## FOREWORD

### The Study

<sup>3a</sup>  
This report is the result of a contract study between the Foreign Agricultural Service, United States Department of Agriculture, and the Institute of Social and Economic Research, University College of the West Indies, Jamaica. The contract was administered by the Western Hemisphere Branch, Regional Analysis Division, Economic Research Service of the Department.

The major objective of the study was to obtain a rational projection of the import demand of the West Indies Federation by 1965 and 1975 for specified and other agricultural products. The contract also specified four subsidiary objectives: (1) Develop long-range projections for the economy, including forecasts of gross national income, etc; (2) estimate aggregate demand for the specified products in 1965 and 1975; (3) determine the magnitude of domestic supplies of these products by 1965 and 1975; and (4) ascertain the extent of import demand for these products by 1965 and 1975 on the basis of long-term supply-and-demand relationships. Analysis was required for the following products: Wheat and wheat flour; corn; rice; other grains, such as oats and barley; sugar and its products; vegetables, including "Irish" potatoes; deciduous fruits, such as apples and pears; citrus fruit; bananas; meat, including poultry; eggs; dairy products; fats and oils; coffee; cocoa; tobacco; and cotton. In addition, other commodities were to be covered if the need was revealed as the study developed. The contract was entered into in May 1960 with the final report to be submitted in a form suitable for publication in 30 months.

At the time the study was undertaken the area covered was the newly formed West Indies Federation which was slated to become a nation within the British Commonwealth. Subsequently, the Federation disbanded with Jamaica and Trinidad and Tobago becoming independent, British Guiana scheduled for independence, and Barbados and the Windward Islands (Grenada, St. Vincent, St. Lucia and Dominica) and the Leeward Islands (Antigua, St. Kitts, Nevis, Anguilla, and Montserrat) remaining as British Dependencies.

The area under study represents a small but important and rapidly growing market for U.S. agricultural exports. Such exports totalled \$20.7 million in 1958 and reached \$30.5 million in 1962, an increase of nearly 50 percent. U.S. agricultural exports to the area in 1962 represented 7 percent of the total for Latin America.

## Study Report

The views expressed and the accuracy of analysis in this report are those of the Institute, and do not necessarily reflect concurrence by the United States Department of Agriculture. The published report is essentially in the form that it was submitted, editing having been done by the Department under an understanding with the Institute that only substantive changes would be submitted for their review.

The final report was received in December 1962. However, it was not accepted until December 1963 pending receipt of working papers and the required analysis on cotton. Extensive editing of the final report was required due to numerous inconsistencies, largely statistical. This problem apparently stemmed in part from the report's being largely a summary of 18 working papers by various research team members. The final report content met major and subsidiary study objectives and included required product analyses.

In editing, British spelling and style have been retained. All tonnage figures are in long tons (2,240 pounds) unless otherwise designated. Generally, in the tables, N. A. means not available and dashes are used to indicate zero. Monetary conversion rates are J£1 = U. S. \$2.80, and BWI\$1 = U. S. \$0.583.

PROJECTED LEVELS OF DEMAND, SUPPLY, AND IMPORTS OF AGRICULTURAL PRODUCTS OF JAMAICA, TRINIDAD AND TOBAGO, LEEWARD ISLANDS, WINDWARD ISLANDS, BARBADOS, AND BRITISH GUIANA, TO 1975

*Part One*

INTRODUCTION AND SUMMARY

Chapter 1

INTRODUCTION

Purpose of study

The purpose of this study is to project the long term supply of and demand and import demand for agricultural commodities in the West Indies. We have made projections of demand and supply for sugar and sugar products, rice, bananas, citrus fruits, root crops, vegetables, corn and cornmeal, pulses, beef, mutton, pork, goat mutton, poultry meat, eggs, milk, fats and oils, and cotton. We have projected demand only for wheat and wheat flour, apples, pears and grapes, tinned and salted meat, tinned fruit and vegetables and cheese (which commodities are not produced in any important quantities in the West Indies) and supply only of cocoa, coffee and tobacco products for which demand is small or for which appropriate demand data were not available.

Having made separate projections of demand based on estimated income elasticities, income and population growth, and projections of supply based on expected changes in acreages and yields, we have arrived at projections of import demand and amounts available for export.

Period of study

The projections relate to the years 1965, 1970, and 1975. The base year chosen for most purposes was 1958, the year for which the most comprehensive data were available. It should be emphasised that this study does not purport to make short term projections, the techniques for which are rather different than those for long term projections.

Area covered

The area which we have covered in this study includes Jamaica; Trinidad and Tobago; the Leeward Islands (Antigua, St. Kitts-Nevis-Anguilla, and Montserrat), Windward Islands (Grenada, St. Vincent, St. Lucia, and Dominica) and Barbados; and British Guiana. At all stages of the study we have considered these as four separate territories.

When this study was started in 1960, the first three of these territories were formed into a federation. In 1961 Jamaica and then Trinidad and Tobago elected to withdraw from this federation. At the present time the Leeward Islands, Windward Islands and Barbados are endeavouring to form a federation of those islands of the British Lesser Antilles. 1/

---

1/ The federation had not been formed at the time this publication goes to press.

When we refer to the West Indies, we include all four territories under review. It is considered, however, that as a national unit, the West Indies is now meaningless, and although in some of our tables and charts we have aggregated the territorial data we have not made projections of main tables for the West Indies as one country. Present trends indicate that the four territories will tend to diverge more as they become independent sovereign states. These differences may influence not only importing and exporting policy but the very structure of the economy. (For instance the trend in British Guiana seems to be toward an economic and social structure different from that in Jamaica and Trinidad and Tobago.) The continued dependence of the Leeward Islands and Windward Islands on external assistance also must influence the policy and structure of the territories. As the study has continued, we have increasingly felt that an aggregation of all territories in the final results would not be very valuable and have therefore presented our information as for four separate national entities, except in the summary tables and charts.

### Method of the study

Details of the methods employed are found in the relevant parts of the study and it is not intended to detail them here. We should perhaps explain briefly at this point the general approach to the study.

Part two presents an account of the projected growth of population and of income product and expenditure. The population projections were made especially for this survey but are provisional pending the results of the 1960 census. A description of the method of projecting is given in part two, chapter 1.

The national income projections in part two were made especially for this study and although for Trinidad and Tobago and Jamaica base period figures were available, these also had to be compiled for British Guiana and most of the smaller islands.

The method of projecting national income follows from that adopted in the West Indies. The method is fairly standard for the various territories, as much of the work has been coordinated in past years by the Institute of Social and Economic Research in the University of the West Indies. However, certain developments appear in this study: One is the projections themselves, since no projections have previously been completed for any of these territories; the second is the considerable use that has been made of input-output tables which have not previously been widely used in this region. We consider that these tables are not only desirable but absolutely necessary for projections, since it is only through such tables that the effects of various assumptions in the entire economy can be gauged. For Jamaica and Trinidad and Tobago, input-output estimates have been projected for the relevant years, and for British Guiana, a base year matrix and inverted matrix have been presented from which any number of different projections can be made.

The methods used in making demand projections are described in part three. In general the method has been to arrive at income elasticities by using budgeting surveys covering different income groups at one period and also by relating consumption trends in the past to income trends. Base year food budgets were available for Jamaica and Trinidad and Tobago but it was necessary to compile them for this study for the Leeward Islands, Windward Islands and Barbados, and for British Guiana. All data were expressed first on a per capita basis, and then projected income and population indicators were

applied to obtain final demand total. No previous studies of this kind had been done in the West Indies and all the data presented in part three was gathered particularly for this study.

On the supply side, studies of supply conditions for various commodities provided most of the raw material for part four. In general the method was to take into account all factors likely to influence acreages and yields, and to project total supplies on the basis of these findings. Naturally a great number of factors of an economic, technical, and physical nature were taken into consideration and our methods of treating these is explained in part four.

In reconciling demand and supply and arriving at import demand we have assumed a constant price relationship between products as a first assumption. Where a product is mainly imported or is produced for export as with sugar and citrus we have generally assumed supply to consumers will be elastic and no considerable changes in price relationships are likely. We have had to make an exception in the case of bananas, where domestic supplies tend to be a residual from exports rather than exports a residual after domestic needs have been met, and have predicted that price adjustments will follow from discrepancies between demand and supply projections. As regards commodities produced mainly for local consumption, we have also predicted price adjustments rather than importations to meet a deficiency between demand and supply, particularly for certain roots and vegetables and fresh milk.

Only for population have we presented two possible projections, but we have only used one throughout the study. It would be possible for us to present any number of projections of the important indicators based on different assumptions regarding income growth, population growth, demand changes and supply changes. We do not favour a method of presentation which proliferates the number of alternative projections and we feel that to present two projections would in most cases emphasise maxima and minima rather than the "average" or most probable course of events. Our technique has been to present one set of what we feel to be the most probable projections, at the same time discussing the modifying influences which certain different assumptions are likely to have on them and in particular we have endeavoured to present our information in such a way that, if proper mechanical equipment becomes available, alternative major assumptions can easily be fed into the base model.

One point which must be mentioned here since it had some influence on our method is that the West Indies is at the moment very much at cross roads as regards its economic future. For most territories the fast tempo of economic advance experienced in the 1950's had already slowed down by 1958 and many of the major trends of the fifties have not been continued into the sixties. This has made it almost impossible to project straight line or curvilinear trends solely from past trends. In fact the economic situation has been such as to discourage the use of purely mathematical relationships and to encourage the assimilation of empirical observations into our general conclusions, and this we cannot help but feel has been of great benefit to the study.

## The importance of agriculture in the West Indies economy

The area is underdeveloped in that per capita income is low, unskilled agricultural labour is the main activity, productivity is low and capital is deficient; also some skills still have to be imported. All these conditions are, however, not of the lowest that can be found, even in the Western Hemisphere, and Table 1 (see appendix) indicates the position which the West Indies occupies in the Americas, in terms of per capita income.

These characteristics are found in all parts of the West Indies. Other characteristics, which are not common to all underdeveloped countries, are that land is a relatively scarce resource and unskilled labour a relatively plentiful one. Agriculture, although important, is not as important as in many underdeveloped countries. In 1959 the export agriculture, sugar cane growing, domestic agriculture, and livestock and fishing sectors contributed about 15 % to the gross domestic product of Jamaica (see Table 3b). In the same year the agriculture sector accounted for 12.5 % of the gross domestic product of Trinidad and Tobago (see Table 4c). In 1960 the export agriculture and other agriculture sectors contributed about 38.5 % to the gross domestic product of the Leeward Islands, Windward Islands and Barbados (see Table 5b). In British Guiana that year the agriculture and the livestock, forestry, and fishing sectors accounted for about 27.2 % of the gross domestic product (see Table 2.5.ii). With the exception of the Leeward Islands, Windward Islands and Barbados the industries included in each sector are shown in the explanatory note for part two.

Trinidad and Tobago's main industry is oil mining (production) and refining, and in Jamaica and British Guiana, the mining industries (bauxite and alumina) contribute very considerably to the economies.

Another characteristic of this region is that although it is underdeveloped, the cash economy is advanced, and the non-market sector is smaller than in many countries of equal living standards. This sector varies, however, from territory to territory and is estimated at about 12 % of the gross domestic product in the Windward Islands and about 2 % in Trinidad and Tobago. Even in the Windward Islands it is a low proportion as compared, for instance, with countries of Africa where it may reach 65 % of the gross domestic product.

Trinidad and Tobago is the most prosperous and developed of the areas with which we are concerned (see tables to part two). Jamaica has the next highest per capita product, Barbados and British Guiana are probably comparable in terms of real income and in all these territories the price level is rather lower than that for Jamaica; finally the Leeward Islands of St. Kitts and Antigua are slightly more prosperous than Montserrat and the Windward Islands. These last territories approximate more to the accepted model of undeveloped territories.

Sugar is the most important agricultural industry in the West Indies and it has been estimated that it provides a living for about three quarters of a million people, including dependents of workers. Sugar is grown in Jamaica where it contributes 6.0 % of the gross domestic product; in Trinidad and Tobago where it contributes 3.0 %; in British Guiana where it contributes 17.0 %; in Barbados where it contributes 28 %; and in the Leeward Islands where it contributes 26 %. Cane is grown by peasants and estates but the latter account for practically all the production in British Guiana and St. Kitts.

Rice is an important product for British Guiana although it is grown in Jamaica and Trinidad and Tobago on a smaller scale. Rice is grown on farms averaging 10 to 14 acres in British Guiana and there are a large number of very small producers.

Bananas is the second most important crop to the West Indies as a whole and is grown for export in Jamaica, the Windward Islands, and Trinidad and Tobago. Although it is sometimes grown by estates it is mainly associated with peasant cultivation.

The other main export products are citrus, grown and processed in Jamaica, Trinidad and Tobago, and Dominica, although smaller quantities are exported from St. Lucia, Grenada and British Guiana; coffee, grown on a rather smaller scale in Jamaica and Trinidad and Tobago; and coconut products, exported mainly for the interterritorial trade. Spices are important in Grenada and are also of some significance in Jamaica. All these crops except coconut are produced mainly by small growers. Although estates account for a significant part of the total product and acreage, the largest number of growers is found in the smaller size groups. Sea island cotton is grown on any important scale only in St. Kitts-Nevis-Anguilla, Antigua, Montserrat and St. Vincent. It is declining in importance but is still the main crop in Montserrat and Nevis. All export agriculture, excluding sugar, accounts for 2.3 % of the gross domestic product in Jamaica, 2.2 % in Trinidad and Tobago and 9.4 % in the Leeward Islands, Windward Islands and Barbados. In British Guiana there are no important export crops other than sugar and rice, both domestic and export accounting for 4.6 % of the gross domestic product.

Great difficulties have been experienced in measuring exactly the scale of domestic food crop production in the West Indies and all figures must be treated with reserve. These crops are of course grown in all territories and are wholly peasant produced. The proportion which they contribute to the gross domestic product is approximately 4 % in Jamaica, 5 % in Trinidad and Tobago, 7 % in the Leeward Islands, Windward Islands and Barbados, and 4 % in British Guiana.

Livestock production has until recently always been mainly a peasant undertaking except for cattle ranching in British Guiana. Recently there has been a trend toward larger units, particularly in poultry and egg production and in beef production in Jamaica. The livestock population of the West Indies is fairly large, related to both human population and land area. All territories produce these products and peasant producers still predominate. The proportion contributed to the gross domestic product is approximately 1.9 % in Jamaica, 1.8 % in Trinidad and Tobago, 2.1 % in Leeward Islands, Windward Islands and Barbados and 3.2 % in British Guiana.

The above remarks indicate that although the West Indies is mainly a primary producing area, the importance of agriculture is not as great as in many countries of a similar stage of development.

### External factors

As this study progressed, the external factors influencing the economic relationship between the various territories and each other and their relationship with the outside world underwent considerable changes. With the break up of the West Indies federation the plans for a customs union were immediately and indefinitely shelved. Two independent

nations, Jamaica and Trinidad and Tobago, appeared on the scene and positive steps are being made toward the independence of British Guiana and a federation of the Leeward Islands, Windward Islands and Barbados.

But inter-Caribbean trade in agricultural commodities is small and indeed is significant only for rice and coconut products. Agriculture in the West Indies is far more likely to be affected in the future by external factors, particularly the consequences of Britain joining a common market in Europe.

It was not within the scope of this study to make a detailed examination of external markets for the main export products. It has, however, become increasingly apparent that changes in the trading relationships of those countries that are main customers of the West Indies may well involve alterations in our projections, and that further study of the effect of the European Common Market should be made when the conditions of Britain's entry into this are more clearly specified.

## Chapter 2

### SUMMARY OF RESULTS

#### The long term growth of the economy

Population. Two simple projections are offered as provisional estimates pending final fertility and mortality tables from the 1960 census.

At the 1946 census the population of the West Indies territories under review was 2,776,056; in 1960, according to the census of April 1960, it was 3,669,528, an increase of 32.18 %.

The first projection was based on the fitting of an exponential function to the data for 1946 and 1960. A growth rate of 1.994 % per annum was derived. This projection gave total population figures for the West Indies as a whole of 3,669,528 in 1960, 4,054,900 in 1965, 4,480,100 in 1970 and 4,949,800 in 1975. 1/ The results by territories are shown in Table 1.2.i.

Table 1.2.i

Estimates by territories of population used in this survey, 1960 and projections

Territory	1960	1965	1970	1975
Jamaica	1,613,148	1,744,400	1,886,500	2,040,100
Trinidad and Tobago	827,957	953,290	1,097,600	1,263,800
Leeward Islands, Windward Islands and Barbados	669,654	719,610	774,010	832,130
British Guiana	558,769	646,530	774,400	858,340
Total	3,669,528	4,063,830	4,502,510	4,994,370

The first projection assumes that the rate of migration will approximate that during 1946-60; a second projection is presented which extracts from the data the influence of

1/ The small discrepancy found between these totals and those in Table 1.2.i is due to approximation in the aggregation and the territorial rates.

migration and presents figures which are based purely on natural growth rates. The results from this projection are that the population totals 3,669,528 in 1960, 4,186,850 in 1965, 4,778,300 in 1970 and 5,451,610 in 1975.

In our projections of demand we have utilised the first population projections, which estimates approximately a continuation of the present trend in population growth. The territorial breakdown of population for this projection is shown in Table 1.2. i.

Jamaica. We briefly examined the economic growth of Jamaica between 1950 and 1960 and concluded that growth had been at an unusually high rate. This high rate was mainly a result of the emergence and development of the bauxite alumina industries and is unlikely to continue. In spite of the high rate of growth in the economy as a whole, agricultural sectors showed only a moderate rate of growth in the past decade and we consider that there will be little change in growth rates of the agricultural sectors. We predict that the share of agricultural sectors will decrease from 16.3 % of the gross domestic product in 1958 to 12.3 % in 1975 (Table 3b).

The average growth rate at constant factor cost was 8.8 % per annum in real value for the period 1954-59. We are unable to predict so high a growth rate for the future but allowing also for population change we have projected a real per capita annual growth rate of 3.7 % between 1958 and 1965, 3.5 % between 1965 and 1970 and 2.8 % between 1970 and 1975. Totals of gross domestic product and national income are shown in Table 1.2. ii.

Trinidad and Tobago. In current prices the gross domestic product (GDP) increased by 156 % between 1951 and 1959. During this period agriculture declined in importance from 18.0 % of the GDP to 12.5 % of the GDP (excluding sugar manufacturing).

In Trinidad and Tobago expansion of the economy has been more dependent on investment in the oil industry than on any other single factor. Although some slowing down in this investment is predicted, it is felt that in general the economy of Trinidad and Tobago will continue to grow at rates approximating those of the past decade and a growth of 135 % is predicted between 1959 and 1975. The aggregates are shown in Table 1.2. ii.

Leeward Islands, Windward Islands and Barbados. In this territory we predict a very slightly greater rate of growth than that which we believe has prevailed in the past decade (although details are not available of past growth rates for all territories). This prediction arises partly from the fact that this territory is at a lower stage of development than other territories and partly from the result of an economic union which is expected to take place between these territories. The growth rate that we have predicted works out at about 2.8 % per annum at constant prices between 1960 and 1975. We expect a decline in the importance of agriculture from about 42 % in 1960 to about 29 % of gross domestic product in 1975. This results from the expected growth of tourism and allied services and some manufacturing mainly in Barbados. The aggregates are shown in Table 1.2. ii.

British Guiana. Although the national income (in current prices) doubled between 1950 and 1960, there was virtual stagnation in the periods 1954-55 and 1957-59, and the spectacular growth in 1956-57 and 1959-60 was due mainly to expansion in the bauxite industry. Very few new industries were introduced and the structure of the economy, with its heavy dependence on sugar and bauxite, altered little in the 1950's. Little change in economic

conditions in British Guiana is predicted and a sectoral growth of 58 % between 1960 and 1975 (at constant prices) is predicted. The importance of agriculture in the product decreases from 26.7 % in 1960 to 20.6 %. In Table 1.2. ii the aggregates are shown in total and per capita form.

Table 1.2. ii  
Projected growth of the West Indies economies

Indicator and territory	1965		1970		1975	
	Total	Per capita	Total	Per capita	Total	Per capita
	Million BWI\$	BWI\$	Million BWI\$	BWI\$	Million BWI\$	BWI\$
<b>Consumption by persons:</b>

Total	3,207	789	4,019	892	4,636	928

#### Long term projections of demand

The final demand has been projected for the food groups cereals, sugar and sugar preparations, roots and starchy vegetables, vegetables and pulses, fruit, meat, fish, milk and milk products, eggs, oils and fats, and cotton. The average income elasticities for the various territories under consideration, viz, Jamaica; Trinidad and Tobago; the Leeward Islands, Windward Islands and Barbados; and British Guiana, have been estimated for 1958 at 0.45, 0.30, 0.45 and 0.30, respectively.

The per capita consumption of food and total demand for future years have been arrived at on the basis of projected income and population growth. The calorie consumptions per capita per day obtained from above show increases during the period 1958 to 1975, from 2,111 to 2,635 for Jamaica, 2,533 to 3,024 for Trinidad and Tobago, 2,040 to 2,445 for the Leeward Islands, Windward Islands and Barbados and 2,200 to 2,254 for British Guiana. The protein and fat contents, for Jamaica only, go up from 56 and 34 grams, respectively, in 1958 to 70 and 47 grams in 1975 (Table 8).

A summary of the results of our demand projections are shown in Table 1.2.iii.

Table 1.2.iii

Projected summary of amounts demanded, all territories

Commodity	1965	1970	1975
	Million pounds		
Cereals	963	1,112	1,273
Sugar and preparations	339	391	443
Roots and starchy vegetables	782	865	955
Vegetables and pulses	306	358	416
Fruit	856	1,096	1,269
Meat	154	185	219
Fish	159	184	208
Milk and milk products	285	341	593
Eggs	39	50	53
Oils and fats	110	128	149
Cotton	4	5	6

Long term projections of supply

Examining the economic resources of the West Indies, we found that land was likely to be the main limiting factor. All regions have a high population density except for the island of Dominica and British Guiana; although more land could be brought into use in these two places, a rugged topography and poor soils impose limits on possible development in these places where population pressure does not appear to be high.

Although there can be some substitution between products, we also noted that for many crops the type of land, site factors and climate limit the crops that can be grown. Much land which can grow bananas is too steep for sugar; much of the acreage under coconut production cannot grow other crops, and so on; so that although substitution is possible in better land, much land is most suitable for specified crops.

Although figures of acreage are unreliable, we found considerable increases since 1946 in areas under export crops, particularly sugar and bananas, for which crop output more than doubled. We found however a slowing down of the rate of increase of production after 1957, and very little growth in output of export crops after that date as compared with the earlier periods.

We show in Table 1.2. iv the projected acreage in cropland for the period under review. Actual limits in the supply of good agricultural land result in projections of a very modest size.

Table 1.2. iv

Projected acreage of cropland, by territories

Territory	1965	1970	1975
	1,000 acres		
Jamaica	681.6	683.2	685.2
Trinidad and Tobago	355.5	365.8	363.6
Leeward Islands, Windward Islands and Barbados	320.0	340.0	363.0
British Guiana	458.6	488.6	497.3
Total	1,815.7	1,877.6	1,909.1

In projecting the acreages for sugar, the trend since 1950, which was less steep than the trend since 1940, was given some weight; but for almost all other crops, particularly tree crops, planting programmes and available land were the main criteria of projecting acreage increases.

We conclude that, given the characteristics of the high population density in relation to land resources, there will be considerable pressure in the West Indies for industrialisation and urbanisation and emigration on the one hand, and for increasing yields on the other. Population pressure may tend to depress yields by the cultivation of marginal and sub-marginal land resources; but we believe that the latter will be of importance in the future period with which we are concerned. The factors which will probably be of most importance in increasing yields are better breeds of plants and livestock and reduction of disease.

Economic factors are also important, but in the West Indies one of the main cost problems, low labour productivity, is difficult to remedy. It is also probably unfortunate but true that so long as labour is plentiful and land is scarce, capital will tend to be spent rather on improving productivity per acre than per man.

As a result of our consideration of acreages and yield factors we project the total supplies of commodities. These are summarized for main commodities in Table 1.2. v.

It will be noted that the rates of growth of production are not high except possibly for cocoa; the growth rate for this product is approximately comparable to that experienced by bananas and sugar in the period 1948-60. The products for which the least expansion is predicted are root crops, sea island cotton, corn and pulses.

Reconciliation of demand and supply and import demand

The reconciliation of demand and supply figures produced data on import demand for those products that are partly locally produced and partly imported. Import demand information for commodities that are wholly imported are derived from the demand table. Import demand is shown in summary form in Table 1.2. vi.

Table 1.2. v

Projection of total production of main commodities, all territories

Commodity	Unit	1965	1970	1975
Sugar	million pounds	2,913	3,279	3,595
Bananas	do.	993	1,101	1,146
Rice	do.	471	561	607
Sea island cotton	1,000 pounds	989	739	734
Copra	1,000 tons	49	52	58
Cocoa	million pounds, dry	35	53	72
Citrus	million pounds	656	725	947

*Part Two*

*GROWTH OF THE ECONOMIES*

Chapter 1

TWO PROJECTIONS OF THE POPULATION OF THE WEST INDIES  
BETWEEN 1965 AND 1975

In April 1960, a population census was taken throughout the West Indies. Since fertility and mortality tables from which more scientific projections could be made are not available, we propose to offer two very simple projections as to the probable levels of the population of the West Indies between 1965 and 1975. It cannot, however, be too strongly stressed that the projections offered in this paper are at best highly provisional and are not intended to be used as more than provisional first estimates.

According to the 1946 census, the population of the West Indies in 1946 was 2,776,056. The census taken on 7th April, 1960, showed that the population of the area had increased to 3,669,528, an absolute increase of 893,472 in 14 years or an intercensal increase of 32.18 %.

The individual breakdown of these two census figures is shown in Table 2.1.i.

Table 2.1.i

Census population, by territories, in 1946 and 1960

Territory	Census	
	1946	1960
Barbados	192,800	232,085
Jamaica	<u>1/</u> 1,295,476	1,613,148
Trinidad and Tobago	557,970	827,957
Windward Islands	251,776	314,649
Leeward Islands	102,333	122,920
British Guiana <u>2/</u>	375,701	558,769
Total	2,776,056	3,669,528

1/ Estimated as at 31st March, 1946, by the Department of Statistics. Jamaica was the only one of the above territories which did not take a census in 1946. Her census taken on 4th January, 1943, recorded Jamaica's population at 1,237,063.

2/ Including Amerindians.

Between these two census years the annual end-of-year population for each of the different territories in the area has been estimated by various official sources as in Table 2a.

Comparing on an overall basis the figures in Table 2a with those given in Table 2.1.i, we notice that the 1960 census figure of 3,669,528 is less than each of the end-of-year estimates since 1957. The discrepancy between the 1957 end-of-year estimates and the 1960 census is 14,859 and by 1959 it rises to 93,942. There are several reasons for this, but perhaps the most important is the method of computing the annual end-of-year population estimates.

Briefly, they have been derived by taking the previous year's population estimate for a particular territory and adding to it the net increase due to the excess of births over deaths, and deducting or adding, as the case may be, net migration for the particular year. So the end-of-year population for any territory in 1950, say, would be computed as follows:

$$\text{End-of-yr. pop. (1950)} = \text{End-of-yr. pop. (1949)} + \text{Net Incr. 1950} \pm \text{Net Migrn. 1950.}$$

The individual estimates for each territory are then aggregated to derive the overall total for the area for that year.

This method of computing the end-of-year estimates suffers from one very obvious and basic defect. If the original base of the estimate is wrong or overestimated, as is the case for some of the territories, then the end-of-year estimates will be out. Naturally, the error becomes cumulative as we derive end-of-year estimates for any considerable period of time. It would appear, therefore, from the figures given in Table 2a that most of the territories have been consistently overestimating their end-of-year population. So if we are to avoid making the same mistake of using inflated base estimates for future years, it is necessary to strike out with some new estimates which start from a proper base. It should be noted, however, that population figures quoted for years previous to 1960 in any part of the text, are the official year end figures.

Data at present available from the 1960 census allow us to attempt only the simplest projections. We offer two projections which are based mainly on information from the 1946 census and such information from the 1960 census as is available.

### Projection 1

The assumptions underlying this projection are quite simple and unsophisticated. From the figures given in Table 2.1.i we know that the population of the area increased from 2,776,056 in 1946 to 3,669,528 in 1960, an intercensal period of 14 years. If we assume that the census population of 2,776,056 in 1946 increased by some constant rate of growth which, when compounded on an annual basis, would give us the census population of 3,669,528 for 1960, then we can derive a natural exponential function of the form  $y = ae^{tr}$ , where  $a$  is a constant,  $e = 2.71828$ , the base of the natural log,  $t = 14$ , the number of intercensal years and  $r =$  the annual compounded rate of growth.

Substituting, we have

$$\begin{aligned}
 2,776,056 e^{14r} &= 3,669,528 \\
 e^{14r} &= \frac{3,669,528}{2,776,056} = 1.32185 \\
 14r &= \frac{\log_{10} (1.32185)}{\log_{10} (e = 2.71828)} = \frac{.12123}{.43430} \\
 r &= \frac{.12123}{6.08020} = .019938
 \end{aligned}$$

which gives us an exponential rate of growth for all the territories of 1.994 %, to three decimal places, over the intercensal period 1946 to 1960.

If we further assume that this constant annual rate of growth of 1.994 % will continue up to 1975, we are able, by fitting an exponential curve to our data and extending it to 1975, to derive estimates of the population between 1965 and 1975. These estimates are shown in Table 2. 1. ii. We have also included in Table 2. 1. ii estimates of the population of the area in 1958 as this is the year on which most of our analysis is based.

Table 2. 1. ii

Estimates of the population of the West Indies, 1946, 1958, 1960, and projections. Projection 1

Year	Projection 1
1946	2,776,056
1958	3,526,600
1960	3,669,528
1965	4,054,900
1970	4,480,100
1975	4,949,800

From these figures we see that the population of the West Indies is expected to increase from 3,669,528 in 1960 to 4,054,900 in 1965, to 4,480,100 in 1970 and to 4,949,800 in 1975. This increase is derived from an average rate of growth of 1.994 %, which is not unreasonable for the area as a whole. It is also possible to derive individual growth rates for each territory.

