minims of the solution of the London College three times a day, for several successive weeks. In these large doses its power in curing the most obstinate cases of psoriasis is very striking, and although its beneficial effects are not evident until it displays its influence on the kidneys, yet it has on no occasion produced any injurious effects. It is not much to be depended on in dropsical affections.

Among the neutral salts operating as direct diuretics, *nitrate of potassa* has long held a place. It passes unchanged to the kidneys, stimulating them to increased action, and augmenting rapidly the quantity of the urinary discharge. It can be readily detected unchanged in the urine, on which account it ought not to be administered in inflammatory affections of the urinary organs; but none of the diuretics can be less depended upon in dropsical effusions, even after the phlogistic diathesis has been subdued. It operates in doses of from *gr. xv.* to  $\mathfrak{ʒi}$ , and requires to be largely diluted. The *chlorate of potassa* operates nearly in the same manner as the nitrate, but it is seldom prescribed as a diuretic. There is some uncertainty with regard to the manner in which *borax* (soda sub-boras) operates as a diuretic; but, from the smallness of the dose (*gr. x.* to  $\mathfrak{ʒi}$ ) required to act on the kidneys, we are disposed to think that it passes entire to these organs. It is readily decomposed by all the mineral acids, common salt, muriate of baryta, and nitrate of silver, all of which, therefore, are to be regarded as incompatible with it in prescriptions.

Those diuretics which undergo decomposition in transitu, and operate directly on the kidneys by one or more of their constituents, comprehend substances from the three kingdoms of nature.

The only animal diuretic is canthariden,† as contained in the blistering beetle, *cantharis officinalis*, and the *mylabris variabilis*, which has lately been introduced from China. The canthariden has not yet been employed in its separate state as a diuretic, but the influence of the blistering beetle on the urinary organs has been long known. Hippocrates employed it in dropsics, and a celebrated diuretic of Tulpius consisted of the tincture of Spanish flies, cardamoms, and sweet spirit of nitre. The internal use of cantharides, however, requires the utmost caution, and when thus employed, whether in the form of powder or of tincture, the freest use of

† Canthariden, in its separate state, is a white substance, in minute micaceous scales, insoluble in water and cold alcohol, but soluble in boiling alcohol, ether, and oil. The knowledge of its solubility in oil is a fact of much practical importance in cases of poisoning by cantharides, in which the administration of oil, by dissolving the canthariden, tends to diffuse the acrid influence of the poison, and consequently ought never to be resorted to.

\* It is detected by testing the urine with infusion of rhubarb or turmeric.

diuretics of a demulcent kind is absolutely necessary. In the form of powder, cantharides, in doses not exceeding two grains, stimulate the kidneys, and cause an increased flow of urine; and it is singular that neither heat in the region of the kidney nor strangury is experienced in this case. They have been found beneficial in ascites, in old worn-out constitutions. When accidentally over-dosed and inflammation of the kidneys supervenes, with bloody urine, insupportable pains in the abdomen, strangury, vomitings, or convulsions, the lancet must be freely employed, with copious dilution, and an enema of warm water, containing from *mxx.* to *fʒi.* of tincture of opium. The employment of oil must be avoided.

The *balsam of copaiba*, *cubebæ*, and the fruit of the *juniper*, owe their diuretic properties solely to the volatile oil which they contain, and which, separated from their other components during the process of digestion, is carried to the kidneys and augments their natural function, it may be readily perceived by their odour in the urine. *Copaiba* in an over-dose causes inflammation of the kidneys; consequently it ought to be carefully avoided when there is the least tendency to ulceration of these organs. It may be administered either in a fluid or a solid form. In the first it is given, combined with mucilage and any bland fluid, in doses of from twelve to thirty minims; or the volatile oil, separated from the resin by distillation, may be rubbed up with sugar, and administered in bland fluids, as an oleo-saccharum, in doses of from ten to twenty minims. The solidification of the *copaiba* is best effected by magnesia, in which state it may be formed into pills;\* or, for the same purpose, it may be formed into a soap, as the union of the alkali does not, in any degree, diminish the efficacy of the balsam. In moderate doses, from *gr. x.* to  $\mathfrak{z}\mathfrak{i}$  of the powder, *cubebæ* are diuretic; in larger doses they are purgative. It is probable that some of the benefit derived from their employment in gonorrhœa may be ascribed to the diuretic influence of the volatile oil so much increasing the urinary discharge as to enable it to wash out the virulent matter in the urethra. We are not aware that they have been employed in dropsical effusions.

In the same manner as the digestive organs separate the volatile oil of *cubebæ* and *juniper-berries*, they separate *veratria*, the active principle of the *colchicum autumnale*, and *scillitina*, that of the *scilla maritima*, from the powder of the dried bulbs of these plants. Although *colchicum*, in full doses, acts powerfully on the excretory ducts of the liver and the pancreas in the duodenum, and brings down a large quantity of bile into the intestinal canal, yet in

\* This is effected by mixing the balsam with one-third of its weight of magnesia, spreading the mixture upon a plate and exposing it to the action of the air for ten or twelve days. It then becomes plastic, and may be readily formed into pills. The activity of the *copaiba* is not diminished by its union with the magnesia.

small doses the *veratria* is separated, taken into the circulation, and stimulates the kidney. As a diuretic, however, it is less powerful than the squill, a circumstance altogether depending on its disposition to run off by the bowels. For diuretic purposes the tincture is the best preparation of the *colchicum*, as the alcohol takes up the gallate of *veratria*, which is less liable to pass the pylorus undecomposed than the acetate, which is always formed when either vinegar or wine is employed as the vehicle for taking up the active principle of the plant, and which passing the pylorus, and bringing down a large quantity of bile from the liver, almost invariably purges. Both the petals and the seeds of the *colchicum* yield the same active principle to alcohol, wine, or vinegar, as the bulb. The dose of the dried bulb, in powder, is from five grains to twelve grains, that of the tincture or the wine from *m. xx.* to *m. lx.*, and that of the vinegar from  $\mathfrak{z}\mathfrak{i}\mathfrak{i}$  to  $\mathfrak{z}\mathfrak{i}$ . Upon the whole, however, the preparations of *colchicum* are much less to be confided in, where morbid accumulations of fluid are required to be lessened, than those of the squill; and it only proves useful as a diuretic when it exerts little influence on the intestinal canal. It, nevertheless, cures dropsies by its stimulant influence on the capillary system, and by its evacuant properties, when given in larger doses than those mentioned as fitted to secure its diuretic influence. Squill is given in substance to secure its diuretic effect; but it is generally prescribed in combination with calomel or the blue pill, or bitartrate of potassa. As a full dose given at first is apt to induce vomiting, it is preferable to commence with doses of a grain of the powder, gradually increasing the quantity to six grains, repeated every fifth or sixth hour. Cullen recommends the bichloride (oxymuriate) of mercury instead of calomel, as an adjunct to squill; but every intention is sufficiently answered by the calomel, and it is much less likely to irritate the bowels. If the combination of squill and a mercurial act on the bowels, the latter must be discontinued, and the mercury introduced by the surface. In some habits, owing to idiosyncrasy, squill excites an eruption on the skin not unlike nettle-rash, accompanied with severe gripings, cold sweats, and occasionally convulsions; in which case the use of the remedy should be discontinued, and cordials with opium administered. Squill is most useful as a diuretic, in doses not exceeding eight grains of the dried bulb: it is incompatible with the alkaline carbonates, astringent vegetable infusions, and solutions of the sulphate of iron.

A decoction of the twigs of the common broom, *spartium scoparium*, has been employed as a diuretic from time immemorial: although nothing is known respecting its active principle, yet whatever it is, the decoction seldom fails to excite the action of the kidneys. As little is known respecting the active principle of *sarsaparilla*, but it certainly affects the kidneys: the alterative influence, however, of this root can scarcely depend on its diuretic properties; and amidst so many better diuretics, it might

be rejected from the list without any inconvenience being experienced by its removal.

Amongst the inorganic diuretics which undergo decomposition in transitu, are salts of *potassa* and *soda*, the alkalies of which only are transmitted to the kidneys. The carbonate and the bicarbonate of potassa, although the one contains double the quantity of carbonic acid of the other,\* both operate nearly in the same manner as diuretics; a circumstance owing to the reduction of the latter to the state of the carbonate, during its decomposition in the stomach. The dose of the carbonate is from ten grains to ʒi, but it may be augmented to three drachms; the bicarbonate may be given in double that quantity. The properties of either, as diuretics, are not lessened by administering them in the state of effervescence with lemon juice or citric acid; this acid being separated during the digestive process in the same manner as the carbonic; and if any febrile heat be present, this is the best method of administering these carbonates. The same opinion may be given of the carbonate and bicarbonate of soda, which, owing to their taste being less disgusting than that of the carbonates of potassa, are more generally employed as diuretics.

The acetate of potassa has considerable claims to attention as a diuretic, if it be not overdosed, for in doses exceeding ʒi it operates as a purgative. In small doses it may be conjoined with infusion of gentian, or that of any light bitter: it operates with more certainty in small doses frequently repeated, than in full doses taken at long intervals. We have seen it ordered in conjunction with bitartrate of potassa; but in this combination the diuretic influence of both salts is destroyed, and a tartrate of potassa is formed by the decomposition of the acetate, and the abstraction of the superabundant tartaric acid from the bitartrate, which purges. The bitartrate in small doses, from gr. x. to ʒi, is a much more useful and certain diuretic than any of the other neutral salts in this division of this order of medicines. We are by no means satisfied that the influence of this salt depends on its alkali finding its way to the kidneys; for, when we reflect that ʒi of the bitartrate contains, gr. v. only of potassa, and that twenty minims of the liquor potassæ contain gr. vii. of potassa, and that the diuretic effect of the ʒi of bitartrate is much greater than that of mxx. of the liquor potassæ, there appears undoubtedly some difficulty in assenting to the accuracy of the theory which

has been stated. The influence of the bitartrate in ascites is well authenticated, and every day's experience confirms the confidence which has been placed in its diuretic powers. The emaciation which the bitartrate causes when taken as ordinary beverage, however, depends on its operation on the intestinal canal. Bitartrate of potassa is beneficially conjoined with squill or colchicum, or with bitter infusions; or, if the salt, when administered alone, have weakened the digestive organs, in combination with tartarized iron. In cases connected with glandular obstructions, we have given it at the same time that iodine was externally applied in the form of an ointment, and always with benefit: and here the dose of the bitartrate may be the same as if the iodine were not employed. The soluble salt, formed by the union of the sub-borate of soda with the bitartrate of potassa, operates, also, powerfully as a diuretic.

Some very active agents are found capable of producing a diuretic effect on the system by stimulating the capillaries to more healthy action, and thus enabling the absorbents to take up fluids already effused in the serous cavities and cellular membrane, and to throw them upon the kidneys, their natural excretories. Tobacco is one of these: it was introduced to the notice of the profession by Dr. Fowler, for this purpose; and when administered in small doses, either in the form of infusion or of wine, so as not to nauseate, it has been given successfully in dropsy. No diuretic, however, requires so much caution in its administration under the most favourable circumstances; and, therefore, it has been less employed than it deserves to be.

Much of the efficacy of *foxglove* depends on the period of the growth of the plant at which the leaves are collected, and the manner of drying and preserving them. In the months of July and August they are in the best state: they should be then gathered, and dried between colourless bibulous paper, in a warm room, and under a moderate pressure. This may appear to be an unnecessary degree of care and trouble, but for the preparation of a medicine of so much activity, and which is administered in grain doses, too much attention cannot be bestowed to preserve all its medicinal powers in the only way in which they can be obtained. When the dried pulverized leaves lose their green colour, some chemical change has taken place in them which deprives them of their native properties. In employing foxglove as a diuretic, it should be recollected that its influence on the capillaries is not obtained in states of the habit exceeding the limits of the healthy standard of tone. In states below that point, it stimulates the capillaries, and diminishes the force and frequency of the pulse, and operates as a diuretic; for in dropsical effusions, whether those of ascites or hydrothorax, no benefit can be expected from the employment of foxglove, as long as any tension of the vascular system exists. It is after tapping and a reduction of arterial action, that decisive advantages are

\* Carbonate of potassa.

Potassa, 1 propor . . . = 48 or 68.57

Carbonic acid, 1 propor = 22 — 31.43

Equivalent 70 100.00

Bicarbonate of potassa.

Potassa, 1 propor . . . = 48 or 47.53

Carbonic acid, 2 propor = 44 — 43.56

Water, 1 propor . . . = 9 — 8.91

Equivalent 101 100.00

obtained from prescribing foxglove in hydroptic affections. It is on the same principle that it is most useful in lax, pale, leucophlegmatic habits; and, if the disease be anasarca, in those cases in which pitting is left on pressure of the affected parts: thence, when this state does not exist, the system must be lowered by bloodletting and purging, before any advantage can be expected from foxglove as a diuretic. It has been found useful to combine it with mercurials, especially the blue pill; and pushing this far enough to effect very slightly the salivary glands: but in cases of either anasarca or ascites, the best adjuncts are bitartrate of potassa, acetate of ammonia, or colchicum; and in constitutions broken down by protracted courses of mercury, the nitric acid.

When foxglove is administered in the form of powder, the dose may be gr. i. repeated for the first two days at intervals of eight hours; after which the intervals should be lengthened according to the effects produced. An infusion made by macerating one drachm of the dried leaves in ℥viii. of boiling distilled water, and ℥i. of cinnamon water, for four hours, speedily produces the diuretic effects of the plant, when given in doses of ℥i. repeated at intervals of five hours. The dose of the tincture should not at first exceed ten minims; but it may be gradually increased until its diuretic influence be perceived. The symptoms of an overdose are nausea, vomiting, vertigo, pulsation in the temples, a sensation of heat throughout the body, sweating, sometimes diarrhoea, and occasionally salivation. One remarkable symptom sometimes occurs, a suppression of urine. The best antidotes, under such circumstances, are, ammonia, brandy and water, opium, and the stimulus of a blister applied over the pubis. One circumstance is particularly necessary to be noticed in prescribing digitalis,—its power of accumulating in the system, like mercury, and suddenly exerting its specific effects when not expected. No medicine, therefore, requires to be more closely watched, whether it be given in moderate doses, long continued, with the view of obtaining diuresis; or administered in gradually augmented doses, to lull delirium and procure sleep in mania. Whenever nausea is felt, it must be noticed and suppressed; for vomiting arrests the diuretic influence of the remedy.

Little requires to be said of *lactucarium* as a diuretic. It has been found useful in hydrothorax, and some other cases of dropsical effusions, by the German physicians; but in this country its place is much better supplied by foxglove.

All bitter tonics produce, more or less, diuretic effects; but the *scucka* root is perhaps better adapted for this purpose than any other: its influence is particularly felt in those cases in which the serous accumulations are the effect of general debility; as for example, those cases of asthenic ascites which sometimes follow acute diseases. In such cases, also, much benefit is obtained from the *ferrum tartarizatum*, which, besides operating as a tonic, has

a direct diuretic influence, and has been found peculiarly serviceable in cases of anasarca connected with affections of the heart; but in these cases its employment must be preceded by purgatives and mercurials. With respect to the employment of *mercurials*, much benefit is derived from their aid in promoting the operation of other diuretics. Thus the diuretic effects of squill are rendered more certain when combined with calomel; and those of digitalis when united with blue pill. In both instances the stimulant influence of the mercurials on the capillary system aids that of the active principle of the other diuretics, and more benefit seems to result from such combinations than when either are administered alone.

From the view which we have given of the substances most commonly employed as diuretics, the practical employment of them as remedial agents may be very briefly stated. In febrile affections much must be done before prescribing diuretics; but in long protracted fevers, whether intermittents or continued fevers, if oedematous swellings occur, their use is indicated and must not be delayed. If they be prescribed during continued fever, it should be recollected that one of the most distressing occurrences in that disease is retention of urine; and, therefore, in prescribing diuretics, it is highly requisite to examine daily the state of the bladder. Most fevers in their termination display critical changes either in the quality or the quantity of the urinary discharge: under such circumstances, it becomes a question—how far are diuretics likely to favour such a crisis? At the commencement of fevers the urine is generally pale; it becomes afterwards high coloured; and at the termination of a paroxysm, if the fever be intermittent or remittent, or, when it begins to decline, if it be of the continued type, a sediment either lateritious or of a pale pink colour is deposited, and has been regarded as critical. But this sediment is to be regarded rather as the result of a certain eustation of actions, than as the excretion of any thing injurious to the habit; and, were diuretics able to promote it, they would be of no avail. Upon the whole, therefore, even as simple evacuants, diuretics are of little value, either in idiopathic fevers or in acute diseases in which fever is a symptom. They have been advantageously administered in many chronic affections, especially those accompanied with eruptions on the skin; but the chronic affections in which their influence is truly beneficial are *dropsies*. This class of diseases depend on such an atony of the capillary system, that instead of the capillaries carrying forward the fluids they contain, they pour them out into the serous cavities, and thence the balance between the exhalation and absorption which exists in health being broken, the effused matter is accumulated to a degree which overpowers the absorbents. Diuretics are prescribed to cure dropsies in nearly every form; and do so by stimulating the capillary system, so that no fresh effusion taking place, the absorbents are enabled to take up the already effused

fluid, and to throw it upon the kidneys, its natural emunctory. When success attends the administration of diuretics in dropsy, one advantage resulting from their employment over drastic purgatives and some other remedies is, the little debility which they occasion. If diuretics, however, be given alone, they are uncertain in their effects, and seldom in that case deserve more than the title of palliatives; but, as adjuncts to other means, they aid materially the evacuation of the effused fluid, and have thus frequently effected the removal of general dropsy. Their success, however, is very precarious; and so many circumstances interfere with their operation, that it is difficult to form a prognosis of their expected effects. Sometimes they operate freely, increasing greatly the discharge of urine, and yet the dropsical swellings continue. In this case some organic mischief must be looked for; and unless this can be removed, no great advantage can be expected from the evacuation of the effused fluid.

The kinds of dropsies in which *direct* diuretics have proved most beneficial are anasarca and ascites; whilst those which operate by diminishing arterial action, and augmenting that of the capillaries, are the best adapted for hydrothorax. But even in any case the influence of diuretics hinges upon so many accidents, that all of them are precarious in their effects. In encysted dropsies they are utterly useless, unless preceded by reducing the sac to the state of an extraneous body.

Diuretics have been much prescribed in calculous diseases; and most of the substances called lithonriptsics are diuretics. We have ample proofs that none of them act chemically in dissolving calculi; nor, indeed, can they be said to be capable of effecting any change on the kidneys sufficient to prevent the formation of calculous matter. It is probable that the benefit accruing from their employment is wholly due to their influence on the digestive organs; and by their aiding in the formation of a better gastric juice, the digestive process being rendered more complete, all the secretions, and consequently all the excretions, must necessarily become more healthy, and cease to deposit the uric and other acids in the pelvis of the kidney.

In conclusion, we would say that the efficacy of this order of remedies depends more on the tact of the prescriber, and his intimate acquaintance with the changes, both structural and functional, which disease produces on the system, than any other. The operation of no other order of medicines is so much modified by circumstances; and no other medicines require so much attention as these for insuring their beneficial effects. The following rules ought always to be strictly observed during the administration of diuretics.

1. The surface of the body must be kept cool.
2. The use of diluents is essential, and ought always to be urged, more especially when the saline diuretics are employed.

3. The patient should, if possible, be out of bed during their operation.

4. The diuretic should be administered in the day-time.

5. After the accumulated fluid has been removed from the serous cavities, and the use of the diuretics suspended or discontinued, tonics should be prescribed.

6. Little advantage can be anticipated from the employment of diuretics in those dropsies which originate from organic affections of the liver or the chylipoietic viscera, and still less in encysted dropsy. It is only in those cases connected with debility and deranged action of the capillary system, that diuretics can be regarded as certain remedial agents.

(A. T. Thomson.)

**DROPSY.** (From the Greek, ὑδρωψία—Latin, *hydrops*:—Th. ὑδρωψία, *water*, and ὠψία, the *look* or *aspect*.) Dropsy is a common term signifying effusion into the cellular tissue, or into any of the natural cavities of the body. With the addition of the epithet *encysted*, it has likewise been employed to designate a very different series of affections, viz. those collections of serous fluids which are contained in factitious sacs, and of which the ovary is more peculiarly the subject. These, as having neither the same origin, nor admitting the same treatment, will be spoken of in a separate article.

Even real dropsies differ so much from each other, in consequence of the organs in whose neighbourhood or in whose substance they form, that they cannot all be comprehended in one article. Thus hydrocephalus, though agreeing in having as one of its terminations an effusion of serum into the ventricles of the brain, can by no means be regarded in the same light with effusion into the larger cavities of the body. Its progress is more rapid, its origin more decidedly inflammatory, and, when it assumes a chronic form, it never gives rise to anasarca, which almost constantly attends hydrothorax or ascites. Hence, therefore, under the common head of dropsy, we can only consider this and other local dropsies, so far as the same theoretical explanation of their phenomena agree with each other; and our chief attention must be paid to the form, origin, and treatment of what is commonly denominated general dropsy. For the peculiar symptoms by which hydrocephalus, hydrothorax, and hydrops pericardii are indicated, we refer to the articles under which these affections are treated.

The ancients appear to have had very crude notions of the cause of dropsy, and any approach to a rational theory of the disease is of very modern origin. Hippocrates explained its occurrence by the corruption and softening of the flesh, and its conversion into water. Celsus states that the common cause of dropsies is too great an abundance of humours. Galen, attempting greater refinement, referred it to refrigeration of the liver, which he assumed might happen either from an affection of that organ itself, or from sympathy with other organs; and

with little modification this theory of Galen was received in the schools till after the discovery of the lymphatics by Asellius.

Forestus, who wrote in the latter part of the sixteenth century, adopts the opinion of Celsus and explains it by the theory of Galen. He assumes that in consequence of the refrigeration of the liver, the veins also become refrigerated: hence a more serous state of the blood and greater abundance of water; and hence, according as the affection is local or general, anasarca or ascites is produced.

Fernelius, apparently seeing the insufficiency of this theory, referred anasarca to refrigeration of the liver, and ascites to a rupture of the vessels which contained the humours. By these, however, it is scarcely possible that he could intend the lymphatic vessels, as he wrote before the discoveries of Asellius had been published, and long before these vessels were supposed to be so general as it is now known that they are.

Semertus, following Fernelius, made a somewhat nearer approach to a rational theory; for while he adopted the old doctrine with regard to anasarca, he attributed the occurrence of ascites to obstruction of the liver and spleen, by which means the vessels were distended with fluid, their extreme mouths dilated, and an escape of serum permitted into the cavity of the abdomen. The discoveries of Asellius gave rise to a different theory, and dropsy was referred to a rupture of the lymphatics. Judging from the language of Lower, it might be supposed that this doctrine had obtained considerable support, when the well-known experiments of this physiologist laid the foundation for a more rational explanation of the phenomena of effusion than any which had yet been given. By tying first the inferior cava, and afterwards the jugular veins, he did much more than any of his predecessors—he proved that effusion might be caused by obstruction in the veins. Neither Sydenham, nor Mead, nor Willis appear to have concerned themselves much with the theory of dropsical effusions, but were content with simply inculcating particular modes of practice. Soon after Mead, or even while he was yet living, Haller was laying the foundation for more rational explanations of the phenomena of dropsy. He adopted the then general theory of absorption by the veins, and lays down distinctly that dropsy may ensue, not only when the veins are obstructed, but when the course of the blood through the veins is retarded by debility, whatever may be its source.\*

Haller did not acknowledge the absorbing office of the lymphatics, but even when, in consequence of Dr. Hunter's doctrines, absorption

was entirely referred to those vessels, it made no difference in the theory of dropsical effusions. It was only necessary to change "veins" into "lymphatics," and it was supposed that a sufficient explanation had been given.

Such is a short outline of the attempts which have been made to explain the phenomena of dropsy; and at the beginning of the present century the general opinion seems to have been that the disease depended upon defective absorption, and that it was essentially a disease of debility. The investigations of various writers into the causes and treatment of hydrocephalus, which served clearly to prove that this disorder had very frequently an inflammatory origin, naturally tended to re-open the general question; and Blackall, Abercrombie, and many others were led to teach that both anasarca and ascites are often attended with and dependent upon inflammation. Former writers had indeed given examples of dropsies successfully treated by bloodletting; but these for the most part were single cases; and no attempt to lay down any general plan had been made till the time of the writers just referred to. Multiplied experience has now determined the question of treatment; and that in many cases an antiphlogistic plan is requisite, is no longer a matter of doubt. But whether dropsy depends upon increased exhalation or diminished absorption, is yet undecided; nor do we feel that the facts are sufficiently numerous to determine the dispute. We shall shortly give the principal arguments for either theory.

That dropsy proceeds from deficient absorption is argued, because, whether we consider the veins or lymphatics the instruments of this function, pressure upon their trunks is followed by an effusion of serum into the parts farthest removed from the heart. This, indeed, till some late experiments by Majendie, was the only real fact which could be adduced in favour of diminished absorption. This physiologist, by inducing an artificial plethora, and then shewing that the function in question was less actively exercised than in those cases where no such plethora existed, has certainly given additional probability to the theory, and, under any circumstances, has proved what before was purely hypothetical—that absorption is capable of being diminished. On the other hand, that increased exhalation is the cause, is argued from the circumstance that absorption actually proceeds in dropsy, that the fat is taken away, and that emaciation advances *pari passu* with the effusion; that this function is always the last to yield, and that it appears to become more energetic in proportion to the general debility of the system; that the exhalents are capable of pouring out very different quantities of fluid, as is seen in the secretion of tears, the sudden increase of perspiration, &c.; and, lastly, that the fluids effused are different from the natural secretions of the parts, containing a much greater quantity of serum; and that this difference would not exist if dropsy were the simple result of diminished absorption.

A far more important question, however, to

\* Sed etiam absque ejusmodi causis hydrops nasci videtur, quoties debilitas aliqua, undecunque nata, iter venosum tardat. Facile enim intelligitur, in universum diutius sanguinis per arterias motum superesse, quem cor proximum terget, priorem vero motum venarum quiescere. Ergo si arteriæ exhalare pergant, venæ resorbere cessant, collectus vapor in hydroperem abibit.

the practical physician, is the condition of the system under which effusion takes place—whether it be a sthenic or asthenic state. Whether we adopt increased exhalation or diminished absorption as the source of effusion, this question will admit of the same decision. Effusion may clearly take place in a state of debility and in a state of undue activity of the system, or of plethora. With regard to absorption, the experiments of Majendie have clearly proved that plethora is unfavourable to this function; and that it is favourable to increased exhalation, the profuse perspirations of persons having a full habit clearly evince. If such individuals are bled, the tendency to perspiration either yields entirely or is greatly diminished.

We have therefore to investigate carefully, in every case of dropsical effusion, the general state of the system by which it is accompanied, for what may be proper for one state will most undoubtedly be injurious to the other.

The only points, then, that we can assert as proved in the theory of dropsy, are—first, that the balance between exhalation and absorption is broken, in consequence of which more fluid is poured out than is taken away; and, secondly, that this may take place from over-activity or from debility of the general system.

Something may attach also to the condition of the blood, but upon this point we have very little satisfactory information. That hemorrhages increase the serous portion of the blood, and that profuse hemorrhage gives rise to dropsy, is certain; and that in dropsies, more especially those accompanied with extreme debility, the blood often exhibits a remarkable difference in the proportions of serum and fibrine, in its coagulability and in its colour, is likewise certain; but we have yet no data by which to connect these phenomena with dropsy as cause and effect.

Almost the only information, till the late advancement of chemistry, which had been obtained respecting the nature of the fluids effused in dropsy, regarded the colour and taste, although in a few instances the consistency and coagulability had been noticed. They have been described as a yellowish serum, as being of the colour of urine, orange-coloured, saponaceous, purulent, bloody; and, in one instance, Morgagni observed the fluid to coagulate without heat. For a more particular account of these fluids we are indebted to Marcet. He examined them in hydrocephalus, ascites, hydrothorax, and in most other dropsies; and he has given a detailed account of the result in the second volume of the *Medico-Chirurgical Transactions*. According to this statement, the prevailing animal substance is albumen, which is contained in very different proportions. There is also a peculiar animal substance which Dr. Marcet names muco-extractive matter, from its being uncoagulable, but soluble in water and other menstrua. Gelatine was not discovered in any of these fluids.

In the fluids of ascites, hydrothorax, hydrocs pericardii, hydrocele, and that which is some-

times effused in the thyroid gland, the albumen is so considerable as to render them coagulable; while in that of spina bifida and hydrocephalus, it is so small in quantity as scarcely to be rendered visible by heat or acids. The specific gravity is exceedingly various both in different dropsies, and in the same dropsy at different periods.

These differences, however, are found to affect principally, if not exclusively, the animal matter only of dropsical fluids; the saline matters being by no means subject to similar variations.

The particular saline ingredients of all these fluids are muriates of soda and potash, sulphate of potash, soda and phosphate of lime, iron, and magnesia. A hundred grains appear to consist of about seventy-two grains of muriate of soda, mixed with a little muriate of potash; between eighteen and twenty grains of soda, brought to the state of subcarbonate; and a mixture of eight or ten grains of sulphate of potash, phosphate of lime, phosphate of iron, and phosphate of magnesia.

The caustic alkali contained in these fluids, Dr. Marcet proceeds to say, appears to be combined with the animal matter in a manner not well understood, and the proportion of the uncombined alkali to the other salts is greater as the specific gravity is more considerable. To this account of the animal fluids Dr. Marcet has subjoined the following table, to show the proportions of saline and animal matter in various dropsical or serous fluids, and in the serum of the blood.

|                                 | <i>Sp. Gr.</i> | Total of Solid Contents. | Quantity of Animal Matter | Quantity of Saline Matter. |

The specific gravity here stated is an average.

I. Dropsies may be acute or chronic, idiopathic or symptomatic, primary or secondary, general or local, inflammatory, sthenic, asthenic, &c. These varieties occur in every cavity in which dropsy itself takes place, but the different forms are more common in one cavity than in another. Thus, the brain is most frequently the subject of acute dropsy; the pleura and pericardium hold the next place in this liability to acute effusions, and the peritoneum the last. The cellular texture is perhaps on an equality in this respect with the pleura and pericardium, but it is seldom affected without some organ suffering at the same time, in whose action it participates. Dropsy of the sthenic character is for the most part an acute, but not always an inflammatory disease. It chiefly assumes the form of anasarca. (See ANASARCA.)

Sometimes it appears to be purely idiopathic, and unattended by disease or affection of any particular organ. In this case the anasarca takes place very suddenly, the whole cellular tissue sometimes becoming in a few hours enormously distended with fluid; and there is considerable heat of skin, with a full and hard pulse, furred tongue, and much thirst. Not unfrequently the patient complains of tenderness over almost the whole surface of the body, especially if strong pressure be made, so that we might be induced to believe that the cellular tissue under these circumstances is in a state of inflammation. The bowels are generally costive; the urine coagulates on boiling, the precipitate thus formed being very various in quantity,—sometimes scarcely rendering the urine at all muddy, at others forming almost a solid mass. This state of the urine, it has been inferred, is conclusive of disease in the kidney;\* but we shall in the course of this article afford reason for questioning this inference: it certainly indicates a disordered function of this organ, and not unfrequently accompanies structural disease of it.

Much more frequently acute dropsy is accompanied by inflammation of the lungs or pleura, and sometimes of both. The pulmonary symptoms, however, are not always very prominent, and they sometimes nearly disappear when the effusion has taken place. In such cases, inquiry into the history of the patients generally shews that they had suffered for several days, or occasionally several weeks, from cough and dyspnoea, and that about the period at which these symptoms diminished in severity, the face was perceived to swell in the morning and the legs at night, and the abdomen, without being very perceptibly enlarged, would not allow the clothes to be buttoned or laced so tight as usual. From this time the swellings increase rapidly; the whole cellular tissue becomes affected, and the countenance is very leucophlegmatic in appearance. At other times the pulmonary symptoms and effusion proceed *pari passu*, or the former precedes the dropsy only by a few hours, but is not relieved by the occurrence of effusion.

The progress now described is generally exhibited in the acute anasarca, from whatever source it may have derived its origin; but not very seldom effusion takes place to a considerable extent into the abdomen at the same time, and the ascites quickly becomes equally marked, if not the more prominent symptom.

Ascites is much less frequently an acute disease than anasarca, and in most cases is the result of previous inflammation. In the article ASCITES we have described several instances of this kind.

The exciting causes of acute dropsy are,—the repression of eruptions, the sudden suppression of perspiration, suspension of the catamenia, or of any other customary evacuation, inflammation of the lungs and pleura,

exposure to cold, &c. It also succeeds scarlet fever, when this disease has run its regular course; sometimes it has succeeded parturition, coming on suddenly and without any pain. In this last case, ascites alone is often observed; but at other times it is accompanied by excessive anasarca. The ascites succeeding parturition is also at times very manifestly dependent upon peritoneal inflammation, and is attended with fever, quick, small, wiry pulse, and excessive tenderness of the abdomen, &c. These symptoms precede the effusion, and the tenderness diminishes, but does not entirely disappear upon its occurrence. In some of these cases, when the abdomen has been emptied, we have discovered an enlarged ovarium, and we are inclined to believe that it is to the irritation produced by disease of this organ, with the additional stimulus of the puerperal state, that the effusion is owing. The termination of such cases is various: in some, after the disappearance of the dropsy, the tumour remains quiescent, and is not attended by any inconvenience; in others the ascites indeed is removed, but the ovary continues to enlarge, and we have at length encysted substituted for peritoneal dropsy.

Dropsy may be acute as to the rapidity of its formation, and yet be the very reverse of an inflammatory disease. This variety is, however, much more rare than the preceding species, but, like it, assumes the form of anasarca or of ascites alone, or of both together. It comes on in general very rapidly, and is unattended by fever or any symptom of increased arterial action. In the article ANASARCA an instance has been mentioned, taken from Dr. Bateman's reports of Diseases in London, where it came on after excessive fright, and was removed by the administration of cinchona. In the form of ascites we have several times seen it follow parturition; the patient being, within a few days of delivery, as large or even larger than at the period of labour. In these instances the only striking symptom is debility: there is neither thirst, nor heat of skin, nor quickened pulse; and the patient appears to suffer no other inconvenience from the effusion than what proceeds from the increase of her bulk. The progress of such cases towards recovery is very slow, and is always impeded by violent depleting remedies. The most successful plan of treating this affection is generally by slight tonics, frictions over the bowels, and bandaging. It ought, however, to be remembered that such patients are liable to become the subject of subacute inflammation; and unless great watchfulness be practised, the disease from this cause may become incurable.

Of the same asthenic character are those forms of effusion which are the consequence of any excessive discharge, and more especially hemorrhage. We have mentioned one instance in the article ANASARCA in which the hemorrhage was the consequence of diseased uterus; and the anasarca (the form such dropsies generally assume) appeared and disappeared, as the hemorrhage prevailed or was

\* Dr. Bright, however, to whom this notion owes its origin, by no means carries this doctrine so far.

suspended. Any other debilitating discharge will unquestionably lead to similar results.

II. We shall now proceed to notice those species of effusion which are always the result of some organic disease, and which may therefore be termed symptomatic or secondary dropsies. They are usually chronic in their course, are seldom attended with acute inflammation, but very frequently accompanied with subacute inflammation.

*Dropsy from disease of the heart.*—This species of effusion is usually preceded by the common symptoms of disease of this organ, and such disease may precede, and often does precede, the occurrence of dropsy for months, and even for years.

The first symptom of dropsy arising from disease of the heart is usually observed in the face, the eyelids being puffed in the morning, and an unusual difficulty of opening them being experienced. This single symptom frequently endures for a very considerable time before any farther progress is observed. Next, the feet swell at night, and the upper extremities become very quickly the site of effusion, and the left arm earlier and more frequently than the right.

The anasarca swelling, which is peculiarly pellucid, usually long precedes the occurrence of ascites; effusion taking place in the peritoneal cavity late in the disease and very slowly. Frequently, indeed, patients are examined, in whom anasarca has been the consequence of cardiac disease, without a single ounce of fluid being found in the abdomen; and sometimes, although more rarely, not even in the cavities of the pleuræ. The pulse is not always characteristic of disease of the heart; and of course the same difficulty must naturally occur in detecting such disease, whether accompanied or not accompanied by dropsy. When, however, effusion begins after long disease, and without pulmonary symptoms, in the face and upper extremities, we may always suspect the heart to be the source of the effusion. In many patients, and particularly in women, this first symptom appears to be followed by partial effusion into the chest, and for some weeks before any farther progress is made, the patient is unable to lie down. At first this difficulty of preserving a reclining posture is very slight, and only an additional pillow is required, the patient at this time being scarcely sensible that the inability of lying down is the consequence of disease. Gradually, however, the effusion increases, progressively involving every part of the system,—the cellular texture and the cavities of the brain, pleuræ, and peritoneum.

The urine in some of these cases at a very early period affords a very slight deposit of albumen upon boiling, and this albuminous secretion becomes more and more abundant in the progress of the disease. Its quantity varies considerably. In a patient who died in the Birmingham Hospital during the present year at a very early stage of the effusion, two months before his death the urine was barely rendered turbid, but the evening he died it was rendered

nearly solid, by boiling. On dissection, the heart was found enormously enlarged, and the aorta very much diseased. The kidneys were perfectly sound. The urine, however, does not coagulate in every case of dropsy arising from disease of the heart, nor is it very easy to say what is the precise state of the system in which this phenomenon does occur.

None of the species of dropsy is more frequently relieved, or we may say for a time even cured, than this; but it very frequently recurs, and at length, favoured by the exhaustion from long disease, and sometimes perhaps even by the remedies that have been necessarily employed, a very copious effusion takes place into the chest, and death often at last occurs very suddenly. Sometimes, and this is no unusual occurrence, the anasarca permanently disappears for some time before death, or remains but in a very slight degree. The oppression of the chest, however, is not diminished, and occasionally a greater determination of blood takes place to the lungs, or these organs become congested, especially if much obstruction occurs in the valvular structure of the left side of the heart. At this period hæmoptysis, acute pneumonia, and pleurisy, are very liable to ensue, and require the most decided antiphlogistic treatment. Even this treatment does no more than afford temporary relief, and inflammation occurs again and again, till the means of the physician are exhausted. To stimulate increases the inflammation, and farther depletion is rendered impossible by the extreme debility of the patient.

The course now described is not peculiar to any one affection of the heart; the symptoms are, more or less, the same under every malady of that organ. Some difference nevertheless exists according as the heart is the subject of what Corvisart calls active or passive aneurism; congestion and inflammation being more common in the former affection than in the latter. Often, indeed, when passive aneurism exists, advantage is derived from the lighter tonics united with diuretics, but active depletion is neither called for nor admissible: it reduces the patient without benefiting him as regards the disease.

*Dropsy from disease of the lungs.*—Under the head of ANASARCA we have given several instances of this affection, when arising from or connected with inflammation of the lungs. For the phenomena attending it under such circumstances, we refer therefore to that article. It is not, however, only after inflammation of the parenchymatous structure of these organs that effusion occurs; it arises also after chronic bronchitis; after chronic pleurisy; and frequently, perhaps generally, in a greater or less degree, in the latter stages of tubercular phthisis.

The phenomena of dropsy, when arising from chronic bronchitis, do not materially differ, excepting as to the rapidity of its progress, from a similar affection after inflammation of the lungs. The face and upper extremities are in both cases the first to become œdematous.

Sometimes this œdema is so slight, that it produces only slight stiffness at first waking in the morning, and is scarcely—occasionally not at all—recognized by the patient as the consequence of any swelling of the eyelids. At a shorter or later period after this, the ancles swell, and the affection in this stage may remain nearly stationary for months and even for years. As, however, chronic bronchitis is liable to pass at particular periods into a subacute, sometimes even into an acute form, there is usually at the same time an increase in the effusion, which will thus be found to increase and subside with every aggravation or alleviation of the original malady. We have in this manner known an individual pass seven or eight years without any material alteration; in the summer enjoying a tolerable state of health, in the winter threatened with a fatal termination from fresh attacks. It ought also to be observed, that each attack leaves the individual in a less favourable state than before. At length the dropsical effusion begins to increase more rapidly; the whole cellular texture becomes anasarcaous; fluid is poured out into the cavities of the peritoneum, the chest, and the brain, and death ensues from the affection of one of these latter cavities. Sometimes the pleura, the pericardium, and the cellular texture of the lungs become so dropsical, that the patient is unable to lie down, and at last appears to die from suffocation; and not unfrequently death takes place very suddenly under such circumstances. Another termination is in effusion into the ventricles of the brain, and the patient dies with the common symptoms of apoplexy, or falls into a dose, and imperceptibly passes from a state of sleep to actual death.

To this general description of the course which dropsy from chronic bronchitis pursues, is to be added, the supervention of fresh symptoms as additional organs become involved. Thus palpitation of the heart supervenes with the effusion of fluid into the pericardium; the dyspnoea increases with the increase of effusion into the pleura or the cellular tissue of the lungs; the digestive organs become more disturbed as their functions are interfered with by the pressure of fluid within the cavity of the peritoneum; and if the brain is involved in the general disposition to dropsy, stupor, paralysis, or apoplexy, may and not unfrequently do ensue.

Dropsy likewise takes place in the latter stages of chronic pleurisy and tubercular phthisis, but it is not often a very prominent affection, and is chiefly confined to the lower extremities. Sometimes, however, the body becomes universally anasarcaous, especially in phthisis,—and very little can be effected for the effusion under such hopeless circumstances.

*Dropsy from disease of the liver.*—This species of dropsy has been recognized from the very earliest periods of medicine of which any record remains, and to this most of the older histories of dropsy refer. The form which it assumes is chiefly that of ascites; and some

peculiar symptoms attend its progress, which deserve consideration in its treatment. Dropsy takes place in the latter stages of most hepatic diseases; nor are we acquainted with any mode of detecting the precise nature of such diseases during life,—whether there is nutmeg liver, or simple enlargement of it, or tubercular disease,—excepting in the last instance, when the bulk of the organ has so far increased that a tolerably correct opinion may be formed by external examination.

Disease of the liver usually exists for a long time before effusion takes place, and its earliest symptoms are little more than those of simple functional dyspepsia. There is flatulence, uneasiness at the stomach after eating, and often some pain and tenderness in the right hypochondrium; and occasionally at a very early period the lower edge of this organ may be perceived harder, larger, and lower in the abdomen than is usual. There is a short dry cough occurring at times throughout the day, but more particularly on first rising in the morning, and the sputa are blackish and occasionally dotted with blood. The pain passes sometimes backwards under the blade-bone; at other times the muscles covering this bone, with the deltoid, become the seat of pain greatly resembling rheumatism, and not unfrequently mistaken for it. The urine is very red and deposits lithic acid, and the evacuations are usually, but not invariably, clay-coloured. In many instances sickness also is present, and a greater or less degree of jaundice. When this last symptom is united with those above enumerated, no doubt can remain that the liver is the seat of some important disease.

When the symptoms now mentioned have continued for some time, the ancles are perceived to swell at night a little, and the abdomen becomes somewhat fuller. The urine at the same time diminishes in quantity, the skin becomes dry and harsh, and the patient suffers from distressing thirst. The progress of the effusion from this period is very various: in some cases ascites is quickly formed, and the lower extremities become anasarcaous throughout; in others the ascites is complete, while there is scarcely any œdema present; and in a third series of cases, the progress of both is very slow: in these last the ancles remain long slightly œdematous without any increase of effusion, and sometimes for two or three weeks together it entirely disappears, so that the patient fancies that the dropsical tendency is gone; again however it returns, and the dropsy becomes permanent. The duration of the disease is likewise various; for while in most cases several months elapse from the commencement of effusion till the death of the patient, in others the effusion takes place only a few days, or two or three weeks before death; and we have sometimes seen the abdomen become excessively distended three or four days only preceding dissolution.

As in dropsy from disease of the lungs, fresh symptoms are added as additional cavities become the seat of effusion; but neither the chest nor the ventricles of the brain so readily

pour out fluid as when the dropsy commences with an affection of the heart or of the lungs. The dyspnoea which usually comes on in the latter stages of hepatic ascites, is chiefly to be referred to the protrusion of the diaphragm into the cavity of the chest, and it is seldom that any cerebral disturbance exists in these cases. Generally, indeed, hepatic patients preserve their intellectual powers to the last in a very extraordinary manner. We have sometimes however seen delirium come on a few hours, or a day or two before death; but this is so usual in the closing scene of all chronic diseases, that it cannot be regarded as an essential part of the affection we are now describing. Under these circumstances the patient gradually wastes away; and death seems the natural result of a debility that had been continually increasing till the moment of dissolution.

*Dropsy from disease of the spleen and pancreas.*—There are no general symptoms by which we can readily recognise these organs as the sources of effusion. With regard to the spleen, its enlargement usually long precedes the occurrence of dropsy; and the diagnosis, consequently, when the patient is seen early, can seldom be difficult. Dropsy from this cause often disappears; and we have known in one instance the effusion and the tumour vanish together, after the latter had existed for many months. The pancreas has not been much observed in dropsy, and we are not acquainted with any case of effusion that could be attributed to an affection of this organ.

*Dropsy from disease of the kidneys.*—Many affections of these organs are capable of inducing effusion, and this is a common consequence when from any cause they are extensively diseased. The kidney is occasionally converted into a scrofulous mass; and we have met with cases, and several others are recorded, in which under such circumstances it formed a prominent tumour in the abdomen. A much less degree of disease is, however, sufficient to produce effusion. The form of dropsy under these circumstances is anasarca, and ascites does not usually take place till later in the disease. The œdema commences in the lower extremities, and in some instances which have come under our notice, the limb corresponding with the diseased kidney, where only one was affected, has swelled most; so that we are induced to believe that œdema in such cases is sometimes the consequence of pressure upon the ascending cava, or at least is aggravated by this pressure.

Dr. Bright has within these few years brought to the consideration of the medical world a peculiar change in the structure of the kidney, which he regards as the cause of dropsy, and the tendency to which change, or its actual occurrence, is indicated by the coagulability of the urine. In these views he is joined by Drs. Christison and Gregory, the latter of whom has however shewn that the peculiar alterations alluded to by Dr. Bright, and the presence of coagulable urine, often occur without dropsy. The peculiar nature of this change we shall

intimate when we describe the morbid anatomy of dropsy.

Three forms of dropsy connected with disease of the kidney may be particularly traced in the cases recorded by the above mentioned physicians:—the first commencing evidently with the respiratory or circulating organs, and united, either from the beginning or as the effusion proceeds, with disease of the kidney; the second, commencing with disease of the kidney, and secondarily affecting respiration and circulation; and a third in which the kidney is the only organ affected throughout. The first species differs little from that which we have already spoken of under the head of dropsy from disease of the lungs, excepting in the supervention of symptoms indicative of renal disease. These symptoms are sickness, vomiting, purging, pain in the loins, often united with coagulable urine; but this last may exist in a very great degree, and for a very long time, without any appreciable alteration in the structure of the kidney. The former symptoms exist in very various degrees, either alone or united, and are sometimes altogether absent.

The second form begins with anasarca only, which quickly becomes universal, and in a longer or shorter time, commonly within a few days, symptoms of inflammation of the lungs or pleuræ, or of both, supervene; and though this may be removed by appropriate treatment, it returns again, each time increasing the disorganization of these organs, and sometimes also extending to the pericardium, and giving rise to adhesions between its surfaces. The dropsy also is, at the commencement of the disease, often easily removable, but still it returns, till at length a few weeks or days before death it disappears altogether. In these cases, it is frequently only the anasarca and ascites that disappear, and the cavities of the chest are found after death to be full of effused fluid. In this as in anasarca from other causes, effusion may take place in the brain; and knowing the sympathy between the kidney and this organ, it is by no means surprising that this is no unusual occurrence.

The third is a much rarer occurrence than the two former. Dr. Bright has given one instance of this, in which no other symptom was present than extensive anasarca with coagulable urine, containing a considerable quantity of the red particles of the blood. The anasarca disappeared under the treatment which was adopted, but the patient died suddenly from inflammation and œdema of the glottis. Dissection appears to have proved that in this instance the kidney was in a state of excessive congestion, if we may not go so far as to call it inflammation.