On the same assumption that the population of each territory increased from its 1946 census to its 1960 census figure by some constant annual compounded rate, we are able to derive the individual growth rate for each territory in the same way we derived the average growth rate for the area as a whole.

Using the same equation  $y = ae^{tr}$  the individual rates of growth calculated to three decimal places are shown in Table 2. 1. iii.

Table 2. 1. iii

Rates of growth of the population of the West Indies, by territories,  
between the 1946 and 1960 censuses

Territory	Annual compounded rate of growth
	Percent
Barbados	1.325
Jamaica	1.566
Trinidad and Tobago	2.819
Windward Islands	1.592
Leeward Islands	1.309
British Guiana	2.849

Using these individual growth rates we can calculate the population for each territory between 1965 and 1975 and by aggregating the results derive an overall estimate for the area as a whole. These individual estimates are shown in Table 2b. For purposes of comparison and ease of reference we have also included in Table 2b derived estimates for each territory for the intercensal years on the basis of the growth rates shown in Table 2. 1. iii.

When we calculate the individual growth rates and aggregate the results we get estimates which are in excess of those obtained from using the average growth rate. (Compare Table 2. 1. ii with Table 2b.) In absolute terms this difference runs from 8,930 in 1965 to 44,570 in 1975. While this difference may appear significant when expressed in absolute terms, it is less than 1 %. This margin of error is undoubtedly due to approximations in calculation as well as the compounding of the individual growth rates and is not statistically significant enough to disturb our projections.

Another useful comparison emerges between the totals shown in Table 2a and those in Table 2b over the intercensal years. In each year the end-of-year estimates given in Table 2a exceed our derived estimates given in Table 2b. The difference in 1947 was a little over 57,000 and by 1959 it had increased to 166,300, nearly three times its original size. This difference can be taken as being indicative, but only roughly so, of the extent of overestimation in the figures given in Table 2a.

Reverting to Table 2. 1. iii, the important point about this table is the different rates of growth which the various territories show. These vary from 2.849 % and 2.819 % for British Guiana and Trinidad and Tobago, respectively, to 1.325 % and 1.309 % for Barbados and the Leeward Islands, respectively.

This variation in the growth rates can be explained by the fact that Barbados and the Leeward Islands, which are traditionally noted as emigration centres, have the lowest rates of growth, whereas Trinidad and Tobago, which has consistently attracted migrants from the Windward Islands, has the highest growth rate. This is not, however, the whole story. Emigration from Barbados and the Leeward Islands has usually been to places

outside the West Indies, that is, to places which are not included in our analysis, and the people who emigrate from these islands very seldom intend to return home except after some extended duration. Hence they are, in a sense, lost to the area.

In the case of Trinidad and Tobago, migrants have always been attracted to it from the Windward Islands. They are not really lost to the area since they do not leave the West Indies. They therefore influence the differential rates of growth by shifting from one area to another. The point which emerges from this very brief treatment seems therefore to be that the different rates of growth registered in Table 2.1.iii are influenced more by migration (whether intra- or extra-West Indies) than by differences in the rate of natural increase for the various territories.

This leads us to the very important question of migration and its probable effects upon our projections. Past trends of migration are hardly the best indicator of the future pattern of migration since the factors which operated in the past may not operate in the future. Further, the amount of migration which takes place in any one year depends on such factors as job opportunities both in the losing and receiving countries, financial resources of the prospective emigrants, family commitments and social ties, to name only a few of the factors. All of these make it extremely difficult to hazard any estimates of the future levels of migration. Nevertheless it is possible within broad limits to discuss the problem of migration in general terms and in the light of present events come up with some rough estimates.

Table 2c shows the net migration from each of the individual territories between 1946 and 1960. Although some years are missing for some of the smaller territories, especially the Leeward Islands, the overall pattern is sufficiently clear cut for our purposes. In any case the available data suggest that the most that those missing years would do would be to accentuate the trend. We see that between 1946 and 1949 the West Indies were on balance net receivers of migrants, that is, arrivals exceeded departures. We notice too that this inflow of migrants quickly dried up in 1949 and gave way to a net outflow in 1950. The chief reason for the inflow between 1946 and 1949 would appear to be the return home of many West Indians after the war.

But starting in 1950 there was a definite outflow of migrants, which steadily gained momentum throughout the fifties. From over 1,000 in 1950 the stream increased to about 40,000 by 1960, if we include an estimate for those islands for which data are not available. Our present analysis does not allow us to go beyond the bare outline of the problem and consider the migration from each territory individually, but we see from Table 2c that the amount of migration from the West Indies throughout the fifties was mainly influenced by migration from Jamaica. The heavy outflow of migrants from Jamaica was directed mainly to the United Kingdom. As a matter of fact, practically the whole stream of West Indian migration in the fifties was to the United Kingdom. The stream continued unabated or rather at an accelerated rate between 1960 and 1962 when the United Kingdom Government imposed certain immigration restrictions upon Commonwealth immigrants. We do not have data to indicate the volume of migration which took place from the West Indies to the United Kingdom between 1960 and July of 1962 when "the ban" was imposed, but informed opinion seems to incline to the view that the volume was about double that in 1959. What we do know however, is that "the ban" has practically dried up the stream of emigrants from the West Indies seeking to enter the United Kingdom. So over the next

few years the volume of migrants leaving the West Indies will be considerably reduced and this will continue until alternative outlets present themselves.

Assuming that no alternative outlets for emigration present themselves to the West Indians over the next three or four years, that is between now and 1965, we can expect the volume of emigration to fall to approximately what it was in the very early fifties. If we assume further that the mounting population pressures operate to open up other countries to West Indian immigrants after 1965, and that the movement takes a few years to get into high speed, we can visualise the volume of migration at the end of the sixties and early seventies as comparable to that of the late fifties and early sixties. What we are in effect assuming is that the volume of migration in the late sixties and early seventies will be about the same as that of recent years before "the ban" was imposed. The assumptions which we make about migration in Projection 1 are therefore that the past rate of migration will on balance be about the same for the years of our projections and that the accelerated rate of recent years will repeat itself after eight to ten years when "the ban" has worked itself out and sufficient internal population pressures have been built up to necessitate another wave of migration from the West Indies.

In conclusion therefore, we see that the main factors which have determined the rate of growth of the population of the area offered in Projection 1 are (1) the rate of natural increase and (2) the volume of migration, both of which are compounded annually in our calculations. And in so far as it is possible to estimate migration, we have tried to build it into our projections by compounding its past influence. We offer Projection 1 therefore, as our estimate of the minimum expected levels of population for the area between 1965 and 1975 on the assumption that the rate of growth of the population will remain constant at 1.994 % compounded annually, and that the rate of natural increase, though increasing, will tend to be counter-balanced towards the end of our period by an accelerated rate of migration. In short, the rate of natural increase and the volume of migration will tend to offset each other at the overall rate of growth of 1.994 % compounded annually for the area. In applying population growth to income growth, we have favoured this projection. However, we present an alternative.

## Projection 2

The basic assumption underlying our estimates offered in this projection is that there will be no migration out of or into the West Indies over the period of our projections. In other words, whatever increases there are in the population of the area will be due solely to the rate of natural increase or the excess of births over deaths. So whereas in Projection 1 we estimate the minimum expected levels of population of the area based on the two main variables of the rate of natural increase and the annual volume of migration, in Projection 2, Table 2.1.iv, we estimate the maximum expected level of the population on the basis of natural increase alone. Assuming, therefore, that there is no migration and that the population of each territory increases over the period of our analysis by the same average rate of natural increase as for the last ten years, we derive the estimates shown in Table 2.1.iv. In other words, we are assuming that the future rate of natural increase for each territory will be the same as its own average rate for the last decade compounded annually. In the case of the Windward Islands and the Leeward Islands, available data did not permit us to go beyond the average rate of increase for the last five years, so that whereas the rate for the larger territories is the average for the period 1950-59, that used for the Leeward Islands and the Windward Islands is for 1955-59.

Table 2. 1. iv

Estimates of population of the West Indies by territories, 1960 and projections, and average rate of natural increase 1950 through 1959. Projection 2

Territory	Average rate of natural increase 1950 through 1959	Census population 1960	Projection 2		
			1965	1970	1975
	Percent	Number	Number	Number	Number
Barbados	2.03	232,085	256,610	283,710	312,370
Jamaica	2.52	1,613,148	1,827,300	2,069,900	2,343,600
Trinidad and Tobago	2.75	827,957	948,660	1,087,200	1,245,700
Windward Islands	<u>1/</u> 3.07	314,649	365,980	425,710	495,190
Leeward Islands	<u>1/</u> 2.40	122,920	138,350	155,770	175,370
British Guiana	3.07	558,769	649,950	756,010	874,380
Total		3,669,528	4,186,850	4,778,300	5,451,610

1/ Average for 1955-59.

What we have in effect done is simply to apply the average 1950-59 rate of natural increase compounded annually for each territory to its 1960 census figure to get estimates of 1965 to 1975.

Comparing these estimates with those in Table 2b we see the disparity is quite substantial but we feel that the two projections offered are sufficiently indicative of the probable upper and lower limits of the population of the area to be useful for our purposes. So whereas we offer Table 2b as the minimum level, we use Table 2. 1. iv as the expected maximum level of the population of the West Indies between 1965 and 1975.

One final point which may perhaps lend cogency to our argument on migration is the inverse movement of the figures for Trinidad and Tobago. Table 2b, which takes migration into account, shows larger estimated populations for Trinidad and Tobago in 1965, 1970, and 1975 than are shown in Table 2. 1. iv, which is based on the rate of natural increase only. Thus, migration as well as the rate of natural increase, is an important factor in the growth of the population of Trinidad and Tobago.

## Chapter 2

### THE ECONOMIC GROWTH OF JAMAICA 1950 THROUGH 1960 AND 1965, 1970 AND 1975

#### Growth of the economy in recent years

Economic growth in Jamaica was phenomenal in the period 1950-60. A visiting economist in 1961 ranked Jamaica's rate of growth with the three fastest growing countries of the world. An examination of the sectoral growth pattern indicates, however, that this growth rate was due to somewhat special circumstances, and that it would be surprising if such a growth rate continued into the future. A slowing down of the growth rate would not necessarily be a symptom of decline or instability in the economy; on the contrary, it might be accompanied by a more balanced advance of all sectors and the greater diversification of the economy. The high rate of growth of the past decade was strongly associated with the rapid growth of one industry, the mining of bauxite and alumina, which grew from having no share in 1950 to having an 8 % share of the gross domestic product by 1960. Although this 8 % may not appear a particularly large share, the importance of this industry in the actual increments to growth in this period is of course much higher and direct and indirect effects of this industry's expansion probably accounted for at least 20 % of total growth of GDP at constant factor cost.

In contrast, agricultural sectors showed a relatively slow rate of growth in both constant and current prices. The share of agricultural industries in the total product fell from 27 % in 1952 to 13.5 % in 1959. However there are grounds for believing that the estimates made for agriculture may have been too high in the early period, so the decline in the importance of this industry may not have been so rapid. Within the agricultural sector, sugar and livestock showed the biggest absolute growth, but their relative importance in the economy as a whole still declined.

Besides mining, the industries which have shown the biggest increases are construction, distribution and services. The construction industry has been affected by important increases in capital formation, both public and private, including substantial increases in housebuilding. We shall consider later the relationships between capital and output on a sectoral basis. Distribution, transport and services have been influenced by the general increase in economic activity. Services have been expanded by the increasing number of tourist hotels which came into operation in this period and the increased number of visitors which has resulted in an increase in the gross domestic product from about J£1.5 million in 1952 to about J£5.7 million in 1959.

In spite of the emergence of several new manufacturing industries in this period the share of manufacturing increased only from 13.2 % of the gross domestic product to 14.2 %.

This, however, is easily explained and is evident also in other West Indian countries. The most important industries in the manufacturing sectors are still the older industries such as the manufacture of sugar, rum and molasses, and soap, oils and other products from coconuts. These industries have not increased at the same rate as have mining, distribution and services so that the increases in manufacturing of the non-staple processing industries only are rather greater than the figures indicate. There is also the fact to be taken into account that many of the new manufacturers are small industries that do not employ a large number of people in comparison with agricultural industries. Their value lies as much in their contribution to employment at the construction stage and in their contribution to self-sufficiency and diversification as in their actual contribution to the gross domestic product.

The manufacturing industries which are of most interest in the agricultural context are those which are concerned with the production of food, drink and tobacco. These industries are mainly older industries in Jamaica; the most important are sugar and rum-making, the processing of citrus and the processing of coconut products. In our input-output matrix for Jamaica, sugar is shown as one sector so that the transactions between farmers and processors are not indicated. Similarly, citrus growing and processing are part of the main export sector. In Table 3b, however, which shows the gross domestic product of Jamaica at factor cost, by industrial origin and at constant prices, we can see the relative growth rates of agriculture and food, drink and tobacco manufacturing as compared with other sectors of the economy during the period 1953-59. As will be seen from the series (Table 3b) all the agricultural sectors increased at a rather slower rate of growth than did non-agricultural sectors; and, as we would expect from this, the sector "manufacturing, food, drink and tobacco" increased relatively slowly too. This follows from the importance of sugar milling and other basic processing industries in this sector.

Export agriculture, for which the figures are fairly reliable, and which in this case includes the banana, citrus, cocoa and coffee industries and a number of minor industries, show quite severe fluctuations over the period under review. These fluctuations are also discernible in the cane series.

The figures for domestic agriculture, and livestock and fishing are less reliable. It appears that these sectors grew slightly faster than population over this period. It is possible, however, that most of this growth is attributable to the livestock industry. Given the unreliable nature of the figures, it would be rash for us to claim that there had been any marked change either way in the production of roots and vegetables on the whole, although material collated for our supply projections indicates some increase in vegetable production accompanied by a small decline in root production.

Although the government sector grew in the period 1953-59, its average annual growth rate was 6.8% as compared with the 8.8% for the economy as a whole (Table 3b) at constant prices. Salary increases brought the government sector's share of the gross domestic product in current prices from 6.3% in 1952 to 7.0% in 1959.

#### Projections for the Jamaica economy 1965, 1970 and 1975

Method. From what has been concluded regarding past growth rates it is evident that we could not consider a simple projection of these into the future. The period 1958-62 already gives some indication of a slowing down of the growth rate. We do not predict a

continued decline in the rate but rather a levelling off to a rate which, although considerably less than that of the 1950's, will still allow for a fairly healthy growth when measured in terms of real income per capita.

In order to obtain a full and comprehensive picture of growth factors and their effects on the economy as a whole a series of inter-industry tables have been developed (Tables 3e. i-iv). These are in respect of the years 1958 (base year), 1965, 1970 and 1975. The choice of the base year rested solely on the availability of up-to-date. It is assumed in the projections that the price level of 1958 continues. The sectoral breakdown was made with several considerations in mind: a) the type of transaction; business, government, households and rest of the world must be separate sectors since their transactions are of a different nature; b) industries mainly exporting were kept separate; c) industries having reliable information were, when possible, kept separate from those having unreliable information; and d) industries having opposite trends were not put in the same sectors when this could be avoided.

Each sector was tackled individually. Past trends were examined. Leading authorities in business, marketing boards, mining and sugar companies, and government were interviewed, and information was gathered on investment plans and on their general assessment of the future of these industries. On the basis of all these enquiries, growth rates were estimated for each sector, but these were not necessarily the same annual average growth rate over the whole period 1965-75.

There were of course some conflicting items when the material was brought together to form a matrix. To solve these, orders of determination in the economy were considered. Export sectors are considered the most autonomous, then production sectors and finally government sectors. In the case of conflict between production sectors — for instance, whether purchases of feeding stuff from the domestic agriculture sector by the livestock and fishing sector should move at the latter or former sector's projected growth rates — a decision had to be taken as to whether or not the supply-elasticity in the supplying sector is great enough to meet the expanded demand. This is of course a first approximation. It enables us to enter somewhere into the spiral of economic activity. Later adjustments could be made as better information becomes available.

According to different growth assumptions, different levels of income could be reached; but we have projected only one set of matrices. Given our actual information, given that there would be no violent changes in industrial structure, and given that there is to be no balance of payments problem or excessive foreign borrowing, income growth can only change marginally from that predicted. The export targets for bauxite and sugar may be considered too high — but this is probably the only sizable variation we can allow for, given the above assumptions. The summary inter-industry table (Table 3f) is presented as it enables rough approximations to be made on the effect of any number of alternative assumptions.

From the main tables we derive gross domestic product, national expenditure, gross national product and national income (Table 3a). We have put these on a per capita basis and have used gross national product per head as our income indicator which is applied in the total demand projections. We feel that in a country where transfer receipts such as overseas remittances are important household expenditure per head would be a more

relevant indicator. But the difference is not great in Jamaica, and by using gross national product we conform to common international practice and thus make international comparisons more valid.

### Sectoral growth rate in Jamaica

The sugar estimates are based on the assumption of exports of 410,000 tons in 1965, 500,000 tons in 1970 and 590,000 in 1975 (all at 1958 prices), plus a small increase in local domestic and manufacturing use.

The rate of growth projected for the export agriculture sector averages about 3 % per annum compounded over the whole period (Table 3d).

Figures on which domestic food crops and livestock products are based were derived from various government departments and from the Sugar Manufacturers Association Livestock Research Department. Domestic food crops show a very small increase, mainly in vegetables. Fruit and roots are predicted to decline. The increase in livestock is not so fast as in the past owing to limitations in the scope for import substitution arising in beef, eggs and poultry.

Information for the mining sector was assessed after discussions with leaders in the industry. The growth rate corresponds fairly closely with estimates recently made by the Jamaica Government. It approximates to 5.2 % per annum (as compared with an annual average of 30 % in the period 1953-59).

The construction sector is closely bound up with the assumptions regarding gross domestic fixed capital formation. It will be noted (Table 3c) that our projections for gross domestic fixed capital formation are J£58.9 million (1965), J£79.2 million (1970) and J£93.5 million (1975). Net fixed capital formation approximates to J£40 million (1965), J£53 million (1970) and J£64 million (1975). If we relate total capital formation for the period 1958-65 to the increment in income for that period we obtain a capital/output ratio of approximately 3.5,  $\frac{\text{(Total net capital formation 1958-64)}}{\text{(increment to income 1958-65)}}$ , as compared with 3.2 in the period 1956-59. The equivalent ratio for 1965-69 is 3.0. This ratio will become larger as more capital is needed to provide an increment of say 1 % in income, if the marginal efficiency of capital declines as may well happen if our projections are achieved, by about 1970. On the whole, capital output ratios have not been a useful tool in projecting the income and capital requirements for Jamaica, since sectoral capital formation figures were not readily available and totals were affected by the peculiar conditions of the expanding bauxite industry. Where possible, data on public and private investment plans were utilised.

The manufacturing sectors were studied by means of a field survey in which questionnaires were submitted to businessmen. The growth rate in these sectors is based on the findings of the survey.

Distribution, transport and services are projected to grow in sympathy with the general growth of the productive sectors. All these, but particularly services, are also influenced by the size of the autonomously generated tourist industry. This industry's expansion was assessed partly in relation to past trends and partly in consideration of hotel investment projects.

We would expect government to become of slightly greater importance in the GDP as incomes increase; it is projected to grow from 6.6 % in 1958 to 7.3 % in 1975.

The projections shown indicate a real per capita (national income) growth rate over the whole economy of 3.7 % per annum 1958-65; 3.5 % per annum 1965-70 and 2.8 % per annum 1970-75.

Our projections do not assume absolutely fixed technical coefficients. For instance, the relatively rapid increase of the public utilities sector, which includes electricity, indicates increased mechanisation of industrial processes. We do however assume that only marginal changes take place in the share of income as between profits and non-profit income. We have assumed a slight increase in household saving from 6.2 % of household income in 1958 to 7 % in 1975. We do not, however, predict any significant increase in the proportion which gross domestic fixed capital formation bears to GDP. Thus shifts from household expenditure to savings and government are only marginal.

### Employment and productivity

If the national income increases from J£177,265,000 in 1958 to J£386,639,000 in 1975 this is a real increment of J£209,374,000 over the period (since figures are all on 1958 prices). If we assume a regular income earner will earn an average of J£400 per annum, this would permit 523,435 new income earners to be absorbed into the work force — given no change in the income of existing members of the work force. During this period it is estimated that approximately 480,000 people will be added to the population of which we might say 60 % or 288,000 were possible job seekers. Thus, although we have not projected growth of the economy of Jamaica at a rate comparable to the last decade, our projections do allow for modest increases in employment and income plus absorption of the new labour force resulting from population increase.

Little information is available on productivity in Jamaica and its changes. Comparisons with other countries in the production of bananas, livestock products, vegetables and coffee show an extremely low productivity of labour, but it is probable that Jamaica is about in the middle of the range of sugar producing countries in this respect. The growth of the mining industry has almost certainly changed technical coefficients in Jamaica over the past decade and job opportunities have not expanded at the same rate as income. While we can predict increases in productivity in the sugar industry consequent on further mechanisation, which may cause some unemployment, we cannot see very many material signs that productivity is increasing in agricultural and manufacturing industries. This is one of the reasons we have favoured predictions of a lower rate of growth than that which has recently prevailed, and which, while sustaining a fairly well diversified economy, does not involve greater increases in new manufacturing industries than in basic agricultural and processing industries. Obviously, radical changes in technical coefficients could lead to errors in our predictions since the distribution of income might be radically altered by such changes.

Note. Reference N. 1.2 (Appendix II) supplied part of the information for this chapter and Tables 3a-3c.

## Chapter 3

### GROWTH OF THE ECONOMY OF TRINIDAD AND TOBAGO

#### Growth of the economy in recent years

The period 1951-59 was one of great expansion in the economy of Trinidad and Tobago. Gross domestic product at factor cost increased from \$308.3 million in 1951 to \$788.9 million in 1959, that is, by 156 %. The largest single contributor was the petroleum and asphalt sector, which increased from \$93.5 million to \$261.4 million during the period. The manufacturing and the building and construction sectors also made significant contributions to the economy.

The contributions made to the gross domestic product by the various sectors are shown in Table 2.3.i for 1951 and 1959. For income, expenditure and product data for 1951 through 1959 see Table 4a.

Table 2.3.i

Trinidad and Tobago: Gross domestic product at factor cost, 1951 and 1959  
(current prices) 1/

Sector	1951		1959	
	Million BWI\$	Percent	Million BWI\$	Percent
Agriculture	55.6	18.0	98.3	12.5
Petroleum and asphalt	93.5	30.4	261.4	33.1
Manufacturing (including sugar and rum)	43.4	14.1	103.9	13.1
Transport and communications	10.0	3.2	25.8	3.3
Government	29.2	9.5	65.9	8.3
Public utilities	9.4	3.0	19.4	2.5
Building and construction	8.4	2.7	48.1	6.1
Ownership of dwellings	8.3	2.7	13.4	1.7
Services	50.5	16.4	152.7	19.4
Total	308.3	100.0	788.9	100.0

1/ See Reference N. 1.3 (Appendix II).

Source: Data and material developed during the study and other available data.

The territory is now entering an interesting and exciting period of economic and political development. At the end of August 1962 the territory achieved independence. This event also poses serious economic problems. The greatest problem is the implications of the European Common Market to the future development of the economy and to the oil industry in particular. Another pressing problem is the future of the sugar industry when the Commonwealth Sugar Agreement expires in 1969.

On the positive side, keen interest has been shown by overseas investors, particularly in manufacturing industries and in building and construction.

It is against this background of apprehension on the one hand and sustained optimism on the other that projections for the economy of Trinidad and Tobago are being made for the period ending in 1975 (Table 4b).

### Sectoral growth rate in Trinidad

#### a. Petroleum and asphalt

Since 1955 when the first submarine well was completed as a commercial producer, greater interest has been shown by the oil companies in submarine drilling. Indications are that this trend will continue because of the decline in the output of land wells and increasing costs in locating additional productive wells on land. The major problem of this switch from land to marine drilling might be a reduction in the labour force in this sector. Employment in petroleum and asphalt (mining and refining) decreased from 16,426 in February 1960 to 15,285 in February 1961. It must not be assumed, however, that this development was entirely responsible for the decrease in the numbers employed.

Two oil companies have recently substantially expanded their oil refineries and the total capacity of the refineries is now approximately 120 million barrels per year. Crude oil will still have to be imported to keep the plants working at capacity, but total importations will eventually decrease as production increases. It is expected that production of crude petroleum will increase at the rate of 5 % per annum.

Production of natural gas has increased from 51,742 million cubic feet in 1956 to 97,652 million cubic feet in 1960. The main users are oil refineries, but substantial quantities are sold to the Electricity Commission, the cement industry and the fertiliser plant. Plans have been formulated for distributing the gas to various parts of the island and consequently significant developments can be expected in the near future.

At present, fears are being expressed that the oil industry might suffer severely if a satisfactory arrangement cannot be made by the United Kingdom Government in the European Common Market negotiations for protection of the industry. If these fears are realised the future of the industry will be in great danger.

The growth of this sector is estimated as follows:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	157	179	196

b. Sugar and rum

Up to 1969 the sugar industry will enjoy the benefits to be derived from the Commonwealth Sugar Agreement. However, the success of the industry after that date will depend on the following factors: (a) whether the Commonwealth Sugar Agreement continues, (b) whether the United Kingdom enters the European Common Market, and (c) whether the Island is allocated a United States quota.

In view of the uncertainties which surround the sugar industry at the present time it is not unrealistic to be somewhat pessimistic about the future of the industry.

It is not expected that production within the near future will exceed the record 1961 crop of 245,700 tons. It is, however, anticipated that local consumption will increase, both for household and manufacturing requirements.

The projections for this sector are:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	126	134	140

c. Agriculture

The relative contribution of this sector to gross domestic product decreased from 18.0 % in 1951 to 12.5 % in 1959. In absolute terms, however, it increased by BWI\$42.7 million during the period.

The major commodities entering the export market are cocoa, citrus and coffee. Exports during the period 1958-60 were as follows:

Commodity	1958		1959		1960	
	Q	V	Q	V	Q	V
Cocoa	18.2	12.7	15.9	10.1	15.9	8.7
Citrus <u>1/</u>	23.6	1.9	N. A.	0.7	25.8	1.6
Coffee	4.5	2.0	5.4	2.4	4.1	1.3

1/ Fresh fruit only.

Source: Data and material developed during the study and other available data.

Q = million lbs. V = BWI\$ million.

In spite of government subsidies to agriculture, especially for cocoa and coffee, production has not increased as rapidly as had been anticipated because adverse weather during the past five years destroyed many of the cocoa seedlings distributed to farmers. It is, however, expected that production will show an appreciable increase when the remaining new clonal plants come into bearing.

Weather likewise affected the output of the citrus. However, as a result of the citrus agreement negotiated between the West Indies citrus producing territories and the United Kingdom Government, it is confidently expected that citrus production will increase significantly during the next few years. Exports of fresh grapefruit may decline because more emphasis might be placed by the Citrus Growers Cooperative on exporting canned grapefruit segments rather than the fresh fruit. The segment plant commenced production in 1962 and it is not yet possible to determine what degree of diversification would result.

Assuming that the drought will not continue, it is expected that the output of the above products will be as follows:

Commodity	1965	1970	1975
	Million pounds		
Grapefruit	142	168	192
Oranges	46	74	84
Cocoa	21	24	30
Coffee	8	11	13

Bananas are not now a major export crop; in 1960, exports totalling 9 million pounds were valued at \$0.5 million. This crop, however, has great potentialities in Tobago.

Minor export crops, such as tonca beans and rubber, are not expected to increase appreciably.

It is not expected that the acreage under sugar cane cultivation will be increased to any great extent. There will most probably be a reduction in the acreage cultivated by estates and an increase in that planted by farmers. However, the position might change if the island receives a substantial United States quota.

For further discussion of considerations influencing exports of agricultural and domestic food crops see part four of this report.

Quarrying is expected to grow to keep pace with the building programme. However, some of the limiting factors are inadequate distribution and the lack of efficient capital equipment.

The projections for this sector are as follows:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	154	194	232

d. Manufacturing

The manufacturing sector has increased rapidly within recent years because of increased production and addition of new industries. As a result, a wide range of products are now being manufactured for local consumption and the export market. Pioneer industries have made a great contribution to this increase.

The 1957 Census of Industry revealed that the gross output of pioneer industries increased from \$5.2 million in 1953 to \$23.1 million in 1957. Since the 1957 census several industries, including the fertiliser industry, have been granted pioneer status, and significant increases are expected. As of December, 1961, 79 pioneer establishments were in operation.

Projections for this sector were based on expansion plans announced by some of the large firms as well as information obtained from the Industrial Development Corporation on industries applying for pioneer status. Assumptions were also made concerning increases which might be expected as a result of the growth of other sectors. The index of growth is as follows:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	197	257	308

e. Transport and communication

The transport problem in the islands is very perplexing and within the past five years has been investigated by commissions and consultants appointed by government.

The serious defect in the system is the competition between the "route" taxis and the buses and railways (including in the public utilities sector). The latter modes of transportation annually incur a deficit. There are other contributing factors, but competition is considered to be the principal reason. Some of the remedies suggested are: (a) zoning the "route" taxis, (b) limiting the number of such taxis. It must also be stated that the increase in the number of motor vehicles (in 1960 the total motor vehicles licensed were 40,988 compared with 35,536 in 1959) poses a serious traffic problem. An early solution to the problem is necessary.

British West Indian Airways, which has recently been acquired by the government, remains in this sector as there may be changes in ownership or partnership during the period covered by the projections.

In spite of the difficulties discussed above, the transport system will continue to grow, not only to accommodate the expansion in the productive sectors but also because of continuing government activity. It will also be enhanced by the increase in population as well as its mobility.

Finally, in assessing the projections indicated below, consideration must be taken of the fact that transportation carried out on their own account by enterprises is excluded. The index of growth is as follows:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	130	160	198

f. Building and construction

The inadequacy of private housing constitutes one of the most pressing problems facing the country. The Housing Census of 1957-58 revealed that of the 161,000 housing units in Trinidad and Tobago, 69,000 (43 %) were grossly overcrowded, that is, with four or more persons per bedroom. Included in this number were over 43,000 units (27 % of all units) in which there was no separate room for use as a bedroom.

The Housing Census also indicated that 66,700 dwelling units or 42 % of the total were neither grossly overcrowded nor of poor quality. Of the remainder, 30,900 units or 19 % of the total were in good condition, but were overcrowded. It may therefore be taken that approximately 63,000 units were in poor condition; that is, they needed to be pulled down and replaced. There was a great deal more overcrowding in "poor" than in "good and fair" units, 60 % of the "poor" units being overcrowded as compared with only 32 % of the "good and fair" units.

It has been estimated that a minimum of about 7,000 units are required annually to take care of population growth within the country, but the annual net addition to the stock of housing is only of the order of 2,000 units.

The government, in order to alleviate the position, is directly engaged in developing housing schemes and also assists in construction projects, as for instance through aided self help schemes. In addition, various concessions have been offered by the government to enterprises willing to embark upon the construction of houses.

In making projections for this sector, the acute housing shortage has been taken into consideration. Construction work done by the sector (excluding construction carried out by government labour and by enterprises on their own account) is expected to be as follows:

	1959	1965	1970	1975
	Million BWI\$			
Total	79.2	145.7	194.2	236.9
Households	19.4	37.5	51.2	75.7
Government	15.8	50.9	68.1	64.8

It must, however, be borne in mind that receipts from government are not exclusively used for the construction of housing.

The increased activity in the other sectors is likewise reflected in this sector:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	184	245	299

g. Public utilities

The main source for the projections of electricity were the report on "A Commercial Approach to Rural Electrification" and "Tobago — Review of Past Operations Together With Projections Until 1972." Varying rates of growth were assumed for the several consumers; however, domestic consumption and consumption by manufacturing industries predominate.

The overall rate of growth for electricity to be generated was taken at approximately 13 % per annum.

Projections for Port Services relied heavily on the Hedden Report on Port Administration and Development, which made several recommendations for the reorganization and development of the port. It is expected that as a result of this reorganization Port Services will become self-supporting. In 1959 it incurred a deficit of BWI\$2.6 million.

It was assumed that the railways will continue to run at a loss.

h. Government

When this study was being undertaken the government's new Development Programme (1963-67) had not yet been finalised. Consequently many assumptions had to be made about the level of government expenditure and the allocation of such expenditure.

As it is the government's policy to make a serious attack on the problem of unemployment, it can safely be assumed that expenditure under the new programme will be not less than that of the previous one. The second assumption which had to be made was that government's expenditure must increase to maintain the results of the last programme, such as maintenance of roads, education and social services generally.

It is believed that the emphasis of the new programme will be on building and construction. The reasons are (1) that this will alleviate the serious housing shortage, and (2) that this type of expenditure will generate employment principally in the manufacturing and household sectors and thus will have an impact on other sectors..

In line with the foregoing assumptions, the index of government's expenditure will be as follows:

	<u>1959</u>	<u>1965</u>	<u>1970</u>	<u>1975</u>
Index	100	195	251	303

In order to achieve these goals, government will have to resort to some of the following sources for revenue: (1) increased taxation, (2) expenditure from surplus balances, and (3) borrowing. However, if government goes through with its plan for a 50-50 share of the oil companies' profits (negotiations are now taking place between government and the oil companies) there will be a substantial increase in government revenue.

## The economy 1959-75

Table 4c shows that the gross domestic product at factor cost will increase from BWI\$ 788.9 million in 1959 to BWI\$ 1,861.4 million in 1975, an increase of 136 %. If we examine the growth in three stages, it will be noticed that the period 1959-65 is one of great expansion and then there is a decline in the annual rate of growth:

1959-65 increase of 65 %

1965-70 increase of 27 %

1970-75 increase of 19 %

The oil companies have not yet announced whether they will undertake large-scale development during the period 1965-75, but if they do the previous rate of growth might be maintained.

### Method

The inter-industry table for 1959 (Table 4d. i) was constructed from the Trinidad National Accounts worksheets. (See Tables 4d. ii, 4d. iii, and 4d. iv for projected years.) The published National Income Report <sup>1/</sup> follows the U. N. system, but the worksheets contain sector accounts and hence there was no problem in constructing the basic table. The accounts, however, include capital as well as current expenditure and it was not possible in all cases to allocate the capital expenditure to the various sectors. It was therefore decided to construct the inter-industry table on the same basis as the U. S. A. and Dutch models. An attempt was made to construct a capital input/output table but this was discarded because of the above-mentioned difficulties.

The worksheets existing at the time dictated the number of sectors to be selected. The major sectors, such as petroleum and asphalt, sugar and rum, manufacturing and building and construction are reliable. The components of the services sector vary in reliability and it was not possible to construct a distribution sector from the information available. The sector accounts are now being expanded and it will be possible in the near future to construct an 18-sector matrix.

Besides the production sectors described above, two other sectors require some description. The profit appropriation sector shows on the receipts side the inflow of gross profit. On the payments side the main outlays are (a) payments to government for company taxes; (b) payments to households as distributed profit; (c) payments to the rest of the world for the distributed profits of expatriate firms; and (d) payments to the savings and investment account for undistributed profits.

The capital account shows the financing of capital formation. It includes also a residual item representing capital inflows and savings of locally owned corporations. A large proportion of the capital inflows would be the reinvested profits of the oil industry.

---

<sup>1/</sup> Reference N 1. 3, Appendix II.

Constant price estimates (1951 prices) exist but only for the expenditure side of the gross domestic product. The data in Table 4d. i to iv are at 1959 prices but it was not possible on all occasions to eliminate the price element. A great deal of information is collected annually (for example, growers' and retail prices, wage rates, export and import prices); consequently, it is not felt that the errors involved in eliminating the monetary movements are large.

## Chapter 4

### GROWTH OF THE ECONOMY OF THE LEEWARD ISLANDS, WINDWARD ISLANDS AND BARBADOS 1/

#### Growth of the economy in recent years

Source information is rather scant for this region, so we have presented two main tables only. Table 5a gives a summary of the gross domestic product, national income and national product for the whole region for the years 1959, 1965, 1970 and 1975. Table 5b shows the industrial origin of gross domestic product on an island basis.

The rate of growth predicted for these territories works out at approximately 2.8% per annum throughout the period. In spite of the fact that both sugar and bananas must be projected at a declining growth rate (see part four) we do not predict a declining growth rate for this region as a whole, for the following reasons.

The smaller islands have not experienced a growth rate comparable with that of Jamaica and Trinidad and Tobago during the past decade although most territories have shown positive growth in terms of per capita real income. They are, however, at present experiencing a lower per capita income than the larger islands and for that reason may be capable of higher rates of growth in the future. We believe also that political uncertainties caused by the breaking up of the larger federation and the difficulties of forming the smaller federation have tended to inhibit growth. If the smaller federation materialises, it should do much to increase stability and to encourage investment. Our projections are based on limited agricultural expansion and on a rather greater expansion in tourism and secondary industries and in distribution, commerce and transport and other service industries.

Table 5b is intended to provide a picture of growth by sectors and territories and can best be used to illustrate a description of the individual economies and the projections for the future.

#### Future growth in Barbados

Barbados is the most important of these economies, having in 1960 approximately one-third of the population of the group and rather more than one third of the national income

---

1/ Some source material for data in this chapter and Tables 5a and 5b can be found in References N 1. 4, N 1. 5, and N 1. 6, Appendix II.

of the group. Barbados has, besides a very important sugar industry (see part four), a number of manufacturing industries and a growing tourist industry, it being estimated that tourists now spend there about BWI\$ 15 million annually.

The Barbados economy showed little growth in the period 1955-60 and our projections after 1965 are rather more optimistic than experience of past periods might suggest. We believe, however, that the period 1955-60 has been an unlucky one for the sugar industry in that climatic and other factors have been against expansion. The basis of our projections for sugar are explained elsewhere. Yield increases in Barbados in the forthcoming period are expected to play an important part. Even so, we cannot predict, with the very limited availability of land in Barbados, that expansion of sugar will be a major factor in future growth.

In Table 5b it will be noted that importance is given to the expansion of the manufacturing and mining, construction, distribution, commerce and transport, services, and government sectors. We base the expansion of these sectors on two main assumptions. First, if Barbados becomes the seat of a new federal government for the area, we consider that this in itself will lead to the expansion of the construction and government sectors. If the federation is accompanied by a customs union as has been assumed we believe that Barbados will obtain a number of manufacturing industries catering for the enlarged market and will also benefit from increased distributive and warehouse activities. The second assumption is that there will be a very considerable expansion of the tourist industry throughout the region and that, in Barbados, the services, distribution, commerce and transport sectors in particular will benefit from this.

If the proposed federation of the Leeward Islands, the Windward Islands and Barbados materialises we should therefore expect very considerable effects on all the economies but in particular on the economy of Barbados. We should not, however, expect the influence on Barbados to be very spectacular by 1965 and up to that year we have projected a rate of growth (Table 5b) that is not significantly greater than that demonstrated during the period 1958-62 when Barbados experienced a growth rate, in terms of real per capita income of only about 1 % per annum. After that period we expect that, unlike Jamaica and Trinidad and Tobago, Barbados will have an increasing rate of growth.

The Leeward Islands are still mainly dependent on sugar, although in recent years tourism has become a very important industry in Antigua. In Table 5b it will be noted that sugar (the main commodity of export agriculture) is expected to increase somewhat from 1960 (which was a relatively poor year) but is not expected to register very significant increases either in St. Kitts or Antigua after that. The other important crop in export agriculture in the Leeward Islands is cotton but, as is explained in chapter 4, no brilliant future is predicted for that crop.

Antigua experienced during the period 1955-1960 the fastest growth rate of any of the smaller islands. The cause of this was the emergence of an important tourist industry; during this period the number of visitors increased from approximately 3,000 in 1955 to about 20,000 in 1960, and in 1960 it was estimated that visitors spent about BWI\$ 5 million in the island. By now the contribution of tourism, in terms of foreign currencies earned, exceeds that of sugar in this island. Sugar, however, still contributes somewhat more to local incomes, owing to the high import content of tourist expenditures. Secondary

industries in the Leeward Islands have been insignificant to date (if we include sugar milling as part of the primary sector) but a number have been discussed, and although we cannot make any firm predictions we have assumed some developments in industry both in Antigua and St. Kitts-Nevis-Anguilla.

Montserrat, the third of the Leeward Islands administrations, has been a declining economy consequent on the falling off of the sea island cotton industry and due also to the heavy migration of people of working age. A small number of export bananas are grown there, but are taken to Dominica for reshipment as they are not sufficient to justify a ship calling there. In 1960, a plant was opened for making tomato paste and this has greatly stimulated the cultivation of tomatoes, for which Montserrat is noted; but as these have generally found a good market as fresh fruit, the plant has been undersupplied. Generally speaking one can predict little likelihood of cure for the economic malaise which appears to have overcome this island, so long as migration continues, as it no doubt will continue if better work opportunities are not forthcoming. Montserrat has a high livestock population and it may well be that, given a small work force, it is in such products that her best chances lie.

It will be noted in Table 5b that in the Leeward Islands we predict the biggest increases in the sectors of distribution, commerce and transport, services, and construction. This is because we predict a continuation of tourist development in Antigua, and its likely extension to St. Kitts, Nevis and Anguilla, all of which have considerable unutilised beach resources.

#### Future growth in the Windward Islands

In the Windward Islands much the same pattern can be seen, except that the main export crop, bananas, is capable of gaining a rather greater expansion in acreage than sugar in the Leeward Islands. This is particularly so in Dominica and St. Lucia (for description of factors affecting supplies of bananas see part four). The Windward Islands have a much more important domestic subsistence economy than have Barbados, Antigua or St. Kitts-Nevis-Anguilla and are exporters of these products to other territories of the group and also to Trinidad and Tobago. As noted elsewhere, it is believed that production of domestic food crops has been reduced by migration and also by competition from banana production. In spite of the probability that these trends will continue we consider there will be a small growth in the non-export agricultural sectors; this prediction is based on the belief that if the federation of the Leeward Islands, the Windward Islands and Barbados comes into being and there is a customs union, the food producing areas will to some extent complement the sugar producing and more urbanised areas, and the expansion of domestic supplies might even reduce imports of such products as meat and dairy products. This pattern of change has already made some headway in Jamaica.

After bananas, cocoa is one of the main exports of this region and, as is explained in part four, a fairly rapid expansion is predicted for this crop. In Grenada, spices such as nutmeg and mace are important exports. Some expansion is predicted for these products but it is probably limited by the fact that they tend to grow best under a fairly intensive type of peasant cultivation and suffer competition from such crops as bananas and cocoa, which may not be more profitable than spices but have more stable prices in world markets.

In the islands of Grenada, St. Vincent and St. Lucia, we have predicted some increase in tourism. St. Lucia appears to offer the most promise for this industry, but Grenada is probably the most advanced at the moment and there are already several tourist type hotels there. The Grenadines, a small string of islands between Grenada and St. Vincent, offer almost unlimited tourist potential and some developments may well occur there during the period with which we are concerned. One of the limiting factors in the Windward Islands has been inferior airports and air services. Both Barbados and Antigua have international airports, and it is easy to see that tourism in both islands has benefited from this. Dominica is an island of rugged grandeur, but owing to the lack of beaches and areas suitable for water sports, it appears that tourism will develop there on a rather more limited scale than in the other three Windward islands.

### Conclusion

Our projections for all these islands are thus based on the assumption that the federation of the Leeward Islands, the Windward Islands and Barbados will materialise. <sup>2/</sup> Following this we expect a small expansion in domestic agriculture and a rather greater expansion in domestic industries and services. We except services and construction in particular to be affected by a predicted expansion of tourism. Regarding the export sectors, we find that in the Windward Islands there is some scope for developing more bananas, cocoa, and probably other fruit crops; at the moment they probably have more unexploited resources than other West Indian islands. We do not expect a very spectacular increase in the export sectors of those islands that specialise in sugar production.

The predicted growth of the respective economies, which serves to illustrate the points made above, is shown in Table 2.4.i.

Table 2.4.i

Leeward Islands, Windward Islands, and Barbados: Predicted growth indicators, 1960 base, 1965, 1970, and 1975

Area	1960	1965	1970	1975
	Indices			
Barbados	100	116	147	201
Antigua	100	138	162	174
St. Kitts - Nevis - Anguilla	100	131	157	175
Montserrat	100	111	115	118
Grenada	100	122	151	174
St. Lucia	100	129	152	181
St. Vincent	100	121	139	166
Dominica	100	123	135	151
The Leeward Islands, the Windward Islands and Barbados	100	122	149	183

<sup>2/</sup> There appears to be some likelihood that Grenada will join in a unitary state with Trinidad and Tobago. For the present we have included Grenada with the other smaller islands.

## Chapter 5

### LONG-TERM ECONOMIC GROWTH OF BRITISH GUIANA

#### Growth of investment, 1950-60

The post-war development in British Guiana began with financial assistance under the Colonial Development and Welfare Act of 1945. With the help of Colonial Development and Welfare Act grants and loans, the government of British Guiana embarked upon development planning. A 10-year Development Plan for 1947-56 (Ref. N. 1. 9, Appendix II) was drawn up in 1947 and revised comprehensively in 1950 providing for an expenditure of BWI\$28 million. It petered out in 1953, and the government launched a 2-year programme for 1954-55, with a planned expenditure of BWI\$44 million. This was to be the forerunner of a long-term programme based on recommendations of the International Bank for Reconstruction and Development Mission (Ref. N. 1. 10). However, during 1944-45 only BWI\$26 million could be spent. The long-term programme was then formulated for 1956-60, and later revised to 1956-59, at a total expenditure of BWI\$91 million (later revised to BWI\$103 million), of which only BWI\$77.5 million was spent till the end of 1959 (Ref. N. 1. 11). Finally there is the Development Programme 1960-64, based on the Berrill Report (Ref. N. 1. 12) at the total cost of BWI\$110 million. All these development plans are oriented towards laying basic services, viz., sea defences, drainage and irrigation, roads and other means of transportation and communication which are essential to economic development. Programmes for geological surveys, research and experimentation for diversification of agriculture, extension of available credit facilities and some social welfare have also been undertaken.

Apart from agriculture, where drainage and irrigation schemes provided expansion facilities, all other producing activities have been left to the private enterprise to develop. To attract entrepreneurs the government has been giving since 1951 considerable income tax and import duty concessions, e. g., tax-holiday for five years from the date of production, generous depreciation allowances, duty-free imports of machinery, building materials, etc. for factories, hotels and so on. British Guiana is, however, very much dependent on foreign private capital. In the absence of a money market in British Guiana, all of the local savings cannot be aggregated for fruitful investments, and the tendency of the local people is to invest their small savings abroad.

Table 2. 5. i shows the gross fixed capital formation in British Guiana during 1950-60.

The government development fund was established in 1954, therefore comparable figures for earlier years are not available. The large amounts of private overseas capital invested in 1951 and 1957-59 are mainly due to expansion of the mining industry, especially for bauxite, and in recent years for alumina.

Table 2. 5. i

British Guiana: Gross fixed capital formation, 1950 through 1960 (current prices)

Year	Total gross fixed capital	Private overseas capital	Government development fund expenditure
	BWI \$ 1,000		
1950	27,400	8,600	—
1951	30,100	18,600	—
1952	25,856	6,541	—
1953	26,871	5,028	—
1954	36,116	6,865	8,608
1955	45,458	5,267	17,522
1956	48,000	6,753	20,559
1957	61,490	29,917	18,310
1958	60,865	16,179	19,881

#### Growth of income, product and expenditure, 1950-60

Although the national income (at current prices) of British Guiana in 1960 was double that of 1950, there was virtual stagnation during the periods 1954-55 and 1957-59. From the table of income, expenditure and product (Table 6a) it may be seen that even though the gross fixed capital formation has shown a substantial increase from 1954 onwards, due to large increases in imports of capital goods and net factor payments abroad as the returns of the invested overseas capital, the national income has not shown any appreciable increase. The spectacular leaps of the economy between 1956 and 1957 and between 1959 and 1960 have largely been due to expansion of the bauxite industry. On the other hand, the poor agricultural crops in 1954-55 and 1957-58 and the fall in world prices of bauxite during 1958-59 caused the stagnation in those years. The economy is also very heavily oriented to foreign trade. The exports mainly consist of food and crude materials, rice, sugar, bauxite and forest products. The major imports are manufactured goods and machinery and transport equipment closely followed by miscellaneous manufactured articles, food and animal feeds. An examination of detailed foreign trade statistics clearly reveals the basic characteristics of a poor, underdeveloped and imbalanced economy, i. e. importation of all manufactured and processed goods in exchange for agricultural products and raw materials. British Guiana has, however, enjoyed in the past fairly favourable terms of trade because of guaranteed markets in rice and sugar and large demands for bauxite and forest products, and this has sustained the economy to a large extent.

Very few new economic enterprises were introduced in British Guiana during the 50's, except for beer, margarine and boat building, and the percentage distribution of GDP at

factor cost by industrial origin (Table 2. 5. ii) shows that the structure of the economy did not change in any appreciable manner between 1952 and 1960, except for the growing importance of the engineering and the building and construction sectors.

Table 2. 5. ii

British Guiana: Gross domestic product at factor cost by industrial origin, 1952, 1956 and 1960

Sector	1952	1956	1960
	Percent		
Agriculture	24.46	18.18	19.60
Livestock, forestry and fishing	7.97	7.13	7.65
Mining	8.62	11.30	8.57
Food processing	10.86	8.04	7.68
Chemicals (incl. other manufacturing and fuel and power)	3.80	3.16	3.39

Professions and personal services	2.33	2.84	6.06
Rent of dwelling	3.83	2.63	1.28
Government	10.24	13.25	9.83
Total	100.00	100.00	100.00

Source: Data and material developed during the study and other available data.

The major components in the producing sectors of the British Guiana economy are sugar (cane production and milling), mining, rice (cultivation and milling) and forestry. These activities are growing apace with the expanding economy. But other industries, viz, fishery and all manufacturing activities, are still in their early stages and thus have little impact on the whole economy.

Since it is not possible to measure the real national product of British Guiana due to lack of proper price indices, a comparison of household net income (personal current expenditure plus savings) at constant prices might throw some light on the real growth of the economy. The figures for per capita household net income (Table 2. 5. iii) show that, because of increases in prices and population, the almost doubled total household net income from 1950 to 1960 does not mean any appreciable increase in economic well-being of the people.

The economy of British Guiana has had some very severe drawbacks: (1) capital resources are invested in primary industries of rice, sugar, forestry and mining, whereas manufacturing industries are grossly neglected, (2) the proportion of land and labour

British Guiana: Per capita household net income 1948 through 1960 (at 1959 prices)

Year	Household consumption expenditure (current price)	Household savings (current price)	Household net income (current price)	Household net income (1959 price)	Cost of living index (1959 = 100)	Household net income (at 1959 price)	Population (including Amerindians)	Per capita net income (at 1959 prices)

Population, Amerindians, 1957-60, British Guiana, 1957-60, Colonial Annual Reports.  
Population, others and migration 1955-60, Quarterly Statistical Digest, Statistical Bureau, British Guiana.  
1948-60 data obtained by adjusting 1957-60 Amerindian and other population figures with the help of natural increase and migration data. A check with 1946 and 1960 census figures has shown an excellent fit; in fact the error is within a few hundreds of census figures.

employed for national output is rather small, as most of the economic activities are concentrated on coastal land and unemployment is about 18 % of the total labour force, (3) public overhead capital investment is very high, due to the necessity of maintaining and building sea defences, roads, and drainage and irrigation systems, (4) credit facilities are inadequate and expensive for small entrepreneurs, and (5) government's social welfare expenditure, mainly in medical and educational facilities, is too little due to inadequate revenue receipts, partly because of the tax-holiday granted to new enterprises. Hence, unless government and private enterprise co-operate in an all out effort for rapid economic growth, it is very difficult to see how British Guiana can break away from her virtual economic stagnation. But the recent political strife in the country is frightening away investment of private capital.

### Changes in productivity

The estimation of labour productivity in the economy of British Guiana cannot be fully undertaken due to lack of detailed data. However, on the basis of the four major industries — rice, sugar, bauxite and timber — the average annual compounded rate of productivity increase may be estimated at 2.3 % for the period 1954-60.

This rate of 2.3 % must be considered as an upper limit for the economy as a whole since other sectors of the economy, particularly the professions and personal services sector, will have a considerably lower rate. Again, as British Guiana is inclined to develop and diversify the agriculture sector, especially rice, and expansion is anticipated in manufacturing sectors, which will be quite new to the labour force, the labour productivity will probably show some decline in the near future.

### Growth of income, product and expenditure, 1960-75

The future of the economy of British Guiana is very much of an unknown quantity due to the political turmoil, dependence on foreign public and private capital and the fluctuating past trend of the economy as a whole.

The method of economic projection has therefore been simply to reconcile between a gross national product (GNP) projection on the basis of an increase in the labour force and productivity and a sectoral growth projection arrived at from the past trends and future development programmes. The finally accepted projection is subjected later on to a feasibility test on the basis of an inter-industry table for 1959 (Table 6c).

Table 2.5. iv shows the three projections of the economic growth of British Guiana for 1960-75.

For the GNP blow-ups, the maximum estimate is based on annual increases of labour force participation at 3.075 % and productivity at 2.3 %. The labour force has been estimated on the basis of the high rate of population growth of 3.07 % annually, together with .005 % of extra employment for the back log of unemployed people, so that the ratio of unemployment to total labour force will be about 6.5 % in 1975 as compared with 18 % in 1956 or 1960. On the other hand, the minimum estimate is based only on the low rate of population growth of 2.849 % annually, ignoring any extra employment and productivity increase.

For the sectoral growth estimates, a detailed analysis has been made of the various economic activities. Apart from government development programmes and policies, the private entrepreneurs have also been approached to indicate their expansion and investment intentions. The sectoral domestic outputs are shown in Table 2.5.v.

Table 2.5.iv

British Guiana: Economic growth, gross national product estimates, 1960 and projections

Item	1960	1965	1970	1975
	Percent			
Gross national product blow-up: maximum	100.0	130.4	169.9	221.5
Gross national product blow-up: minimum	100.0	115.3	133.0	153.0
Sectoral growth	100.0	119.6	137.8	158.0

Table 2.5.v

British Guiana: Estimated sectoral domestic outputs, 1960 and projections (at 1960 prices)

Sector	1960	1965	1970	1975
	BWI\$ 1,000			
Agriculture	79,528	90,209	97,830	102,821
Livestock, forestry, and fishing	25,044	35,604	44,862	55,777
Mining	41,216	55,375	60,370	67,873
Food processing	114,359	131,274	141,340	148,076
Chemicals	3,776	5,213	6,214	7,233
Engineering	2,572	2,689	4,137	5,585
Other manufacturing	17,503	22,797	34,312	50,811
Fuel and power	3,558	6,109	8,852	12,850
Distribution	51,725	59,604	68,674	78,861
Transport and communications	30,319	35,472	40,622	46,341
Banking and insurance	9,846	13,258	17,457	22,551
Professions and personal services	25,567	33,718	41,901	50,006
Building and construction	90,413	98,018	103,460	111,760
Rent of dwelling	7,501	9,751	12,414	13,539

Some of the main items contributing to the growth are rice in agriculture and food processing; timber in forestry; shrimp and marine fishing in fishery; bauxite and other ores and alumina in mining; drugs in chemicals; knitwear, saw-milling, ice-making, boots and shoes, enamel ware, glass and pottery, cement, bicycle tyres and tubes and textile mills in other manufacturing; electricity in fuel and power; air transport and

private road vehicles (taxis, buses, trucks and carts) in transport and communications; and professions, personal services and catering in professions, etc. The estimates are based on available land for rice, opening up of the interior for forestry, investment and output estimates in mining, saw-milling etc., and the government's policy to encourage private enterprise and the willingness and anticipated participation of private enterprise in the development of manufacturing and service sectors. Although government is actively investigating and supplying economic reports to private entrepreneurs about the possibilities of various engineering and manufacturing industries, such as small-scale steel rolling and melting plants, light building materials, enamel wares, boots and shoes, glass and pottery, bicycle tyres and tubes, textile mills, cement, and canning, very few of these industries could be included in our estimates as most of them are still in the investigation stage, and private enterprises do not seem to be willing to commit themselves to further investment at the moment.

One must note that we have not projected the production of sugar at a high rate because, owing to the limitation of the guaranteed market for sugar exports at a high price, the industry has already reached the optimum economic level. Expected growth in the sugar industry will come from increased peasant cultivation and intensive production methods which will be sufficient to take care of the expanding domestic market.

The output data for the above main economic activities are given in Table 2.5.vi. For rice the figure for 1960 is the amount actually milled, whereas the figures for other years are the estimated milled equivalent of rough rice after a deduction of 10% for seed and feed for animals. For sugar, 1960 was a very good year; the annual average production and exports for 1957-60 were only 302,000 and 280,000 tons, respectively.

The growth rates for the services sectors of the economy have been assumed to follow in general the growth of the whole economy. As for building and construction, the greater part of which is fixed capital formation, we have estimated the capital formation from 1959 capital output ratios with some adjustment for the mining and other manufacturing sectors, the investments in which are expected to change to some extent.

On the basis of above sectoral growths, the GDP at factor cost and GNP figures arrived at are as shown in Table 2.5.vii.

The differences between GDP and GNP are due to net factor income payments to rest of the world, most of it being the dividend and profit of the private overseas capital invested in British Guiana.

Comparing the GNP blow-ups and sectoral growth pattern, we are inclined to accept the latter projections. Since in an under-developed economy the growth process will lower the productivity due to difficulties in acquiring new skills required for diversified economic activities, and since the only labour intensive activity is going to be the rice industry, the sectoral growth projection appears to us as the most likely pattern of economic growth in British Guiana. It may be remembered that 1960 was a very good year as against the stagnant period of 1957-59, and therefore the indicated growth by 1975 will not be a negligible achievement in view of the past trend of the economy.

Table 2. 5. vi

## British Guiana: Estimated output of selected items 1960 and projections

Item	Unit	1960	1965	1970	1975
Rough rice	1,000 long tons	200	286	329	348

On the basis of the sectoral growth projection it is expected that there will be little improvement in the unemployment situation in the future. The ratio of unemployment to total labour force is expected to go down to 13 % in 1975 from 18 % in 1960. There was no change in the unemployment position between 1956 and 1960.

The structure of the economy will not be appreciably changed either as may be seen from the percentage distribution of the GDP at factor cost by industrial origin (Table 2.5.viii). Except for livestock, forestry and fishing, mining, chemicals, engineering, other manufacturing, fuel and power, banking and insurance, the percentage contributions of the other sectors have either remained stationary over the years or declined to some extent. However, the absolute amounts of GDP from chemicals, engineering, fuel and power, and even other manufacturing, are so small that the economy will still remain predominantly agricultural, or, if we bring in forestry and mining, will be based on primary industries only.

Estimates given in Table 6b of expenditure, GDP, GNP, and national income, and per capita figures for each based on the low rate of population increase (which seems to be more acceptable than the high rate), show that after 1965 the economy of British Guiana will lapse again to a stagnant period. Unless there are more investments in the economy than are envisaged in our projection, the growth in national income will be barely sufficient to maintain the per capita income level reached in 1965. This is mainly because of the high rate of population growth, an exponential rate of 2.849 % annually, and also our conservative estimate of future growth of the economy. Even if the exports will be higher than imports from 1965 onwards, it is rather difficult to anticipate considerably higher investments in the economy either by the government because of high public debt charges, or by the private entrepreneurs with their faith in British Guiana shaken by political strife and turmoil.