A peculiarity in patients suffering under this dropsy is their extreme liability to be affected by calomel. Dr. Bright and Dr. Gregory have related instances illustrative of their proneness to severe salivation from very small quantities of mercury, and we have ourselves witnessed cases of the same kind.

Much importance is attached by Dr. Bright and the Edinburgh physicians to the coagu-

lability of the urine, as indicating extensive change in the structure of the kidney,—much more, indeed, than it appears to us the evidence afforded is able to sustain. Dr. Wells has long ago shown that this symptom appeared and disappeared under circumstances in which it could not fairly be regarded as the consequence of organic disease. He saw it suddenly induced by the exhibition of mercury: he knew an individual in whom it appeared probable that the coagulability of the urine had existed for nine years: he also pointed out the frequency of its occurrence in that form of dropsy which succeeds scarlatina; and showed, likewise, that with the disappearance of the dropsy the kidneys ceased to pour out serum. Dr. Bright himself contends only for functional disease in the first instance, leading secondarily as in other cases to organic disease; although it must be confessed, from the great stress he lays upon this one symptom, a cursory reader might easily mistake his meaning. Dr. Elliotson, also, is reported to maintain that the urine may strongly coagulate for a time without any change in the structure of the kidney.

We are, however, disposed to go even farther than this; and, without denying that in some instances coagulable urine is the consequence of serious primary disease in the kidney, nevertheless to maintain,—that in many instances it is merely a symptom very remotely connected with organic alteration in the kidneys. As a secreting organ, the kidney is especially liable to be affected by the pabulum afforded it; and should the blood reach it in an imperfect state, whether in consequence of indigestion, imperfect change in the lungs, or inordinate action of the heart, or insufficient nervous influence, we may expect that its function will be impaired. Accordingly we see it deposit yellowish sediments in indigestion, lateritious sediments in febrile diseases, and phosphates after injury of the spine. Now in very many of the cases, perhaps in the majority, of dropsy with coagulable urine, the effusion is preceded by inflammatory symptoms of the organs of respiration; and in many there is disease of the heart. Considering the important changes that take place in the blood during its passage through the lungs, we can hardly be surprised that an affection of these organs should influence the secretion of urine; and again, while apoplexy is distinctly traceable to hypertrophy of the heart in some cases, it surely is not extraordinary that by this organ also the secretion of the urine should be modified. But we are not left only to theory on this point: the numerous cases in which the urine coagulates, already referred to, and in which organic disease cannot fairly be presumed to exist, confirm to a certain extent this view of the subject, while morbid anatomy still farther corroborates it. In two instances which we have lately had an opportunity of examining, where the urine had strongly coagulated during life, no disease whatever was observable in the kidney. To one of these we have already referred. The

other occurred in a lady who had been suffering from pulmonary symptoms, and symptoms of disease of the heart, for nine months when we first saw her. At this time the urine coagulated strongly, and continued to do so till the period of her death, three months afterwards. Yet, while the left lung, the pleura, and the heart exhibited serious disease of long standing, and while the liver was also diseased, though in a slighter degree,—there was no appreciable change whatever in the substance of the kidneys. A small cyst containing a colourless fluid was seated on the superior convex portion of the left kidney, but did not in the slightest degree interfere with its structure. In this case there had never been any pain in the back.

The view we now contend for is by no means unimportant as a guide to practice; for the plan of treatment must necessarily be different, according as we consider the kidney primarily or secondarily affected. Should we find reason to believe that the respiratory organs are the earliest and principal sufferers, our chief attention must be paid to them. As a guide also to a correct prognosis, this view is most important; because, if the kidney is to be regarded as organically diseased in every case of coagulable urine, all such cases would be evidently hopeless, and little would remain for the physician but to smooth the path to a fatal termination.

The next question which presents itself connected with this state of the urine, is the condition of the system in which it exists. Dr. Blackall regarded it as inflammatory; Dr. Prout regarded it rather as proceeding from irritation than inflammation;\* and other authors appear to have paid scarcely any attention to this part of the subject, excepting so far as stating that it could not be relied upon as a guide in practice. That it is at times connected with an inflammatory state of the kidneys, the following case, which occurred in our practice several years ago, abundantly proves.

A girl, twenty-three years of age, applied on the 11th of July, 1823, complaining of severe pain across the back in the region of the kidneys, with shivering and frequent sickness. A short time before, the right foot had swelled, but at the time of her application this had subsided. Her urine was of a dark brown colour, depositing a thick precipitate upon the addition of tartarized antimony, and becoming of the consistency of melted butter by boiling. She made water very frequently, but very little at a time. She complained of pain in the pudenda. The catamenia were scanty, but regular to the period. She had had scarlet fever six months before, and her urine had been of the dark colour, now mentioned, ever since, but occasionally becoming a little clearer. This case was regarded as inflammation of the kidneys, and treated accordingly, and on the 21st of July she was convalescent; the urine had then returned to

\* Prout on the Urinary Organs, first edit. p. 48.

a healthy state, being lighter in colour, and affording no coagulum upon boiling. On the other hand Dr. Blackall has given a case of dropsy after scarlatina, in which the urine remained coagulable after the effusion had disappeared, and regained a healthy state under the administration of cinchona. At the present time we have a case of dropsy with coagulable urine, in which the quantity of serum greatly diminished for a few days after taking sulphate of quinine.\* Dr. Bright also remarks, that occasionally we find anasarca even with coagulable urine so marked by debility that tonics and steel give decided relief.

Dr. Wells had seen the urine become coagulable after the exhibition of mercury, and this is now a well known effect of mercury. Dr. Bostock observes that in a great majority of cases of persons in apparent health, serum may be detected in the urine, by the appropriate tests, and that in his own person he had observed it to be increased to a considerable amount by the slightest causes. In a patient, of the Birmingham Hospital, who had had anasarca connected with bronchitis, after both diseases had disappeared, and the urine, which had originally been coagulable, had recovered its healthy condition, it was found one day immediately after dinner to be rendered almost solid by heat, and the next morning the same means did not detect a single particle.

These few facts abundantly confirm the opinion of Dr. Prout, that taken alone "as a symptom, the albuminous urine does not, in the present state of our knowledge, indicate the use of any particular remedy or mode of treatment; but that, nevertheless, it is a symptom of which we ought always to be aware, since, taken in conjunction with the others, it may be occasionally useful in directing us to form a more correct judgement of the general nature of the disease."

Albuminous urine appears to be much more intimately connected with anasarca than with ascites. Dr. Wells found it, in twenty-four cases out of thirty-seven, connected with anasarca; in fourteen cases of ascites previous to anasarca, there was no serum in the urine; and in eight cases of anasarca subsequent to

ascites, the urine in all contained serum, and in one it was rendered solid by heat. Of the seven cases related by Dr. Christison, anasarca was the principal form of dropsy in six, and in the seventh only was the ascites a prominent symptom. Much the same proportion is observable in Dr. Gregory's cases; and in the twenty-three cases recorded by Dr. Bright, anasarca was the form of effusion in all.

We cannot dismiss this part of the subject without some observations on the composition of coagulable urine. Dr. Bright believed that the dark brown colour was frequently owing to the presence of the red globules of the blood, and in this opinion he is supported by Dr. Gregory. The case of inflammation which we have already given strongly supports this view, and there are few physicians probably who will doubt the possibility of its occurrence. This point therefore we may now leave: a much more important part remains, viz. to afford our readers the best means of investigating some of these points themselves.

All the writers referred to (and in numerous instances we have confirmed the fact by our own experience) state that coagulable urine has a much less specific gravity than healthy urine; and Dr. Gregory has given two tables containing the result of an equal number of trials with coagulable and with healthy urine. The average specific gravity in fifty cases was in healthy urine 1022.46, the highest being 1033, and the lowest 1005; while in the coagulable urine, the highest was 1023.5, and the lowest 1006.5.

With regard to the best means of detecting albumen when it exists in urine, we may observe that heat, while it is of readiest application, will generally be found sufficient. It is often advisable, however, to make use of re-agents, and of these corrosive sublimate is the most delicate. The nitric and muriatic acids are also employed for the same purpose, as is also the ferro-prussiate of potash, and alcohol. With respect to the effects of these latter re-agents, Drs. Gregory and Bostock are somewhat at issue. The former says that he never knew a case in which they caused a precipitate when heat had no effect, while Dr. Bostock observes, "I have also found certain states of the urine where heat had no effect, but where muriatic acid threw down a precipitate, and again where muriatic acid had no effect, but where the albumen was detected by the bichloride of mercury, or the ferro-prussiate of potash." All, therefore, that can be deduced is, that all these re-agents should be employed in succession in suspected urine, when the first fails to discover albumen.

*Dropsy from disease of the uterus and ovaries.*—Many of the affections of the uterus, after they have existed long, give rise to dropsical effusions into the lower extremities. Sometimes this appears to be the result of pressure only upon the great vessels, when the uterus is either enlarged itself or contains a tumour of considerable size. At

\* The patient here alluded to was in the Birmingham Hospital, and died soon after the above was written. The body was examined, but there was no alteration in the structure of the kidneys. The cortical part was paler than usual, but retained its natural structure, and the tubuli were perfectly distinct. The kidneys were exhibited to several of the medical officers of the establishment, who all agreed that there was no change whatever of structure. The liver in this case was, if anything, smaller than natural, and externally had exactly the appearance of lung; internally it appeared as if it were pervaded by inspissated bile, and was firmer than natural. The peritoneal coat had contracted numerous adhesions with the diaphragm. The heart was remarkably small, the walls of the right cavity were very thin, while those of the left compared with the right were enormously thick. These were the only unusual appearances about the body. This man had been a spirit-drinker.

other times the effusion appears to be the result of the hemorrhage to which, under certain forms of disease, the uterus is peculiarly liable. This therefore is not fairly to be referred for its origin to organic disease of the uterus; the dropsy is simply the consequence of the hemorrhage, and hemorrhage from any other organ would give rise to similar results. With regard to the ovaries, we know that they are themselves the seat of those affections which are called encysted dropsies, and in this light they do not at present demand our consideration. But affections of the ovaries appear sometimes to produce real ascites, while they still present only the character of nearly solid tumours, and at the same time the lower extremities become œdematous. We have already mentioned our suspicion that ascites is sometimes a consequence of ovarian disease, subsequent to parturition, and we have met with cases of bronchitis in which ascites has taken place earlier than probably it would have done, had not ovarian disease existed previously.

*Morbid anatomy.*—This naturally divides itself into two parts:—first, the morbid anatomy of the serous membranes and cellular tissue, which are the immediate sources of the effusion; and, secondly, the morbid changes of the various viscera, in consequence of which the serous membranes and the cellular tissue assume a dropsical disposition.

1. The most ordinary appearance in the serous membranes is thickening and opacity, which are more or less manifest in every serous membrane of the body. Thus in hydrocephalus, the lining of the ventricles, though seldom separable as a membrane, is evidently firmer and more condensed than natural; but the changes referred to are much more easily seen in the pleura, pericardium, and peritoneum. All these membranes become opaque or thickened; coagulable lymph is thrown out; and we not unfrequently find large layers of lymph converted into factitious membranes. Tacheron\* says, “The pleura has been found thickened and covered with a layer of villous matter, oily to the touch, whitish, and similar to the intestines of the eow when converted into tripe.” The same author has given an example of both pleura and the peritoneum becoming tuberculated. Dr. Ayre has related a case of ascites in which he found the peritoneum thickened and opaque, quite white, and having nearly the thickness of chamois leather. In the Quarterly Review of Foreign Medicine, a case is given of a woman who became dropsical after being brutally kicked by her husband: in thirteen years she was tapped 665 times, and on dissection the peritoneum was found cartilaginous and three lines thick.

So far as the serous membranes themselves are concerned, these appear to be the principal

changes. With respect to the cellular tissue, Portal tells us that in dropsy it is more or less thickened, that the cells are dilated, and many converted into one, and that he had seen the intermuscular cellular tissue put on a cartilaginous appearance under such circumstances.\*

Morgagni relates a case of anasarca in which the tissue was thickened, and, as he says, the fluid, from the frequent intervention of the cellular layers, assumed the likeness of gelatine. Bichat observes that in prolonged cases of leucophlegmasia, the subcutaneous fluid is by degrees infiltrated through the prolongation of the areole of the skin, separates their fibres, and sometimes penetrates to the epidermis, which it bursts in different places, and the fluid escapes through the apertures which are thus made.† In the case above referred to, from Morgagni, the cuticle had been thus raised, but not burst, so as to form immense bladders, which were filled with water.‡ The cellular tissue itself is in such cases remarkably bleached.

This perhaps is the proper place for noticing the changes which occur in the absorbent vessels and veins. It has been often assumed that the former may be dilated and burst, but we know no cases which afford confirmation to such an opinion. That the absorbent vessels are more easily detected in dropsical bodies is true, but this probably is chiefly owing to the removal of the adipose substance of the system. Dr. Hodgkin, however, has lately rendered it probable that these vessels are in some way connected with effusion. He has related several cases of dropsy in which the absorbent glands, and especially those surrounding the great vessels, were enlarged and indurated.§ This enlargement appears to consist throughout of an uniform texture, rather the consequence of a general increase of the whole gland, than a new structure displacing the original one. It is simply an hypertrophy therefore of the glandular system. In illustration of this morbid growth, five cases are given, two in children, one nine and one ten years old; one in a man aged thirty, and two in persons of fifty years of age. In four of these cases the spleen was enlarged; and a fifth case of enlarged spleen with general induration of the absorbent glands is referred to, drawings of which were made by Dr. Carswell, and are contained in his collection.

In local anasarca the veins frequently exhibit peculiar appearances. Sometimes their cavities are completely obstructed by fibrinous clots, which have evidently formed during life. In other cases the internal membrane is thickened, red, and covered with coagulable lymph. Occasionally pus is found in their cavities.

Diseases of the arteries are often found in dropsy, and particularly aneurisms of the aorta.

§ Medical Gazette. January 21, 1832.

\* Recherches Anatomico-Pathologiques, vol. iii. p. 196.

The late Mr. Freer believed that inflammation of the lining membrane was common. We are not aware that this observation has been confirmed, but we have seldom opened a patient dying with general dropsy who did not exhibit some disease of this membrane. This generally consists of scrofulous or bony deposits, with frequent ulceration; and we once saw the descending aorta beset with numerous incipient aneurisms, from this cause, few of them being larger than a good sized pea.

2. The lungs are frequently found with the appearances consequent to bronchitis. The bronchial membrane is inflamed, and its texture thickened, sometimes even ulcerated. The cavities of the bronchi and air-cells are filled with a frothy fluid, and sometimes with pus. At other times we find the common results of pneumonia, congestion of the lungs, serous infiltration, hepatization, purulent infiltration, &c. When dropsy of the pleura has existed long, the lung is often so much compressed as to form a solid body, wholly or in part impervious to air.

Tubercles are not unusually discovered in dropsical patients, although no suspicion of tubercular phthisis may have existed during life.

The various organic alterations of the heart are also frequent in this disease, and may, doubtless, be regarded as the original cause of effusion. For a more minute account of these morbid changes we refer the reader to the articles on the diseases of this organ.

The liver exhibits an immense variety of appearances in dropsy. It is sometimes hard and scirrhus, many instances of which are given by Morgagni.\* Dr. Baillie says in many cases of ascites the liver is diseased, being hard and tuberculated; and in another place he has particularly described the kind of change which is here meant. The tubercles which are formed in this disease occupy the whole mass of the liver, are placed very near each other, and are of a roundish shape. They give an appearance every where of irregularity to its surface. When cut into, they are found to consist of a brownish or yellowish white solid matter. They are sometimes of a very small size, so as not to be larger than the heads of large pins; but most frequently they are as large as small hard nuts, and sometimes larger. When the liver is thus tuberculated, it feels much harder to the touch than natural, and not uncommonly its lower edge is bent a little forwards. Its size, however, is not generally larger than in a healthy state, and sometimes Dr. Baillie thought it was smaller. If a section of the liver be made in this state, its vessels seem to have a smaller diameter than they have naturally; and it frequently happens that the liver is of a yellow colour from the bile being accumulated in its substance. The gall-bladder is generally contracted, and of a white colour, from its being empty. Dr. Baillie also mentions a peculiarly hard liver, which exhibits, when cut into, no peculiar structure, and is also accompanied by incipient ascites. This state of the liver has

frequently fallen under our notice, and we have found it still only unusually firm when the ascites has been very considerable.

Dr. Bright has described an appearance of the liver, probably the more advanced stage of the last morbid structure, and which seems really to deserve the name of scirrhus. The substance of the liver is hardened throughout, and bands of thickened cellular membrane, like ligamentous matter, pervade every part: in some parts of the liver from which this description is drawn, it formed one-third of the whole structure. Although, when seen externally, the liver appeared tuberculous and knotty, yet when examined internally, there were no tubercles. The liver is also sometimes studded with large white tubercles; and we have seen the structure of the organ so completely obscured by their accumulation, that it could scarcely be recognised. This disease, however, seldom gives rise to effusion till it has made very extensive progress. The weight of the liver in such cases is often very great: in a patient whom we examined last year, it amounted to eleven pounds.

The changes now enumerated form indeed but a small part of the modifications to which this organ is liable, and which are found to give rise to effusion. The observation of Dr. Bright, however, that those changes in the structure of the liver by which the branches of the vena portæ are compressed more frequently give rise to dropsy than any of the circumscribed changes, (as tubercles of various kinds, and hydatids occurring imbedded in their substance,) is perfectly accordant with our own experience; and the observation we have just made respecting the period of effusion in tubercular disease of the organ, drawn as that observation is from numerous facts which have fallen under our notice, is an additional confirmation.

The colour of even what is called a healthy liver is exceedingly various, and hence, from colour alone, it is not easy to draw any positive conclusions. Sometimes, however, the variation is so decided that we cannot hesitate to pronounce the structure diseased. The most remarkable of these changes is that which has been termed the *nutmeg* liver, and this term more completely explains the appearance than any lengthened description can do. Sometimes the whole liver is much lighter than usual; at others it is yellow, and appears to be filled with inspissated bile; and Dr. Bostock has rendered it probable that this is actually the case, for in a liver of this kind submitted to his examination, he inferred from numerous experiments that it contained cholesterine, the substance which forms the basis of biliary calculi. In a liver which we examined within these few days, the colour externally was that of hepatized lung, and it might easily have been mistaken for this organ so far as the colour was concerned. The interior was very dark, yet we could scarcely say that the structure was diseased.

The spleen is also frequently found in a diseased state in dropsy. It is sometimes

\* Epist. xxxviii.

much harder than natural, and at the same time considerably enlarged. It will occasionally attain an enormous bulk, forming a very prominent tumour in the abdomen, and after continuing some time, giving rise to effusion, by which the tumid spleen is subsequently concealed. The structure of the spleen does not in such cases appear altered, but is only firmer and more compact, still retaining its natural colour and granulated appearance. Sometimes this organ is covered with small white cartilaginous bodies, probably tubercles, as we once found them in a man whose lungs were studded with similar particles; and Dr. Hodgkin has related a case in which they seem to have pervaded the substance of the organ. In this instance the spleen was at least nine inches long, five broad, and proportionably thick: its structure consisted of an almost infinite number of small white globules, which appeared to arise from deposits in the cellular tissue of the organ.

The pancreas is seldom diseased in dropsy: we have sometimes thought it much harder than natural, but on cutting into it, it has invariably exhibited a natural structure.

The kidneys are subject to various diseases, and very different morbid structures are exhibited in them in cases of dropsy. Dr. Bright thinks that his investigations will authorise three varieties *generally* attended by albuminous urine:—“In the first a state of degeneracy exists, which, from its appearance, might be regarded as marking little more than simple debility of the organ” (anæmia). “In this case the kidney loses its usual firmness, becomes of a yellow mottled appearance externally; and when a section is made, nearly the same yellow colour, tinged with grey, is seen to pervade the whole of the cortical part, and the tubular portions are of a lighter colour than natural. The size of the kidney is not materially altered, nor is there any obvious morbid deposit.” This state of the kidney is well known as the consequence of dram-drinking, but it certainly is not confined to the victims of intemperance. It is frequently found in patients who have suffered from tedious and exhausting disease; and Dr. Bright himself states that he had observed it in a case of diarrhoea and phthisis, and of ovarian tumour. We have observed it in a woman who died from disease of the heart, and in whose lungs there were softened tubercles, none of which had been discharged. In this instance the urine did not afford the slightest coagulation by heat. In the most advanced stage of this disease Dr. Bright thinks that there is a more decided alteration of structure, and that some portions are consolidated so as to admit of very partial circulation: in which state the surface has a somewhat tuberculated appearance, the projections being paler than the rest, and at this period the urine is coagulable.

The second form is one in which the whole cortical part is converted into a granulated texture, and where there appears to be a copious morbid interstitial deposit of an opaque white substance. In its earliest stage this only produces externally an increase of the natural mot-

ted appearance, or sometimes that of fine sand sprinkled more abundantly on some parts than others. The same appearance is slightly observable internally on making a longitudinal section. After the disease has continued some time, the deposited matter becomes more abundant, and innumerable specks of no definite form are observed on its surface. The cortical part exhibits, on being cut into, a similar appearance. Later in the disease the granulated state begins to show itself externally in frequent slight uneven projections on its surface, and the kidney is rather larger than natural.

In the third form the kidney is quite rough and scabrous to the touch externally, and rises in numerous small projections, yellow, red, and purplish. The organ is often inclined to be lobulated, and on making an incision, the texture is found approaching to cartilaginous hardness. The tubular portions are observed to be drawn nearer to the surface, and it appears like a contraction of every part of the organ, with less interstitial deposit than in the last variety.

Dr. Bright also mentions two other conditions of the kidneys, in which coagulation of the urine is sometimes observable. One of these consists in a preternatural softness of the organ; the other in the blocking up of the tubular structure by small portions of a white deposit, bearing the appearance of small concretions. In the former, a corresponding loss of firmness has been observable in the heart, liver, and spleen; and in the latter, the cortical portion has been firmer than usual, and the tubuli have assumed a waved direction.

These are by no means the only diseases of the kidney that give rise to or are attended by dropsy. It is sometimes scrofulous. We have seen it converted into a steatomatous tumour so large that it formed a prominent tumour in the abdomen. In another case the right kidney was five or six times its natural size, soft, and divided into lobules. On opening it, it was found full of scrofulous matter, which occupied the whole of the cortical part and the interstices of the tubuli, which were scarcely at all traceable. The left kidney equalled the right in size, but was less diseased. The cortical substance was changed into a granulated fatty substance, presenting much the appearance of the liver under some circumstances. The tubuli were in this instance quite distinct. In this case, which is copied from notes taken in 1826, the urine had come away stillatim, and the patient had suffered very much from excoriation of the pudenda. She never complained of any particular pain till six weeks before her death, when she became anasarcaous. The symptoms then agreed with those of Dr. Bright's and Dr. Gregory's cases. From the urine during the whole period coming away stillatim, this secretion was not particularly examined. We have particularly mentioned this case because it illustrates the remark of Dr. Gregory, that the persons in whom he found the morbid alterations of the kidney, were either those who had led irregular lives, or who presented the usual character of the strumous diathesis. Again, in a case which we examined a few

days ago, the left kidney contained several calculi; and its structure, though much wasted, was remarkably healthy in appearance, while the right kidney was pale, and the tubuli were very indistinct in consequence of an interstitial deposit of a whitish substance.

These, probably, are only a few of the deviations from health which occur in the kidney, and which give rise to or accompany dropsy. With regard to any of these changes being necessarily connected with albuminous urine, enough has been shown above to prove that at present the subject requires additional investigation. We have found albuminous urine to a very considerable extent without any corresponding alteration in the structure of the kidney; and we have related one instance of Dr. Bright's first variety in which the urine did not coagulate. It cannot, however, be considered improbable that this phenomenon is connected with some peculiar condition of the organ, and that, when long continued, it will lead to some peculiar morbid alteration of structure. But what this condition or this alteration may be, must still be regarded *sub judice*; and we should mislead our readers in no slight degree if we called upon them to believe that anything further in this matter has yet been discovered, than a more frequent coincidence between coagulable urine and disease of the kidney than had been previously suspected. This coincidence, though frequent, is not invariable; nor are the symptoms which are reported to indicate it more to be relied upon.

*Prognosis.*—The prognosis in dropsy must naturally vary much according to its origin, its combination with organic disease, its duration, and the debility of the individuals who are the subjects of it.

Acute dropsies, *ceteris paribus*, are more curable than chronic, and idiopathic are more curable than secondary dropsies. With regard to acute dropsies our judgment must be greatly guided by the concomitant circumstances. If there be any vital organ seriously affected, as the lungs or the heart, our chance of removing the effusion will be governed greatly by the control we may be able to obtain over the original disease. Thus, if *anasarca* succeed bronchitis, a permanent recovery from the dropsy cannot be expected without the disappearance of the bronchitis. It will indeed sometimes happen, as we have mentioned in a previous part of this article, that effusion will disappear a short time before death; but this clearly is no cure of the secondary disease. In healthy constitutions, which have been uninjured by irregular habits of living, the acute dropsy will, under proper treatment, usually terminate favourably; but in those who have been weakened by drinking or other irregularities, or who are originally of debilitated constitutions, we can seldom venture to predict recovery.

With regard to secondary dropsy, we may state that those arising from disease of the heart usually admit of removal, but the disappearance of the effusion is seldom permanent. Nevertheless, longer or shorter intervals of ease are afforded; and, under cautious treatment,

months, and even years may elapse between the first occurrence of effusion and the fatal termination. The same remark to a certain degree holds good of that species of dropsy which accompanies disease of the lungs, but it is certainly less curable than the former species. The effusion which succeeds hepatic disorders is almost always fatal, and by no means affords a chance of cure in an equal degree with the two former modifications. There are, however, some cases of ascites connected with enlargement of the liver, in which the effusion will disappear repeatedly under the use of diuretics, and in a few instances we have known a considerable time elapse before it has returned. That which succeeds or is accompanied with extensive disease of the kidney seems absolutely incurable when the renal disturbance has produced any extensive change of structure; but the symptoms of this change are by no means at present satisfactorily ascertained.

*Treatment.*—In the treatment of dropsy, as in every other disease which falls under the care of the physician, certain general principles are first to be considered; and, secondly, the circumstances by which these principles are more or less modified.

It has already been stated that dropsies are sthenic or asthenic, or in different periods of their progress that they partake of both conditions—at one time the sthenic, at another the asthenic predominating. To this point, then, attention must first be paid, and an antiphlogistic or a contrary regimen pursued accordingly.

Should the effusion have arisen suddenly, and should local inflammation be present, whether of the lungs or any other organ, bleeding must by all means be resorted to; and it must be carried far enough to affect the system, to reduce the pulse, produce faintness, or relieve the immediate inflammatory symptoms.

The bleeding may be repeated should the inflammation continue, and should the strength of the patient permit. But even when this is much reduced, and venesection can scarcely be justified, local bleeding may be advantageously employed, and in all such cases cupping is much more efficacious than leeches. The glasses should be applied as near as may be possible to the affected organ, and to the part of the organ which is most implicated. Accordingly, in disorders of the lungs, the blood should be drawn from the region of the chest; and if, which will frequently occur, one part of the organ is particularly affected, the glasses should be applied opposite to it. The same remark holds equally good in dropsy connected with inflammation of the pleura. In this case the chest should always be examined without covering, for by its dilatation, contraction, &c., much additional assistance is afforded to the diagnosis. Next to bleeding, counter-irritants are indicated in all those cases in which there are local affections, and it may be necessary to continue these for a considerable time. Indeed in all chronic disorders, if counter-irritation be advisable at all, it is ad-

visible to persist in it, either till the disease for which it is employed has disappeared, or till the strength of the patient seems to suffer from its effects. Whoever has examined a dropsical patient when pleuritis has been present, must have remarked the presence of factitious membranes of very different ages, and in comparing them with the previous symptoms he will usually be able to fix upon precise periods at which some of them were first formed. A little further reflection will lead him to the conclusion that at no time had the tendency to pleuritic inflammation been completely overcome, and although, at particular stages, evident and very severe exacerbations had taken place, yet that through the whole disease the inflammatory action had more or less persisted. Under such circumstances, reason clearly points out one course, viz. to continue the remedy while the slightest trace of inflammation remains. In inflammation of the pleura, (perhaps of serous membranes generally,) this is particularly necessary, for it is not always painful, and may proceed a great way without exciting surprise. And it is this point that appears to us most important in that species of dropsy to which Dr. Bright has assigned the morbid state of the kidney for its origin. We have already expressed our doubts whether in the majority of such cases the inflammation of the serous membrane be not the primary disease; at any rate it is frequently concomitant, and in no slight degree accelerates a fatal termination. Under such circumstances it is to the local inflammation and not the effusion that attention must be paid; if the former continue, the disappearance of the latter will be of no avail. Bleeding is not only called for in dropsy when local inflammatory symptoms are present; a general state of plethora equally demands it. Our chief dependence for an accurate diagnosis in this case is the full hard pulse, and in great measure also the previous history of the patient. We cannot, however, too strongly inculcate the necessity of care in bleeding individuals of irregular habits, and who have indulged excessively in drinking, especially spirit-drinking, or in any other debilitating vice. Whatever may be their appearance, or however hard and firm their pulse, such persons ill bear extensive sanguineous depletion; they sink rapidly afterwards into a low typhoid state, without the possibility of rousing the system to healthy and energetic action.

Of the two principal modes of overcoming inflammation, bleeding and counter-irritation, we have perhaps for this place said enough. Of internal remedies, the two most powerful unquestionably are the antimonium tartarizatum, and calomel in combination with opium. The former, to be really serviceable, should be administered in the doses recommended by the Italian physicians, and thus given, its efficacy in inflammation is most extraordinary. Nor is its effect merely felt in depressing the inflammatory action; it acts upon the bowels and upon the skin, and thus, not unfrequently, by promoting the functions of these organs, but

especially of the last, it favours even directly the removal of the effusion. The principal inconvenience which is experienced from this medicine is the nausea and sickness which it induces, particularly after the first few doses. This, however, in most cases soon disappears, and the patient is able to take from one to three or even four grains at a dose without the slightest nausea. It will indeed occasionally happen that an individual cannot obtain what has been well termed *the tolerance* of the medicine; this, however, is so rare a case that it does not contradict the general position. Calomel and opium have been long known as peculiarly useful in those inflammations which throw out plastic lymph, such as iritis, cyananche laryngea, &c. These, however, are by no means the only forms of inflammation in which calomel and opium may be advantageously substituted for venesection or any other mode of bloodletting. Whenever the strength of the patient is too much reduced to admit of further sanguineous depletion, while still the inflammatory symptoms continue unsubdued, this combination may be usefully employed. It should be given as frequently as every three hours, and according to the age of the patient the dose may be proportioned from two to four grains of calomel, with from half a grain to two grains of opium, every time. It may be continued till the mouth becomes slightly affected, but it will be seldom advisable to carry it farther than this. What has been now said merely refers to the subduing of any inflammation which may be present, which may give rise to or accompany the dropsical effusion. But to these we may often add diuretics or purgatives. Of the different articles which are employed for this purpose we shall speak more particularly in a subsequent part of this article. We here only intimate that in addition to the plan for overcoming any local inflammation or general plethora, we are also called upon to attempt the removal of the effusion by stimulating the secretions of the bowels and kidneys.

While on the one hand we frequently find dropsical effusion united with inflammation, so on the other the system is sometimes, though perhaps more rarely, in a state of general debility. In this last condition a very opposite practice must be adopted, and the most powerful tonics, such as quinine and the different preparations of steel, may be not only safely administered, but may even be demanded. We must not, however, forget that mere weakness will not justify the use of these remedies, because this may and frequently does occur when local inflammation is present. A great object will therefore be to distinguish these different states; for what will be useful to the one will unquestionably be injurious to the other. For the diagnosis we must refer to the histories of dropsies as we have laid them down in the present article, and under ASCITES and ANASARCA. When, after proper investigation, we are fully satisfied that the system is in a state of great general debility, the sulphate of quinine and the different preparations of steel

may be given. It will, however, often happen that a debilitated patient cannot bear such powerful tonics, and that their stimulating power produces feverishness and general irritation. In this case we may have recourse to the vegetable bitters, and if the patient is very feeble, the Iceland moss will be found to be one of the most useful remedies which the *Materia Medica* affords.

Between these two plans, however, we may be called upon to take a middle course, and alternately to depress and support the strength of the system, accordingly as inflammatory symptoms or the reverse predominate. Here reliance must be placed upon the judgment of the medical attendant. Under such circumstances local depletion will generally be much preferable to general, and the peculiar symptoms will generally point to the affected organ. We have already stated that cupping, when it can be effected, is to be preferred to leeches, as the quantity of blood taken is more easily ascertained, and far less fatigue induced to the patient.

The remarks now made equally apply to every form of effusion, but some modification of treatment is peculiarly called for according to the organs from which the dropsy derives its origin. It is to these points, therefore, that we now more particularly call the attention of our readers.

*Treatment of dropsy connected with disease of the heart.*—Next to the general considerations which have already been mentioned, we have to recollect that any obstruction in the flow of blood from the right to the left side of the heart will be very likely to produce congestion in the lungs, and for the relief of this symptom we may be called upon merely to diminish the general mass of blood in the system. And again, should the size of the heart be greatly increased, even though no very material disease should exist in the valvular structure of the organ, the lungs may be so compressed that they may be unable to receive, without inconvenience, even their usual complement of blood; and for this cause also depletion may be necessary. These observations may not appear to bear immediately upon the treatment of dropsical effusions, but without a reference to the organs upon which such effusions depend, it will be impossible in any case to conduct them to a successful termination. Our first attention then is due to the condition of the heart and its influence upon the lungs; our second must be directed to the dropsy itself.

In the first place, we must consider whether there exists a sthenic or asthenic state of the general system. If the former prevails, recourse may be had to drastic purgatives, particularly to elaterium and croton-oil, with or without previous bloodletting, according to circumstances; and in few cases does more good effect follow the exhibition of remedies. They must be repeated every two or three days till the effusion entirely disappears. By this means we must not, however, expect that the dropsy will be prevented from returning; but consi-

derable intervals of ease will be afforded, and the patient may be enabled to live comfortably for several years, the dropsy occasionally recurring and being restrained by treatment.

Some patients, however, ill bear excessive purging, and we are then compelled to use other means, and chiefly diuretics. Of these the *digitalis purpurea*, or common fox-glove, is one of the most efficacious in the effusion which depends upon disease of the heart, and which is connected with some degree of debility. In this respect our experience corroborates the opinions of Drs. Withering and Blackall, that it is most successful where the debility is completely marked, the countenance pale, the pulse weak, and the muscular energy lessened. We have usually preferred the infusion, and have administered it in half-ounce doses two or three times a day, till it has increased the urine, had a decided effect upon the pulse, or produced some other of its peculiar consequences.

The propriety of giving *digitalis* in cases of debility, naturally suggests its use in those cases in which it is necessary to commence the treatment by bleeding; and accordingly this plan was recommended by Dr. Withering, and has been confirmed by Dr. Blackall, as probably by most physicians who have paid much attention to the action of this drug. Dr. Blackall has mentioned one symptom which is decidedly opposed to the exhibition of *digitalis*, viz. "a membranous tensive pain in the head, sometimes over one eye, with a sort of disturbance of the brain, which occasionally attends an overdose before any other bad signs have appeared; if neglected, it is followed by convulsions." The same physician also remarks, very correctly, that when the urine is decidedly increased, the *digitalis* ought to be suspended, as its debilitating effects are then apt to become greater than the system can bear with impunity. The diuretic effect of *digitalis* is sometimes greatly increased by its combination with opium, as indeed is the case with many other diuretics.

Sometimes the dropsy consequent to disease of the heart occurs in such a state of general debility, that somewhat of a tonic plan is required. We have repeatedly seen such a state occur in females, in whom there has been either a miserable hysterical state, or positive and decided hypochondriacism. Active stimulants, it is evident, must be as injurious to such patients as depleting measures; both, though from different causes, will increase the turbulent action of the heart and the distress of the patient. Under these circumstances we have found great benefit from the *ferrum tartarizatum*, either in combination with a tonic or with a diuretic, such as the *infusum genisteæ* or the *infusum taraxaci*; these appear to strengthen the system generally, while they act powerfully upon the kidneys.

In the latter, or rather the last stage of this species of dropsy, the anxiety, or we might say the anguish of the patient, is inconceivably painful to witness. Often the mind remains unclouded, and all the natural feelings of

affection for relatives, and attachment to life for their sake, remain unimpaired. When the disease has attained this point, it is only in our power to afford temporary and very imperfect relief by means of opium and ether. These must be given in frequent doses, and large enough to ensure their specific effect. Fortunately, painful as the stage is which we are now considering, it does not last long; the patient shortly falls into a state of stupor, and sleeps, as it were, to death, or dies instantaneously, and very unexpectedly to the attendants.

*Treatment of dropsy connected with disease of the lungs.*—On this form of dropsy we have not much to add to the remarks which we have just made with regard to the effusion when connected with disease of the heart. Bleeding, general and local, may be and frequently is necessary; and, in addition to this, counter-irritation, especially by means of the tartarate of antimony, ought strictly to be enforced. With respect to medicine more immediately calculated to remove the effusion in this as in the preceding form of dropsy, we are chiefly dependent upon purgatives and diuretics. With regard to the former, they ought never to be exhibited while we suspect the lungs to be the subject of inflammation. It is, we believe, a remark of Sydenham, that violent purgatives are injurious in pneumonia, and we have had frequent occasion to confirm the opinion. When, however, effusion is present in the chest or in the lungs, without any sensible inflammatory state, the drastic purgatives frequently afford the most remarkable relief, and sometimes suffice alone for the entire removal of the dropsy. As a diuretic, digitalis appears less serviceable in dropsy consequent to disease of the lungs, than where the heart is the original seat of disorder. Squills, however, in combination with laudanum and the neutral salts, particularly the sulphate of magnesia, act very powerfully upon the kidneys, and in some instances speedily and entirely remove the effusion. It is in this form of dropsy that the supertartrate of potash deserves the greatest confidence, as it keeps up a constant flow from the kidneys and the bowels together, without inducing that debility which drastic purgatives or digitalis are so apt to occasion.

*Treatment of dropsy connected with disease of the liver.*—This is probably the most difficult of any species of dropsy to treat successfully, in consequence partly of the broken-down constitution in which it generally occurs, and partly from the obscurity in which the different diseases to which the liver is liable are involved. When we can satisfy ourselves that this organ is the subject of inflammation, without any remarkable change in its structure, local bleeding and counter-irritation are required in the first instance; and, in the second place, those internal medicines which are known more particularly to act upon the biliary secretions, such as the different preparations of mercury, and the nitro-muriatic acid. Mercurial frictions may also be had recourse to with advantage in very many cases. The

mercury should be persisted in till the mouth is effected, and benefit has sometimes been derived from keeping up salivation for a considerable time. In addition to placing the system under the influence of mercury, some medicines are required more immediately to act upon the kidneys, and through their increased action to carry off the effused fluids. In the article ASCITIS we have mentioned the utility of combining many diuretics together; and in the form of dropsy that we are now considering this practice is more particularly demanded. Among the most efficacious under these circumstances are squill, colchicum, liquor ammoniæ acetatis, and the spiritus ætheris nitrici, given in combination of two or more, and administered every three or four hours. When, however, the colchicum is given, much attention is necessary that it does not induce its peculiar symptoms, which are precisely those of cholera. This may take place in peculiar constitutions after a single dose only, but more commonly, like digitalis, it accumulates in the system, and its effects are not developed till after the medicine has been continued for several days. Digitalis is not often applicable to dropsy connected with extensive hepatic disease, as its debilitating effects are greater than patients so affected can bear. Dr. Fowler made very numerous and satisfactory experiments upon the nicotiana *tabacum*, and why this medicine should so completely have fallen into desuetude it is difficult to determine. It is certainly one of the most powerful diuretics which the Materia Medica contains, and we have never seen any evil effects resulting from its use. It has appeared to us particularly useful in dropsy connected with enlargement of the liver and spleen, but little to be relied upon when the principal disease is situated in the chest. The reports of Dr. Fowler are unfortunately not full enough to enable us to draw any very accurate conclusions as to the nature of the diseases in which he found it most beneficial; but five of the successful cases in which he used it were the consequence of agues; and enlargement of the spleen is well known to be a common consequence of this disorder. The form we have used is the infusum nicotianæ of Dr. Fowler, which is made by pouring a pint of boiling water upon an ounce of tobacco. This is suffered to macerate for an hour in a covered vessel, and fourteen ounces only are strained off, to which two ounces of rectified spirits of wine are added to make it keep. Thirty drops are given at first three times a day in water, and the dose is gradually increased, till it augments the flow of urine, or produces sickness and giddiness. The dose has been carried, by Dr. Fowler, as high as one hundred and eighty drops at night, and one hundred in the morning.

With the exception of abstaining from mercury, it does not seem necessary to lay down any other plan than what has now been referred to, when the disease of the liver amounts to change of structure. It ought, however, to be always kept in mind, that when the liver is

tuberculous, or we have reason to believe that it is affected with hydatids, mercury may weaken the patient, but can have no effect upon the disease. How far under such circumstances it may be advisable to try iodine, or the muriate of lime, may be very properly a subject of consideration. In a case of apparent simple enlargement of the liver, in a girl of twelve years of age, but unconnected with dropsy, we certainly derived great advantage from employing the former, and under similar circumstances, connected with effusion, we should certainly be inclined to afford it a trial.

*Treatment of dropsy connected with disease of the kidney.*—Dr. Bright, who has most attended to this subject, appears to lay the principal stress upon the supertartrate of potash; but in this, as in every other modification of dropsy, reference must first be had to general principles. We have already stated our opinions at some length respecting the signs by which the affections of these organs may be ascertained. When, therefore, we feel convinced that the kidneys are diseased, the same rules which have been laid down for the treatment of other local disorders will apply here, and local depletion with counter-irritation must be as proper in the one case as in the other. At the same time we confess that on this point we have not experience for our guide, so far as this particular organ is concerned. We may, however, mention a fact that has been related to us on good authority connected with diabetes mellitus, and which has some analogy with the disease now under consideration. The medical man to whom a patient with this disease applied, and from whose urine he had collected a considerable quantity of sugar by evaporation, rubbed in the unguentum antimonium tartarizatum over the loins; and while the irritation was kept up, the sugar entirely disappeared from the urine. Other symptoms, however, supervened, which compelled him to suspend the ointment, and the sugar was again found in this fluid. The supertartrate of potash has the same effect in this dropsy as when disease of the lungs or pleura is present.—We are sorry to say that we have little more to add on this subject, as it is one to which at present little attention has been paid, and respecting which our actual knowledge is anything but precise. We would, therefore, most strongly inculcate the observance of general principles in its treatment, till farther investigations shall have clearly demonstrated those peculiar modifications of practice which may be demanded by the particular organ.

We may here very properly terminate our consideration of particular forms of dropsy. They, however, by no means exhaust the subject; and careful observation would probably find signs no less marked in effusion occurring after the disease of other organs, and a consequent propriety of modifying the treatment. What we have already said will, we trust, afford a somewhat clearer view of the principles upon which dropsy ought to be treated, than has yet been published. It will show that

certain general principles apply to all, but that these are more or less modified according to particular circumstances, and the organs which give rise to effusion in the first instance, or become involved in the course of the disease. There is nothing empirical or irrational in this treatment. Dropsy is not (as it is too often regarded by men even highly intelligent and much engaged in practice,) the consequence either of debility alone or inflammation alone; it is neither always a sthenic nor asthenic state of the system in which it occurs; it may be one or the other, or the one may alternate with the other. Since we find that different organs are the original causes of effusion, the treatment of the local diseases is not to be neglected in the great anxiety to remove the dropsy. Neither is effusion to be neglected; but we are to use different remedies according to the organs which are affected. Some of these we have endeavoured to point out; in doing so we do not pretend to be free from error; but the road is opened for others, to pursue a similar line of observation. If this is carefully followed, we do not question but that a few years will add a mass of information respecting the peculiar power of medicines in this disease, which may go far to diminish its present ill repute, as one of the opprobria medicinae.

*Of the particular remedies employed in dropsy.*—We should not consider that we completed the subject of the treatment of dropsy, did we not offer a more complete record than we have yet done of the various medicines which have been proposed as specifics in this disease. We may comprehend these under the various heads of purgatives, diuretics, emetics, sudorifics, tonics, frictions, scarification, acupuncture, paracentesis. The operation of some of these we have already discussed, and here, therefore, we shall do no more than enumerate them.

*Purgatives.*—The principal of these are the croton *tiglium*, from which the croton oil is expressed, and in which form alone we know the remedy in this country. The dose is a single drop, and this will operate in many instances most violently, producing within half an hour sickness, vomiting, and profuse alvine discharges. Dr. Good recommends the alcoholic solution first proposed by Dr. Nimmo, but we have never found the oil do any real mischief. There are individuals upon whom it will not act at all, or who require four or five drops to ensure the operation. With such idiosyncrasies the oil must of course be given in the larger dose.

Elaterium is also given with the same intent. We have mentioned under the article ANASARCA, that the form we prefer is, viz. two grains of elaterium (or half a grain of *elatin*) combined with a scruple of the extract of gentian, and divided into four pills, one to be given every hour till free evacuations are procured.

The common elder and the dwarf elder (*sambucus nigra*, *sambucus cbulus*;) have formerly enjoyed a high reputation as hydragogues; and the former is particularly recommended by

Sydenham. Every part of these plants is emetic and purgative, but the most potent is the inner bark, which may be taken in powder or infusion. The dose of the former is said by Dr. A. T. Thomson to vary from five grains to half a drachm; we have, however, no personal experience upon the subject, nor can we say to which species of dropsy it is most applicable. If the remark of Sydenham be correct, that it acts equally upon the kidneys and bowels, we should expect it to be particularly serviceable in effusion connected with disease of the liver, when it is thought advisable to unload the system quickly, as experience seems to prove that ascites (and this is the form which usually accompanies hepatic disorder) usually yields more completely to diuretics than to purgatives.

*Rhamnus catharticus*, or common buckthorn, is another hydragogue highly praised by Sydenham, but which, like the elder bark, has gone out of fashion. Sydenham employed it in syrup, and states that it removes the effusion without disturbing the circulation, or rendering the urine higher coloured, as other purgatives are accustomed to do; but that it has the inconvenience of inducing excessive thirst. The dose of the recent berries is one scruple, that of the dried berries a drachm. The dose of the syrup prepared according to the London Pharmacopœia is from half an ounce to an ounce, the patient drinking freely at the same time of demulcent fluids.

*Helleborus niger*, or black hellebore, has also been used as a hydragogue; and Avicenna, —no mean authority so far as the mere action of remedies is concerned,—observes that he had seen more wonderful effects from it than from any other remedy—"but it will not always equally work wonders." The dose as a hydragogue is from ten grains to a scruple. In the employment of black hellebore much care is necessary that the extract be fresh, for, by keeping, it appears very soon to lose its medicinal qualities. The dose above mentioned may be repeated at the end of six or eight hours if no operation shall have ensued; but in practice the utmost caution is necessary that the peculiar poisonous effects do not follow. In some individuals the smallest dose induces inconceivable anxiety. In the few instances where this has occurred in our own experience, the individuals were known to be incapable of bearing the mildest narcotic medicines, from the intolerable distress which always followed their exhibition.

Many other purgatives, as gamboge, jalap, scammony, neutral salts, have at various times been in vogue for the cure of dropsy, but it scarcely seems necessary to speak of them here more particularly. They all in great measure act in a similar manner, viz. by producing free watery discharges, and thus stimulating the absorbent function. The supertartrate of potash is rather a mild aperient than a purgative, and occasionally acts also most powerfully as a diuretic. It is remarked, however, by Dr. Ferriar, that it sometimes "neither increases urine nor stool, yet it cures." Its use in

dropsy was, we believe, first particularly pointed out in this country by Dr. Home, and in his reports he has related twenty cases in which it was employed. We collect generally from them that it was most beneficial where there was an inflammatory action present in the system, and where there was no actual organic disease. At the same time it appears in some instances to have been serviceable where the liver was deranged. Its action is chiefly that of an aperient, producing profuse watery evacuations, without exciting thirst or feverishness. Dr. Thomson states the dose as a hydragogue to be from four drachms to six drachms, in an electuary. Dr. Mason Good says that in order to ensure its aperient action, it ought never to be given in less than ounce doses; but our experience by no means corresponds with this. We have frequently succeeded by giving only drachm doses three or four times a day; after the second day profuse watery evacuations often follow to such an extent that we are obliged to suspend the medicine. In the intervals the milder tonics may be advantageously employed. (See *CATHARTICS*.)