Table 2.5.ix

British Guiana: Ratios of "final demand" domestic outputs to  
"growth" domestic outputs, 1960 and projections

Sector	1960	1965	1970	1975

Total	116.95	115.97	112.90	110.46

The feasibility test by inter-industry analysis has been attempted to examine any imbalances in the economy. From the Leontief inverted transaction matrix of the inter-industry table for the economy of British Guiana 1959 (Tables 6c and 6d), total supply of goods and services necessary to meet the projected final demands (i. e. , government and household expenditures, exports and gross domestic capital formation) have been estimated for 1965-75. Allowing for imports in the same proportions of imports to total supply as in 1959, we have obtained the "needed" domestic outputs. The ratios of these "needed" domestic outputs to our sectoral growth domestic outputs (Table 2. 5. ix) show that a larger proportion of imports than in 1959 will be necessary to balance the economy. However, by 1975 livestock, forestry and fishing, chemicals, other manufacturing, and fuel and power will be well advanced in their bid towards import substitution, and engineering will also make significant progress. An interesting fact is that mining has more export potential than at present and even by 1975 it will not be fully exploited. The major bottlenecks appear to be the agriculture and food processing sectors, where imports will be increasing, and also the building and construction sector which would require more expansion. On the other hand, distribution, transport and communications, banking and insurance, and professions and personal services will be more than adequate. Thus the imbalances in the economy require significant efforts in import substitution activities, especially in processing and manufacturing industries.

## EXPLANATORY NOTE FOR PART TWO

### LIST OF INDUSTRIES INCLUDED IN EACH SECTOR

Territory and sector	Activities included
<u>Jamaica</u>	
1. Sugar cane growing	Farmers, estates, factory — sugar, rum molasses and rum bottling.
2. Export agriculture	Banana, citrus, coffee, cocoa, pimento, ginger, other export growing and processing (packing, pulping, washing, drying, roasting where applicable). This sector excludes local consumption of these commodities and includes all distribution of exports between grower and ports of loading.
3. Domestic agriculture	<u>Cultivation only</u> of pulses and vegetables, herb tea, flowers, rice, tobacco, root crops, fresh fruit. Forestry and products for processing, e. g. , mangoes, ackee, pineapple, coconuts. Also all commodities consumed domestically that are mainly export goods.
4. Livestock and fishing	Poultry, eggs, milk, fish, meat production.
5. Mining and quarrying	Bauxite, alumina, gypsum quarrying.
6. Construction	All private and public capital formation and maintenance of capital except small items of repair (in Manufacturing 4).
7. Manufacturing 1: food, drink and tobacco	Coconut products, cassava, cigarettes, cigars, oils and soaps, biscuits, cornmeal, bakeries, condensed milk, beer, carbonated beverages, ice making, liqueurs, ice cream, animal feeds, pimento oil, sugar confectionery, rice milling, tobacco curing, canning and preserving, macaroni, local beverages, butchers.
8. Manufacturing 2: textiles, fibres and leather	Clothing, cloth, buttons, mattresses, zip fasteners, straw goods, footwear, leather products, shoe heels, coir products, rope and cordage.

Territory and sector	Activities included
9. Manufacturing 3: heavy industries	Cement, stresscrete, gypsum products, blocks, tiles, boat building, wooden containers, wooden handicraft, plumbing,, sawmills, metal beds, aluminium products, metal fixtures, furniture and fixtures, metal containers.
10. Manufacturing 4: miscellaneous	Newspapers and publishers, advertising, paper products, petrojel, records, tyre retreading, batteries, dyes, anhydrous alcohol, neon signs, job printing, rubber stamps, charcoal, toilet preparations, motor repair, paint, oxygen, plastics, carbon dioxide, electrical repairs.
11. Distribution	All wholesale, retail, commission agents, etc.
12. Public utilities	Water, gas, electricity.
13. Transport, etc.	Wharfage, stevedoring, cold storage, citrus packing, rail-road, road passenger, shipping, travel agents, taxis, airline agents, airlines, communications.
14. Services	Banking, life insurance, general insurance, building societies, real estate, mutual finance, other investment, Industrial Development Corporation, education, medical and health, legal, hotels, restaurants, clubs, recreation and entertainment clubs, cinema, racing, Jamaica Broadcasting Corporation, other — laundries, barbers, beauticians, tailoring, shoe repair, photography.

#### Trinidad and Tobago

1. Petroleum and asphalt	Mining and refining of oil; mining of asphalt, natural gas.
2. Sugar and rum	Manufacture of sugar, rum, molasses, bitters and bagasse.
3. Manufacturing	All other manufacturing.
4. Transport and communications	Taxis, trucks, buses, air services, telephone and cable and wireless.
5. Public utilities	Port services, harbour master, electricity, railways, post office.
6. Building and construction	Building and construction done on behalf of other industries and services, government and households.
7. Government	Central and local.

Territory and sector	Activities included
8. Services	Distribution, tourism, banking, domestic services, etc.
9. Agriculture	Export and domestic agriculture, livestock and fishing, forestry and quarrying.
<u>British Guiana</u>	
1. Agriculture	Rice, sugar cane, coconut and copra, other agriculture (fruits and vegetables, coffee, cocoa, corn, etc., ground provisions, tobacco leaves, fodder, etc.).
2. Livestock, forestry and fishing	Cattle, pigs, etc., poultry, milk, eggs, honey, etc., hides and skins (raw). Forestry and charcoal making, balata and barks. Fishing — sea, inland and aquarium.
3. Mining	All minerals, stone and stone-crushing, sand, etc.
4. Food processing	Rice milling, sugar and molasses, beverages — alcoholic and others, oil and fat, meat, coffee, tobacco, bakery, dairy products, milk pasteurisation, canned foods, etc.
5. Chemicals	Drugs, oxygen, soap, matches, paints and dyes, fertilisers, etc.
6. Engineering	Foundry, boat building, repair and maintenance of machinery, metal manufactures, electrical and transport equipment.
7. Other manufacturing	Furniture, leather, knitwear and dressmaking, jewellery, handicrafts, printing, saw-milling, concrete blocks, all non-metal manufactures.
8. Fuel and power	Electricity, fuel oil and lubricants.
9. Distribution	Wholesale and retail trade, commission agents, travel and insurance agents, film distributors, marketing organisations, storage and warehouses, wharves, advertising, gasoline distribution and petrol pumps.
10. Transport and communications	Air, river, and sea, railways, road (excluding all transports not available for hire outside). Post and telecommunication, cable and wireless, radio, harbours.
11. Banking and insurance	Commercial banks, post office savings bank, insurance companies, co-operative societies, money-lenders, pawn-brokers, real estate dealers, investment companies.

Territory and sector	Activities included
12. Professions and personal services	Professions, tailors, barbers, domestics, laundries, funeral parlours, cinemas, sports clubs and fairs, professional societies, schools (excluding government), religious and welfare missions (churches, hospitals, Red Cross, etc.), catering.
13. Building and construction	Repairs and maintenance of land and buildings, fixed capital formation.
14. Rent of dwelling	Actual and imputed rents of all residential dwellings.
15. Government	Local and central government income and expenditure (excluding working of government enterprises).
16. Household	Salaries and wages, etc. , income from property and farms, professions, etc. , profit (net of all taxes) and consumption expenditures.
17. Foreign countries	Imports and exports of goods and services and current transfers.
18. Gross domestic fixed capital formation	Net change in stocks, capital formation in building and plant and machinery, prospecting and exploring for minerals, and improvements of land.

**THE PROJECTION OF DEMAND**

Chapter 1

**DEMAND AND INCOME**

Given the expected growth in population and in income per capita, the estimation of future demand depends primarily on the relation assumed to exist between demand and income. This is normally expressed in terms of the income elasticity of demand for the different products and product-groups under consideration. The statistical measurement of these income elasticities may be carried out by one, or both, of two different methods. Time-series data relating to income and consumption per capita and to changes in prices over a suitable period may yield serviceable estimates both of income elasticities and of price elasticities. Alternatively, survey data relating to consumption or expenditure by different groups of households in a given period may be analysed to show the relation between total household income or expenditure and the demand for individual items. A single survey however will not permit the estimation of price elasticities, since the price situation must normally be assumed to be the same for all the households taking part in it.

In the present study, reliance has had to be placed mainly on the second or cross-sectional method, since satisfactory time-series data for a sufficient number of years are not available. Whenever possible however, the changes which have taken place in recent years in average consumption levels (some of which are of substantial magnitude) have been taken into account in determining the elasticity to be used for purposes of projection.

Expenditure surveys for cost-of-living index purposes have been made in several West Indian territories, and some estimates of income elasticities based on this material have already been published (Ref. D.1.). For the purpose of the present study, a number of special analyses were made of the results of the survey carried out in Jamaica in 1958. Use has also been made of some of the results of other surveys, but it has not been possible to analyse these in the same detail.

The Jamaica survey was carried out by the Government Department of Statistics, and a report based on it was issued in 1960 (Ref. D.2). It covered 1,160 households divided roughly according to the distribution of total population between the main urban area, Kingston, the other main towns on the island, and the rural areas. The survey records were made available by courtesy of the Department, but it bears no responsibility for the use which has been made of them for this study.

An itemised food budget, including both purchased foods and those obtained as gifts or from domestic production, was requested from each participating household for two weeks at different periods of the year. Information was also asked for on other principal categories of expenditure during the year, and on the earnings of members of the household.

In view, however, of the difficulty of obtaining reliable estimates of household income, the analysis of demand elasticities has been based on the recorded total expenditure of the household as the determining or independent variable.

In order to carry out the analysis, households from the rural areas and from Kingston were first grouped into a series of household types of constant composition in order to eliminate the influence of variations in size and numbers of children on the expenditure pattern. The records for each of the most numerous of these groups were then analysed by fitting for each of the major commodity groups a semi-logarithmic equation of the form

$$y = a + b \log x$$

where  $x$  represents total household expenditure and  $y$  the expenditure on the particular product-group under investigation. The income elasticity of demand, represented mathematically by  $\frac{x}{y} \frac{dy}{dx}$ , is equal, in this formulation, to  $b/y$ , the average value of  $y$  being taken in order to give the average elasticity for each sample. <sup>1/</sup> By this procedure a number of estimates of the elasticity for each product-group are obtained. These may, in appropriate cases, be combined by suitable methods of averaging to give an overall estimate of elasticity for the whole population.

The above equation is only one of a number of different equations from which estimates of income elasticity may be derived. The choice of the equation depends on the nature of the relationship assumed to exist between total expenditure and expenditure on a particular item, and in particular, on the change (if any) expected to occur in the value of the elasticity as the income or consumption-level itself changes. In the above formulation the elasticity is assumed to diminish as the income or consumption level rises, and this seems in general a more satisfactory assumption than the hypothesis of a constant income elasticity, especially in projecting demand from a base period in which the initial elasticity is high, as it is for many commodities in the West Indies. The semi-logarithmic equation is not the only type which satisfies an assumption of this kind, but it has the merit of being readily calculated and simple to apply for purposes of projection.

After obtaining the elasticity estimates in this way, it is necessary to consider how far they seem to give a valid representation of the demand situation in 1958 and in what respects, if any, it is desirable to adjust them in projecting future levels of demand. In the present instance it was necessary first of all to allow for the fact that only a relatively small part of the whole survey sample could be used in the elasticity analysis, and that the households included were of small size and had relatively few children. As would be expected, they had considerably higher average values of total expenditure and of expenditure on food per person than the whole sample. Part, but not the whole, of this difference is due to the relatively small number of children in the households analysed. A rough estimate was therefore made of the difference in expenditure per equivalent adult between the households included in the elasticity analysis and households in the whole of the sample, and the average elasticities derived from the analysis were adjusted to the estimated average rates of expenditure in the full samples of both urban and rural households. Since the

<sup>1/</sup> In practical computation using common logarithms  $b$  must be multiplied by  $\log_{10}$  (.43429. . .) to obtain the estimate of elasticity.

semi-logarithmic formula assumes that income elasticity varies inversely with the level of consumption or expenditure, the effect of the adjustment was in nearly every case to increase the elasticities above the calculated figures; in general however, the adjustment was relatively greater for the rural than the urban households.

Having arrived in this way at estimated figures valid both for the rural and urban sections of the sample, we must next take account of the fact that the data used for the analysis related to the expenditure incurred by the housewife on the different items purchased and not to their quantity or their value at ex-farm or import prices. It is well-known that the elasticity of expenditure on a given type of food has in general a higher value than the elasticity of the quantity purchased, because part of the additional expenditure incurred by higher-income families is devoted to higher priced varieties of food or to products whose value includes a higher proportionate element of processing or distributive costs. The element of quality elasticity may play an important part in determining the total expenditure elasticity, and estimates of its effect can be obtained from surveys (such as the United Kingdom National Food Survey) in which the elasticity can be separately measured both for quantities purchased and for expenditure. In the Jamaica survey, no precise allowance for this "quality factor" was possible, but since what is required for purposes of projection is an estimate of the quantitative elasticity in terms of farm output or imports, a downward adjustment, determined in the light of general probabilities, was made to the estimates resulting from the procedure described above. In most cases this second adjustment largely cancelled the effect of the first so far as the urban households were concerned, but for the rural sample the elasticities remained on the whole higher than the unadjusted figures resulting directly from the analysis.

If the figures obtained in this way could be taken as valid estimates of the income elasticities of demand for the rural and urban sections of the total population respectively, it would be sufficient to weigh them according to the rural and urban proportions of expenditure on each commodity in order to calculate average figures applicable to the population as a whole. This procedure, however, assumes that the survey was in fact representative of the whole population, an assumption which cannot be taken for granted without question. The survey was conducted by random methods and was intended to give a representative sample, but it seems probable that, like most surveys, it failed to give adequate representation to the highest income-strata. The average food expenditure recorded in the survey (J£26.4 per capita per year) falls substantially short of the official estimate made for national income purposes of the total personal expenditure on food, which works out at an average for 1958 of about J£39.8 per capita. An exact agreement between these two figures is not to be expected for a number of reasons; in particular the national income estimate includes the expenditure of non-residents, which must be excluded in order to give a figure comparable with the survey average, while the latter is subject to errors of recording which are obviously much more likely to result in under-estimation than in over-estimation. It is however difficult to explain in these ways more than a small part of the relatively large discrepancy between the two figures. If the national income estimate is to be taken as approximately accurate, therefore, it seems necessary to assume that the highest income-groups among the population, say the wealthiest 10 to 15 percent, were substantially under-represented in the survey. The difference would be largely accounted for if the survey average could be taken to represent the expenditure of say 85 percent of the population, and if the average food expenditure of the remaining 15 percent were assumed to have amounted to about J£100 per capita per year or about J£2 per week. This is by no means an improbable figure — it was in fact exceeded by about 14 percent of the two-

adult households surveyed in Kingston. But if this is the explanation of the discrepancy between the two estimates, it follows that a group of households whose income elasticity of demand must be much lower than the general average was in effect excluded from the survey sample. It must be remembered that the weighting appropriate to the averaging of elasticities over different sections of the population is proportional not to their numbers, but to their expenditure, and this will give the under-represented wealthy consumers a much higher weight than they would receive on the basis of their numbers. These considerations seem too important to be ignored, and although the allowance for the under-represented income-groups can only be made on a very rough basis it has been assumed that its effect is to reduce the elasticities applicable to the whole population in 1958 by about 10 to 15 percent as compared with the weighted averages resulting from the calculations previously described.

## Chapter 2

### FOOD EXPENDITURE IN JAMAICA IN 1958: SURVEY RESULTS

Details of the expenditure on food recorded in the Jamaica survey are summarised in Table 3.2.i. Before discussing the elasticity estimates derived by the methods outlined above, attention may be drawn to certain features of the food expenditure pattern as revealed by these figures.

The most striking feature is the large difference in average expenditure between the urban and rural groups of households. The Kingston families spent about 2 <sup>1</sup>/<sub>2</sub> times as much on food per capita as the rural families, and on fresh meat and fish, and milk products and eggs their rate of expenditure was about three times that of the rural families.

Part of this very large difference is explained by the variation in household size and composition, the rural families being much larger and including a much larger proportion of children than the urban households. This factor, however, can be allowed for by comparing only rural and urban households of identical composition in the special elasticity analysis (see Table 3.2.ii). When the comparison is made on this basis the total food expenditure of the rural families rises to about half the Kingston rate and there are roughly corresponding changes in the averages for individual food groups. It is noteworthy that when households of identical composition are compared the Kingston rate of expenditure on roots and starchy vegetables is lower than that of the rural households.

A further part of the total difference is explained by differences in price levels between the two areas, Kingston prices being generally higher, though the price records on which this statement is based (which were made available by the Jamaica Department of Statistics) show that there are some products, especially imported items, which are at times cheaper in Kingston than elsewhere on the island. The food groups mentioned above as showing the greatest relative difference in expenditure levels are also those for which the difference in price levels seems to have been greatest. The difference in prices amounted to perhaps 20 to 30 percent for fresh meat and fish and possibly to somewhat more for fresh fruit and vegetables (other than roots and starchy vegetables). Fresh milk was substantially more costly in Kingston than elsewhere and there was a similar though smaller difference in the price of eggs. Many foods however were (and are) subject in Jamaica to official price-control orders, and these (which include condensed milk, butter and cheese) are practically always sold at uniform prices throughout the island.

It is clear, therefore, that when allowance is made for both these factors, much the greater part of the difference in expenditure levels remains unaccounted for and reflects a genuine quantitative difference in consumption. In many respects indeed, the two groups

of households seem to belong to different worlds. The upper stratum of the Kingston households represents a middle-class standard of expenditure and consumption not very different from what might be found in Europe, while the lower strata among the rural households exhibit the consumption and expenditure pattern of the West Indian peasant diet. Over 20 per cent of the rural households included in the analysis, for instance, recorded no consumption of fresh meat or fish, but the proportion among the Kingston households which had no consumption of these products was negligible. The changes in food consumption which occurred during the last decade represent in many respects a process of transition between these two modes of life, and there seems no doubt that this process will continue to characterise the demand pattern of the next twenty years, assuming that the rise in average income levels and the spread of urban consumption habits is maintained.

Table 3. 2. i

Average food expenditure per person per week, Jamaica Expenditure Survey, 1958

Item	Kingston	Other towns	Rural	Total or weighted av.
Number of households	352	127	681	1,160
Number of persons	1,138	506	3,209	4,853

## Chapter 3

### INCOME ELASTICITIES OF DEMAND IN JAMAICA

A summary of the evidence as to income elasticities for the principal food groups as devised from the Jamaica survey is given in Table 3.3.i. For six of the most important of these groups the regression coefficients from which the elasticities are calculated are shown in Table 3.3.ii which also gives the corresponding coefficients of correlation and the estimated standard errors of both the regression and the correlation coefficients.

The figures in the right-hand column of Table 3.3.i are the general averages which have been derived from the survey figures after making the adjustments already described in order to reach estimates which can be taken as applicable to the population as a whole. Before using these figures as the basis of the estimated elasticities required for purposes of projection, however, it is desirable to consider them in relation to the changes in average income and consumption levels in Jamaica which have taken place during the last decade. So far as possible two sources of information as to changes in consumption between 1950 and 1958 have been used; these are the quantitative estimates, where available, of average consumption per capita, and a deflated series of estimates of personal expenditure per capita on certain commodities derived by applying an index number of retail prices to the national income estimates of expenditure at current prices in different years. Unfortunately, however, the dearth of reliable statistical material has made it necessary to confine this examination to a few of the major products or product-groups.

In respect of meat and dairy products and of total food expenditure there is good agreement between the recorded changes and those calculated from the estimated elasticities. In the case of sugar, estimates published by FAO (Ref. D.8) show an increase in per capita consumption in Jamaica between 1950 and 1958 of 19 percent, which is reasonably consistent with the estimated elasticity derived from the survey (though the latter relates to a group of products including confectionery for which the income elasticity is probably higher than for sugar itself). For the remaining food groups however the agreement is less close, and in some cases there is difficulty in reconciling the estimated actual changes in consumption with the survey evidence as to demand elasticity.

In the case of oils and fats, supply statistics appear to place it beyond doubt that average consumption per capita rose between 1950 and 1958 by about 80 percent, which implies a much higher income elasticity than is warranted by the survey evidence. Retail prices of these products appear to have fallen somewhat in relation to those of food in general, but the increased consumption cannot be explained by substitution at the expense of butter since the consumption per capita of butter itself more than doubled during the period. Domestic production of copra in Jamaica was however much lower in 1950 than in 1958 since recovery

 2A + C<sub>2</sub> = Households with 2 adults and 1 child 5 to 14 years old.  
 3A = Households with 3 adults.

2/ After adjustment as described in text.

from the effects of the 1943 hurricane was still incomplete. It seems necessary to suppose that consumption levels were abnormally low at this period and that the short-fall in supplies was not made good by imports. In predicting future levels of demand, therefore, the experience of the 1950's may perhaps be disregarded; at all events it seems impossible to ignore the survey evidence as to income elasticity so far as future years are concerned. (It will however be observed from Table 3.4.i. that Jamaican consumption of oils and fats was still much lower in 1958 than that of other territories.)

The consumption of cereal products appears (both from the deflated expenditure estimates and from the tonnage statistics of total supplies) to have increased considerably more than would have been expected on the basis of the survey evidence as to income elasticity. To give a close fit to the deflated expenditure estimates the income elasticity in 1958 would have to be raised to rather more than unity; the supply statistics indicate an increase of average consumption per capita between 1950 and 1958 of about 45 percent, which if wholly due to the rise in income levels would suggest an income elasticity in 1958 of about 0.75, two-thirds greater than the estimate derived from the survey of about 0.45. An elasticity significantly exceeding the latter figure however would be impossible to reconcile with the general evidence relating to income elasticities for cereals in other underdeveloped areas, which do not seem to exceed 0.5 even in the low-income countries of Asia and Africa where standards of living and of food consumption are undoubtedly lower in many cases than in the West Indies.<sup>1/</sup> Mainly for this reason, therefore, it has seemed desirable, in spite of this conflict of evidence, to adhere to the survey-based estimate of 0.45 as the average income elasticity in terms of quantity for the cereals group as a whole in Jamaica.

By contrast with cereals, the average consumption of roots and starchy vegetables, which in countries such as Jamaica represent an important alternative to cereals as sources of carbohydrates, seems to have been falling. However, the supply statistics for this group, which includes many products grown by rural households for their own use, are in the nature of things somewhat conjectural. Substitution in response to price changes may account for part of the change in the relative consumption of root vegetables and of cereals, since the average prices of the former appear to have risen somewhat during the 1950's in relation to those of cereals.

Even in the absence of price changes, however, a rise in the consumption of purchased cereals such as bread and rice at the expense of the subsistence carbohydrate foods would be one of the consequences to be expected from a shift in consumption habits towards a diet of the urban type and away from that characteristic of the traditional rural mode of life. It is evident from the survey analysis that the consumption of roots and starchy vegetables is considerably lower in Kingston households than in rural households. This lower consumption in Kingston is important even though it conflicts with the difference in consumption levels which would have been predicted from the estimates of elasticity within both the rural and urban groups of households (the latter being in every case positive, as they are for all other product groups). In interpreting the survey estimates of elasticity however, it must be remembered that they relate to groups of food that include a number of

---

<sup>1/</sup> See "Agricultural Products, Projections for 1970", Food and Agriculture Organization, 1962; Annex, Table M4.

different products which were not of the same relative importance in Kingston and in the rural areas, a larger proportion of the total being represented by potatoes among the urban households. Other evidence suggests that both Irish potatoes and sweet potatoes have a considerably higher income elasticity than the other products in the group, and when this is allowed for, a low, or even negative, elasticity among urban households for some of the other root vegetables is not necessarily inconsistent with the survey evidence.

It must be admitted that the statistical evidence on these points is not as conclusive as might be wished. It seems reasonable nevertheless to take the differences in expenditure on root vegetables between rural and Kingston households (expenditures are consistently higher among rural households) as giving an indication (when considered in relation to the difference in total expenditure between the same groups) of the change to lower expenditure on root vegetables that would be associated with the increase in income experienced by families moving from the rural to the urban section of the population. In relation to such a change in income the elasticity of demand for root vegetables is obviously negative. Now a continued rise in average income levels in Jamaica seems certain to be associated to a certain extent with growing urbanisation (the term being taken in a broad sense to include changes towards a more urban type of diet which may well affect households living in rural areas as well as those which actually move from the country into the towns). Thus it seems appropriate, in considering the future demand for roots and starchy vegetables, to assume that part of the increase in average income which is expected in future years will be accounted for by an increase in the urban or urbanised section of the population, whose diet will conform to the pattern indicated by the urban sample in the expenditure survey, while part will be due to an overall increase both in urban and in rural income per capita. If so, the elasticity for projection purposes should be an average of the different elasticities appropriate to these two changes.

In the light of these considerations a small negative value was assigned to the income elasticity of demand for root vegetables other than potatoes; for the latter, however, a fairly high positive elasticity was assumed.

The evident need, in this instance, to take account of the influence of urbanisation on the pattern of consumption as a factor distinct from the increase of real income by itself may seem to suggest the desirability of making separate estimates for all foods of the possible change due to urbanisation and of combining these changes with those expected from a uniform overall increase in average income in making the final demand projections. Trial calculations showed, however, that for products other than root vegetables an almost identical result was reached whichever method was used and that the attempt to take explicit account of the urbanisation factor added considerable complications to the process of calculation without appreciably influencing its outcome. This is of course a reflection of the fact that the urban-rural contrasts in consumption indicated by the 1958 survey, although striking and important in themselves, do not, in respect of most commodities, differ in any major way from those to be expected on the basis of the difference in total expenditure between the urban and rural groups of households and the average demand elasticities emerging from the analysis. The roots and starchy vegetables are the only major exception to this statement, and this is the justification for departing from the usual procedure in estimating their demand elasticities.

In general, then, the survey evidence has been accepted as the basis for the estimation of the income elasticities for each of the different product groups. But in projecting the

## Explanation of Symbols:

Y<sub>1</sub> = Total expenditure per household on food (less alcoholic drinks).  
 Y<sub>2</sub> = Expenditure per household on cereals and bakery products.  
 Y<sub>3</sub> = Expenditure per household on sugar, sweets and condiments.  
 Y<sub>4</sub> = Expenditure per household on roots and starchy vegetables.  
 Y<sub>5</sub> = Expenditure per household on fresh meat and fish.  
 Y<sub>6</sub> = Expenditure per household on milk products and eggs.  
 z = Logarithm of total household expenditure.

2A = Households with 2 adults  
 2A + C<sub>1</sub> = Households with 2 adults and 1 child under 5 years old.  
 2A + C<sub>2</sub> = Households with 2 adults and 1 child 5 to 14 years old.  
 3A = Households with 3 adults  
 $\sigma$  = Standard deviation.  
 $\hat{\sigma}$  = Standard error.

demand for individual products, separate estimates of elasticity are in most cases necessary for the products falling within each group. Thus while the income elasticity for most kinds of fresh meat is put at 1.10, poultry is given the higher elasticity of 1.50, while a much lower figure (0.10) is assigned to salt meat; within the cereals group similarly a lower elasticity has been assumed for rice and corn meal than for wheat flour and its products. In the estimation of these individual elasticities there is inevitably a greater element of personal judgement since precise statistical evidence comparable to that used in estimating the group elasticities is not in most cases available. However, in most cases the nature of the probable relationship between the elasticities for different types of food within a given category is reasonably certain.

The formula employed in making the projections on the basis of the elasticities thus established assumes the continuance during the period covered by the projection of the semi-logarithmic relation between demand and income. On this assumption the projecting equation is:

$$\frac{Y + \Delta Y}{Y} = 2.3026 \eta \log_{10} \frac{X + \Delta X}{X}$$

where  $\eta$  is the income elasticity of demand for each commodity,  $Y$  the base period consumption per capita and  $X$  the base period income per capita. This equation gives an estimate of average demand per capita of population, from which the aggregate demand is derived by multiplying by the projected relative population for the data in question and by the aggregate supply in the base year 1958.

## Chapter 4

### INCOME ELASTICITIES OF DEMAND IN OTHER WEST INDIAN TERRITORIES

The estimates of income elasticity for the other West Indian territories are rather less firmly established than those for Jamaica, since, apart from the article by Cumper already referred to and some unpublished work by Taylor there is little direct evidence on which to base them. Cumper's estimates of income elasticity relate to Barbados in 1951-52 and to British Guiana in 1956. In both cases the foods with the highest elasticities were meat and dairy products, for which the figures reached or surpassed unity; most other foods fell within a range of values from about 0.4 to about 0.8, but cereals in British Guiana had a small negative elasticity when home-produced rice was included, though a positive value of about one-half was reached when it was excluded.

On the whole the evidence did not seem to justify any major departure from the elasticity values arrived at for Jamaica except where this was clearly indicated by the known differences between the territories in income levels and in the general patterns of food consumption. It will be seen however from Table 3.4.i. in which the estimated levels of food consumption and expenditure in the different territories are compared, that some of these differences are important.

The principal contrast between the diets of the four areas is in the consumption of cereals, which is much higher in British Guiana and Trinidad and Tobago than in Jamaica or the smaller islands. This is mainly due to the large consumption of rice in British Guiana and Trinidad and Tobago, both of which have considerable numbers of East Indians in the population. Roots and starchy vegetables are consumed in relatively small quantities in these territories, especially in British Guiana, where peasant agriculture is mainly centred on the production of rice. In the smaller islands, the general pattern of consumption resembles that of Jamaica, as does the racial constitution of the population. The populations of the individual islands in this group differ from one another in many respects, but it is possible to find social groups within the Jamaican community with fairly strong resemblances to each of them. The Windward Islands are paralleled by the hill areas of Jamaica and share with them a common dependence on a similar type of subsistence agriculture, while Barbados and the Leeward Islands are comparable with the flatter and lower-lying regions of Jamaica which are dominated, like them, by the plantation sugar economy.

In comparing the estimates of food expenditure and gross domestic product, there are certain differences in price levels between the territories which should be taken into account. Food prices and retail prices in general are probably highest in Jamaica and lowest in British Guiana and Barbados. Thus the difference in gross domestic product per capita between Jamaica and British Guiana was less in real terms than appears from the table,

while food expenditure reckoned at a common price level would probably have amounted to much the same figure in both territories. There is no doubt however that Trinidad and Tobago enjoyed the highest level both of real income and of food consumption, and the group of smaller islands the lowest, even though the latter include Barbados which, individually, had an average real income per capita not very different from that of Jamaica and considerably higher than those of the territories with which it is grouped.