*Diuretics*.—*Digitalis* holds the first place, in modern times, in this class of medicines; but as, in the course of this article, we have already mentioned the circumstances which render it most appropriate in dropsy, we shall only refer the reader for a more particular account of this drug to the article *DIURETICS*.

The squill is certainly a very powerful diuretic, but its powers are much increased by uniting it with other diuretics, particularly the neutral salts. In some cases, where the inflammatory action is at all high, its operation is greatly favoured by small doses of blue pill administered in such a manner as slightly to afflict the mouth. Dr. Blackall observes, that it is much to be depended upon, when, with an oppression of the chest, the urine is scanty, high coloured, and without serum. How far this last remark is perfectly correct may be questioned; but that it is highly serviceable when the urine is high coloured, is perfectly in accordance with our own experience.

The attention of British practitioners was first called to the diuretic properties of the *pyrola umbellata* by Dr. W. Somerville, and they are so well attested, that we cannot but regret that more attention has not been paid to it. It is a native of North America, and belongs to the natural family of *Ericææ*. The latest account is that of Dr. Bigelow, professor of *Materia Medica* and Botany in Harvard University, in the United States. "In a number of dropsical cases," says this gentleman, as quoted by Messrs. Churchill and Stephenson, "when first given, it made a distinct and evident impression on the disease, communicating an increased activity to the absorbents, followed by a great augmentation of the excretion from the kidneys. The benefit, however, with me has been in most instances temporary, and it was found better to omit the medicine for a time, and to resume it afresh, than to continue it until the system had become insensible to its stimulus. After

suspending it for a week or two, the same distinct operation took place on returning to its use, as had been manifested in the first instance. It proved in almost every instance an acceptable medicine to the patient, and was preferred, both for its sensible qualities and its effects on the stomach, to other diuretics and alteratives which had been prescribed." The paper of Dr. Somerville, which is contained in the fifth volume of the *Medico-Chirurgical Transactions*, is valuable from the post-mortem examination of Sir James Craig, to whom the plant had afforded very important benefit. In this instance the liver was studded with innumerable tubercles, the peritoneum throughout was thickened, and the intestines were glued together with coagulable lymph.\* The lungs on the left side were sound, but compressed on the right side by three pints of water. The pericardium contained six ounces of water, and the heart was somewhat larger than usual. The history of this case abundantly proves that the original malady was in the liver. According to Dr. Somerville, the virtues of this plant do not reside in any volatile principle, and he found consequently that a decoction acted much more energetically than an infusion. In order to make this decoction, an ounce of the dried plant, including the root, stalks, and leaves, is cut into small pieces, and macerated twelve hours in two pints of cold water, and then boiled till it yields one pint of strained liquor. Mr. Carter found that thirty-four pounds avoirdupois of the recent herb produced four pounds of extract, which had the same properties with the decoction. Five scruples of this extract in pills or in solution may be given in twenty-four hours.

The *spartium scoparium* or common broom, the *leontodon taraxacum* or dandelion, the *apium petroselinum* or common parsley, the *juniperus communis*, and the *colchicum autumnale*, all possess considerable diuretic properties, and may frequently be united with some of those above-mentioned, with much advantage. The meadow-saffron is perhaps the most powerful of all these, and we have succeeded with it in conjunction with mercurials, in acting upon the kidneys in hepatic disease when no other remedy had any effect. The *spiritus colchici ammoniatus* of the London Pharmacopœia is the preparation which we have chiefly relied upon, given in half-drachm doses three times a day, with a blue pill night and morning, and sometimes mercurial frictions over the abdomen being added.

In the 57th number of the *Journal Hebdomadaire* for October, 1831, M. Lemasson has given a detailed account of the employment of the bark of the root of the *chicoceca racemosa auguifuga*, or snowberry tree, belonging to the natural family of the *Rubiaceæ*. This bark furnishes a bitter principle, chrys-

tallizable in delicate needles, without smell, of a bitter and rather an astringent taste, soluble in water, very soluble in alcohol, especially when warm, and reddening the tincture of turnsole; in this principle all the peculiar medical properties reside. This remedy is said by M. Lemasson to be chiefly applicable to atonic dropsies. A decoction of the bark is made by macerating two drachms of the bark in eight ounces of water, then boiling for ten minutes, and straining the liquor off, which is divided into two doses, and the second dose is taken two hours after the first. The cases related by M. Lemasson are all connected with great general debility of the system. One was a case of chronic bronchitis with slight dilatation of the heart, and in this patient the feebleness was very considerable. Two were the consequence of syphilis and mercurial courses, to which universal anasarca succeeded, but without any particular visceral disease. In one patient affected with dilatation of the right cavities of the heart, the exhibition of the bark was preceded by bleeding. The effect in all was an improvement of the appetite, and a great increase in the flow of urine. The medicine is administered as above-mentioned in two four-ounce doses, with an interval of two hours between the first and second dose; when this affects the kidneys, they continue their action for several days, and the medicine is not again exhibited till the urine diminishes. In the first case which is related, it was given on the 18th of June, on the 20th of the same month, and not again till the 5th of July, after which it was not repeated. In the second case it was only given twice. On the 22d of May, and on the 29th, both terminated successfully, and the medicine had a similar effect of increasing the appetite and the flow of urine together.

*Emetics*.—These have been recommended by some authors, and cases have been given, in which they have succeeded when other remedies had failed. We have ourselves no experience of their effect in this disease, and they appear to be banished from modern practice. We shall content ourselves therefore with this intimation.

*Sudorifics*.—These are unquestionably in some cases highly useful, more particularly however when disease of the lungs is present. The vapour-bath has occasionally been successful in such cases. The celebrated Dampier cured himself by covering himself all over with sand, heated by the sun, in California, for an hour, after which "he was carried to his bed and well covered with clothes, where he fell into a profuse sweat, after which he recovered daily." The compound ipecacuanha powder has in this way been successful, and we have seen ascites attended with liver disease removed by it, though the patient died soon after, from the original malady.

*Tonics*.—Every species of dropsy may in some part of its course require the exhibition of tonics, for a state of debility easily follows

\* As, however, he had been frequently tapped, this last appearance was probably a consequence of the operation, and not a part of the original disease.

depletion, however necessary it may have been; and it has not infrequently happened that a patient has been cured of dropsy, and died of the weakness induced by the remedies. To obviate this, appears to have been the object of the celebrated electuary of Dover, which is a combination of scammony, sulphuret of iron, and crude mercury. Of this formula Dr. Blackall says, that "it has certainly performed many cures, and there is so much debility in the disease, that the addition of tonics to purgatives, never indifferent, is particularly desirable here, when it can be made with safety." Steel and bark are the principal tonic remedies that have been used in dropsy, and we consider the ferrum tartarizatum to be the best preparation of the former, as it unites a diuretic with its tonic properties. We have usually given it in combination with infusum calumbæ, and particularly in those asthenic dropsies in which the heart or the lungs are diseased. In the asthenic dropsy consequent to chronic bronchitis, united with counter-irritation of the chest, it will sometimes alone remove the effusion. The sulphate of quinine is given with the same intention, and in weak and serofulous habits it seems preferable to the preparations of steel. Dr. Blackall prefers bark also in the debility consequent to dropsy after an acute disease. In the exhibition of these tonics the utmost care is necessary that they are not given in an inflammatory state of the system, nor while the tendency to inflammation remains; but when by bleeding, digitalis, and other evacnants, the effusion has nearly disappeared, and the urine recovered its natural state and quantity, tonics will complete the cure, and secure the patient from a relapse.

The action of the remedies just mentioned is more distinctly known than that of the tonic pills of Bacher, and which we have noticed under the article ASCITES. More like cream of tartar than common tonics, these pills seem sometimes to be merely anti-hydroptic, removing the effusion without inducing any increase in the urine or alvine evacuations. The dropsies in which we have found them most useful are those which occur in girls about the age of puberty, without manifest derangement of any particular organ, and we have observed them to be more useful in ascites than anasarca. The younger Bacher, in speaking of black hellebore, says that it is not applicable to cases in which the solids are firm, nor when the fibre is greatly relaxed and weakened, but when, with some degree of debility, the circulation is irregular, and determined to some particular organ. We may observe, however, that in many of the cases he has related, no such determination is indicated by the symptoms enumerated, and in our own practice they have seldom been of use, when there has been evidence of organic disease. The action of these pills, as we have already mentioned, is often imperceptible, but at other times they procure copious evacuations from the kidneys and bowels, and sometimes,

according to Bacher, they cause profuse perspiration. The following is the formula of Bacher, as published by his son:—

R Extracti hellebori nigri,  
Myrrhæ solutæ, aa, ʒi.

Cardui benedict. pulv. ʒiiiʒi. M.S.A.

Fiat massa acra sicco exsiccanda, donec formandis pilulis aptasit. Singulæ ad gramæ sex.

Ten of these pills were given three times a day.

We have repeatedly cautioned medical practitioners against the danger which may ensue from the poisonous properties of the black hellebore, and here therefore we shall only inculcate extreme watchfulness whenever this remedy is exhibited.

It is probable that many other of the common mineral and vegetable tonics may be employed in asthenic dropsy, and it will always be advisable that the practitioner should, as far as possible, be provided with substitutes, as, from particular idiosyncrasies, individuals are sometimes incapable of taking what may in other respects be the most appropriate remedy.

*Friction.*—Under the head of ASCITES, we have referred to a case in the 49th volume of the Philosophical Transactions, in which friction with oil effected a cure in an old case of ascites. We are unacquainted with the particular symptoms which more particularly indicate this remedy, but there certainly can be no objection to it in any case in which the abdomen is free from tenderness.

*Blisters.*—These sometimes afford great relief, and we have often had recourse to them in our own practice. They are not, however, always unattended with danger, and whenever they are applied, the surgeon ought to be requested to attend to their progress. We have more than once seen death hastened by the blistered surface becoming inflamed, and mortification ensuing.

*Scarifications.*—These are indeed the *opprobria medicinæ*. They afford relief from the pressure and weight of the effused fluid, but too often at the same time give rise to inflammation, gangrene, and death. Yet there may be cases in which the distention is so great and the distress so intense, that the operation may not only be justified, but may be demanded. Upon this head we would briefly remark, that in old and very debilitated persons they should seldom, perhaps we might more properly say, they should never be practised, and that in young persons in whom the reparative process is more readily set up, great attention should be paid to their appearance and progress. The mere presence of dropsy will make no difference as to the proper manner of treating the wounds; but if inflammation be present, or gangrene, the same local and general remedies must be recurred to, as if no effusion had existed; nor indeed is this only useful to the wounds; frequently when the fluid has escaped, the tonic and stimulating remedies which the surgical treatment has required, have prevented the return of the effusion.

*Acupuncture.*—This is only a milder manner than scarification, of effecting the mechanical escape of the fluid; and the remarks made upon the former, are equally applicable to the present remedy. Evil consequences are perhaps less frequent, but still they do not unfrequently occur. (See *ACUPUNCTURE.*)

*Paracentesis.*—Of this operation we have spoken under the head of *ASCITES*, nor does it appear to us necessary to add to the remarks which we have there made.

*Diet.*—The only point that remains to be noticed is that of diet, but upon this head we do not feel called upon to make many remarks, nor should we indeed have mentioned it at all, had it not been for the vulgar opinion which formerly prevailed, that fluids ought not to be allowed to dropsical patients. Even this notice is perhaps quite unnecessary, as the error is, so far as we know, completely exploded. Sir Francis Milman first examined the question, and gave the most satisfactory evidence that the restriction from fluids was not only not beneficial, but was in many cases even injurious; and since his time so much additional evidence has been obtained to the same purpose, that to allow dropsical patients as much fluid as they wish to drink is become an axiom in the treatment of the disease. It has been well ascertained that many diuretics only stimulate the kidneys in proportion to the quantity of liquid in which they are given.

With respect to the nicer question of food, it seems unnecessary to make any remark; this must be varied with the nature of the dropsy, and the symptoms by which it is attended; and whoever understands the meaning of a phlogistic and antiphlogistic regimen will know how to apply either of these, or to vary from one to the other, in the disease of which we have been treating, as circumstances may require.

(John Darvall.)

*DYSENTERY.*—This word is derived from the Greek word *δυσεντερία*, which is compounded of *δύς* (*difficile, ægre, malè,*) and *έντερον* (*intestinum*), and signifies that the intestines are morbidly affected. By Celsus the disease is named *tormina*, from one of its leading symptoms; and by Cælius Aurelianus *rheumatismus intestinorum cum ulcere*. Dr. Ballingall applies to it the not inappropriate appellation of *colinitis*. By certain French writers it is called *colitis* (colite), and in common language it is named *flux* or *bloody flux*, according as the intestinal discharges are free from blood or sanguinolent. It is placed as a genus in the class *pyrexia*, and order *profluvia* of Dr. Cullen; in the class *fluxus*, and order *alvijfluxus*, of Sauvages; and, very correctly, in the class *hæmatica*, and order *phlogotica*, of Dr. Mason Good.

*Division of the disease.*—Dysentery consists, in its early and acute stage, of inflammation of the mucous membrane of the intestines, especially of the colon and rectum. This inflammation, by implicating the other coats of the bowel, and by generating ulcers, may produce

extensive and very intractable disorganization, giving rise to symptoms less acute than those of the early stage, but bearing a considerable resemblance to them. Hence it appears that there is a natural division of the disease into an acute and chronic form; the first consisting of inflammation, the second of its occasional effects, supervening on attacks of the acute disease, which have been imperfectly treated, or which our art has proved too feeble to subdue.

Various writers have proposed divisions of the acute stage into species, and complex arrangements of this kind are to be found in systematic works. From what has been stated respecting the nature of the disease, it will be manifest that any distinction between cases of uncomplicated dysentery must be principally founded either on the degree of inflammation, or the extent of intestine affected by it. The former circumstance unquestionably gives rise to various shades of discrepancy between different cases, but admits of no precise line of demarcation by which any assemblage of cases can be contradistinguished from others. The extent of bowel implicated in the disease constitutes a somewhat more important ground of distinction, for it is supposed that in the warmer regions a larger portion of intestine is affected with inflammation than in temperate climates; and that this circumstance, coupled with certain effects produced on the constitution by a high temperature, invests the disorder named by recent writers *tropical dysentery*, and by Sauvages *dysenteria æquinoctialis*, with a peculiarity of character meriting special notice. It will hence appear that uncomplicated dysentery may be considered under two heads, the first comprising that form of the disease most frequently observed in temperate climates, whilst tropical dysentery is discussed under the second. It should be remarked, however, that though the distinction between the extremes of these varieties may be very manifest, intermediate degrees will be found, and such it has not unfrequently occurred to the writer of this article to observe in the south of Europe, which might be referred with almost equal propriety to either the one form or the other. Besides these varieties in the character of simple dysentery, its complications with other diseases require attention.

The following definition of dysentery will perhaps be found sufficiently precise:—Frequent mucous or muco-sanguinolent stools, pain in the abdomen, griping, and tenesmus, generally accompanied with pyrexia.

*The uncomplicated dysentery of temperate climates.*—Premising that many degrees of intensity are found in this affection, from the slight sporadic case in which the general health is but little deranged and no danger threatens life, to the wide-wasting epidemic which has proved the scourge of fleets and armies, we shall present a sketch of as mild a form as the disease is almost ever observed to wear. A case of this description may commence with feculent and liquid stools, and they may become subsequently mucous,

with occasionally a slight admixture of blood; or, they may be of the latter character from the beginning. There is little if any fixed pain in the abdomen; but considerable griping previously to the patient's rising to the night-chair, with a peculiar sense of working or commotion in the bowels, often referred to the situation of the sigmoid flexure of the colon; there is generally some heat at the anus, but the sensation extending thence up the rectum is one rather of irksomeness than of heat, and it induces very distressing straining, constituting the affection called *tenesmus*; the dejections do not exceed seven or eight in the day, and after they have acquired the mucous or sanguinolent character, traces of feculent matter are occasionally perceptible in them. Dysuria is rarely observed, dyspnœa never, though both of these morbid states are very general attendants of more severe cases of the disease; the appetite is generally impaired; the thirst is considerable; the tongue is sometimes furred, occasionally natural, and the pulse is little, if at all, quickened or affected with respect to its force. The mean duration of this slight form of the disease is from seven to eight days; it may be said to be never fatal, but it not infrequently lays the foundation of chronic dysentery, and often leaves such a tenderness of the bowels as renders them more prone than before to morbid action from cold or other causes. We should presume that the inflammation in such a case as this was slight in degree, and limited to the rectum and inferior portion of the colon.

A more intense form of the disease than that which has just been described, will be found of frequent occurrence when dysentery is prevailing epidemically. This more severe disease may be preceded by diarrhœa, which we have observed to be a very general precursor of dysentery in whatever climate we have witnessed it; or it may occur without this premonitory symptom. Occasionally a well-marked rigor, followed speedily by febrile heat, introduces the disease; whilst, in other cases, the first symptom is pain in the bowels, to which the mucous stools characteristic of dysentery in a short time succeed. In many instances some slight derangement of the stomach and bowels, indicated by flatulency, costiveness, inappetency, nausea, and occasionally vomiting, is experienced for some days before the attack. When the disease is fully formed, the characteristic mucous or muco-sanguinolent stools are passed very frequently, with great pain, an extreme degree of straining, and a feeling as if the viscera themselves were about to be discharged. Feculent stools occasionally intervene between the dysenteric discharges, and pure blood is sometimes voided in considerable quantity, especially in an advanced stage of the disease. After the disorder has subsisted some days, it is not unusual for the patient to void portions of a substance resembling suet, tallow, or flesh. A sense of heat, or, as the patients express it, burning at the anus, extending thence up the rectum, and which becomes excessive when there is a call to empty the

bowels, is much complained of. When fever has occurred from the commencement of the disease, it of course subsists throughout its progress; and in cases in which it has not existed from the first, it uniformly arises when the intestinal disorder has become so fully formed as we are now describing it to be. There is a warm skin; a hard, generally frequent and small pulse; the tongue is either covered with a white mucous coat, or it is dark and dry; there is great prostration of strength, and the urine is scanty, high-coloured, and is passed with pain and difficulty. The griping which precedes each evacuation is very distressing throughout the disease; but only in an advanced stage, and in a case which has held its course uninfluenced, at least beneficially, by treatment, is there much if any permanent pain in the abdomen. When it occurs, it is generally situated in the hypogastric region, and is increased by pressure. Its presence, especially if it is accompanied by fulness and tension of the abdomen, may be generally considered as a bad omen, as indicating that the inflammation has extended to the exterior tunic of the bowel. Dyspnœa is frequently observed to co-exist with the symptoms, denoting that the peritoneal surface of the intestines is affected. Throughout the disease there is loathing of all solid food, and the thirst is great, sometimes intense; and it is attended with this distressing circumstance to the patient, that in many cases every thing which is taken to allay it produces tormina, and an instantaneous and irresistible impulse to go to stool.

Should no relief be afforded by the remedies employed, the prostration of strength becomes great; the pulse feeble, with coldness of the extremities; the tongue either furred and brown, or glazed, red, and aphthous; the discharges from the intestines are dark and offensive; the mind is low and desponding; hiccough is an occasional symptom, and death sometimes takes place in a period varying from a fortnight to three weeks from the commencement of the attack. But much more frequently, even in bad cases, some mitigation at least of symptoms is obtained, and the disease degenerates into a chronic form.

Restoration to health may be expected when there is diminution of pain in the abdomen, of tenesmus, and of the frequency of the discharges, and especially if, instead of the mucous or muco-sanguinolent dejections, the stools become natural. An abatement of the febrile symptoms and thirst, and a return of appetite, are favourable signs; but all favourable symptoms are to a certain extent fallacious, for after a truce of a few days we may discover that we have that insidious and slowly-wasting disease, chronic dysentery, to combat.

This description, which comprises the two extremes of the disease as it has fallen to our lot to observe it in Europe, is drawn from personal observation. For an account of dysentery as it occurs between the tropics, we must be indebted to the able men who have witnessed its ravages in those regions.

*Tropical dysentery.*—The following is Sir G. Ballingall's description of tropical dysentery, or, as he very properly terms it, colonitis.

“The form of flux now under consideration commences in general with much of the appearance of a common diarrhœa; frequent and unseasonable calls to stool, with an irresistible inclination to strain over it. The evacuations are generally copious, of a fluid consistence, without any peculiar fœtor; sometimes streaked with blood, and at other times a small quantity of blood is voided in a separate form, unmixed with the faecal matter. The pulse, in this stage of the disease, is seldom altered; the heat of the skin is not perceptibly increased, and the tongue is frequently but little changed in its appearance. There is always a great prostration of strength and depression of spirits; the former symptom being always strongly dwelt upon by the patient; the appetite is indifferent, and the thirst urgent. To these symptoms succeed a fixed pain in the hypogastrium, more or less acute; the pain extending to, and peculiarly urgent in, one or both iliac regions, and sometimes to be traced along the whole course of the colon, with a sense of fulness, tension, and tenderness upon pressure; and on applying the hand to the surface of the abdomen, a preternatural degree of heat is frequently perceptible in the integuments. The evacuations now become more frequent and less copious; they consist chiefly of blood and mucus, or are composed of a peculiar bloody serum, which has been very aptly compared to water in which beef has been washed or macerated. A suppression of urine and distressing tenesmus now become urgent symptoms; the indifference to solid food increases, while there is an uncontrollable desire for liquids, particularly cold water, which the patient prefers to any drink that may be offered to him, and from which he expresses his inability to refrain, though prepossessed with the idea of its being injurious. The tongue is now generally white and furred; sometimes, however, exhibiting a florid, smooth, and glassy appearance, with a tremulous motion when thrust out; the skin is either parching hot, so as to render it even painful to retain the hand in contact with it, or covered with profuse perspiration, insomuch that it may often be observed standing in large drops on the surface; the pulse is still frequently but little affected; sometimes, however, it assumes a febrile quickness, without any other remarkable feature; at other times it will be found without any increase of velocity, but full and bounding, with a peculiar thrilling sensation under the fingers. This state of the pulse, whenever it takes place, always denotes extreme danger, and shows that the disease is rapidly hurrying on to the final stage, in which the lassitude and dejection so conspicuous throughout its course are now converted into the utmost degree of anxiety, depression, and fear of death. The patient generally shows an inclination to dwell upon symptoms which to a spectator would appear of minor importance. He evinces the greatest reluctance to part with his medical attendant,

though fully sensible how unavailing the efforts of medicine are likely to prove. The discharges by stool, which are frequently involuntary, are now accompanied with the most intolerable fœtor; they are frequently mixed with shreds of membrane, and quantities of purulent matter; a protrusion of the gut, forming a complete procidentia ani, takes place; and cases are not wanting where a portion of the inner coat of the intestines amounting to some inches has been thrown off in a state of mortification.”\* It is needless to say what must be the result of such a case as this, unless it is efficiently succoured in an early stage.

*Diagnosis.*—The only diseases with which dysentery can possibly be confounded are cholera, hemorrhoidal flux, and diarrhœa.

The rapidity of the march of cholera, compared with the long duration of dysentery, is alone an important ground of distinction between them. Cholera occasionally ceases in twenty-four hours, and perhaps never lasts beyond a week; whilst the mean duration of dysentery is probably about a fortnight, and many cases endure for months. Vomiting is a uniform attendant of cholera, and is seldom observed in dysentery; the purging, during a considerable part of the course of dysentery, is mucous or muco-sanguinolent, whilst its prevailing character in cholera is bilious. Tenesmus is a most distressing symptom of dysentery, but in cholera it is generally absent. In cholera the alvine discharges are copious, and are passed with violence; the very reverse is the case in dysentery, and the former disease is attended with spasms of the extremities, which are not perceived in the latter.

The tumours at the margin of the anus; the blood flowing from the commencement of the disease unmixed with mucus; the comparative absence of tenesmus; the freedom from abdominal pain; and the solid nature of the feculent discharges, which are observed in hemorrhoids, will secure us from confounding this disease with dysentery.

The distinction between dysentery and diarrhœa is easily drawn, in the more advanced stage of the former disease, from the mucous and sanguinolent condition of the alvine discharges; but the testimony of the writer must be added to that of Sir James McGrigor and many others in proof of its extreme difficulty, in many cases, in an early stage. If it is then to be found at all, it must be sought in the character of the prevailing epidemic rather than in that of any individual case submitted to our observation. We believe that the pathological condition in dysentery, and in cases of severe diarrhœa, is in its nature the same; but that the inflammation of the lining of the digestive canal is more intense and enduring in the former than in the latter disease. In both cases, the first effect of this inflammation is the rapid expulsion of the ordinary contents of the intestinal canal; but the inflammation existing in dysentery remains after the canal is entirely emptied, and gives rise to those secre-

\* Observations on Dysentery, p. 49.

tions from the lining membrane which constitute the discharges characteristic of the disease. In certain cases, those unpreceded by diarrhœa, the site of the inflammation in the lower part of the bowels seems to have the effect of retaining the natural contents of the canal, and of causing, from the first, evacuations consisting merely of matters secreted from the bowels.

From the description given of epidemic choleric fever, (see CHOLERA,) it will be manifest that from the moment the choleric stage is fully formed, no confusion can arise between this disease and dysentery. The spasms, serous discharges, and early collapse of the former disease, are extremely distinctive. But in the incipient stage of the two disorders, some difficulty might be experienced, which would, however, be dispelled by a reference to the character of the prevailing epidemic.

In this view of the diagnosis of intestinal affections attended with increased discharge, it is impossible not to be struck with the strong relation which in their rudimental stage they generally bear to each other—a relation which cannot but lead to the suspicion, that, however widely different in character and danger they may be when fully formed, the primary pathological condition is, in all, if not identical, certainly closely analogous.

*Chronic dysentery.*—This may be considered as almost a more distressing termination of the acute form than death itself, for recoveries from it are rare, and it is fatal after an amount of protracted suffering which is extreme. The fever which attended the acute form subsides, and a temporary recruiting of strength and appetite is experienced, but this truce from distress proves deceptive. The patient occasionally feels sharp pains of the bowels, with frequent stools, consisting of food apparently little changed by the process of digestion, mixed with slight streaks of blood: these symptoms may subside, and continue to recur at intervals, either from some manifest imprudence in regimen, or without any assignable cause, until extensive disorganization of the intestine takes place. The stools are then mucous and bloody, sometimes mixed with purulent matter; or such dejections as these alternate with discharges of sanies, or of offensive, ill-digested fæces, the number of evacuations varying from three or four to seven or eight in the day. The abdomen at the same time feels full and hard, without being very painful on pressure; the urine is high-coloured, and is passed with pain. The patient, when in bed, lies on his side, with the body much curved, and the lower limbs in the position of extreme flexion on the abdomen, so as to relax its muscles as much as possible. The pulse is feeble, intermitting, and generally slow, excepting towards evening, when some degree of fever occurs. The tongue is often bright and glossy; the skin is cold, sallow, dry and rough; the lips appear exanguinous; emaciation proceeds rapidly; the feet and legs become œdematous, and ascites occasionally takes place; the patient sometimes

becomes jaundiced; and finally, after the lapse of weeks or months, he sinks from irritation and exhaustion.

The odour of persons suffering under this disease is peculiar, and the same may be occasionally observed in the acute disease: no description could convey an idea of it to one who had not experienced it, but if once recognized, it cannot be forgotten; it is very offensive, and at the same time acid. It is independent of that of the matter ejected from the bowels.

Acute dysentery occasionally leaves the bowels in a condition less decidedly morbid than that just described, and one from which the patient generally recovers, but after a considerable lapse of time, perhaps of years. This condition is indicated by attacks of diarrhœa, commonly of the henteric character, recurring at intervals of three or four weeks, and lasting for a few days: during the attacks the dysenteric odour is perceptible about the person of the patient.

*Complications of dysentery.*—This disease is found combined with fevers, that is, instead of the pyrexia symptomatic of the local affection, some form of idiopathic fever exists in conjunction with dysentery; and if the fever is a contagious one, the two may be communicable together. Knowing as we do the proclivity of fevers to affect the intestinal lining, it cannot be matter of surprise that the large intestines should be occasionally the seat of such affection. There are other diseases, too, with which it is occasionally found combined.

The complication with typhus occurs under the operation of debilitating causes, such as want of food; and where numbers of persons being accumulated in a space proportionately small, proper ventilation and cleanliness are impracticable. From these causes it has frequently proved more fatal to the garrisons of besieged towns than the assaults of the enemy. It is characterized by a remarkable stupor, resembling that of a drunken man; by head-ach, vertigo, and delirium; the eyes are dull and very sensible of the impression of light; on some day between the fourth and the sixth day, a miliary or petechial eruption often appears on the neck, breast, and arms; the tongue, teeth, and gums are covered with dark sordes, and the pulse is frequent and small, or, when the danger is imminent, intermitting. The dejections are frequent, scanty, composed of mucus mixed with dark-coloured blood, and of an extreme fetor; the urine is high-coloured, as if stained with blood; nasal hemorrhage is not unfrequent, but it does not prove critical; the usual colic pains of dysentery are severe during the first four or five days; they then abate, and are again increased about the ninth or eleventh day, when a diarrhœal discharge comes on which frequently destroys the patient rapidly. When the case is fatal, death generally occurs from the ninth to the thirteenth day, but sometimes as early as from the third to the seventh.

Dysentery occasionally complicates the early

stage of intermittent fever, and in this stage it may be found either during the paroxysm only, or, which is much more frequently the case, as a permanent disease associated with the ague. But its existence at the commencement of intermittents is very rare in comparison with its occurrence at a more advanced period, when disorganization of the liver and other abdominal viscera has resulted from the long continuance of the disease. Its supervention in the advanced stage of ague constitutes a melancholy complication, and is very frequently accompanied or followed by general dropsy; the patient lingering in much suffering until released by death. (See INTERMITTENT FEVER.)

Pathological researches have proved the complication with disease of the liver to be much less frequent than was supposed; yet there seems no doubt that, in a form of dysentery occasionally met with in warm climates, there is such a complication. The affection of the bowels commences in the form of diarrhœa; the stools are variously coloured, black, green, or deep yellow; they are preceded by considerable griping, felt principally about the umbilicus; they are frothy, accompanied by much flatus, and cause considerable scalding or excoriation about the arms. After a few days they become white and mucous, with an occasional admixture of imperfectly digested aliment. Throughout the disease, there is inappetency, nausea, intense thirst, a yellow fur on the tongue, great oppression in the epigastrium, and a frequent pulse. It is a slow disease, lasting for weeks or months; and in its progress great emaciation, hiccup, and bilious vomiting, are superadded to the other symptoms. This form of dysentery, which is sometimes called hepatic flux, may terminate in health, in incurable disease of the bowels, or in abscess of the liver.

The following graphic sketch of a form of dysentery more intense than the foregoing is drawn by an experienced observer of the diseases of warm climates. According to the views of the writer, which are most probably accurate, it should be referred to the complication of dysentery with hepatic affection which we are at present describing.

“The patient is at first languid, and loses at the same time his appetite and hilarity of mind. Sometimes he complains of pain in the region of the liver, increased by pressure, and in some degree relieved by the expulsion of flatus from the stomach; but this pain is very trifling, or at least much more slight than might be expected from the condition of the liver as discovered after death. The presence of this symptom denotes the true character of the disease; but in many cases it is entirely wanting, and hence the greater obscurity. In many cases the most acute observer can discover no sign of bad health, but a white tongue and a pulse more frequent than usual.

“Matters remain in this state during a period varying from four to eight days, and the inexperienced practitioner apprehends little danger; but in this respect he is deceived;

for an insidious fever depresses the patient by almost imperceptible degrees, till the actual symptoms of dysentery, namely, tenesmus and very frequent alvine discharges, display themselves with great violence. These symptoms are accompanied by ardent fever, delirium, oleaginous sweat, febrile anxiety, and urgent thirst, whilst the tongue is covered with a yellow fur, which is converted towards the close of the disease into a permanent dark crust. A large quantity of green, bilious, and sanguineous matter flows from the bowels, and finally convinces the medical attendant that the morbid condition of the liver and bile is the exciting cause of the flux. There is not much pain in the bowels in this stage of the disease; but the tenesmus is most distressing, and occasionally protrudes a portion of the rectum from the anus. Subsultus tendinum, hiccup, and cold sweats take place; and, unless relief is afforded before the disease reaches this stage, death speedily ensues.”\*

*Pathological appearances.*—These vary according to the period of death and the nature of the case. If dysentery prove fatal in an early stage, the appearances are those of inflammation simply, or of inflammation and gangrene of the mucous membrane of the large intestines, with few or no traces of ulceration. If at a more advanced period, the other coats of the bowels are found to participate in the disease, and numerous and extensive ulcers are discovered. In inflammation, the external appearance of the bowel is healthy; but, on opening it, portions of its mucous membrane throughout the whole extent of the colon and rectum, and occasionally some part of the small intestines, are found of a bright red or brownish colour, and sensibly elevated above the level of the more healthy parts which are interposed between them. These inflamed portions are sometimes covered with a puriform, sanguineous, or sanious secretion, which gives them the appearance of ulceration; but if this is scraped off with the back of a scalpel, and the part is washed, the surface is found unbroken. False membrane is sometimes found deposited on the mucous coat. Dr. O'Brien describes it as occurring both in the large and small intestines, but as being most frequent and remarkable in the colon and rectum. In some cases, he informs us, it occurred in patches, but in others the mucous membrane was covered by a uniform layer of white lymph.† Gangrene is denoted by blackness or lividity, and morbid softness of the membrane, the muscular coat occasionally partaking of the softness; and in some instances by vesicles full of a fetid fluid.

In cases which have terminated fatally in a more chronic stage, there is thickening of the tunics of the intestine, and the bowel is contracted in diameter and ulcerated. The ulcers are diffuse or follicular. The former may be of the size of a sixpence or a shilling, or an

\* De Dysenteria Regionum Calidarum. Archibaldo Robertson Auctore. Edm. 1817.

† Transactions of King and Queen's Colleges, vol. v.

extensive portion of the membrane may be in a state of almost continued ulceration, the diseased surface being varied by portions in a state of red fungous elevation, running irregularly over it, and separating the ulcerated spaces from each other. The follicular ulcers are of the size of split peas; their concavity is lined with pus, and their edge is surrounded by a red circle. The follicles are occasionally found in a state of inflammation, having a tubercular appearance, compared to small-pox. The ulceration occasionally perforates the coats of the intestine so as to allow its contents to escape into the cavity of the abdomen. This accident and its consequences deserve separate consideration. (See PERFORATION.) Adhesions of the peritoneal surface to the adjacent viscera, and serous effusion into the cavity of the abdomen from the extension of inflammation to the exterior tunic of the intestines, are not unusual occurrences.

Other viscera, beside the bowels, are occasionally found to show traces of disease. The mesenteric glands are sometimes enlarged and inflamed, and the omentum is described by Dr. Jackson as being in some cases dry and shrivelled, in others gangrenous, and occasionally forming a new and fleshy looking substance, which confines the intestine in such a manner as to obstruct its canal.\* The liver has been supposed to be generally affected in dysentery, and it is occasionally found small and indurated or enlarged, and at the same time of a firmer consistence than natural, or an abscess has been found in it in that form of the disease called hepatic flux; but pathological researches have proved that changes in its structure are much less frequent than was imagined, and by no means essential to dysentery. Even in cases of this disease in which this organ is functionally affected during life, or in which researches after death show that its structure has undergone a change, (and the instances where this latter occurrence is discovered bear a very small proportion indeed to the whole amount of examples of fatal dysentery;) there is great reason to think that the irritation is rather propagated from the intestinal canal to the liver, than that the reverse order of causation takes place. There is no organ of the body of which the influence in generating disease has been so much overrated by medical men as the liver, occasionally perhaps from mere carelessness, but too often, we apprehend, from a not very creditable wish to run with the current of popular opinion, which throughout Great Britain and her dependences is strangely favourable to hepatic and bilious doctrines.

*Causes.*—Dysentery is generally most prevalent during the latter end of summer and autumn, when the alterations of temperature are sudden, and especially when there is a considerable discrepancy between the heat of the day and night; but there is no season of the year in which it is not found occasionally

to make its attacks, provided the body be exposed to the cause peculiarly favourable to its production, cold or chill after comparative warmth. It is much more prevalent in the warmer latitudes than in temperate climates; probably in some degree from the circumstance, that in the former situation the heat of the day is followed by great comparative cold at night, the chilling effect of which is aided by the heavy dews which are so general in the warmer regions of the earth. The operation of the same cause is manifested in the case of soldiers, who are frequently attacked in numbers after a night-encampment or bivouac on damp ground.

Unwholesome food, the abuse of spirituous liquors, and the drinking of bad wine, bring on attacks of the disease in climates and situations where it prevails; but indulgence in fruit, which is often assigned as its cause, does not appear to have such an effect.

Malaria is supposed to be a cause of dysentery, and there is reason to think the supposition correct. The disease occurs in the climates, situations, and seasons favourable to the production of periodic fevers; it is occasionally combined with them, and appears to succeed or supplant them, as though it were owing to a continuance of the operation of the febrile cause, modified in its nature or influenced in its effect by extrinsic circumstances. The analogy between dysentery and other forms of bowel complaints and such fevers has struck the eye of observers from Sydenham to Jackson. It is difficult to assign to the first-mentioned causes, cold and bad diet, and to malaria, their respective share in the production of the disease. It is probable that sporadic cases are frequently owing to the former exclusively, and that they may co-operate in producing attacks of the disease when it is prevailing epidemically; for instance, malaria having been applied, exposure to cold or dietetic errors may immediately bring on an attack.

The discrepancy of testimony as to the contagious nature of this disease is extreme; but were the question one which the preponderance of great names could decide, it would probably be answered in the affirmative. So general was the belief in its contagious nature some years ago, that contagious pyrexia is inserted among the characteristics of the disease in Cullen's Nosology, as if it were an acknowledged and incontrovertible doctrine. But in the present day we believe there is scarcely a medical man of much experience in the disease who believes it to be contagious; and the writer has never seen a single case which he had the least reason to attribute to such a cause. The conflict of opinion on this point is perhaps to be explained by certain authors having seen many cases of dysentery complicated with typhus, and by their having ascribed to the disease, generally, that which is true only of one of its complications.

*Treatment of acute dysentery.*—The nature of the disease being ascertained, the practice to be pursued becomes sufficiently obvious. Bloodletting naturally presents itself as one

\* A Sketch of Febrile Diseases, by Robert Jackson, M.D., Stockton and London, 1817, p. 439.

means of subduing the inflammation; and if the constitution sympathises with the local affection, so that there is general fever, with a warm skin and a frequent and sharp pulse, blood should be taken freely from the arm. We should not rely upon general bleeding as the sole mode of depletion in the disease, for experience teaches us that the inflammation of mucous membranes is less amenable to this remedy than that of most tissues; but it should be followed by local bleeding by means of leeches; and in the milder order of cases this may altogether supersede general depletion. Twenty or thirty leeches should be applied along the course of the colon, or to any point of the abdomen where pain is felt, the parts being subsequently covered with a hot poultice. The repetition of leeches must of course depend upon the intensity and duration of the disease, and the degree of relief afforded by the first application. Should griping, purging, and particularly fixed abdominal pain continue, they may be repeated on the following day, or each succeeding day, to the third or fourth time, if the circumstances mentioned indicate the propriety of the repetition; their number in the later applications being regulated by the necessity of the use and the strength of the patient. It should be remarked, however, that the first application, if vigorous, frequently affords so much relief, that, by the aid of internal medicine, the disorder proceeds thenceforward very steadily to recovery. Hot fomentations and the warm bath will be found serviceable after the bleeding, and subsequently the abdomen may be blistered with benefit.

Purgatives are generally administered; and, during a considerable period, when the retention of feculent matter in the cells of the colon was erroneously supposed to constitute the very essence of the disease, they were principally depended upon by some practitioners for its cure; and though the more correct views at present entertained may seem to forbid their employment, experience teaches us that to unload the bowels, when requisite, with gentle laxatives, is not only safe but beneficial. Were the writer to digress into a question of general therapeutics, but one connected with the present subject, he would remark that though laxatives are found prejudicial in neuralgic irritation of the intestinal canal, he has never observed injurious effects from their moderate and judicious employment in inflammation of its mucous lining; and that he has detected the most extensive lesions of this membrane, where the practitioner had rigidly abstained from them. It is desirable, however, that the abuses which heretofore existed, regarding their employment in dysentery, should not be resuscitated, and on this account it appears advisable to specify the sole circumstances under which they should be administered in this disease, and the precautions this administration requires.

In every case of dysentery, the first remedial measure should be directed to subduing the essential disease, the intestinal inflammation;

the primary and paramount means, therefore, are the general or local bleeding, or both, as the circumstances of the case may require. In that form of the disease which is unpreceded by diarrhœa, a dose of castor-oil, sufficient to expel the matters lodged in the intestines, may be given after a little respite from suffering has been obtained by bleeding; and should its operation be tardy, it may be accelerated by a mild emollient enema. In that more frequent form of the disease which has diarrhœa as a precursory symptom, purgatives should by no means be employed early; but in any form of dysentery, should a considerable period have elapsed without a feculent discharge, a mild laxative will be advisable, for the retained matters are generally in a morbid condition, and can scarcely fail to be a greater source of irritation to the inflamed membrane than the operation of a gentle laxative. The repetition of medicine of this kind will of course depend on the circumstances of the case; should the alvine discharges become feculent and copious, it need not be repeated. No more proper laxative can be selected than the oleum ricini, aided in its operation by a mild, tepid, and emollient enema. Some practitioners think favourably of a solution of neutral salts with which a proportion of tartarized antimony is combined; but it seems doubtful whether the irritating effect of the salt on the intestines would not counterbalance the benefit likely to accrue from the diaphoretic action of the antimony.

Mercury is so powerful a subsidiary of general and local bleeding in the cure of inflammation, that we should naturally expect benefit from it in this disease; and experience proves its prudent employment to be of great service. It might be objected to on the same ground as purgatives, the dread of an irritating effect from it on the inflamed intestine; but the result of its employment, our only safe guide, shows the apprehension to be erroneous, provided the medicine be properly administered. It is a remedy more generally applicable to dysentery in warm latitudes than in this country; but if employed with prudence, and merely as subsidiary to the general or local bleeding, or both, advantage will be derived from it wheresoever the disease may be prevailing. A grain and a half of calomel, combined with from five to ten grains of Dover's powder, or half a grain of opium; or five grains of hydrargyrus cum creta, likewise combined with the opiate; may in this country be administered at intervals of four hours, the period being lengthened when the symptoms begin to abate. It is not necessary to excite ptyalism, although this is a contingency from which no evil result need be apprehended, provided the medical attendant be sufficiently watchful of the effect of the remedy to prevent its being excessive. In warmer climates, the same dose of mercury, combined with a smaller proportion of Dover's powder, or a grain of ipecacuanha, may be given every hour or two till some effect is produced on the disease or the system. In our Indian settlements the practice is much

bolder than this, calomel being administered in doses of a scruple. Mr. Annesley gives such a dose nightly, followed by an oily or a saline purgative in the morning, till the dejections become natural and healthy;\* and calomel in such doses is a familiar remedy with British physicians in tropical climates.

Diaphoretic medicines are employed by many medical men in dysentery. The cerated glass of antimony, which was a favourite remedy with Sir John Pringle and others, probably owed great part of its influence over the disease to its power of exciting perspiration; and the combination which has already been mentioned, that of a mercurial preparation with Dover's powder, perhaps derives part of its very great utility from the same property. Ipecacuanha alone is a valuable medicine of this class. It may be given in large doses in the form of pills without exciting vomiting, as in the manner recommended by Mr. Twining in the Calcutta Transactions. By combining it with extract of gentian he exhibits as much as six grains, which he repeats at intervals; and, as he assures us, with an excellent effect. A decoction of three drachms of the root, boiled in a quart of water down to a pint, administered in portions of three or four ounces, as an enema, and repeated once or twice in the day, we have often found to have the effect of allaying irritation and tenesmus, and to be generally beneficial. The same medicine is frequently combined with calomel, or other mercurial preparations, with considerable improvement of the efficacy of both. Emetics are favourites with some practitioners, but the benefit to be derived from them is much more certainly and easily attained by nauseating or diaphoretic doses of ipecacuanha.

Tenesmus is frequently a distressing symptom. Of course effectual relief can be afforded only by the general process for subduing the disease; but it may be allayed by anodyne enemata, of which a solution of three or four grains of opium in a small quantity, not more than two ounces, of starch muelage, constitutes a very good one. Dr. Abercrombie recommends injections of lime water, at first diluted with milk or thin arrow root, with the addition of an opiate. It should be impressed on the minds of junior practitioners that enemata administered with the view of allaying tenesmus should be small, for this affection is aggravated by distending the lower portion of the intestinal canal with bulky fluids. Mild emollient elysters have already been recommended as adjuvants to the oleum ricini when there is retention of feculent matter in the intestines; but it should be understood that their employment in these cases is admissible only when the irritation of the inferior portion of the canal is not extreme. We have met with instances in which even the introduction of the pipe could not be borne. In such cases as these, tenesmus and irritation may be allayed by opium, Dover's powder, a dose of laudanum,

or by opiates combined with infusion of cusparia or balsam of copaiba, administered by the mouth.

Dr. Cheyne, whose practice in the dysentery of this country has been very extensive, thinks highly of the power of opium in its cure, and gives the following summary of his experience of its efficacy and that of other remedies. The mode of treatment he found most generally useful was bloodletting, followed by calomel and opium, and this by balsam of copaiba and farinaceous diet; and he says, "were the same cases again to be placed under my care, I would not hesitate to give opium in doses of four or five grains, as it was the opium chiefly that seemed to arrest the progress of the inflammation; and whatever in such a case procured respite to the patient from agony, sometimes proved of permanent benefit."\* This testimony, proceeding from such a quarter, should have great weight. The concluding clause contains a truth of much importance, and one applicable to many diseases besides dysentery.

Swathing the abdomen with flannel, so applied as not to press painfully, is useful as a means of keeping the temperature uniform. Should abdominal pain require relief, hot fomentations may be frequently and freely resorted to. If the anus be inflamed or excoriated, it should be bathed with goulard water; and it may be protected from the acrimony of the discharges by being anointed with unguentum cetacei, or wax and oil.

The diet throughout the disease should be mild and light, consisting of arrow-root, milk, simply, or with gum acacia dissolved in it, rice or barley-water, and mucilaginous and bland matters of this description; they should be given in small quantities at a time, and the whole amount of what is taken should be small.

*Treatment of chronic dysentery.*—Our indications here are much more perplexed, and our difficulties much greater, than in the acute form of the disease. That intestinal ulcers occasionally heal has been proved by Dr. Troilet;† and Dr. Latham, in his account of the disease which prevailed in the Penitentiary at Milbank, has given an excellent description of intestinal ulcers in the progress of reparation: hence we should not utterly despair of success in this very intractable malady. As in most diseases which are but little amenable to our art, the remedies proposed are very various. Those which deserve the most confidence are small doses of hydrargyrum eum cretâ or calomel with Dover's powder, or the same mercurial preparations with opium and ipecacuan; lime-water; vegetable astringents and bitters, as kino, catechu, cusparia, quassia and logwood; nitric acid; opium; balsam of copaiba or tolu; or various combinations of these remedies, as a strong decoction of cusparia with nitric acid and laudanum, recommended by Dr. Abercrombie. The late Dr. Jackson, whose experience of this

\* Sketches of the Diseases of India, p. 417.

\* Dublin Hospital Reports, vol. iii.  
† Journal Général de Médecine.

form of disease was very extensive, placed much reliance on small general bleedings, repeated at intervals of a week; but in a disease attended with so much debility as this, very moderate local bleeding from the integuments of the abdomen, and the application of blisters to the same parts, appear to be safer methods of accomplishing the object to be attained. Moderately stimulating and oleaginous frictions of the abdomen, the part being subsequently swathed with flannel, are occasionally found useful; and the warm salt-water bath is soothing to the patient, and generally beneficial to the disease. Powdered charcoal, combined with powder of ipecacuan and rhubarb, has been found advantageous; and Dr. Abercrombie speaks favourably of a combination of the same substance with Dover's powder. The writer has found considerable temporary benefit in this distressing affection from the sulphate of copper, administered in the manner recommended by Dr. Granville in various chronic affections of the bowels. It is given in doses of half a grain, with an equal quantity of opium; and is gradually increased, if necessary, sometimes to the extent of three grains, with half-a-grain or a grain of opium three times a-day. Where there is reason to suppose that the lower part of the intestinal canal is the seat of ulceration, various injections are employed with advantage. A weak solution of acetate of lead or white vitriol has the effect of allaying irritation; whilst a solution of blue vitriol, or one of corrosive sublimate in lime-water, excites foul and sluggish ulcers to healthy action, and in some cases has appeared to aid materially in effecting a permanent cure. These injections should not consist of more than two or three ounces of fluid, for great irritation is produced under the circumstances mentioned by distending the canal by large enemata.

The diet, throughout the disease, should consist of the mildest and most bland farinaceous food, taken in small quantity, solid animal food and all stimulating matters being rigidly forbidden. Solid food, in any considerable quantity, must be injurious as a more mechanical irritant in that condition of the intestines which beyond a doubt exists in chronic dysentery; whilst liquid freely taken excites griping, passes rapidly through the bowels, and must tend to disturb that reparatory process which it should be our object to encourage. If the disease have commenced in a district where dysentery is endemic, change of air is a remedy of first importance, and one without which all other means will often prove nugatory. A sea voyage has frequently proved very advantageous.

The treatment to be adopted in dysentery, complicated with idiopathic fevers, will be gathered from the rules contained in this article, and in the articles on continued and periodic fever. The combination with liver disease, the hepatic flux of Ballingall and others, requires mercurial treatment by means of blue-pill, calomel and opium, or inunction, till pyalism is induced; and this, unless the exhaustion of the patient forbid it, is to be kept up till the

discharges assume a healthy appearance. Laxatives are occasionally requisite, and of these castor-oil is the most proper. The warm-bath, sudorifics, blisters, and bandaging the abdomen with flannel, are as important as in the treatment of the uncomplicated disease; and should the tenesmus prove distressing, it may be allayed by any of the forms of anodyne enemata recommended in that disorder.

(Joseph Brown.)

DYSMENORRHEA, (from  $\delta\upsilon\varsigma$ , *agre*;  $\mu\acute{\eta}\nu\epsilon\varsigma$ , *menses*;  $\acute{\eta}\acute{\epsilon}\omega$ , *fluo*;) *painful or difficult menstruation*.—This disease is important from its occasional extreme obstinacy; from the great suffering which it produces, and from the contrariety of opinion which prevails as to its nature, and the treatment required for its relief. In healthy menstruation there is often no warning whatever of the period; more generally there is some degree of discomfort, consisting of a sensation of weight and fulness about the pelvis, with a bearing down and aching of the thighs, but usually the suffering is so slight as not to call for medical aid; in dysmenorrhœa, however, the menstrual period is accompanied with such acute pain and suffering, and is looked forward to with such apprehension, that the patient is eagerly inclined to seek for relief, and is but too often driven from one remedy to another with but trifling advantage.

The time at which the pain comes on varies in different cases. In many the pain precedes the discharge, or else the discharge is exceedingly scanty as long as the pain lasts; but as the quantity increases to a full flow, a subsidence of the suffering takes place; in these cases the pain will last only a few hours. In other instances the discharge is more profuse than natural during the whole continuance of the pain, is apparently expelled in gushes, and is then usually mixed with coagulated blood. In a few more rare cases the pain will only occur in the latter part of the menstrual period, accompanied either with a diminution or an increase of the flow, and ceasing only after every vestige of the discharge has passed off.

All these varieties will be found in practice, though in the histories of this disease some have been often omitted, and most authors have described the pain as occurring only at the onset, and ceasing when the full and free evacuation takes place.

The pain often resembles the grinding pains of the first stage of labour, and is similarly in paroxysms of short duration and frequent recurrence. There is also, in the intervals, a constant aching pain down the legs, with a dragging sensation in the back and loins; there is sometimes, also, a sensation of bearing down in the pelvis, with even an actual lowering of the uterus. All these pains will vary in degree; for in some severe cases the paroxysms have been so violent that the patient has rolled on the bed or the floor with agony, and, in a few instances, the writer of this article has noticed severe convulsions of the character of tetanus, even amounting to regular opisthotonos. The expulsion of a membranous substance has been

observed in dysmenorrhœa by Morgagni,\* who described it as generally consisting of a small bag, containing a fluid, on which account it was usually mistaken at that time for a very early abortion. More particular notice was attracted to this peculiarity in modern days by the late Dr. Denman, who satisfactorily established the fact that the membrane was expelled at least as frequently in single as in married women, and that it had the appearance of a triangular cast of the cavity of the uterus, having an exact resemblance to the membrana decidua. It would seem that where a bag containing a fluid was really discovered, it must have been an ovum, at an early period of conception, particularly as such women are very liable to miscarry. Dr. Denman was of opinion that this membrane, although often not noticed, was expelled in every case of dysmenorrhœa. That he was wrong in this conjecture is now well known, as, though occasionally met with, it is by no means common, although there are often substances perceived which at first sight resemble it, but which consist merely of coagula of blood, with the colouring matter separated. From the supposition that the membrane is *always* expelled, and that it consists of coagulable lymph exuded from the lining of the uterus, necessarily resulting from inflammatory action, has arisen a very faulty opinion of the nature of the disease, and a most mistaken and pernicious mode of treatment, *when universally applied*.

Dysmenorrhœa may arise at any period of life at which the menstrual function is performed. It will sometimes exist from the time of puberty and cease upon marriage; in other instances the first attack is immediately after marriage, and lasts till the patient becomes pregnant; in some it does not appear till after child-birth. It has been often stated that no woman can become pregnant whilst this disposition to dysmenorrhœa exists; but this is far from being correct; the error arising from the fact that such patients are particularly liable to abortion at a very early period, which abortions have been supposed to be merely unusually aggravated attacks of the complaint. Nor again, as has been generally considered, is pregnancy a cure for a previously existing dysmenorrhœa, unless by great care and management the first two or three months are safely passed over.

It would appear that the immediate cause of this distressing disease is extreme irritability of the uterus; and as it is well known that great irritation is but a step removed from inflammation, it is very probable that in some cases, where a membrane is expelled, inflammation of a peculiar character may be excited. It does not follow as a certainty that the separation of a cast of fibrine from a mucous surface is the result of decided inflammatory action. Some pathologists have gone so far as to dispute the possibility of pure inflammation arising in a membrane where no blood-vessels are to be found, although they ramify profusely in the submucous tissue. The tu-

bular casts of lymph from the lining of the intestines are often brought on by irritation alone, as by the improper and excessive administration of calomel; and in croup, the fibrinous tube, which is occasionally formed in severe cases, is not found adherent by vascular union to the surface on which it is deposited. Although he does not exactly agree in these views, it certainly appears to the writer that the pain of dysmenorrhœa is no proof of inflammation, any more than the pain of labour; and it may be stated that generally there is no other sign of inflammation present but pain; that the pulse is merely quickened during the immediate paroxysm, at which time alone the skin is hot or the face flushed; frequently indeed the skin is damp and cold, and the face pallid. On two occasions, where blood was drawn from the arm during the painful period, no buffy coat or contracted cupped surface was found to exist. Although the writer does not deny the occasional existence of inflammation, particularly in plethoric and robust constitutions, yet he believes that in by far the majority of cases acute irritation alone exists. The women most liable to this complaint are those possessing great susceptibility of frame, who are subject to hysterical affections, and who have strong passions and ardent temperaments. Dysmenorrhœa will often occur only at those periods of life when there is great constitutional disturbance, or much mental excitement, as at the early years of menstruation, or shortly after marriage.

*Treatment.*—This has varied according to the view taken of the nature of the disease. Those who consider it to be universally of an inflammatory character, have of course recommended bloodletting, local and general, frequent depleting medicines, and a spare diet. Where the deciduous membrane has been certainly and habitually expelled, it is not improbable but that benefit may be derived by local bloodletting to a moderate extent; but *as a general rule*, such treatment is not required, and in many instances it has done considerable mischief by the extent to which it has been carried. By the character of the constitutions usually affected, by the spasmodic nature of the pain, and by the success of a very opposite class of remedies, it would appear that the disease is rarely inflammatory, perhaps never purely so, but that it arises from a peculiarly irritable condition of the uterine organs. On this principle the treatment is twofold: 1. to relieve the immediate pain during the menstrual period; 2. to regulate the general health in the intervals. For the first purpose, opium is the best remedy, where it can be borne, and particularly when combined with ipecacuanha, and with camphor in doses of four to ten grains. Immediately before the expected attack, the bowels should be opened by a mild purgative or a warm-water injection; the patient might also put the feet in warm water, or sit in a warm hip-bath. At this time, should the pulse be full and frequent, the countenance flushed, and general plethora prevail, the local abstraction of blood by cupping on the loins,

\* Epist. 48, art. 12.

or by leeches to the pudenda or groins, might be advisable.\* At the onset of the pain, opium (or any of the other narcotics, if more suitable,) may be given in full doses, combined as before mentioned, and repeated every hour or two according to the effect. Belladonna plasters may be applied to the sacrum; injections of warm mucilage, containing belladonna or opium, may be frequently thrown into the vagina; and, in addition, we may direct suppositories or clysters, containing from one to two grains of opium. Hot fomentations to the pubes, loins, and perineum are also frequently of great service. Ether, assafœtida, and ammonia may be taken at intervals. Hot gin-and-water is a very popular remedy, and will often subdue the pain. These medicines, however, should be cautiously administered, should there be much heat of skin and feverish excitement.

In the intervals of the periods the general health is to be regulated, and the constitution to be strengthened so as to be rendered less irritable. It would be advisable, should the patient be married, that intercourse should be avoided for about a week before the expected attack. In the majority of cases the preparations of iron are the best remedies which can be given, combined so as not to produce too great excitement of the circulation. Equal parts of vinum ferri and the compound spirit of sulphuric ether (3℥ to 3i) may be given two or three times a day, or the *mistura* or *pilula ferri composita* of the London Pharmacopœia may also be tried. A useful combination is the sulphate of iron, the compound extract of colocynth, and the soap and opium pill, two grains of each. The natural chalybeate waters seem on the whole to be more serviceable than any artificial preparations. Where iron disagrees, some of the other metallic tonics may be of advantage, particularly the zinc. The vegetable tonics do not appear to be of much use; we must except, however, the senega, which Dr. Chapman of Philadelphia has confidently recommended, especially in those cases where a membrane has been habitually expelled. He was induced to try this medicine from a supposed analogy between this form of the disease and eroup, as regards the formation of fibrine from a mucous surface; he advises four ounces of the decoction to be taken daily. In obstinate cases a course of mercury has been found the means of cure, particularly when combined with sarsaparilla. Repeated blisters or caustic issues to the sacrum have also been tried, and in some instances successfully. The bowels should be kept open, but not too much so, and the purgatives should not possess an irritating character. Moderate exercise is advisable, but all violent exertions are to be avoided. The diet should be nutritious, but not stimulating. Cold hip-bathing will be found of use, and much benefit will arise

from the regular employment, night and morning, of cold-water injections into the vagina, especially if combined with the superacetate of lead. In a few cases there has been a remarkable connexion between the existence of this disease and rheumatism in the same person, and the medicines, such as guaiacum and colchicum, given to relieve the rheumatic symptoms, have at the same time cured the dysmenorrhœa. This was accidentally noticed in a case, some years ago, by Dr. Gooch, with regard to guaiacum, and he consequently was induced to try that medicine where the painful menstruation existed without the rheumatism, and sometimes with success. Further trials, by the writer of this article, have confirmed this observation in several instances, and it is remarkable (since Dr. Gooch's observations were never published) that the same remedy has been highly spoken of by Dr. Dewees of America, in a recent publication.

(C. Locock.)

DYSPEPSIA. See INDIGESTION.

DYSPIHAGIA, derived from δύσ, *difficultly*, and φάγω, *to swallow*. This term is applied to express a difficulty or impossibility of swallowing. When the extent and compound nature of the apparatus for deglutition is considered, it becomes obvious that this is a symptom which may arise from many and essentially different causes. Thus, all affections of the mouth, tongue, and pharynx, all lesions of nutrition, circulation, or innervation of the œsophagus, the pressure of tumours on this tube, &c. will give rise to this distressing and often fatal symptom.

In the common acceptation of the word, however, it is used to express affections of the œsophagus itself, either the result of some morbid condition of the part, or of pressure from neighbouring tumours. To these we shall principally direct our attention in this article; first enumerating the principal causes of dysphagia that have hitherto been described. These are

1. Congenital malformations of the mouth, tongue, soft palate, pharynx, and œsophagus.
2. Disease of the mouth, tongue, and pharynx.
3. Disease of the œsophagus.
4. External and internal tumours pressing on the œsophagus.
5. Disease of the cardiac orifice.
6. Affections of the larynx and epiglottis.

The congenital malformations of the mouth, pharynx, and œsophagus, which would act in producing dysphagia, are principally the extreme smallness of the tongue, the *microglossia* of Andral, a state, according to this author, owing to an arrest of development, and the consequent existence of the *hyoid* portion only of the tongue. Under these circumstances deglutition becomes extremely difficult, and several individuals so afflicted have been obliged to introduce the fingers in order to assist the process by pushing the food into the pharynx. We are not aware of any case of

\* In the writer's opinion it is only in such cases that bloodletting is desirable; but it is fair to state that many eminent practitioners lay great stress on free and repeated removal of blood in nearly all cases of dysmenorrhœa, from the belief that the pain necessarily denotes inflammation.

the opposite state (macroglossia) being known to produce dysphagia.

Adhesions of the tongue, either to the lower lip, or to the inferior part of the mouth, have been sometimes observed; indeed Andral considers that state called tongue-tyed, to be merely a lesser degree of this malformation.

The last congenital malformation connected with the mouth is the absence of its anterior orifice; this is also to be looked on as an arrest of development; for it is the normal state of the mouth in the early periods of fetal life.

The pharynx is occasionally irregularly developed, terminating in a cul-de-sac, and presenting partial dilatations and hernie of the internal membrane through the muscular fibres. The examples of absence of the part, or its duplication, have only occurred in monsters.

The malformations of the œsophagus are stated to be somewhat more numerous than those of the pharynx. Thus, in some cases, the upper portion terminates by a cul-de-sac, between which and the stomach there is nothing but cellular membrane. In other cases this is reversed, the tube proceeding upwards from the cardiac orifice for a few inches, and there terminating. In a few instances the œsophagus has been found reduced to a mere cord, while in others the obliteration did not take place till within a short distance from the cardiac orifice. (*Andral.*) Other malformations are described, such as its division into two canals; (*Blues, Obs. Méd. rurior; see also Billard and Michel;*) its obliteration above and persistence below forming a communication with the trachea, (*Martin, Observateur des Sciences Médicales, 1825.*)

In cases of congenital obliteration of the œsophagus, the symptoms, as observed in new-born children, are sudden vomiting when any fluid is attempted to be swallowed; this vomiting occurring without effort, and the ingesta being thrown up unaltered. In a case of absence of the œsophagus, (*Journal Comp. Dict. des Sciences Méd.*) the drink was ejected through the nose; and it would appear that in some cases, as in stricture, a tumour may be observed in the neck previous to vomiting. The children of course die of inanition. In the case published by Sir Astley Cooper, the infant lived for eight days; in that recorded by Van Cuyck three days; and in the example of obliteration first alluded to, the child lived eight days, during which time the stools and urine continued. It is scarcely necessary to remark, that in these melancholy cases we can do nothing but appease the cravings of hunger by nutritive injections and baths.

This is not the place to describe the various affections of the mouth and pharynx, attended with dysphagia, although they constitute the most common causes of dysphagia. For information on these subjects, the reader is referred to the several articles in which the individual diseases of the MOUTH, PHARYNX, &c. are particularly spoken of.

The sources of dysphagia arising from a morbid condition of the œsophagus are, its

acute or chronic inflammation, the growth of fungous or cancerous tumours from its interior, spasm, and paralysis.

Acute inflammation of the œsophagus does not seem to be a common disease in the adult, the tube at this period of life being but little excitable; but in the infant, according to Billard, (*Traité des Maladies des Enfants,*) it is more frequently met with, which perhaps is owing to the state of congestion in which the mucous membranes are often found after birth. In fact, œsophagitis may be an intra-uterine disease, as is proved by the occurrence of follicular ulceration in the part, in still-born children. The prominent symptom of this disease in the new-born child is an immediate vomiting when an attempt is made to swallow fluids: this vomiting is constant, often without any apparent effort; the milk is thrown up unchanged, and in several cases the usual symptoms of gastric inflammation have not been observed. A remarkable case of this disease is recorded by Dr. Abererombic, in his work on the Pathology of the Digestive System. The symptoms were fever and difficulty of swallowing; the attempt to swallow sometimes excited cough, and frequently vomiting, with ejection of a soft membranous substance. This disease we have never seen but in one case, where the patient died of acute phthisis, and where there was difficulty of swallowing and vomiting. Here, however, the pharynx was affected.

Much has been written on stricture of the œsophagus, but the true pathology of the disease has not as yet been sufficiently recognized. There can be little doubt that in the great majority of cases it is the result of a chronic inflammation of the whole or part of the tube, producing an hypertrophy of its different tunics, but principally of the sub-mucous cellular tissue. The most perfect analogy exists between it and the disease called scirrhus of the pylorus and cardia, which is now admitted by the best pathologists to be the result of a chronic inflammatory process. The exciting causes, and the history of the various cases of stricture of the œsophagus, tend strongly to establish this opinion. Admitting this to be the case, we may hope to relieve the disease in its early period, and at all events we have a key to its physiological treatment even in its advanced stages.

The thickening is sometimes general, but more commonly partial, and varies from that which would slightly narrow the tube, to its complete obliteration. It is almost always progressive, but Dr. Good mentions a case where the morbid process appeared to have been arrested, after having produced such a narrowing of the tube, as to prevent voluntary deglutition: this state continued for twenty years, during which the patient was supported by means of food introduced by a silver canula into the stomach. But this is a very rare case; almost every patient afflicted with this disease must die a slow and painful death. In some instances, ulcerations have been met with above or below the stricture, (*Baillie;*) and

in a few the semi-cartilaginous cellular tissue has become bony, as we see in other cases of chronic irritation of this structure. A dilatation often occurs immediately above the obstruction, which is sometimes visible when the patient attempts to swallow. (*Ozier*, Edin. Med. Comment. iii.)

Vegetations and other morbid growths have been met with in the œsophagus, where they produce a great and commonly fatal obstruction. A remarkable case of this kind is detailed by Dr. Monro, in which, whenever the patient retched, a large fleshy excrescence was thrown up into the mouth, reaching to the teeth. On dissection this was found to be a polypus, extending nearly through the whole course of the œsophagus.

We have before stated that dysphagia arising from a morbid condition of the œsophagus may generally be referred to chronic inflammation, spasm, or paralysis; let us, before speaking of the treatment of stricture, contrast the symptoms of these different affections.

1. *Chronic inflammation or organic stricture.*—Invasion slow, the obstruction at first slight, but gradually increasing. Attempts to swallow often exciting great pain along the course of the tube to the base of the skull. Fluids more easily swallowed than solids in the advanced stages. Salivation, cough, hectic, and ejection of purulent matter—duration of the disease considerable. Exciting causes—irritations of mucous membranes.

2. *Active neurosis or spasmodic stricture.*—Invasion sudden, accompanied with a sense of constriction in the throat, and pain, even when the patient does not attempt to swallow. Disappearance often sudden—occasional relaxation by the use of the probang; relief from antispasmodic medicines; absence of hectic and signs of ulceration; exciting cause often mental emotion; occurring in nervous, irritable, hysteric, and melancholy persons.

3. *Passive neurosis, or paralysis of the œsophagus,* may arise from disease of the cerebro-spinal axis, or occur independently of it. Sudden loss of the power of swallowing *without the symptoms of spasm.* No obstruction found by the probang. Cure by electricity.

Before speaking of the treatment of these species of dysphagia, we must remark that the spasmodic stricture may, from its violence or frequent occurrence, cause organic disease of the tube, by the injury done to the circulation and innervation of the part. In this way a spasmodic may pass into an organic affection, as ileus may pass into enteritis. This fact must always be borne in mind in the treatment of a case of spasmodic dysphagia.

The treatment of organic stricture has been hitherto nearly empirical. In its early stage, when any chance exists of effecting a cure, time is often lost by the exhibition of useless nostrums; and great injury done by using bougies, when the part is in a state of acute irritation. In such a case, every thing that can irritate or excite the part should be most

carefully avoided; the lancet should be used, and leeches boldly and repeatedly applied to the neck. These means should be followed by counter-irritation; and it is possible also that the use of mercury might assist in the removal of the disease. Indeed, we have a decided example of its efficacy in a case related by Dr. Munkley, (*Medical Transactions*, vol. i.) where in a very unpromising case, a perfect cure was effected by the use of this medicine. (See also *Rush*, Enquiries and Observations: *Dobson*, Medical Observations and Inquiries, vol. vi.)

In the advanced cases, advantage has occasionally been obtained from the use of the bougie, and the exhibition of hemlock. In such cases a seton would probably be useful, and the diet of the patient must be spare and unirritating.

The treatment of the second species must be that of spasmodic affections generally. It is often connected with deranged bowels, in which cases the judicious use of purgatives, followed by nervous and tonic remedies, will be advantageous. During the spasm antispasmodics may be given. A patient thus affected should avoid all debilitating causes, the use of very hot or cold drinks, and sudden changes of temperature. Constant exercise in the open air seems to be the best preventive.

It is obvious that the treatment of the passive neurosis, or paralysis of the tube, will depend on the presence or absence of organic disease in the brain or spinal marrow. If such should not be present, the best remedy appears to be electricity, of the good effects of which several examples are recorded in Dr. Monro's learned work. In one case the patient could only swallow when seated on the electric stool. This affection seems generally to be curable.

The pressure of tumours exterior to the œsophagus is not an unfrequent cause of dysphagia. They may be enumerated as follows: 1. Aneurisms of the aorta. 2. Enlargement of the bronchial glands. 3. Encephaloid tumours growing from the posterior mediastinum. 4. Enlargement of the cervical vertebrae. 5. Abscess in the neck. And, 6. Bronchocele. The diagnosis of most of these affections is difficult. In the case of aneurism of the aorta, the disease has more than once been mistaken for stricture of the œsophagus; and in one instance the tumour was ruptured by the incautious use of the probang. (*Abercrombie*.) A very remarkable case of encephaloid tumour, producing dysphagia and symptoms of phthisis, is detailed in the *Dub. Hos. Reports*, vol. v, in the report of the Meath Hospital.

The last cause of dysphagia which we shall notice, is the existence of disease in the larynx and epiglottis. On this subject much useful information may be obtained from the work of Louis, (*Recherches sur la Phthisie*.) It is obvious that any state of the larynx which causes pain or difficulty in its movements during deglutition, must be a cause of dys-

phagia, and there are cases where this is the prominent symptom. Destruction of the epiglottis, or its tumefaction from œdema, will give rise to the same symptom from different causes. Of the last source of dysphagia, two most interesting examples have occurred lately to ourselves. In both patients there was great œdema of the neck, and in the cellular membrane in the neighbourhood of the parotids, and the epiglottis was so swollen as to form a large tumour preventing deglutition. In such cases the drink is discharged through the nose. Free puncturing with a lancet might prove serviceable in this affection.

(*William Stokes.*)

**DYSPNŒA.** Difficult or disordered breathing. This term, which is generally applied to those derangements of the respiratory function which interfere in a *sensible* manner with its performance, would not be inapplicable to all instances of defect in this important process. Although in many instances only a symptom, dyspnœa is one of such importance, that it often becomes a principal object of treatment, as it constitutes the chief danger of the disease. For this reason it is important to examine more closely into its nature, and to distinguish between its several causes.

The muscular act of inspiration is excited by a sensation arising from the presence of black blood in the lungs. This act, in the natural state of the function, removes the sensation by supplying air, which converts the venous into arterial blood. But a variety of causes, presently to be considered, may impede or interrupt this conversion, and then the sensation becomes more or less perceptible and painful, and excites exertions of the respiratory forces, increased in extent and frequency, to relieve it. These may prove so far effectual as to supply the defect and remove the sensation of oppression; then there is hurried breathing rather than actual dyspnœa; but when, as is frequently the case, these supplementary exertions are insufficient to effect the due arterialization of the blood, it accumulates in the branches of the pulmonary artery and veins, and occasions the most oppressive and distressing sensations. A person suffering from them complains of an oppression on his chest, and cannot bear even the weight of the bed-clothes; he feels the room too small, and begs to have the windows opened; he is restless, and endeavours to find relief by sitting up; however great his courage, he is depressed and becomes alarmed by a feeling of impending suffocation. The semi-erect posture, by permitting a more extensive dilatation of the chest, often gives some relief; and to this degree of dyspnœa, obliging the patient to sit up, the term *orthopnœa* has been applied.

As the elements or principal parts concerned in the function of respiration are three, namely, the blood, the respiratory machine, and the air, the causes of dyspnœa may arise from changes in any of these. As the peculiar condition of the blood which is called venous is the immediate cause of the sensation of

dyspnœa, so the blood being (if we may use the expression) *more venous* than usual, may give rise to the feeling of dyspnœa, without any derangement of the respiratory apparatus. Of this nature is the dyspnœa arising from violent exercise, which ceases as soon as the flow of venous blood to the lungs becomes moderated by rest. Whether other processes, such as increased secretions, the digestion of blood, &c. be capable of producing the like effect, that is, of so changing the blood, that although the respiration be healthy, this fluid is not arterialized with sufficient rapidity to prevent the feeling of dyspnœa, is uncertain; but the stethoscope teaches us that the function of respiration is more active in some individuals than in others, and that there is also a difference in the same individual at different times. Lænnec ascribed certain cases of habitual dyspnœa, in which the sound of respiration was even more distinct than usual, to an increased necessity of breathing, (*besoin de respirer*;) and although we should scarcely admit his instances (chronic bronchitis) to be cases in point, we think such a cause of dyspnœa to be in accordance with the pathological view which we have given. It seldom happens that persons with lungs in healthy action can exhibit such a state, the relative power of the organs being greater than the supposed increased demand; but those whose lungs are defective in consequence of disease, although not usually suffering from the defect, do certainly experience dyspnœa after taking food, and at other times, in a manner that will well admit of this explanation. It is through the blood, rather than in any other way, that diseases of the heart sometimes give rise to dyspnœa; any impediment to the pulmonary circulation causing an imperfection in the oxygenating process.

The following are the derangements of the respiratory function that may occasion dyspnœa: 1. derangements that interfere with the respiratory movements; 2. derangements that obstruct the passage of air to and from the pulmonary cells; 3. derangements in the pulmonary tissue that obstruct the action of the air on the blood.

1. The first of these, namely, those that interfere with the respiratory movements, are of two kinds; *a.* derangements of the mechanism of respiration, including spasm, paralysis, weakness or pain of the intercostal muscles, diaphragm, and other muscles concerned in respiration; rigidity or ossification of the cartilages or ligaments of the ribs, pain or rigidity of the pleura, and distortions of the spine or ribs: *b.* derangements external to the respiratory machine, but interfering with its movements, as pregnancy, abdominal tumours, and acute pain of the peritoneal coverings. Of these causes, spasm and paralysis of the respiratory muscles are the most important. In tetanus, and in paralysis resulting from severe injuries of the brain and spinal marrow, or from narcotic poisons, the dyspnœa thus produced is generally the immediate cause of death. In typhus fevers and other complaints of the extreme adynamic kind, dyspnœa arises

from absolute weakness of the respiratory muscles; and hence the utility of stimulants. In other instances of fever, in which the brain is severely affected, the breathing is often hurried—in such cases the affection of the respiration depends on the condition of the brain and nervous system. Acute pain, whether in the thorax or abdomen, frequently produces an apparent dyspnœa, by rendering the full exercise of the organs of respiration intolerable. This especially occurs in pleurodyne, and in some cases of pleuritis and diaphragmitis. Ossification, rigidity, or distortion of the thoracic parietes, and the pressure of abdominal tumours, do not often occur to a degree sufficient in themselves to produce dyspnœa; but by curtailing the sphere of the function, their presence may convert any trivial attack on it, by bronchitis or other cause, into one of a serious nature.

2. The second division of this class of causes of dyspnœa, those that obstruct the passage of air to and from the pulmonary cells, may properly be divided into, *a.* obstructions of the air-tubes, and, *b.* compression of the lung. Obstructions of the air-tubes may proceed from the state of the lining of the tubes themselves, from matters effused in them, or from tumours pressing upon them. Tumefaction of the mucous membrane of the trachea and bronchi, whether proceeding from inflammation, congestion, or œdema, and spasmodic constriction of the muscular fibres of the glottis and bronchi, are the derangements of the tubes themselves which not unfrequently occasion dyspnœa. Effusions in the air-tubes are the causes of dyspnœa in many diseases; and they may be either a redundancy of the ordinary secretion of mucus, as in slight inflammation, or of a new character, as coagulable lymph in plastic inflammation; pus, serum, and puita in the various degrees of bronchitis and catarrh; blood in bronchial hemorrhage and pulmonary apoplexy; tubercular and other matters from phthisical excavations, &c. Compression of the lung, by effusion into the sacs of the pleuræ and pericardium, whether of air, as in pneumothorax; or of liquid, as in pleurisy, hydrothorax, and dropsy of the pericardium; and by tumours in the thorax; is the other cause of dyspnœa which operates by obstructing the the passage of air to and from the pulmonary cells.

3. The last class of derangements of the respiratory function that become causes of dyspnœa, are diseases in the pulmonary tissue itself, obstructing the due action of the air on the blood. Such are, *a.* the obliteration and filling up of the cells by effusion, of lymph, serum, and pus in peripneumony; of blood in pulmonary apoplexy; of serum in pulmonary œdema; and of tubercular matter in phthisis: *b.* an alteration in the condition of the membranes forming and lining these cells or vesicles; such as, the thickening and increased rigidity of the tunics of enlarged cells in pulmonary emphysema; and we conceive that an altered state of the lining mucus, the natural function of which when healthy is to facilitate

the transfer of oxygen to the blood, is another cause which may give rise to dyspnœa. We have before noticed an excessive *quantity* of this mucus as a cause of obstruction to the passage of the air to and fro in the air-tubes, but we here suppose such a change in its *chemical quality* as would deprive the function of its aid. The bronchial secretion has been proved by late experiments to be much under the influence of the nervous system, and those cases of what is called nervous dyspnœa, in which signs of bronchial spasm are absent, and the sound of respiration distinct and even puerile, are probably referable to the last-named cause.

Besides in the blood, and in the organs of respiration, dyspnœa may sometimes have its cause in the third element of the respiratory process, the air. A deficiency of oxygen is, perhaps, the only state of the air that can *directly* occasion the feeling of dyspnœa; for carbonic acid, carburetted hydrogen, and other noxious gases, when in considerable quantity, do so rather by exciting spasm or some other derangement of the respiratory apparatus. The stertorous breathing of those who have been exposed to the fumes of burning charcoal is also an indirect effect, and proceeds from the poisonous agency of the evolved gases on the nervous system. Although a defective proportion of oxygen in the air may contribute to the oppression which some persons of low respiratory powers experience in crowded rooms, other causes, such as heat, noxious animal effluvia, &c. have at least an equal share in exciting it. The dyspnœa felt at great altitudes, where the atmosphere is exceedingly rare, may with more fairness be attributed to the cause in question.

When a case of dyspnœa presents itself, it must be of great importance to discover from which of these several causes it arises; which we can never do with certainty without an examination of the physical signs. These will supply the desired information by positive indications in the case of organic disease within the chest, whether affecting the bronchi or the pulmonary tissue; and in the other cases enumerated, auscultation will give such negative signs, as will in the greater number of instances, in conjunction with the general symptoms, lead to an estimation of the true nature of the cause. For the characteristic signs of the diseases mentioned as causes of dyspnœa, we refer to their several articles respectively.

We have cited, however, one instance of the production of dyspnœa, in which, if it be not idiopathic, the symptom is not referable to any distinct disease. We allude to the case of *increased want of breath*,—"besoin de respirer," as Laennec has termed it,—and which we have referred to the venous condition of the blood increased beyond its natural standard. Such a dyspnœa can be detected only by the absence of the signs of every other cause: where, therefore, a dyspnœa occurs, whilst pure air is found to penetrate freely into every part of the lungs, and the diseases which modify the state of the bronchial membrane and its secretion

have not existed, the disorder must be necessarily referred to an unusually venous or carbonized state of the blood. If we attempt to rise one link higher in the chain of causes, we shall find that physiology reveals to us only one probable mode in which this state is itself produced; and that is, by an excessive formation of those secretions which are, in relation to the blood, defective in carbon. Such is urea, a predominant principle in the urine. From its formation, principally, the carbonic acid exhaled from the lungs is supplied, and if we assume the possibility of deviation from the healthy proportion of this supply, we enter on ground less sanctioned by experience than by analogy. We conclude this subject with the remark, that the medicines which Laennec commended as capable of diminishing the "besoin de respirer," (belladonna, stramonium, conium, &c.) if they act as narcotics, deadening the sensation of dyspnoea, would not be eligible; but if they act, as is not improbable, by diminishing the secretions which render the blood venous, then they really would relieve the function, and not merely stifle the symptom.

(C. J. B. Williams.)

**DYSURIA** (from *δύς*, *agere*, and *ούρον*, *urina*.) Dysuria, or difficulty in voiding the urine, is a symptom of many different diseases, and arises under a variety of circumstances. Although only a symptom, it well merits careful consideration, from the suffering which it occasions, and the serious consequences to which it often speedily leads.

Dysuria exists in every degree, from the slightest to the most intense, when the difficulty terminates in a total inability to expel the urine. The consideration of the subject in this extended sense will lead us to treat of retention of urine, which, though peculiarly the province of the surgeon, is an object of deep interest to the practical physician.

Dysury is often attended with smarting pain; sometimes the pain is lancinating or shooting, at other times it is accompanied by the most distressing efforts to expel the contents of the bladder, such as have been described in the article **CALCULUS**. Pain, however, is not a necessary accompaniment of dysury: thus, the imperfection with which men advancing in life discharge the last drops of urine, although wholly unattended with pain, is a true dysury, though in almost all those cases where the expulsion of the urine is prevented by a deficient power in the muscular coat of the bladder, there is no pain. In such instances, as the difficulty of discharging the contents of that organ increases, no urine escaping, or only a small quantity constantly dribbling away, the urine gradually accumulates and produces distension of the bladder. If the progress of the disease has been slow, and the patient is not of an inflammatory habit, the bladder sometimes acquires a size almost incredible. It expands in all directions, pressing downwards, backwards, and laterally, filling all the pelvis not occupied by fixed viscera, and forcing behind and above

it those that are moveable. Under such circumstances the bladder has risen to the umbilicus, or even higher, pushing up the adjacent organs upon the diaphragm, and thus impeding respiration. Such enormous distention has occurred chiefly in females, in whom the bladder is much less irritable than in men; and the quantity of urine evacuated by the catheter in these cases has sometimes amounted to twelve quarts. Instances, indeed, are recorded where it is said to have been more than five times as great; but in all probability many of these extraordinary histories have originated in mistake or exaggeration. Frank relates a case in which forty quarts of urine were found in the bladder after death.\* To allow of such expansion of the bladder, its coats must be healthy and pliant, which in many instances of urinary disease is far from being the case. When this organ is indurated and contracted, a comparatively small accumulation of urine may prove fatal.

The fluid descending through the ureters finding a resistance to its entrance into the bladder, fills and dilates those tubes, and at length produces the same effect on the cavities of the kidneys. The pressure thus caused on them diminishes or wholly arrests their secretion, while the absorbent vessels carry a part of the urine into the circulating mass. The perspiration, which now becomes profuse, has a strongly urinous smell, and the taste of urine has even been perceived in the mouth.† Under such circumstances inflammation of the distended viscera speedily takes place; and if no relief be obtained, the urine escapes by a gangrenous aperture in the bladder or urethra, into the surrounding cellular substance, or into the peritoneal cavity. The extent to which the urine is diffused in the cellular membrane is often extraordinary, sometimes reaching as high as the soft parts covering the chest. When the urethra has given way behind a stricture, the scrotum is usually swollen enormously by the acrid fluid, which strikes with gangrene whatever it touches: at other times, the only visible indication of what has happened is a dark sphacelated ring surrounding the orifice of the urethra.

Retention of urine, when accompanied by inflammation, is always productive of great constitutional disturbance: the skin is hot; the pulse rapid; the thirst urgent; the tongue speedily covered by a dark crust, and great anxiety and restlessness prevail. Vomiting, hiccup, and extreme tenderness of the abdomen indicate the communication of disease to the peritoneum; low delirium comes on, and the patient dies comatose or convulsed.

We can in general depend on the report of the patient as to the existence of difficulty in expelling the urine; but it often requires a very careful examination, before we can ascertain the true state of the bladder. The urine may flow with pain, or dribble away insensibly, or the patient may feel not the slightest inclination to

\* J. P. Frank, De curand. hom. morb. Retentio urinae.

† Heberden, Comment. de Morbis.

discharge it; yet under all these circumstances the bladder may become disturbed to such a degree that the most dangerous consequences result from neglecting to relieve it. Distention of the bladder can seldom be mistaken, if the finger be applied to its lower fundus through the rectum or vagina, while the other hand is laid upon the hypogastrium: in general a distinct undulation of the fluid may be produced by this method. All doubt, however, will be removed by calling in surgical aid, and having the catheter introduced. Some striking instances are recorded, where the bladder in a state of excessive distention has been mistaken for a collection of purulent matter, or for abdominal dropsy, or ovarian tumour; and proposals have been made for the evacuation of the fluid by tapping.

*Causes.*—The circumstances which interfere with a due performance of the excretion of the urine are very numerous. Dysury may arise from the acrimony of the urine irritating the passages through which it is forced, and increasing their natural sensibility; thus, both alkaline urine and that which contains an excess of acid, have this effect. Difficulty in voiding the urine is also occasioned by an irritated or inflamed condition of the urinary organs, or of the adjacent and associated parts; by which the healthy sympathy between the muscles which retain, and those which expel the urine, is disturbed or destroyed. Thus, dysury exists in gonorrhœa; with inflamed prostate gland; with urinary calculus in any of the tubes or cavities, provided it occasion irritation; it also exists in cystitis; in inflamed ureter; in nephritis; and with inflamed hemorrhoids; inflammation of the rectum, and irritation of it from worms, or from the tenesmus of dysentery. The dysuria which accompanies this last disease is often productive of great distress, and has in our own experience sometimes occasioned retention, requiring the warm bath, and even the catheter. Dysuria also occurs in the painter's colic, from a sympathy between the bladder and the intestines in their state of spasmodic irritation. The irritations and inflamed conditions of the vagina and uterus produce dysuria: thus it is met with in the newly-married; in cases of gonorrhœa in females; in the early period of pregnancy, and as a warning symptom in approaching abortion. Dysuria is likewise a principal symptom of the warty excrescence which occasionally forms at the orifice of the female urethra.\*

A frequent cause of dysury, and of its more aggravated form, *strangury*, is the internal exhibition of cantharides, and their external application in the form of blisters and issues: we have also known vesication from scalding water produce the same symptom; but this sympathetic effect is of rare occurrence. Other substances, of a much milder nature than cantharides, are productive of irritation of the urinary organs when taken in excess: thus Rhenish wine and new beer have been known to occasion dysuria; and the latter is considered by continental writers as no

unfrequent cause of puriform discharge from the urethra. Increased secretion of urine, as in diabetes, and from the operation of diuretics, is often attended with pain and difficulty in voiding it. In some individuals asparagus is productive of much urinary irritation; but we have never observed this effect from gooseberries, which are more powerfully diuretic than many drugs referred to this class in the *Materia Medica*.

Dysuria sometimes exists, as a mere nervous affection, in connection with hysteria; and sometimes it arises from neuralgia of the bladder. The influence of dentition, which is so often manifested in disorder of the digestive organs, is occasionally extended to the urinary apparatus. This affection is also produced by every thing which mechanically obstructs the discharge of urine: thus, strictures of the urethra or prepuce; enlargement of the prostate gland; varicose veins at the neck of the bladder; polypous or fungous growths of its internal lining; intromission of the bladder,† the intestines falling into the cavity so produced; projecting folds of the mucous membrane—are all occasional causes of dysury. It may also originate from calculi in any of the urinary passages, from the kidney downwards; from hydatids; coagula of blood; inspissated mucus; false membranes or laminae of coagulated albumen plugging the ureter or urethra. Morgagni‡ and others have given accounts of such membranes, found in the bladder or urethra, or expelled with the urine; but cases are also recorded which serve to support the idea that part of the internal surface of the bladder is sometimes thrown off and discharged by the urethra.‡

Through the kindness of Dr. Weir, a remarkable case of this nature fell under our observation some years ago. A female, who was delivered by the forceps after the head of the child had been arrested for twelve hours, had, two days afterwards, an inflammatory attack with pain in the hypogastrium. Incontinence of urine followed; several small sloughs came away, and one was extracted from the meatus. About three weeks from delivery, retention of urine took place, and, after many hours, a large slough was forced off suddenly with a gush of urine, which continued to flow to the extent of two quarts. On carefully examining the slough, it was found to consist of a thin membrane without any perforation, six inches in length by four in breadth. One of its surfaces was granulated, rough with earthy particles, and stained with blood of a brown colour; the other presented the appearance of cellular membrane,

with small flattened masses of what looked like adipose tissue. It was very extensible, and on minute inspection an appearance of muscular fibres could be traced within its substance. That the bladder had in this case suffered a very severe injury was obvious; for the urine, for some time before and for a considerable time after the discharge of the slough, was mixed with blood, and deposited much purulent mucus: there was also at one period a phosphatic deposit from the urine, and two minute spongy calculi were voided. No opening could be detected between the vagina and bladder; and after the slough had been discharged, six or seven ounces of urine were from time to time voided in a stream.

The obstruction producing dysuria is sometimes dependent on a change in the position of the bladder, as in hernia of that organ, and in prolapsus of the rectum or uterus.

Ruysch gives a very curious case of complete prolapsus of the uterus, accompanied by the most excruciating urinary sufferings, in which he cut into the front of the prolapsed tumor, and extracted several calculi with a successful result.\*

On other occasions the cause of obstruction to the flow of the urine lies exterior to the bladder and urethra; as when it arises from ligatures round the penis, swelling of the prepuce, aneurism of the corpora cavernosa, abscesses in the vicinity, carcinomatous indurations, tumours within the pelvis, the gravid uterus, retroverted uterus, the menstrual fluid collected behind an imperforate hymen, faeces or other hard substances lodged in the rectum.

Inability to void the urine sometimes arises from rupture of the bladder, which may either be complete, or involve only the mucous and muscular tunics. The sudden occurrence of pain in the region of the bladder, and incapacity to expel the urine after the reception of an injury, the absence of tumor of the bladder when examined through the rectum or vagina, and the scanty discharge of jets of bloody urine by the catheter, will in general point out the real nature of the accident. It is to be observed in relation to the diagnosis, that although the bladder have been ruptured, there is often circumscribed tumor in the hypogastric region. In an instance of ruptured bladder which occurred in our practice some years ago, a urinary abscess which pointed in the hypogastrium was punctured on the twelfth day after the accident, and the patient survived till the twentieth. On inspection, the small intestines were found glued together, and to the abdominal peritoneum, by an albuminous exudation; and thus a partition was formed between the upper and lower portions of the abdominal cavity, which stretched across in an arched form a little below the navel. The lower cavity, which was of great extent, and communicated under the left Poupart's ligament with a sinus passing for several inches down the thigh, was more than half filled with putrid urine, pus, flakes of albumen, and liquid faeces; for the intestines had given way in se-

veral places. The bladder was seen lying collapsed in its natural situation, and presented posteriorly, on the left side of its upper fundus, a rounded opening about two inches in diameter. The peritoneal coat was extensively separated at this point, and its edges hung loose in flocculent shreds. It is probable that in this case only the mucous and muscular tunics were at first ruptured, and its long duration afforded some slender hope of a favourable termination: the only chance of success was from an early puncture of the hypogastric tumor, which we proposed in the second day after the accident, but it was overruled in consultation.

Dysury often originates in a want of power in the muscles which expel the urine. The muscular fibres of the bladder, if long kept on the stretch, gradually lose more and more of their contractile force, and at length become wholly paralysed. Instances of this description are of daily occurrence, when individuals have been prevented from emptying the bladder by delicacy, or by the absorbing engagements of business or pleasure. The pressure of the child's head in the latter stages of parturition often keeps the urine pent up, and thus induces inability to expel it after the obstacle is removed. The same loss of power in the fibres of the bladder, though in a much more dangerous form, arises from affections of the brain and spinal cord, and from pressure and disorganization of the nerves which supply the bladder: in this way difficulty of voiding the urine occurs in fevers, in extravasations and effusions within the cranium, in pressure from fractures of the bones, and in injuries and chronic diseases of the spinal cord.

Among the causes of dysuria, there is none more familiar to common observation than the exposure of the body to cold. It acts by producing a contraction of the urethra, more especially in men, disturbs and destroys the natural consent of parts, and in the end induces a torpor of the bladder. Wherever a predisposition to dysury exists from mechanical obstruction or otherwise, the action of cold becomes an immediate exciting cause.

*Treatment.*—In attempting the treatment of cases of difficulty or inability of voiding the urine, our first object ought to be to ascertain the cause from which it proceeds, and, if possible, to remove that which has occasioned the symptom: if we succeed in accomplishing this, the dysury in a great majority of cases will cease. In every instance of this affection it is of especial importance to discover how far it is connected with an inflammatory or plethoric condition of the body, or of the urinary organs in particular; and should it be so, to have speedy recourse to bloodletting or leeches. When dysury occurs during pregnancy, or is symptomatic of approaching abortion, the adoption of this practice will generally be required.

When the affection is of a spasmodic character, or accompanied by pain or irritation, the warm-bath, warm applications of various kinds, and opiates by the mouth, friction, or enema, will be found of the greatest utility. The last

\* *Observ. Anat. Chirurg. Ob. 1.*

of these remedies is particularly serviceable in that form of dysury which is caused by the application of cantharides. In many cases of dysury, even where it depends on a certain degree of mechanical obstruction, the operation of a smart purgative has produced immediate relief; and in every instance it is a safe rule to unload the bowels as speedily as possible, for by this means we relieve the neck of the bladder from pressure, and promote the healthy sympathy of the parts. In dysury and retention of urine of a spasmodic character, the tincture of the muriate of iron, in small repeated doses, has proved a valuable remedy in the hands of the late Mr. Cline and many others. The sudden affusion of cold water on the genitals and neighbouring parts has sometimes procured a flow of urine when all other methods have failed, partly, perhaps, by causing a relaxation of spasm, but chiefly by rousing the contractile powers of the bladder. But when the vigour of this organ is actually impaired, we must have recourse to stimuli of far more effective and permanent operation. Blisters to the loins and sacrum, the formation of eschars by moxa or potassa, and the cautious exhibition of cantharides, are the remedies which will be found of most avail.

When dysuria appears to be connected with the scanty secretion or acrimonious quality of the urine, diluents are to be given freely, along with such mild diuretics as the spiritus ætheris nitrici, spirit of juniper, decoction of the fibrous roots of the leek, liquor potassæ with hyoseyamus, bicarbonate of soda, or Seltzer water. Stronger diuretics are in severe cases given with advantage, such as the parsley breakstone (*alchemilla arvensis*), seeds of the wild carrot (*daucus sylvestris*), and the oil of turpentine. Dysury from alkaline urine must be treated on the plan already laid down in the article CAL-  
CULUS.