Table 3.4, i

Food consumption per capita of population, by territories, 1958

Item	Jamaica	Trinidad and Tobago	Leeward Islands, Windward Islands and Barbados	British Guiana

Source: Data and material developed during the study and other available data.

In view of the part played by rice in the diet both of Trinidad and Tobago and British Guiana its income elasticity must clearly have a much lower value in these territories than in Jamaica or the smaller islands. In British Guiana the elasticity was taken as equal to

zero for rice, but a relatively high elasticity (0.80) was assumed for wheat flour in view of the likelihood of increased demand for bread as diets become more sophisticated and less dependent on subsistence production. In Trinidad and Tobago, on the other hand, rice was assumed to have a small positive elasticity, but since the consumption of wheat flour is already fairly high it was given a rather lower elasticity than that estimated for Jamaica. These values, when weighted in accordance with the estimated contribution of the different products to the calorie value of the 1958 diet, give average income elasticities for all cereals of about 0.3 in Trinidad and Tobago and British Guiana compared with the average of 0.45 for Jamaica. In the smaller islands the elasticity for rice is assumed to be the same as in Jamaica and that for wheat flour rather higher, giving an average elasticity for all cereals of about 0.6.

Table 3.4.ii

Estimated average income elasticities for food groups, by territories  
(Weighted according to 1958 calorie consumption per capita)

Food groups	Jamaica	Trinidad and Tobago	Leeward Islands, Windward Islands and Barbados	British Guiana
Cereals	0.45	0.3	0.6	0.3
Sugar and sugar preparations	0.4	0.4	0.4	0.4
Roots and starchy vegetables	-0.06	0.3	0.1	0.3
Vegetables and pulses	0.55	0.3	0.5	0.55
Fruit	0.65	0.55	0.65	0.8
Meat and poultry	0.9	0.8	0.6	0.9
Fish	0.45	0.55	0.4	0.4
Milk products (excl. butter) and eggs	0.7	0.5	0.7	0.6
Oils and fats	0.65	0.45	0.65	0.35
Average of all above				
Average of all above foods	0.45	0.3	0.45	0.3

Potatoes are also given a lower elasticity in Trinidad and Tobago and British Guiana than in the other territories, but other root vegetables are assumed to have a positive elasticity of 0.25 compared with the small negative elasticity assigned them in Jamaica. In the smaller islands it is assumed that the elasticity for potatoes is the same as in Jamaica, while that for other root vegetables is effectively equal to zero. For roots and starchy vegetables as a group the elasticities in terms of calories average out at about 0.3 in British Guiana and Trinidad and Tobago and 0.1 in the smaller islands compared with an overall figure of slightly less than zero for Jamaica.

There are a number of other differences between the territories in the elasticities assumed for different foods, all of which have again been arrived at mainly in the light of the differences in average 1958 consumption levels. Thus fresh vegetables and pulses are given a considerably lower elasticity in Trinidad and Tobago than elsewhere while fruit and butter were for a similar reason assumed to have relatively high elasticities in British Guiana. In both these territories the elasticities for fresh milk, cheese and vegetable oils were reduced below the Jamaica figures, as also were the Trinidad and Tobago values for butter and condensed milk. In the smaller islands a large part of the total consumption of meat appears to consist of salt pork, for which the elasticity seems likely to be small; this has the consequence of reducing the average elasticity for all meat in terms of calories below the comparable average for the other territories.

The approximate average elasticities for the different territories in terms of calories, weighted in accordance with the estimated calorie values of 1958 consumption per capita, are shown for the major food groups in Table 3.4, ii. Overall average income elasticities in terms of calories have been calculated by F.A.O. for a large number of other areas and published in the report already referred to. <sup>3/</sup> These calculations give, for example, averages of 0.30 for Mexico, 0.40 for Africa and the Near East (excluding South Africa) and 0.62 for Asia and the Far East (excluding Japan). As shown by the table, the averages for the West Indies work out at about 0.45 for Jamaica and the smaller islands and 0.3 for Trinidad and Tobago and British Guiana. If all the West Indian territories are grouped together the combined average comes to about 0.4.

Chapter 5

PROJECTIONS OF FINAL DEMANDS

With the elasticities estimated as described, and the data on expected growth of income and population as visualised in the long-term economic projections, the final demands may now be projected to 1975.

The relevant data of growth for the various territories are given in Table 3.5.i.

For the estimation of demand, the suitable index for Jamaica has been considered to be the per capita national income. For the other territories (Trinidad and Tobago; the Leeward Islands, Windward Islands and Barbados; and British Guiana) the index used was per capita consumption expenditure. Although consumption expenditure is supposed to have a constant relationship with the growth of national income in general, we have considered this relation not to be true for these three territories because of the unbalanced structure of their economies.

The details of food consumed per capita and its calorie contents are shown for each of the territories in Tables 7a to 7d. Protein and fat consumption is shown in Table 8 for Jamaica only. Summary Table 3.5.ii, showing the per capita consumption per day of calorie, protein and fat, by food groups, will be useful for comparison of food consumption in the various territories. The calorie content of food in 1958 was highest in Trinidad and Tobago, and British Guiana. Although Jamaica had a higher per capita income in 1958 than British Guiana, the calorie content of Jamaican food consumption was lower than that of British Guiana. This is presumably because expenditures on food have not been much different in both territories in spite of large differences in income, and furthermore, the income distribution in Jamaica may be considered as having a significantly higher range than in British Guiana. However, as a result of future economic growth in the other territories, by 1957 British Guiana will have the lowest calorie consumption. Thus, it is estimated that the calories will increase from 2,111 in 1958 to 2,635 by 1975 in Jamaica, 2,533 to 3,024 in Trinidad and Tobago, 2,040 to 2,455 in the Leeward Islands, the Windward Islands and Barbados, and 2,200 to 2,254 in British Guiana.

Protein and fat contents of food have been estimated for Jamaica only. It is estimated that the consumption of protein per day will go up from about 56 grams in 1958 to about 70 grams by 1975, and the consumption of about 34 grams of fat in 1958 will increase to about 47 grams by 1975. The protein and fat consumptions in other territories will also be about the same since major sources of protein by food groups are starchy foods, meat and fish, and those of fat are starchy foods, meat, fish, milk and oils, etc. Fruits are also an important source for protein and fat, but the consumption of fruits differs widely among the territories. However, the presence of more starchy foods and oils and fats in the food consumption of other territories will offset the lower consumption of fruits, sugar and eggs, and thus protein and fat consumption will be comparable with that of Jamaica.

Thus, the nutritional value of food consumption in these territories does compare favourably with other countries having similar income and climatic conditions, etc. It may also be noted that the above analysis is based on main food items only, and estimates of tea, coffee, cocoa, and alcoholic and non-alcoholic beverages could not be considered in our study. The inclusion of these items will increase the calorie content to some extent and present a more favourable picture.

## *Part Four*

### *PROJECTIONS OF SUPPLY*

#### Chapter 1

#### LAND UTILISATION IN THE WEST INDIES

##### Basic resources

Conditions of supply in any country are determined by the basic resource pattern. Local resources of land and labour may not be limiting factors in countries where there are untapped and unexploited areas of land and local labour supplies. In such countries capital is likely to be the main limiting factor. In the West Indies, both land and capital are limiting factors and, although there has been a plentiful labour supply in most territories, there is now evidence of regional labour shortages in some small islands and rural areas caused by migration. The resource pattern is therefore somewhat complex. In general however, the economies can be characterized by the statement that there is a pressure of population on land resources, with consequent pressures to increase industrialization, to increase the net output from agriculture and to increase emigration. The island of Dominica in the Windward Islands and the hinterland of British Guiana are the only areas in which this generalization is not applicable.

The limitation of land resources has in a sense simplified our problems of making projections. Generally speaking, there are known limits to the quantities of land suitable for any one commodity, and acreage can only be increased by substitution. Although increased prices could make possible the cultivation of certain lands not now cultivated, this could only relate to certain commodities and to limited areas. Thus land must impose early limits in total acreage cultivated. Even if we include the island of Dominica and the British Guianese hinterland, it does not materially expand the extensive frontier since most of the land in the former is too rugged and in the latter of too low soil quality to represent anything approaching large unexploited land resources.

##### Existing land use pattern

Table 9a indicates the land use pattern in the West Indies. These figures were derived from censuses and surveys taken at various dates for certain territories. The information has not been brought up to date since the years indicated. An agricultural census is now in process of tabulation and although no firm information is available, there are preliminary indications that a number of small farms may have gone out of production, owing probably to migration. Nevertheless, the acreage under sugar and other cash crops is known to have increased, so that even if food crop acreages have declined, we do not expect to find a decrease either in total crop land, or in land area under farms.

Table 9a shows that land in farms as a proportion of total land area varied from 5.5% in British Guiana (1952) to 91.7% in Barbados (1946). British Guiana however, is exceptional,

and without that country, Dominica with 37.8% had the lowest proportion of its land area in farms. Trinidad and Tobago's figure of 41.7% was probably significantly influenced by the considerable areas held as mining leases.

Using the 1960 census population figures, if we measure population density by relating population to total land, Barbados is by far the most densely populated area with .5 acre per capita, Grenada is next with .9 acre per capita, and the least populated areas are Dominica with 3.3 acres per capita, and, on a different order of magnitude, British Guiana with 95.1 acres per capita. If, however, we measure population density in terms of land in farms, while Barbados is still the most densely populated, St. Vincent, Trinidad and Tobago, and St. Kitts-Nevis-Anguilla all appear to be more heavily populated than Grenada. In terms of crop land per capita, Dominica is the least densely populated, followed by British Guiana, Montserrat and Grenada, all in second place (Table 9c).

These comparisons are of interest because they lead to the question of how far the total land area in farms represents the total land area suitable for farming and how far the total land area in crops represents the total of land suitable for crops. In other words, how much of unused land is suitable for bringing into farm occupancy and how much land not now under crops could be used for crops?

One would expect, in an area where land has been the main limiting factor, to find a fairly economic use of this resource. Only Barbados stands out as a model in this respect; in most other territories there is little doubt that some expansion could take place. Nevertheless it is perfectly evident that such expansion, whether of total farm area or of total crop land must be of a marginal nature as compared with current totals; only in Dominica and British Guiana is significant expansion likely to be possible and this is unlikely to exceed more than 20% of the current totals within the period with which we are concerned.

The figures in Table 9a indicate that a sizeable part (44% without British Guiana and 90% with British Guiana) of the land area is not in farm occupation. In British Guiana this low occupation ratio is of course related to the usual problems of developing a continental area of tropical bush with low soil quality and poor drainage. In the island territories, however, the reason for a fairly low occupancy is the rugged nature of the terrain. The island with the least rugged land surface is Barbados and here the ratio of farm area to total area is high. Dominica is by far the most rugged and, although there is more unused land potential in Dominica than in the other Lesser Antilles, this territory must always show a low occupancy rate. The figures for Antigua are biased by the inclusion of Barbuda, a dry uncultivable island with a low population and fairly large land area. The Trinidad figures are also biased by the inclusion of Tobago and by the high percentage of land tied up in oil leases and in swampland. Nevertheless Antigua on its own and Trinidad do not have the same problems of ruggedness that Jamaica, St. Vincent, Dominica, Grenada and to some extent, St. Lucia and Montserrat have. Grenada comes out rather well in all these comparisons since it appears to be, if anything, rather more rugged than St. Lucia and at least as rugged as St. Vincent, but has a higher proportion of its land in crops. This fact may have some significance in that it may indicate that not only Dominica but St. Lucia and St. Vincent have more occupiable land than their topography would indicate. However, we feel that such possible increases are small except in Dominica. We feel, moreover, that higher prices for cash crops would not necessarily lead to cultivation of additional acreage unless such additional acreages are as accessible and as simple to cultivate as those now

in production. Some land may be made accessible by new roads. Where this is impossible however, we do not consider that, within the income structure we have postulated, farmers will increase cultivation of inaccessible patches of soil in the mountains in Jamaica or in the Windward Islands, such as has happened in Grenada's recent past.

### Projected land use pattern

Table 9a shows the present land cultivation pattern as observed at the most recent census dates. In Tables 9b and 9d these areas have been projected on the following assumptions.

The total acreage of crop land is derived from aggregating the average projections made for the individual crops, which is explained in the next chapter.

The acreage under pasture is derived also in relation to projections of livestock numbers, although only for improved pasture can these be considered a fairly exact relationship.

In Jamaica, we have assumed some increase in the land in farms between 1958 and 1965. On the other hand, it is suspected that, due to migration, marginal land may be going out of cultivation; we do not predict much if any increase in total land in farms between 1965 and 1975. We do, however, consider there will be some increase in the ratio of pasture to woodland and an even bigger increase in the proportion of pasture that is improved.

Since so much land in Trinidad and Tobago is tied up in oil leases and crown forests, it is not unreasonable to suppose some increase in the area of farmland in the period. We consider, however, that after 1970 any increase in the area of farms is likely to be associated with increased pasture rather than crop land. The increases are not expected to be large.

For the Leeward Islands, Windward Islands, and Barbados, we have predicted small increases in farm areas since there is some room for increased farm use of land in Dominica. If the hoped-for expansion in bananas takes place, it is expected that new areas will come into use, although a considerable part of the expanded acreage would probably come from land already in farms but not cultivated. Although we expect some increases in pasture land improvement, it appears that in the small islands the biggest part of the increase will be in crop land.

In British Guiana we have assumed a rather greater increase in the farm area. This follows from known plans to increase rice acreage and to bring unoccupied land into rice cultivation. We expect also that cattle ranching may spread to some unoccupied land, thus increasing the area of farms further, although improved grasses may lead to intensive rather than extensive expansion of this industry. The assumptions mainly based on our projections for rice, sugar and cattle cultivation indicate an increase of farm land from 5% to 7% of total land area, and the proportion of crop land to total farm land is assumed to increase from 11% to 14%.

We should like to think that future increases in production will come from a better utilization of land rather than bringing of more marginal land into cultivation. Already one

finds examples of bananas and other crops being grown on land which can hardly be classed as cultivable, and which will not be cultivable after a few years exposure to wind and rain with the natural vegetation removed. Land tenure problems are among the many problems facing proper land use. Some of the better uncultivated lands are owned by estates or by small owners who do not utilise them. There is little doubt that a proper scientific approach to the land use problem would advocate intensifying production and possibly reducing the actual area of crop land. Due partly to institutional factors, we have not been able to predict a very significant move in this direction in this period, although some increases in yields are projected. (See chapter 3.)

## Chapter 2

### SCALE OF PRODUCTION OF AGRICULTURAL COMMODITIES

In the last section we discussed the general pattern of land use in the West Indies as we believe it to have been in 1958 and as we expect it to be if our projections are a fair picture of the future. Tables 9a to 9d illustrate this broad land use pattern, but in these tables we show crop land as a total. In this chapter we shall discuss the breakdown of crop land into the various crops and also discuss some figures for populations of commercial trees and livestock. Following this discussion of scale of production, we shall in the next chapter discuss intensity of production and in the following one, total supply. It should be noted that the tables relevant to this and the following two chapters, Tables 11 to 20, are arranged under commodities. This facilitates the assessment of the scale effect and the intensity effect on total supply.

First, however, we draw attention to Tables 10a-d, which show how the total crop land in each territory is made up. These totals are derived from already published censuses and surveys (see Refs. G1 to G4) and from compilation of published data made at the Institute of Social and Economic Research. Where we have obtained more up-to-date figures in the course of making commodity studies, we have substituted these.

It will be noted that the figure of total crop land does not agree with the aggregated acreages for the individual crops. Crop land is defined as: "Land under tree crops and medium and short term crops, land in process of preparation for crops or normally cropped but fallow."

In the Jamaica figures we find that the aggregate of land under the various crops is greater than the total of crop land. This is mainly because there is extensive intercropping in coffee, cocoa, bananas, coconuts and more particularly among roots and vegetables and fruits mainly consumed domestically. In Trinidad and Tobago there is less intercropping so that the difference is smaller. In British Guiana, known totals for rice and sugar are given for past years, while data for other crops was taken from the 1952 census in which a reconciliation had already been made.

For the Windward Islands, Leeward Islands and Barbados we find that the aggregate acreage of individual crops is lower, not higher, than the figure of total crop land, in spite of the fact that some intercropping takes place (although not as extensively as in Jamaica). The difference in those totals is thought to be due mainly to the fact that the 1956-58 sample surveys of the Windward Islands omitted some crop land then in fallows, and may have omitted a number of small lots under crops. These differences underline some of the

problems associated with using available source material. Although we get this discrepancy in the total, some figures of individual crops (for instance, rice, sugar, cotton and banana) are probably rather more accurate than those for food crops and tree crops.

Starting with sugar cane, we shall discuss the sources and assumptions on which the figures relating to scale of production are based.

The main sources of data on sugar cane are the British West Indies Sugar Association and Sugar Manufacturers' Associations in the various territories, and also information from agricultural departments. Although of rather greater reliability than information relating to most crops, sugar information is by no means perfect, particularly in relation to the Windward Islands where there are no large sugar exporting industries and because much of the crop is produced by peasants.

Sugar cane acreage can be expressed in two ways, either as acreage cultivated or as acreage reaped. Sugar cane takes at least 15 months to mature so that of the overall acreage, only cane that is ripe will be cut. The acreage reaped is thus usually slightly lower than the acreage cultivated but is not usually lower than 90% or higher than 96% of the cultivated acreage. The amount of cane that is uncut at the end of a season due to immaturity may be the result of a deliberate planting policy; but in recent years, many acres of mature cane have remained uncut because of strikes, labour disputes, incendiarism, and in some cases, acute seasonal and regional shortages of labour which could not always be cured by calling on labour from other more populous islands or areas. In one or two cases, factory breakdowns have been to blame.

In Table 11a, we have shown acreages reaped for the period 1940-60 as this figure is considered to be more reliable than the figure for acreages cultivated. It will be noted that the acreage increased from a total of 231,000 acres in 1940 to 443,747 in 1960. The greatest increase was in Jamaica—44,484 to 186,787 acres.

Several estimates of future sugar cane production have been made for this study and account has been taken both of the trend since 1940 and the trend since 1950 which is less steep than the former. Consideration has been given to the limitations on good sugar land which have already slowed down expansion in such territories as Barbados and St. Kitts and are likely to be more important in other territories in the future than they have been in the past. The projections shown in Table 11b are thus based on a rate of expansion of acreages of 5% between 1958 and 1965, 3% between 1965 and 1970 and 1% between 1970 and 1975. In Table 11c acreage reaped is taken at 95% of the total under cane for projection 1, and 90% for projection 2.

As regards rice, no, or little expansion is seen in the acreage of the two smaller producers, Jamaica and Trinidad and Tobago, but in British Guiana, by far the largest producer, the expansion of the rice industry and its development as a major exporter are major policies of government and the industry. Three major development projects are under way which will bring new acreages into rice production. Programmes for the drainage of now unused land will eventually bring into cultivation an additional 100,000 acres for rice. Although there might be small increases or decreases in acreages of present small holders, it is evident that these are likely to be very marginal in comparison with the major schemes.

Although occupancy of these lands has already started, organisational difficulties such as lack of credit, housing, and the need for frequent cleaning may make the rate at which they are occupied slower than was at first expected. Thus the increase in acreages actually in production is projected as being quite gradual. Past increases in rice acreage are shown in Table 12a and the projections are shown in Table 12b.

We have shown past scale of production of bananas, by acreage over a past period in Table 13a and in Table 13b by the number of bearing roots in 1958, by farm size. The figures for the time series are felt to be of very dubious reliability. After careful consideration we have often had to select what we felt to be the best of several contradictory sources.

In banana production, both land and labour are seen as possible limits to acreage expansion. In Jamaica, the problem is reduced fertility, particularly on slopes where the natural vegetation has been removed and erosion has been permitted. This problem is also apparent in the Windward Islands, although in both Dominica and St. Lucia, due to land tenure problems, better banana land lies idle while inferior slopes are cultivated, and there is much room for expansion. Serious discussions have already been held regarding the start of an export industry in British Guiana. Here, land is likely to be plentiful, but we do not consider there is likely to be a major development in this period.

Naturally, at the present time, marketing problems tend to overcloud the future banana situation; nevertheless, we do not think land limitations are a negligible factor and have given the above considerations some weight in making supply projections.

Sea island cotton is grown only in the smaller islands, and although production is very small it is important in the economies of small islands such as Nevis and Montserrat. Table 14a shows the acreages under this crop in the West Indies since 1940. The assumptions underlying acreage projections shown in Table 14d are that in Antigua, only peasants will be operating towards the end of the period. The 1,200 acres still in production in 1974/75 is considered to be land suitable for cotton only. In Montserrat, it is considered that 1,000 acres or so may be in production, in spite of emigration, because of limited feasibility of other crops. Similar limitations may apply in Nevis, but here it is thought other crops will win land from cotton. In St. Vincent it is thought that other crops will inevitably win land from cotton. Thus we conclude that this industry is likely to decline from about 6,112 acres in 1959/60 to about 4,200 in 1974/75.

If the acreage declines to this extent, it is also possible that sea island cotton might go out of production altogether since it can be spun only on certain spindles and it may be uneconomic for the processing to be continued if only a negligible quantity is produced.

Ascertaining the scale of production of citrus trees and coffee for this study has presented innumerable problems; many of these trees are grown in scattered plantings and cannot easily be enumerated. The acreage figures shown in Tables 10a to 10d are based on acreage equivalents estimated in some cases from source material which gives tree population only. The acreages have, in some cases, been estimated from conversion factors suggested by the Farmers Guide (Jamaica Agricultural Society) and from various agricultural ministries and departments.

Figures of tree population for citrus are shown in Table 15a. Since figures for acreages of both citrus and coffee are considered of dubious reliability, we have not detailed the projection any more than to present estimated acreages in Tables 10a to 10d; but we have presented detailed figures of final, total supplies for citrus (Table 15b) and coffee (Table 16).

For cocoa, estimates have been more easily obtained, since there have been major replanting schemes in all major producing territories which plan to replace all old planting with new clonal material. However, estimates going further back than 1958 are still of extremely dubious reliability. So we have not considered it relevant to include a past time series (Table 17a). The projections shown in Table 17b are based on the replanting programme. Estimates in more detailed form are shown in Tables 17c and 17d. Production from different aged trees, and acreage bearing at different dates can be derived from these tables.

For coconuts, as with other tree crops, acreages and figures of tree population are difficult to come by. To some extent, we have had to work backwards from known data regarding final tree yields and land use as between non-bearing and bearing trees to derive most of the information on scales of production so that our figures must be considered very provisional, particularly in respect to Trinidad and Tobago and Jamaica. There are very definite limits to land available for coconut cultivation in the West Indies since this crop will grow well only in fairly low lying, but well-drained land. Our projections of acreage are thus trends towards limits. In projecting production of copra, we fitted an asymptote curve of the type  $y^c = k + a(b^x)$  with known acreage as the limiting factor. This was also a close fit with figures of copra production over the past decade. Of course, improvements in production per acre could alter this trend, but we have felt with most crops — perhaps more particularly with this one — that the land limitation is a real one within this period. Even in British Guiana, where a number of sand reefs could be used for coconut cultivation, the additional acreage possible is not high as most of the coastland has poor draining, unless artificially drained — usually not an economic proposition for coconut cultivation.

The figures for coconut acreage and tree population are shown for a base year and for 1965, 1970 and 1975 in Table 18b, and figures for past copra production in Table 18a.

No accurate figures exist to show past trends in acreage of domestic food crops. So much of these products is grown on small lots, not recorded in the 1943-46 census, that a comparison between figures at that census and later surveys is not valid. We believe however, that the acreage of root crops is declining in Jamaica and possibly also in other territories, and we attribute this partly to migration, partly to urbanisation and partly to the growth of banana and cocoa cultivation by peasants, particularly in the Windward Islands. Early and very provisional figures from the 1961 census also indicate that a number of small, mainly subsistence farms may have gone out of production in Jamaica due, no doubt, to migration, or in some cases to farmers finding employment in the mining industries.

We expect a continued decline in the acreage of roots and little change in the acreage of vegetables. The acreage of corn and pulses appears to have been declining in all areas since 1950 and we expect this trend to continue. Our conclusions are summarised in Table 19.

We should emphasize however, that we consider roots and vegetables may be fairly competitive with certain cash crops for land; thus price factors, which we shall discuss in a later section, may be more important than for products which have a more specialized land need.

Only marginal increases in acreage under tobacco are predicted because methods of cultivation and the cash return are making the crop generally uncompetitive with other crops (see Table 20).

The scale of production of crops is measured in acreage or tree population. In livestock production we have preferred to consider stock numbers of more relevance than acres under pasture (although with the development of greater acreage of improved pasture the concept of acreages and yield per acre becomes more meaningful). Totals of grassland improved and unimproved are, however, shown in Tables 9a and 9b.

Livestock numbers at specified censuses as compared with those at a later date appear in Table 21a, and projections of livestock numbers appear in Table 21b. Although there may be some difference in coverage among smaller farms, the comparisons are probably rather more valid than would be a similar comparison for crops, acreages or tree populations. Comparisons are not available for all territories because of the lack of data.

Cattle population increased in Jamaica, Montserrat, and Trinidad and Tobago, but appears to have remained unaltered or decreased slightly in other islands. The increase in Jamaica's herd, which is believed to be continuing, is largely a result of the developments in the beef industry pioneered by the mining and sugar companies. Since Jamaica's costs are too high at present to make exportations of beef feasible, Jamaican livestock populations are likely to be increased only in response to the local demand position, supply conditions permitting.

Certain limitations may, however, make supply lag behind demand. Natural rates of increase can only permit a growth in meat supplies of about 10% per annum unless new stock is introduced. The dairy industry, moreover, has been thwarted in its development by marketing, management and organisational problems, and if these should be overcome, supplies of beef might show no increase temporarily while changes in the structure of the cattle population take place.

We consider that in all territories there will be a relative increase in dairy herds as compared with beef herds. We expect, however, that many islands, particularly those in which crop cultivation has been affected by migration, will expand meat production. Many of the small islands already have a high cattle population, however, and indications are that increases in production must come from livestock improvement rather than more cattle.

In British Guiana, where grazing is very extensive, we expect the growth of numbers to be limited to some extent by reproduction rates and to some extent by lack of capital for developing new areas. Here again we expect that production increases must come rather from pasture and livestock improvement, than from greater numbers of livestock.

Figures of small stock population are not reliable. We believe that the goat population would decline if better methods of agriculture and husbandry were practised since goats are destructive to economic plants and must be fenced out of improved pasture. It is almost certain that goats cause economic losses almost equal to the value of their increment to the net product although they are of undoubted value to inhabitants of arid, non-productive regions. Although we can only go by guesswork based on observation, we believe the goat population will tend to decline as higher standards of living are reached.

Pigs, like goats, are at present mainly scavengers in the West Indies, living on what they can find. However, more farmers are rearing pigs as a farm activity. They are generally fed on coconut meal when feeding takes place, so that it is believed that their expansion may be partially related to growth of the coconut industry. A recent report on the pig industry recommended that it would be more economic to import feed and export coconut meal, but it is considered doubtful that this change in the economic pattern of the industry will take place.

No section of agriculture in the West Indies has been revolutionized so much as has the poultry and egg industry in the last decade. Here a major changeover has occurred from the backyard poultry system to proper methods of feeding, rearing and housing. Unfortunately, no comparable figures are available in two periods for Jamaica, Trinidad and Tobago, and British Guiana and we have not found it possible to make an accurate assessment of the extent to which scale of production, as compared with yields, is responsible for the vast increase in supplies both of poultry meat and eggs that has taken place over this period.

### Chapter 3

## THE EFFECT OF CHANGES IN INTENSITY OF PRODUCTION ON TOTAL SUPPLY

In this chapter we shall consider the influence that changes in intensity of production have had and are likely to have on supply.

In measuring intensity of production we have related a quantity of product to land area, as for instance, tons of cane per acre, or a quantity to unit of production such as coconuts per tree, or pounds of meat per carcass, milk per cow, and so on. In this section we discuss the quantitative results of our conclusions on yields. In chapters 5 and 6 we discuss qualitatively the conditions which influence yields.

In measuring the influence of yields in total product we wish to abstract this from the effect of scale on product. One method of doing this is to relate the yields of a base period to the acreage of a later period and relate the total product that results to that which actually occurred in later years. This can be expressed by the equation

$$100 = \frac{Q_n - R_n \frac{Q_0}{R_0}}{Q_n} = X \text{ Yield factor}$$

where  $\frac{Q_0}{R_0}$  = Base period yield,  $R_n$  = Acreage at period n and  $Q_n$  = Supply at period n.

If we use this equation to relate total production of milled sugar, we find that, comparing the period 1940-49 with the period 1950-59, the product for Jamaica in the second period is 5.5% lower than it would have been with the yields of the first period; that for Trinidad and Tobago it is 20.3% higher; for the Leeward Islands, Windward Islands and Barbados it is 23% higher; and for British Guiana 17.5% higher.

Changes in quantities of milled sugar are due mainly to changes in yields of cane per acre. Factory efficiency and the sucrose content of cane must also influence the quantity (see discussion of processing—chapter 6). Yields of cane per acre for the period 1950-60 are shown in Table 11d. Production of sugar, 1940-60 is shown in Table 11h.

We have first projected yields of cane per acre; these are shown in Table 11e. In projecting these yields, various considerations have been taken into account which are described in chapters 5 and 6.

If we apply the yield factor to the total product of cane and the acreage under cane for 1965, 1970 and 1975, and compare it with the period 1950-59, we find that of the total supply of sugar cane in 1975, 32% is due to a projected increase in yields in Jamaica; 13% in Trinidad and Tobago, 7% in the Leeward Islands, Windward Islands and Barbados, and 5% in British Guiana. The recovery of milled sugar from sugar cane is projected at the same rate as that for 1940-60 (see Table 11f). Table 11i shows projections of sugar production.

For bananas, yields can be expressed in pounds which relate to stems per root or stems per acre (which is also of course a function of roots per acre). Table 13c indicates that there is a great variation between these factors in different territories. Since the exact influence of the root/stem ratio as compared with the root/acre ratio on actual yields cannot easily be predicted, we have simply projected the yield in terms of pounds and stems per acre. Applying our yield factor to total projected production and acreage, we estimate that in Jamaica, Trinidad and Tobago, and Grenada there will be no change in yield; in Dominica and St. Vincent, 5% of the additional production in 1975 will be due to increases in yield and in St. Lucia 3% will be due to changes in yields. (See Table 13e.) See Table 13d for projected acreages of bananas.