Should inability to void the urine have arisen from long voluntary retention of it, the patient ought to immerse his feet in warm water, and, placing the penis in a basin of the same, make gentle pressure on the hypogastrum, and endeavour to evacuate the bladder, when he will often succeed without any farther assistance. The immersion of the penis in warm water rarely fails to give great relief in the painful micturition which attends gonorrhœa. When difficulty of voiding the urine occurs, as it very often does, after parturition, the simple expedient of making pressure on the hypogastrum with a warm sponge will not unfrequently save the patient from the necessity of having the urine drawn off by the catheter. But to this instrument we must have recourse in very many cases of retention of urine; and it is fortunate that the surgeon possesses in it the means of removing a symptom which is at once most distressing and dangerous. The catheter, however, is not always successfully employed, even by surgeons of acknowledged eminence and dexterity; and it then becomes a question how the danger can best be averted. If the symptoms are not urgent, a little delay may still be allowed, to give a farther trial to the most im-

portant of the remedies already enumerated, and to the well-directed employment of sounds and catgut bougies; but we must on no account wait so long as to incur the slightest risk of gangrene or rupture of the bladder. The only means now remaining by which the life of the patient can be saved, is, to puncture the bladder, or open the urethra behind the obstruction, should such be the nature of the case. This, however, is in the province of the surgeon, and therefore foreign to the nature of our work.

(*W. Cumin.*)

ECTHYMA, (from *ἐκ*, *ex*, and *θεῖν*, *fervere*,) a disease of the skin, characterised by an eruption of phlyzacious pustules, neither contagious nor infectious.

*Synonymes.*—*Τέρμιθος* vel *θέρμιθος*,\* et *ἐπι-  
νυκτις*,† (*Græcorum*;) *therebinthus*, (*Latino-  
rum*;) *albotin* vel *albotes*,‡ *schera* et *botsor*,§  
(*Araborum*;) *terminthus*, (*Wiseman, Turner,  
Lorry, Plenck*;) *epinyctis*, (*Sauvages*;) *psori-  
de crustacée*, (*Alibert*;) *erbsenblattern*,  
(*Teutonicæ* *sec. Plenck*;) *eiternde flechte*, (*sec.  
Sprengel*;) *papulous scall*; *ulcerated letter*.

By the term with which Willan chose to designate this disease he lost hold of the thread which led us to the knowledge which the ancients had concerning it. In the synonymy we have endeavoured to recover it, thus to connect ancient experience with modern observation, the only substantial use of learning.

The eruption in this disease consists of large round pustules generally distinct and sparingly scattered, each having a hard, red, elevated base, terminating in a thick, hard, greenish or

\* "Some will have the denomination from the likeness of the pustule to the fruit of the *terebinthus*. Others, with more reason, read it *ἐπίεθθος*, *cicer*, which it somewhat resembles." Turner. Vide Hipp. Epidem. lib. ii. sect. 11; De Humor. xi. 1; Galen. in Exeg. diet. Hipp. item Comment. 3, De Humor. et Comment. 4, in lib. vi. Epidem.; Ægin. l. iv. c. 4; Ætiii. lib. ii. tetrah. iv. c. 63; Pæs. Cæc. p. 615, 616; M. Aurel. Sev. l. de Epinyctid. part. ii. contr. 3; Dioscorides Alexand. vide Gorraei defin. Med.; Oribas. lib. vii. Synop. cxxxvi.

† From *ἐπι* and *νύξ*, so called, according to some, because the eruption first appeared, or only appeared, by night, and, according to others, because it was most troublesome at night. But whatever be the reason of the etymology, it is plain, from the description of this eruption left us by the best authorities, that it consisted of phlyzacious pustules. Vide Hipp. Prorrh. 2, De Intern. Affect.; Celsus, lib. v. c. 28, sect. 15; Paul Ægin. lib. iv. cap. 9; Oribas. Synops. lib. vii. c. 37. The Arabians translated the term by *sera* or *schera*, and sometimes *botsor*, (*Avicenn. lib. iv. fen. vii. tom. iii. c. 1.*) which last being of the same etymology restored it to its natural connexion with *terminthus*. Actuarius, as it appears to us with little show of reason, insists on a distinction between *epinyctis* and *terminthus*, (*Meth. Med. lib. ii. c. 11, 12.*) Some authors, bearing entirely upon the derivation of *epinyctis*, have been led into the mistake of considering it the same as the *urticaria tuberosa*—an error which Sennertus very properly corrects.

‡ Fallop. l. de Morb. Gall. c. 5, tom. i. p. 686.

§ Avicenn. lib. iv. fen. 3, t. i. and f. 7, t. iii. c. 1; Hensler de Herpete, p. 30; Roussel de Herpete, § 99.

dark-coloured scab, which, falling off, leaves generally a livid red spot of longer or shorter duration, sometimes a superficial cicatrix, more rarely an ulcer, seldom a tubercle.

This eruption is frequently confined to the extremities, appearing most commonly on the legs, on the outer side of the thighs, arms, and forearm, frequently on the abdomen, nates, lumbar region, neck, and front part of the chest, rarely on the face or scalp, and very seldom occupies the whole body.

The pustules sometimes break out together in successive crops; but generally they appear, go through their progress, and terminate, independently of each other, some being on the decline whilst others are appearing.

This eruption is sometimes, but not generally, accompanied with fever; it is more frequently attended with restlessness, a state of general irritation or erythema, and sleepless nights. Morbid phenomena produced by gastric and intestinal irritation, as anorexia, &c., almost always appear during the course of the eruption. Sometimes fever, anxiety, great general distress, and pains of the limbs precede the eruption, which subside on its appearance. If the pustules be abundant, thickly set, violently inflamed, and acquire a great size, considerable symptomatic febrile action may be present; and if they necrate, are slow in their progress, and of long continuance, emaciation, debility, and regular paroxysms of hectic fever supervene.

Each pustule generally commences in a circumscribed red inflamed point, which becomes gradually raised, and in the course of a few days acquires a size varying from that of a lentil to that of a sixpence; their apex is soon observed to point with pus, whilst the base continues hard, circumscribed, and of a bright red colour; at the end of three or four days the pus dries, and scabs, more or less thick, are formed, which, when they fall, leave spots of a dark red colour. The pustules vary in size, from that of a small pea to that of a sixpence or larger. They are generally distinct, but sometimes they form irregular clusters. Their development is frequently accompanied with very acute stinging pains, similar to what precedes *erysipelas*, or the *herpes zoster*.

From this their usual course considerable deviation is sometimes observed. Their progress is sometimes tediously slow and imperfect. Suppuration in some cases is established rapidly, and in others it is only effectual after many days; sometimes the pus is in very small quantity, occupying only the apex of the pustule, the base remaining broad, hard, and inflamed; sometimes, more especially on the hands and feet, the pus raises the cuticle over all the extent of the pustule, giving it the appearance of a bleb or *bulla*. Some of the pustules are occasionally resolved, thin, white scabs forming successively over their surface; sometimes ulcerations, more or less deep, succeed the pustules, especially those seated on the lower extremities, or such as follow scarlatina or small-pox, and sometimes slight indurations succeed to the scabs. The pustules are not always distinct, but sometimes as it were con-

fluent, and though generally accompanied with a burning, itching or stinging pain, they are also sometimes entirely free from any painful sensation.

It has been doubted whether the term pustule was properly applied to the eruption of ecthyma, which supposes an active inflammation and suppurative action to constitute the essence of the disease,—a supposition inconsistent with the state of system existing in all cases as the predisponent cause of this disease; and it has been asserted that a minute examination does actually disclose a state of vessels differing materially from such an action; that, instead, a lesion of some minute vessel takes place in each spot of ecthyma, and a kind of petechiæ are thus produced. But from some cause, depending either on a minor degree of debility of the system to that in which the petechiæ remain quiescent, or on a greater degree of irritability of the skin, attempts are made to repair the mischief by the vessels of the part, and inflammatory action takes place. The minute vessel thus ruptured has its extravasated contents mixed with the coagulable lymph poured out by the vessels labouring to repair the mischief, and the mixed fluids, drying on the spot, form the minuter scabs. But the constitution being unequal to carrying through the process in a healthy manner, irregular attempts at suppuration take place, and the bulk of the scab is usually surrounded by and partly mixed with a minute portion of ill-formed pus, which, drying, increases the bulk of the scab. Many of the minute vessels concerned in this process being too relaxed, their secretion is mixed with and deeply coloured by red globules, which escape under the increased action. The scab now becomes a cause of irritation to the surface on which its basis rests; the bloody purulent secretion increases, becomes inspissated, and attached to the mass; ulceration gradually destroys the surrounding cutis, and the margin of sound skin becomes elevated and thickened. The scab, by the continuance of this process, is gradually elevated and rapidly enlarges, a fresher and broader ring of growth being added to its basis every three or four days.\*

This ingenious account of the process of the eruption of ecthyma is not in strict accordance with the phenomena, but, on the contrary, is in many respects at variance with them: it rests in its chief points upon suppositions purely gratuitous, for it has yet to be ascertained, and we are inclined to deny it, that even petechiæ are nothing more than ruptures of minute vessels; and it is directly contradicted by other observers who have examined attentively the structure of the pustules of ecthyma at the different stages of their progress. According to them, in their *first* state of red elevations, there exists only a vascular injection with a round circumscribed tumefaction of the skin; that, in their *second* state, a certain quantity of purulent serosity is deposited, under the epidermis, at their summit, more

\* Plumbe, on Diseases of the Skin.

rarely over all their surface; that, in their *third* state, a substance of the nature of a false membrane is deposited in the centre of the elevation, which is evidently perforated; that, in the *fourth* state, after this substance has been extracted and the epidermis removed, the pustule appears in the form of a little cup surrounded with a hard broad border; and that, in their last and *fifth* state, the border, during the following days, gradually disappears, whilst a small cicatrix is formed under the scab, the centre of which is sunk into the point where the perforation had been observed.\*

The phlyzacious pustules of ecthyma may be developed in the healthiest body by the local application of certain irritating substances. Thus tartar emetic, in powder or in ointment, after the manner of Autenrieth, is capable of giving rise to them; and the same has been observed of certain pulverulent matters, as metallic powders, sugar, and lime, which accounts for its being frequently seen in masons and grocers. But it is more commonly met with as a symptom and effect of a general disordered state of body, or a sympathetic consequence of irritation or inflammation of some internal organ. Hence it has been observed to supervene upon unusual fatigue, long continued exertion, much night-watching, great mental anxiety, and strong moral affections; and it has been most frequently observed in persons who have injured their constitutions by previous excesses, by the abuse of spirituous liquors; or who have suffered in consequence of deficient nourishment, or unwholesome food, or surfeits; whose health has been impaired by dwelling in dark, damp, cold, and close habitations; or by habits of sloth and uncleanness; or whose constitutions have been debilitated by the effects of malignant fevers, as small-pox, measles, and scarlatina. Hence it is favoured by a moist and cold atmosphere, though it occurs most frequently in spring and summer; and is met with frequently in infants, in the decline of life, and in women, more especially during pregnancy, or whilst suckling, or coexisting with amenorrhœa; and is frequent in large cities, hospitals, prisons, garrisons, work-shops, and manufactories. For the same reason it is so often accompanied with symptoms of gastric and intestinal disorders, with loss of appetite, pain in the epigastrium, irregularity of the bowels, lassitude, headach, &c.; and has been observed frequently coexisting with chronic inflammation of the mucous membrane of the stomach and intestines, with such concomitant symptoms as inflammation of the conjunctiva, and of the mucous membrane of the pharynx; and has sometimes been observed to be critical in acute *gastro-enteritis*. In predisposed habits, trifling local irritation will produce it, as leech-bites, and even the friction of the clothes; so that some authors have remarked the pustules to be frequently seated under the wrist-

bands and collar of the shirt, the waistband of the breeches, and at the gartering-place above the knee.

Though the eruption of ecthyma preserves its character with comparative constancy, and is one of those cutaneous affections the least convertible and disposed to pass into others, it sometimes develops itself in the exacerbations of other inflammations of the skin, as in *lichen*, *prurigo*, *scabies*, and *variola*, but shews, in general, a closer connexion with *furunculi*.

Though such is the general appearance, course, and causes of this disease, they admit, as we have noticed, of considerable diversity, sufficient, in a practical point of view, to justify a division of the genus into several species; and though we prefer the specification of Willan and Bateman to that of Alibert, (*psoris crustacea acuta* and *psoris crustacea chronica*,) as being more true, precise, and practical, we shall venture upon a slight alteration of the name of one species, so as to make them all more distinct and consistent; and shall add to the genus the syphilitic form of the disease. The following will therefore be our arrangement.

1. *Ecthyma vulgare*.
2. *Ecthyma infantile*.
3. *Ecthyma lividum*.
4. *Ecthyma fibrile*.
5. *Ecthyma syphiliticum*.

1. *Ecthyma vulgare*.—*Syn.* Epinyctis vulgaris (*Sauvages*); Psoris crustacea acuta (*Alibert*); Ecthyma aigu (*Rayer*); die gewöhnliche eiternde flechte (*Teutonice*).

In this species of ecthyma, generally after some days of languor and general oppression, of loss of strength and appetite, of derangement of the digestive functions, of headach, of pains in the bowels or of the limbs, and after less refreshing nights, with, more rarely, redness and inflammation of the conjunctiva, and sore-throat from erysipelatous inflammation of the pharynx, an eruption, accompanied with sharp stinging pains, appears on some part of the extremities, or on the neck, shoulders, or breast. This eruption, which is usually completed in three or four days, consists of small red circumscribed elevations of the skin, not yielding or disappearing on pressure; for three or four days they continue to enlarge, becoming surrounded with an inflamed areola, which is hard and circular, and in young subjects of a bright red colour; having suppurated at their apex, which is distinguished by a small dark point, after a day or two they break, discharging first pus and afterwards a thinner fluid, which quickly concretes into dark-brown or greenish scabs. The constitutional derangement which preceded the eruption is now abated; the inflamed areola extends itself, becoming gradually paler as it enlarges; in about a week, all the pain, soreness, and inflammation subside, and the scabs soon after fall off, leaving no mark behind. If they continue adherent to the skin for a longer time, which sometimes happens, they leave, when detached,

\* *Ecthyma*, Dictionnaire de Médecine et Chirurgie Pratique.—*Ch. Ed. Asselin*, Essai sur l'Ecthyma, Paris, 1827.

a dark-red spot, or, more seldom, a superficial cicatrix, in size resembling those of small-pox, but less deep. If the pustules be situated in the neighbourhood of lymphatic glands, these latter sometimes become swollen and inflamed.

The whole process of this eruption, in general, occupies from seven to fourteen days, and one eruption frequently completes the disease.

This species is most commonly met with in spring and summer; it affects principally young people and adults, and is occasionally observed in women during gestation. It frequently follows excessive fatigue, severe or prolonged exertion, night-watching, nurse-tending, anxiety, vexation, and other emotions of mind, errors of diet, and indulgence at table. It appears to be very much connected with the state of the digestive organs, but seems to depend upon something more than their mere derangement. It has been well expressed by Bateman, by a state of distress of the constitution. It is also sometimes observed as critical of acute gastro-enteritis.

In general, this species does not stand much in need of the interference of art. Gentle, cooling, and saline purgatives, as senna, manna, and tartarised soda or potass; acidulous diluent drinks, as whey; and light, cooling diet, afford ample means of cure. In robust, sanguine, or plethoric subjects, a small blood-letting accelerates the progress of the eruption, and renders these means more efficacious. If much irritation and restlessness be present, and much local uneasiness, the tepid bath is the surest means of affording relief. If the alvine evacuations are unhealthy, five grains of the pulv. hydrargyr. cum creta may be taken at bed-time, with a few grains of Dover's powder, but even this is seldom necessary. The diluted sulphuric acid, simple or aromatic, is a good tonic as the disease declines. If the local affection demands any treatment, an emollient poultice is the best.

2. *Ecthyma infantile*.—*Syn.* Terminthi neonatorum—Schälblasen, *Teutonicè*, (*Plenck*.)

In infants of a constitution naturally weak, or disordered by bad or insufficient suckling, or by being brought up by hand upon food not suited to the powers of their digestion, an eruption of phlyzacious pustules is a common occurrence.

In this species, as the former, the eruption is partial, chiefly affecting one particular part of the body, and, as in the former also, several pustules may appear together; but more commonly the disease consists of a successive eruption of individual pustules, by which its duration is sometimes extended to several months. The pustules are first observed near the groins, on the abdomen near the umbilicus, near the axillæ, and on the thighs or nates; sometimes they are not confined to the trunk and extremities, but also occupy the face and scalp. The course and progress of each individual pustule is the same as that of the *ecthyma vulgare*, but they are in general more irregular in their size, a large being frequently

observed by the side of a very small one; their form is circular, but they vary more in colour, being sometimes of a bright red, sometimes of an amaranthine, and sometimes of a livid colour, according to the strength or weakness of the infant. The pustules of this species are more disposed to suppurate extensively, and more apt to terminate in ulcerations, which in weakly infants heal imperfectly, being covered by a thin, filmy cicatrix, easily re-opening or abraded, marked by a peculiar puckering of the surrounding skin. In some severe cases, generally only to be found amongst the most indigent, gangrenous eschars and deep sloughing ulcers, similar to those of *erysipelas infantile*, are not uncommon terminations of the pustules of this species. Occasionally, also, after threatening suppuration, the pustules gradually diminish and terminate by a succession of desquamations.

The process by which an improper nourishment develops this disease appears to consist not only in a deranged state of digestion and assimilation, but also in the production of inflammatory affections of the alimentary canal; for chronic inflammations of the digestive organs are frequently observed in connection with this eruption. But all the chronic derangements of the abdominal organs of infants are capable of inducing this eruption, and hence phlyzacious pustules are common symptoms of the marasmus which depends upon obstruction of the mesenteric glands. Cold and moisture appear frequently to furnish the exciting causes of this eruption. According to Plenck, it has sometimes prevailed epidemically.

The treatment of this species consists in changing the nurse or in altering her milk by diet or medicines, or in adapting the diet of the child to the powers of its digestion. For this last purpose, asses' milk, goats' milk, and whey afford very useful resources. The air, exercise, and clothing of the patient also deserve attention. In mild aperients, as castor-oil, manna, and magnesia, with mild mercurial alteratives and soda, and, if there be any feverishness or fretfulness, small doses of nitrate of potass and the tepid bath, the medical treatment consists. As soon as it can be borne, the ferrum tartarizatum, given in small doses, affords a convenient alterative and tonic. The chloruret of potass and the pyroligneous acid, both in small doses, are said to have been found particularly serviceable in this eruption, as, also, the Peruvian balsam and sulphate of quinia. Nor is the local treatment of the pustules, if large, unimportant. If there be much pain or irritation, fomentations of the decoction of poppy-heads frequently afford relief; in superficial ulcers, with profuse acrimonious discharge and itching, weak solutions of chlorine or chlorate of lime are most useful applications.

3. *Ecthyma lunatum*.—*Syn.* Terminthus (*Anctor. Var.*); Psoride crustacée sordide (*Alibert*); ecthyma chronique (*Rayer*).

An eruption of large phlyzacious pustules, sometimes acquiring a very considerable size, having their base hard, elevated, of a dark

livid red colour, and continuing highly inflamed, even after scabbing takes place; slow in their progress, extensively distributed over the body, and generally connected with a state of cachexy; these circumstances afford the distinguishing features of this species of ecthyma, which, though in different stages, is accurately represented in Plate XLIII. of Bateman's Delineations, and in Plate LIII of Alibert.

The pustule of this species is more analogous to an ill-conditioned boil, being more extensive and prominent than is usual in ecthyma. Suppuration is seldom completed in less than eight or ten days, when the pustules break and discharge a curdy, sanious, or bloody fluid, which is soon converted into hard dark scabs, and these are encircled with a hard violet or livid red-coloured areola. The surface covered by the scabs is slow in healing, and the ulceration sometimes extends beyond the limits of the pustule; but the ulcerated cavity is soon filled up with hard dark-coloured scabs, firmly attached, seldom separating for many weeks, sometimes not for months. Though the ulceration extends, it is always surrounded by a deep-seated hardness and by a dark inflamed border, and, when not covered by a scab, which sometimes happens if they have been removed by violence, tedious ulcers, with callous edges, discharging a sanious pus, are often the consequence. When the scabs fall off, dark red-coloured patches, or cicatrices of a violet red colour, remain for a considerable time over the parts which have been occupied by the pustules. Sometimes the pustules are long stationary, and do not proceed to suppuration, but are followed by tubercles of a violet colour; these may, however, ultimately proceed to suppuration and ulceration, and thus leave irregular cicatrices in the skin. In this species the pustules are more entirely independent of each other's progress, and may continue to succeed one another without any order for several months. They are often attended with extreme pain and soreness, generally without fever; but sometimes considerable constitutional irritation is present, and in protracted cases hectic fever: in some cases the respiration is remarkably affected.

Ecthyma luridum is always a symptomatic affection, a consequence of cachectic disorder of the habit. For this reason, it prevails most during the winter season, and is most commonly met with amongst persons advanced in life, or amongst those whose constitutions have been broken down by misfortunes or imprudence. Hence the indigent who inhabit dark, damp, and narrow streets and cellars, whose means and habits seldom allow them the comforts of cleanliness; prisoners confined to dark and dreary dungeons, filthy, squalid, and ill-fed; those who have been exposed to great hardships and hard labour; or those who have been compelled to live upon unwholesome food, particularly such as is hard, dry, smoked, and salted; and such as have abused their health by an irregular life, particularly those addicted to the use of ardent

spirits, are most frequently the subjects of this disease. The state of body which prepares for this disease may also be produced by previous diseases, as in febrile affections, when the cure or the crisis has been imperfect; and in this way it occurs very frequently as a sequel of scarlatina, measles, and small-pox.

The essential point in the treatment of the ecthyma luridum consists in correcting the faulty state of habit upon which this disease depends, and this object, the cure of the cachexy, is not to be attained by any one simple method of treatment, but by the combination of several,—neither by depuratives, nor alteratives, nor tonics, but by a happy adaptation and adjustment of them all. The experienced physician knows, that to renew and regenerate the organizing and organizable fluids of the body, before proffering a supply it is necessary to excite a demand, and that to give vigour and activity to the function of nutrition, it is useful to diminish the volume of the nutritive fluid; that, whilst in this way activity is given to the process of nutrition, care should be taken to modify, by the proper use of alteratives, the action of the organs, by whose united functions the nutritive fluid is created; and that these actions may be performed satisfactorily and effectually, it is necessary by stimulants or tonics to support the action of the nervous system, until the new, fresh, and healthy blood is of itself capable of doing so. In these three intentions, the indications of the cure of cachexy consist. Therefore, in the commencement of the disease, mild cooling purgatives, or very small repeated bloodlettings, (from two to four ounces,) and light nutritious diluting drinks, are good preparatory measures; whilst any distressing irritation may be relieved by opiates, the action of any organ which is deficient may be solicited or modified by its appropriate specific stimulus, and the vigour of all may be increased by exalting artificially that of the nervous system. From this view the practitioner will readily understand the application of such remedies as sarsaparilla, guaiacum, and taraxacum; of saline mineral waters; of antimony and mercury, either alone or as they are more conveniently united in Plummer's pill; of vegetable and mineral acids, of decoction of cinchona, of sulphate of quinia, and chalybeates; of the fresh and sea-water tepid bath and cold sea-bathing; of whey, asses' milk, milk diet; of food, light, nutritive, and easy of digestion; of wine in small quantities; of gentle exercise in open dry air; of warm clothing; and, as much as may be possible, of quiet and repose of mind.

The local treatment, when the state of the pustules demands it, consists in emollient applications and softening plasters to favour a benign suppurative process; but when they shew any malignant appearance or disposition to gangrene, it is best arrested by nitrate of silver in solution, the butter of antimony, or caustic potash.

4. *Ecthyma febrile*.—*Syn.* Ecthyma cachecticum (*Bateman*); Psoriasis crustacea acuta (*Alibert*); Ecthyma aigu (*Rayer*).

After febrile symptoms of two or three days' continuance, accompanied by headach, pains of the limbs, loss of appetite, disordered digestion, irregularity of the bowels, great restlessness, and sometimes delirium, there appears an eruption of numerous and scattered phlyzacious pustules, generally smaller than in the other species. The pustules are commonly first observed upon the extremities, to which, either dispersed or clustered together in irregular patches, they are sometimes confined; but they also frequently appear first upon the breast, in other cases on the forehead; and sometimes extend over the whole trunk, the face, and the scalp. The eruption of the pustules is accompanied with a burning stinging sensation, or with itching or tingling, and a great desire to relieve it by scratching. After the first eruption fresh pustules continue to break out daily, until the skin is thickly studded with them; and as the successive pustules go through their different stages of inflammation, suppuration, and desquamation, at similar periods after they arise, they are necessarily seen under all these conditions at the same time; the rising pustules exhibiting a bright-red line at the base, which changes to a purple or chocolate tinge as the inflammation declines, whilst little laminated scabs are formed upon their tops: when these fall off, a dark stain is left, which remains for some time. The pustules which occupy the breast and abdomen are generally less prominent than those on the face and arms, contain less matter, and terminate rather in scales than scabs. Pustules may continue to succeed each other, in the manner just described, for several weeks, the average duration of the disease being from two to four months. The best representation of this species of ecthyma is that in *Bateman's Delineations*, Plate XLIV.

On the appearance of the eruption the febrile symptoms are diminished, but not removed, for a state of constitutional irritation, of erethism, or hectic, continues during the progress of the disease, which is invariably accompanied by great languor, and by much depression both of the spirits and muscular strength. The pulse is generally quick and small; the skin hot, dry, and harsh; the tongue dry, red, and glazed; the gums tender, swollen, and bleeding easily, sometimes to a considerable extent; and there is generally an inflammatory state of the fauces and pharynx, in which superficial ulcerations may be observed; this inflammatory state sometimes extends to the Schneiderian membrane and conjunctivæ. The legs and feet are occasionally œdematous.

The ecthyma febrile is always a symptomatic disease depending upon an inflammatory state of the mucous membrane of the stomach, and connected with a congestive state of the abdominal circulation, corresponding

to that disorder of body described by writers under the term of scorbutic cachexy. In persons of this state of body this eruption declares itself at the change of season, in spring and autumn, from exposure to inclemencies of weather. It occurs most frequently after the body has arrived at full maturity, particularly in those debilitated by a long series of excesses; and it is occasionally seen in the crude convalescence of gastritis imperfectly cured.

The nature of the ecthyma febrile affords satisfactory indications for its cure. If the eruption be extensive, the local inflammation severe, or if it be attended with much fever, depletion by small venesections, by leeches to the anus, epigastrium, or hypochondriac regions, or by cooling saline purgatives, is a necessary measure; whilst the secretion of the liver is to be solicited by mild mercurial alteratives, taking care to prevent their affecting the constitution,—a circumstance, however, liable to occur in this disease, even from very small doses. The mercurial alterative may be combined with antimonials, as the James's powder, or with Dover's powder. These, with the tepid bath if there be much irritation, diluting acidulous drinks and light diet, constitute the means of cure. In milder cases, cooling saline purgatives and acidulated drinks will, in the commencement, be found sufficient; and when the febrile symptoms have abated, the Plummer's pill combined with a course of taraxacum affords an alterative treatment of great value.

These remedies may be succeeded by the diluted sulphuric acid and preparations of cinchona, as soon as the state of the stomach admits them. The warm alkaline or salt-water baths are very useful subsidiary means, and the diet throughout should be mild, light, easy of digestion, and nutritious.

When the pustules are the seat of much pain, of itching, or uneasiness, local applications are of considerable use. Of these a solution of chlorate of soda is one of the best. Dr. A. T. Thomson found great advantage from the following:

R Plumbi acetatis, ʒss.  
Acid. hydrocyan. ʒiii.  
Unguenti cetacei, ʒiii.

M. fiat unguentum partibus cutis nudis applicandum.

The ecthyma febrile has only been accurately described by *Bateman*, *Alibert*, *Hewson*,\* and Dr. A. T. Thomson.†

5. *Ecthyma syphiliticum*.—*Syn.* Syphilide pustuleuse phlyzaciée (*Rayer, Bielt*); Pustular venereal disease (*Carmichael*).

Under the influence of the venereal virus, modified no doubt by some peculiarity of constitution, natural or acquired, an eruption of phlyzacious pustules is frequently observed; and which, in a classification founded entirely on

\* The North American Medical and Surgical Journal, January 1826.

† *Bateman's Synopsis*, 7th edit. 1829.

the external characters of disease, we are justified in placing under the genus *ecthyma*.

The pustules of the *ecthyma syphiliticum* succeed each other, are generally sparingly scattered and distinct, and seldom very numerous, and have been by Lagneau, on account of their large size, compared to those of small-pox; they are most frequently seated upon the limbs, and especially upon the legs; but they have been observed upon every part of the body. They first appear under the form of a livid spot, in breadth somewhat less than that of a shilling, but also sometimes larger; throughout a considerable extent of this spot, the epidermis becomes raised and gradually distended by a greyish sero-purulent fluid, whilst the tumefaction slowly increases, and is surrounded by a broad areola, invariably of a livid copper colour, one of the characteristic distinctions of this species of *ecthyma*. After a few days the pustule opens and discharges a liquid, which concreting forms a very hard blackish or brownish black scab; the scab becomes by degrees very thick, furrowed circularly, and is generally of a regular round form. The progress of the pustule most commonly takes place without any symptoms of local inflammation; there is little increase of heat; the surrounding parts are free from pain; a slight smarting is all that the patient feels. The scabs are strongly adherent, and they may remain undetached for an indefinite time; but when they fall off, either spontaneously or by means of emollient applications, they expose round ulcerations, most commonly deep, having their edges abruptly precipitous, formed of a hard violet-coloured tissue, and their bottom of a greyish, pale, unhealthy aspect. These ulcerations seldom extend, but the scab gradually forms again, and is successively detached; until at last, by means of appropriate treatment, the new scabs are formed less thick, the ulcerated surfaces become healthy, and are succeeded by a permanent round cicatrix, of a copper colour.\*

Infants born infected with the syphilitic virus present most commonly this form of eruption. In this case the pustules are very numerous, broad, flat, superficial, and of an oval form. They become covered with blackish scabs, of no great thickness, which are followed by small ulcerations. A very characteristic general appearance of the countenance, which it would be difficult to describe, attends this complaint. The skin is foul, the features are drawn, and the whole body is emaciated, wan, and, as it were, etiolated; the countenance is wrinkled, giving the appearance of extreme old age, and a peculiarly diseased odour is exhaled.†

The pustules of the *ecthyma syphiliticum* are distinguished from those of the other species by being surrounded by an areola less broad, but of a dark copper or violet colour; by their thicker scabs, furrowed circularly; by being succeeded by ulcers round and deep, with pre-

cipitous edges, and being invariably followed by a depressed indelible cicatrix, and by being generally attended by some concomitant constitutional symptoms, such as inflammation and superficial ulcerations of the fauces, pains of the bones, sometimes *iritis*, whilst the history of the case affords the evidence of some primary affection.

Mr. Carmichael, who is peculiar in his opinions in limiting the true syphilitic disease to one form of eruption, does not consider the phlyctenous pustules to be of that nature. He considers them as consecutive of a peculiar primary ulcer, which he describes as characterized by a reddish brown surface, bordering closely on the phagedenic character, having its edges raised and well defined, not excavated, but either on a level with the surrounding skin or considerably raised above it, appearing at its commencement in the form of a small pustule, attended with itchiness. According to his observation the secondary eruption is preceded by fever.\*

The view which Mr. Carmichael entertains of this eruption leads him to consider mercury as unnecessary for its cure; he therefore depends upon antimonials, sarsaparilla, and guaiacum for the constitutional remedies; zinc lotions and rest in the primary affection; sulphur fumigations, or equal parts of tar and sulphur ointment as the local remedies in the secondary eruption. But as this method of treatment has not met with general sanction, the greater number of practitioners think it safest to have recourse to the specific cure. This has been already described at length under *Aene Syphiliticum*. (See ACNE.)

When an infant at the breast is the subject of this eruption, the remedy should be introduced through the system of the nurse, either by administering to her the liquor oxymuriatis hydrargyr., or by the friction of mercurial ointment; and if the health of the nurse does not allow of this manner of introducing mercury, the same may be effected by giving the infant the milk of a goat which has been submitted to the friction of mercurial ointment. These methods have been used at the Hospital of St. Louis at Paris, and followed with the most complete success. But the mercury, if necessary, may be also directly given to the infant; either small doses of the hydrargyrum cum creta, or minute doses of the oxymuriate of mercury in decoction of elm bark or emulsion of bitter almonds, as recommended by Dr. A. T. Thomson.†

(T. J. Todd.)

ECZEMA, (from ἐκζέω, *effervesco*.) is a disease of the skin, characterized at its commencement by the existence of minute vesicles, which are usually closely crowded together, and terminate either in the absorption of their contained fluid, or in its effusion and subsequent concretion into thin scales. It is accompanied with a burning heat and tingling of the inflamed

\* Cuzenave et Schedel, *Abrégé Pratique*, &c. Paris 1828.

portions of the skin. The disease is not contagious, is usually unattended with fever, and may, for the most part, be traced to some irritating cause, either acting directly on the cutaneous surface, or internally through the medium of the constitution.

Willan and Bateman, who have always endeavoured to seize on the earliest appearances presented by cutaneous diseases, as being the most constant and characteristic, have placed eczema in their sixth order, *vesiculæ*; whilst Alibert, whose classification is usually founded on the more obvious, though less distinctive, phenomena occurring in the advanced period of these affections, a period when several species which were originally dissimilar often become confounded in their external features, though still unlike as to their eventual progress, and as to their appropriate modes of cure, has placed it in his order "*dartre squameuse*." Thus he has grouped it along with some of the true scaly diseases, and along with some of the papular ones. Struck, however, by the abundant serous secretion by which it is usually moistened, (and which should have led him to a knowledge of its essentially distinct nature, by turning his attention to its primitive vesicular form, the source of this moisture,) he adds the characteristic epithet "*humide*."

M. Bielt, who, to an intimate acquaintance with the labours of his own countrymen in this department of pathology, adds an extensive knowledge of the works which have appeared on the subject in England and Germany, usually manifests a decided preference for the classification and general views of Willan and Bateman. But in respect to eczema, he thinks these authors have too many subdivisions of the disease, and have spoken in too sweeping a manner of the absence of inflammation around the vesicles, and of fever; as the former almost always exists to a certain extent, and if the local affection occupies much space, some fever usually results. The latter fact, however, we think is very plainly hinted at, if not expressly stated, by Bateman himself. If the cutaneous affection be very severe and extensive, we often also find inflammation of the mucous membranes to coexist.

Rayer, a more recent writer, whose views often manifest a somewhat singular coincidence with those which Bielt has been in the habit of publicly teaching for many years past, emits the same opinion as to the unnecessary subdivision of this affection in the English classification, and proposes to substitute a two-fold division, viz. into *acute* and *chronic*, as more practical and useful than the triple one into *eczema solare*, *eczema impetiginodes*, and *eczema rubrum*; against which, in addition to the want of uniformity in the grounds on which it is formed, it may be objected that the first and third are really the same disease, differing only in respect to their cause, or the degree of attending inflammation; and against the second, that it is really a complication of two diseases, and not a distinct, well characterized, simple species. Averse, however, to interfere with an arrangement so universally adopted in these

countries as that of Willan and Bateman, we shall not here deviate from it, convinced that in pathology, as well as in pharmacy, the modern taste for uniformity and simplification of nomenclature, whenever it has deprived us of terms recalling well-marked sensible characters, effects or causes, has tended to do injury to a science so strictly practical as that of medicine. Names that make a strong impression on the memory are here often much more desirable than those whose only merit is their consistency with a purely scientific but unimpressive uniformity.

Eczema most frequently appears simply as a local disease, preferring, unlike the true scaly diseases, those situations where the sebaceous follicles abound, as the ears, axillæ, groins, upper and inner part of the thighs, scrotum, margin of the anus, and in women, moreover, the external parts of generation, the nipples, and adjacent portions of the breast; or it selects those parts which are much exposed to external influences, as the hands, arms, and face. At times, however, it is a much more extensive disease, and occupies successively nearly the whole cutaneous surface; and this is especially the case when it originates in the use of mercury, or in some other cause acting through the medium of the constitution.

1. *Eczema solare* chiefly occurs in persons of a delicate skin, after long exposure to the rays of a summer sun. Sportsmen, and those who take very long walks in this season, mowers, harvest labourers, and others whose business exposes them particularly to the above cause, are its most frequent subjects. It is occasionally preceded by a slight feeling of general indisposition; and some degree of tension, together with heat and tingling, is felt in the portion of skin which is to be the seat of the eruption. This is most commonly the backs of the hands and fingers, and the face, neck, and arms, especially in women, or those who happen to have them long uncovered whilst in the sun. The skin is usually pale, and is crowded with thick-set microscopical vesicles, so closely approximated as to leave no interstices of redness. Occasionally, however, there is a slight blush round each vesicle; and this species occurs usually, as Bateman mentions, in the upper part of the arms or on the breast, particularly in females, and is commonly called *heat spots*. In men of a sanguineous temperament who use violent exercise in hot weather, phlyzacious pustules, or painful and slowly suppurating tubercles not unfrequently make their appearance in the midst of the eczematous eruptions.

The vesicles are very small and acuminated, and contain a limpid fluid, which soon becomes milky and is absorbed; or after slightly increasing in size, they burst and effuse their contents, which concrete and form minute brownish yellow scales or scabs, and the whole disease, if not very extensive, finally terminates in desquamation within one or two weeks from its commencement. The larger the surface at first attacked, and the greater the irritation, the more likely is the affection to spread successively to new and extensive portions of the cutaneous

superficies. Some precursory indisposition, as we have just stated, may occur, but much more frequently it is absent, the eruption coming out almost immediately after exposure to the sun's rays. It usually begins and terminates in an acute form, but at times it passes almost immediately into a chronic inflammation, with an abundant exudation of a viscid fluid, which rapidly concretes in the form of thin scales, and is attended with tenderness, redness, and excoriation of the affected skin. In these prolonged cases, as Bateman remarks, the effused fluid seems to be of an acrid nature, inducing inflammation, and occasionally superficial ulceration of the parts with which it comes in contact, and the disease assumes somewhat of the form of impetigo. The duration of this affection seems to be little under the influence of medicine, and usually requires little more than the protection of the part from the exciting cause, and the frequent employment of tepid ablutions.

2. *Eczema impetiginodes* is preceded and accompanied by a painful tension, formication, and pruritus, and is distinguished from the other varieties by the occasional intermixture of pustules, into which its vesicles, which are deeply imbedded in the skin, become, themselves, not unfrequently converted. All this gives it a considerable resemblance to some of the forms of impetigo, to which it is also allied in the similarity, or rather the identity, of its causes, which for the most part consist in the habitual contact of various irritating matters. Thus the irritation induced by the repeated application of lime, sugar, alkalies, &c. to the hands, gives rise to eruptions, (bricklayer's itch, grocer's itch, &c.) which are vesicular in some individuals and pustular in others, and are apt to assume a chronic form when the exciting cause long continues to be applied. Thus, also, either a vesicular or a pustular inflammation may be induced by the irritation of sulphur or sulphurated alkalies, used for the cure of common itch, and be mistaken for the continuance of this disorder.

Similar eruptions may be caused by a blister, a mercurial plaster, Indian varnish, valerian root, diachylon, frictions with croton oil, opodeldoc, or ammoniacal liniments, and many other stimulating external applications. Exposure to the heat of a forge or a strong fire has sometimes excited it, as has likewise the internal use of various medicinal substances, as opium, antimony, copaiba, &c. Irregularities in diet and excessive drinking are also reckoned amongst its occasional causes. When the skin is very delicate, this eruption has been known to manifest itself within three or four hours after the application of a Burgundy pitch-plaster, and to be productive of much distress. We have known an individual in whom almost every species of plaster, even the mildest and least irritating, has given rise to this affection, and have seen it ensue in another after the employment of the common linseed poultice. The mixed eruption of vesicles, pustules, and boils occasionally induced by a blister or other irritating plaster,

often extends to a considerable distance from the centre of irritation, overrunning a considerable portion of the chest, back, abdomen, &c., inducing much pain and feverishness, and persisting occasionally, as Bateman remarks, for a fortnight or upwards, but without any eventual injury.

The eczema impetiginodes, if its extent be not great, may run through its course in from one to three weeks. Occasionally, however, it passes into an obstinate pustular or scaly disease, and this we have seen it do within a fortnight after its commencement. In its ordinary course, the vesicles break and discharge an acrid fluid that irritates the adjacent skin, which becomes inflamed, thickened, fissured, and excoriated in streaks, as if torn by the nails. At this period its resemblance to impetigo is still more striking than at an earlier stage.

In the treatment of this affection, in addition to the removal of the irritating causes, and the use of the antiphlogistic and local soothing measures to be detailed at the end of this article, we must at the same time endeavour to remove that morbid state of the system of which the proneness to these eruptions from slightly irritating causes is an evidence; and it is in this part of the treatment of cutaneous disorders that the French practitioners, who have anticipated and excelled us so much in the employment of the antiphlogistic and soothing measures just alluded to, appear to have fallen short; the proper attention to the regulation of the functions of the digestive organs being too often overlooked by them. The most remarkable instances of this extreme irritability of the skin which we have met with, have been in individuals labouring under dyspeptic symptoms of an old date; but we do not by any means wish to insinuate that this is universally the case. *Eczema impetiginodes*, as well as impetigo itself, seems to fall under the head of *dartre squammeuse crustacée* in Alibert's arrangement.

3. *Eczema rubrum* is the most severe and most inflammatory variety of this affection, and is, like the others, preceded by a feeling of stiffness, heat, and tingling. It takes its specific name from the diffuse or erythematous redness on which the vesicles make their appearance. At first it has somewhat of the appearance of erysipelas, but may be easily distinguished from it by the roughness which it presents to the touch, and which, on minute examination with a lens in a favourable light, is found to depend on the presence of innumerable small and crowded transparent vesicles. These in two or three days become opalescent, and in size about equal to a pin's head, after which they usually burst and pour forth their contained fluid, which inflames and excoriates the parts with which it comes in contact. The disease successively invades new portions of the skin, and is accompanied as it proceeds with swelling of the true skin and cellular membrane. The discharge from the vesicles is often very abundant, has a peculiarly heavy odour, and concretes rapidly into yellowish

incrustations. Hardening on the patient's linen also, it causes much pain, by coming in contact with the excoriated surface, which in some cases is so extensive as to occupy the greater portion of the body. When so widely spread and severe, it causes much suffering, and a certain degree of febrile excitement is necessarily the consequence.

It usually makes its first appearance about the scrotum or inner part of the thighs or groins, but this is not constant. Its duration is indefinite. If limited in extent, it may run through its course within a fortnight; but if it has occupied the greater part of the surface of the body, it may last for a couple of months or even longer, when at length the encrusted secretion drops off. But the morbid cuticle continues to exfoliate for a considerable time after, and this is occasionally attended with the loss of the hair and nails. Of this affection, mercury is one of the most frequent causes. The *mercurial eczema* (sometimes miscalled erythema) seems to have been first clearly noticed by Benjamin Bell, in his Treatise on Gonorrhœa and Lues Venerea, and was subsequently more fully investigated by Dr. Moriarty, Dr. Spens, and Dr. McMullin, and by Mr. Alley and Mr. Pearson.

Dr. McMullin's description of it, in the second volume of the Edinburgh Medical and Surgical Journal, represents it as a much more serious affection than Bateman and most succeeding writers have done. According to Dr. McMullin, it is ushered in with a well-marked febrile paroxysm, and is accompanied by dry cough, difficult respiration, and sense of tightness across the præcordia—the skin being remarkably hot and the seat of an itching and prickly sensation. On the first or second day, a diffused redness and numerous crowded papulæ (vesicles) make their appearance, generally on the scrotum, thighs, or fore-arms first, or on those parts where mercurial frictions have been made. The cuticle soon exfoliates, and the fauces and eyes become somewhat inflamed. The above symptoms, which, according to Dr. McMullin, characterize the first stage, last for one or two weeks, and if the disease be in a mild form, recovery may ensue immediately after the desquamation; but if severe, a second and much more serious stage ensues, in which the skin is studded with innumerable vesicles, which soon discharge an irritating fluid of a nauseous odour. This, by concreting into large incrustations of a reddish or dark colour, constitutes the third stage. The inflammation of the fauces, eyes, and eye-lids now becomes exasperated, and the face is deformed by a mask of encrustations fissured in various directions. The affection occupies successively a large surface of the body, which in its excoriated state is the seat of great irritation, and the pain is exasperated by the weight of the body in lying, as well as by the contact of the concremented matter. The latter is liable to crack or be torn across on the slightest change of posture, and thus new raw surfaces are continually becoming exposed. A fever of the typhoid type accompanies these

extreme cases; yet, which is singular, the appetite continues unimpaired throughout. The catarrhal symptoms generally undergo an exacerbation towards the conclusion, as is manifested by the increased anxiety and pain in the chest, the cough, and bloody expectoration. The pulse becomes frequent, feeble, and irregular, the tongue black and parched, and diarrhœa, delirium, convulsions, gangrene of the skin, and death close the scene.

In the above description we scarcely recognize the comparatively mild disease described by Bateman, whose account certainly agrees much more closely with the affection usually met with in practice.

In mercurial eczema, in addition to the catarrhal affection of the air-passages, a tendency to inflammation in the mucous membrane of the intestines often coexists, as is manifested by the facility with which diarrhœa is induced. Dysury too is an occasional but much rarer symptom. The catarrhal affection is not mentioned by Bateman; and by some other writers, who speak of it, it is considered to be merely a casual complication. Dr. Gregory thought that both the affection of the skin and that of the mucous membrane were the effect of cold caught whilst under mercurial influence; but Mr. Pearson's experience does not confirm this opinion. Rayer strangely intimates that the occurrence of eczema mercuriale may be obviated by taking the precaution of shaving the part to which mercurial frictions are to be made. When we recollect, however, that it may be induced by almost every form of mercurial medicine, and that too whether internally or externally administered, we cannot place much confidence in this mode of prevention. That inflammation of the skin should result from the internal exhibition of mercury, is in no respect more wonderful than that severe and even fatal enteritis should originate in its external employment, as in the instances recorded by Dr. Crampton.

Those cases of eczema rubrum which originate in the use of mercury, are generally the most extensive. Local examples of it on exposed parts seem to be sometimes induced by the influence of very hot weather, and a succession of red patches generally make their appearance in such a manner as to prolong the disease to several weeks, without, however, any evident derangement of the general health. Amongst its occasional causes have been reckoned, a stimulating diet, the constant use of shell or sea-fish, &c. Some individuals are subject from slight or inappreciable causes to a very frequent recurrence of this affection about the ears, face, and back of the neck, accompanied with swelling and redness of the face, and a considerable puffiness about the eye-lids; which obtain for it in popular language, but very improperly, the appellation of erysipelas, from which it differs both in its duration and the degree of danger attending it, as also in the presence of vesicles in place of bullæ. Occasionally minute pustules are intermixed with the vesicles, and make the crup-

tion approximate more closely to the description of the impetiginous variety of eczema.

Eczema in its chronic form, which often proves a very intractable disease, (its removal, especially in elderly persons, being attended with great difficulty, and its relapses frequent,) has perhaps not been sufficiently attended to by Bateman.

According to Rayer, who has given an excellent description of it, it may occur as the sequel to any of the acute varieties above described. In it the inflammation often extends deep into the true skin and cellular membrane, giving rise to a thickening, roughness, and inequality of the surface, which becomes fissured and excoriated, and is not unlike a part which has been lately blistered; being raw and moist in some points, and presenting a scurfy appearance from adherent cuticle or dry and foliated secretions in others. It is in this advanced stage of eczema that its identity with the *dartre squammeuse humide* of Alibert is most obvious. The secretion of acrid lymph is uninterrupted, and the itching so intolerable, that the unfortunate patient cannot abstain from tearing the surface with his nails, and thus aggravating and perpetuating the disease.

This state may continue with little variation for months or even years; the cuticle, which assumes a yellowish tinge from the contact of the discharge, being at frequent intervals exfoliated in large patches. The inflammation is liable to frequent exacerbations; and occasionally, after appearing to be almost subdued, it bursts out with increased violence, either on the same place, or in some distant part of the body.

One of the most frequent seats of chronic eczema is about the external ears, and from thence it not seldom extends into the meatus auditorius externus, and thus sometimes induces deafness. In like manner, when it exists on the face, it may spread from the external surface of the nose to the nostrils; and in both this and the preceding case it proves peculiarly obstinate. When seated on the lips, they occasionally become considerably swollen, and we have seen it in this state present an appearance which might in young persons have been mistaken for a scrofulous affection. When it attacks the scalp, it is not unfrequently confounded with tinea. There is great itching. The hair is at first matted together with the abundant discharge, but this, gradually diminishing, is succeeded by a constant firfuraceous desquamation, beneath which the skin on examination is found to be red, shining, and tender.

In its chronic form, eczema frequently manifests itself also on the upper and inner part of the thighs; the scrotum and prepuce in men, and about the external organs of generation and the breasts in females; and in all these situations the itching is most intolerable.

The circumference of the anus is also very frequently attacked by it, simultaneously or alternately with other parts of the body. It often occurs here by an extension of the disease

from the scrotum or thighs; but in some of the most obstinate examples it is a strictly insulated affection, confined to the verge of the anus, perineum, and cleft of the buttock; in which situations a serous secretion concreting into thin, laminated, semitransparent scales, like exfoliated cuticle, takes place at intervals. In these cases it seems often to be connected with dyspepsia and an irregular state of the bowels, the stools being unnatural, and affording evidence of vitiated intestinal and biliary secretion, inasmuch as they are often peculiarly fetid, black, and tenacious, and expelled with so much difficulty as to give rise to the belief in the existence of a stricture of the rectum. But this difficulty seems to depend merely on a spasmodic state of the sphincter, induced by the chronic irritation in the skin and contiguous portion of the mucous membrane of the rectum; for the patient is at times able to evacuate the bowels freely. The empirical use of bougies in such cases cannot fail greatly to aggravate the patient's sufferings and perpetuate the evil, by the forcible extension of the excoriated parts. The sensation of burning heat and itching becomes greatly aggravated on getting warm in bed, demanding all the resolution which the individual can summon up to avoid scratching and exasperating it with his nails, an operation which in his sleep almost inevitably takes place. The exacerbations to which this affection is liable sometimes alternate and sometimes coincide with those of the dyspeptic affection. It is one of the many examples of the intimate sympathy which subsists between the external outlets of mucous membranes and the more internal and distant parts of their surface. Ascarides sometimes coexist with this disease, and though there is no reason to suppose them capable of producing it, save when a peculiar predisposition exists, they must doubtless tend much to exasperate the irritation and prolong its existence. We have known this affection alternate with small patches of lichen, psoriasis, or eczema on the arms or neck. Sedentary habits, too free a mode of living, especially in regard to the use of wine and malt liquors, and costiveness, are sure to aggravate it. With regard to the treatment of it, little can be expected from local applications; frequent ablution with cold water affords a momentary relief; but it is to great temperance, steady and active exercise, a due regulation of the bowels, and a correction of the vitiated and irritating nature of the alvine discharges, that we can alone look for permanent benefit.

*The diagnosis* of eczema is occasionally attended with considerable difficulty, as cases not unfrequently present themselves where papulæ and pustules coexist with the true eczematous disease; thus allying the case at once to lichen, impetigo, and eczema, and making us wish that the idea of Burns had been acted on, in establishing as an appendix to our present classification a set of composite genera to which those specimens of cutaneous disease which are of a mixed character, and display an affinity to two or more of the simpler forms,

might be referred. For the consolation of the student in this department of pathology, we may mention that we have seen the most practised eye puzzled by such combinations; and individuals, who had made cutaneous disorders their peculiar study for years, confess themselves unable to dispose satisfactorily of such examples in any part of our present arrangements.

In the first stage of the affection, when it exists in its simple form, the only diseases with which we are liable to confound it are some of those of the papular kind, and scabies. From the former it may be satisfactorily distinguished by the colour of the minute vesicles, or more certainly still by puncturing them with a needle, and thus demonstrating the fluid nature of their contents. Their subsequent progress, too, is dissimilar. From scabies, or common itch, the diagnosis, especially of the impetiginous form of eczema, notwithstanding what is asserted by professed writers on the subject, we have often found by no means easy. Its preference for those situations where the sebaceous follicles abound—a knowledge of the preceding causes, such as exposure to great heat or other local irritants—the closeness and uniformity with which its minute and acuminated vesicles are distributed,—the accompanying tumefaction—the tingling and smarting rather than itching which attends them—will, it is said, enable us to distinguish it from scabies, in which the vesicles are more apart—larger and more unequal in size—less transparent, or of a duller colour, and without any inflammation at their base—intermingled with minute ulcerations and small dark scabs—attended with a sensation of simple itching—and, finally, occupying chiefly the intervals of the fingers, the wrists, and the flexures of the articulations generally.

The presence or absence of a contagious quality, and the effects of treatment, which are usually dwelt on as points of distinction, are not very creditable grounds on which to form our diagnosis. To discover the nature of a disease when it has been already cured, or when it has spread to other persons in consequence of our incompetence to decide on its true nature, is not satisfactory to any of the parties concerned.

A complication of itch and eczema is not an impossible occurrence, and of course must present much difficulty. Indeed, we have heard of such cases by which the medical attendants were greatly embarrassed, till in the frequent handling and examination of the parts they have themselves contracted scabies, and thus become fully convinced of the existence of at least one part of the disorder.

The miliary eruption may be easily distinguished by the constitutional symptoms which precede or accompany it; and simple erythema, by the absence of all feeling of roughness such as characterizes eczema rubrum even in its early stage, and depends on the elevation of the nascent vesicles. Inattention to this circumstance has led some writers improperly to describe the eczema mercuriale as

a species of erythema. Impetigo is sometimes distinguishable with difficulty, if at all, from that species of eczema in which pustules present themselves. The existence of pustules from the very commencement, and the greater thickness and prominence of the crusts, belong more especially to the former. In a practical point of view, however, their diagnosis is not very important. It is often far from easy to distinguish psoriasis of the scrotum and penis from eczema of the same parts when in its advanced and scaly stage: the greater thickening and hardness of the integuments in the former, and the fact of vesicles or humidity never having been present, will aid our diagnosis. When eczema has existed a considerable time, its red, chopped, and scaly surface approximates closely to the appearance of lichen agrius. But even when vesicles no longer exist, as is the case in the more advanced and drier stages of eczema, minute disseminated scaly points will frequently shew their former seat, and disclose the true nature of the disease. Eczema of the breast and nipple in its scaly stage, which it has generally attained to before we are consulted, presents to the eye merely a collection of thin and generally yellowish crusts, and is accompanied with a burning itchininess; at this period we shall in vain search for vesicles. Chronic eczema, indeed, in its later periods, when it has passed into a scaly state with numerous erosions and ulcerations, is scarcely recognizable at first sight, even by the most experienced eye. It is to the history of the case that we must here look for decisive information.

In what we have said of the diagnosis of this very frequent and very distressing cutaneous affection, we have been actuated by a desire to represent it in all its true difficulties; as we know that the most zealous students often turn with disgust from the investigation of diseases of the skin upon finding these difficulties so infinitely greater than they are represented in books, and begin in despair to suspect that they want the tact necessary for their successful study. When made aware of the obscurity which they often present even to the most experienced, this cause of discouragement will in some degree be done away with.

*The prognosis* of the acuter forms of the disease, especially when they depend on some obvious cause of local irritation, is generally favourable. In those cases where the mercurial eczema has assumed its most formidable aspect, the danger has been attributable probably not so much to this affection in itself as to the cachectic habit of the patient, exhausted by previous and co-existent disease as well as by the profuseness of the discharge. In the majority of those instances where chronic eczema is very obstinate, and where the most carefully adapted local treatment has proved unavailing, we should be led to suspect that there is something materially wrong with the state of the general health. We have seen such cases which had existed for years, and resisted for nearly as long a time the most judicious and energetic topical measures.

In the aged it is peculiarly unmanageable, and a cure often almost hopeless. Alibert speaks of the *dartre squammeuse humide*, in its aggravated form, as one of the most obstinate and insufferable diseases to which humanity is liable; the irritation which it keeps up, and the despondency which innumerable relapses tend to generate, having in some instances, according to him, led the unfortunate patient to the commission of suicide.

*Treatment.*—The introduction of the soothing plan of treatment constitutes the most remarkable improvement which has taken place in regard to the management of the cutaneous diseases in these latter times. In mild cases, if we can succeed in subduing for a time the irritation which exists, nature will often do the rest, and re-establish the natural actions of the part. In no class of these diseases are soothing measures more called for than in the vesicular forms, in which the inflammation is usually characterized by considerable acuteness and a high degree of irritation. This is peculiarly the case with some of the varieties of eczema.

Great relief may usually be afforded by frequent ablution with tepid water or mucilaginous decoctions, as those of bran, marshmallows, poppy heads, or of gruel or milk and water; by mild poultices, with or without the addition of goulard, and by local and general tepid baths. Mr. Plumbe condemns in strong terms the use of ointments, and recommends the employment of the common spirit-wash in incipient cases. Lotions containing prussic acid have been found to have much influence in allaying the pruritus. When the patient is young and of a sanguinous temperament or plethoric habit, venesection should not be neglected, and leeches and cupping in the vicinity of the disease are most important auxiliaries. The diet should be light and very sparing. Bateman recommends the use of bark and serpentaria, but on no very clear indications. Mild diluents, gentle laxatives, and the use of the vegetable or mineral acids, are generally all the internal medicine necessary, especially in the acuter and more rapid forms of the affection. As to the propriety of the employment of acids, so usually recommended in cutaneous disorders, we might, if guided by theory alone, have some doubts; for in certain habits, as has been remarked by Sir A. Carlisle, they of themselves occasionally excite much irritation in the skin. Thus many people are affected with pimples shortly after taking them, together with burning heat in the face and itching over the whole body. Yet here, as elsewhere, preconceived notions with regard to the propriety of a therapeutic agent in disease, derived from a knowledge of its influence in a state of health, must not be put in competition with the practical results of experience, and we have certainly seen very troublesome cases of eczema yield rapidly whilst acid drinks were used. The mineral acids (sulphuric and nitric) seem, indeed, to have considerable influence in the later periods in diminishing both the exudation

and the itching of the affected parts; whilst in the earliest and most inflammatory stage those of the vegetable kind, on account of their cooling properties, perhaps deserve the preference.

In the mercurial eczema, if its attack be violent, Bielt, we believe, never omits the precaution of taking blood from the arm, as the best means of obviating or moderating those symptoms of irritation in the mucous membranes of the respiratory and digestive organs which occasionally complicate it. Pearson recommends the use of diaphoretics; but the irritable state of the stomach and bowels frequently renders them improper: and in those very rare cases where typhoid symptoms supervene, the employment of bark will often, for the same reason, be found inadmissible. Opiates have very usually been recommended by way of allaying irritation and procuring sleep, but their exhibition requires much circumspection, as opium has occasionally been known, in this as well as in the healthy state of the skin, to induce severe itching; and Dr. Moriarty met with one case in which it apparently was the cause of a relapse. The daily use of the tepid bath usually affords much relief by removing the secretion and keeping the surface pliant. Where, however, the excoriations are very extensive, even the tepid bath cannot well be borne, and the effort of getting in and out of it causes much suffering. The heat of the bath must be carefully regulated, for if of too high a temperature, it will inevitably aggravate the inflammatory tendency in the cutaneous surface. The pain caused by the rigidity and contact of the incrustations may be in some degree alleviated by the application of the linimentum calcis. Repeated changes of the linen are indispensable, and will sometimes, from the abundance of the secreted matter, be necessary as often as three or four times in the course of one day. The return to mercury in these cases is to be avoided, if possible; as even its mildest preparations have occasionally induced a recurrence of the disease, an effect which took place in a case recorded by Dr. Crawford, from the incautious application of citrine ointment to the still morbid skin. In some urgent cases, however, mercury has been again exhibited, and with impunity.

When eczema has become chronic, the local treatment should still in almost every case be of the soothing kind. Hence a steady perseverance in the use of tepid mucilaginous decoctions, of lotions containing the acetate of lead, of local and general baths, continues, as in the first stage, to be proper. General and local bloodletting and other *antiphlogistic* measures will still often afford us most valuable assistance in subduing this obstinate affection; the propriety of their employment and repetition being of course determined by a joint consideration of the state of the constitution and of the local inflammation in each individual case. We cannot, however, help thinking that, in this country at least, the utility of these measures has, till within these very few years,

been greatly overlooked, and that their employment, even at the present moment, is quite too infrequent. This may perhaps in a great degree be attributed to their never once being alluded to by Bateman, whose bias seems to have been altogether towards the opposite mode of treatment, or the frequent exhibition of tonics. His prepossession, too, against the use of aperients in eczema is not justified by the experience of others, as they are often found to be highly beneficial. We have known very severe cases yield to the combined employment of baths, mineral acids, and laxatives. When these and the other measures detailed above disappoint us after having been fairly tried for at least three or four months, recourse may be had to the cautious use of Fowler's solution, or of tincture of cantharides. Amongst Bielt's numerous cases under the influence of those powerful medicines, we do not recollect to have seen them ever do mischief; and hence we participate fully in the sentiment with which he frequently prefaces their prescription, namely, that no medicine, however active, is dangerous in prudent hands. Mucilaginous and diluent drinks enter largely into all his plans of treatment, and must tend materially to obviate the danger of gastric irritation during the use of energetic internal medicines. Whether the beneficial influence which arsenic and cantharides often display depends on their immediate action on the skin, or whether it is attributable to their effecting a species of counter-irritation on the mucous membrane, and a consequent equalization of the circulation in the cutaneous and mucous surfaces, is utterly unknown. Their great power as modifiers of the actions of the skin is, however, indisputable. The exhibition of fractional doses of the corrosive sublimate also, given in a decoction of dulcamara, occasionally effects a cure where other measures have failed.

Caustic applications, as the nitrate of silver or diluted muriatic acid, have sometimes been used, as is mentioned by Rayer, with a view to changing the mode of irritation in the part; but they are not unattended with risk, and violent exacerbations and deep cicatrices have resulted from their employment. In the advanced scaly stage stimulant applications have sometimes been of use, by exciting a more active inflammation, and thus subverting the existing morbid action. Ointments containing the red precipitate or tartrate of antimony, and blisters have occasionally been had recourse to with this view, and with success; but the practice is rather empirical, and the result dubious. In an indolent and scaly state, alkaline and sulphur baths may perhaps sometimes be useful; but if too early employed, they are sure to aggravate the inflammation, and in the great majority of cases the vapour bath is to be preferred to them.

When there exists any obvious derangement of the general health, little improvement need be expected till this state be first counteracted. Country air and a careful regulation of the diet are here points of the first importance; alterative doses of calomel or blue pill, with the decoction of sarsaparilla, will sometimes also be of great

service. In those cases where there is a marked inflammatory diathesis, indicated by a full pulse, heat of skin, thirst, headach, drowsiness, &c., Dr. Elliotson has found much benefit from mercurial medicines, given so as slightly to affect the mouth, in conjunction with venesection and a low diet. Such a mode of employing mercury, in a disease of which it is itself an occasional cause, will, however, demand great circumspection.

The use of water-dressings, in preference to all ointments and greasy applications, has long been zealously advocated by Dr. Macartney, who has directed much of his attention to the study of diseases of the skin. Indeed the beneficial effects which may be produced in this and several other cutaneous inflammations, merely by keeping the inflamed part constantly moist by means of lint wetted either with cold water or a weak solution of the acetate of lead, and enveloped in oiled silk, are unquestionable and striking. We do not, however, think that the employment of ointments is in all cases injurious, having known eczema of the ears and face, though attended with extreme irritation, receive immediate relief, and get speedily well under the use of an ointment composed of cold cream and the liquor plumbi acetatis in the proportion of two or three drops to the ounce, in conjunction with the repeated application of a cooling lotion, consisting of the acetate of ammonia, accurately neutralized, largely diluted, and holding a minute portion of the acetate of lead in solution.

If the disease have existed about the face for a considerable time, an issue or perpetual blister to the nape of the neck or the arm effects a useful counter-irritation, and will thus often tend both to accelerate the cure and to prevent a relapse. A free state of the bowels and a frequent use of the bath seem also to have much influence in guarding against a recurrence of the affection.

The propriety of a cooling and sparing diet throughout every stage of the disorder, and even for a considerable time after its disappearance, cannot be too strongly insisted on.

(W. B. Joy.)

**EDUCATION, PHYSICAL.** Education, in the ordinary acceptation of the term, refers only to intellectual and moral cultivation. Mr. Locke, however, has taken a wider and juster view of the subject, and in his excellent Treatise inculcates strenuously the attentions necessary for preserving and strengthening the bodily constitution. This branch has been denominated *physical education*.

If medical science affect something more than the mere adaptation of remedies to a few special diseases; if it embrace the more enlarged and comprehensive purpose of promoting general health, and preserving the bodily frame in the full and vigorous exercise of all its functions, then is the subject of physical education entitled to a prominent place in every work which professes to treat of the science, or to display its most useful applications. No applications of its principles can be more useful

than those which regulate the physical management of the young; for even in infancy, and still more when childhood passes onward to adolescence and puberty, are errors of ignorance and prejudice daily committed, which sow deeply the seeds of disease, consigning many a sufferer to an early grave, or entailing miseries which render life a burden rather than a blessing. However difficult it may be to correct the manifold errors by which, in early life, health and happiness are sacrificed, it must at least be right to point out to those who wish to learn, what are the principles by which the first of earthly blessings, a sound mind in a sound body, can be best ensured. With bodily health, mental is here associated, for the connexion is intimate: if the body languishes, the mental powers, which act only through bodily organization, must fall far short of that energy and activity of which they would otherwise be capable; while the irritability of mind to which weakness and ill health are prone, is sure to act unfavourably on all the moral feelings. In the present article the design is to lay down principles rather than rules; for the latter never can be so framed as to admit of universal application, and when indiscriminately used, they either, through necessary variableness of effect, fail to inspire confidence and in time fall into disuse, or the good which they do accomplish is sure to be balanced by a portion also of evil. To lay down principles is the safer and better course, for though physiological truths are what few even among the most intellectual classes of society are prepared to comprehend, their education unhappily leaving them utterly unacquainted with the structure and functions of their own frames, still the dissemination of these truths, especially in connexion with a subject of such deep and universal interest, may not be wholly unavailing, but may rather prove the means of exciting enquiry, and of thus dispelling that ignorance to which so much of the ill health of every period of life may be distinctly traced.

Man, in his relation to external objects, is subjected by nature to certain laws; in other words, there exist between man and the external world certain definite and immutable relations, as obligatory as a positive ordinance. If the relation be disregarded, the law violated, the penalty ensues with a certainty that cannot be evaded. It is well, then, as all are subjected to these laws, are capable of acting in conformity with them, and sure to suffer when betrayed, whether by ignorance or wilfulness, into infringing them, that some consideration should be bestowed on them, in order that errors of ignorance at least may have some chance of being avoided.

The natural laws which connect man with the objects around him have been appropriately classed under three heads; namely, the physical, organic, and moral. Vitality confers no exemption from the laws of matter and motion. To these the human body is subject equally as if it were not endued with life. It is true that, while animated, it possesses to a certain extent powers capable of modifying their operation;

still it never ceases to be under their influence, and it is liable to suffer whenever that influence is overlooked or miscalculated. The body gravitates, and when deprived of support falls to the ground, equally as if it were inanimate. Physical laws, therefore, are worthy of consideration in order that no injury may accrue from their violation. But animated bodies are subjected to laws peculiar to themselves; and as life is always connected with organization, these laws are called organic. It is with them that we are more immediately concerned on the present occasion. Man, however, is not only an organized and animated being, but also a moral and intellectual one; and is, in consequence, subject to further laws in relation to this part of his nature, namely, the moral. As his moral and intellectual powers, however derived essentially from his spiritual nature, are dependent on organization for their exercise and manifestation; as the several powers act interchangeably on each other; and as a close analogy resulting from this connexion subsists between the organic and moral laws, it will be necessary to take some notice of the latter in the following pages.

The organic laws may be subdivided according as they regard respectively the preservation of the species and of the individual. The former of these may here be passed over as not essential to the present purpose, the preservation of the individual being that which chiefly claims attention in discussing the principles of physical education.

The animal body is connected more immediately with the external world by digestion and respiration, it being through these processes that it derives the elements by which it subsists. Food and air are indispensable so long as life endures; and if either be withheld, or depraved in quality, or too scantily supplied, the animal languishes and prematurely dies. Other elements are most probably combined; there being reason to believe that the electric conditions of the atmosphere exert an influence on the animal economy neither slight nor unimportant. We know too little, however, on this subject to make it the ground-work of any reasoning.

On the regulation of diet much of the health of the body depends. All animals are destined by nature to feed on particular aliments, for digesting and assimilating which they are furnished with an appropriate organization. Some are herbivorous, some graminivorous, some carnivorous. Man being by nature omnivorous, a mixed diet of animal and vegetable food is best fitted for his adequate nutrition, being most accordant with his organization; and this fact ought to serve as a sufficient reply to all those who decry either animal or vegetable diet. The proportions best suited for supporting perfect health must ever vary in individual instances, being dependent on age, temperament, habits of life, state of health, climate, season of year, and other incidental circumstances. The general principle being clear, sufficient ground should be specially shewn whenever it is deemed necessary to depart from it, or to modify its ap-

plication. To display the properties of the several articles of food, both animal and vegetable, is the province of dietetics. See DIETETICS.

The quantity of food deserves as much consideration as its quality. It should be such as the stomach can easily digest, and sufficient to repair the waste which the body continually undergoes. In the young, too, it should provide for the growth of the body, which in them is, up to a certain age, progressive. Deficiency of sustenance leaves the body imperfectly nourished, checks its natural growth, and begets various diseases marked by debility. Excess, on the contrary, promotes inordinate nutrition, induces corpulence, oppresses all the functions of life, and through the various efforts made by the constitution to dispose of or get rid of it, lays the foundation of by far the greater portion of human maladies. In the functions more immediately essential to mere animal existence, nature influences by feelings antecedently to any exercise of reason, and, with respect to the nutrition of man, has given him appetite both to incite him to take food, and to assign a limit to his use of it. A healthy stomach, supplied with simple diet, will, if the intimations of appetite be heeded, be rarely guilty of excess. But though the stomach is thus satisfied, and the natural appetite ceases, it is still capable of taking more food, and even of digesting it. Viands tempting to the palate will incite a fresh appetite, under which the quantity of food required for health, and which consistently with health ought not to be exceeded, is often more than doubled. Pampered with luxuries, and rather *living to eat* than *eating to live*, numbers become slaves to a sensual gratification of the lowest kind.

Excess is the vice rather of adults than of the young, who are rarely either gourmands or epicures, unless through the fault of those who rear them. The law of temperance, however, is common to all, and, however it may be disregarded by the inconsiderate or the sensual, cannot be violated with impunity.

Co-ordinate with nutrition, in its being essential to animal life, is respiration. It differs in one respect, that while food is required only at intervals, appetite being the natural incitement and measure of quantity, air is necessary every moment; and as the process goes on uninterruptedly, no incitement of appetite is needed for inhalation of air. The capacity of the lungs, too, being definite, no intemperance can be practised; and with regard to this function it is quality rather than quantity that requires to be attended to. This, however, is of the very first importance; for if pure air be not breathed, health cannot be preserved. Of injury from impure air the young are peculiarly susceptible, and this requires to be attended to in many parts of their ordinary management.

Next in importance to food and air, as a means of maintaining health and vigour, is exercise, which is to be considered not merely as it regards locomotion, but as applying to all the actions of the animal frame which minister to existence, and by which the several functions

are sustained. The actions immediately essential to existence are, happily, independent of the will, and are thus secured against the effects of indolence or caprice. Respiration, though not wholly an involuntary process, is so far independent of the will for its ordinary exercise, as to continue uninterruptedly, through the whole period of life, without effort and almost without consciousness. Thus circumstanced, and secured as its organs are by their compact and admirably constructed mechanism, it might be conceived that this process at least might escape the evil influences of heedlessness or error; yet no function of the frame has suffered more from the pernicious effects of folly and fashion, effects the reality of which it would be difficult to credit, were it not attested by woeful experience and daily observation. Circulation, too, is independent of the will, its organs being excited sufficiently to ensure the regular continuance of their actions, by the fluid which digestion supplies and which respiration vitalizes. Yet here, also, though nature has provided for the regularity of this function, and rendered it independent of direct interference, man contrives indirectly to disturb it by over-excitement through excess of nutritive matter and abuse of various stimulants. So far is the body ensured against the neglect or imprudence of the individual, that what is absolutely necessary for existence is carried on by the mere incitement of appetite, and through actions in which the will has no share. But though mere existence is thus capable of being maintained for a while with little effort, voluntary exertion is still necessary for giving even to these independent functions the activity necessary for healthful vigour. Unless exercise, in its ordinary sense, be taken, neither respiration nor circulation can fully accomplish the purposes which they are intended to serve; and proportional decline of health and strength must ever ensue. Exercise conduces to healthful digestion, perfect respiration, and efficient circulation. Neglect of exercise weakens the stomach, inducing changes in the digestive processes unfavourable to the formation of healthful chyle; it tends to reduce the capacity of the chest, and thus to render the respiratory process less effective; and it diminishes the actions of the heart and arteries to the extent of suppressing some of the most important functions to which they are subservient, namely, those which take place in the capillary system. For propelling blood duly into *all* the capillary vessels, a certain portion of exercise is indispensable. If this be not taken, some or other of those vessels will be inadequately supplied; and in proportion must their functions decline, while the blood which ought to pervade them is thrown back on the larger trunks, overloading and oppressing the general system.

Life subsists through a series of motions, and all these should be maintained in regular and adequate exercise. If any become suspended, or decline beneath the activity necessary for the due performance of their respective functions, the organs shrink, and more or less impression on the general health ensues, ac-

ording to the importance of the parts assigned to quiescence. If there be total suspension, the organ then undergoes changes wholly subversive of its character and functions. A vessel which ceases to convey its proper fluid becomes soon changed into a solid cord. Muscular fibres, if consigned to inactivity, waste progressively, with proportional loss of power, until at length they approach the state of simple membrane. The laws of muscular action require that the muscle, in order to retain even its natural structure, must be continued in the adequate exercise of its natural functions, else it declines both in volume and power, and all the functions to which its actions are subservient, become impeded in consequence.

The foregoing sketch, though brief and imperfect, may suffice to shew what is meant by referring to the natural laws. The subject, however, is not yet sufficiently matured for an elementary exposition of the whole of them, and at all events the writer of the present article is unprepared to attempt it. Whatever remain, therefore, applicable to the present purpose, must be left for the occasions which in the course of this essay may call for their introduction.

In pursuing the subject of physical education, the period of life to which it applies may be divided into the consecutive stages of Infancy, Childhood, Adolescence, and Puberty. The distinctions are sufficiently intelligible without assigning exact limits to each. To do so by a division of years would conduce but little to precision, for individuals differ so much, that similar ages do not necessarily indicate corresponding stages of development either in bodily or mental powers.

**INFANCY.**—The management of infants has been much improved in modern times, and many hurtful prejudices have been utterly extinguished. None, at least in this country, even of the most ignorant, deem it necessary at the present day to swathe the infant's body so as to deprive its limbs and head of all free motion, as was long the universal practice, and in some countries, even of Europe, continues to be so. The infant is now suffered to enjoy the unrestrained exercise of its muscular energies so far as its limited powers of exerting them permit. This was a great emancipation, and conducive not only to physical but also to moral improvement. The exercise of every natural power is accompanied with pleasurable feeling, and, without resorting to metaphysical refinements, it may, from a close analogy, be averred that the infant is sensible of pleasure from the free exercise of its motive powers, and suffers pain from their restriction. These sensations excite moral emotions, and without any great stretch of imagination it is possible to detect the dawning of an irritable temper at a period of life when a moral feeling is scarcely supposed to exist, and to trace its development to irritations which enlightened caution might prevent. Even at this early period the moral laws are not to be disregarded. These laws pronounce that moral feelings no less than the physical powers ac-

quire force by exercise, and that the surest way of weakening those which, when tending to excess, lead to evil, is to consign them as much as possible to quiescence. Great care is therefore necessary not to arouse angry passions, and especially in infancy, when the other moral feelings, and the intellectual powers by which they are in later years controllable, are too imperfectly developed to be of avail. The principle is applicable to every period of life, and the interesting stage now under discussion should have the full benefit of it.

The present occasion does not call for minute details of the management of infants, which are so familiarly known and so much under the guidance of competent advisers, being for the most part regulated by enlightened medical attendants, that a few general remarks may here suffice. They may be comprised under the heads of clothing, food, state of bowels, air, temperature, cleanliness, exercise, moral discipline, and habits.

**Clothing.**—The clothing of infants should be soft in texture, so as not to irritate their tender skin. It should be made so as to give free play to all the limbs, no part being subjected to constriction or undue pressure, and should also be so simple as to admit of being quickly adjusted. The process of being dressed is irksome to most infants, causing them to cry, and exciting as much mental irritation as they are capable of feeling. It should, therefore, be rendered as brief as is compatible with the ablutions required, and with the necessary adaptation of the garments to their several purposes. By a very little ingenuity they may be so constructed as to be put on and removed with little delay. It would be well if pins could be wholly dispensed with, their use being hazardous through the carelessness and stupidity of nurses, and even through the ordinary movements of the infant itself. Soft tapes, loops and buttons, hooks and eyes, or other such fastenings, might be beneficially substituted.

**Food.**—That the infant should derive its earliest sustenance from the mother's breast was so obviously designed by nature, that the abstract propriety of mothers suckling their offspring admits of no dispute. The question, however, whether all mothers should discharge this duty is not thus determined, the condition of the mother and her capability of performing it requiring to be taken into account, as well as the wants of the child. When a mother is young, healthy, and sufficiently robust, it is her bounden duty, as it ought to be her dearest pleasure, to foster in her bosom the being which she has brought into existence, and to nourish it with the food expressly provided by nature for its use. Every consideration, both physical and moral, pleads for this exercise of maternal function. By it the bodily health of both mother and child is promoted, while it excites in both the purest emotions of the heart.

All mothers, however, are not capable of performing this duty; and, unfortunately, among the higher and middle classes of society, a considerable portion, through errors of

physical education, and the debilitating effects of various pernicious practices proceeding from fashion, luxury, and dissipation, are incapable of undertaking it. Thus error perpetuates itself, and in its natural consequences comes to act in a circle. The dissipated mother neglects her child, and this child, if a female, commences life under disadvantages which, by weakening her frame, tend to unfit her for eventually acting as a mother. Extreme delicacy of constitution, diseased condition of the frame, defective secretion of milk, may forbid the mother to suckle her child. Unless she can perform the duty with safety to herself and benefit to her infant, she ought not to attempt it. In this case a young and healthy wet-nurse is the best substitute. But even this resource is not always attainable, and then it is consolatory to reflect that children may be reared without material prejudice to health, by what is termed feeding by hand, though extreme care is requisite to make the substitution effectual. In this case the process of nature should be emulated as far as possible, and food should be imbibed by suction from a nursing-bottle, rather than swallowed from a spoon. Much injury results from giving infants food too gross for their digestive powers. If nursing by hand, as it is termed, be resorted to, the food, for the early months at least, should approach as nearly as possible to human milk. Milk and water, with a little sugar, is quite enough for the first two months, after which some farinaceous matter may be combined. Thick gruel, panada, biscuit-food, and such matters, are much too solid, at least in very early infancy. They overload the stomach, causing indigestion, flatulency, and griping. These create a necessity for purgative medicines and carminatives, which again weaken digestion, and by the unnatural irritation perpetuate the evils which render them necessary. Thus many infants are kept in a continual round of repletion, indigestion, and purging, with the administration of cordials and narcotics, who, if their diet were in quantity and quality suited to their digestive powers, would need no aid from physic or physicians.

The frequency with which medical aid is required for infants under gastric and intestinal disturbance, and the numerous infantile maladies which spring from this source, are sufficient proof that their ordinary diet is not as rational as it might be rendered. From errors of diet are the digestive functions of infants chiefly, if not solely, liable to be impaired, and, when these become so, correction of diet, rather than the exhibition of drugs, should be relied on for remedying the evil. We are far from inculcating that on such occasions medical advice should not be resorted to; on the contrary, our persuasion is, that, when such disturbance arises, medical counsel is absolutely necessary, as the medical adviser is more likely to see the real nature of the evil, and adopt rational means for its correction, than they whose injudicious proceedings occasioned it. But we would strenuously advise the medical attendant to be sparing of his drugs, unless he

see adequate cause for exhibiting them. We are well aware that, even in infancy, the bowels may become loaded, and their lining membrane coated with redundant mucus, and that purges, even of calomel and antimony, with rhubarb or scammony, may be required to cleanse them, and restore healthy secretion. But such remedies should not be prescribed on every trivial occasion, and at all events a succession of such drastic purges can very rarely be needed. The stools, if rightly understood, will furnish a sufficiently certain guide. If there be evidence of redundant and vitiated secretion, and if the removal of this by purgatives relieve pain and restore tranquil feelings, no doubt can attach to the means by which these effects are obtained. But it sometimes happens that some tinge in the feces, some incidental pain, misleads the practitioner, inducing him to believe that more purging is needed, when the prevailing distress may be owing to the irritation caused by the purgatives already too freely administered. In this case he will do well to pause, and, by abstaining from interference, suffer the bowels to recover the tranquillity which his remedies serve but to disturb. It is a valuable part of medical science to know when to resolve on doing nothing, and an excellent result of moral courage to dare to act on that resolution. On such occasions it is not true that medical skill is at fault or in abeyance. It only evinces the sagacity to perceive that nature is competent to her own work, and that she ought not be interrupted in completing it.

In judging of the intestinal secretions of infants, there is a source of fallacy which deserves to be noticed. Mucus accumulates on the lining membrane of the stomach and bowels, and becomes morbid, inducing disease. The irritation of purgatives, too freely given, will also cause an increased secretion of mucus manifested in the stools. The matters discharged, however, are very different in their nature, and can hardly deceive an experienced eye. In the former case, the mucus is opaque, dense, ropy, or membranous; in the latter, it is limpid and fluid. Purgatives relieve the former condition; they exasperate the latter.

Infants naturally have free bowels, and, if properly fed, they need no medicine. Even in purging off the meconium, art is often superfluously resorted to, or at least prematurely employed. The first milk of the mother's breast is the natural purge, and oftentimes even this is not required. A too early exhibition of castor-oil, as is very generally practised, is unwise. A little manna is less irritating, and will in general suffice. Simple suppositories were formerly much in use, and perhaps they have been too much laid aside. When distress, however, arises from distension or flatulency under retention of the meconium, some aperient is needed, and, for certainty of effect, castor-oil is perhaps most to be relied on. With respect to the general management of the bowels of infants, the principle is that they should be kept free, and by the mildest and least irritating means. This is all that

health requires. It may be finally remarked, however, that no course of proceeding can be more prejudicial than, having first overloaded the stomach and then administered purgatives, followed by carminatives and narcotics, to return to the dietetic errors which created the necessity for all this discipline.

*Air.*—It is of importance that infants should breathe a pure atmosphere. During the day this is in general sufficiently attended to; but at night they are very apt to be placed under circumstances unfavourable to a free circulation of the air around them. Apprehension of cold causes them to be then more closely enveloped with clothing, especially about the head: curtains are drawn in order to exclude cold air; nay, through extreme care, a thin covering is not unfrequently thrown over the face of a sleeping infant, confining the respired air, and impeding the access of fresh air required. All these practices are bad, and ought to be avoided. The head should not be muffled, curtains are objectionable, and the face should not be covered during sleep. Pure air is needed, and a supply of this should be ensured without giving way to undue apprehension of cold, of which the danger is very slight, unless great imprudence be practised. Infants should be guarded from cold, but much heat is prejudicial. On this as well as on several other accounts, the child should not lie in the bed with the nurse. After having sucked, it should be placed in a cradle with just so much covering as is necessary for preserving the natural temperature.

*Cleanliness.*—Cleanliness is essential to the health of infants, the functions of the skin being of high importance, and requiring to be kept in due activity. The body should be washed all over once a day at least, and impurities should never be suffered to remain for any time in contact with the skin. At first the water used should be tepid, but after a few months the temperature should be gradually lowered, until cold be employed, unless there be such extreme delicacy and deficient reaction as to render this hazardous. Children bear well the transient application of cold, which is in general succeeded by a genial glow, both refreshing and invigorating. Many weakly children are renovated in health and strength by means of a daily plunge in a cold bath.

*Exercise.*—Infants, for the first month or two, sleep so much that there can be no exercise save that of being carried about in the nurse's arms. After this time it is advisable to suffer them to exercise their limbs freely, by laying them frequently on a bed, sofa, or carpet, and allowing them to roll and kick at their good pleasure. The delight which this affords evinces how grateful such freedom is to their animal feelings.

There is one very common mode of exercising infants, which, we think, deserves particular notice—we mean the practice of *hoisting* or raising them aloft in the air. This practice is of such venerable antiquity, and so universal, that it would be vain to impugn it. The plea-

sure, too, which most children evince under it, seems to show that it cannot be so objectionable as a cursory observer would be disposed to consider it. Still there are hazards which ought not to be wholly overlooked. The risk of accident is one of some amount: children have slipped from the hands, and sustained serious injury. Some people are so energetic as to throw up children and catch them in descending. This rashness there can be no hesitation in reprobating, for however confident the person may be of not missing hold, there must ever be risk of injury from the concussion suffered in the descent, and even from the firmness of grasp necessary for recovering and maintaining the hold. The motion of the body, too, has a direct tendency to induce vertigo; and when the liability of the infant brain to congestion and its consequences is considered, when the frequency of hydrocephalus in infants is borne in mind, an exercise which impels blood to the brain will not be regarded as wholly insignificant. There is one more objection which seems not to have attracted attention. The hold taken of a child in the act of hoisting it, is by the hand grasping the chest. The fingers and thumb placed on each side of the sternum, compress the ribs, and any one with the hand so placed will at once perceive that if the pressure were strong, and the resistance from the elasticity of the ribs weak, the impression on the chest resulting would correspond exactly with the deformity named *chicken-breast*. That any force is ever used capable of inducing speedily such a change is in the highest degree improbable; but that reiterated pressure of this kind, however slight, would in a weakly child have power to impress and distort the chest, few, we imagine, will doubt.

Rocking was formerly in almost universal use with infants, though not meant precisely as exercise. Every cradle had its rocker, by means of which it was put in vibratory motion whenever the infant was to be set asleep. The expedient answered its purpose; but the propriety of inducing sleep by such means is very questionable, or rather must be utterly disallowed. Sleep here ensues because the motion promotes a congestive state of the vessels of the brain inducing a degree of vertigo. For the reasons already assigned when discussing the exercise of hoisting, this cannot be salutary, and must be scarcely safe in the delicate brains of infants.

*Moral management.*—To notice the moral discipline of infancy may excite a smile; and yet it is a subject of no slight moment. From the hour of birth the infant is a moral being, and subject to the moral laws; and it is the duty of those who are responsible for its culture to see that these laws be not infringed. Bodily health, too, being more or less affected by mental excitement, a treatise on physical education would be incomplete if this source of disturbance were disregarded. Infants possess several propensities and passions of great activity; and as neither the countervailing

sentiments, nor the intellectual powers by which they are to be controlled in after-life, are at this age equally developed, it is the more incumbent on those who govern them to regulate, on sound principles, the dispositions which they display. Good dispositions are capable of being cultivated, and evil of being restrained, even in the cradle. But they who undertake the task should look well after the government of their own minds; for if in pursuing it they yield to the impulse of feelings, unrestrained by the higher sentiments and unguided by the intellect, their measures will be ill adapted to the ends desired, and little likely to attain them. An irritable nurse is unfit for the care of a fretful child. The fretfulness may be owing partly to natural disposition; it often arises from impaired health, or from slight sufferings occasioned by some injudicious management. Rendered uneasy by overloaded bowels, constriction from the clothing, misplaced pins, or other source of disquietude, the infant has no resource but to cry; and if the cause of distress be not removed, habitual fretfulness and irritability of temper may become established. In a child of natural good temper, when the distress is relieved, calmness returns; but if the temper be naturally irritable, this becomes aroused by the pains endured, and especially if under its sufferings the child be harshly or unkindly treated: so that even when the bodily distress ceases, equanimity is not restored. Children cry from pain; they cry also from passion; and no tones can be more distinct than those which express the respective feelings. The one should be promptly quieted by removing the cause of pain; the other is less speedily corrigible, requiring both time and a system of sound moral discipline, to prevent habits of irritability acquiring strength by reiterated excitement. When the natural temper is irritable, causes of irritation should be carefully avoided; the irritability should be calmly but steadily repressed; other faculties of the mind, too, should be called forth, as indirectly suspending the exercise of the irritable feelings; and according as the mental powers become progressively developed, the higher sentiments and intellectual faculties should be so cultivated as to ensure them that predominance over the animal propensities which the Creator has allotted to them, and on the maintenance of which all virtue and happiness depend. To exercise this controlling power in due time is the greatest good which the infant can experience; it lays the foundation of all moral improvement, and cannot be too early commenced. No error can be more pernicious in its consequences than to be reckless of exciting the passions of children, without considering how they are to be allayed. Some have been so misguided as wantonly to excite such passions in order to habituate the parties to self-control; but this error is so mischievous, and so irreconcilable with all sound principle, that it must be of rare occurrence. Even carelessness, however, in this respect is in-

excusable; and no child should be subjected to any irritation that can be avoided. Frequent excitement will, in the naturally irritable, confirm ill temper, while it will endanger the establishment of it, even in those who are naturally more calm. Irritability of temper in children should be regarded rather in the light of a disease to be remedied, than of a fault to be punished. They are as nature made them, and no more accountable for irritability of temper than for a weak digestion or other bodily infirmity. The possession of an irritable temper is a misfortune rather than a fault, and the being so unhappily circumstanced merits pity rather than reproof. All the assistance which kindness and sympathy can render should be given in support of the struggles which such a being has to maintain within his own breast. Imperturbable calmness is required in the government of children, who readily distinguish whether reproof or punishment proceed from excited passion, or are resorted to solely for their correction or improvement. This discussion, however, must terminate here. Enough has been said to mark the close connexion that subsists between moral discipline and physical welfare. Tranquillity of mind is essential to good health, and the government of the passions is important towards attaining the ends of physical education.

In rearing children it is necessary to bear in mind the force of habit, by which, in many parts of the animal economy, regularity is maintained with a precision which the dictates of reason could never command. Many of the bodily functions are signally under its influence; and on the principle that activity gives vigour, while quiescence leads to abatement of energy, much of moral discipline may be founded on the formation of habits during those early years when the self-controlling powers of the individual are yet but imperfectly developed. In respect of food, of sleep, of the alvine discharges, a disposition to periodic recurrence is clearly discernible; and by attending to it, regularity of the respective functions may be sensibly promoted. Fixed periods for taking food are desirable, and they should be frequent. It is unwise to load the stomach with fresh food until the previous meal has been digested and passed onward to the intestines. From this error the gastric and intestinal irritations of infancy oftentimes proceed. Regular habits of evacuating the bowels, if duly established, have much effect in superseding the use of medicine. So prone are the bowels to make at certain periods efforts for their own relief, that if from any cause the periodic impulse be resisted, the effort ceases, and is not again actively renewed until the next revolving period arrives; accumulations, productive both of inconvenience and injury, going on during the interval. It seems needless to pursue further the consideration of infancy. What has been said furnishes sufficient guidance for conducting the ordinary management of health, and for guarding against

the errors to which this stage of life is exposed. So many of the principles inculcated in the foregoing inquiry apply to the next stage, or that of childhood, that this may be more briefly discussed.

CHILDHOOD.—In considering the stage of childhood, we shall, for the sake of method, pursue the same arrangement that was followed in treating of infancy, without deeming it necessary, however, to dwell more circumstantially on any point than its merits may specially require.

The clothing of childhood should possess the same properties as that of infancy. It should afford due warmth, be of such materials as do not irritate the skin, and so made as to occasion no unnatural constriction.

On the feeding of children their health is much dependent; and in this respect injury is often done from regulating their diet according to some preconceived system founded on partial experience or imperfect observation. Children, to support their natural growth, require ample sustenance, and this admitted truth is with many a sufficient reason for overloading their stomachs, and with food of too nutritious a kind. Others again, from having seen healthy children reared on a low diet, and, also from having occasionally witnessed disease brought on by excess of animal food, unaware, too, of the hazard of generalising from insufficient facts, hastily conclude that low diet is wholesome, and animal food prejudicial. No exclusive system can in this respect be right, nor can any precise rule of diet be possibly laid down, as this requires to be adapted in every case to the particular constitution concerned. It has been already shewn that a mixed diet of animal and vegetable food is that which nature has designed for human beings; their organization being fitted for its use. The period, too, when animal food may begin to be used seems also indicated by nature, and some portion of it seems fairly admissible as soon as teeth appear sufficient to masticate it. These, however, are but general truths, which require continually to be modified in their application by special circumstances. The constitution of the child, and the effects of particular diets, will in general indicate sufficiently how it may be best sustained. If of a sound constitution, free from fever or evidences of plethora, with healthy bowels, a cool skin and clear tongue, the diet may be liberal, and some animal food may be conjoined. It is not wise to stint the growth of children by a too low diet, for, however it may for a while appear to agree, it induces a state of body deficient in vigour and unfit for maintaining full health. Children so reared are prone to scrofula, and to several other diseases marked by impaired energy of frame. Yet neither should children be pampered; for this leads to evils no less formidable, though of a different character. Large meals oppress the stomach, cause indigestion, and by overloading the bowels, obstruct one of the most important excretions. Too much animal food supplies blood in excess, begetting a

proneness to fever and inflammation; and every one is aware how large a portion of the diseases of children is thus characterised. So long as the general health is unimpaired, the body and mind active, and no evidence present to mark excess of nutriment, that food may be allowed which natural appetite calls for, and which appears to yield adequate nutrition; and in such case a mixed diet of animal and vegetable food will be found the best for this purpose. But if languor at any time ensues, and febrile indications become manifested,—if the pulse become frequent, the skin hotter than natural, the tongue white and furred, the bowels irregular,—then, though these several symptoms should be only in slight degree, and unattended with any specific derangement amounting to what is considered disease, not only should the diet be lowered, and its animal part for a time withdrawn, but measures should be taken to correct the state of repletion which has been suffered to arise. For some time after its removal, too, care should be taken to keep the diet under that which occasioned the constitutional disturbance.

These observations apply to children of sound constitutions and robust health, and attention to them may be the means of averting much disease. In such the plethora so induced is positive; that is, the blood generated exceeds what the constitution in its most healthful state could need or dispose of. But there is another, and a numerous class of constitutions in the management of which further principles are needed. These are by nature less robust, and, possessing less powers of resisting slight influences, their health becomes more or less impaired. The weakness induced disinclines to exercise; and thus a further source of derangement is superadded. Under these circumstances, the nutritive matter introduced into the system, though not exceeding what the same constitution in a state of health and vigour would require, is redundant under its altered condition. The enfeebled powers cannot dispose of it; and hence arises a state of relative plethora, producing all the evils of the positive, while, from the partial weaknesses that co-exist, it is capable of inflicting still more injury on the frame. It is the *plethora ad vires* of the older writers; and the febrile state which it induces is, like that of the positive plethora, relievable by evacuations and abstinence. But for the restoration of perfect health, something more is needed than merely getting rid of the febrile excitement. Suitable treatment will abate the plethora, remove the fever, and correct the incidental derangements, so as to bring back the constitution to the point from which the occurrence of relative plethora had caused it to deviate, and increased caution in diet may prevent the plethora recurring. But by adhering to this caution, the food required for full health may be withheld, and feebleness of habit becomes established. In this state, while it is necessary to limit the diet so long as evidences of renewed plethora are prone to recur, the necessity of improving the habit, so as to enable it to bear more

adequate nutrition, should be borne in mind. Moderating by cautious depletion the circulation when overcharged, preserving a free state of excretions, increasing the exercise, restoring tone by cold ablution or the shower-bath, with other alterations contributory to the same end, will, if judiciously applied and steadily persevered in, restore many such constitutions to a state of vigour capable of bearing the diet of full health, and exempting the parties from manifold diseases to which they would otherwise be exposed. It will be perceived that the measures here enjoined are partly remedial, partly restorative; and it is of the first importance that the right order of their employment be not reversed. If, while the remedial measures are needed, the fear of debility or other prejudice lead to the premature use of restorative means, the whole corrective process is disturbed and rendered impracticable, and disease more or less formidable is sure to result.