Rice yields for the periods 1951-55 and 1956-60, and projected for the years 1965, 1970 and 1975 are shown in Table 12c. The yield factor between the 1956-60 average and 1975 is 27% in Jamaica, 14% in Trinidad and Tobago and 14% in British Guiana. Projections of rice production are shown in Table 12d.

Yields for sea island cotton during the period 1940-60 are shown in Table 14b. It will be noted that yields per acre increased in the area as a whole between the 1940's and the 1950's, although they did not increase in all territories. Projected changes in yields for the years 1965, 1970 and 1975 are slightly higher than for the year 1960, but rather below the average of 1955-60. This means that changes in yields will have a negligible effect (Table 14e).

Information on citrus and coffee, roots, vegetables, corn and pulses has been of so dubious a nature that we have preferred to make projections in terms of total supply only. Although approximate projections of acreages are included in Tables 10a to 10d, so as to indicate roughly the changes in land use, it is not felt that they are reliable enough to use as a basis for projection of yields.

For cocoa, however, more reliable information exists on account of the new planting programme. Because of this programme, yield factors are very important in local supply and, comparing the 1975 projected supply with the 1960 supply, we find that in Jamaica 2.3% of the increased supply (expressed as yields per bearing acre) is a result of yield factors, in Trinidad and Tobago 21.6%, and in Grenada 34%.

Some figures showing estimates of coconut yields are shown in Table 18b. There is a complete lack of reliable information on past yields per acre or per palm. The yield factor, in terms of nuts per acre is approximately 10% in Jamaica and Trinidad and Tobago, and 12% in other territories. But, data are not considered reliable enough to estimate effects of the bearing/non-bearing ratio on yields in the future.

No information is available on the yield factor in tobacco but the yield in Jamaica in the past has been about 410 pounds per acre—about half the world average.

There are a number of methods of measuring cattle yields; one can measure return in meat per acre, meat per animal slaughtered and meat produced in relation to total cattle population. Figures for slaughterings are not complete because only registered slaughterings are available. There seems little case for reckoning returns per acre in an area where so little grassland has been improved. We have taken as a crude measure the meat per head of the total cattle population and quarts of milk per head of the population of cows of two years and over.

These estimates show little change in the relationship between meat and cattle population. The reason for this, however, is partly that we have projected an increase in the proportion of cows to total cattle for most areas. In terms of yields of meat per acre of pasture, we expect some increase as more improved pasture comes into being, but we cannot express the yield factor quantitatively. The relationship between cow numbers and total milk supplies is more exact. Here the yield factor as between 1958 and 1975 is estimated at 18.7% in Jamaica, 4.8% in Trinidad and Tobago, 10.4% in the Leeward Islands, Windward Islands and Barbados and 9.4% in British Guiana.

## Chapter 4

### THE ESTIMATION OF TOTAL LOCALLY PRODUCED SUPPLIES OF COMMODITIES

We have endeavoured to isolate the factors influencing yields and total acreage in the base period to ascertain the importance of each in total supply. It should be noted however that many of our source data gave total production as a more reliable figure with rather less reliable information on yields and acreages. However, having tried to isolate the scale factor from the intensity factor in the base period, we have for most products projected these two factors and derived total projected supply from these. It should be emphasized that the supply projections were drawn up independently of the demand projections. Although in the case of subsistence or non-cash consumption, reconciliation had, of course, to be made at an early phase of the study.

For sugar we present final supply tables for milled sugar. The totals for cane can be derived from tables of yields and acreages (Tables 11e and 11f). It is the final product, milled sugar, with which we shall mainly be concerned in our comparison of demand and supply.

Final productions of rough rice and milled rice are shown in Table 12a and final projections are shown mainly in the form of milled rice, with milling rates indicated (Table 12c). Total production figures for bananas for a past period are not very reliable but we show projections in Table 13e. For sea island cotton, past trends in production are shown in Table 14c and projections of production in Table 14f. For tree crops, data on past production is extremely scant; we have, however, shown some figures for citrus in Table 15b, coffee in 16, cocoa in 17a, and copra in 18a. Total production figures for the projections are shown in rather more detail for cocoa, for which crop the new planting programme has enabled better estimates to be made than for other tree crops. For vegetables and roots, figures of acreages and yields were virtually non-existent and our estimates are based much more on our assessment of the total products. (See Table 19.) Naturally, estimates of the acreage and yields were used in this assessment, but for the base year at any rate, estimates of the total supply were considered more reliable than estimates of average equivalents.

For livestock products also (see Table 21c), the base year estimates depended on assessments made of supplies coming forward rather than on assessments of numbers and yields. For milk, for instance, the total supplies to households and to the condensery were the basis for the estimates. Data on yields were fragmentary, but of course yields and stock numbers were taken into account when projecting future supplies.

Then the method of estimating future supplies depended very much on the availability of different types of source data. In some cases we were able to work purely from independent projections made of yields and the scale of production (acreages, tree numbers, livestock numbers, etc.), while in others we were inclined more to picture local supply itself, as the first assessments have given due weight to what fragmentary data were available on the factors influencing supply.

## Chapter 5

### FACTORS INFLUENCING YIELDS AND PRODUCTION: ECONOMICS AND FARM ORGANISATION

#### Changes in growers' prices 1955-60

Comparative prices cannot mean a great deal in areas where the general price levels are different. However, the figures in Table 4.5.i below do give some indications of recent changes in prices paid to growers of sugar cane.

Table 4.5.i

Prices per ton paid to farmers for sugar cane by territories, 1955 through 1959

Territory	1955	1956	1957	1958	1959
	BWI\$				
Jamaica	12.44	12.78	14.68	13.16	12.66
Trinidad and Tobago	11.97	10.98	14.53	11.44	12.30
Antigua	11.65	11.30	14.61	11.00	13.20
St. Kitts	12.80	12.21	16.54	13.01	13.20
Barbados	15.17	14.68	17.55	14.87	15.80
British Guiana	8.94	9.48	11.05	9.00	8.70

Source: British West Indies Sugar Association.

Prices for cane vary to some extent with the sucrose content of the cane and also are influenced by the average price per ton of sugar exported, which itself may depend on how much has to be sold outside the negotiated price quota. It will be noted that 1957 prices were highest but that in most territories 1959 prices were higher than those of 1958.

If the production of cane reaches the figure which we have predicted we expect an increased proportion of total sugar will be sold at prices below the negotiated price. However, the effect of this is likely to influence prices by approximately 8% to 10% in any one year.

In British Guiana the price of higher quality rice has risen consistently since 1955 as is shown in Table 4.5.ii.

Table 4. 5. ii

British Guiana: Prices per 180 pound bag of rice, 1955 through 1960

Year	Export types f. o. b.			Local Brown A
	Supergrade	First	Second	
	BWI\$			
1955	19.65	18.75	17.85	17.05
1956	19.65	18.75	17.85	17.05
1957	19.50	17.85	16.05	17.05
1958	21.30	19.20	16.95	18.80
1959	21.30	19.20	16.95	18.80
1960	21.30	19.20	16.95	18.80

Source: 1. Reports of British Guiana Rice Marketing Board 1950-51 to 1960-61.  
2. Reports of the Rice Conferences.

The price of rough rice paid to growers who sold rough rice directly to the mills increased from \$3.25 per bag of 140 lbs. in 1950 to \$6.80 per bag in 1961. The average price paid to growers who sell milled rice rather than rough rice has depended on changes in the export price but, in general, has followed the trend shown in Table 4. 5. ii.

In Jamaica, growers of bananas are paid on the basis of the count bunch but in all other areas by weight, which makes comparison difficult. Growers in all territories are paid on the basis of actual realisation, which final price is the true grower's price. There are seasonal variations in banana prices, but Table 4. 5. iii gives the average prices in Jamaica and the Windward Islands over the period 1955-60.

Table 4. 5. iii

Annual average prices of bananas in Jamaica and the Windward Islands, 1955 through 1960

Year	Jamaica greenboat, J £ per ton	Jamaica growers, shillings per count bunch	Windward Islands growers, cents per lb.
1955	£ 74. 8. 0	9/-	4.75
1956	£ 73. 1. 0	9/2	5.00
1957	£ 77. 3. 0	9/6	5.00
1958	£ 74. 1. 0	9/5	4.00
1959	£ 68. 3. 9	8/10	4.75
1960	£ 66. 2. 10	8/8	4.00

Source: Data and material developed during the study and other available data.

This indicates some decline in growers' prices following a decline in the Jamaica green-boat, or export, price, which is also used as an indicator for deciding growers' prices in the Windward Islands.

Information on price changes is not easily available for all products, but Table 4. 5. iv shows some recent changes in prices which will indicate the general trends for the various commodities.

Table 4. 5. iv

Prices of various commodities, 1954-55 through 1959-60

Year	Growers' prices		F. O. B. prices	
	Coffee, Jamaica, price per pound	Cocoa, Jamaica, shillings per 100 pounds	Copra, West Indies area export price, BWI \$ per ton	Cotton, MSI 2/ Antigua, BWI cents per pound clean lint
1954/55	2s. 5d.	254	300	106-112
1955/56	2s. 5 ½d.	154	300	100-106
1956/57	2s. 6d.	129	300	110-116
1957/58	2s. 5d.	104	300	111-117
1958/59	2s. 1 ¾d.	154	320	99-105
1959/60	1s. 9 ½d.	154	340	84- 90

1/ Rates for smaller quantities than 100 pounds are slightly less.

2/ MSI (Montserrat Sea Island).

Source: Data and material developed during the study and other available data.

When we summarise all the trends in export crops we cannot but conclude that there has been a slight decrease in all products. The two crops in which there have been price increases, copra and rice, are those for which the export market is mainly or wholly a regional one. All other prices reflect the general world situation of falling commodity prices since 1955. However, due mainly to established markets and trading agreements, price fluctuations are rather less than would be exhibited in the world market over the same period.

Turning now to domestic food crops and livestock products, we find that information on growers' prices is fragmentary. Although movements in retail prices are not exactly the same as movements in growers' prices, the broad trend is the same.

The retail prices of all foods were about 10% lower in the country although Irish potatoes and tomatoes were frequently higher. The retail price index for all food items increased in Jamaica from 100 in December 1955 to 103.5 in December 1956, 105.9 in December 1957, 109.6 in December 1958, 112 in December 1959, and 122 in December 1960. Table 4. 5. v shows retail prices for selected foodstuffs in Kingston for various periods from 1955 to 1961.

Table 4.5.v

Retail prices for selected foodstuffs in Kingston, Jamaica, for selected periods

Commodity	1955	1959	1960	1961
	Dec. av.	annual av.	annual av.	annual av.
	Pence	Pence	Pence	Pence
Roots, yams, lb.	5.17	6.14	6.50	6.92

Fish, snapper, lb.	26.00	30.00	27.60	29.00

Source: Data and material developed during the study and other available data.

In Jamaica, beef prices show the most marked increase. The price of this product was controlled between 1940 and 1960 although between 1950 and 1960 the controlled price increased from J£4.15.0. per 100 pounds liveweight to J£7 per 100 pounds liveweight, or or 180s. per 100 pounds w.d.c. <sup>1/</sup> After decontrol the price increased to about 240s. per 100 pounds w.d.c. <sup>1/</sup> It is too early to say what effect the decontrol has had on supplies since slaughterings in 1961 must to some extent have been the result of decisions made before price control. Also the number of legal as against total slaughterings would increase after decontrol anyway. Supplies were increasing in 1962 and the price appeared to be stabilising, averaging 48 J pence per pound in the first six months of 1962, which would indicate that a new equilibrium is being established.

In Trinidad and Tobago, the food section in the retail price index increased from 100 in January 1952 to 126.5 in December 1955 to 138.9 in December 1959. Noting some individual prices, it is observed that fresh beef increased from 77.9 cents per pound in 1955 to 86.2 cents per pound in 1959, fresh pork from 77.3 cents to 83.6 cents per pound, sweet potatoes from 9.7 cents to 10.3 cents per pound, yams from 7.1 cents to 10.6 cents per pound and tomatoes from 31.1 cents to 36 cents per pound. Trinidad and Tobago imports much of its sweet potatoes from St. Vincent and there is little doubt that competition from banana, and also emigration of growers has reduced the supply and increased prices.

<sup>1/</sup> Warm dressed carcass.

## The shape of the supply-price function

While in some underdeveloped economies with a large peasant sector, aggregate agricultural supply functions are thought to be negatively rather than positively price elastic, recent trends in the West Indies indicate that the supply price function for all agricultural commodities is generally positively elastic, and not least so in areas of peasant production. In fact there are sound indications that peasant responses to price increases up to 1957 were greater than those of estates. This is probably due partly to the fact that estate lands have not been so easily extended as have peasant lands and also to the fact that estate labour costs have increased as greater peasant opportunities have emerged.

The amount of substitution of one crop for another which can take place following relative price changes is somewhat limited by physical conditions in some places, and also to some extent by organisational factors. If, for instance, no mill exists nearby to accept deliveries, sugar will not be grown; or one might cite the case of specialisation in arrow-root in St. Vincent and nutmeg in Grenada which has been partly due to the existence of marketing organisations. Some substitution has undoubtedly taken place in response to relative price changes, but we believe that this has been marginal in the case of export crops and has probably seriously affected the production of roots and vegetables only. Root crops may actually have declined in acreage or remained static. The output of vegetables and other domestic foods has not increased in line with population increases.

We consider therefore that price-supply responses have been positive for most of the main export products, although not necessarily positive for domestic food crops. The relationship is not measurable in quantitative terms, partly because the price levels, which have tended to stimulate supplies, have been price levels of an undefinable period. In tree crops, for instance, we consider that until recent years, memories of pre-war prices, and fears of a return to such levels of prices may have inhibited some expansion, while for most of the shorter term crops, last season's prices will probably have had a greater influence in the amount supplied.

## Returns to growers

Table 4.5.vi shows recent estimated gross returns per acre per annum for various crops.

Although production costs have been estimated for various crops these have been generally for one or two farms only. Only for rice have properly sampled studies been made (Ref. S.b.2. and S.b.3.) <sup>2/</sup>. One of the problems however is that straight comparisons between estate and peasants are meaningless since the peasant and his family undertake most of the work on a peasant farm.

Considering peasant production alone, however, some calculations made at various times for national income estimates indicate very roughly the receipt per acre for labour and profit after all outgoings have been met. These figures indicate that where banana can be grown it is the most profitable crop for peasants in terms of returns per acre. In territories where banana is not grown, sugar is generally more profitable than ground provisions, vegetables or coconuts, on a per acre basis.

---

<sup>2/</sup> A cost survey for cocoa has been undertaken in Grenada.

1/ Roots crops.

Source: Data and material developed during the study and other available data.

In certain conditions rice yields more revenue than sugar for a small farmer in British Guiana, and in Trinidad and Tobago and Grenada cocoa may yield more revenue than banana. Conditions of production naturally influence these comparisons a great deal.

As regards estates, where sugar is grown on a significant scale it is considered the most profitable crop; there are only minor cases of sugar acreages being given over to other crops on estates and these are not representative. On the contrary, where substitution has taken place, it has probably been in favour of sugar.

In the absence of more exact cost data, we can only give general conclusions. Fairly definite trends are, however, in evidence.

The traditional sugar economy has not suffered from competition from the newer cash crops such as banana and cocoa. Sugar still remains one of the most profitable cash crops. Banana and cocoa expansion may have resulted in a decline in the acreage of less profitable domestic crops, particularly roots, but has probably been achieved mainly by more intensive intercropping and by the cultivation of new areas. Supply has been positively elastic to price increase for most products, and substitution effects due to relative price changes have been negligible. It is not so certain whether we can predict a continuation of this characteristic of positive elasticity, since available new areas are now limited. (See part four, chapter 1.) Perhaps the most important factor is a negatively elastic labour supply curve which is becoming apparent in some areas. This is discussed in the section on labour and manpower problems in this chapter. Already there are indications that supply-price functions have not been positively elastic to the same extent in the period 1957-62 as they were earlier, and we feel labour factors may be the main cause of this change.

## External trade agreements

The prices which are paid to growers for export crops are of course a reflection of the world market price. The subject of the future of world market prices is outside the scope of this study, and in particular we would not be in a position to make an assessment of the effect that Britain's possible entry into the Common Market would have on the return for the various commodities. We feel it is relevant, however, that we refer to the price arrangements which apply to sugar, copra and rice, and to some of the buying arrangements for other products.

Although as far back as 1929 a commission suggested to the United Kingdom Government that colonial sugar should be purchased at a fixed price, no measures were taken until 1932 when the United Kingdom introduced Colonial Sugar preference certificates by which all sugar exported to the United Kingdom received an extra £1 per ton over the world price. This price was not sufficient to alleviate a condition of bankruptcy and severe unemployment which existed in West Indian Colonies. During the war a guaranteed market was offered but shortages of equipment made it difficult for producers to improve their productive capacity or increase their efficiency. Between 1946 and 1949 the United Kingdom Government guaranteed a market for West Indies sugar and these guaranteed marketing arrangements were extended to 1952. World prices were considerably higher on the average, however, when the British Commonwealth Sugar Agreement came into being. The agreement was initially extended to 1959, and has now been extended to 1968.

Under this agreement all Commonwealth countries agreed to an export quota, the overall agreement quota. Of this total, two-thirds was to be purchased by the United Kingdom at a price which would be negotiated annually and which would be based on costs of production rather than on world prices. The West Indies share of the overall quota is 900,000 tons; only 640,000 tons was, however, the negotiated price quota (revised to 672,000 tons in 1960). The difference between the overall agreement quota and the negotiated price quota is sold at the world price plus the advantage of preferential tariffs applicable to all Commonwealth countries. Any exports over and above the 900,000 tons can be sold in world markets at the world price. In addition, however, the Commonwealth producers have a quota of production under the International Sugar Agreement.

Since 1954 total production has exceeded the overall agreement quota for the West Indies, and the quantity of sugar sold in unguaranteed markets increased by 1960 to 157,148 tons. The West Indies has from time to time obtained the benefit of short-falls by other Commonwealth producers. Also, since the United States embargo on Cuban sugar, part of the West Indies surplus has been disposed of to the United States at premium prices. The quota premiums will be reduced by 1964, but it is expected that a more certain U.S. market will exist so long as the present political situation between Cuba and the United States persists.

Thus, in spite of the growth of non quota production in the area, prices, when averaged over the whole of the exports, have only been influenced marginally.

Although we have predicted a fairly substantial increase in production up to 1968, we do not consider for the reason given above that the average price will be seriously affected although a decline of up to 10% might be expected. The events after 1968 are uncertain,

but we have preferred to assume that some arrangements will be made for Commonwealth sugar after that period which will not make the situation significantly less advantageous than that now ruling. In any case we have considered that physical limitations are likely to slow the rate of expansion after 1965, so that if marketing difficulties do arise they are unlikely to be aggravated by the rates of growth of output that have been experienced over the past twenty years.

Of the other commodities with which we are concerned, rice and coconut products have been subject to agreements covering quantities and prices, but these agreements have been of an intra-regional nature.

The West Indies Rice Agreement dates from 1946 when the then Marketing Board of British Guiana entered into an agreement with the individual governments of the Leeward and Windward Islands, Barbados, and Trinidad and Tobago. The agreement required the delivery of a given grade of bulk rice at a fixed price according to the need of the island. The first agreement lasted until 1954. British Guiana could not deliver the full quota during the first few years; but in the meantime output was being increased. The agreement was then extended to 1956, and a separate agreement was made with Jamaica. The agreements affected bulk rice only; packaged rice could be sold privately.

In 1956 a new agreement was drawn up between British Guiana on the one hand and the government of the West Indies Federation on the other hand. It was decided to review the price annually at an annual rice conference.

These agreements controlled by far the major part of rice trading in the British Caribbean and they still continue in being although the position has reverted to one in which agreements are being made between British Guiana and individual governments. Although cost studies have been made and have been extensively quoted at rice conferences, the price has on the whole been settled purely by higgling and bargaining, and although some increases have been given, on the whole the price of rice has been held by the threat of buying countries to abandon the agreement and buy from cheaper world markets.

It is doubtful whether the buying territories could have purchased better overseas, and certainly when one takes into consideration delivery and supply problems they have benefitted immeasurably from the agreement. More recently British Guiana's bargaining position has been improved by the fact that she has found other markets in the region. The agreement with the other British Commonwealth Territories, however, gives her a more assured market position than any of the other arrangements she has made.

The West Indies Oils and Fats Agreement dates from the second world war when it was seen as a means of protecting supplies. In 1947 it became a permanent peace-time institution with the object of protecting and encouraging the local production of coconut products. All the islands of the West Indies and British Guiana are signatories to the agreement. The purpose of the main clauses in the agreement, which has been periodically renewed since 1947, has been to prevent growers of coconuts from disposing of coconuts and copra outside the region, and to prevent processors from importing from outside the region.

The result of the agreement has been that imports of vegetable oils to the area or exports from the area have been insignificant over the past fifteen years, so that it has

appeared that a very fine balance has existed between total supplies of copra and demand by processors, although it might well be considered that the limitation on supplies has inhibited growth of processing.

Processing firms exist in all territories except Montserrat and St. Kitts, but in the smaller islands they make a limited range of products. Larger plants for making edible oil, fats and soaps exist in Barbados, Trinidad and Tobago, Jamaica and British Guiana. The main coconut growing territories are Jamaica, Trinidad and Tobago, British Guiana and the Windward Islands; the latter export copra to Barbados for processing. Jamaica has been to some extent a separate limb of the agreement in that she has been self supporting and has not, owing mainly to distance and transport problems, imported raw material from the Eastern Caribbean. Of recent years Jamaica has had an export surplus, and has found a market for raw coconuts in the United States.

There is little doubt that the agreement has done much to build up the coconut industry in the West Indies, to encourage better methods, and to create a strong consumer demand for cooking oils, locally produced edible fats, and soaps. Toilet soap is made in Jamaica and Trinidad and Tobago.

#### Other institutional arrangements

Some organisations exist for the protection of the interests of farmers as such; for example, the Cane Farmers Associations in various islands, the Banana Producers Associations, and the Rice Producers Association in British Guiana and various other associations. In addition, various organisations, such as the Sugar Producers Associations, the West Indies Sea Island Cotton Association, the coconut industries, Cocoa Boards and Banana Boards, and the Rice Marketing Board in British Guiana may be concerned to a large extent with marketing problems. Some of these, particularly in Jamaica, are public boards. Others, such as the Sugar Producers Associations, are associations of the firms or individuals concerned in production.

It would not be relevant here for us to discuss these various organisations and their functions in detail, but it should be noted that such organisations have had a very important influence on improving agricultural methods, and certain of them take an active part in research and in distributing fertilizers, running machinery pools, and distributing seed material.

Those industries which are organised partly or wholly on an estate basis are also served by strong trade unions. Although strikes have at times dislocated production, the worst ones have frequently been unofficial. On the whole it must be agreed that the unions have contributed much not only to improving wages and conditions, but indirectly to bringing about more efficient and labour saving methods. It is largely due to their activities that "sweated labour" forms of agricultural work are declining in the area and although this leads to some adjustment problems it should also assist a trend towards high income forms of agricultural activity.

## Labour and manpower problems

As has been explained, small farms exist side by side with large estates in the West Indies and in most places the worker who earns wages on the large estates may also have a plot of land to cultivate.

The casual nature of employment in the West Indies makes it very difficult to measure unemployment and underemployment. Most agricultural workers can find work for part of the year, but rarely can they find sufficient work to constitute full time regular employment.

The sugar industry is habitually one which has depended on a large labour force ready and available for seasonal work, so that in the main sugar growing areas there are two distinct periods: "in-crop" when there is work for all and "out-of-crop" when only a minority of regular workers are employed. This pattern still exists in spite of partly successful efforts by many estates to spread work throughout the year.

It was estimated by the British West Indies Sugar Association in 1958 that of a total of 3 million people in the region, 184,000 were directly employed in estates and factories; with their families this would mean about three-quarters of a million people were directly dependent on the industry. This did not include thousands of small farmers who sold cane to the factories but were not directly employed by them.

The labour force employed in sugar has not increased at the same rate as production over the past decade. In some areas workers have been made idle by mechanisation, particularly of the loading and transporting operations. Follow-up studies in Jamaica indicate that most of these workers have either migrated or have been absorbed in the general expansion of this and other industries.

In crops such as cocoa, banana and citrus we find a pattern of numerous small peasants and a few estates. Considering the frequency pattern there is still a tendency for numbers of growers to inflate the lower end of the distribution, and for acreage and production to inflate the upper end. However, in banana, medium-sized farms contribute substantially to the total product. Where land is available for peasants to grow bananas it is not so easy for estates to find wage labour for this industry. In coconut, estates predominate and difficulties of finding labour have been experienced in this industry where banana production has increased. The coconut industry is, however, saved by the fact that demands in labour need not be specifically timed and coconuts can generally wait until labour is free from more exacting crops.

Rice production in British Guiana has traditionally been carried out by small producers who also work seasonally on sugar estates; but with the development of new rice areas some distance from the main sugar areas, this pattern is becoming less pronounced. Nevertheless rice growing is still a predominantly part-time peasant crop. It has been estimated that about 25% of all labour is paid labour. Nevertheless much of this is supplied by the farmers themselves, who work in turn on each others' farms.

The expansion of the livestock industry has been inhibited to some extent more by shortage of managerial categories of labour than by shortage of unskilled types. This is particularly evident in the Jamaica dairy industry where there is a large unfulfilled demand

from the condensery and from households, and where it is felt that the development of larger dairies has failed largely because of lack of skilled management.

Details are not yet available from the 1960 census, but estimates of the labour force made by governments indicate that in Jamaica in 1957, 49% of the labour force was engaged in agriculture; in Trinidad, in 1956, 25%; and in British Guiana in the same year 39%. We should expect to find the proportions slightly lower at a more recent date as the effect of migration and urbanisation has definitely been at the expense of the agricultural labour force rather than that of other sectors.

This urbanisation is illustrated in Jamaica by reference to figures comparing the population of Kingston and St. Andrew (the most important urban area in Jamaica) in 1943 and 1960. In 1943, the population of Kingston and St. Andrew was 238,229 or 19.25% of the total population of Jamaica, and in 1960 it was 421,718 or 26.14% of the total population.

Detailed, reliable figures on net migration are not available for all territories. It was estimated as 6,800 in Jamaica in 1958, and 16,300 in 1959. The period 1959-62 has been the heaviest migration period, and it is believed that the Leeward Islands and Windward Islands have lost more, proportionate to their total population, than have the larger islands. Indeed, in Montserrat with a population of 12,000 at the 1960 census it is believed that between 20% and 25% of the population has been lost by migration in the last four years.

Migration has undoubtedly affected the rural areas more than urban areas, and has led to seasonal labour shortages in many territories. These seasonal shortages have been met by temporary movements of workers from one island to another in the Leeward Islands, Windward Islands and Barbados, and to a lesser extent from one area to another in Jamaica.

Migration is associated, by some observers, with the attitude of mind which appears to exist among many West Indians, that agricultural labour, and particularly that associated with the sugar industry, is to some extent degrading and associated with slavery. How far this attitude exists is difficult to say, but it is felt that a better approach and wider acceptance of agriculture as a way of life would follow a change from low-skilled, cheap labour type of production to more specialised forms bringing higher income. But of course such an agricultural revolution presupposes that educational standards will be raised and the necessary skills will be forthcoming.

### Investment in agriculture

Unfortunately, estimates of gross domestic fixed capital formation do not give very exact breakdowns of capital formation by industry, but broad figures indicate the amount of capital invested in agriculture in the four territories for the period 1956-60 (Table 4.5.vii).

From import returns we find that in 1959 Jamaica imported BWI\$4,379,894 worth of farm implements, machinery and tractors, Trinidad BWI\$1,944,000, the Leeward Islands, Windward Islands and Barbados approximately BWI\$452,000 worth, and British Guiana BWI\$3,598,895. (A small part of the tractor imports may have been for non-agricultural purposes.)

Table 4. 5. vii

Gross domestic fixed capital formation in agriculture, by territories, 1956 through 1960

Territory	1956		1957		1958		1959		1960	
	Agriculture	Total	Agriculture	Total	Agriculture	Total	Agriculture	Total	Agriculture	Total
	Million BWI\$									
Jamaica	16.8	186.2	23.5	250.1	20.2	227.5	22.1	221.3	24.5	248.2
Trinidad and Tobago	8.0	120.8	7.4	147.5	9.0		10.8		14.2	
Leeward Islands, Windward Islands and Barbados	6.7	39.0	7.8	45.0	6.9	44.0	44.0	49.0	11.6	52.0
British Guiana	4.3	48.0	N. A.	61.5	N.A.	60.9	12.7	59.1	N.A.	77.9

Source: Data and material developed during the study, and other available data.

Capital output rates have been computed for the economies of Jamaica and Trinidad and Tobago, but, for the economies as a whole, these rates have been rendered rather meaningless because of big fluctuations in mining investment. In Jamaica, increments to product in agriculture are not very high. Taking the total of gross domestic fixed product in constant prices at 1959 and comparing it with 1956 we find an increment of BWI\$ 17.6 million only; but the gross investment in agriculture totalled BWI\$ 65.8 million for 1957, 1958 and 1959 (at current prices). Although quantitative data are not available, there is evidence that returns in capital are greater in agriculture in the smaller territories, particularly where there has been an expansion in banana.

One of the problems of measurement arises from the fact that it is well nigh impossible to evaluate capital formation brought about by the non-cash activities of peasant farmers who may clear land, drain it and carry out other improvements with no cash transaction having been registered. The costs of establishing banana must of course vary from site to site, but some estimates have been given which indicate costs of approximately BWI\$ 400 per acre in Jamaica, BWI\$ 570 in Dominica, and BWI\$ 810 in St. Lucia. Net returns on banana are likely to be sufficient to recover this cost within two to three years.

Credit has been available to farmers under various government schemes and fairly considerable funds have been loaned under peasant development schemes of Development and Welfare projects. Credit has also been available through sugar companies (usually just on an annual basis) and other marketing organisations. To generalise, one might say that credit has probably been more readily available than has the extension work necessary to ensure proper returns on the investment. Where credit is given on crop liens, of course repayment is generally ensured, but there is evidence that many small farmers are carrying a heavy burden of indebtedness. This is probably most serious in British Guiana where

rice growers often owe considerable sums to machinery suppliers, landlords and millers. In a rice survey done in British Guiana in 1957 (see Ref.S.b.3, Appendix II) there was much evidence of under-utilisation of machinery on larger and medium farms, much of which was being purchased with credit. This led to higher costs of production actually being found on some mechanised farms than were found on non-mechanised farms.

Investment in the sugar industry has been greatly assisted by a system of compulsory saving which takes the form of three tax funds into which it is compulsory for manufacturers to pay a certain amount, which in most territories is J£2.15s. per ton of sugar. Of this amount, 10 shillings (J£1 in St. Kitts) must go to the Sugar Labour Welfare fund and the remainder to the Price Stabilisation fund and the Sugar Rehabilitation fund.

Although only the latter fund was intended for capital investment in the industry, the Price Stabilisation fund has, by agreement, been extensively raided for capital improvements. Each year, something like J£1,500,000 accrues to these last two funds in all territories and has constituted a useful source of investment capital to supplement private resources of sugar companies. No figures are available, however, to show the total of investment in sugar.

### The size of farms

The West Indies is an area which includes both large estates and small farms. The larger estates, however, which are mainly concerned with the growing of coconuts and sugar, do not encompass acreages of the extent which might be found in continental areas, or in territories where the surface of the land is less broken by rugged mountain ranges. As would be expected, some of the larger areas are those of sugar estates and cattle ranches in British Guiana; but the vast majority of farms in numerical terms are those which are occupied by small-scale producers, and are worked by the operator and his family.

Although a number of factors have been causing changes in the size distribution of farms it is not easy to identify these or to show the true pattern of change. In Table 4.5.viii we show the size distribution of farms by acreages in the Windward Islands, Jamaica, and Trinidad and Tobago for two periods, and for the Leeward Islands and Barbados for one period only.

In the territories for which comparable data are available, it must be noted that the exact definition of small plots and farms below five acres may be different as between the two periods. It is considered however, that the information relating to large holdings has a higher degree of accuracy.

The figures indicate that there has been a reduction in the area of farms of 100 acres and over in all territories listed except St. Lucia, and in Trinidad and Tobago, where the increase is negligible. In Jamaica the reduction is greatest and although this may be partly due to some statistical discrepancies it also follows from the fact that a few estates have been broken down into small holdings, and from the growth of the banana industry, which is mainly a small farmer's crop. In the intermediate size groups we find again some decline in acreages. It appears that all acreages lost to larger and medium sized holdings have supplemented acreages of farms below ten acres and small plots. The growth of the acreage under small plots has been quite significant. However, we feel that differences

Table 4. 5. viii

Source: Data and material developed during the study and other available data.

in definition made it impossible to say how much of the increase is actually in small plots and how much in farms of less than five acres. In particular, the Trinidad and Tobago figures for small plots in 1956 is probably inflated by omissions from other size groups.

If comparable figures for the Leeward Islands were available we should expect to find an increase in small farms at the expense of estates, because estates have been broken up in Nevis and Montserrat to make land available to small farmers. In Antigua, a similar government scheme has resulted in allocation of estate land to peasants, but the big movement took place in Antigua in the 1930's when considerable estate acreages were allocated to peasants. In British Guiana, we should expect to find in recent years an increase in the relative importance of small farms. This is not because of the breakup of estates so much as because of new acreages reclaimed by drainage schemes being generally made available to peasant farmers.

Provisional figures for the 1961 census give some indications that migration from the country into the town, in Jamaica, and migration outside the territories themselves may have reduced the number of farms, particularly those of less than 10 acres. Until figures of acreages are available, however, it is difficult to say whether this trend has reduced acreages in each size group. It may mean that some operators are farming slightly larger areas, which may affect the total acreage within size groups only marginally. There is, however, some evidence that emigration has reduced the cultivation of roots and certain vegetables. Available information shows this as the only sector for which we can identify a decline in production totals.

Although figures of sizes of farms growing certain main crops were estimated in various censuses these are not felt to be reliable enough to permit comparisons between dates. For certain crops, figures of deliveries from large and small farmers are available, and we have been able to assess the changing position from these.

Sugar is grown by peasants and estates in Jamaica, Barbados, Antigua and Trinidad and Tobago, but in St. Kitts and British Guiana, peasant cultivation is negligible and the peasants' share in the total has not shown any change in the past two decades.

In Jamaica, the peasants' share of total cane supplied to mills increased from 25.5% of the total in 1940 to 38.8% in 1955, and to 44.2% in 1959. We believe that this increase in the peasants' share has been one of the main factors, if not the main factor, in depressing yields in Jamaica when they have been rising in most other territories. We do not however envisage a continuation of this trend towards greater peasant participation in cane production.

In Barbados it is estimated that peasants' acreage reaped increased from about 7,000 or 18% of the total in 1940-46 to 10,000 or about 22% of the acreage in 1955-60. In Antigua, peasant acreages are estimated at about 40% of total acreage, and there has been little change since 1950. In all cases, peasant yields are slightly lower than those of estates, so that a 40% share of the acreage would indicate less than a 40% share in actual cane deliveries.

Table 13b shows the size distribution of banana growers in certain territories. No figures are available that would show if the size pattern of banana farms has changed. We

believe that the growth of the banana industry since 1920 has resulted in an increase in the number of farms of five acres and less, particularly in the Windward Islands.

Rice is grown mainly by small farmers, and the policy of bringing new lands into cultivation will have increased the number of farms below twenty acres in British Guiana in spite of the fact that two centrally operated holdings of estate dimensions have been included in the scheme. Available figures indicate that yields per acre are higher on small farms than on larger farms. This is because some peasants cultivate more intensively than estates. As with rice, we should find livestock production in British Guiana more intensive with small producers than with ranchers. Thus an increase in the number of small farms may not mean lower yields. This characteristic, however, is likely to apply only to territories in which extensive cultivation is possible, and in which profit-to-capital ratios are more or less independent of yield-per-acre ratios.

For tree crops such as cocoa, coffee, citrus and coconut, we should expect estate cultivation to be more efficient than peasant cultivation. Pure stand cultivation is more general on estates than on small farms and is likely to increase the yield of any given product per acre (although not necessarily to increase the cash return per acre). An exception to this may be when a land-extensive crop, such as coconut, is intercropped with a more land-intensive crop, such as banana, when the yield of the former may benefit from better cultivation and fertilising practices intended mainly for the latter.

As regards other crops — tobacco, roots, vegetables, corn and pulses — available information does not indicate the effect of farm size on yield. Sea island cotton shows a definite relationship between estate cultivation and higher yields. Since we have predicted that estates are likely to discontinue this crop, we can expect a depressing effect in yields which might, however, be countered by better seeds and better practices.

The yield and quality of beef has been upgraded in Jamaica by the introduction of ranching methods. This, however, has probably upgraded the weight per head rather more than the weight per acre, as the method is essentially one of extensive cultivation. We have taken into account that ranching areas may be increased relative to small cattle holdings when considering our projections.

All in all, we can conclude that the breaking up of estates in some areas has tended to have a depressing effect on yields. We believe that migration and urbanisation are counteracting this to some extent since they are leading to a consolidation of some smaller holdings, and also possibly to abandonment of some marginal land. If efficiency of production is to be maintained in the future, it seems unlikely that it will come about by political pressures to break up estates and make the land available to small farmers. However, if land-hunger were to become an urgent problem (supposing, for instance, migration were completely curtailed and industrialisation received any kind of set-back), then political considerations in favour of land-reform might off-set those in favour of increasing efficiency.

## Chapter 6

### FACTORS INFLUENCING YIELDS AND PRODUCTION: PHYSICAL AND TECHNICAL

#### Breeding, disease and climatic factors

Research into the most suitable types of plants for West Indian conditions has been undertaken by governments, by such organisations as the Citrus, Coconut and Banana Boards, and by private businesses or their agents, such as the Sugar Manufacturers Association.

Considerable advances in improving sugarcane types have been made by the Central Cane Breeding Station, run by the West Indies Sugar Producers Association (BWISA), where attention has been given both to disease resistance and to increasing yields in the various climates and soils of the different islands. These variations in soil and climate have demanded specialised attention to each territory. In British Guiana, for instance, there are alternating wet and dry seasons, and this makes two crops of quick ripening varieties possible whereas other territories favour growth of canes taking longer to mature.

The recommendations of the Cane Breeding Stations are usually fairly promptly adopted. In Barbados for instance the B 37161 variety is being replaced by newer varieties such as B 45154, B 4744 and B 47419. There have been rapid changes to more resistant varieties when diseases have broken out in various islands.

The BWISA has a dynamic approach to cane breeding and holds that an ideal variety can only be vaguely formulated since cultivation conditions and disease conditions are changing most of the time. They consider that efficiency is likely to be improved in the future mainly by varieties with increased sugar content in the present range rather than by higher yields in the fields.

Thanks to the work of such organisations as the Central Cane Breeding Station, diseases are not nearly such a limiting factor in sugarcane cultivation as in the cultivation of most other commercial crops, but there have been some outbreaks of "leaf scald". The loss from diseases has not been computed, but has probably only been marginal, taking the area as a whole.

Rainfall has a very important influence on the growth of sugarcane. The main sugarcane areas of the West Indies range from Antigua with an average annual rainfall of 41.52 inches per year to British Guiana with an average annual rainfall in the principal

sugar cane areas of just under 100 inches. Naturally rainfall is a most important determinant of yields in those areas in which rainfall is on the average low. Rainfall is of particular importance in Antigua, St. Kitts and Barbados. These facts are illustrated in Table 4.6.i, which also indicates that inadequate rainfall may have been of importance in depressing yields in Jamaica.

Table 4.6.i

Average yields of sugar cane and average rainfall,  
by territories, 1940-49 and 1950-59

Territory	Average rainfall (inches per year)		Average yield (tons of sugar cane per acre)	
	1940-1949	1950-1959	1940-1949	1950-1959
Antigua	41.52	43.83	15.65	19.59
Barbados	48.76	65.52	24.82	33.37
British Guiana	94.31	95.46	<u>1/</u> 27.49	36.23
Jamaica	74.23	54.46	27.83	22.48
St. Kitts	55.37	55.82	26.92	30.55
Trinidad and Tobago	63.19	66.30	22.42	28.84

1/ Estimated.

Source: Data and material developed during the study and other available data.

Historically the most important banana in the West Indies has been the gros michel. But this banana is susceptible to Panama disease, which was identified in Jamaica in 1911, and has almost entirely disappeared as an export type. The lacatan is now the main variety, and now represents 95.3 % of total exports from Jamaica.

Other diseases which affect banana production are leaf spot and burrowing soil nematode. These diseases are much more prevalent in Jamaica than in the Windward Islands, due mainly to the run down nature of much of Jamaica's soils. Most of these diseases are more easily controlled by spraying than is Panama disease. Leaf spot seriously reduces the effective leaf surface of the affected plant, and if allowed to go unchecked will stunt the plant and result in lower grading or total rejection. Intensive spraying is necessary, and in some flat areas orchard oil has been sprayed from light planes. This, however, is impossible in most areas, and spraying must continue to be an important cost of production in banana cultivation.

In breeding of banana plants, a great deal of emphasis has been given to disease control, but up to recent years the effect on weights and yields was marginal. Banana types take many years to breed, but several new varieties are now under trial and it is hoped that they will be more efficient in weights and more disease resistant.

Climatic factors are very important in banana cultivation. Heavy windstorms, not necessarily of hurricane force, can cause up to 100 % mortality as in parts of St. Lucia when hurricane Abbey struck in 1960 and as happens in some parts of Jamaica almost annually. In spite of the large loss from this factor little attention appears to have been given in the breeding programmes to a more wind resistant variety.

The British Guiana Rice Marketing Board has been the most important medium of research into the breeding of rice and control of disease. Improved breeds have been introduced, which have probably tended to be more disease resistant, but have not expanded yields over a large area.

Climate factors are the most important determinant of seasonal fluctuations in yields, and flood and drought are often the most important causes of diseases. In British Guiana weather conditions are extremely uncertain. In 1955, severe flooding destroyed approximately 30 % of the total autumn crop, and in 1957 a prolonged drought practically eliminated the spring crop and reduced the autumn crop. In rice production, water control is likely to have a greater importance in the future than are improvements in breeds, which are already well advanced.

The extent to which different citrus varieties have been grown has depended very much on the type of market concerned. For instance, as larger proportions of total Jamaican output have been processed rather than sold, types which are good for processing rather than for fresh fruit markets have been developed. Research and the distribution of insecticides and fertilizers are carried out through local processing associations.

Perhaps the most important development in breeding has been the appearance of a new fruit in Jamaica, a hybrid of the orange and tangerine, the ortanique. It has very superior qualities for travelling and for table use. Its appearance is likely to affect materially the future supplies of the industry, and to give Jamaica an advantage over other citrus producers.

Diseases such as citrus canker and pests such as fiddler beetle are widespread in the area and in Dominica. The once flourishing citrus industry suffered a substantial reduction in production and export between 1956 and 1959. The mortality among young plants has been very high due partly to inadequate care and spraying. In Jamaica, it has been estimated that between 1947 and 1954, 14,000 acres of citrus, mainly oranges, were established, and that by the end of 1960 only 7,500 acres survived or were in a condition to merit fostering.

We can thus conclude, regarding citrus, that both the breeding of new types and overcoming of some disease problems are likely to influence yields and supplies.

Regarding vegetable and root production, there is little attempt at present to improve varieties or control diseases, although spraying against common garden pests is probably becoming more widespread. Experiments in other tropical countries indicate that attention to suitable varieties is the main key to efficient vegetable production. We can expect some advances in this field, associated with more scientific production methods, but the results cannot be guaranteed.

Sea island cotton, although a minor crop in the West Indies, could no doubt have been of much greater importance had it not been for the pink boll weevil. In some years considerable proportions of the crop have been destroyed by this pest. Governments have endeavoured to control this pest by ordering a "closed season" for cotton growing during which all plants must be uprooted and burned. Nevertheless with increasing peasant farmers, as against estate producers, production and practices of share croppers and migratory cultivators, who are common in cotton growing regions make control difficult.

The common cotton grown in the West Indies is Montserrat Sea Island. In 1954-55, Antigua planted 733 acres of VH8, an intermediate variety evolved to suit Antigua conditions. While it is evident that this latter is a better quality cotton and slightly more disease resistant, it is difficult to estimate the difference in yields due to plant types, since the VH8 is grown mainly by estates, and the MSI by peasants. The average yield of VH8 between 1955 and 1960, was about 35 % higher than MSI.

If the sea island cotton industry survives, we may expect to find some progress in the control of disease and plant types. But improvements in the last few years seem to have been counteracted by deterioration in many of the soils on which cotton is grown.

Perhaps there is no other product that has been so influenced by genetic factors as has cocoa. In the major cocoa producing territories of Grenada, Jamaica, and Trinidad and Tobago, a complete replacement of all old stock by a new government produced clonal material is planned. The result of those projects is likely to increase yields from the low average of about 170 pounds per acre to something between 500 and 600 pounds per acre when the plants are mature. Thus genetic factors must be seen as the main cause of the rather significant expansions which we have projected.

In the coconut industry, disease and climatic factors have been of overwhelming importance. The two big killers are lethal yellowing, which has caused one hundred percent mortality of the larger palms in some areas of Jamaica, and red ring, which can also cause one hundred percent mortality. Red ring is endemic in Trinidad and Tobago and British Guiana, and is perhaps worse than the lethal yellowing in that it favours young trees rather than older ones, and may devastate a complete new plantation just at the pre-bearing stage. The loss of palms from these diseases throughout the area has probably approached fifty percent of the palm population. In some areas, the existence of the diseases has very definitely deterred operators from taking up this crop.

Climatic factors have been of little less importance in Jamaica. The hurricane of 1944 destroyed approximately 40 % of the bearing coconuts, and that of 1951 about 25 %.

Thus the breeding of disease resistant and, if possible, wind resistant varieties has been given precedence in research over factors affecting production ability. The red-ring nematode in Trinidad and Tobago has recently been identified, however, and in Jamaica, the widespread introduction of Malay dwarfs, which are resistant to lethal yellowing, has met this problem.

While no one can predict the course of new or old plant diseases, we feel that diseases and hurricanes are less likely to have a destructive influence in the future than they have had in the past.

Livestock improvement in the West Indies has mainly taken the form of upgrading of crossbred native livestock with imported stock, and efforts made by the various governments have met with some success. In Jamaica, however, the development of a local type of dual purpose cattle has gone rather further, and the Jamaica Hope is considered a breed in its own right. Recently much controversy has taken place as to whether this breed can become the basis for an expanding dairy industry. Many authorities favour the Holstein. Since this argument has not yet been resolved by the specialists it is difficult for us to quantify the likely effects of genetic improvement on output. In any case, the effects of improvement on the higher quality stock are likely to be marginal. Of far greater importance are the large numbers of low quality and scrub livestock which tend to downgrade the herd in all territories. This problem is likely to be a long term problem, but we expect some improvement within the period with which we are concerned. Nevertheless we are rather doubtful whether genetic improvements will be as important as improvements in herd and pasture management in the hoped for increase in yields.

Nutritional deficiencies have been one cause of disease in livestock, but have only been a major problem in areas where there has been over-stocking, particularly when associated with long droughts. Only in British Guiana is foot and mouth disease endemic; there it led to serious mortality in 1955 and again in 1960. The control of this disease is extremely difficult in a territory which has vast frontiers in common with other underdeveloped and underpopulated countries, and we have felt it necessary to allow for the possible effects of this disease when projecting production of beef for British Guiana.

Perhaps the second most serious livestock disease is the Newcastle disease of poultry. This has reduced the poultry flock in Trinidad and Tobago to rather less than half the number that had been planned. Here again we find difficulty in assuming that this disease can be completely controlled in the near future, although some improvements in control are already evident.

### Fertilizers

The sugar industry in the West Indies switched from using mainly pen manure to the larger scale utilisation of chemical fertilizers in the 1940's, and there is little doubt that the increases in yields experienced in most territories in the past decade are largely the result of better fertilizing practices.

The following figures indicate the extent to which the use of fertilizers has increased within recent years:

Imports of fertilizers by territories, 1950, 1955, 1958, 1959

Territory	1950	1955	1958	1959
	1,000 tons			
Jamaica	13.2	22.8	37.8	41.4
Trinidad and Tobago	6.0	18.6	20.3	20.2
Barbados	12.6	14.5	15.6	15.6
British Guiana	N. A.	17.2	26.9	<u>1/</u> 24.0

1/ 1960.

Source: Data and material developed during the study and other available data.

The other main sugar cane producing island, St. Kitts, imported annually 3,500 tons of fertilizer in 1958-60. The application of St. Kitts, although high by the standards of other small islands, has not showed as marked an increase over the period 1950-59 as in the larger territories. This is thought to be due to the fact that natural soil fertility there is high, and the optimum amount of fertilizer has probably been in use for some time.

Crops which are mainly produced by peasants frequently suffer from lack of fertilizers, and this is one of the main reasons why, in the West Indies, peasant production has lower yields than estate production. Nevertheless there has been a surprising increase in the use of chemical fertilizers by peasants, particularly those growing bananas. Banana fertilizers are distributed by the local banana growers association, and in some territories a subsidy is paid. In coffee production a compound of ammonia, superphosphate and muriate is recommended, and various compounds of nitrogenous, phosphorous and other chemical fertilizers are recommended by departments of agriculture in various territories.

Fertilizer trials have been conducted in Jamaica for all crops, and some of the results have been encouraging. For coconuts, for instance, a crop which traditionally did not get much fertilizer, there are indications that the yield could be doubled with proper fertilization during the pre-bearing and bearing years; and it has been apparent, where coconut is intercropped with banana, that it responds well to fertilizers meant for the bananas.

Probably the most nearly controlled experiments in fertilizers have been in sugar cane. Even so, the lack of complete control of genetic and side factors has made it inadvisable for us to give an arithmetical relationship between yield increases and fertilizer application. In tree crops in particular, where genetic factors are difficult to control, the agronomists concerned prefer not to derive an exact arithmetical relationship between application and yields; so we have made some qualitative observations only.

The larger estates and better producers of sugar are probably nearing the optimum fertilizer application. Considering, therefore, that they grow the larger part of the crop, it is not considered that there is as much scope for large increases in yields as in mainly peasant crops. Rice is mainly a peasant crop, and fertilizer expenditures are not so marked as in some crops. We expect to find the highest fertilizer responses in crops such as bananas, cocoa, coffee and citrus, and also in coconut, which is being produced with banana on a larger scale and on a few estates is now being subjected to intensive production with fertilizer application.

Perhaps the most spectacular results are those gained after the fertilization of improved pasture. Cattle weights, which will usually double (in terms of liveweight per acre) as between improved and unimproved pasture, will often double again as between non-fertilized and fertilized pangola grass. In Jamaica some experiments showed a liveweight gain of 1,000 pounds per acre after fertilization of pangola grass. It is, therefore, possible to predict that the use of fertilizers is likely to be important in increasing beef and milk production, or in reducing the land area necessary for producing a given quantity of meat or milk.

## Feeding stuffs

As with fertilizers, the use of imported balanced feeding rations in agriculture in the West Indies has grown considerably in recent years, as can be seen from the following figures:

Imports of animal feeding stuffs, by territories, 1950, 1955, 1958, and 1960

Commodity	Jamaica				Trinidad and Tobago				British Guiana			
	1950	1955	1958	1960	1950	1955	1958	1960	1950	1955	1958	1960
	1,000 pounds				1,000 pounds				1,000 pounds			
Grains and cereals	1,059	964	2,241	2,325	3,719	576	7,846	2,189	N. A.	210	151	118
Prepared meals	2,491	11,336	30,906	35,963	7,036	366	27,448	8,562	N. A.	4,997	1,993	15,089
Other kinds	—	802	1,129	1,303	1,267	—	2,635	6,363	N. A.	641	279	707

Source: Data and material developed during the study and other available data.

The most spectacular increase is in prepared meals, and about 75 % of this is poultry rations. The figure for this item fluctuate in Trinidad and Tobago somewhat, but it is thought that this to some extent follows the trends in the poultry industry due to Newcastle disease.

Rice, corn and pulses all contribute something to stock feed in the West Indies, but one of the most important locally produced livestock foods is coconut meal. This is traditionally fed to pigs, and an expansion in pig numbers usually accompanies expansion of the coconut industry. One expert (Ref. S. 5. 4. ), however, suggests that coconut meal should be sold for export, and pigs should be fed on imported balanced rations. Pigs, sheep and goats are usually scavengers, and only a minority are fed a proper ration, however. While it is thought that the practice of rearing pigs on scientific feeding principles will increase, it seems unlikely that there will be a drastic revolution in feeding methods such as that which has recently taken place for poultry.

In line with our projections of livestock numbers, and allowing for more increase in scientific feeding, we project the import demand for feeding stuff as follows:

1960 and projected annual import demand for feeding stuffs in Jamaica, Trinidad and Tobago, and British Guiana

Commodity	1960	1965	1970	1975
	1,000 pounds			
Grains and cereals	4,632	5,790	7,133	8,569
Prepared meals	59,614	80,470	98,360	113,266
Other kinds	8,373	11,303	13,815	15,909

## Recovery rates and intermediate products

Certain of the products with which we are concerned undergo some processing within the West Indies. This varies from simple milling processes, such as those deriving milled rice from rough rice, to fairly complicated secondary processes such as manufacturing canned fruit juices or soaps and cooking oils, or (in Jamaica only) condensed and evaporated milk. In this chapter we outline these processes and endeavour to indicate how efficiency in these processes affects the yield.

The rate at which sugar is recovered from sugar cane is partly a measure of efficiency. The rate may, however, be more closely related to the sucrose content of the sugar cane. This is determined partly by plant types but mainly by weather conditions. In some cases, sucrose content is affected by the sugar cane's having been burned, either deliberately or accidentally.

The efficiency in the factory itself varies according to the age of the machinery, standards of management and supervision. The size of the factory is also important. In St. Kitts, where there is one large centralised factory, the grinding rate is 125 tons of sugar cane an hour, while in Barbados and Jamaica, where there are a number of smaller, less efficient factories, the average grinding rate is 37.37 and 56.17 tons an hour, respectively.

In Table 11g we have shown the tons of sugar cane necessary to make a ton of sugar. It will be noted that there is a great deal of variation between territories, which is as much due to differing climatic conditions as to factory efficiencies. Since changes in recovery rates are likely to be marginal, we have not projected any change in the existing rates for the period 1960-75.

Rice milling rates, on the other hand, are expected to increase. This follows the change from a large number of small, poorly equipped mills to larger, more centralised mills utilising modern machinery. The estimated rates are shown in Table 12c, and account has been taken of these in our projections.

Both cocoa and coffee undergo some processing. This takes the form of fermenting in the case of cocoa and roasting in the case of coffee. Little information is available on recovery rates. We expect some increase in the efficiency of fermenting cocoa since here, too, there is a trend to more centralised fermentaries, but we have not been able to isolate this factor from others influencing yields. In coconuts, the problem of determining the number of nuts necessary to make a ton of copra or of raw oil is aggravated by the fact that there are usually primary processes that take place on the farm or plantation. Some estimated recovery rates are, however, shown in Table 18b. We do not expect any decline.

In sea island cotton, recovery rates can be influenced by ginning efficiency and by the proportion of stains to clean lint. We have not been able to project any changes since the present state of the industry (discussed elsewhere) is hardly likely to encourage investment into improved methods.

We have not been able to derive exact recovery rates for different types of citrus, and in Table 15b only the input of fresh citrus to processing firms is shown. Unfortunately no total product figures are available from processors, and as a considerable quantity enters home consumption we would not take exports as indicative of total supplies.

Cornmeal is manufactured in most parts of the West Indies, and the recovery rate varies from 50 % to 70 %. No change in this rate is predicted.

Considering products now which enter into a rather more advanced stage of manufacture, but whose main raw material is one of the products with which we are concerned, the most important are rum, condensed and evaporated milk, and oils and soaps.

Rum is not manufactured directly from sugar syrups except in some of the smaller territories. It is manufactured from molasses, a by-product of sugar. Therefore, rum does not compete with other end uses of sugar except in the sense that the greater the factory efficiency achieved, the less molasses may be available for making rum. We do not, however, conclude that this trend, which is a long term one, will materially affect supplies of rum within this period.

Condensed and evaporated milk is made in Jamaica at a condensery which was set up in 1940 to provide an outlet for local milk and to replace part of the large importation of this product. In 1957 a ban on the importation of milk and butterfat solids for manufacture was lifted, and the condensery was able to increase output by using imported raw materials. Sweetened condensed milk also utilises sugar and each 14 oz. tin contains the equivalent of 6 oz. of sugar and 1.7 pints of standard full-cream liquid milk. Thus in 1960 approximately 12 million pounds of sugar were utilised by the condensery.

Oils and fats products rank among the more important secondary products produced in the West Indies from local raw materials. Table 18c indicates the production in Jamaica, Trinidad and Tobago, Barbados, and all territories, of the main final products — soaps and edible fats and oils. Greater factory efficiency has improved recovery rates, and has enabled higher value products, such as toilet soaps, to be manufactured. There are also industries utilising vegetable fats which further other secondary processes for making such products as shampoos, toothpastes and cosmetics. We have included the main products only in this table. Projections of total supplies, Table 18d, are based on the assumption that factory capacity will be expanded to meet the demand, and imported vegetable oils will be utilised if local supplies are not forthcoming.

Apart from the condensery and rum manufacture, other manufacturing enterprises also utilise sugar as an input. Exact quantities are not available, but from our input-output table on Jamaica, Table 3. e. i, we see that in 1958 J£1,042,000 was spent on sugar products by the food manufacturing sector (which includes the condensery but excludes the rum industry) at the local price of approximately J£36 per ton. This would account for about 29,000 tons of sugar. In Trinidad and Tobago approximately BWI\$2,600,000 worth of sugar for use as raw material was bought by the manufacturing sector in 1959. Many of the industries utilising sugar products are small confectioneries and other food plants. Substantial quantities are also used by manufacturers of alcoholic and non-alcoholic drinks.

Other than those mentioned there are a few minor industries utilising agricultural products. Fruits and vegetables are canned, mainly for local use, and the canning of sausages and bacon has recently started in Jamaica. In Jamaica, food manufacturing has been projected to grow at a moderate rate. (See projections of the growth of the economy of Jamaica, Table 3d.) Taking the area as a whole there is a fairly wide variety of food processing industries, and we have not been able to deal separately with a number of the minor ones.

*Part Five*

*RECONCILIATION*

Chapter 1

**RECONCILIATION OF DEMAND AND SUPPLY AND IMPORT DEMAND**

Having made independent estimates of demand based on projections of income growth, population growth, and calculated income elasticities of demand (see part three), and independent estimates of supply based on projections of acreages and yields (see part four), we now bring these together to estimate import demand, or to estimate how much will be available for export after local needs have been met. All estimates are in terms of quantities, and unless otherwise stated it is assumed that prices remain constant.

Sugar

The summary table for sugar is shown in Table 22a. Sugar is of course mainly an export crop and although very small quantities of specialised products are imported we feel that import substitution has been carried about as far as is possible, and that the small quantity of sugar imported is likely to continue to have approximately the same proportion to total consumption as in the base year. The main object of the summary table is thus to show how much will be available for export after local needs are met.

Sugar is used for manufacturing and for household use. These end uses are shown separately. It must be noted, however, that in Jamaica, household consumption includes sugar passing through the condensery, and in all territories sugar used for manufactured sugar preparations such as confectionery is included in household demand. The manufacturing demand includes mainly sugar utilised by fruit processors, cake manufacturers and beverage producers. It will be noted that the amount available for export in 1975 bears approximately the same relationship to total production as in 1958. The movement in local demand is slightly lower than that for local supply, but manufacturing demand, projected on the basis of our inter-industry tables (see part two and relevant tables referred to in Appendix III) increases at a slightly greater rate than supply. Nevertheless, on the basis of inquiries conducted for the surveys of economic growth (part two) we were not able to project a very substantial increase in manufacturing demand.