Regulation of the bowels is one of the most important attentions by which the health of childhood is preserved. Children of sound health, who are properly fed and have sufficient exercise, will rarely need aperient physic. Nature is fully equal to her own work, and if not obstructed will effectually perform it. Still the bowels of children will occasionally get deranged, and their incidental irregularities cannot be too soon rectified; for, independently of the local distress which a disordered state of bowels occasions, so long as this continues, a most important function of health is suspended, and part of its duties becomes transferred to other organs unfitted for discharging them. Various irritations, too, resulting from nervous sympathy, ensue. To restore a healthy state of bowels whenever these become deranged, is an important part of the physical management of childhood. For this, simple means should be preferred; but if they fail to re-establish regular evacuations with healthy secretions, more active remedies must then be resorted to, the direction of which belongs not to this place.

Children should breathe a pure atmosphere both by day and night. By day they should be much in the open air, and allowed to exercise their limbs freely, short of fatigue. Long walks are objectionable, and a single over-exertion of this kind is capable of doing permanent injury. In treating of exercise we wish to give one caution applicable to that period when the child first attempts to walk. Its early efforts are viewed with so much delight that they are apt to be encouraged and prolonged without regard to the mischief which they may occasion. The bones of infants have little resistance, and time is required ere those of the legs are capable of sustaining the weight of the body. If prematurely subjected to it they actually bend and become curved; and many an inconsiderate mother has to mourn over the deformity which she has herself created. In the upper classes of society this result perhaps is not frequent. It occurs chiefly to young mothers who have weakly

children, and for obvious reasons the first child is most exposed to it. Among the poor it is very common, though their indiscretion springs from somewhat different feelings. With them it is less the indulgence of maternal emotions, gratified by the child's exhibition of strength, that leads to this distortion, than the necessity of confiding very young children to the care of others but a few years older. This distortion, if timely noticed, is capable of correction, even after sensible curvature has taken place. Such children are in general feeble; and renovation of strength with the regular action of the several muscles of the limb may counteract the injury sustained, and cause the deformity to disappear. But to produce this effect the original cause of distortion must be sedulously avoided, until firmness of bone and strength of muscle remove all hazard of perpetuating or renewing the evil. In addition to other means of establishing the necessary vigour of frame in such cases, a daily plunge in a cold bath is of signal efficacy.

It is hardly necessary to enter further into the physical discipline of childhood; nor is it required in this stage of existence to make any distinction between males and females. Happily for the latter, they are, during childhood at least, strangers to those restrictions and injurious practices from which in later years they are doomed to suffer so severely. From this period on to puberty a marked difference prevails in the management of boys and girls, greatly to the prejudice of the latter; and it is to the errors thus committed, and the calamitous evils which they inflict, that attention will be chiefly directed in the following pages.

ADOLESCENCE.—Boys, though oftentimes too much confined by the prevailing systems of school discipline, have on the whole considerable liberty, and they avail themselves of it so as to exert freely and actively their muscular energies. By such exercise their growth is promoted, their vigour improved, their health maintained, and a robustness of frame acquired exceeding that of girls to a degree far beyond what mere difference of sex would account for. Very different is the fate of female childhood as it passes onwards to adolescence. When this latter stage is approached, the trammels of error, prejudice, and false system begin to be imposed, restraining the free exercise of body and mind, and conforming both, not to what reason and right feelings enjoin, but to what fashion and vanity dictate. The body, instead of being suffered to attain its just proportions uninfluenced by interference of art, is to be trained into those forms which the caprice of the day admires, however unnatural, or however unbecoming in the eye of unvitiated taste. The limbs, formed for activity, and requiring free exercise for the development of their structure and the maintenance of their powers, as well as for the preservation of general health, are to be restricted to those movements to which a fancied gracefulness attaches, even though the best powers both of body and mind wither under the blighting influence of the vicious system. The mind

fares no better; for instead of the cultivation of those intellectual powers and moral feelings which conduce to utility, happiness, and virtue, the best years of life are wasted on vain accomplishments, which even when attained are too dearly purchased, yielding but a very inadequate recompense for the time and toil bestowed on them, and which in a large proportion of instances, from being forced against nature, and without the talents that would justify such assiduous cultivation, are never acquired to the extent of answering a single good purpose, being sure to be abandoned as soon as the parties become free agents, and released from the controul of their unrelenting taskmasters. Each of these subjects will require to be considered more in detail; and above all, attention must be forcibly drawn to those horrible ravages in female health that result from the visceral lesions which the tyranny of fashion occasions. To any one impressed with the reality and extent of the evils here deprecated, it is difficult to think or write on them with perfect calmness. We shall endeavour as much as possible to confine ourselves to a plain exposition of the evils deplored, and of these we shall adduce only such evidences as admit of unequivocal demonstration.

Of boys it is unnecessary to say much, as the principles already inculcated apply to them equally as to infants and children. To them the advance from childhood brings but greater freedom; and if the confinement of school exceed what sound reason and the philosophy of nature would sanction, they redeem the mischief by the active unrestrained gambols in which they indulge when school-hours are over. They pass much time in the open air, exercise freely, take food with appetite, and digest it thoroughly; whence the stomach and bowels are seldom disordered, and their sleep is sound and refreshing. Their clothes, too, make no injurious pressure; all their muscles are at liberty to act, and the free exercise of these promotes both their growth and activity, ensuring thus the regularity and efficiency of the several functions to which these muscles are subservient.

With girls, the ordinary modes of proceeding are much less healthful. It is not that their health is less an object of regard, or less carefully tended, but other considerations than those of health obtain an undue share of attention, and various practices subversive of health are pursued in ignorance of the extensive mischiefs to which they lead. After childhood, education formally commences, and from this period certain objects of maternal solicitude are pursued with a zeal and earnestness which, if well directed, would be worthy of all praise. As it is, that of good intentions only can be awarded; for the tendency of much that occurs at the periods of life now under consideration is to render valueless all the cares lavished, by breaking down the constitution.

The first error is that of restraining the free motions of the body and limbs, so natural at this period of life, and in which the young of

both sexes so much delight. The young lady is now to cultivate manners, to practice a certain demureness supposed to be becoming, to attend to her carriage, keeping her head erect, and her shoulders drawn back; and if from inability to continue the muscular efforts necessary for this end, she fail to do what nature does not empower her to accomplish, negligence or obstinacy is imputed, reproach is cast, which, being felt as unjust, irritates the moral feelings; and thus a slight error in physical discipline becomes a fruitful source not only of bodily injury but of moral depravation. It is a well established fact with respect to muscular energy, that the contractions of muscular fibres on which their actions depend, require intervals of relaxation; that, if the contractions be prolonged without this relief, they in a certain time fail, so that no effort of the will can continue them. In other words, the muscles tire, and an interval of repose is necessary to fit them for renewed effort. This is familiarly instanced by the experiment of holding the arm extended, when, even though no weight be held in the hand, the continued muscular action required for maintaining this position cannot be sustained for many minutes. If this be true of the firm and robust muscles of adults, how much more forcibly does the principle apply to the tender and immature muscles of early life. To preserve a good carriage, to keep the head and shoulders continually in that position which the dancing-master approves, require considerable muscular powers, such as no girl can exercise without long, painful, and injurious training, nor even by this, unless other measures to be hereafter noticed, be resorted to in aid of her direct endeavours. We would not here be understood as undervaluing a good carriage, which is not only pleasing to the eye, but is, when natural, absolutely conducive itself to health, as resulting from that relative position of the several parts connected exteriorly with the chest, which allows greatest freedom to the internal organs. To ensure a good carriage, the only rational way is to give the necessary power, especially in the muscles chiefly concerned; and this is to be done, not by wearying those muscles by continual and unrelieved exertion, but by invigorating the frame generally, and more especially by strengthening the particular muscles through varied exercise alternated with due repose. Attention to general health, suitable diet, regular bowels, moderate but regular exercise, not of particular muscles only, but of the whole frame, cold bathing when needed, and other such measures, will maintain a good carriage by giving that power which the more direct means so generally practised serve but to exhaust. All this may appear trivial and of slight importance, yet the principle inculcated is far from being so; and it applies to this early stage of life as forcibly as to those more advanced. Nay, more so; it is at this stage that its observance is of greatest moment; for if it be here disregarded, effects may result, which, though not immediately obvious, are capable of laying the foundation of evils that

cannot afterwards be redeemed. It is possible that the principle might be more clearly illustrated, more forcibly inculcated in connexion with those later periods of life when the consequences of disregarding it are more prominent; but we prefer dwelling on it in its earliest and simplest applications, as a clear conception of these will materially assist in unravelling and comprehending the more complex conditions which are hereafter to be noticed. The evils produced by errors in physical education oftentimes begot actual disease, and the nature of this will ever be more intelligible in proportion as we ascend to the causes which primarily induce it. It has been shewn that direct endeavours to enforce what is called a good carriage necessarily fail of their effect, and that instead of strengthening they enfeeble the muscular powers necessary for maintaining it. This fact soon becomes perceptible; weakness is noticed, and instead of correcting this by the only rational mode, that of invigorating the weakened muscles, mechanical aid is called in to support them, and laced waistcoats are resorted to. These undoubtedly give support,—nay, they may be so used as almost wholly to supersede the muscular efforts, with the advantage of not tiring, however long or continuously employed. Improvement of carriage is manifested, the child is sensible of relief from a painful exertion, the mother is pleased with the success of her management, and this success appears to superficial observation fully to confirm the judgment which superintends it. In the present ignorance that prevails on all points of animal physiology, it would be quite impossible to convince any mother so impressed that she was doing otherwise than ministering to her child's welfare. Yet what are the consequences to which her measures tend, and which such measures are daily and hourly producing? It has been shewn in the foregoing pages, when noticing the organic laws, that a muscle consigned to inactivity not only loses power, but becomes attenuated and wasted, its nutrition failing from want of that energy which due exercise alone can confer. The fact is notorious, the principle unquestionable, although its application to the case under consideration has been little heeded. The muscles of the back and chest, restrained in their natural and healthful exercise by the waistcoats called in to aid them, and more signally in after-life by the tightly laced stays or corsets, become attenuated, and still further enfeebled, until at length they are wholly dependent on the mechanical aid, being quite incapable of dispensing with it for any continuance.

At first, laced waistcoats are used rather for the convenience of suspending other parts of the dress than with any view of giving support to weak muscles, or of influencing the shape; and confined to such use they would be perfectly harmless. In time, when weakness becomes inferred, not from any evidences of actual debility, but merely from the girls not being able to maintain the unnatural and constrained posture which fashion and false

taste enjoin, the advantage of compressing the chest by means of the waistcoat, so as to give support to the muscles of the back, becomes discovered, and the mechanical power supplied by the lace affords but too effective means of accomplishing this compression. The effect pleases the mother, promoting, as it does, her dearly-prized object—a good carriage; it is endured by the girl as the lesser of two evils, for though at first irksome, it releases her from the pain of endeavours which she has not power to continue to the extent required. As years advance, various causes combine to render this practice more inveterate and more pernicious; and still the potent instrument, the lace, lends its ready and effectual aid. The extent to which this practice prevails, and the degree to which it is carried, are too notorious to need being dwelt on. Extreme cases we wish not to state, lest they should appear exaggerations; but daily observation displays to all who walk our streets, and still more signally to those who frequent our assemblies of fashion, the many victims who, through tight lacing, sacrifice health, and too often life, at the shrine of empty vanity.

It is time now to scrutinize the further injuries which this unnatural practice inflicts. The first evil is already suffered in the dorsal weakness occasioned by mechanical support having superseded muscular energy. The muscles are become enfeebled and attenuated; their physical condition unfits them now for doing that for which nature designed them; the stays are become indispensable, and, so strong is the faith in their necessity, that a proposition to discard them would be accounted monstrous. A conception that they could be laid aside would be regarded as quite too improbable to be for a moment entertained. But now a taper waist becomes an object of ambition, and the stays are to be laced more closely. This is still done gradually, and, at first, imperceptibly to the parties. The effect, however, though slow, is sure, and the powers of endurance thus exercised come in time to bear almost unconsciously what, if suddenly or quickly attempted, no heroism could possibly sustain.

The derangements to which this increased pressure gives rise must now be considered. The first is the obvious impediment to the motions of the ribs which this constriction of the chest occasions. For perfect respiration these motions should be free and unrestrained, and, as has been already noticed, perfect respiration is necessary to those changes in the blood which fit it for nutrition and the other purposes of the animal frame. In proportion as respiration is impeded, is the blood imperfectly vitalised; and in the same ratio are the nutritive and other functions dependent on the blood inadequately performed. Here, then, is one source of debility which affects the whole frame, reducing every part below the standard of healthful vigour. According, also, as each inspiration of air becomes less full, the wants of the system require, as a compensation, increased frequency; and thus quickened respira-

tion commences, disturbing the lungs, and creating in them a tendency to inflammatory action. The heart, too, becomes excited, the pulse accelerated, and palpitation is in time superadded. All these effects are capable of resulting from mere constriction of the chest; they become fearfully aggravated when, at a more advanced stage, as will be more fully shewn in the sequel, additional sources of irritation arise in flexure of the spine, and in derangements of the stomach, liver, and other organs subservient to digestion. The foregoing disturbances are formidable enough, and sufficiently destructive of health, yet they are not the only lesions which tight lacing induces. The pressure, which is chiefly made on the lower part of the chest, and to which this part most readily yields, extends its malignant influence to the abdominal viscera also. By it the stomach and liver are compressed, and, in time, partially detrued from the concavity of the diaphragm, to the great disturbance of their functions; and being pressed downwards, too, these trespass on that space which the other abdominal viscera require, superinducing still further derangements. Thus, almost every function of the body becomes more or less depraved. Nothing could have prevented the source of all this mischief and misery from being fully detected and universally understood, but the slow and insidious process by which the aberration from sound principle effects its ravages, and on this account it is that we lay so much stress on the remoter evils when considering the primary errors, for it is only by tracing those to their source, and by connecting the several visceral lesions which ultimately take place with the incipient and apparently harmless errors which form the earlier links in the chain of causation, that any hope can be entertained of those evils being early understood or effectually rectified.

It must be seen that the same principles apply to every stage of this destructive system, and that, however insignificant the effects of the early waistcoats may appear when compared with those of the tight-laced corset, the same false principle is manifested throughout. The girl's waistcoat, if used otherwise than as a support for the other articles of dress, is improper. When tightened in order to support the back, instead of giving strength, it produces real weakness by the effect on the dorsal muscles already described; and when further straitened, so as to diminish the waist, it then commences that suicidal process which years of suffering and ill health are afterwards to complete.

But there are further evils yet to be noticed. The mere weakness of back, so often adverted to, becomes in its turn an aggravating cause of visceral lesion. The body cannot be always cased in tightly-laced stays; their pressure may be endured to any extent under the excitement of the evening display, but during the day some relaxation must take place. Under it, the muscles of the back, deprived of their accustomed support, and incapable of themselves to sustain the incumbent weight, yield,

and the column of the spine bends, at first anteriorly, causing round shoulders and an arched back; but eventually inclines to one or other side, giving rise to the well known and too frequently occurring state of lateral curvature. This last change most frequently commences in the sitting posture, such females being, through general debility, much disposed to sedentary habits. As soon as lateral curvature commences, the lungs and heart become still more disturbed; anhelation from slight exertion, short cough, and palpitation ensue; and at this time, chiefly in consequence of the pulmonary derangement, alarm begins to be entertained, and the approach of phthisis apprehended. Medical aid is now sought, and as the more obvious malady is within the chest, and from the excitement which prevails presents an acute character, blood is drawn, and other means are resorted to suited for arresting inflammatory action. And to a certain extent the practice is necessary and right, for in this state there is often so much inflammation and congestion as fully to justify depletory treatment. Should the disease, however, be misconceived as primary inflammation of the thoracic contents, the relief, however signal at the time, must be transient, and, unless attention be given to those causes from which the perpetual derangements spring, enduring health has little chance of being restored. Removal of the spinal flexure by using a recumbent instead of a sitting posture; alternating this with regular and proper exercise so as to call into renewed action the weakened and wasted muscles; invigorating these still further by cold sponging and stimulant frictions; and, finally, renovating the general health by regulation of bowels, suitable diet, the cold shower-bath, and such tonic medicines as the constitution may need, are the appropriate and only effectual means by which this state of health can be permanently improved.

The views of spinal curvature here presented will be found more fully stated in a paper in the 5th volume of the *Midland Medical and Surgical Reporter*, to which the reader is referred.

We have already mentioned the injury which constriction of the chest inflicts on the liver and stomach. Either or both of these organs may under this disturbance display the ordinary evidences of local inflammation or congestion, and to these will apply all that has been already stated respecting the heart and lungs. The local inflammation or congestion may be real, and require depletion together with other active remedies, but they are liable to recur if the original disturbing causes be not rectified. They are sensibly aggravated as soon as the spine begins to yield, for according as the body bends forward, the lower ribs in connexion with the sternum are forced inwards, increasing the pressure made on the liver and stomach, and further irritating these if already brought into a state of excitement.

But all the evils produced by the vicious course so long and so obstinately persisted in are not yet enumerated, an important train of consequences being yet to be noticed in the

derangements of the uterine system. When the age of puberty is approached, the organization distinctive of sex becomes more fully developed, and in the female constitution certain changes take place the suppression or retardation of which is fraught with injury to health. Of these changes one of the most important, and that which is most liable to be affected by contingent influences, is menstruation. This function we mean here to consider only so far as it is prejudiced by the causes of ill health now under consideration. For menstruation to commence at the proper age and to continue regular and perfect, it is requisite that the whole frame be in a healthful state and every function adequately performed; consequently, the general depravation of habit lately described is eminently unfavourable to the establishment of this natural process. There is also required a certain vigour of constitution capable of propelling blood with sufficient energy into the capillary vessels, which vigour habits enfeebled in the way lately noticed do not possess. It is further necessary that the larger trunks leading to these capillaries be not overcharged, else congestion takes place, which further debilitates the overloaded vessels, rendering them still less capable of propelling their contents into the capillaries by the secreting functions of which they would be relieved. Yet this congestion is prevented by the impeded circulation arising from constriction of chest, and by the disturbance of the abdominal viscera lately explained. It is necessary, also, to take into account the various coincident efforts made by the constitution towards preparing for the signal revolution in the system which incipient menstruation indicates. When these efforts are defeated by menstruation not commencing at the proper period of life, much additional derangement of health ensues, and blood which ought to be disposed of by the uterine vessels becomes either congested in the surrounding tissues, or determined to other parts, so as to cause vicarious hemorrhages of various kinds. Thus the regularity and efficiency of the uterine functions, so essential to female health, become impeded and impaired by the injudicious measures which, when first resorted to in childhood, are little suspected of exerting any such influence.

Although so much has been attributed to constriction of chest in impairing general health, and occasioning special derangements, and assuredly not more than strict truth warrants, many other errors of physical education lend their aid to produce that feebleness of constitution and delicacy of health of which so many females are the victims. These shall be now considered under the same arrangement which was followed with respect to the earlier stages.

*Clothing.*—The clothing of young females is far from being what reason would sanction. It is oftentimes deficient in the necessary warmth, the materials being too slight to yield protection against the vicissitudes of a variable climate, and too much of the person being wholly exposed. Errors of this kind, how-

ever, are much more common and carried to much greater lengths at the period when *education*, in its usual sense, may be said to be completed; that is, when the young lady passes from the restraints of the school-room to the dissipations of fashionable life. As, however, this change usually takes place before the body has attained its full vigour, the following remarks on the dress and conduct of females, on first leaving school, belong properly to our subject. If the errors of dress are less signal in the attire worn by day, they reach their acme when the evening route or midnight ball is to be attended. At these seasons the tightly-laced stays, exposed chest, and thin draperies, furnish a combination of influences, the continued effects of which no constitution could withstand; while to these is yet to be added that of respiring for hours a heated and vitiated atmosphere, and, after this, of passing, when relaxed and exhausted, into the cold currents of a frosty night air. So far from wondering that many suffer from these egregious imprudences, our surprise should be that any escape; and instead of the inherent delicacy so often imputed to the constitution of females as explanatory of their peculiar ailments, we have ample proof, in their powers of resisting such noxious influences, that they possess conservative energies not inferior to those of the most robust male. Were men to be so laced, so imperfectly exercised, so inadequately clothed, so suffocated, so exposed, their superiority of bodily vigour would soon cease to have any existence.

Defect of clothing, though most signal in the chest and shoulders, is not confined to the upper part of the body. The feet require warmth, which subservience to fashion prevents. They cannot be compressed but at the cost of much suffering, some distortion, and the infliction of positive disease. Fashion also permits the legs to be covered with only the thinnest materials. Thus the capillary circulation of the feet, rendered sufficiently languid by the general weakness, becomes further impeded by the pressure of tight shoes, and the debilitating effects of cold. The crippled state, too, thus occasioned, is a further obstacle to efficient exercise, and so adds to the general debility.

*Food.*—The food of the young of both sexes, as indeed of every age, should be suited to the particular constitution. The general principles for regulating it have been already laid down. It should, for reasons already assigned, be rather nutritious than spare. The effects of casual repletion are less prejudicial, and more easily corrected than those of inanition; still the bounds of temperance should never be exceeded. There should be a due admixture of animal food, but wine and stimulants are needless and improper. It is to be hoped that no caution is needed at the present day against a practice, not unknown in the last century, of females inclining to corpulency reducing themselves by abuse of acids. The effect was produced by destroying the tone and injuring the structure of the digestive organs, and from

the evils which resulted, we would fain hope that a practice so pernicious has been for ever abolished.

At the ages under consideration the state of the bowels requires to be attended to ; and here again, girls suffer in a much greater degree than boys. The abdominal congestions to which their whole course of discipline subjects them, have no means of relief save the increase of alvine excretions. There is, therefore, even more to be carried off through this outlet than a state of health would supply. Yet from the general debility and deficient exercise the alvine discharges are very prone to be irregular and inadequate. Much disease would at this age be averted, and the conservative powers of the constitution would have a far better chance of being effectively exercised, if a regular and healthful state of bowels was maintained. For this there should be not only daily evacuation in sufficient quantity, but, what is still more important, the matter discharged should be of a healthy character. And here we would caution medical men against being misled by false delicacy so as to trust to reports, which are never to be relied on. Ocular inspection furnishes an indication of the highest value, both in exhibiting and withholding medicines ; and so assured are we of its absolute necessity as a guide to medical judgment, that we cannot understand how a medical practitioner can conscientiously perform his duty who disregards it. As it is the duty of the medical practitioner to avail himself of this source of information when attending patients under disease, it is equally so to point out to convalescents the importance of it to the maintenance of general health. Were the state of bowels in young females more attended to, ample evidence would be furnished of the necessity of some evacuant or corrective discipline, long before the accession of actual disease ; and, what is of more importance, much accumulated and too often intractable disease might thus be altogether averted.

*Exercise.*—What has been already stated with respect to air and temperature in infancy and childhood can be so readily applied to the more advanced ages, that they need not here be further discussed. Exercise, however, demands some additional notice. Boys enjoy this freely, and of the best kind, in the unrestrained indulgence of their youthful sports. By means of these every muscle of the frame comes in for its share of active exercise, and free growth, vigour, and health are the result. It would be happy for girls if some portion of such latitude were allowed to them also. But it is far otherwise. Even under the more favourable circumstances of country life, they are too much restricted from the free exercise which health requires. Their very dress unfits them from taking it, and the alleged indecorum of those active movements to which youth and spirits instinctively incline, is a bar to even the attempt being made. At their age the measured, slow-paced, daily walk is quite insufficient even for the muscles specially engaged, while it leaves many others wholly unexercised.

If this be true of the more hale and robust inhabitants of the country, how much more forcibly does it apply to the delicate and attenuated residents of towns, and especially to the inmates of female schools. Of these establishments the systems and habits require much revision, and until some effective reformation takes place, of which there is yet but little prospect, they will not fail to excite our sympathy and regret for the blanched aspects, shadowy forms, and sickly constitutions so continually presented, and which it is so painful to witness. Such beings are as little fitted for encountering the toils or fulfilling the duties of life, as are plants of a hothouse for being transferred to the open borders.\*

\* The amount of exercise, or rather the extent to which the *want of exercise* is carried, in many boarding-schools, will appear incredible to those who have not personally investigated the subject. The following is the *carte* of a young ladies' boarding-school, drawn up on the spot, a few years since, from the report of several of its inmates :—

- At 6 in the morning the girls are called, and rise.
- From 6 to 8, learning or saying lessons, *in school*.
- 8 to 8½, at breakfast.
- 8½ to 9, preparing lessons *out of school*, (*some of the girls permitted to do so in the garden.*)
- 9 to 1, at various tasks, *in school*.
- 1 to 1½, *out of school*, but must not go out of doors ; reading or working, and preparing for dinner.
- 1½ to 2, at dinner.
- 2 to 5, *in school*, various tasks.
- 5 to 5½, tea.
- 5½ to 6, preparing to go out ; dressing, or reading, or *playing in school*.
- 6 to 7, walking, generally arm-in-arm, on the high road, many with their books in their hands, and reading.

Two days in the week they do not walk in the evening at all, being kept in for *dancing* ; but, by way of amends, they go out on two other days, from 12 to 1, and then they miss *writing*. It is to be remarked that they *never go out unless the weather is quite fine at the particular hours allotted for walking*. They go to church, all the year round, twice every Sunday, on which day no other exercise is taken.

- From 7 to 8, for the older girls, reading or working in school, (this is optional,) and then prayers ; for the younger, play in school, and prayers.

- At 8, the younger go to bed.
- From 8 to 9, the older, reading or working, as before.
- 9, to bed.

The twenty-four hours are, therefore, thus disposed of :—

|  | Hours. |
|--|--------|
| In bed, (the older 9, the younger 10,) . . . . .                                       | 9      |
| In school, at their studies and tasks . . . . .  | 9      |
| In school, or in the house, the older at optional studies or work, the younger at play | 3½ †   |
| At meals . . . . .   | 1½     |
| Exercise in the open air . . . . .   | 1      |
|  | 24     |

The above account was taken from a second or third-rate school, and applies more particularly to the season most favourable for exercise,—*summer*. It is to be remarked that the confinement is generally greater in these than in schools of a higher order. That the practical results of such an as-

† Younger only two hours and a half.

By the foregoing statements we do not mean to cast the slightest reflection on those by whom these seminaries are superintended. We have ever found them most solicitous for the health of their pupils, sedulous to preserve it, and when disease arose, unremitting in devoted attentions. But the system is faulty, and for this they are not accountable. By the influences and prejudices which uphold that system, they, like others, are chained; and until the system itself yield to increasing knowledge, juster views of the animal economy, a more correct conception of mental energies and of the injuries which their over-excitement occasions both to themselves and to the bodily frame, and a firm resolution not to barter health for vain accomplishments;—in other words, until both mental and physical education undergo considerable reformation and be founded on more rational principles, the evils must exist to an extent which no superintendent of a seminary can control. We are sorry to be compelled by truth to add that we have often found the same pernicious regimen carried to as great a height, although on a smaller scale, in private families, under the eye of a fashionable governess and a fond but injudicious mother.

Hurried breathing, short cough, palpitation, constitute a state of indisposition or actual disease is considered to exist. Weak back, with incipient curvature of spine, in time aggravate these deviations from health. Irregular

tounding regimen are by no means overdrawn in the preceding pages is sufficiently evinced by the following fact, a fact which we will venture to say may be verified by inspection of thousands of boarding-schools in this country. We lately visited, in a large town, a boarding-school containing forty girls; and we learnt, on close and accurate inquiry, that there was *not one* of the girls who had been at the school two years (and the majority had been as long) that was not more or less *crooked*! Our patient was in this predicament; and we could perceive (what all may perceive who meet that most melancholy of all processions—a boarding-school of young ladies in their walk) that *all* her companions were pallid, sallow, and listless. We can assert, on the same authority of personal observation, and on an extensive scale, that scarcely a single girl, (more especially of the middle classes,) that has been at a boarding-school for two or three years, returns home with unimpaired health; and, for the truth of the assertion, we may appeal to every candid *father* whose daughters have been placed in this situation. Happily, a portion of the ill health produced at school is in many cases only temporary, and vanishes after the return from it. In the schools in which the vacations are frequent or long, much mischief is often warded off by the periodical returns to the ordinary habits of healthful life; and some happy constitutions, unquestionably, bid defiance to all the systematic efforts made to undermine them. No further proof is needed of the enormous evil produced by the present system of school-discipline than the fact, well known to all medical men, that the greater proportion of women in the middle and upper ranks of life do not enjoy even a *moderate* share of health; and persons, not of the medical profession, may have sufficient evidence of the truth, by comparing the relative powers of the young men and young women of any family in taking bodily exercise, more particularly in *walking*. The difference is altogether inexplicable on the ground of sex only.—J. F. EDITOR.

bowels attend, impairing still further the general health, and giving rise also to special ravages of the most formidable kind. A hard and tumid abdomen follows, the precursor and eventually the index of mesenteric derangement, which, next to phthisis, is perhaps the most intractable malady of youth with which the physician has to contend. Other evils, referrible to the erroneous system and to the debility occasioned by it, may also be seen. Of these, chilblains are very common, and, when they occur, add greatly to suffering and to the further decline of health. They arise from failure of circulation, and, locally considered, are analogous to frost-bitten parts; being in fact so many partial mortifications resulting from loss of vitality in the capillary vessels. The surgical treatment which they receive is not always judicious. Regarded too much as local sores, and the irritability which they display being too much heeded, rest is enjoined, and thus even the insignificant exercise previously taken is suspended. Far better would it be, when this evidence of impaired vigour presents itself, to disregard the local ailment, and look solely to the constitutional state in which the local malady has its origin.

It is a prevalent opinion with teachers and parents that it is more conducive to the progress of education to keep a child at school when in infirm health, where the studies may still be continued, at least in some degree, than to interrupt them entirely by a removal to the parental roof. This is a great and often a fatal mistake. By such delay nothing is lost that can under such circumstances be accomplished: feebleness of body is little favourable to the full exercise of mental energies. Mental faculties depend for their manifestation and exercise on bodily organs, and in proportion as the organs are weakened, does the vigour of the faculties decline. By suffering both organs and faculties therefore to acquire renewed vigour, powers of effective exertion are recoverable to an extent fully capable of compensating for the temporary inactivity. It is a great mistake to conceive that education advances in proportion to the time devoted to it, or to the earnestness with which it is pursued. Mental powers are capable of a certain exertion only, and if they be overstrained, or too assiduously employed, they weary and decline, accomplishing much less than, with unimpaired vigour and more moderate exertion, they would be capable of doing in much less time. Every student is conscious of the inequality of his mental powers under different states of bodily health and different degrees of mental weariness, and fully sensible how little progress he makes when a forced effort is required. The mind, too, requires variety of exercise in order to employ and gratify the various faculties of which it consists, and if it be chained down to a few objects, and especially if these be little congenial to its prevailing tastes and capabilities, the labour turns to little account. Under the systems of education which prevail, years are wasted in pursuits which ought not to occupy a tenth part of the time, if their value

were rightly estimated, and the real powers of the mind properly directed. And this leads us to consider, what has hitherto been but too little attended to in conducting education, the direct influence which the exercise of the mental powers has on the bodily health.

In the few following remarks on this subject we shall draw freely from an admirable paper published in the sixth volume of the *Phrenological Journal*, entitled, "On Mental Exercise, as a Means of Health." The principles inculcated are of the highest importance, and though emanating in this instance from phrenological views, they have also so sure a basis in established physiology, that they may be beneficially applied even by those who still close their eyes to the truths of a science in which the writer of this article has no hesitation to avow his firm belief; and which, justly estimated, has more power of contributing to the welfare and happiness of mankind than any other with which we are acquainted.

The importance of muscular exercise as a means of preserving and improving health is generally admitted. It ministers to the health of the body, and, as the brain has its due share of this advantage, mental energies are also promoted by it. "But there is great reason to believe that exercise of mind, regular active employment both of intellect and of moral feeling, of which the various parts of the nervous system are the organic media, contributes so essentially to the well being of the whole system, that it cannot be neglected without inflicting positive injury; and that, independently of its mental advantages, it is necessary to the enjoyment of full physical health." It is essential to health that the functions of the nervous system be well performed. But the intellectual powers, with the affective and moral feelings, form a part of these functions, and so intimately connected are the physical and mental energies that they mutually influence each other; so that, in proportion as nervous stimulus is unduly expended on the one, it becomes withdrawn from the other. Deficient or irregular exercise of nervous functions gives rise to much suffering, and in no class of beings more signally than in that to which so much of this essay has been devoted, namely, of young females of the upper and middle ranks, more especially those "of a delicate and nervous constitution, who, without any existing disease, without even having undergone any severe indisposition sufficient to debilitate the system, are nevertheless habitual invalids, and can scarcely venture beyond the limits of the drawing-room, or withdraw themselves from the rays of the sun, without some evil, real or imaginary, instantly overtaking them, and forcing them back to their retreat."

Some of the sources of this extreme delicacy, and the means of remedying it, it has been the object of the foregoing pages to explain. "Young men of the same rank suffer infinitely less, because the constantly recurring calls of business and public life operate upon them as stimuli, and, in spite of themselves, exercise the feelings and employ the intellect on objects

of some permanent value and importance, and thus keep up a stir of life and excitement of the system which is favourable to the health of all the functions, and to which unhappily many of the opposite sex remain, especially in their youthful years, altogether strangers."

"The three grand sources of vitality, failure or weakness of which may induce infirm health and delicacy of constitution, are the digestive, the sanguiferous, and the nervous apparatuses; and, accordingly, whenever great debility is observed to exist without any marked local disease, its true cause will almost to a certainty be found in weakness or deficiency affecting one or other of the three great systems of organs just named. If digestion, for instance, be radically feeble, then the chyle or nutritive material will fail, and weakness follow. If the lungs and circulating system be weak, the respiration will be imperfect, and the blood being inadequately acted on by air, its composition will be impaired, and, sent in this state through the bloodvessels, it will no longer afford the usual stimulus and support to any of the organs, and hence again constitutional delicacy. And, lastly, if the nervous functions be defective, not only will the mind suffer, but all the functions of the body will participate with it in languor, because all of them will receive a diminished and vitiated supply of nervous stimulus, a due share of which is essential to their healthy action."

The digestive, respiratory, and sanguiferous functions have been already noticed so far as the purposes of this essay require. It remains, then, only to pursue the consideration of nervous functions as involving and affected by the exercise of mind. So dependent is every part of the frame on the brain and nerves, that if the communication between them be cut off or obstructed by dividing or compressing the nerve which conveys nervous influence, the function of the part, however healthy it may be in every other respect, will cease, be diminished, or otherwise disturbed. When any organ, too, is stinted of its due share of nervous stimulus by the too great activity of some other part absorbing more than its own proportion, the function becomes weakened. Thus a diminution in the tone of all the other organs of the body will be experienced during an over-excitement of a few in writing or thinking intently, processes during which the vital actions and nervous energy are so much concentrated in the head, that from pure want of it the extremities become cold, and the action of the heart is lowered so as to weaken and retard the pulse, thus shewing that a weak and inactive nervous system must exert an unfavourable influence on the general health.

For guidance in strengthening and developing the nervous system so as to render it fit for the adequate performance of all its functions, we must look to the general principles of physiology and the dictates of experience. "When any living part is called into frequent and regular exercise, especially if the system is not yet arrived at full maturity, it is observed to become gradually more and more susceptible of action;

to increase in size within certain limits determined by the constitution; and thereby to gain strength, as indicated by an increased power of enduring fatigue, and a greater capacity of withstanding the influences of the common causes of disease to which previously it would have yielded almost immediately. The physiological explanation of this, as proved by experiments, is, that exercise causes an increased action in the nerves and bloodvessels of the part, by which its vitality is augmented, and a greater supply of blood and nervous stimulus sent to it to sustain and repair the greater waste that is taking place, and also to supply additional substance to fit it for the unusual demands made on it. The results of this process are visibly exemplified in men whose habits or profession lead them to constant muscular exertion; in sportsmen, for instance, in blacksmiths, dancers, porters, &c.; and if it is less manifest in other parts of the body besides the muscles, it is only from other tissues admitting of less expansion, and showing their increased power in a different way. The improvement of the memory is a familiar instance of an increase of mental power produced by exercise; and the beating sense of fulness and quickened circulation in the head induced by intense study or thought, shows that an organic process goes on when the brain is in activity, similar to that which takes place in the muscular system under exercise." On the contrary, when the organ is little used, little expenditure of its power and substance takes place, little blood and little nervous energy are required for its support, and therefore little is sent; nutrition in consequence soon becomes languid, and strength impaired. To all these laws the brain is subject equally as the rest of the body. Frequent and regular exercise gives it susceptibility of action, with power to sustain it, the nervous energy acquiring strength as well as the vascular. Disuse of its functions, or, in other words, inactivity of intellect and of feeling, impairs its structure, and weakens the several powers which it serves to manifest. The brain, therefore, in order to maintain its healthy state, requires to be duly exercised; and as it consists of several parts, each performing its proper function, and as what holds good with respect to the whole collectively, is equally true of each part individually, it follows that for healthful and adequate exercise every function requires its due share of employment, else not only do the portions consigned to inactivity become impaired, but the general health becomes deranged by the irregular distribution of nervous stimulus thus occasioned. But such is the nature of the mental functions, that each must be excited by its proper stimulus, or both it and the portion of brain subservient to it are consigned to inactivity and consequent loss of power. No one would think of exercising the eye by sound, or the ear by colours. The effect of mere quiescence arising from the want of appropriate stimulus is signally manifested in the case of persons, and especially of the young, who in one situation manifest certain faculties very feebly, but who, when removed to another in which appropriate and adequate

stimulus is supplied, evince powers such as they were never previously supposed to possess. When we consider how few of all the faculties which the mind possesses are duly exercised in the courses of education, both for males and females, which prescription, prejudice, and fashion have ordained, we can have little difficulty in comprehending how nervous derangements of various kinds result from causes so efficient in producing them. "An appropriate example may be found in the case of a nervous young lady, whose education has communicated nothing but accomplishments, who has no materials of thought, and no regular and imperative occupations to interest her and demand attention; who takes no active part in promoting the welfare and comfort of those about her; who looks to others for support and sustenance; and whose brain is in fact half asleep. Such a person has literally nothing on which to expend half the nervous energy which nature has bestowed on her for better purposes. She has nothing to excite and exercise the brain, nothing to elicit activity; her own feelings and personal relations necessarily constitute the grand objects of her contemplations; these are brooded over until the mental energies become impaired; false ideas of existence and of providence spring up in the mind; the fancy is haunted by false impressions; and every trifle which relates to self is exaggerated into an object of immense importance. The brain, having literally nothing on which to exercise itself, becomes weak, and the mental manifestations are enfeebled in proportion; so that a person of good endowments, thus treated, will often exhibit something of the imbecility of a fool. But suddenly change the circumstances in which such a person is placed; suppose, for example, that her parents lose their health or fortune, and that she is called on to use her utmost energies in their and her own behalf; that in short her brain and mental faculties, her intellect and her moral and social feelings, are blessed with a stimulus to act; the weakness, the tremors, the apprehensions which formerly seemed an inborn part of herself, disappear as if by enchantment; and health, vigour, and happiness take place, solely because now God's law is fulfilled, and the brain with which he has connected the mind is supplied with that healthful stimulus and exercise which he ordained to be indispensable to our comfort and welfare."

We once attended a young lady for various nervous complaints, who possessed the most exquisite sensibility of frame we ever witnessed. For years she had endured almost every form of the most aggravated hysteria. She was brought up with every refinement of education, and the habitual indulgence of every luxury, her parents appearing to live only for the purpose of ministering to her gratifications. Such was her acuteness of sensibility that at certain times the mere opening or closing of a door was agony; such her helplessness, that oftentimes she could scarcely muster energy enough to raise her hand to her head. In the midst of this her father became bankrupt, and soon after died.

His family were now obliged to labour for their support, and on this feeble creature devolved much of the care of providing them subsistence. She had talents and she exerted them. With the assistance of friends she opened a school, which she superintended with unremitting assiduity. Her nervous maladies vanished, and for years she persevered steadily in her altered but more happy course of life. It would have been fortunate if she had commenced this earlier; for the delicacy of constitution created by early mismanagement laid the foundation of phthisis, of which she eventually became a victim.

While inactivity of brain leads to evil, over-excitement is no less injurious; and if persisted in without suitable relaxation, exhaustion and permanent weakness are the results. In ordinary education both errors are committed. The mental powers exercised are too few, and these are continually overworked, while the larger portion is left to chance for obtaining any exercise at all. In education, too, attention is too exclusively directed to the intellectual powers, while the effective and moral faculties are unheeded, or only acted on through the intellect. And yet they admit of rational culture equally as the intellectual powers, while on them and on their government do the virtue and happiness of mankind far more depend. Intellect is no doubt capable of assisting in this government, but never can the moral feelings be disciplined through intellect alone. Ethical discourses, the most eloquent and conclusive, may be pronounced, but alone they reach not the heart. The moral sentiments, to be truly cultivated, must be felt; objects must be presented capable of exciting emotions; and then intellect may interpose to assign the just limits of their indulgence. No discourse on charity can have the effect of a real opportunity for doing a benevolent action. No lecture on justice can make impression equally as an occasion of exercising this quality, especially where other incitements opposed to it require to be overcome. A conquest thus gained does more to confirm the principles, from the deeper impression made by a practical example beyond that of a speculative rule, and from conscious satisfaction and heartfelt pleasure derived from every victory over self, when once the victory is completed, than all that the most profound moralists ever wrote. The minds of the young should be exercised in all the faculties by which their social condition in after-life is to be maintained, and in this some attention should be given to the natural order of their development; for some precede others in activity, and also become more quickly matured. Most of the affections and moral sentiments may be observed in their manifestations even in the cradle. Of the intellectual powers, those which are employed in acquiring a knowledge of the external world are earliest developed. The reflective faculties advance more slowly, and hardly attain full power until the body reaches its full growth. Much of our ordinary courses of education is in opposition to these facts. Many of our classical books which mere boys are con-

demned to read, require not only mature intellect, but considerable knowledge of the world for their comprehension.

The object of education is to fit human beings for maintaining their social relations, and performing all their several duties in life. For this end they should learn the properties of bodies, and also the qualities by which men act on these and on each other. Minute and intimate knowledge of all these it would be impracticable for any individual to attain, nor is it necessary; but an outline of them is within the reach of all, and this, which to any ordinary capacity would be only pleasurable acquirement, may prove of much practical utility, while by exercising the cerebral organs it will invigorate both these and their functions, be a source of much pure gratification, withdrawing the mind from selfish and sensual pursuits, and through its manifold influences have a beneficial effect on the general health. The various branches of natural science are among the best exercises on which the young mind can be employed; for while they engage a large number both of the knowing and reflecting faculties, they incite also several of the higher sentiments by presenting to the mind the wisdom and goodness of the great Creator, so abundantly displayed in all his works; the benevolent purposes for which all these are designed, the good which they impart, and the happiness which they diffuse. Such contemplations withdraw the mind from selfish passions, consigning them to that quiescence which lightens the task of keeping them under due control.

Above all other studies, however, that of the mind itself is the most interesting and the most important. By it alone can we form a just estimate either of ourselves or others, or have any clear conception of the powers with which nature has endowed us. Some knowledge of these powers must be of material assistance to us in regulating their exercise, ascertaining their objects, and restraining their excesses. The subject, however, is far too copious for this place, and unsuited for the present occasion. What has been adduced was necessary in order to convey any conception of the influence of mental actions on the bodily frame, and to show the intimate connexion that subsists between mental and physical education. That the foregoing sketch of the latter is far from complete we are well aware. Many points of detail have been passed over or slightly noticed, which would admit of more copious illustration and more explicit instruction. If we mistake not, however, enough has been advanced to display the principles on which physical education should be conducted; and an outline at least has been furnished which each reader may readily fill up according to his intelligence, and to the condition of life to which it is to be applied.

(*E. Barlow.*)

**ELECTRICITY.**—When a substance has acquired the power of first attracting and then repelling light bodies placed in its vicinity, and of emitting sparks, it is, in the language

of electricians, said to be *excited*. These phenomena, we are told, were first observed by Thales of Miletus in a piece of amber, which by the Greeks was called *ἤλεκτρον*, and hence the origin of the term electricity.

Electricity may be developed by several means, the chief of which are friction, the contact of dissimilar substances, pressure, variations of temperature, and chemical action. In the present article we shall confine ourselves to the first-mentioned source, and shall dwell even upon it no further than may be necessary for rendering intelligible what we shall have to say respecting the therapeutic applications of the electric fluid.

When a glass rod is rubbed with silk, and then brought close to a little sphere of elder pith suspended by a silk thread, a combination commonly called an electric pendulum, the sphere is first attracted by the glass, and, upon contact, immediately repelled. But upon substituting for the glass rod one of metal, no such phenomena will be observed. Such experiments have suggested a division of bodies into two classes, the electrics and the non-electrics, or those which admit and those which do not admit of being rendered electric by friction. Glass, sulphur, wool, silk, and all resinous substances are electrics. Carbon, the several metals, water, and every variety of organized substance, in consequence of the water which all such include, acid and saline solutions, &c. are non-electrics. This division, however, we shall presently find to be based upon an erroneous supposition. All bodies, in fact, are electrics; and if there are some which, under ordinary circumstances, do not appear to become excited by friction, it is because the electricity is permitted to flow from them into the earth as fast as it is generated.

This brings us to another division of bodies, having reference to their electrical relations, founded on a different principle, namely, that which resolves them into conductors and non-conductors, or rather into those which are with facility and those which are with difficulty traversed by the electric fluid; for, strictly speaking, there is no absolute non-conductor. If a glass rod be applied to an excited body, it will become electrified merely at the point of contact. But if a metallic rod, suspended upon silk, be applied in a similar manner, it will at the same instant exhibit symptoms of excitement at every point. This simple experiment illustrates sufficiently the difference of the conducting powers of the two rods.

When a body is surrounded on every side by non-conductors, it is said to be insulated. Thus a ball of metal resting upon a cake of resin, or a stool with glass legs, or suspended by a silk thread, is insulated, for it is in connexion with the earth only through the medium of non-conductors. If the insulation were perfect, the ball once electrified should continue so for an indefinite time. In practice, however, this never occurs, for the reason already assigned, namely, that there are no absolute non-conductors. Dry air is probably the best insulator with which we are acquainted; but,

by impregnation with aqueous vapours, it acquires conducting powers.

The two divisions just noticed admit of being reduced to one, the electrics being non-conductors, and the non-electrics conductors. It is, in fact, owing to this latter coincidence that some bodies appear incapable of being excited. Thus, if a disc of copper, held in the hand, be rubbed with a silk-handkerchief, it does not become excited; but if, before the application of the friction, it be insulated, the usual phenomena manifested by electrics will present themselves.

In every case of electrical excitement two distinct powers are contemporaneously developed. Thus, when glass is rubbed by silk, both become electrified, as may be proved by approaching them in succession to an electric pendulum. The electricity of the glass, however, is different from that of the silk, for when either is communicated to two contiguous pendulums, these repel each other. But when the electricity of the glass is communicated to one pendulum, and that of the silk to the other, attraction ensues. These different powers require to be designated by different names, and hence the terms *vitreous* and *resinous*, which, whatever be the substances rubbed, are applied to the distinct energies developed by the process of friction. Such was the language of Dufay. But, in more modern times, these designations have been by some replaced, particularly in Great Britain, by the terms *positive* and *negative*, introduced by Franklin, the former corresponding to the vitreous, the latter to the resinous electricity of Dufay. This difference of nomenclature depends upon the different opinions entertained by these philosophers respecting the nature of the electric influence. Dufay viewed it as a compound, Franklin as a simple fluid. The former referred all electrical phenomena to the resolution of the compound into its vitreous and resinous elements. The latter explained them by supposing that all bodies, in their natural or neutral state, contain a certain quantity of the electric fluid, and that the processes, which produce electrical excitement, operate merely by disturbing this proportion, and thus causing an accumulation in some and a deficiency in others. We shall not enter here into any criticism upon the respective merits of these rival hypotheses. Suffice it to say, that the theory of Dufay is that adopted by the highest authorities in science, principally, as it would seem, because of its analogy to that which is alone applicable to the kindred subject of magnetism.