Rice

The pattern of rice production and trading emerges clearly from Table 22b. British Guiana, the main producer and supplier to other territories, becomes more important in this role as production in other territories declines and their demand increases. In British Guiana approximately 10 % of rice (rough rice, milled rice equivalent) is retained

by farmers for stock feed and seed, and a rather lower proportion for other territories. Since we do not predict a significant change in the structure of this industry, we assume that these ratios will remain constant. It will be noted that by 1975 British Guiana should be able to supply the needs of the importing territories and have about 125 million pounds left for export elsewhere. The other territories at present import negligible quantities of rice, mainly packaged rice from outside the region; but the steps which are being taken to improve the quality of British Guiana rice may reduce this even further.

### Bananas

For bananas, we have not been able to consider quantities available for export purely as a surplus after home demand has been met. The banana industry is geared to the export trade and most bananas above a certain size are made available for export. The supply on the local market depends largely on the proportion of rejects, and the greater the number of bananas grown for export the greater will be the supply on the local market. We have therefore projected total supply and export supply on the one hand, and independently have projected local demand. If the residual between total production and export production falls short of or exceeds the projected demand we expect a price adjustment to follow. We have shown the deficiency or surplus in Table 22c. It will be noted that in Jamaica and Trinidad and Tobago a significant deficiency is projected after 1965. This would indicate a tendency for increased prices on the local market. In Trinidad and Tobago by 1970, we predict local demand actually exceeding total production. If exports continue, this would lead to a considerable increase in the local price of the product or, alternatively, Trinidad and Tobago might import substandard bananas from the Windward Islands for domestic use. An alternative assumption is that local price increases are sufficient to put Trinidad and Tobago out of the export market and make her a domestic supplier only. British Guiana is not at present a banana exporter, but plans are well advanced to introduce an export business to that territory, and our projections are based on the assumption that she will be an exporter by 1965.

### Citrus

For citrus, although exporting is one of the main objectives of production, the local market is sufficiently strong for amounts available for export to be considered more in the nature of a surplus after local needs have been met. The main exporters are Jamaica, Trinidad and Tobago and Dominica; other territories produce mainly for domestic use. All the export figures in Table 22d are expressed in fresh fruit equivalents, since gross weights of tinned exported products would be misleading, and data on net weights are not available. Canned produce is exported from Trinidad and Tobago and Jamaica, and lime juice in barrels is exported from Dominica. Fresh fruit is exported also, but in Trinidad and Tobago and Jamaica, a greater part of the crop goes to processing than to export of fresh fruit.

### Coffee, cocoa and tobacco

No estimates were made of demand for coffee, cocoa and tobacco products. The first two crops are not important, and for tobacco the budgetary data is thoroughly unreliable. Some projections of amounts likely to be used for local consumption were however made

for coffee and tobacco at the time that supply was being examined, and are presented in Tables 5.1.i and 5.1.ii. Local use of cocoa is negligible, and it can be assumed that initially all production is available for export (see Table 17d).

Table 5.1.i

Jamaica: Supply, demand, imports and exports of coffee, 1958 and projections

Year	Total production	Exports and stock	Imports	Local consumption
	1,000 pounds			
1958	5,626	2,865	127	2,888
1965	5,670	2,031	negligible	3,639
1970	6,889	2,586	negligible	4,303
1975	7,137	2,308	negligible	4,823

Note: Trinidad and Tobago is also a coffee producer, but no figures of production or local use are available. About 800 pounds of extracts were exported in 1958.

Table 5.1.ii

Jamaica: Supply, demand, imports and exports of tobacco and products, 1961 and projections

Year	Tobacco leaf, local production	Cigarettes, local production	Cigars			Estimated import requirement, cigarette tobacco
			Total production	Exports	Local consumption	
	1,000 lb.	Millions	Millions	Millions	Millions	1,000 lb.
1961	1,300	727	16.3	5.9	10.4	1,551
1965	1,360	750	17.5	7.0	10.5	1,675
1970	1,550	770	19.0	10.0	9.0	1,861
1975	1,800	800	21.5	11.5	10.0	2,094

Note: All territories grow tobacco for domestic use, but in the main it is a non-cash crop. St. Lucia, Grenada and Barbados, Trinidad and Tobago, and British Guiana make cigarettes locally, mainly from imported tobacco. No estimates of projected demand are available.

## Cotton

Sea island cotton is produced in the West Indies for export as raw cotton (Table 5.1. iii). Cotton waste and stained cotton are retained for non-textile use in the domestic market — normally about 5 to 10 percent of production. The decline in production in the last 20 years is expected to continue through the 1975/76 crop year (Table 14f). Production is expected to continue to be exported through 1975.

Considerable import demand exists for textiles in the West Indies, mainly for piece goods. The United Kingdom presently supplies more than 80 percent of the area's piece goods requirements. As an example of import demand, textile imports by Jamaica average 3.7 million pounds for the period 1955-59 compared with 0.1 million pounds of clothing for the same period, but in raw cotton equivalent. Such imports increased to 6.5 million pounds and 0.9 million pounds respectively for the period 1960-62. Jamaican exports of cotton textiles in raw cotton equivalent decreased from 0.8 million pounds of raw cotton equivalent in 1955-59 to 0.4 million pounds in 1960-62. On the other hand, comparable exports of clothing in raw cotton equivalent for this period increased from less than 0.1 million pounds to 2.5 million pounds. This illustrates the practice of importing piece goods for the manufacture of clothing for export. Similar trends have developed in other West Indian areas, primarily in Trinidad and Tobago and Barbados.

Raw cotton imports for the area as a whole increased from 1.0 million pounds in 1950-54 to 5.0 million pounds in 1960, with projections of 6.0 million pounds for 1975 (Table 5.1. iii). Such imports, together with waste from domestic cotton production, represent internal consumption levels of raw cotton. Total cotton consumption estimates, taking into account textile and clothing imports and exports, are not possible since even rough estimates of the cotton textile and clothing trade for the area as a whole are lacking.

Table 5.1. iii

Production, imports, exports, and consumption of  
raw cotton in the West Indies in selected years

Year	Production <sup>1/</sup>	Imports	Exports	Consumption
	1,000 pounds			
1950-54 (average)	1,869	986	1,700	1,155
1955-59 (average)	2,040	3,459	1,900	3,599
1960	898	4,996	800	5,094
1965	989	4,140	900	4,229
1970	739	4,956	700	4,995
1975	734	5,932	700	5,966

<sup>1/</sup> Cotton production is shown by calendar year but is actually for split years; the year shown is the second year of the split year combinations. For example, 1960 production shown is actually the 1959/60 harvest.

## Oils and fats

Projections have been made of demands for edible oils and fats. The local supply of these products has increased considerably in recent times and a further significant rise is predicted since it is assumed that factory capacity can expand almost as fast as demand. British Guiana imports some domestically produced oils and fats from other territories, but apart from these, imports are mainly of olive oil and other specialised products for which local substitutes might not be available. We have therefore projected the demand for imports separately in Table 22f. It is also assumed that Jamaica will expand factory capacity sufficiently to export small quantities of oils and fats. Soap is also produced in the region and supply figures are shown in Table 18c, but no projections of demand are available.

The demand for copra, the only important vegetable oil grown in the region, will naturally follow from the demand for oils, fats and soap. In Table 22e we have based the demand for copra on the needs of the factories, assuming they expand production of oils and fats to cater to the growth in demand for these products, and the production of soaps at approximately the same rate. It will be noted that all territories become net importers of raw materials in 1970 (in Jamaica supplies were projected to fall between 1965 and 1970 on the assumption that there would be hurricane damage in that period). Trinidad and Tobago and British Guiana are seen as persistent net importers.

Alternatively, it could of course be assumed that factory capacity increased only in line with availability of supplies of domestic raw materials. In this case we should have to assume that finished oils and fats products were imported in greater proportion than are indicated by Table 22f. By 1975 in Trinidad and Tobago approximately 18 % of the quantity shown as home produced would be imported, and in British Guiana approximately 30 % would be imported.

## Roots and starch vegetables

According to our separate projections of demand and supply a fairly large deficiency in root crops will arise in all territories during this period. The reasons for this have been explained in part four. There is a fairly significant trade in roots within the islands of the Leewards, Windwards and Barbados, and some trade between these islands and Trinidad and Tobago. This latter trade, however, is unlikely to continue, if, as we predict, domestic deficiencies arise in other territories.

The imports of root vegetables from the outside world consist wholly of Irish potatoes, and it is assumed in the first instance that the deficiencies (see Table 22g) will be met by importing larger quantities of Irish potatoes. This does not necessarily follow however. It may be that part of the demand will go unmet or that different types of starch foods will be substituted. In any case we expect price increases in this product, and it is probable that final demand will depend, in this case, more on price elasticities and elasticities of substitution than on income elasticities.

## Vegetables

For vegetables we expect some increase in local supplies but not in the scale of increases in demand, so that imports may be expected to increase. Imports at present consist mainly of onions, garlic, and to a lesser extent carrots and lettuce. We should expect imports of these to increase more than other green vegetables, and there are some local vegetables for which we should not expect imports to fill the deficiency, but rather for prices to increase as demand increases. The supply position of vegetables is however an unknown quantity, since a considerably high production could emerge without pressure on scarce land resources by means of more intensive production. This has been discussed elsewhere. Table 22h indicates the demand, supply and import position of vegetables.

## Corn and pulses

Corn and pulses are in much the same position as roots and vegetables; only marginal increases (and in some cases decreases) in production can be expected, and in these crops, we do not expect much can be gained from more intensive methods. These products, particularly corn, are used for animal food. The demand for this use and for household use is shown, with import demand, in Tables 22i and 22j.

## Livestock products

All territories except British Guiana are net importers of beef. Although some trade in live cattle has taken place between British and French islands in the eastern Caribbean the quantities are negligible compared with total demand and supply figures. In recent years Jamaica has reduced her dependence on overseas beef supplies, but we are not able to predict complete self-sufficiency in beef for any territory except British Guiana for which we predict a small surplus for export by 1970. In Table 22k we indicate the projected demand, supply and import position.

Other fresh meat (see Table 22L) includes pork, goat, and mutton of sheep and lamb. The latter is mainly imported, pork is mainly locally produced while goat is wholly locally produced. Considering these meats separately we found that a deficiency arose between supply of goat and projected demand. It is unlikely that goat would be imported, but imported mutton might well be substituted. Imports of pork are expected to increase little as supply will increase nearly as much as demand. There is, however, unlikely to be very much change in the sheep population.

There has been a revolution in the production of poultry meat and eggs in recent years and now the territories are practically self-sufficient in these items, which formerly were mainly imported or not available. In Trinidad and Tobago, however, the supply of poultry meat has been seriously reduced by Newcastle disease, and as income elasticity is high for this product in Trinidad and Tobago we expect her to continue to be a substantial net importer of poultry meat.

Generally speaking however, apart from Trinidad and Tobago and perhaps some continuation of a small quantity of imports into certain of the Leeward Islands and

Windward Islands, we expect the area to be self sufficient in these products. Tables 22m and 22n indicate that imports may be necessary to meet temporary shortages, but that on the whole supply approximates to demand.

Fresh milk cannot be imported, and the deficiencies which our projections show between demand and supply will not be filled by imports. We might expect some price increase or some substitution of other milk goods. On the whole, however, we expect households will simply do without fresh milk, and we would not like to say whether the income saved will be spent on food or non-food purchases. If more fresh milk became available, it would naturally act as a substitute for processed milk products. The opposite is not necessarily the case, however, and if the projected fresh milk demand is not met, we do not expect that there will be a significant increase in demand for milk products on this account alone. (See Table 22o.)

Jamaica is the only territory which has a condensery, and since 1957 she has imported milk solids for the condensery to make up the deficiency in local fresh milk production. In our projections (Tables 22o and 22p) we assume that the condensery supplies local demand for processed milk, except small imports of specialised products, and that imports of milk solids make up the deficiency of fresh milk to the condensery.

## APPENDIX I

### NOTE ON IMPORT DATA—TABLES 23a-23d

In tables 23a-23d we present tabulated summaries of the total imports, in quantity terms, of certain selected agricultural and other related products for Jamaica, Trinidad and Tobago, British Guiana and Barbados. For Jamaica and British Guiana the series run from 1945 to 1960, a sixteen year span. For Trinidad and Tobago the period extends from 1949 to 1960 and for Barbados from 1946 to 1958.

The selection of the items which are included in the summary tables has been determined mainly by the USDA contract requirements. We have, however, also included a few commodities which, though not expressly required for our immediate exercise, are none-the-less valuable as they are basic import items and possess much trading potential.

Except for one or two small points the list of commodities considered is self explanatory. Meat and Meat Preparations are presented as Group 1. This group is further subdivided into four main sub-groups: (i) Meat — Fresh, chilled or frozen (ii) Meat — Dried, salted, smoked or pickled (iii) Meat Preparations, and (iv) Meat in Airtight Containers. The main items of each sub-group are also shown.

Dairy Products and Eggs are presented as Group 2. The main items of this group are Milk, Cheese, Butter, Eggs and a smaller residual item of Miscellaneous Dairy Products. The only one of the above items which is further broken down is Milk. It is divided into its three main categories of (a) Tinned Milk (unsweetened) or, as it is commonly called, evaporated milk (b) Tinned Milk (sweetened), commonly called condensed milk and (c) all other forms of milk, whether Dried, Skimmed or Powdered.

Butter includes both table and cooking butter but excludes margarine and other butter substitutes which are included under Edible Oils and Fats. The quantity of eggs imported each year has not been included in the overall quantity total for Dairy Products and Eggs, as imports of eggs are recorded in various quantity units in the different territories. Some territories record imports of eggs in dozens while others record them in pounds, or some may even give both quantity measures. There are also instances when imports of eggs have been recorded in great hundreds 1/ as well as in plain numbers of eggs.

Group 3, Fish and Fish Preparations, is self explanatory, but in Group 4, Cereals and Cereal Preparations, the figures for Jamaica require some explanation. In this group, the Jamaica figures for Wheat and Wheat Flour include a small quantity of Rye and Flour of Rye between 1946 and 1953. After 1953 this item is recorded separately. After 1953

1/ A great hundred = 120.

too, imports of Counter and Baking Flour are entered under Baking Products (n.e.s.). This undoubtedly explains the substantial drop in the quantity of Wheat and Wheat Flour imported in Jamaica after 1953 which is correspondingly made up by the substantial increase in Baking Products. These individual movements do not, however, disturb the overall pattern.

Deciduous Fruits are shown as Group 5. The group is divided into three main sub-groups: (i) Fresh, (ii) Dried and (iii) Preserved or Tinned. For Fresh, we show Apples and Grapes separately, and group all other Fresh Deciduous Fruits together. In Barbados, we have had to simply make an omnibus item of all Fresh Fruits. Dried fruits include such items as raisins, currants and prunes, whereas for Preserved and Tinned we include such items as canned pears, peaches, apricots and other preserved fruits. It is not worthwhile to extend the group beyond these items.

The most we could do in the case of Group 6, Vegetables, was to abstract the principal items of Irish Potatoes, Peas, Beans and Lentils and Tomatoes, and group all other vegetables together as "Other Fresh Vegetables". In Barbados, tomatoes are included with other fresh vegetables. The other category of vegetables, Tinned and Preserved Vegetables, also includes dried vegetables in some instances.

For Group 7, Beverages (Non-Alcoholic), we have shown only the three main items of cocoa, coffee and tea. Cocoa includes both raw and powdered cocoa while coffee includes both raw and ground coffee as well as coffee extracts and essences.

Group 8, Feeding Stuffs for Animals, corresponds to Division 08 of the Standard International Trade Classification, Feeding Stuffs for Animals (not including Unmilled Cereals). Sub-group (a) Grains and Cereals, includes such things as hay and fodder, bran and pollard, while sub-group (b) includes feeds like linseed cake and meal, and fish and meat meal.

Group 9, Edible Oils and Fats, has had to be restricted to the three main items of margarine and other butter substitutes, lard and lard substitutes and cooking oil, all of which are grouped together to comprise the overall group. The other groups are self-explanatory.

The quantity unit used throughout is mainly thousand pounds. The difficulty involved with Eggs has already been stated and the unit used on each tabulated summary is clearly stated. The other notable exceptions are Molasses and Syrups, which quote quantities in thousand liquid gallons, and Preserved and Tinned Fruits, which quote quantities in thousand liquid gallons and thousand pounds. Cotton and Cotton Piece Goods are expressed in thousand square yards while Fertilisers, which refer only to imports of manufactured fertilisers, are in thousand tons.

A dash in any column signifies that the quantity of the item concerned was less than one thousand units. We have also corrected all units to the nearest thousand, so that where imports are less in quantity than 500 they are corrected downwards and vice versa. All blank spaces mean that the information was not available.

The principal sources of the data presented in Table 23a-23d and discussed in this Appendix are the Annual Trade Returns for each territory, while our subsidiary sources of information were mainly the Caribbean Yearbooks or Colonial Office Annual or Biennial Reports on the individual territories. The problem of reconciling data from these various sources did not present itself.

Manufacturing 3	7.0	3.5	10.6	3.7	13.3	3.7	14.8	3.4
Manufacturing 4	3.0	1.5	4.5	1.6	5.3	1.5	6.1	1.4
Public utilities	1.9	.1	4.2	1.5	4.8	1.3	5.3	1.2
Distribution	31.9	16.1	44.6	15.6	54.9	15.2	77.2	17.7
Transport, etc.	11.9	5.9	17.3	6.1	20.9	5.8	29.0	6.6
Ownership of dwelling	6.7	3.4	10.2	3.6	12.0	3.3	16.7	3.4
Services	37.4	19.8	59.9	21.0	83.2	23.0	93.6	21.5
Government	13.1	6.6	19.3	6.8	26.7	7.4	32.1	7.3
Gross domestic product	198.7	100.0	284.4	100.0	360.8	100.0	437.1	100.0

Note: Figures in Tables 3b are based on 1956 prices. There are small differences in the industrial content of sectors as between these tables, i.e., sugar manufacturing is in sugar cane growing (including manufacture of sugar) above and in Manufacturing 1 in Table 3b. Export agriculture includes its own distributive activities above. They are in Distribution in Table 3b. These differences (and others of negligible importance) arose because it was not possible to re-arrange data for 1950-59 in classifications thought most desirable for projections.

Sources: Percival and D'Andrade — The National Income Accounts of British Guiana 1948-51.  
O'Loughlin — The Economy of British Guiana 1952-56.

Kundu — Inter-Industry Table for the Economy of British Guiana 1959 and National Accounts 1957-60

Note: Export taxes or duties have been treated by Percival and D'Andrade (page 83) as direct taxes and by O'Loughlin (page 62) as government income from property. U. N. Standard System (page 36) considers export duties as part of indirect taxes. Hence for 1948-56 the national income and GDP at factor cost figures, as given by Percival and D'Andrade and O'Loughlin, have been decreased by the amounts of export duties.

1/ Sub classes may not add to total land area due to sampling errors.

2/ Figures for British Guiana have been taken from the 1952 Census except that 1958 figures of rice and sugar acreage have been embodied under crops.

3/ Includes ruinate used as pastures.

4/ Includes unknown area of improved grassland.

5/ May include unknown area of forest not in farms.

6/ Includes ruinate not used as pasture.

7/ Excludes built on land or service areas in farms.

Sources: Agricultural Statistics — Series 2 No. 1, Federal Statistical Office (1960), Agricultural Statistics for Jamaica 1958; and Some Statistic Tables on West Indian Agriculture, by D. I. Edwards, Institute of Social and Economic Research, Jamaica.

Note: Crop land — land under tree crops and medium and short term crops, land in process of preparation for crops or normally cropped, but fallow Permanent meadow and pasture, grassland (improved and unimproved) and other land suitable for grazing animals.  
Forest and woodland — tree covered land not suitable for growing.  
Other land — land not falling into above categories.

Table 11e

Sugar cane: Projected yields per acre reaped, by territories

Territory	Tons of cane per acre		
	1965	1970	1975
Antigua	20.00	20.00	20.00
Barbados	35.00	37.00	40.00
British Guiana	40.00	40.00	40.00
Jamaica	25.00	30.00	35.00
St. Kitts	35.00	37.50	40.00
Trinidad and Tobago	30.00	32.50	35.00

N. B. For reasons for basic assumptions see Text.

Assumptions: <u>Antigua:</u>	Yields beyond 20.00 tons to the acre very unlikely. Calculated at 20.00 t. p. a. throughout (maximum).
<u>Barbados:</u>	Substantial increases expected. Estimated at 35 t. p. a. in 1965 increasing by .50 t. p. a. per annum up to 1975.
<u>British Guiana:</u>	Double crop each year. Increases expected. Yields expected to approach 40 t. p. a. Estimated at 40.00 t. p. a. throughout (maximum).
<u>Jamaica:</u>	Low yields in 1950's. Estimated at 25 t. p. a. in 1965, creeping to 35 t. p. a. in 1975.
<u>St. Kitts:</u>	As Barbados.
<u>Trinidad and Tobago:</u>	Available figures refer to Estate cultivation only. On the basis of lower yields for peasants, overall estimates placed at 30 t. p. a. in 1965 creeping to 35 t. p. a. in 1975.

Table 11f

Sugar cane: Projections of production, by territories

Year	Antigua	Barbados	British Guiana	Jamaica	St. Kitts	Trinidad and Tobago	Total
	Tons						
1965	248,300	1,648,885	3,626,360	3,817,600	475,720	2,701,500	12,518,365
1970	255,740	1,795,425	3,735,120	4,718,580	525,000	3,014,408	14,044,273
1975	258,280	1,960,400	3,772,480	5,560,030	565,560	3,278,800	15,395,550

Assumption: That acreages will increase as per Table 11c, projection 1. That yields will be equal to figures in Table 11d.

Table 11g

Average of tons of cane per ton of sugar, by territories, 1940-60

Territory	Tons
Antigua	8.36
Barbados	8.73
British Guiana	10.60
Jamaica	9.49
St. Kitts	8.33
Trinidad and Tobago	9.64

1/ Production figures of rice are milled equivalents of rough rice and not the actual milled quantities. The amounts of rough rice used for animal feed and seeds, etc., and not milled at all, are about 10% of total rice equivalents for British Guiana, and 5% for Trinidad and Tobago, and Jamaica.

2/ Sources: Reports of the British Guiana Rice Marketing Board 1960-61.

3/ The difference between acreage planted and acreage reaped is accounted for by the volunteer growth of rough rice in the spring from the grains scattered in harvesting the preceding autumn crop.

4/ Yield per acre is obtained from production of rough rice and acreage reaped.

5/ Except for 1951 and 1952 no firm figures are available. Figures for other years are best estimates arrived at from fragmentary data.

Sources: a) for 1951-52 - Steer and Benson - A Survey of Rice Industry, Government of Trinidad; b) for other years - Colonial Report, Trinidad and Tobago, 1953, 1955, 1956, 1957; Annual Statistical Digest - C.S.O., Trinidad; Tobago, 1953, 1957, 1960; Administration Report of the Agricultural Department, Trinidad and Tobago, 1954, 1955, 1956.

6/ Estimated from the production of rice, assuming rough rice to milled rice ratio at 100:60.

7/ Sources: a) for 1950-51 - Rice Acreage in Jamaica, Department of Statistics, Jamaica 1955; b) for 1952-60, Annual Reports of the Department of

Agriculture, later on Ministry of Agriculture and Lands.

Data not available for Trinidad and Tobago.

Table 13c

Banana: Acreage, yield, and production, by territories, 1958 <sup>1/</sup>

	Jamaica	Dominica	St. Lucia	St. Vincent	Grenada	Trinidad and Tobago
Total acreage	100,000	7,050	3,580	8,825	12,800	13,500
Bearing roots (1,000)	63,990	2,559	2,127	1,346	<sup>3/</sup> 6,916	<sup>4/</sup> 6,049
Roots per acre	640	363	594	153	<sup>3/</sup> 494	<sup>4/</sup> 406
Pounds per acre	<sup>2/</sup> 4,694	10,747	16,781	7,233	3,728	4,664
Pounds per root	<sup>2/</sup> 7	30	29	47	N. A.	N. A.
Total production (1,000 pounds)	<sup>2/</sup> 469,425	75,765	62,077	63,835	47,719	62,968
Exports (1,000 pounds)	298,800	68,484	56,111	57,700	43,133	9,880
Other production (1,000 pounds)	170,625	7,281	5,966	6,135	4,586	53,088

<sup>1/</sup> Inconsistent data make it impossible to compute meaningful weights per stem and numbers of stems per root. However, a special banana study indicated about 30 pounds per stem in Jamaica and 25 pounds per stem in most other areas. Stems per root estimates ranged from 0.26 to 0.54 in 1946 and 0.18 to 0.86 in 1958.

<sup>2/</sup> Reduced to exclude unmarketed production estimated at 30 percent of total stem production.

<sup>3/</sup> 1960. Acreage for 1960 was 14,000.

<sup>4/</sup> 1960. Acreage for 1960 was 14,900.

Source: Data and material developed during the study and other available data.

Barbados: Imports of selected agricultural and related

Commodities 2/	Unit of quantity	1946	1947	1948	1949
1. MEAT AND MEAT PREPARATIONS	1,000 pounds	4,692	5,175	4,887	5,095
(i) Meat — Fresh, Chilled or Frozen	do.	389	438	651	759
(a) Bovine cattle	do.	279	319	496	631
(b) Sheep or lamb	do.	46	80	92	55
(c) Swine	do.	35	-	-	-
(d) Poultry	do.	29	39	63	73
(e) Other	do.	-	-	-	-
(ii) Meat — Dried, Salted, Smoked or Pickled	do.	4,103	4,214	3,692	3,943
(a) Bacon	do.	-	-	-	-
(b) Ham (all kinds)	do.	259	240	164	181
(c) Pork	do.	3,196	3,518	3,362	3,552
(d) Beef and Veal	do.	648	456	166	210
(e) Other	do.	-	-	-	-
(iii) Meat Preparations	do.	-	-	-	-
(a) Sausages (all kinds) 3/	do.	-	-	-	-
(iv) Meat in Airtight Containers	do.	200	523	544	394
(a) All other meats (n. e. s.)	do.	-	-	-	-
2. DAIRY PRODUCTS AND EGGS 4/	do.	2,023	2,539	2,271	3,254
(i) Milk (all kinds)	do.	1,324	1,925	1,685	2,399
(a) Tinned (unsweetened)	do.	-	-	-	-
(b) Tinned (sweetened)	do.	-	-	-	-
(c) Dried, skimmed or powdered	do.	-	-	-	-
(ii) Cheese	do.	73	84	135	134
(iii) Butter	do.	626	530	451	721
(iv) Eggs	1,000 doz.	-	-	-	-
(v) Miscellaneous Dairy Products	1,000 pounds	-	-	-	-
3. FISH AND FISH PREPARATIONS	do.	-	-	-	-
(a) Fresh, chilled, frozen	do.	-	-	-	-
(b) Dried, salted, smoked, pickled,	(a) do.	(a) 346	(a) 279	(a) 47	(a) 127
(c) Canned or preserved fish	(b) 1,000 quintals	(b) 2,145	(b) 22	(b) 27	(b) 28
(d) Other preparations	1,000 pounds	-	-	-	-
4. CEREALS AND CEREAL PREPARATIONS	do.	48,609	49,555	52,035	51,784
(a) Breakfast cereals 5/	do.	-	-	-	-
(b) Oats	do.	4,550	6,177	5,632	6,062
(c) Wheat and wheat flour	do.	22,474	23,504	24,710	22,539
(d) Maize (corn) grain and meal	do.	5,454	6,349	6,692	5,244
(e) Barley	do.	43	27	74	190
(f) Rice	do.	16,059	13,432	14,792	17,685
(g) Biscuits (sweetened and unsweetened)	do.	29	68	135	65
(h) Macaroni and spaghetti 6/	do.	-	-	-	-
5. DECIDUOUS FRUITS	do.	-	-	-	-
6. VEGETABLES	do.	7,014	6,937	5,381	4,241
(a) Irish potatoes	do.	5,322	4,673	3,504	1,589
(b) Peas, beans and lentils	do.	1,463	2,079	1,605	2,381
(c) Other fresh vegetables	do.	58	89	176	152
(d) Tinned and preserved	do.	171	96	96	119
7. BEVERAGES (Non-Alcoholic)	do.	813	800	596	652
(i) Cocoa	do.	183	181	215	458
(ii) Coffee	do.	471	274	183	56
(iii) Tea	do.	159	345	198	138
8. FEEDING STUFFS FOR ANIMALS	do.	14,447	18,496	19,130	18,529
(a) Grains and cereals	do.	4,716	4,809	5,042	4,927
(b) Prepared meals	do.	3,467	5,492	6,902	7,956
(c) Other	do.	6,264	8,195	7,186	5,646
9. EDIBLE OILS AND FATS	(a) do.	(a) 402	(a) 51	-	-
	(b) 1,000 gallons	(b) 24	(b) 88	(b) 42	(b) 61
10. TOBACCO	1,000 pounds	269	275	249	268
(a) Tobacco (unmanufactured)	do.	240	245	232	237
(b) Tobacco (manufactured)	do.	29	30	17	31
11. SUGAR AND SUGAR PREPARATIONS	do.	2	-	59	24
(a) Molasses and syrup	1,000 gallons	-	-	176	-
12. SOAP AND SOAP PREPARATIONS	1,000 pounds	37	41	19	79
13. COTTON PIECE GOODS	1,000 sq. yds.	2,362	2,120	2,170	3,126
14. FERTILIZERS (manufactured)	1,000 tons	10	8	10	12
15. LEATHER	1,000 pounds	83	129	56	49

1/ See Appendix I, "Note on Import Data". 2/ Some group totals are not the sum of their respective subgroups. 3/ Included in Group (iv) Meat in Airtight Containers up to 1954. 4/ The quantity totals of this group exclude eggs. 5/ Included in Oats up to 1954.