In order to a consistent explanation of all known electrical facts, it is only necessary to suppose, with Dufay, that electricities of the same name repel, and of contrary names attract each other, and with a force varying in the inverse ratio of the square of the distance. This principle of the action of the elementary fluids at a distance is applicable to a multitude of phenomena, amongst others, for example, to the charging of the Leyden phial. By electricians it is known under the name of *induc-*

*tion or influence.* It may be illustrated by the attraction already noticed as occurring when we approach an excited glass tube to an electric pendulum. The vitreous electricity of the tube decomposes the natural fluid of the ball of the pendulum, attracting its resinous and repelling its vitreous element; the attraction, however, being more energetic than the repulsion, inasmuch as it is exerted at a shorter distance. But, as the ball is insulated, its constituent electricities are merely separated from each other, but cannot leave it; hence it will itself be carried towards the tube, and with a momentum corresponding to the difference of the opposed forces.

There is but one point more connected with the theory of electricity to which it is necessary to advert here. When a body is electrically charged, the free electric fluid is confined solely to its surface, and does not, as experiment proves, dip to any appreciable depth into its substance. Its distribution, however, on the surface is never equable, except in one case, namely, when the body is a sphere. In all other solids it accumulates in greatest quantity upon the most prominent or projecting points. But the tendency of the electric coating of an excited body to escape, is, as Laplace has shewn, proportional to the square of its thickness. Hence we deduce the practical inference that a body studded with points cannot be strongly charged, for before much free fluid has been communicated to it, such a quantity will have accumulated at the points as to flow out in a continued stream, by forcing a passage through the atmosphere.

Having disposed, in this short summary, of the principles of electricity, we shall now briefly describe such articles of electrical apparatus as are indispensable with a view to its application as a medicinal agent. These are the machine, the insulating stool, the director, the Leyden jar, and the discharging electrometer.

The electrical machine is the piece of apparatus employed for the purpose of obtaining electricity in considerable quantity. It consists essentially of three parts; the rubber, the substance rubbed, and the conductor or conductors, for there are sometimes two of them. The substance rubbed is invariably of glass, and is sometimes a flat disc, but more usually a cylinder. By a winch handle, attached to one extremity of its axis, a motion of rotation is given it, and it is thus made to slide upon the rubber, which is nothing but a leathern cushion, to which a small quantity of an amalgam (composed of one part of tin, two parts of zinc, and six parts of mercury,) is usually applied, and to which is appended a flap of silk, which embraces the semi-circumference of the cylinder, or, in the case of the *plate*, in which there are two cushions, extends from an extremity of the vertical to one of the ends of the horizontal diameter. The friction exerted between the glass and the rubber effects a continued decomposition of the electric fluid residing on their common surface, the vitreous or positive element being determined

to the glass, and the resinous or negative element to the cushion. The latter passes at once to the negative conductor which is in contact with the rubber,\* and from it, if uninsulated, into the earth. The former develops, by the process of induction, electricity of the same name in the positive conductor, which is an insulated metallic cylinder, or system of cylinders, straight or curved, presenting to the glass a number of points, which are placed at a distance from it not exceeding a quarter of an inch. When positive electricity is required, the negative conductor must be uninsulated, by hanging upon it a metallic chain so that it may reach the ground. On the other hand, when negative electricity is required, the negative conductor is insulated, and the positive one put in connexion with the earth. In order that the machine may work well, it is necessary that it be rendered perfectly clean and dry, by placing it before the fire, and rubbing it carefully with silk or flannel. Especial care must be taken that the conductor of which the electricity is wanted be well insulated, and this is best ensured by gently heating its glass leg; for the deposition of hygrometric moisture upon it is thus rendered impassible.

The nature of the insulating stool is announced by its name. The back may be of any material, but the legs are invariably of glass, this being the strongest of all non-conducting substances.

The director is a brass rod of about a foot in length, terminating at one end in a ball of the same metal, and at the other in a glass handle. The ball admits of being screwed off, and, when removed, exposes to view the extremity of the director ending in a fine needle-point. This point should also screw off, for the purpose of being occasionally replaced by one composed of baked wood, or of brass covered with lac varnish.

The Leyden jar is a cylindric glass vessel, coated within and without to about two-thirds of its height with tin-foil, and closed above by a wooden plug perforated by a brass wire, which terminates outside in a ball or knob, and inside in a chain prolonged so as to reach the inner coating. To charge the jar, its knob is made to touch one of the conductors of the machine while in action, its outer coating being, at the same time, uninsulated by being held in the hand, or in any other way put in connexion with the earth through conducting substances. The inner coating obviously acquires the electricity of the conductor which it touches, while the outer surface becomes, at the same time, charged with the opposite fluid in virtue of the principle of *influence*. To *discharge* the jar, the two surfaces are to be connected by some good conductor. Thus, upon applying one end of a metallic wire to the outer coating, and approaching the other to the ball or knob, the opposite electricities rush together, presenting the phenomena of the

\* In the plate-machine there is no negative conductor, the cushions being, through the wooden frame, in connexion with the earth.

spark,—that is, a flash of light accompanied by a sharp snapping sound, and both surfaces return to the natural state.

Of the discharging electrometer there are many modifications. It is, however, essentially nothing but a brass rod terminated by balls, and supported in the horizontal position by a glass leg. If, while a jar is charging, one end of the rod is placed within one-eighth of an inch of its knob, the other extremity being connected, through some conductor, with the outer coating, a very slight charge will cause the spark to pass between them. If the distance be now increased to a quarter of an inch, a stronger charge must be communicated to the plial before its spontaneous discharge will take place, and so on, so that, by properly adjusting the distance, we can regulate the maximum charge at pleasure.

When a spark is taken by approaching the knuckle to a machine in action, it causes a peculiar pungent sensation, the nature of which it is not easy to convey by description. Generally speaking, however, when thus produced, it is not, unless the machine be very powerful, accompanied by much pain. But if a loaded jar be discharged through the body, which may be readily done by applying one hand to the external coating and the other to the knob, a sensation of an exceedingly distressing kind will be experienced, which is usually and very appropriately denominated the *shock*. The distance to which the shock extends depends upon the magnitude of the coated surface and upon the intensity of its electricity. Thus, with a certain charge, it is felt at the wrists, with a stronger at the elbows, and with a still stronger, even at the chest. A surface of thirty square inches, when loaded by a common machine, is capable of destroying mice and small birds, and there are few individuals of the human species who can receive with impunity the maximum charge of a square foot, or one hundred and forty-four square inches. It is worthy of remark that the bodies of animals destroyed by the electric shock are very prone to putrefaction, that the irritability of the muscular system seems almost entirely destroyed, and that their blood does not coagulate. Similar observations have been made upon animals struck by lightning.

The influence of the shock seems particularly directed to the nervous system. A small charge passed through the head of a bird deprives it of sight, and a considerable one received in the head by Mr. Singer had the effect of a violent blow, and was followed by a temporary loss of memory. When a jar is discharged along the spine of a person in the erect position, the action of the muscles is for a moment suspended, and he falls to the ground. Electricity, therefore, produces a paralyzing effect when brought to bear upon the centre of the nervous system. But when transmitted to the muscles of a limb, the invariable consequence is their spasmodic contraction, and this is true even though the member be in a paralytic state. Some recent researches, which will be noticed under the head

of GALVANISM, render it highly probable that the muscles are not directly sensible to the stimulus of electricity, but that they are thrown into convulsive action by the electric fluid, merely because of its traversing the nerves by which they are supplied.

Electricity was very early employed as a therapeutic agent, and is even still resorted to by physicians, though it has lost much of the celebrity which it once enjoyed. The diseases in which it is applied are the different forms of paralysis, including amaurosis and deafness when functional affections, epilepsy, hysteria, chorea, chronic rheumatism, particularly those forms of it which produce stiffness of the joints, cases of retention or suppression of the menstrual flux, nervous headaches, and local pains unconnected with inflammation, asphyxia produced by drowning or the irrespirable gases, enlargements and obstructions of the glandular system. These are the affections for which it is still prescribed, and occasionally with success. But there is scarcely a disease in nosology for which it has not at one time or another been recommended.

As a remedial agent, electricity may be applied in five different ways. The first method, which is, we believe, at present employed, is to *excite* the patient by placing him upon an insulating stool, and putting him in connexion with the prime conductor of a machine in action. This is what is called the electric *bath*. It was strongly recommended by Priestly, apparently under the impression adopted from the Abbé Nollet, that the animal functions are, under such circumstances, discharged with increased vigour, particularly the circulation of the blood and the cutaneous secretion. Such effects are sometimes observed, but by no means invariably. The bath was employed by Lit and De Haen, two early writers upon medical electricity, for the treatment of hysteria.

The next and simplest method of applying electricity to the cure of disease is to present the member, or part affected, to the prime conductor of the machine, and thus cause it to receive a succession of sparks; or, what is more convenient, to place the patient on a chair, and convey to him the sparks by means of a director connected with the conductor by a chain. The patient may manage the director while the operator works the machine.

The third mode consists in placing the patient upon an insulating stool, putting him in connexion, through means of a chain or metallic rod, with the prime conductor, and drawing sparks from the seat of disease or pain by simply presenting to such part the knuckle, or, should the operator dislike receiving the spark himself, an uninsulated director. This method of operating has the advantage over the preceding that it conjoins the electrical bath with the influence of the spark. It is, therefore, that usually adopted by those experienced in the medicinal administration of electricity. The force of the spark is proportionate to its length, so that, by properly diminishing this, its strength may be reduced to any required standard.

A favourite mode with some practitioners of applying sparks is to *give* or *draw* them across flannel. For this purpose, a director, terminated by a large ball, which is to be covered with a fold of flannel, is approached in the usual way to the organ to be electrified. Instead of a single strong spark, a series of weak ones will thus be produced, which, emanating at the same instant from several of the woollen fibres, extend over a considerable surface and produce in it a peculiar pricking sensation. The ball of the director may be naked, the flannel being laid on the part of the body which is to be submitted to the influence of the sparks. This method is supposed to be particularly suited to the treatment of rheumatism and paralysis, especially in patients who cannot endure the stronger forms of electricity.

The next form of medical electricity to be noticed is the *aura*, or jet of air, which proceeds from an electrified point. This is the modification of the electric influence to which ulcers, excoriated surfaces, and delicate organs, such as the eye and testicle, are usually subjected. The common method of employing the *aura* is to present a pointed director, connected by a chain with the conductor of the machine, and held by a glass handle, to the part affected. The particles of air in contact with the point are highly electrified, and, of course, immediately repelled. The same occurs to those which take their place, and so on in succession, producing a current of highly excited air, which, as has been just described, is directed upon the organ which is the subject of electrical treatment. The *aura* may also be applied by placing the patient upon an insulating stool, and directing an uninsulated pointed director to the seat of disease. It is, however, seldom resorted to, as its efficacy is more than questionable.

When the point which terminates the director is of baked wood, this being a bad conductor, the electricity does not issue in a continuous stream, but as a succession of minute sparks, which produce in the part of the body upon which they are directed a sensation perfectly similar to that which attends electrization across flannel. This kind of electricity is applicable to cases where the *aura* is not sufficiently energetic, and where the sparks proceeding from a ball are found too pungent.

For the application of electricity to deep-seated parts, such as the interior of the mouth or the bottom of the external meatus of the ear, a particular form of director has been devised, the description of which may with propriety be given here. A glass tube of about one-tenth of an inch internal diameter is left open at one end, and is closed at the other by a cork, through which there slides a brass wire, terminated within by a ball, which, as in the common director, screws over a point. To apply this instrument, the open end of the tube is introduced, we shall suppose, into the ear, and the internal extremity of the wire being brought as close to it as may be deemed advisable, sparks, or the *aura*, are communicated or drawn in the usual way. The glass

tube, being a non-conductor, prevents any lateral divergence of the electric fluid, and directs it upon the point placed immediately beneath its orifice.

When *shocks* are deemed necessary, we must have recourse to the Leyden jar, and this constitutes the fifth form under which electricity may be exhibited medicinally. The method, of course, consists in discharging a loaded jar through the affected part or member as often as may be considered advisable. The readiest method of accomplishing this is to place the free extremity of a copper wire, wound about the outer coating of a charged phial, in contact with one end of the course which it is intended to make the electricity traverse, and then bring the knob of the jar to the other end. When the knob comes within the striking distance of the body, the discharge takes place, and the shock is felt in the interval which separates the knob and wire. Against this method, however, the objection lies that we are not enabled to measure the amount of the charge, and that the shock, therefore, does not admit of being graduated according to the feelings of the patient, or the nature of the disease. To attain this object, it is necessary to interpose the discharging electrometer, already described, in the arc which connects the outer and the inner coatings of the phial. The knob of the jar being now placed in contact with the conductor of a machine in rotation, and at the selected distance from one of the balls of the electrometer, the discharge takes place as soon as the free electricities have acquired sufficient tension to force their passage through this interval, and a shock is felt in the part of the body which completes the circuit. If this be too strong, the ball of the electrometer must be placed at a less distance from the knob; if too weak, the distance between them must be augmented. The two parts of the body between which it is intended that the electricity shall pass are to be touched by the balls of two separate directors, held by an assistant, and connected, by means of chains, the one with the electrometer and the other with the outer surface of the jar. Thus, if one of the directors be in contact with the hip, and the other with the knee, when the discharge takes place, the shock will be felt along the entire thigh.

This method of regulating the shock should be familiar to such as employ electricity in the practice of medicine. The discharge of a small jar proves fatal, as we have seen, to the smaller animals; and there can be no doubt but that by means of a battery of no very great surface human life might be destroyed. The power, too, of sustaining the shock is very different in different individuals, and even varies in the same person so as to differ at different times, and in different states of the system. These circumstances enjoin caution in the administration of electricity, particularly by means of the jar, and it may be added that, in point of fact, its injudicious and indiscriminate use has proved extremely injurious. To this effect may be quoted the

case of a young girl labouring under paralysis of the right arm, related by Dr. Harte, (Phil. Trans. vol. iii.) who, after two shocks, became universally paralytic. From this state she was with difficulty recovered by judicious medical treatment, but relapsed upon being again subjected to three discharges of the Leyden jar. After the lapse of four months she was again relieved of the maladies inflicted upon her by electricity, and, nothing discouraged by his first failures, the doctor, it is said, would have resorted to the shock a third time, but Priestly quaintly observes, "the girl being more nearly concerned in the experiment than her physician, thought proper to decline it." The medical reader who resides in the vicinity of an electrizing quack will, no doubt, be able to call to mind similar cases.

In the employment of electricity as a curative agent, there are certain precepts to be borne in mind, without an attention to which disappointment will be often experienced, and unmerited discredit thrown upon a really efficacious means of subjugating morbid action. These may be reduced to the following heads.

1. Electricity should be only considered as auxiliary to other modes of medical treatment which experience has shown to be advantageous. Thus, in rheumatism, it may be combined with diaphoretics; in chorea, with tonics; and in paralysis, with medicines which, like strychnia, stimulate the nervous system, a practice recently adopted for the cure of palsy arising from the absorption of lead.

2. We should always commence with its weaker forms, such as the bath or aura, next proceed to sparks, and finally, should these prove insufficient, to shocks, taking care to regulate their strength by the means already described, and avoiding their exhibition, when of such degrees of energy as to prove distressing to the feelings of the patient. The sparks applied in anaurosis, or for the discussion of glandular tumours, must be feeble, and in such cases shocks are quite inadmissible. To communicate the latter, a jar, four inches in diameter and six in height, will be found amply sufficient, and its knob need never be placed at a greater distance from the ball of the electrometer than one-fourth of an inch. An interval of from one to two tenths of an inch will, generally speaking, be sufficient.

3. The electrization should be performed daily, and be persevered in for at least a month, if necessary, and a cure must not be despaired of because there is no immediate relief experienced; for the good effects of electricity generally require a long time for being developed.

4. The *aura* may be applied for from five to ten minutes. The number of shocks passed in one direction should not exceed twelve, nor the number of sparks applied to the same part twenty-four.

5. In local affections, the electric fluid should be confined to the diseased part or organ. But in diseases, such as chorea and epilepsy, in which the entire system seems to

be engaged, it must be applied generally over the body. Such parts, however, as are affected with pain, or any unusual sensation, should be particularly dwelt upon.

The *modus operandi* of electricity, in the cure of disease, is considered obscure. It would appear, however, in its ordinary forms, to act as a simple stimulant. Upon the nervous system, indeed, it is by many supposed to exercise a particular influence, of the nature of which we shall be enabled to form some idea, should the hypothesis broached in modern times, and which refers the functions of the nerves to currents of electricity transmitted through them from the brain and spinal chord, turn out to be correct. We shall revert to this subject in the article GALVANISM, and shall here merely remark that, assuming the theory alluded to to be sound, it will be proper, in the medicinal administration of electricity, to cause the positive fluid to pass through the body always in the direction of the ramification of the nerves. This precept is particularly insisted upon by some foreign electricians.

The spark received from substances resinously electrified differs, in some respects, from that which issues from surfaces vitreously charged. It is more pungent, and has a different shape, being shorter, and not so regular in form. As medicinal agents, however, they appear both to produce similar effects. A contrary opinion has indeed been maintained by some, who have represented resinous electricity as a sedative, and vitreous as a stimulant. This theory, which is quite unsupported by facts, is not a modern invention. It originated in 1779, with Bertholon of Montpellier, who resolved diseases into two classes, those which depended on an excess, and those which were the consequence of a deficiency of the electric fluid, and treated the former with resinous, the latter with vitreous electricity. It is not necessary to enter upon any formal refutation of such an absurd hypothesis. In it, however, may be recognized the germ of the more celebrated but equally unfounded nosological notions put forward two years after by Dr. John Brown, in his "*Elementa Medicinæ*."

It has been long suspected, and indeed rendered almost certain by a variety of facts, that the electrical state of the atmosphere has an appreciable influence upon the animal economy. The lower animals seem aware of an approaching thunder-storm, as would appear from the uneasiness which they manifest, the cries which they utter, and their running about in a state of alarm in search of shelter. Many individuals also of the human species, particularly those labouring under certain chronic complaints, or who possess what may be called a great degree of mobility of the nervous system, experience at such times very peculiar sensations. Observations such as these, and many others of a similar description which might be quoted, demonstrate very completely that the animal machine is frequently sensibly affected by the electricity of the atmosphere; and there is even nothing improbable in the conjecture which has been often hazarded, that the salubrity or

insalubrity of particular districts and seasons, the existence and the character of epidemic diseases, are in some way connected with, if not immediately dependent upon, the same influence. Upon none of the many branches, however, of this interesting subject can we be said to possess positive knowledge. Experiments must be multiplied before we can acquire data to reason with any precision upon it. Indeed it is only within a few years that these could have been instituted with any prospect of success. Our means of research are at present sufficiently delicate to enable us to commence such an inquiry with advantage; and it is much to be wished that meteorologists may henceforward register the variations in the electrical state of the atmosphere with as much diligence as those which occur to its temperature and pressure.

(James Apjohn.)

**ELEPHANTIASIS.** There are two different diseases which possess this common name; they are usually distinguished by the epithets *Arabian*, or of the Arabians, and *Grecian*, or of the Greeks. We shall treat of them under these terms.

**ELEPHANTIASIS ARABUM, (Elephant Leg.)** The earliest account we have of this disease is by Rhazes, an Arabian physician, who lived in 850. In the Arabian language this affection is denomination *dal fil*, which imports literally *morbis elephas*, elephant disease. The Arabians sometimes contract *dal fil* into *fil*\* alone, literally, *elephas*, *elephant affection*. This appellation was applied to the disease by the Arabians, in consequence of the huge mis-shapen appearance of the affected limb being supposed to bear some resemblance to the form of the leg of an elephant.

Elephant leg is known in the West Indies by the name of *Barbadoes leg*; sometimes it is there denominated *yanu leg*, from the supposed resemblance the affected extremity has to the fantastic forms which this root occasionally assumes. In Ceylon it is called *Galle leg*, and on the peninsula of India it is denominated *Cochin leg*, from its being indigenous to these places. In the Malabar language it is called *anay kaal*, a term which, like *dal fil*, imports elephant leg.

**Geographical distribution.**—This disease is in a remarkable degree endemic in the island of Barbadoes, on the south-west coast of Ceylon, in the neighbourhood of Cochin, on the Malabar coast, in some parts of Japan, in Egypt, and in Abyssinia. It occurs not unfrequently in almost all of the West-India islands and British settlements of South America; in the Polynesian isles; and in the provinces of Castile and the Asturias in Spain. Sporadic cases occur over Europe generally, and perhaps in all parts of the world.

**Persons liable to this disease.**—In Barba-

does elephant leg was, until about the year 1704, confined to the black population. A white inhabitant was attacked in that year; and before the year 1760, when he died, the disease was common among the white population. In general, it would appear that imported Europeans are not liable to the disease unless they reside for a considerable time in the island. It is perhaps owing to this circumstance that soldiers are very rarely affected with it.\*

In Ceylon the disease is confined to the indigenous inhabitants, including the half-caste and Creoles. Imported inhabitants, comprehending Europeans, Africans, Malays, or natives of the peninsula of India, may be said to be exempted from its influence. There is only one instance known of a native of Europe having become affected; and in his case the disease did not appear before he had been a resident at Point de Galle between thirty and forty years.

Soldiers and other imported Europeans are not liable to it at Cochin.

The disease affects all ages, although in general it appears in the early period of life; and, in some rare cases, in the first year. Both sexes seem to be equally liable to it, and no condition of life confers an immunity from its influence. Individuals who enjoy every comfort, and who are not exposed to great vicissitudes of temperature or changes of weather, are as liable to elephant leg as those who endure the hardships and privations of life.

**Symptoms.**—The constitutional excitement, or primary stage of this disease, generally comes on suddenly, with rigors, headache, nausea, pain in the back and loins; to these follow great heat of skin, alternating with profuse perspiration, and ardent thirst. Some particular part of the body (for, notwithstanding the name, the disease is not exclusively confined to the leg,) becomes red, hot, swelled, and painful, especially along the tract of the lymphatic vessels, so as to resemble, in some measure, an erysipelatous affection. The febrile excitement becomes lessened in two or three days, and soon entirely disappears. This circumstance is followed by a cessation of the local inflammatory symptoms, the heat, redness, and pain; and the swelling becomes also greatly reduced, although the part affected rarely returns to its natural size. Paroxysms of this kind succeed each other at intervals of various length, and frequently with some degree of regularity; sometimes they occur as often as once a month, and at other times not oftener than once in six months. Every successive attack adds to the effusion and consequent morbid enlargement of the part affected.

Every part of the body seems to be liable

\* *Fil alfil*, Arabic; *ulfeel*, Sanscrit; *fil*, ulfwall, *alphant*, Greek; *elephas*, Latin. (Thomson.)

\* Dr. Hendy states that horses are liable to the disease in Barbadoes, and that it had been reported to him that dogs, horned cattle, and poultry, were sometimes affected with it.

to this affection. It has been observed in the head, the tongue, the neck, the breasts, the abdomen, the thigh, and the skin in general. The condensation of the cellular tissue of newborn or very young children is a form of elephantiasis. The parts most frequently affected are the superior and inferior extremities, the vulva, and the scrotum.

The internal organs are also liable to become affected. Is it not probable that some varieties of enlargement of the liver, and the sarcomatous morbid structure of the ovaria and uterus, are kindred affections, if not the same?

Dr. Musgrave thinks this disease should be termed the *migratory inflammation of the lymphatic system*. He says, "whatever may be its original seat, the patient is never secure, while the constitutional disturbance subsists, from a sudden retrocession to some vital organ. I have seen it in the same case translated from the scrotum to the head, from thence, after a few hours, descend with the rapidity of lightning to the abdomen; again migrate to the chest, to return perhaps to the encephalon and prove fatal there; or, under more favourable circumstances, resume its comparatively harmless situation, and run its subsequent course, as if nothing untoward had occurred; and, while occupying the different cavities, giving rise to the ordinary symptoms of acute inflammation of that particular viscus which it had selected for its temporary abode."\*

It is not common for more than one part of the body to become morbidly enlarged in the same individual, although this circumstance sometimes occurs. A schoolmaster at Point de Galle had both arms and both legs affected. The scrotum is sometimes greatly increased in size: there was a mendicant at Galle, in whom it descended to the ankle, and who, when he sat to solicit alms, used to sit upon this part of the body, as he would have done upon the trunk of a tree! The leg is, we believe, the part of the body which is most frequently affected, and sometimes it becomes enormously enlarged. Occasionally the swelling is uniform; but commonly the skin is rough, rugged, and scaly, and the enlargement divided into unequal protuberances, which are intersected with deep fissures. The writer of this article was requested to visit a woman at Galle, who, although only about twenty-five years of age, had both of her inferior extremities so much enlarged and deformed, that the back part of the legs rested upon the ground and projected behind the heel, about nine or ten inches. The fissures and interspaces between the projecting and pendulous protuberances had ulcerated, and were discharging a most offensive smies. Life could not be long preserved under such extensive disease.

*Organic changes.*—This disease is evidently, in the first instance, constitutional; and the local affection seems to be a result of some

form of the process of inflammation, which recurs at intervals. A quantity of sero-albuminous fluid is effused from the exhalents into the cellular tissue of the affected part, which is not removed by adequate absorption; and the part of the body that may be affected becomes tumid, hard, and mis-shapen.

Upon examination after death, the subcutaneous tissue of an affected limb is found hard, dense, and interspersed with small cells filled with serous fluid: the aponeurosis which covers the muscles is thickened, as also the cellular and intermuscular tissue. The muscles are less red than natural. The arteries and veins are commonly not materially altered.

It deserves to be remarked, that the effused fluid in this disease is always coagulated; it consequently differs much from the serous effusions found in anasarca or ascites. It is still unascertained why it is so seldom absorbed, and so rarely excites inflammation and consequent ulceration. This effusion appears to be extra-vascular, although the fluid does not seem to have the effect of an extraneous body.

*Remote causes.*—We know nothing satisfactory respecting the remote causes of elephant leg. It is admitted to be comparatively a new disease in Barbadoes, in as far as imported, if not Creole whites are concerned; and no very important recent change has been observed in the climate of the island.

The aboriginal inhabitants of Demerara are not liable to this affection, although it is not rare among imported and Creole Africans and the half-caste. It occurs occasionally among the Creole whites; and perhaps there are about two cases of elephant leg in the colony among the imported Europeans. The progeny of Dutch families are more liable to morbid enlargements of the body than British Creoles. In this colony the disease is chiefly observed on the sea-coast.

In Ceylon it scarcely ever occurs except among the indigenous inhabitants of about eighty miles, or one-ninth, of the sea-coast of the island. At Point de Galle, which is the principal village embraced by the above range, the disease is extremely frequent; so much so that perhaps one-third, if not one-half, of the susceptible inhabitants are more or less afflicted with morbid enlargement of some part of the body. In other respects this is as healthy a portion of the island as any other: it is remarkably free from remittent or intermittent fever. Elephant leg seems to be endemic in the south-west coast only; and persons who are regularly affected with periodic attacks in that part of the island escape a recurrence of the paroxysms when they change their place of residence to the interior, or to another part of the coast. Cochin is considered a very healthy station for troops.

*Exciting causes.*—The exciting causes are equally obscure. Drs. Hillary and Hendy attribute it to sudden changes of temperature; but we think without good foundation. We

\* Edinburgh Med. and Surg. Journal. No. 92.

have known the disease affect nearly every member of a large wealthy family in Galle, the females of which, as they did not expose themselves to the sun, were not liable to a transition of temperature of above ten or twelve degrees during a whole year. Dr. Hillary was of opinion that the local affection is a consequence of the precursory fever, while Dr. Hendy adopts a very different view of its pathology, and considers the fever to be a result of the topical inflammation; asserting that unless the local affection is severe, there is no fever. In cases where the internal organs are affected, and the functions impaired, constitutional excitement may thereby be excited; but it is difficult to conceive that a febrile affection should be the result of the chronic enlargement of an extremity.

In some respects there is a considerable analogy between erysipelas and the disease in question. During the early stage of elephant leg the external characters of both diseases are similar. The topical affection in either disease rarely terminates in abscess. In erysipelas the inflammation is, however, commonly much more confined to the skin than in this disease; and so far as we are acquainted with the latter affection, it differs from erysipelas in regard to its periodicity, or liability to recur at short intervals, without any appreciable cause.\*

*Treatment.*—The treatment recommended by Rhazes seems to be as consonant to reason, and as consistent with the pathology of the disease, as any that has been suggested. It consisted of general bleeding in violent cases; emetics, laxatives, a light diet, and confinement to bed. When an inferior extremity was affected, he recommended that the limb should be rubbed with an epitheme composed chiefly of alum and vinegar, and that it should be bandaged from the toes to the knees. The natives of Ceylon seldom resort to any other remedial means in this disease, but keep their couch or rather their mat, and drink freely of ginger tea. Dr. Musgrave asserts that, “in addition to warmth locally applied, and the ordinary purgative and febrifuge medicines, mercurial saturation of the system was the best means of securing the patient against the erratic disposition, and accordingly pytalism was the usual *companion* of convalescence from an attack of this very common complaint:” for, he adds, “I am indeed strongly disposed to believe that, since the mercurial treatment has become general, the number of cases, ending in a local or permanent deposition of lymph, has been materially lessened.”—“Many individuals subject to this disease, whom I have attended for a number of years, continued to shake off each successive return

without retaining the slightest trace of its having existed, or at most with a trifling induration of the inguinal glands.”

In the case of a young lady, at Point de Galle, belonging to a family several of the members of which were affected with this disease, the first attack was treated by the free application of leeches and warm fomentations. Calomel was administered so as slightly to affect the mouth. A second attack which occurred shortly afterwards was treated in the same manner. Effusion did not take place, and no return of the disease was experienced for the two years she was under observation.

When either of the great cavities was implicated, Dr. Musgrave had recourse to the lancet. Some of his medical brethren were afraid to bleed, from an “idea that the inflammation was erysipelalous.” He is of opinion, however, that “the redness differs little from that of phlegmon, and suppuration under the form of genuine abscess is an extremely common occurrence; while, on the other hand, external gangrene is rarely, and vesications are almost never observed.” Dr. Musgrave seems to have had extensive experience in this disease, and his plan of treatment certainly deserves a trial. It may, however, be observed that, according to his doctrines, pytalism should be the “*companion*” of almost every disease that occurs in the West Indies.

Authors who have described this disease, generally, if not universally discountenance the amputation of a morbidly enlarged limb. They assert that the constitutional symptoms are apt to recur, accompanied with inflammation of some of the viscera, or of an extremity of the other side of the body. To amputate a limb while the paroxysm of fever continued to return, although at distant intervals, would, in the present state of our knowledge of this affection, be injudicious; but if the recurrence of acute symptoms had ceased for a very long period, we should be much disposed to recommend the removal of a huge, deformed, and perhaps ulcerating mass of leg or arm. The writer amputated the arm of a native of Ceylon on account of an enormously enlarged fore-arm and hand, similar to the case recorded in the Edinburgh Medical Journal, vol. xiii. page 54, by the late Dr. Kennedy. In this instance the man continued healthy, and no other limb became affected.

Cases have occurred, in which, in consequence of ulceration, a great quantity of a glairy fluid has been discharged, and the morbid enlargement has undergone a reduction to a very considerable extent. An artificial outlet of this kind has been tried in the serotum, and, according to report, with advantage. Iodine, from the advantage which has been derived from it in goitre, might be tried with some prospect of benefit: the patient should always, if possible, be removed from the district where the disease is endemic.

(J. Scott.)

\* Soldiers and sailors in the West Indies are frequently affected with smart attacks of an ephemeral fever, accompanied with an inflammatory state of the lymphatics of the extremities. The writer of this note has seen, in such cases, a red line from the foot to the groin, indicating the course of the lymphatic trunk.—J. F. EDITOR.

**ELEPHANTIASIS GRÆCORUM.** (*Tubercular elephantiasis.*) Much confusion existed, till very lately, in consequence of this term having been applied to two totally dissimilar affections.

The Arabians, we have seen, appropriated the term answering in their language to elephantiasis to an enormously swollen state of the leg; whilst the Greeks designated by it the peculiar tubercular disease which we are about to describe; the appellation being probably suggested to them either by the severity and protracted duration of the disorders, or by the coarseness and insensibility of the skin presenting some analogy to the rough hide of the elephant. The tubercular elephantiasis occasionally, also, received the name *leontiasis* from certain of the old Greek writers, in consequence of a fanciful likeness which they discovered in the stern and wrinkled visage, with its prominent brow and round eye, to that of a lion. It is the *juzam* of the older Arabians, and is still designated by a very similar name not only in Arabia, but also in Egypt, Persia, and India.

The translators of the Arabian writers entailed additional obscurity on a subject already sufficiently involved, by rendering the Arabic word which indicates this tubercular disease, by the Latin term *lepra*, which is properly applicable only to the well-known scaly affection; and the error hence arising has received, even in our own day, still further countenance and circulation, by its adoption in the splendid work of Alibert, and in the invaluable system of Frank.

Elephantiasis of the Greeks is characterized by the existence of numerous flattened glossy tubercles, of a reddish or dark colour, varying in size from that of a split-pea to that of a large nut, and occupying usually the face, ears, or limbs. The skin is irregularly thickened and wrinkled, with a diminution of its sensibility, and a swollen appearance of the affected part. The hairs fall off from almost all parts of the body except the scalp. When a European is the subject of this frightful disease, the whole skin of the parts attacked becomes of a dirty brownish or bronzed colour, approaching to that of a Mulatto. As the disease advances, some of the tubercles terminate in resolution, whilst others crack and ulcerate; these ulcerations, however, rarely become either deep or extensive, but furnish a glutinous matter which concretes into solid crusts, beneath which cicatrization usually takes place. The progress of each tubercle is quite independent of those in its neighbourhood, and is unaccompanied with pain, save in the ulcerated state.

One of the most accurate descriptions of the disease is that by Dr. Kinnis, who saw several cases of it in the Isle of France. The face was generally swollen, with large tubercles on the forehead, separated from each other by deep furrows; and smaller and more confluent ones on the cheeks, which occasionally hung down, so as to depress the angles

of the mouth; the alæ of the nose were dilated, distorted, and covered with tubercles; the ears thickened, enlarged, and studded over with similar substances, and the lips penetrated by hard whitish bodies, which looked somewhat like recent cicatrices. In Mulattoes the tubercles were of a light livid or copper colour, and in blacks a shade deeper than the surrounding skin. The cuticular lines and folds were every where more distinct and larger than natural. "The deeply wrinkled forehead, the bare swollen eyebrows, the heavy pendulous cheeks, the irregular expanded nose, the depressed mouth, and the thickened elongated earlobes, combined to render the whole visage singularly harsh and uncouth."

Similar reddish shining tubercles, but of a smaller size, usually exist within the month, occupying the palate, uvula, and fauces, and frequently undergo a superficial ulceration: but this is attended with so little pain that the individual is often quite unaware of their existence, even when they are in the ulcerated state. The mucous membrane of the nose is occasionally implicated, being liable to an abundant discharge of matter, to hemorrhage, and even to ulceration. The sense of smell is often totally lost, the breath becomes very fetid, and the nose may eventually be flattened from the destruction of the septum. The frontal sinuses are sometimes attacked, as is indicated by a dull pain in this region; and the voice, in almost every instance, becomes nasal and hoarse, and affords evidence of the larynx being affected. The conjunctiva of the eye occasionally suffers, and the vision becomes in some degree obscured.

The progress of the tubercles on the extremities is altogether similar to that of those on the face; they develop themselves slowly, become inflamed, and subsequently pass into resolution or ulceration. They are most numerous on the external surfaces of the limbs, whilst the inside of the thighs and arms, and the flexures of the joints usually escape. The skin of the fore-arms and of the legs is often not only tuberculated, but also scaly and scabbed, and particularly so about the knee and elbow joints.

In the case of a young man which we saw some years ago in the Hôpital St. Louis at Paris, thin filmy scales were very evident between the tubercles. These existed chiefly on the face and arms, which were of a dirty brown colour, whilst the seat of old ulcerations was marked by still browner discolourations. There was considerable insensibility in some of the diseased patches about the wrist. The case was of old standing, and accompanied by great emaciation and debility. Ulcerations of the alæ nasi and throat had taken place, and the voice was much affected.

But, although a slight degree of scalliness occasionally occurs, as in the above case, it is not a characteristic feature of the disease; for it is neither an original nor a universal symptom.

The feet and hands are usually much swollen,

and the motions of the joints greatly impeded by the tubercles. The nails are often coarse and furrowed. The sores are for the most part of an indolent character, with a reddish or a foul surface, little discharge, and hard and irregular edges. When the ulcerations are seated on the fingers or toes, they are apt to sink deep and terminate in gangrene; and a very serious mutilation of the extremities by the sloughing off of one or more of their phalanges is the consequence.

The tubercles very rarely make their appearance on the trunk of the body. The parts attacked become, in a great degree, benumbed, but rarely, if ever, lose their sensibility altogether.

Frank describes the disease as being accompanied with great torpor of mind and sluggishness of body, somnolence, and disturbed sleep. Mental depression amounting to extreme melancholy is the natural consequence of so hopeless a malady. Yet the general health, for a length of time, suffers infinitely less than could have been anticipated; the actions of the respiratory and digestive organs continue long unaffected, and even the cutaneous functions are still tolerably performed, as is evidenced by the abundant perspiration which can be excited by active exercise. The pulse in Dr. Kinnis's cases was generally accelerated and feeble; but others state that it remains throughout the greater part of the disease natural.

The affection has rarely been witnessed by a medical practitioner at its very commencement. In Mr. Lawrence's patient, whose case is detailed in the *Medico-Chirurgical Transactions*, it seemed to have begun by a general swelling of the head and face, and stiffness of the limbs after a wetting; on the subsidence of the swelling the tubercles began to appear on the ears, face, &c. which were at first of the same colour as the surrounding skin, but became subsequently of a reddish and sometimes of a livid hue.

The progress of the disease is very slow, and its termination, though it may be deferred for many years, almost always fatal, the unfortunate patient being in the mean time dreadfully deformed and mutilated, and literally dying by inches. Recovery is, indeed, a very rare occurrence. In Mr. Lawrence's case, the tubercles, it is true, disappeared in a great measure; but from the sudden impairment of the general health, which had been hitherto good, and from the simultaneous occurrence of thoracic symptoms, there was too much reason to apprehend that disease of the lungs had only supplanted that of the skin.

Dr. Adams has described as one of the symptoms of elephantiasis as it occurs in Madeira, a femoral tumor situated in the upper and front part of the thigh. This was absent in the case which Mr. Lawrence has so ably described, but was found by Dr. Kinnis in most of those he had an opportunity of examining—occasionally on one side only, but more frequently on both. It was placed a few

inches below Poupart's ligament, and was of an oblong form, as if arising from the enlargement of two inguinal glands, and was about two or three inches in length, and moveable under the skin. At intervals of from one to four months, these swellings were liable to attacks of acute inflammation, preceded by rigor, and accompanied with febrile symptoms, which subsided after three or four days, leaving the tumour nearly as before. These swellings have, however, in one or two instances been known to proceed to suppuration.

As to the *libido inceptibilis* which has been mentioned as one of the features of the disease, a great diversity of sentiment appears amongst the authors who have treated of it. The majority of these (Vidal and Johannis, Baneroff, Niebuhr, &c.) certainly affirm its existence, but Dr. Adams, on the contrary, asserts that the genitals become wasted; or if the disease come on before puberty, their development is interrupted, as seems to have happened in Mr. Lawrence's case, in which the serotum was shrivelled up and the testes were unnaturally small and soft; and in the four cases which fell under Dr. Bateman's notice, both the appetite and the power were lost. Dr. Kinnis, on the other hand, who had still more extensive opportunities of observation, did not meet with this wasting of the sexual organs in a single individual, the testes in males and the breasts in females being always of their natural size; and the venereal appetite usually continued in its natural state. Menstruation is recorded to have been regular in two of the affected females, and a third had lately borne, and was still suckling, two children.

From this want of accord amongst persons who have had abundant opportunity of observing the complaint, we are at least justified in concluding that increased sexual propensities are not amongst the essential characteristics of the disease. It is possible that still more extensive inquiry may reconcile the apparent contradiction amongst authors, and shew that the tendency to disease in the organs of reproduction may be variously modified by climate, or by peculiar local circumstances, which have hitherto escaped investigation. Alterations in the intensity of these feelings is not a very rare occurrence in some cutaneous affections; and it is not improbable that the extension of irritation and of morbid action to the urino-genital mucous membrane may, in one stage of the affection, give rise to their unnatural exaltation, which may yet be followed, at a subsequent period and more advanced stage, by the very opposite state. Pathology affords many analogous instances, in which a low degree and an early stage of chronic irritation in a secreting organ, leads to its increased action, whilst a higher degree of inflammation, or a more advanced period of the disease, often interrupts its functions altogether, and terminates in the atrophy of its structure.

From a careful review of the evidence, both positive and negative, we are forced to conclude that the affection of the mammary and seminal glands, like the femoral tumour, is at most only an occasional complication.

An account of elephantiasis, in some respects differing from that of other writers, has been given by Mr. Robinson, in the tenth volume of the *Medico-Chirurgical Transactions*. According to him, it is one of the commonest diseases in Hindostan; but there are two distinct varieties, and these have been usually confounded together.

In the first variety, which, from the accompanying insensibility, he proposes to call *E. anasthetos*, (the *Barras* of Avicenna and the *Sombharry* of the natives,) there appear one or two circumscribed light-coloured patches, which are shining, wrinkled, and on a level with the surrounding skin. These occur usually on the hands and feet, and are altogether insensible. They spread slowly till the surface of the whole body may be at length implicated, and its sensibility lost. There is neither pain nor itching, and usually no swelling. After a few months the internal functions become deranged, the pulse gets very slow and heavy, "as if moving through mud;" the bowels grow costive, and there is much sluggishness of mind and tendency to somnolence. The skin of the extremities becomes fissured and rough, and ulcers appear under the metatarsal or metacarpal joints, the integuments seeming to be simply absorbed, or sloughing off in successive layers of about half an inch in diameter, without any previous tumour, suppuration, or pain. A sanious discharge ensues, the muscle, pale and flabby, is in its turn destroyed, and joint after joint drops off. Yet the miserable sufferer clings to life, eats voraciously, and crawls about with little but his trunk remaining, till he is carried off at length by diarrhoea or dysentery. Mr. Robinson has never seen the larger joints attacked by it, the nose destroyed, or any bones affected save those of the hands and feet. The tuberculated species may occasionally supervene upon this variety, but they have no necessary or constant connection.

The second species he mentions is the tubercular elephantiasis, which commences in the face by florid semi-transparent shining patches of cuticle; the skin becomes irregularly thickened, and gives a bloated appearance to the face and ears. The arms, neck, chest, and lower part of the trunk, and the legs, become subsequently affected. The skin of the tuberculated parts is not insensible, but is affected with heat and itching. A frequent sense of weight and pain in the head, with a lethargic state of mind, ensue. The pulse is slow and feeble, the voice hoarse, and the bones of the nose and palate often become carious. It is in this species alone, and in its commencement only, that the venereal passion is increased. In the after stages the testicles are absorbed. The fingers and toes do not, at least till a very late period, become at

all numb. Bateman, though his description is in most respects accurate, has, Robinson thinks, in some points confounded these two varieties. The dropping off of the fingers and toes, the insensibility of the skin, and the extreme torpor of mind and body belong to the first; the tubercles, ulceration of the palate, and affections of the cartilages and bones of the face, together with the frequent occurrence of the oblong glandular swelling in the groin, to the second. The mizar, which is so useful in the first species, is injurious in the other; for which last arsenic is the best remedy.

Our knowledge of the morbid anatomy of elephantiasis is still very imperfect, both as regards the state of the skin, and of the subcutaneous cellular membrane. The epidermis is extraordinarily thickened, and the tubercles themselves have by some been described as solid fatty tumours rooted in the true skin, whilst others speak of them as small cysts containing a reddish glutinous fluid. The cutis vera has usually been found inflamed in those spots only, when the tubercles were in a state of relaxation and suppuration. The subjacent muscles and tendons have been, in some instances, observed to be matted together. The immediate cause of death has, in most cases, appeared to be the extension of inflammation to the mucous membrane of the trachea and pharynx, and to the lungs.

As to the causes which give rise to this affection, little is with certainty known. Its origin has been ascribed to want of cleanliness and to unwholesome diet, especially the constant use of bad fish; to long continued exposure to the heat of a tropical sun, by some writers; and to dampness of situation, or occupations requiring the frequent immersion of the limbs in cold water, by others. The number and incongruity of these supposed causes naturally dispose us to attach little credit to any of them. There is strong reason to believe that it is occasionally hereditary. A few instances favourable to the notion of its being propagated by contagion are on record; but, on the other hand, innumerable examples of individuals having been exposed for years with impunity to the closest contact with the diseased, as in the case of husbands and wives, parents and children, &c. throw much doubt on the reality of this mode of origin, and force us to attribute its occasional propagation in a family, either to hereditary predisposition, or to exposure to similar exciting causes, or both.

The disease occurs chiefly in warm climates. Arabia, India, Africa, Madeira, the Isle of France, and some of the West-India Islands, (into which last it is supposed to have been introduced by the slave-trade,) are amongst its chief localities. But northern latitudes do not enjoy a perfect exemption from its ravages, for in Norway and Iceland, elephantiasis, or at least a very similar disease, (*spedalskhed*, *rade-syge*, *liktrea*,) occasionally prevails.—(See Hufeland's *Journal* for October 1819, Henderson's *Residence in Iceland*, &c.)

The *pelagra* of the Milanese territory, the

*rosa asturica* of Spain; the *Crimæan disease* mentioned by Pallas and Gmelin, as occurring in the neighbourhood of Kherson and of Astracan; and the *mal rouge* of Cayenne, are all closely allied to it.

Of the treatment of a disease which is almost always incurable, all that need be said may be comprized in a few words. A mild unstimulating diet, tepid baths, and soothing applications to the skin when in the ulcerated state, are points in the propriety of which all are agreed. The use of sarsaparilla and guaiacum, and of mild alterative doses of mercury with antimony, have, along with change of residence, occasionally produced a temporary amendment,

In the case at the Hôpital St. Louis, to which we have already alluded, though it was in a very advanced stage, considerable improvement was effected by the use of such simple means as the following, viz. confining the patient to a milk diet and mucilaginous drinks, along with minute doses of opium, and baths to allay irritation. This patient was under the care of M. Biett, one of the most enlightened and least exclusive practitioners in Paris; and a great variety of more energetic treatment had previously been employed with no permanent benefit.

All agree that the large employment of mercury aggravates the disease, and this, too, is often the case with arsenic, though in the

form of the Asiatic pills, in which it is combined with black pepper, it enjoys a high reputation among the native physicians in the east.

Bark has been extolled by Dr. Thomas Heberden, in Madeira, and the mineral tonics have been recommended by others. Dr. Schilling, at Surinam, found much benefit from the use of the warm bath, and stimulant vapour baths, spirituous frictions, and gentle exercise; and, in truth, the more frequent occurrence of the disease on the extremities than on the trunk, renders it probable, that it is somehow connected with deficient vitality, or imperfect circulation in the skin of these parts, and justifies the employment of such measures.

From observing a temporary amelioration to take place on the occurrence of an erysipelas, and from the fact that the spontaneous subsidence of each individual tubercle is usually preceded by a degree of inflammatory action, it has been ingeniously proposed by Rayer to excite a slight degree of inflammation in the diseased skin by the use of stimulant applications, such as ammoniacal liniments, tincture of cantharides, ointments containing hydriodate of potass, &c. Should their action prove too irritating, he directs us to alternate their employment with that of the warm bath. With the view of promoting absorption, the internal use of iodine might also be tried.
